About this document

This document contains reference information that is intended to help you use the header files, macros, and functions provided by the IBM® z/OS® XL C/C++ runtime to write C or C++ applications.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line (|) to the left of the change.

You may notice changes in the style and structure of some of the contents in this document; for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

Who should read this document

This document is intended for application programmers interested in writing C and C++ applications using the z/OS XL C/C++ runtime.

How to read syntax diagrams

This section describes how to read syntax diagrams. It defines syntax diagram symbols, items that may be contained within the diagrams (keywords, variables, delimiters, operators, fragment references, operands) and provides syntax examples that contain these items.

Syntax diagrams pictorially display the order and parts (options and arguments) that comprise a command statement. They are read from left to right and from top to bottom, following the main path of the horizontal line.

For users accessing the Information Center using a screen reader, syntax diagrams are provided in dotted decimal format.

The following symbols may be displayed in syntax diagrams:

Symbol	**Definition**
▸▸——	Indicates the beginning of the syntax diagram.
——▸	Indicates that the syntax diagram is continued to the next line.
▸——	Indicates that the syntax is continued from the previous line.
——▸◂	Indicates the end of the syntax diagram.

Syntax diagrams contain many different items. Syntax items include:
- Keywords - a command name or any other literal information.
- Variables - variables are italicized, appear in lowercase, and represent the name of values you can supply.
- Delimiters - delimiters indicate the start or end of keywords, variables, or operators. For example, a left parenthesis is a delimiter.

- Operators - operators include add (+), subtract (-), multiply (*), divide (/), equal (=), and other mathematical operations that may need to be performed.
- Fragment references - a part of a syntax diagram, separated from the diagram to show greater detail.
- Separators - a separator separates keywords, variables or operators. For example, a comma (,) is a separator.

Note: If a syntax diagram shows a character that is not alphanumeric (for example, parentheses, periods, commas, equal signs, a blank space), enter the character as part of the syntax.

Keywords, variables, and operators may be displayed as required, optional, or default. Fragments, separators, and delimiters may be displayed as required or optional.

Item type
Definition

Required
Required items are displayed on the main path of the horizontal line.

Optional
Optional items are displayed below the main path of the horizontal line.

Default
Default items are displayed above the main path of the horizontal line.

The following table provides syntax examples.

Table 1. Syntax examples

Item	Syntax example
Required item. Required items appear on the main path of the horizontal line. You must specify these items.	►►─KEYWORD─required_item─────────────────────►◄
Required choice. A required choice (two or more items) appears in a vertical stack on the main path of the horizontal line. You must choose one of the items in the stack.	►►─KEYWORD─┬─required_choice1─┬──────────────►◄ └─required_choice2─┘
Optional item. Optional items appear below the main path of the horizontal line.	►►─KEYWORD─┬───────────────┬─────────────────►◄ └─optional_item─┘
Optional choice. An optional choice (two or more items) appears in a vertical stack below the main path of the horizontal line. You may choose one of the items in the stack.	►►─KEYWORD─┬──────────────────┬──────────────►◄ ├─optional_choice1─┤ └─optional_choice2─┘

Table 1. Syntax examples (continued)

Item	Syntax example
Default. Default items appear above the main path of the horizontal line. The remaining items (required or optional) appear on (required) or below (optional) the main path of the horizontal line. The following example displays a default with optional items.	 KEYWORD default_choice1 optional_choice2 optional_choice3
Variable. Variables appear in lowercase italics. They represent names or values.	Repeatable item. An arrow returning to the left above the main path of the horizontal line indicates an item that can be repeated. A character within the arrow means you must separate repeated items with that character. An arrow returning to the left above a group of repeatable items indicates that one of the items can be selected,or a single item can be repeated.	 Fragment. The fragment symbol indicates that a labelled group is described below the main syntax diagram. Syntax is occasionally broken into fragments if the inclusion of the fragment would overly complicate the main syntax diagram.	 **fragment:**  ,required_choice1 ,required_choice2 ,default_choice ,optional_choice

Where to find more information

For an overview of the information associated with z/OS, see *z/OS V2R2 Information Roadmap*.

Information updates on the web

For the latest information updates that have been provided in PTF cover letters and documentation APARs for z/OS, see the online document z/OS APAR book (http://publibz.boulder.ibm.com/cgi-bin/bookmgr_OS390/Shelves/ ZDOCAPAR).

This document is updated weekly and lists documentation changes before they are incorporated into z/OS publications.

The z/OS Basic Skills Information Center

The z/OS Basic Skills Information Center is a Web-based information resource intended to help users learn the basic concepts of z/OS, the operating system that runs most of the IBM mainframe computers in use today. The Information Center is designed to introduce a new generation of Information Technology professionals to basic concepts and help them prepare for a career as a z/OS professional, such as a z/OS system programmer.

Specifically, the z/OS Basic Skills Information Center is intended to achieve the following objectives:

- Provide basic education and information about z/OS without charge
- Shorten the time it takes for people to become productive on the mainframe
- Make it easier for new people to learn z/OS.

To access the z/OS Basic Skills Information Center, open your Web browser to the following Web site, which is available to all users (no login required): z/OS Basic Skills in IBM Knowledge Center (http://www.ibm.com/support/knowledgecenter/zosbasics/com.ibm.zos.zbasics/homepage.html)

How to send your comments to IBM

We appreciate your input on this documentation. Please provide us with any feedback that you have, including comments on the clarity, accuracy, or completeness of the information.

Use one of the following methods to send your comments:

Important: If your comment regards a technical problem, see instead "If you have a technical problem."

- Send an email to mhvrcfs@us.ibm.com.
- Send an email from the "Contact us" web page for z/OS (http://www.ibm.com/systems/z/os/zos/webqs.html).

Include the following information:

- Your name and address
- Your email address
- Your phone or fax number
- The publication title and order number:
  z/OS XL C/C++ Runtime Library Reference
  SC14-7314-07
- The topic and page number or URL of the specific information to which your comment relates
- The text of your comment.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute the comments in any way appropriate without incurring any obligation to you.

IBM or any other organizations use the personal information that you supply to contact you only about the issues that you submit.

If you have a technical problem

Do not use the feedback methods that are listed for sending comments. Instead, take one or more of the following actions:

- Visit the IBM Support Portal (support.ibm.com).
- Contact your IBM service representative.
- Call IBM technical support.

New and updated information in z/OS Version 2 Release 2

This document contains terminology, maintenance, and editorial changes, including updates to header files, macros, and functions.

New information

- New functions:
  - printf() extended support, see "fprintf(), printf(), sprintf() — Format and write data" on page 588
  - scanf() extended support, see "fscanf(), scanf(), sscanf() — Read and format data" on page 625

Changed information

- The following header files were updated:
  - "stdio.h" on page 68 has been updated to support the __BLOCKED macro.
- The following functions were updated:
  - "exec functions" on page 436
  - "getaddrinfo() — Get address information" on page 684
  - "__librel() — Query release level" on page 968
  - "__osname() — Get true operating system name" on page 1166
  - "pthread_security_np(), pthread_security_applid_np() — Create or delete thread-level security" on page 1324
  - "spawn(), spawnp() — Spawn a new process" on page 1693
  - "system() — Execute a command" on page 1805
  - "uname() — Display current operating system name" on page 1951

Chapter 1. About IBM z/OS XL C/C++

For an introduction to z/OS XL C/C++ and for information on changes to z/OS XL C/C++, see *z/OS XL C/C++ User's Guide*.

AMODE 64 considerations

AMODE 64 restrictions are indicated as a dependency or as a restriction note. For example:

Restriction: This header file is not supported in AMODE 64.

Following are restrictions for AMODE 64:

- Hiperspace™ is not supported.
- The SPC facility is not supported.
- The following header files are not supported:
  - csp.h
  - ims.h
  - leawi.h
  - mtf.h
  - re_comp.h
  - regexp.h
  - spc.h
- The following feature test macros are obsolete:
  - _LARGE_FILES
  - _LARGE_MEM

  See the feature test macro description for more details.
- The following feature test macros are not supported:
  - __LIBASCII
  - _OE_SOCKETS
- The following functions are not supported:
  - advance()
  - brk()
  - compile()
  - __console()
  - __csplist
  - ctdli()
  - fortrc()
  - __openMvsRel()
  - __pcblist
  - re_comp()
  - re_exec()
  - regcmp()
  - regex()

  - sbrk()
  - sock_debug_bulk_perf0()
  - sock_do_bulkmode()
  - step()
  - tsched()
  - tsetsubt()
  - tsyncro()
  - tterm()
  - valloc()
- The following external variables are not supported:
  - __loc1
  - loc1
  - loc2
  - locs

Chapter 2. Header files

This part describes each header file, explains its contents, and lists the functions that use the file. The function descriptions are described in Chapter 3, “Library functions,” on page 89.

The header files provided with the z/OS XL C/C++ Library contain macro and constant definitions, type definitions, and function declarations. Some functions require definitions and declarations from header files to work correctly. The inclusion of header files is optional, as long as the necessary statements from the header files are coded directly into the source.

The C/C++ header files are shipped in the CEE.SCEEH* data sets and in the /usr/include directory in the Hierarchical File System (HFS).

The following header files are not supported in AMODE 64:

- csp.h
- ims.h
- leawi.h
- mtf.h
- re_comp.h
- regexp.h
- spc.h

Use the `#include` directive to select header files to include with your application, for example, **`#include <stdio.h>`**.

For information about the `#include` directive, see *z/OS XL C/C++ Language Reference* and *z/OS XL C/C++ User's Guide*.

Feature test macros

Many of the symbols that are defined in headers are “protected” by a feature test macro. These “protected” symbols are invisible to the application unless the user defines the feature test macro with `#define`, using either of the following methods:

- In the source code before including any header files.
- On the compilation command.

Note that the LANGLVL compiler option does not define or undefine these macros.

The following feature test macros are obsolete in AMODE 64:

- _LARGE_FILES
- _LARGE_MEM

See the feature test macro description for more details.

The following feature test macros are not supported in AMODE 64:

- __LIBASCII
- _OE_SOCKETS

Table 2 summarizes the relationships between the feature test macros and the standards. ‘Yes’ indicates that a feature test macro makes visible the symbols related to a standard.

Feature test macros that do not apply to POSIX standards are not listed in this table.

Table 2. Feature Test Macros and Standards

Feature Test Macro	POSIX.1	POSIX.1a	POSIX.2	POSIX.4a	XPG4.2	XPG4.2 Ext	SUSv3
_ALL_SOURCE	Yes	Yes	Yes	Yes	Yes	Yes	
_ALL_SOURCE_NO_THREADS	Yes	Yes	Yes		Yes	Yes	
_OE_SOCKETS	Yes	Yes					
_OPEN_DEFAULT	Yes	Yes	Yes				
_OPEN_SOURCE 1	Yes	Yes	Yes	Yes			
_OPEN_SOURCE 2	Yes	Yes	Yes	Yes	Yes	Yes	
_OPEN_SOURCE 3	Yes	Yes	Yes	Yes	Yes	Yes	
_OPEN_SYS	Yes	Yes	Yes	Yes			
_OPEN_SYS_IPC_EXTENSIONS	Yes	Yes			Yes		
_OPEN_SYS_PTY_EXTENSIONS	Yes	Yes			Yes	Yes	
_OPEN_SYS_SOCK_EXT	Yes	Yes		Yes	Yes		
_OPEN_THREADS	Yes	Yes		Yes			
_POSIX1_SOURCE 1	Yes						
_POSIX1_SOURCE 2	Yes	Yes					
_POSIX_C_SOURCE 1	Yes						
_POSIX_C_SOURCE 2	Yes		Yes				
_POSIX_C_SOURCE 200112L	Yes	Yes	Yes				Yes
_POSIX_SOURCE	Yes						
_XOPEN_SOURCE	Yes		Yes		Yes		
_XOPEN_SOURCE_EXTENDED 1	Yes		Yes		Yes	Yes	
_XOPEN_SOURCE 500	Yes		Yes		Yes	Yes	
_XOPEN_SOURCE 600	Yes	Yes	Yes		Yes	Yes	Yes

The following feature test macros are supported:

_ALL_SOURCE

This feature test macro exposes the following namespaces: POSIX.1, POSIX.1a, POSIX.2, POSIX.4a draft 6, XPG4, and XPG4.2, as well as additions to z/OS UNIX drawn from Single UNIX Specification, Version 2.

In addition, defining _ALL_SOURCE makes visible a number of symbols which are not permitted under ANSI, POSIX or XPG4, but which are provided as an aid to porting C-language applications to z/OS UNIX System Services. Extensions made visible with the following feature test macros are implicit in _ALL_SOURCE:

- _OPEN_SYS_DIR_EXT
- _OPEN_SYS_EXT
- _OPEN_SYS_IPC_EXTENSIONS
- _OPEN_SYS_MAP_EXTENTION
- _OPEN_SYS_PTY_EXTENSIONS
- _OPEN_SYS_SOCK_EXT
- _OPEN_SYS_SOCK_EXT2
- _OPEN_SYS_SOCK_IPV6

If _OPEN_THREADS is not explicitly defined in the application, _ALL_SOURCE will define _OPEN_THREADS 1 except when any of the following are present:

- _ALL_SOURCE_NO_THREADS
- _UNIX03_THREADS
- _XOPEN_SOURCE 600

_ALL_SOURCE does not expose functionality first introduced in Single UNIX Specification, Version 3 under macro definitions _XOPEN_SOURCE 600 or _POSIX_C_SOURCE 200112L, although it does tolerate interfaces made visible by defining _OPEN_THREADS to 2 or 3.

In order to stabilize the namespace, no future extensions, whether POSIX, XOPEN, or MVS™, will expand the definition of _ALL_SOURCE. Any future enhancement will require new, explicit feature test macros to add symbols to this namespace.

_ALL_SOURCE_NO_THREADS

This feature test macro provides the same function as _ALL_SOURCE, except it does not expose threading services (_OPEN_THREADS).

_IEEEV1_COMPATIBILITY

In 1999, the C/C++ Runtime Library provided IEEE754 floating-point arithmetic support in support of the IBM Java group. The Java™ language had a bit-wise requirement for its math library, meaning that all platforms needed to produce the same results as Sun Microsystems' fdlibm (Freely Distributed LIBM) library. Therefore, Sun Microsystems' fdlibm code was ported to the C/C++ Runtime Library to provide IEEE754 floating-point arithmetic support. Subsequent to the C/C++ Runtime Library's 1999 release of IEEE754 floating-point math support, IBM's Java group provided their own support of IEEE754 floating point arithmetic and no longer use the C/C++ Runtime Library for this support.

Beginning in z/OS V1R9, a subset of the original fdlibm functions are being replaced by new versions that are designed to provide improved performance and accuracy. The new versions of these functions are replaced at the existing entry points. However, as a migration aid, IBM has provided new entry points for the original fdlibm versions. Applications that take no action will automatically use the updated functions. There are two methods for accessing the original functions.

This feature test macro provides an environment for the following C/C++ functions:

- do not include <math.h>
- include <math.h> and define the _FP_MODE_VARIABLE feature test macro

Either of the above will cause the application to be running in what is called "variable" mode with respect to floating-point math functions called within the compile unit. See z/OS XL C/C++ Programming Guide for more details on the environment variable.

The second method is through a feature test macro, described here, that can be used by applications that do include <math.h> and do not define the _FP_MODE_VARIABLE feature test macro.

If the application conforms to the rules of the second method, then the feature test macro can be used to access the original fdlibm versions of the following functions:

```
acos(), acosh(), asin(), asinh(), atan(), atanh(), atan2(),
cbrt(), cos(), cosh(), erf(), erfc(), exp(), expm1(), gamma(),
hypot(), lgamma(), log(), log1p(), log10(), pow(), rint(), sin(),
sinh(), tan(), tanh()
```

A recompile and relink of the application is required to access the original fdlibm versions.

`_ISOC99_SOURCE`

This feature test macro makes available all interfaces associated with ISO/IEC 9899:1999 except for interfaces requiring a compiler that is designed to support C99. This feature test macro also exposes the namespace normally exposed by the _MSE_PROTOS feature test macro, unless _NOISOC99_SOURCE is defined. The _ISOC99_SOURCE feature test macro is not required when a compiler that is designed to support C99 is used.

Note: If both _NOISOC99_SOURCE and _ISOC99_SOURCE are defined before inclusion of the first header, new C99 interfaces will not be exposed.

`_LARGE_FILES`

The _LARGE_FILES feature test macro enables certain functions to operate on MVS data sets and z/OS UNIX files that are larger than 2 GB in size and VSAM extended addressability data sets larger than 4 GB in size. When this feature test macro is selected it must be used in conjunction with the compiler option LANGLVL(LONGLONG) to activate the `long long` data type.

The following functions are enabled to operate on z/OS UNIX files of all sizes by expanding appropriate offset and file size values to a 64-bit value:

```
creat(), fcntl(), fgetpos(), fopen(), freopen(), fseek(), fseeko(),
fsetpos(), fstat(), ftell(), ftello(), ftruncate(), getrlimit(),
lockf(), lseek(), lstat(), mmap(), open(), read(), setrlimit(),
stat(), truncate(), write()
```

The _LARGE_FILES feature test macro also enables the fseeko() and ftello() functions to operate on MVS data sets larger than 2 GB and VSAM data sets larger than 4 GB by expanding the parameter and return type width to 64 bits. The fgetpos(), fopen(), freopen(), and fsetpos() functions implicitly support operations on these sized data sets and therefore do not require the _LARGE_FILES feature test macro to be defined.

Note: Using AMODE 64 obsoletes this feature test macro. Large files are automatically supported in the LP64 programming model, therefore automatically included for AMODE 64 C/C++ applications. The c99 compiler defines the `long long` data type as a standard type by default.

Restriction: This feature test macro is incompatible with the __LIBASCII feature test macro.

`_LARGE_MEM`

This feature test macro is provided for AMODE 31 applications that need access to AMODE 64 values. Use of large memory support requires LANGLVL(LONGLONG).

Note: This feature test macro is obsolete in AMODE 64. Large memory support is automatic in the LP64 programming model, therefore all behaviors with respect to large memory are automatically included for AMODE 64 C/C++ applications.

`_LARGE_TIME_API`

This feature test macro exposes new typedefs, structures, and functions so that an application can work with constructed calendar times up to and including the artificial limit of 23:59:59 on December 31, 9999 UTC.

`__LIBASCII`

This feature test macro provides an ASCII-like environment for the following C/C++ functions:

```
access(), asctime(), atof(), atoi(), atol(), chdir(), chmod(),
chown(), creat(), ctime(), dllload(), dllqueryfn(), dynalloc()
ecvt(), execv(), execve(), execvp(), fcvt(), fdopen(), fopen(),
freopen(), ftok(), gcvt(), getcwd(), getenv(), getgrnam(),
gethostbyaddr(), gethostbyname(), gethostname(), getlogin(),
getopt(), getpass(), getpwnam(), getpwuid(), getservbyname(),
getwd(), inetaddr(), inet_ntoa(),isalnum(), isalpha(), iscntrl(),
isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace(),
isupper(), isxdigit(), link(), localeconv(), mbstowcs(), mbtowc(),
mkdir(), mknod(), mktemp(), nl_langinfo(), open(), opendir(),
perror(), popen(), ptsname(), putenv(), readdir(), regcomp(),
remove(), rename(), rexec(), rmdir(), scanf(), setenv(),  setkey(),
setlocale(), setvbuf(), sprintf(), sscanf(),  stat(), statvfs(),
strcasecmp(), strerror(), strncasecmp(),  strtod(), strtol(),
strtoul(), system(), tempnam(), tmpnam(),  toascii(), tolower(),
toupper(), uname(), unlink(), utime(),  utimes()
```

For each application program using one or more of these functions, where the input/output is ASCII, add the following feature test macro:

- #define __LIBASCII
- Recompile using the CONV(ISO8859-1) option to cause the compiler to generate all strings defined in the source program in ASCII rather than EBCDIC format.

Note:

- This feature test macro is not supported in AMODE 64.
- Enhanced ASCII and __LIBASCII are independent, and should not be used together. Using Enhanced ASCII and __LIBASCII together is not supported.
- The libascii functions are as thread-safe as the runtime library with the exception of the getopt() function. The libascii getopt() function is not thread-safe. The second argument is changed for a short period of time from EBCDIC to ASCII and then back to EBCDIC. This feature test macro is incompatible with the _LARGE_FILES feature test macro.

`_LONGMAP`

Programs compiled with the LONGNAME compiler option and which use POSIX functions must define _LONGMAP when using the Prelinker outside of a z/OS UNIX shell environment.

`_MSE_PROTOS`

The `_MSE_PROTOS` feature test macro does the following:

1. Selects behavior for a multibyte extension support (MSE) function declared in wchar.h as specified by ISO/IEC 9899:1990/Amendment

1:1994 instead of behavior for the function as defined by CAE Specification, System Interfaces and Headers, Issue 4, July 1992 (XPG4), and

2. Exposes declaration of an MSE function declared in wchar.h which is specified by ISO/IEC 9899:1990/Amendment 1:1994 but not by XPG4.

Note: Defining _ISOC99_SOURCE or using a compiler that is designed to support C99 also exposes this namespace provided that _NOISOC99_SOURCE is not also defined.

_NOISOC99_SOURCE

This feature test macro prevents exposure of new interfaces that are part of the C99 standard. This feature test macro must be defined before inclusion of the first header in order to prevent new C99 interfaces from being exposed.

Note: If both _NOISOC99_SOURCE and _ISOC99_SOURCE are defined before inclusion of the first header, new C99 interfaces will not be exposed.

_OE_SOCKETS

This feature test macro defines a BSD-like socket interface for the function prototypes and structures involved. This can be used with `_XOPEN_SOURCE_EXTENDED` 1 and the XPG4.2 socket interfaces will be replaced with the BSD-like interfaces.

Restriction: This feature test macro is not supported in AMODE 64.

_OPEN_DEFAULT

When defined to 0, and if no other feature test macro is defined, then all symbols will be visible. If in addition to _OPEN_DEFAULT only POSIX and/or XPG4 feature test macros are defined, then only the symbols so requested will be visible. Otherwise, additional symbols (for example, those visible when the LANGLVL(EXTENDED) compiler option is specified), may be exposed.

When defined to 1, this provides the base level of z/OS UNIX functionality, which is POSIX.1, POSIX.1a and POSIX.2.

_OPEN_MSGQ_EXT

This feature test macro defines an interface which enables use of select(), selectex() and poll() to monitor message and file descriptors.

_OPEN_SOURCE

When defined to 1, this defines all of the functionality that was available on MVS 5.1. This macro is equivalent to specifying `_OPEN_SYS`.

When defined to 2, this defines all of the functionality that is available on MVS 5.2.2, including XPG4, XPG4.2, and all of the z/OS UNIX extensions.

When defined to 3, this macro is equivalent to specifying _ALL_SOURCE.

If _OPEN_THREADS is not explicitly defined in the application, _OPEN_SOURCE will define _OPEN_THREADS 1 except when any of the following are present:

- _ALL_SOURCE_NO_THREADS
- _UNIX03_THREADS
- _XOPEN_SOURCE 600

_OPEN_SYS

When defined to 1, this indicates that symbols required by POSIX.1, POSIX.1a, POSIX.2 are made visible. Any symbols defined by the _OPEN_THREADS macro are allowed.

If _OPEN_THREADS is not explicitly defined in the application, _OPEN_SYS will define _OPEN_THREADS 1 except when any of the following are present:

- _ALL_SOURCE_NO_THREADS
- _UNIX03_THREADS
- _XOPEN_SOURCE 600

Additional symbols can be made visible if any of the exposed standards explicitly allows the symbol to appear in the header in question or if the symbol is defined as a z/OS UNIX System Services extension.

_OPEN_SYS_DIR_EXT

This feature test macro defines the interface and function prototypes for __opendir2() and __readdir2().

_OPEN_SYS_FILE_EXT

When defined to any value with #define, _OPEN_SYS_FILE_EXT indicates that symbols required for file conversion, file tagging, and file attributes manipulation functionality are made visible.

_OPEN_SYS_IF_EXT

When defined to 1, this feature test macro exposes BSD-like socket definitions found in <net/if.h> and <sys/ioctl.h> that are needed to manipulate network interfaces. This feature test macro is made available beginning with z/OS V1R9.

_OPEN_SYS_IPC_EXTENSIONS

This feature test macro defines z/OS UNIX extensions to the X/Open InterProcess Communications functions. When _OPEN_SYS_IPC_EXTENSIONS is defined, the POSIX.1, POSIX.1a, and the XPG4 symbols are visible. This macro should be used in conjunction with _XOPEN_SOURCE.

_OPEN_SYS_MUTEX_EXT

This feature test macro allows pthread condition variables and mutexes in shared memory. When this feature is defined, pthread_mutex_t and pthread_cond_t will grow significantly in size.

When either _XOPEN_SOURCE 600 or _UNIX03_THREADS are defined, the namespace includes all elements made visible by the _OPEN_SYS_MUTEX_EXT macro. In this case, _OPEN_SYS_MUTEX_EXT is redundant and does not need to be defined by the application.

_OPEN_SYS_PTY_EXTENSIONS

This feature test macro defines z/OS UNIX extensions to the X/Open Pseudo TTY functions. When _OPEN_SYS_PTY_EXTENSIONS is defined, the POSIX.1, POSIX.1a, XPG4, and XPG4.2 symbols are visible. This macro should be used in conjunction with _XOPEN_SOURCE_EXTENDED 1.

_OPEN_SYS_SOCK_EXT

This feature test macro defines the interface for function prototypes and structures for the extended sockets and bulk mode support.

_OPEN_SYS_SOCK_EXT2

This feature test macro defines the function prototype and interfaces for accept_and_recv().

_OPEN_SYS_SOCK_EXT3

This feature test macro defines the function prototypes and interfaces for multicast source filtering.

_OPEN_SYS_SOCK_EXT4

This feature test macro defines interfaces in netinet/in.h used for sending UDP reply packets on the same inbound interface as the request arrived.

_OPEN_SYS_SOCK_IPV6

When defined, indicates that symbols related to Internet Protocol Version 6 (IPv6) are made visible.

Defining _XOPEN_SOURCE to 600 will expose the IPv6 symbols required in Single Unix Specification, Version 3. However, these symbols only comprise a subset of the complete namespace associated with _OPEN_SYS_SOCK_IPV6. Although an application is allowed to define both macros, such an application may not be strictly conforming to Single UNIX Specification, Version 3.

_OPEN_THREADS

When defined to 1, this indicates that symbols required by `POSIX.1`, `POSIX.1a`, and `POSIX.4a(draft 6)` are made visible.

When defined to 2, additional pthread functions introduced in z/OS V1R07 from Single UNIX Specification, Version 3 are made visible, along with those made visible when this is defined to 1. The following symbols are added to the namespace when _OPEN_THREADS is defined to 2:

Interfaces	Constants
pthread_getconcurrency()	PTHREAD_CANCEL_ENABLE
pthread_setconcurrency()	PTHREAD_CANCEL_DISABLE
pthread_setcancelstate()	PTHREAD_CANCEL_DEFERRED
pthread_setcanceltype()	PTHREAD_CANCEL_ASYNCHRONOUS
pthread_sigmask()	
pthread_testcancel()	
pthread_key_delete()	

When defined to 3, all pthread functions required for the Threads option of Single UNIX Specification, Version 3 are exposed, although behavior and function signatures are still based on the POSIX.4a draft 6 specification. In addition to the symbols exposed by _OPEN_THREADS 2, _OPEN_THREADS 3 adds the following symbols to the namespace:

Interfaces	Constants
pthread_atfork()	PTHREAD_CANCEL_CANCELED
pthread_attr_getguardsize()	PTHREAD_COND_INITIALIZER

Interfaces	Constants
pthread_attr_getschedparam()	PTHREAD_CREATE_DETACHED
pthread_attr_getstack()	PTHREAD_CREATE_JOINABLE
pthread_attr_getstackaddr()	PTHREAD_EXPLICIT_SCHED
pthread_attr_setguardsize()	
pthread_attr_setschedparam()	
pthread_attr_setstack()	
pthread_attr_setstackaddr()	

Thread interfaces listed above and first exposed by _OPEN_THREADS 2 or 3 are fully compliant with Single UNIX Specification, Version 3. However, the other threading interfaces in the library will not exhibit the new behavior or use function signatures changed in the new standard. Applications that define _UNIX03_THREADS or _XOPEN_SOURCE 600 will obtain threads support that complies fully with Single UNIX Specification, Version 3.

If _OPEN_THREADS is defined with _XOPEN_SOURCE 600, _OPEN_THREADS takes precedence and overrides the default threads behavior of _XOPEN_SOURCE 600. However, _OPEN_THREADS and _UNIX03_THREADS are mutually exclusive.

Note: Feature test macros _OPEN_SYS, _OPEN_SOURCE, and _ALL_SOURCE incorporate _OPEN_THREADS 1 by default, if _OPEN_THREADS has not been explicitly defined in the application, except when any of the following are present:

- _ALL_SOURCE_NO_THREADS
- _UNIX03_THREADS
- _XOPEN_SOURCE 600

_POSIX1_SOURCE

- When defined to 1, it has the same meaning as _POSIX_SOURCE.
- When defined to 2, both the POSIX.1a symbols and the POSIX.1 symbols are made visible. Additional symbols can be made visible if POSIX.1a explicitly allows the symbol to appear in the header in question.

_POSIX_C_SOURCE

- When defined to 1, it indicates that symbols required by POSIX.1 are made visible. Additional symbols can be made visible if POSIX.1 explicitly allows the symbol to appear in the header in question.
- When defined to 2, both the POSIX.1 and POSIX.2 symbols are made visible.
- When defined to 200112L, the Single UNIX Specification, Version 3 symbols are made visible, including POSIX.1 and POSIX.2. Since Version 3 is aligned with the ISO C standard (ISO/IEC 9899:1999), this definition of the feature test macro also exposes the C99 namespace.
- The _POSIX_C_SOURCE 200112L definition is available beginning with z/OS V1R9. Targeting earlier releases will result in an error during compile-time.
- Additional symbols can be made visible if POSIX.2 explicitly allows the symbol to appear in the header in question.

_POSIX_SOURCE

When defined to any value with `#define`, it indicates that symbols required by `POSIX.1` are made visible. Additional symbols can be made visible if `POSIX.1` explicitly allows the symbol to appear in the header in question.

_SHARE_EXT_VARS

This feature test macro provides access to POSIX and XPG4 external variables of an application from a dynamically loaded module such as a DLL. For those external variables that have a function to access a thread-specific value, it provides access to the thread-specific value of the external variable without having to explicitly invoke the function.

Individual variables can be externalized by using the feature test macros prefixed with _SHR_ and the feature test macros that are shown as follows. The entire set can be accessed by defining _SHARE_EXT_VARS.

Note: When an application is compiled with the XPLINK or LP64 option:

- The POSIX and XPG4 external variables will be resolved through the C runtime library side-deck in the SCEELIB data set and will be accessible from all dynamically loaded modules. See *z/OS XL C/C++ Programming Guide* for more details.
- The _SHARE_EXT_VARS feature test macro, and the following feature test macros with the _SHR_ prefix, are only necessary for accessing the thread-specific values without having to explicitly invoke the function.

_SHR_DAYLIGHT

To share access to the daylight external variable from a dynamically loaded module such as a DLL, define the _SHR_DAYLIGHT feature test macro and include time.h in your program source.

_SHR_ENVIRON

If you have declared char **environ in your program and want to access the environment variable array from a dynamically loaded module such as a DLL, define the _SHR_ENVIRON feature test macro and include stdlib.h in the program source.

_SHR_H_ERRNO

To share access to the h_errno external variable from a dynamically loaded module such as a DLL, define the _SHR_H_ERRNO feature test macro and include netdb.h in your program source.

_SHR__LOC1

To share access to the __loc1 external variable from a dynamically loaded module such as a DLL, define _SHR__LOC1 feature test macro and include libgen.h in your program source.

_SHR_LOC1

To share access to the loc1 external variable from a dynamically loaded module such as a DLL, define _SHR_LOC1 feature test macro and include regexp.h in your program source.

_SHR_LOC2

To share access to the loc2 external variable from a dynamically loaded module such as a DLL, define _SHR_LOC2 feature test macro and include regexp.h in your program source.

_SHR_LOCS

To share access to the locs external variable from a dynamically loaded module such as a DLL, define _SHR_LOCS feature test macro and include regexp.h in your program source.

_SHR_OPTARG

To share access to the optarg external variable from a dynamically loaded module such as a DLL, define the _SHR_OPTARG feature test macro and include unistd.h or stdio.h in your program source.

_SHR_OPTERR

To share access to the opterr external variable from a dynamically loaded module such as a DLL, define the _SHR_OPTERR feature test macro and include unistd.h or stdio.h in your program source.

_SHR_OPTIND

To share access to the optind external variable from a dynamically loaded module such as a DLL, define _SHR_OPTIND feature test macro and include unistd.h or stdio.h in your program source.

_SHR_OPTOPT

To share access to the optopt external variable from a dynamically loaded module such as a DLL, define the _SHR_OPTOPT feature test macro and include unistd.h or stdio.h in your program source.

_SHR_SIGNGAM

To share access to the signgam external variable from a dynamically loaded module such as a DLL, define the _SHR_SIGNGAM feature test macro and include math.h in your program source.

_SHR_T_ERRNO

To share access to the t_errno external variable from a dynamically loaded module such as a DLL, define the _SHR_T_ERRNO feature test macro and include xti.h in your program source.

_SHR_TIMEZONE

To share access to the timezone external variable from a dynamically loaded module such as a DLL, define the _SHR_TIMEZONE feature test macro and include time.h in your program source. To avoid name space pollution when _SHR_TIMEZONE is defined, the timezone variable must be referred to as _timezone.

_SHR_TZNAME

To share access to the tzname external variable from dynamically loaded module such as a DLL, define the _SHR_TZNAME feature test macro and include time.h in your program source.

__STDC_CONSTANT_MACROS

This feature test macro is required by C++ applications wishing to expose macros for integer constants as documented in <stdint.h>.

__STDC_FORMAT_MACROS

This feature test macro is required by C++ applications wishing to expose macros for format specifiers as documented in <inttypes.h>.

__STDC_WANT_DEC_FP__

This MACRO will be added to the C99 DFP specification (for C and C++). The user will define this MACRO when DFP support is wanted. It will cause all DFP-oriented definitions in <math.h> and other headers to be exposed if __IBM_DFP is defined.

__STDC_LIMIT_MACROS

This feature test macro is required by C++ applications wishing to expose limits of specified-width integer types and limits of other integer types as documented in <stdint.h>.

_TR1_C99

This feature test macro exposes the C++ TR1 C99 name space as described in Chapter 8 of *ISO/IEC DTR 19768: Draft Technical Report* on C++ Library Extensions.

When both the _TR1_C99 and _AIX_COMPATIBILITY Feature Test Macros are defined, the _AIX_COMPATIBILITY takes precedence. This affects the copysign(), scalbn(), and the floating point classification functions.

When both the _TR1_C99 and _FP_MODE_VARIABLE feature test macros are defined, float overloads are not supported for the following functions:

atan2(), copysign(), fdim(), fma(), fmax(), fmin(), fmod(), frexp(), hypot(), ldexp(), modf(), nextafter(), nexttoward(), pow(), remainder(), remquo(), scalbln(), and scalbn()

Also, when both the _TR1_C99 and _FP_MODE_VARIABLE feature test macros are set, the long double overloads are not supported for frexp() and ldexp().

This feature test macro requires the use of the z/OS V1.10 z/OS XL C++ compiler or later.

_UNIX03_SOURCE

This feature test macro exposes new Single UNIX Specification, Version 3 interfaces. It does not change the behavior of existing APIs, nor expose interfaces controlled by feature test macros such as _XOPEN_SOURCE_EXTENDED. Functions and behavior exposed by _UNIX03_SOURCE are a subset and not the complete implementation of the Single UNIX Specification, Version 3. To expose the full Single UNIX Specification, Version 3 implementation available in the C/C++ Runtime, see _XOPEN_SOURCE or _POSIX_C_SOURCE.

Release	Interfaces Exposed with _UNIX03_SOURCE
z/OS V1R6	dlclose(), dlerror(), dlopen(), dlsym()
z/OS V1R7	sched_yield(), strerror_r(), unsetenv()
z/OS V1R8	flockfile(), ftrylockfile(), funlockfile(), getc_unlocked(), getchar_unlocked(), putc_unlocked(), putchar_unlocked()
z/OS V1R9	posix_openpt(), pselect(), sockatmark()

Note: This feature test macro does not expose any new pthread interfaces. See _OPEN_THREADS and _UNIX03_THREADS to expose pthread interfaces.

_UNIX03_THREADS

This feature test exposes all pthread functions, function signatures, and behaviors required for the Threads option of Single UNIX Specification, Version 3. The macro is available for compiles targeting z/OS V1R9 or later.

Defining _UNIX03_THREADS exposes the content covered by feature test macro _OPEN_SYS_MUTEX_EXT, so that the latter is redundant and need not be defined with _UNIX03_THREADS.

It is not necessary to define this feature test macro, if _XOPEN_SOURCE is defined to 600. Unless _OPEN_THREADS is defined, _XOPEN_SOURCE 600 will make available the same interfaces and behaviors as _UNIX03_THREADS.

_UNIX03_THREADS and _OPEN_THREADS are mutually exclusive.

_UNIX03_WITHDRAWN

Defining this feature test macro exposes any language elements, previously in the Legacy Feature Group or marked obsolescent, that have been removed from Single Unix Specification, Version 3. These elements would not otherwise be visible in the namespace exposed by compiling with _XOPEN_SOURCE 600 or POSIX_C_SOURCE 200112L.

The following withdrawn symbols are exposed when _UNIX03_WITHDRAWN is defined:

Functions	**Constants**
brk()	CLOCK_TICKS
chroot()	IUCLC
cuserid()	L_cuserid
gamma()	NOSTR
getdtablesize()	OLCUC
getpagesize()	PASS_MAX
getpass()	_SC_2_ C_VERSION
getw()	_SC_PASS_MAX
putw()	_SC_XOPEN_XCU_VERSION
regcmp()	TMP_MAX
regex()	XCASE
sbrk()	YESSTR
sigstack()	
ttyslot()	
valloc()	**External Variable**
wait3()	__loc1

_VARARG_EXT_

This feature test macro allows users of the va_arg, va_end, and va_start macros to define the va_list type differently.

_XOPEN_SOURCE

This feature test macro defines the functionality defined in the XPG4 standard dated July 1992.

When defined to 500, this feature test macro makes available certain key functions that are associated with Single UNIX Specification, Version 2.

When defined to 600, this feature test macro exposes the complete implementation of the Single UNIX Specification, Version 3, including the namespace defined by _POSIX_C_SOURCE 200112L as well as namespaces associated with the X/Open System Interface (XSI) extension and these options and option groups:

- File synchronization
- Memory mapped files
- Memory protection
- Realtime signals extension
- Thread stack address attribute
- Thread stack size attribute
- Thread process-shared synchronization
- Thread-safe functions
- Threads
- Encryption option group
- Legacy option group
- XSI streams option group

The use of _XOPEN_SOURCE 600 exposes namespaces covered by several other feature test macros, and as such, makes those macros redundant. The following need not be defined when _XOPEN_SOURCE 600 is defined:

_ISOC99_SOURCE
_UNIX03_THREADS
_UNIX03_SOURCE
_XOPEN_SOURCE_EXTENDED
_POSIX_C_SOURCE
_OPEN_SYS_MUTEX_EXT
_POSIX_SOURCE

If _OPEN_THREADS is defined with _XOPEN_SOURCE 600, _OPEN_THREADS takes precedence and overrides Single UNIX Specification, Version 3 threads behavior. Whenever _OPEN_THREADS is in effect, the _OPEN_SYS_MUTEX_EXT extensions are also dropped, unless the application explicitly defines this macro.

The _XOPEN_SOURCE 600 definition is available beginning with z/OS V1R9. Targeting earlier releases will result in an error during compile-time.

Full support of Single UNIX Specification, Version 3 requires use of a C99 compliant compiler. Most of the namespace is available to older compilers, but some elements of Version 3 (such as . <complex.h> or <tgmath.h>) will not be visible.

_XOPEN_SOURCE_EXTENDED

When defined to 1, this defines the functionality defined in the XPG4 standard plus the set of “Common APIs for UNIX-based Operating Systems”, April, 1994, draft.

aio.h

The aio.h header file contains definitions for asynchronous I/O operations. It declares these functions:

aio_read() aio_write() aio_cancel()
aio_suspend() aio_error() aio_return()

Note: There are several sockets oriented extensions to asynchronous I/O available with the BPX1AIO callable service, such as asynchronous accept(), asynchronous accept_and_recv(), asynchronous forms of all five pairs of read and write type operations, and receiving I/O completion notifications via an ECB, exit program, or through a message queue. The <aio.h> header contains all the structure fields, constants, and prototypes necessary to use BPX1AIO from a C program. These extensions are exposed when the _AIO_OS390 feature test macro is defined. The BPX1AIO stub resides in SYS1.CSSLIB and must be bound with your program. For a more detailed description of asynchronous I/O services, see BPX1AIO in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

arpa/inet.h

The arpa/inet.h header file contains definitions for internet operations.

arpa/nameser.h

The arpa/nameser.h header file contains the definitions used to support the construction of queries and the inspection of answers received from a Domain Name Server available in a network. It also contains the macros GETSHORT(), PUTSHORT(), GETLONG(), and PUTLONG() that are used to construct or inspect DNS requests.

assert.h

The assert.h header file defines the assert() macro that allows you to insert diagnostics into your code. You must include assert.h when you use assert().

cassert

The cassert header file contains definitions for C++ for enforcing assertions when functions execute. Include the standard header into a C++ program to effectively include the standard header <assert.h> within the std namespace.

```
namespace std {
#include <assert.h>
    };
```

_Ccsid.h

The _Ccsid.h header file declares functions, symbols and data types used in CCSID to codeset name conversion.

cctype

The cctype header file contains definitions for C++ for classifying characters. Include the standard header into a C++ program to effectively include the standard header <ctype.h> within the std namespace.

```
namespace std {
#include <ctype.h>
    };
```

ceeedcct.h

The ceeedcct.h header file contains C declarations of the Language Environment condition tokens.

cerrno

The cerrno header file contains definitions for C++ for testing error codes reported by library functions. Include the standard header into a C++ program to effectively include the standard header <errno.h> within the std namespace.

```
namespace std {
#include <errno.h>
    };
```

cfloat

The cfloat header file contains definitions for C++ for testing floating-point type properties. Include the standard header into a C++ program to effectively include the standard header <float.h> within the std namespace.

```
namespace std {
#include <float.h>
    };
```

cics.h

The cics.h header file declares the iscics() function, which verifies whether `cics` is running.

ciso646

The ciso646 header file contains definitions for C++ for programming in ISO646 variant character sets. Include the standard header into a C++ program to effectively include the standard header <iso646.h> within the std namespace.

```
namespace std {
#include <iso646.h>
    };
```

climits

The climits header file contains definitions for C++ for testing integer type properties. Include the standard header into a C++ program to effectively include the standard header <limits.h> within the std namespace.

```
namespace std {
#include <limits.h>
    };
```

clocale

The clocale header file contains definitions for C++ for adapting to different cultural conventions. Include the standard header into a C++ program to effectively include the standard header <locale.h> within the std namespace.

```
namespace std {
#include <locale.h>
    };
```

cmath

The cmath header file contains definitions for C++ for computing common mathematical functions. Include the standard header into a C++ program to effectively include the standard header <math.h> within the std namespace.

```
namespace std {
#include <math.h>
    };
```

collate.h

The collate.h header includes declarations of functions that allow retrieval of information regarding the current locale's collating properties. It declares these functions:

cclass()	collequiv()	collorder()	collrange()	colltostr()
getmccoll()	getwmccoll()	ismccollel()	maxcoll()	strtocoll()

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this topic. For still more information, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

complex.h

The complex.h header file contains function declarations for all the complex math functions listed below.

cabs()	cabsf()	cabsl()	cacos()	cacosf()
cacosh()	cacoshf()	cacoshl()	cacosl()	carg()
cargf()	cargl()	casin()	casinf()	casinh()
casinhf()	casinhl()	casinl()	catan()	catanf()
catanh()	catanhf()	catanhl()	catanl()	ccos()
ccosf()	ccosh()	ccoshf()	ccoshl()	ccosl()
cexp()	cexpf()	cexpl()	cimag()	cimagf()
cimagl()	clog()	clogf()	clogl()	conj()
conjf()	conjl()	cpow()	cpowf()	cpowl()
cproj()	cprojf()	cprojl()	creal()	crealf()
creall()	csin()	csinf()	csinh()	csinhf()
csinhl()	csinl()	csqrt()	csqrtf()	csqrtl()
ctan()	ctanf()	ctanh()	ctanhf()	ctanhl()
ctanl()				

The complex.h header file defines the following macros:

complex
expands to _Complex, where _Complex is a type specifier.

_Complex_I
expands to const float _Complex with the value of the imaginary unit

I expands to _Complex_I

Compile requirement: Use of this header requires a compiler that is designed to support C99.

cpio.h

The cpio.h header file contains CPIO archive values.

csetjmp

The csetjmp header file contains definitions for C++ for executing nonlocal goto statements. Include the standard header into a C++ program to effectively include the standard header <setjmp.h> within the std namespace.

```
namespace std {
#include <setjmp.h>
    };
```

csignal

The csignal header file contains definitions for C++ for controlling various exceptional conditions. Include the standard header into a C++ program to effectively include the standard header <signal.h> within the std namespace.

```
namespace std {
#include <signal.h>
    };
```

csp.h

Restriction: This header file is not supported in AMODE 64.

The csp.h header file declares the __csplist macro, which obtains the CSP parameter list.

These macros are *not* supported under z/OS UNIX and they are not supported for C++ applications.

cstdarg

The cstdarg header file contains definitions for C++ for accessing a varying number of arguments. Include the standard header into a C++ program to effectively include the standard header <stdarg.h> within the std namespace.

```
namespace std {
#include <stdarg.h>
    };
```

cstddef

The cstddef header file contains definitions for C++ for defining several useful types and macros. Include the standard header into a C++ program to effectively include the standard header <stddef.h> within the std namespace.

```
namespace std {
#include <stddef.h>
    };
```

cstdio

The cstdio header file contains definitions for C++ for performing input and output. Include the standard header into a C++ program to effectively include the standard header <stdio.h> within the std namespace.

```
namespace std {
#include <stdio.h>
    };
```

cstdlib

The cstdlib header file contains definitions for C++ for performing a variety of operations. Include the standard header into a C++ program to effectively include the standard header <stdlib.h> within the std namespace.

```
namespace std {
#include <stdlib.h>
    };
```

cstring

The cstring header file contains definitions for C++ for manipulating several kinds of strings. Include the standard header into a C++ program to effectively include the standard header <string.h> within the std namespace.

```
namespace std {
#include <string.h>
    };
```

ctest.h

The ctest.h header file contains declarations for the functions that involve debugging and diagnostics. The diagnostic functions are:

cdump() csnap() ctest() ctrace()

ctime

The ctime header file contains definitions for C++ for converting between various time and date formats. Include the standard header into a C++ program to effectively include the standard header <time.h> within the std namespace.

```
namespace std {
#include <time.h>
    };
```

ctype.h

The ctype.h header file declares functions used in character classification. The functions declared are:

isalnum() isalpha() isblank() iscntrl() isdigit()
isgraph() islower() isprint() ispunct() isspace()
isupper() isxdigit() tolower() toupper()

_XOPEN_SOURCE

isascii() toascii() _tolower() _toupper()

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this topic. For still more information, see “Internationalization: Locales and Character Sets” in *z/OS XL C/C++ Programming Guide*.

cwchar

The cwchar header file contains definitions for C++ for manipulating wide streams and several kinds of strings. Include the standard header into a C++ program to effectively include the standard header <wchar.h> within the std namespace.

```
namespace std {
#include <wchar.h>
    };
```

cwctype

The cwctype header file contains definitions for C++ for classifying wide characters. Include the standard header into a C++ program to effectively include the standard header <wctype.h> within the std namespace.

```
namespace std {
#include <wctype.h>
    };
```

decimal.h

The decimal.h header file is not supported under z/OS C++ applications.

The decimal.h header file contains declarations for those built-in functions that perform fixed-point decimal operations. The functions declared are:

decabs()   decchk()   decfix()

The header file also contains definitions of constants that specify the ranges of the `decimal` data types.

dirent.h

The dirent.h header file contains constants, prototypes, and typedef definitions for POSIX directory access functions. It declares the following functions.

_OPEN_SYS_DIR_EXT

__opendir2()   __readdir2()

_POSIX_SOURCE

closedir()   opendir()   readdir()   rewinddir()

_XOPEN_SOURCE

seekdir()   telldir()

_XOPEN_SOURCE 500

readdir_r()

This header file can be used by C++ POSIX(OFF) functions.

dlfcn.h

The dlfcn.h header file declares the following macros for use in the construction of a dlopen() mode argument::

RTLD_LAZY
Relocations are performed at an implementation-defined time.

RTLD_NOW
Relocations are performed when the object is loaded.

RTLD_GLOBAL
All symbols are available for relocation processing of other modules.

RTLD_LOCAL
All symbols are not made available for relocation processing by other modules.

dlclose() dlerror() dlsym() dlopen()

dll.h

The dll.h header file declares the following functions:

dllload() dllqueryvar() dllqueryfn() dllfree()

Use this header file when using these functions to import functions and variables from a DLL.

dynit.h

The dynit.h header file contains information for dynamic allocation routines. Specifically, it contains declarations of the dynalloc() and dynfree() functions, the definition of the dyninit() macro, declarations of related structures, and definitions of related constants.

env.h

The env.h header file is used to declare the setenv() and clearenv() functions, which are used in POSIX programs to set and clear environment variables. The env.h header file requires the `_POSIX1_SOURCE 2` feature test macro.

errno.h

The errno.h header file defines the symbolic constants that are returned in the external variable errno.

Table 3. Definitions in errno.h

EACCES	Permission denied
EADDRINUSE	Address in use

Table 3. Definitions in errno.h (continued)

EADDRNOTAVAIL	Address not available
EADV	Advertise error
EAFNOSUPPORT	Address family not supported
EAGAIN	Resource temporarily unavailable
EALREADY	Connection already in progress
EBADF	Bad file descriptor
EBADMSG	Bad message
EBUSY	Resource busy
ECANCELED	Operation canceled
ECHILD	No child processes
ECICS	Function not supported under CICS®
ECOMM	Communication error on send
ECONNABORTED	Connection aborted
ECONNREFUSED	Connection refused
ECONNRESET	Connection reset
EDEADLK	Resource deadlock avoided
EDESTADDRREQ	Destination address required
EDOM	Domain error
EDOTDOT	Cross mount point (not an error)
EDQUOT	Reserved
EEXIST	File exists
EFAULT	Bad address
EFBIG	File too large
EHOSTDOWN	Host is down
EHOSTUNREACH	Destination host can not be reached
EIBMBADCALL	A bad socket-call constant in IUCV header
EIBMBADPARM	Other IUCV header error
EIBMCANCELLED	Request canceled
EIBMCONFLICT	Conflicting call outstanding on socket
EIBMIUCVERR	Request failed due to IUCV error
EIBMSOCKINUSE	Assigned socket number already in use
EIBMSOCKOUTOFRANGE	Assigned socket number out of range
EIDRM	Identifier removed
EILSEQ	Illegal byte sequence
EINPROGRESS	Connection in progress
EINTR	Interrupted function call
EINTRNODATA	Function call interrupted before any data received
EINVAL	Invalid argument
EIO	Input/output error
EISCONN	Socket is already connected
EISDIR	Is a directory
ELEMSGERR	Message file was not found in the hierarchical file system
ELEMULTITHREAD	Function not allowed in a multithreaded environment
ELEMULTITHREADFORK	Function not allowed in child of fork() in multithreaded environment
ELENOFORK	Language Environment member language cannot tolerate a fork()
ELOOP	A loop exists in symbolic links encountered during resolution of the path argument
EMFILE	Too many open files
EMLINK	Too many links
EMSGSIZE	Message too long
EMULTIHOP	Multihop is not allowed

Table 3. Definitions in errno.h (continued)

EMVSBADCHAR	Bad character in environment variable name
EMVSCATLG	Catalog obtain error
EMVSCPLERROR	A CPL service failed
EMVSCVAF	Catalog Volume Access Facility error
EMVSDYNALC	Dynamic allocation error
EMVSERR	An MVS internal error
EMVSEXPIRE	Password has expired
EMVSINITIAL	Process initialization err
EMVSNORTL	Access to the z/OS UNIX version of the C RTL is denied
EMVSNOTXP	z/OS UNIX are not active
EMVSPARM	Bad parameters were passed to the service
EMVSPASSWORD	Password is invalid
EMVSPATHOPTS	Access mode argument conflicts with PATHOPTS parameter
EMVSPFSFILE	PDSE/X encountered a permanent file error
EMVSPFSPERM	PDSE/X encountered a system error
EMVSSAF2ERR	SAF/RACF error
EMVSSAFEXTRERR	SAF/RACF extract error
EMVSTODNOTSET	System TOD clock not set
ENAMETOOLONG	File name too long
ENETDOWN	The local interface to use or reach the destination
ENETRESET	Network dropped connection on reset
ENETUNREACH	Network unreachable
ENFILE	Too many open files in system
ENOBUFS	No buffer space available
ENODATA	No message available
ENODEV	No such device
ENOENT	No such file or directory
ENOEXEC	Exec format error
ENOLINK	The link has been severed
ENOLCK	No locks available
ENOMEM	Not enough space
ENOMSG	No message of desired type
ENONET	Machine is not on the network
ENOPROTOOPT	Protocol not available
ENOREUSE	The socket cannot be reused
ENOSPC	No space left on device
ENOSR	No stream resource
ENOSYS	Function not implemented
ENOSTR	Not a stream
ENOTBLK	Block device required
ENOTCONN	The socket is not connected.
ENOTDIR	Not a directory
ENOTEMPTY	Directory not empty
ENOTSOCK	Descriptor does not refer to a socket
ENOTSUP	Not supported.
ENOTTY	Inappropriate I/O control operation
ENXIO	No such device or address
EOFFLOADboxDOWN	Offload box down
EOFFLOADboxERROR	Offload box error
EOFFLOADboxRESTART	Offload box restarted
EOPNOTSUPP	Operation not supported on socket
EOVERFLOW	Value too large to be stored in data type
EPERM	Operation not permitted

Table 3. Definitions in errno.h (continued)

EPFNOSUPPORT	Protocol family not supported
EPIPE	Broken pipe
EPROCLIM	Too many processes
EPROTO	Protocol error
EPROTONOSUPPORT	Protocol not supported
EPROTOTYPE	The socket type is not supported by the protocol
ERANGE	Range error or pole error
EREMCHG	Remote address changed
EREMOTE	Too many levels of remote in path
EROFS	Read-only file system
ERREMOTE	Object is remote
ESHUTDOWN	Cannot send after socket shutdown
ESOCKTNOSUPPORT	Socket type not supported
ESPIPE	Invalid seek
ESRCH	No such process
ESRMNT	srmount error
ESTALE	The file handle is stale
ETIME	Stream ioctl() timeout
ETIMEDOUT	Socket not connected
ETOOMANYREFS	Too many references: cannot splice
ETXTBSY	Text file busy
EUSERS	Too many users
EWOULDBLOCK	Problem on nonblocking socket
EXDEV	A link to a file on another file system was attempted
E2BIG	Argument list too long

The errno.h header file also defines errno, which is a modifiable `lvalue` having type `int`. If you intend to test the value of errno after library function calls, first set it to 0, because the library functions do not reset the value to 0.

`strerror()` or `perror()` functions can be used to print the description of the message associated with a particular errno.

To test for the explicit error, use the macro names defined in errno.h, rather than specific values of these macros. Doing so will ensure future compatibility and portability.

errno.h also declares the __errno2() prototype.

exception

The exception header file defines several types and functions related to the handling of exceptions.

```
namespace std {
    class exception;
    class bad_exception;
    typedef void (*terminate_handler)();
    typedef void (*unexpected_handler)();
    terminate_handler
        set_terminate(terminate_handler ph) throw();
    unexpected_handler
        set_unexpected(unexpected_handler ph) throw();
    void terminate();
    void unexpected();
    bool uncaught_exception();
    };
```

bad_exception

```
class bad_exception : public exception {
    };
```

The class describes an exception that can be thrown from an unexpected handler. The value returned by what() is an implementation-defined C string. None of the member functions throw any exceptions.

exception

```
class exception {
public:
    exception() throw();
    exception(const exception& rhs) throw();
    exception& operator=(const exception& rhs) throw();
    virtual ~exception() throw();
    virtual const char *what() const throw();
    };
```

The class serves as the base class for all exceptions thrown by certain expressions and by the Standard C++ library. The C string value returned by what() is left unspecified by the default constructor, but may be defined by the constructors for certain derived classes as an implementation-defined C string. None of the member functions throw any exceptions.

terminate_handler

```
typedef void (*terminate_handler)();
```

The type describes a pointer to a function suitable for use as a terminate handler.

unexpected_handler

```
typedef void (*unexpected_handler)();
```

The type describes a pointer to a function suitable for use as an unexpected handler.

fcntl.h

The fcntl.h header file declares the following POSIX functions for creating, opening, rewriting, and manipulating files.

_POSIX_SOURCE

creat() fcntl() open()

features.h

The features.h header file contains definitions for feature test macros. For information on feature test macros, see “Feature test macros” on page 3.

fenv.h

The fenv.h header contains the following data types, macros and functions. This header is supported under IEEE Binary Floating-Point only and is required to define the feature test macro _ISOC99_SOURCE or requires the compiler that is designed to support C99 to expose the functionality. The decimal floating-point macros, prefixed by FE_DEC_ and _FE_DEC_, are used by the fe_dec_getround and fe_dec_setround functions to get and set the rounding mode of decimal floating-point operations. Decimal floating-point functionality additionally requires the __STDC_WANT_DEC_FP__ feature test macro to be defined.

Data types

fenv_t represents the entire floating-point environment.

fexcept_t
represents the floating-point status flags collectively.

Macros

FE_DIVBYZERO
defines the divide by zero exception

_FE_DEC_AWAYFROMZERO
rounds away from zero

FE_DEC_DOWNWARD
rounds towards minus infinity

_FE_DEC_PREPAREFORSHORTER
rounds to prepare for shorter precision

FE_DEC_TONEAREST
rounds to nearest

FE_DEC_TONEARESTFROMZERO
rounds to nearest, ties away from zero

_FE_DEC_TONEARESTTOWARDZERO
rounds to nearest, ties toward zero

FE_DEC_TOWARDZERO
rounds toward zero

FE_DEC_UPWARD
rounds toward plus infinity

FE_INEXACT
defines the inexact exception

FE_INVALID
defines the invalid exception

FE_OVERFLOW
defines the overflow exception

FE_UNDERFLOW
defines the underflow exception

FE_ALL_EXCEPT
defines the bitwise OR of all the exception macros.

FE_DOWNWARD
rounds towards minus infinity

FE_TONEAREST
rounds to nearest

FE_TOWARDZERO
rounds toward zero

FE_UPWARD
rounds towards plus infinity

FE_DFL_ENV
defines the floating-point environment as it was available at program start up

Functions

feclearexcept()
feraiseexcept()
feupdateenv()
fegetenv()
fesetenv()
fe_dec_getround()
fegetexceptflag()
fesetexceptflag()
fegetround()
fesetround()
fe_dec_setround()
feholdexcept()
fetestexcept()

float.h

The float.h header file contains definitions of constants listed in ANSI 2.2.4.2.2, that describe the characteristics of the internal representations of the three floating-point data types, float, double, and long double. The definitions are:

`Constant`
Description

`FLT_ROUNDS`
The rounding mode for floating-point addition.

`FLT_RADIX`
The radix for z/OS XL C applications. The FLT_RADIX value depends on the compile option FLOAT. FLOAT(HEX) gives value 16. FLOAT(IEEE) gives value 2.

`FLT_MANT_DIG`
`DBL_MANT_DIG`
`LDBL_MANT_DIG`
The number of hexadecimal digits stored to represent the significand of a fraction.

`FLT_DIG`
`DBL_DIG`
`LDBL_DIG`
The number of decimal digits, *q*, such that any floating-point number with *q* decimal digits can be rounded into a floating-point number with *p* radix FLT_RADIX digits and back again, without any change to the *q* decimal digits.

`FLT_MIN_EXP`
`DBL_MIN_EXP`
`LDBL_MIN_EXP`
The minimum negative integer such that FLT_RADIX raised to that power minus 1 is a normalized floating-point number.

`FLT_MIN_10_EXP DBL_MIN_10_EXP`
`LDBL_MIN_10_EXP`
The minimum negative integer such that 10 raised to that power is in the range of normalized floating-point numbers.

`FLT_MAX_EXP`

DBL_MAX_EXP
LDBL_MAX_EXP
The maximum integer such that FLT_RADIX raised to that power minus 1 is a representable finite floating-point number.

FLT_MAX_10_EXP
DBL_MAX_10_EXP
LDBL_MAX_10_EXP
The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.

FLT_MAX
DBL_MAX
LDBL_MAX
The maximum representable finite floating-point number.

FLT_EPSILON
DBL_EPSILON
LDBL_EPSILON
The difference between 1.0 and the least value greater than 1.0 that is representable in the given floating-point type.

FLT_MIN
DBL_MIN
LDBL_MIN
The minimum normalized positive floating-point number.

DECIMAL_DIG
The minimum number of decimal digits needed to represent all the significant digits for type long double.

FLT_EVAL_METHOD
Describes the evaluation mode for floating point operations. This value is 1, which evaluates all operations and constants of types float and double to type double and that of long double to type long double.

DEC_EVAL_METHOD
The decimal floating-point evaluation format.

FLT_MAXDIG10
DBL_MAXDIG10
LDBL_MAXDIG10
The number of base 10 digits required to ensure that values which differ by only one smallest unit in the last place (ulp) are always differentiated.

FLT_SUBNORM
DBL_SUBNORM
LDBL_SUBNORM
Characterize the presence or absence of subnormal numbers:

- -1: indeterminable
- 0: absent (type does not support subnormal numbers)
- 1: present (type does support subnormal numbers)

FLT_DECIMAL_DIG
DBL_DECIMAL_DIG
LDBL_DECIMAL_DIG
The number of decimal digits, n, such that any floating-point number with p radix b digits can be rounded to a floating-point number with n decimal digits and back again without change to the value.

FLT_TRUE_MIN

DBL_TRUE_MIN
LDBL_TRUE_MIN
The minimum positive floating-point number.

The float.h header file also contains constants that describe the characteristics of the internal representations of the three decimal floating-point data types, _Decimal32, _Decimal64, and _Decimal128. The prefixes DEC32_, DEC64_, and DEC128_ are used to denote the types _Decimal32, _Decimal64, and _Decimal128, respectively.

Constant
Description

DEC32_MANT_DIG
DEC64_MANT_DIG
DEC128_MANT_DIG
The number of digits in the coefficient.

DEC32_MIN_EXP
DEC64_MIN_EXP
DEC128_MIN_EXP
The minimum exponent.

DEC32_MAX_EXP
DEC64_MAX_EXP
DEC128_MAX_EXP
The maximum exponent.

DEC32_MAX
DEC64_MAX
DEC128_MAX
The maximum representable finite decimal floating number.

DEC32_EPSILON
DEC64_EPSILON
DEC128_EPSILON
The difference between 1 and the least value greater than 1 that is representable in the given floating point type.

DEC32_MIN
DEC64_MIN
DEC128_MIN
The minimum normalized positive decimal floating number.

DEC32_SUBNORMAL_MIN
DEC64_SUBNORMAL_MIN
DEC128_SUBNORMAL_MIN
The minimum subnormal (denormalized) positive Decimal Floating Point number.

DEC_EVAL_METHOD
The decimal floating-point evaluation format.

fmtmsg.h

The fmtmsg.h header file contains message display structures.

fnmatch.h

The fnmatch.h header file contains filename matching types.

fpxcp.h

The fpxcp.h header file declares floating-point exception interfaces.

__ftp.h

The __ftp.h header file contains definitions for FTP resolver functions.

ftw.h

The ftw.h header file contains file tree traversal constants.

glob.h

The glob.h header file contains pathname pattern matching types.

grp.h

The grp.h header file declares functions used to access group databases.

_POSIX_SOURCE

getgrgid()	__getgrgid1()	getgrnam()	__getgrnam1()

_OPEN_SYS

initgroups()	setgroups()

_XOPEN_SOURCE_EXTENDED 1

setgrent()	endgrent()	getgrent()

_XOPEN_SOURCE 500

getgrgid_r()	getgrnam_r()

iconv.h

The iconv.h header file declares the `iconv_open()`, `iconv()`, and `iconv_close()` functions that deal with code conversion.

_Ieee754.h

The _Ieee754.h header file declares IEEE 754 interfaces.

ims.h

Restriction: This header file is not supported in AMODE 64.

The ims.h header file declares the ctdli() function that invokes IMS™ facilities. The function is *not* supported from a z/OS UNIX program running POSIX(ON).

inttypes.h

The following macros are defined in inttypes.h. Each expands to a character string literal containing a conversion specifier which can be modified by a length modifier that can be used in the *format* argument of a formatted input/output function when converting the corresponding integer type. These macros have the general form of PRI (character string literals for the fprintf() and fwprintf() family of functions) or SCN (character string literals for the fscanf() and fwscanf() family of functions), followed by the conversion specifier, followed by a name corresponding to a similar type name in <inttypes.h>. In these names, the suffix number represents the width of the type. For example, *PRIdFAST32* can be used in a format string to print the value of an integer of type **int_fast32_t**.

This header defines the type **imaxdiv_t**.

Note: Requires long long to be available.
imaxdiv_t is a structure type that is the type of the value returned by the imaxdiv() function. It is functionally equivalent to lldiv_t.

Compile requirement:

In the following list all macros with the suffix MAX or 64 require long long to be available.

PRId8	PRId16	PRId32	PRId64
PRIdLEAST8	PRIdLEAST16	PRIdLEAST32	PRIdLEAST64
PRIdFAST8	PRIdFAST16	PRIdFAST32	PRIdFAST64
PRIdMAX			
PRIdPTR			
PRIi8	PRIi16	PRIi32	PRIi64
PRIiLEAST8	PRIiLEAST16	PRIiLEAST32	PRIiLEAST64
PRIiFAST8	PRIiFAST16	PRIiFAST32	PRIiFAST64
PRIiMAX			
PRIiPTR			

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>
int main(void)
{

int8_t i =  40;
printf("Demonstrating the use of the following macros:\n");
printf("Using PRId8, the printed value of 40 "
"is  %" PRId8"\n", i);
printf("Using PRIiFAST8, the printed value of 40 "
"is  %" PRIiFAST8"\n", i);
printf("Using PRIoLEAST8, the printed value of 40 "
"is  %" PRIoLEAST8 "\n", i);
return 0;
}

Output:

Demonstrating the use of the following macros:
```

```
Using PRId8, the printed value of 40 is  40
Using PRIiFAST8, the printed value of 40 is  40
Using PRIoLEAST8, the printed value of 40 is  50
```

Compile requirement:

In the following list all macros with the suffix MAX or 64 require long long to be available.

Macros for fprintf family for unsigned integers:

PRIo8	PRIo16	PRIo32	PRIo64
PRIoLEAST8	PRIoLEAST16	PRIoLEAST32	PRIoLEAST64
PRIoFAST8	PRIoFAST16	PRIoFAST32	PRIoFAST64
PRIoMAX			
PRIoPTR			
PRIu8	PRIu16	PRIu32	PRIu64
PRIuLEAST8	PRIuLEAST16	PRIuLEAST32	PRIuLEAST64
PRIuFAST8	PRIuFAST16	PRIuFAST32	PRIuFAST64
PRIuMAX			
PRIuPTR			
PRIx8	PRIx16	PRIx32	PRIx64
PRIxLEAST8	PRIxLEAST16	PRIxLEAST32	PRIxLEAST64
PRIxFAST8	PRIxFAST16	PRIxFAST32	PRIxFAST64
PRIxMAX			
PRIxPTR			
PRIX8	PRIX16	PRIX32	PRIX64
PRIXLEAST8	PRIXLEAST16	PRIXLEAST32	PRIXLEAST64
PRIXFAST8	PRIXFAST16	PRIXFAST32	PRIXFAST64
PRIXMAX			
PRIXPTR			

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
uint32_t i =  24000;
printf("Demonstrating the use of the following macros:\n");
printf("Using PRIuPTR, the address of the variable "
"is  %" PRIuPTR "\n", i);
printf("Using PRIXFAST32, the printed value of 24000 "
"is  %" PRIXFAST32"\n", i);
printf("Using PRIxLEAST32, the printed value of 24000 "
"is  %" PRIxLEAST32 "\n", i);
return 0;
}
```

```
Output:

Demonstrating the use of the following macros:
Using PRIuPTR, the address of the variable is  538874544
Using PRIXFAST32, the printed value of 24000 is  5DC0
Using PRIxLEAST32, the printed value of 24000 is  5dc0
```

Compile requirement:

In the following list all macros with the suffix MAX or 64 require long long to be available.

Macros for fscanf family for signed integers:

SCNd8	SCNd16	SCNd32	SCNd64
SCNdLEAST8	SCNdLEAST16	SCNdLEAST32	SCNdLEAST64
SCNdFAST8	SCNdFAST16	SCNdFAST32	SCNdFAST64
SCNdMAX			
SCNdPTR			
SCNi8	SCNi16	SCNi32	SCNi64
SCNiLEAST8	SCNiLEAST16	SCNiLEAST32	SCNiLEAST64
SCNiFAST8	SCNiFAST16	SCNiFAST32	SCNiFAST64
SCNiMAX			
SCNiPTR			

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    int32_t i;
    printf("Enter decimal value ");
    scanf("%" SCNdFAST32, i);
    printf("Print result: %" PRIdFAST32 "\n", i);
   return 0;
}

Output:

Enter decimal value 23
Print result: 23
```

Compile requirement:

In the following list all macros with the suffix MAX or 64 require long long to be available.

Macros for fscanf family for signed integers:

SCNo8	SCNo16	SCNo32	SCNo64
SCNoLEAST8	SCNoLEAST16	SCNoLEAST32	SCNoLEAST64
SCNoFAST8	SCNoFAST16	SCNoFAST32	SCNoFAST64
SCNoMAX			
SCNoPTR			
SCNu8	SCNu16	SCNu32	SCNu64
SCNuLEAST8	SCNuLEAST16	SCNuLEAST32	SCNuLEAST64
SCNuFAST8	SCNuFAST16	SCNuFAST32	SCNuFAST64
SCNuMAX			
SCNuPTR			
SCNx8	SCNx16	SCNx32	SCNx64
SCNxLEAST8	SCNxLEAST16	SCNxLEAST32	SCNxLEAST64
SCNxFAST8	SCNxFAST16	SCNxFAST32	SCNxFAST64
SCNxMAX			
SCNxPTR			

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    intmax_t i;
    printf("Enter hex value ");
    scanf("%" SCNxMAX, i);
    printf("Print result: %020" PRIxMAX "\n", i);
    return 0;
}

Output :

Enter hex value 0x32
Print result: 00000000000000000032
```

iso646.h

The header file iso646.h allows the user to use the following macros in place of the associated operator.

Macros	**Operators**
and	&&
and_eq	&=
bitand	&
bitor	|
compl	~
not	!
not_eq	!=
or	||
or_eq	|=
xor	^
xor_eq	^=

langinfo.h

The langinfo.h header file contains the declaration for the `nl_langinfo()` function. The header file also defines the macros that, in turn, define constants used to identify the information queried by `nl_langinfo()` in the current locale. The following macros are defined:

Table 4. Item Values defined in langinfo.h

Item Name	Description
ABDAY_1	Abbreviated first day of the week
ABDAY_2	Abbreviated second day of the week
ABDAY_3	Abbreviated third day of the week
ABDAY_4	Abbreviated fourth day of the week
ABDAY_5	Abbreviated fifth day of the week
ABDAY_6	Abbreviated sixth day of the week

Table 4. Item Values defined in langinfo.h (continued)

Item Name	Description
ABDAY_7	Abbreviated seventh day of the week
ABMON_1	Abbreviated first month
ABMON_2	Abbreviated second month
ABMON_3	Abbreviated third month
ABMON_4	Abbreviated fourth month
ABMON_5	Abbreviated fifth month
ABMON_6	Abbreviated sixth month
ABMON_7	Abbreviated seventh month
ABMON_8	Abbreviated eighth month
ABMON_9	Abbreviated ninth month
ABMON_10	Abbreviated tenth month
ABMON_11	Abbreviated eleventh month
ABMON_12	Abbreviated twelfth month
ALT_DIGITS	String of semicolon separated alternative symbols for digits
AM_STR	String for morning
CODESET	Current encoded character set of the process
CRNCYSTR	Local currency symbol, preceded by '-' if the symbol should appear before the value, '+' if the symbol should appear after the value, or '.' if the symbol should replace the radix character.
D_FMT	String for formatting date
D_T_FMT	String for formatting date and time
DAY_1	Name of the first day of the week
DAY_2	Name of the second day of the week
DAY_3	Name of the third day of the week
DAY_4	Name of the fourth day of the week
DAY_5	Name of the fifth day of the week
DAY_6	Name of the sixth day of the week
DAY_7	Name of the seventh day of the week
ERA	String of semicolon separated era segments
ERA_D_FMT	String for era date format
ERA_D_T_FMT	String for era date and time format
ERA_T_FMT	String for era time format
MON_1	Name of the first month
MON_2	Name of the second month
MON_3	Name of the third month
MON_4	Name of the fourth month
MON_5	Name of the fifth month
MON_6	Name of the sixth month
MON_7	Name of the seventh month
MON_8	Name of the eighth month
MON_9	Name of the ninth month
MON_10	Name of the tenth month
MON_11	Name of the eleventh month
MON_12	Name of the twelfth month
NOEXPR	Negative response expression
NOSTR	Negative response string
PM_STR	String for afternoon
RADIXCHAR	Radix character
T_FMT	String for formatting time
T_FMT_AMPM	String for formatting time in 12-hour clock format
THOUSEP	Separator for thousands
YESEXPR	Affirmative response expression
YESSTR	affirmative response string

Note:

The YESSTR and NOSTR constants are kept for historical reasons. They were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using these constants in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this topic. For still more information, see “Internationalization: Locales and Character Sets” in *z/OS XL C/C++ Programming Guide*.

lc_core.h

The lc_core.h header file contains locale-related data structures.

lc_sys.h

The lc_sys.h header file contains definitions used by the localedef utility for building references to locale methods in ASCII locales.

__le_api.h

The __le_api.h header file declares the following AMODE 64 C functions in Language Environment®:

__le_ceegtjs()
__le_msg_add_insert()
__le_msg_write()
__le_cib_get()
__le_msg_get()
__le_set_debug_resume_mch()
__le_condition_token_build()
__le_msg_get_and_write()

Restrictions:

- This header is supported in AMODE 64 only. For AMODE 31, the leawi.h header file should be used.

leawi.h

Restriction: This header file is not supported in AMODE 64. For AMODE 64, the __le_api.h header file should be used.

The leawi.h header file contains internal macros. The header file is required for applications that use Language Environment Application Writer Interfaces (LE AWI).

libgen.h

The libgen.h header file contains definitions for pattern matching functions.

limits.h

The limits.h header file contains symbolic names that represent standard values for limits on resources, such as the maximum value for an object of type `char`.

Table 5. Definitions of resource limits (limits.h)

ATEXIT_MAX	2048
BC_DIM_MAX	32768
BC_SCALE_MAX	32767
BC_STRING_MAX	2048
CHAR_BIT	8
CHAR_MAX	127 (_CHAR_SIGNED)
CHAR_MAX	255
CHAR_MIN	(-128) (_CHAR_SIGNED)
CHAR_MIN	0
COLL_WEIGHTS_MAX	2
__DIR_NAME_MAX	256
EXPR_NEST_MAX	32
INT_MAX	2147483647
INT_MIN	(-2147483647 - 1)
LINE_MAX	2048
LLONG_MAX	(9223372036854775807LL)
LLONG_MIN	(-LLONG_MAX-1)
LONG_MAX	2147483647
LONGLONG_MAX	(9223372036854775807LL)
LONG_MIN	(-2147483647L - 1)
LONGLONG_MIN	(-LONGLONG_MAX - 1)
MB_LEN_MAX	4
NGROUPS_MAX	300
PASS_MAX	255
_POSIX_ARG_MAX	4096
_POSIX_CHILD_MAX	25
_POSIX_DATAKEYS_MAX	32
_POSIX_LINK_MAX	8
_POSIX_MAX_CANON	255
_POSIX_MAX_INPUT	255
_POSIX_NAME_MAX	14
_POSIX_NGROUPS_MAX	8
_POSIX_OPEN_MAX	20
_POSIX_PATH_MAX	255

_POSIX2_BC_BASE_MAX	99
_POSIX2_BC_DIM_MAX	2048
_POSIX2_BC_SCALE_MAX	99
_POSIX2_BC_STRING_MAX	1000
_POSIX2_COLL_WEIGHTS_MAX	2
_POSIX2_EXPR_NEST_MAX	32
_POSIX2_LINE_MAX	2048
_POSIX2_RE_DUP_MAX	255
RE_DUP_MAX	255
SCHAR_MAX	127
SCHAR_MIN	(-128)

Table 5. Definitions of resource limits (limits.h) (continued)

SHRT_MAX	32767
SHRT_MIN	(-32768)
SSIZE_MAX	2147483647
UCHAR_MAX	255
UINT_MAX	4294967295
ULONG_MAX	4294967295U
ULONGLONG_MAX	(18446744073709551615ULL)
ULLONG_MAX	(18446744073709551615ULL)
USHRT_MAX	65535
When compiled with SUSV3 thread support (_UNIX03_THREADS or _XOPEN_SOURCE 600), limits.h adds the following constants:	
PTHREAD_STACK_MIN	4096 (1048576 in 64-bit)
_POSIX_THREAD_DESTRUCTOR_ITERATIONS	4
_POSIX_THREAD_KEYS_MAX	128
_POSIX_THREAD_THREADS_MAX	64

localdef.h

The localdef.h header file defines data structures for locale objects which are loaded by setlocale(). The data structures in localdef.h are not a supported programming interface.

locale.h

The locale.h header file contains declarations for the localdtconv() and localeconv() library functions, which retrieve values from the current locale, and for the setlocale() function, used to query or change locale settings for internationalized applications.

The locale.h file declares the `lconv` structure. Table 6 below shows the elements of the `lconv` structure and the defaults for the C locale.

Table 6. Elements of lconv Structure

Element	Purpose of Element	Default
char *decimal_point	Decimal-point character used to format non-monetary quantities.	"."
char *thousands_sep	Character used to separate groups of digits to the left of the decimal-point character in formatted non-monetary quantities.	""
char *grouping	String indicating the size of each group of digits in formatted non-monetary quantities. The value of each character in the string determines the number of digits in a group. A value of `CHAR_MAX` indicates that there are no further groupings. 0 indicates that the previous element is to be used for the remainder of the digits.	""

Table 6. Elements of lconv Structure (continued)

Element	Purpose of Element	Default
char *int_curr_symbol	International currency symbol for the current locale. The first three characters contain the alphabetic international currency symbol. The fourth character (usually a space) is the character used to separate the international currency symbol from the monetary quantity.	""
char *currency_symbol	Local currency symbol of the current locale.	""
char *mon_decimal_point	Decimal-point character used to format monetary quantities.	"."
char *mon_thousands_sep	Separator for digits in formatted monetary quantities.	""
char *mon_grouping	String indicating the size of each group of digits in formatted monetary quantities. The value of each character in the string determines the number of digits in a group. A value of CHAR_MAX indicates that there are no further groupings. 0 indicates that the previous element is to be used for the remainder of the digits.	""
char *positive_sign	String indicating the positive sign used in monetary quantities.	""
char *negative_sign	String indicating the negative sign used in monetary quantities.	""
char int_frac_digits	The number of displayed digits to the right of the decimal place for internationally formatted monetary quantities.	UCHAR_MAX
char frac_digits	Number of digits to the right of the decimal place in monetary quantities.	UCHAR_MAX
char p_cs_precedes	Value indicating the placement of the currency symbol in a nonnegative, formatted monetary quantity. For a list of valid values, see Table 7 on page 42.	UCHAR_MAX
char p_sep_by_space	Value indicating the use of white space in a nonnegative, formatted monetary quantity. For a list of valid values, see Table 7 on page 42.	UCHAR_MAX
char n_cs_precedes	Value indicating the placement of the currency symbol in a negative, formatted monetary quantity. For a list of valid values, see Table 7 on page 42.	UCHAR_MAX
char n_sep_by_space	Value indicating the use of white space in a negative, formatted monetary quantity. For a list of valid values, see Table 7 on page 42.	UCHAR_MAX
char p_sign_posn	Value indicating the position of the positive_sign for a nonnegative formatted monetary quantity. For a list of valid values, see Table 7 on page 42.	UCHAR_MAX

Table 6. Elements of lconv Structure (continued)

Element	Purpose of Element	Default
char n_sign_posn	Value indicating the position of the `negative_sign` for a negative formatted monetary quantity. For a list of valid values, see Table 7.	UCHAR_MAX
char *left_parenthesis	Negative-valued monetary symbol. **Note:** This element is an IBM-specific extension.	""
char *right_parenthesis	Negative-valued monetary symbol. **Note:** This element is an IBM-specific extension.	""
char *debit_sign	Debit_sign character string. **Note:** This element is an IBM-specific extension.	""
char *credit_sign	Credit_sign character string. **Note:** This element is an IBM-specific extension.	""
char int_p_cs_precedes	For international formatting, value indicating the placement of the currency symbol in a nonnegative, monetary quantity. For a list of valid values, see Table 7.	UCHAR_MAX
char int_n_cs_precedes	For international formatting, value indicating the placement of the currency symbol in a negative, monetary quantity. For a list of valid values, see Table 7.	UCHAR_MAX
char int_p_sep_by_space	For international formatting, value indicating the use of white space in a nonnegative, monetary quantity. For a list of valid values, see Table 7.	UCHAR_MAX
char int_n_sep_by_space	For international formatting, value indicating the use of white space in a negative, monetary quantity. For a list of valid values, see Table 7.	UCHAR_MAX
char int_p_sign_posn	For international formatting, value indicating the position of the positive sign for a nonnegative monetary quantity. For a list of valid values, see Table 7.	UCHAR_MAX
char int_n_sign_posn	For international formatting, value indicating the position of the negative sign for a negative monetary quantity. For a list of valid values, see Table 7.	UCHAR_MAX

For a list of valid values, see Table 7.

Table 7. Monetary Formatting Values

Element	Values	
cs_precedes	0	The `currency_symbol` succeeds the value for the formatted monetary quantity;
	1	The `currency_symbol` precedes the value for the formatted monetary quantity

Table 7. Monetary Formatting Values (continued)

Element	Values
sep_by_space	0 No space separates the currency_symbol from the formatted monetary quantity;
	1 If currency_symbol and sign string are adjacent, a space separates them from the value. Otherwise, the currency symbol and value are separated by a space.
	2 If currency_symbol and sign string are adjacent, a space separates them from each other. Otherwise, the sign string and value are separated by a space.
sign_posn	0 Parentheses surround the quantity and currency_symbol;
	1 The sign string precedes the quantity and currency_symbol;
	2 The sign string succeeds the quantity and currency_symbol;
	3 The sign string immediately precedes currency_symbol;
	4 The sign string immediately succeeds currency_symbol;
	5 Substitute debit_sign or credit_sign for negative_sign or positive_sign, respectively. **Note:** This value is an IBM-specific extension.

The locale.h file declares the dtconv structure:

```
struct dtconv {
        char *abbrev_month_names[12];   /* Abbreviated month names      */
        char *month_names[12];          /* full month names             */
        char *abbrev_day_names[7];      /* Abbreviated day names        */
        char *day_names[7];             /* full day names               */
        char *date_time_format;         /* date and time format         */
        char *date_format;              /* date format                  */
        char *time_format;              /* time format                  */
        char *am_string;                /* AM string                    */
        char *pm_string;                /* PM string                    */
        char *time_format_ampm;         /* long date format             */
        char *iso_std8601_2000;         /* ISO 8601:2000 std date format*/
};
```

Note: This structure is an IBM-specific extension.

The locale.h file also contains macro definitions for use with the setlocale() function:

LC_ALL	LC_COLLATE	LC_CTYPE	LC_MONETARY
LC_NUMERIC	LC_TIME	LC_TOD	NULL
LC_MESSAGES	LC_SYNTAX		

The aspects of a program related to national language or to cultural characteristics (such as time zone, currency symbols, and sorting order of characters) can be customized at run time using different locales, to suit users' requirements at those locales. See the internationalization topic in *z/OS XL C/C++ Programming Guide*.

math.h

The math.h header file contains function declarations for all the floating-point math functions:

No feature test macro required.

Notes:

1. nan(), nanf(), and nanl() functions are supported under IEEE only.
2. For the C99 math functions, it is required to define the feature test macro _ISO_C99_SOURCE or requires a compiler that is designed to support C99 to expose the functionality.

absf() absl() acos() acosf() acoshf()
acoshl() acosl() asin() asinf() asinhf()

nearbyint() nextafter() nexttoward() pow() quantexp()

remainder() rint() round() scalbn() scalbln()

sin() sinh() sqrt() tan() tanh()

tgamma() trunc()

For example:
- _Decimal32 ceil(_Decimal32)
- _Decimal64 ceil(_Decimal64)
- _Decimal128 ceil(_Decimal128)

_TR1_C99: The following functions provide additional overloads.

acos() acosh() asin() asinh() atan()

atanh() atan2() cbrt() ceil() copysign()

cos() cosh() erf() erfc() exp()

exp2() expm1() fabs() fdim() floor()

fma() fmax() fmin() fmod() frexp()

hypot() ilogb() ldexp() lgamma() llrint()

llround() log() log10() log1p() log2()

logb() lrint() lround() nearbyint() nextafter()

nexttoward() pow() remainder() remquo() rint()

round() scalbln() scalbn() sin() sinh()

sqrt() tan() tanh() tgamma() trunc()

- If any argument corresponding to a double parameter has type long double, all arguments corresponding to double parameters are effectively cast to long double. The return type will be the same return type as if the 'C' long double version of the function was called.
- Otherwise, if any argument corresponding to a double parameter has type double or an integer type, all arguments corresponding to double parameters are effectively cast to double. The return type will be the same return type as if the 'C' double version of the function was called.
- Otherwise, all arguments corresponding to double parameters are effectively cast to float. The return type will be the same return type as if the 'C' float version of the function was called.

Object-like macros: Additional object-like macros provided by the math.h header are described.

Note: The floating point macros and the macros INFINITY and NAN are supported under IEEE only.

DEC_INFINITY
A constant expression of type _Decimal32 representing infinity.

DEC_NAN
A quiet decimal floating NaN for the type _Decimal32.

HUGE_VAL_D32
A constant expression of type _Decimal32 representing +infinity.

HUGE_VAL_D64
A constant expression of type _Decimal64 representing +infinity.

HUGE_VAL_D128
A constant expression of type _Decimal128 representing +infinity.

HUGE_VALF
A very large positive number that expands to a float expression

HUGE_VALL
A very large positive number that expands to a long double expression.

INFINITY
A constant expression of type float representing positive infinity.

NAN A constant expression of type float representing a quiet NaN.

FP_INFINITE
The value of the macro fpclassify for an argument that is plus or minus infinity. This expands to an integer constant expression.

FP_NAN
The value of the macro fpclassify for an argument that is not-a-number (NaN). This expands to an integer constant expression.

FP_NORMAL
The value of the macro fpclassify for an argument that is finite and normalized. This expands to an integer constant expression.

FP_SUBNORMAL
The value of the macro fpclassify for an argument that is finite and denormalized. This expands to an integer constant expression.

FP_ZERO
The value of the macro fpclassify for an argument that is positive or negative. This expands to an integer constant expression.

FP_FAST_FMA
Indicates that the fma function generally executes about as fast as, or faster than, a multiply and an add of double operands.

FP_FAST_FMAF
This is the float version of FP_FAST_FMA.

FP_FAST_FMAL
This is the long double version of FP_FAST_FMA.

Note: Decimal floating-point does not support FP_FAST_FMAD32, FP_FAST_FMAD64, and FP_FAST_FMAD128.

FP_ILOGB0
The value returned by ilogb() if its argument is zero.

FP_ILOGBNAN
The value returned by ilogb() if its argument is a NaN.

MATH_ERRNO
This is defined as value 1 (one) and is used for testing the value of the macro math_errhandling to determine whether a math function reports an error by storing a nonzero value in errno.

MATH_ERREXCEPT
This is defined as value 2 and is used for testing the value of the macro math_errhandling to determine whether a math function reports an error by raising an invalid floating point exception.

math_errhandling
This macro expands to an expression that has type int and the value MATH_ERRNO, MATH_ERREXCEPT, or the bitwise OR of both. This implementation defines this macro as MATH_ERRNO.

Function-like macros or C++ function templates: Additional function-like macros or C++ function templates provided by the <math.h> header are listed.

fpclassify()	isfinite()	ininf()	isgreater()	isgreaterequal()
isless()	islessequal()	islessgreater()	isnan()	isnormal()
isunordered()	signbit()			

The header file includes declarations for the built-in functions abs() and fabs(). For information about built-in functions, see "Built-in functions" on page 93.

The math.h header file declares the macro HUGE_VAL, which expands to a positive `double` constant expression, not necessarily representable as a `float`. Similarly, the macros HUGE_VALF and HUGE_VALL are respectively `float` and `long double` analogs of HUGE_VAL.

For all mathematical functions, a *domain error* occurs when an input argument is outside the range of values allowed for that function. If a domain error occurs, errno is set to the value of EDOM.

A range error occurs if the result of the function cannot be represented in a float, double, long double, _Decimal32, _Decimal64, or _Decimal128 value. If the magnitude of the result is too large (overflow), the function returns the positive or negative value of the macro HUGE_VAL, HUGE_VALF, HUGE_VALL, HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128, as applicable, and sets errno to ERANGE. If the result is too small (underflow), the function returns 0.

A pole error occurs if the function has an exact infinite result as the finite input arguments are approached in the limit (for example, log(0.0)). If a pole error occurs, the function sets errno to ERANGE.

float_t and double_t are floating-point types whose type depends on the value of FLT_EVAL_METHOD. FLT_EVAL_METHOD is 1 which implies both float_t and double_t are double.

Note: Decimal floating-point does not support FP_FAST_FMAD32, FP_FAST_FMAD64, and FP_FAST_FMAD128.

memory.h

The memory.h header file contains declarations for memory operations.

monetary.h

The monetary.h header file contains the declaration for the strfmon() function.

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this topic. For still more information, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

msgcat.h

The msgcat.h header file contains message catalog structures and definitions. The data structures in msgcat.h are not a supported programming interface.

mtf.h

Restriction: This header file is not supported in AMODE 64.

The mtf.h header file contains declarations for the multitasking facility (MTF) functions:

tinit()
tsched()
tsyncro()
tterm()

tsched() is a built-in function.

This header file also contains definitions of macros for certain return values from the above functions.

This header file is supported only under z/OS C applications. The functions are *not* supported under z/OS UNIX.

_Nascii.h

The _Nascii.h header file contains the externals for the correspondence table and functions that support bimodal application development.

ndbm.h

The ndbm.h header file contains definitions for ndbm database operations.

netdb.h

The netdb.h header file contains definitions for network database operations.

net/if.h

The net/if.h header file contains network interface structures and definitions.

_OE_SOCKETS
_OPEN_SYS_IF_EXT 1

The following structures are declared:

- ifaddr
- ifconf
- ifnet
- ifreq

The following macros are declared:

- IF_ADJ
- IF_DEQUEUE
- IF_DEQUEUEIF
- IF_DROP
- IF_ENQUEUE

- IF_PREPEND
- IF_QFULL
- IFF_ALLMULTI
- IFF_BRIDGE
- IFF_BROADCAST
- IFF_CANTCHANGE
- IFF_CHECKSUM
- IFF_DEBUG
- IFF_LOOPBACK
- IFF_MULTICAST
- IFF_NOARP
- IFF_NOTRAILERS
- IFF_POINTOMULTIPT
- IFF_POINTOPOINT
- IFF_PROMISC
- IFF_RUNNING
- IFF_SNAP
- IFF_UP
- IFF_VIRTUAL
- IFNET_SLOWHZ
- IFQ_MAXLEN

_OPEN_SYS_SOCK_IPV6
_POSIX_C_SOURCE 200112L

The following structure is declared:

- if_nameindex

The following macro is declared:

- IF_NAMESIZE

The following functions are declared:

- if_freenameindex
- if_indextoname
- if_nameindex
- if_nametoindex

net/rtrouteh.h

The net/rtrouteh.h header file contains network routing structures and definitions.

netinet/icmp6.h

The netinet/icmp6.h header file defines structures and constants for ICMPv6 header options.

The following structures are exposed with this header file:

- icmp6_hdr
- nd_router_solicit
- nd_router_advert

- nd_neighbor_solicit
- nd_neighbor_advert
- nd_redirect
- nd_opt_hdr
- nd_opt_prefix_info
- nd_opt_rd_hdr
- nd_opt_mtu
- mld_hdr
- icmp6_router_renum
- rr_pco_match
- rr_pco_use
- rr_result

The following definitions are associated with the icmp6_hdr structure:
- icmp6_data32
- icmp6_data16
- icmp6_data8
- icmp6_pptr
- icmp6_mtu
- icmp6_id
- icmp6_seq
- icmp6_maxdelay

The following definitions are associated with ICMPv6 Type and Code values:
- ICMP6_DST_UNREACH
- ICMP6_PACKET_TOO_BIG
- ICMP6_TIME_EXCEEDED
- ICMP6_PARAM_PROB
- ICMP6_INFOMSG_MASK
- ICMP6_ECHO_REQUEST
- ICMP6_ECHO_REPLY
- ICMP6_DST_UNREACH_NOROUTE
- ICMP6_DST_UNREACH_ADMIN
- ICMP6_DST_UNREACH_BEYONDSCOPE
- ICMP6_DST_UNREACH_ADDR
- ICMP6_DST_UNREACH_NOPORT
- ICMP6_TIME_EXCEED_TRANSIT
- ICMP6_TIME_EXCEED_REASSEMBLY
- ICMP6_PARAMPROB_HEADER
- ICMP6_PARAMPROB_NEXTHEADER
- ICMP6_PARAMPROB_OPTION

The following definitions are associated with the nd_router_solicit structure:
- ND_ROUTER_SOLICIT
- nd_rs_type
- nd_rs_code

- nd_rs_cksum
- nd_rs_reserved

The following definitions are associated with the nd_router_advert structure:

- ND_ROUTER_ADVERT
- nd_ra_type
- nd_ra_code
- nd_ra_cksum
- nd_ra_curhoplimit
- nd_ra_flags_reserved
- ND_RA_FLAG_MANAGED
- ND_RA_FLAG_OTHER
- nd_ra_router_lifetime

The following definitions are associated with the nd_neighbor_solicit structure:

- ND_NEIGHBOR_SOLICIT
- nd_ns_type
- nd_ns_code
- nd_ns_cksum
- nd_ns_reserved

The following definitions are associated with the nd_neighbor_advert structure:

- ND_NEIGHBOR_ADVERT
- nd_na_type
- nd_na_code
- nd_na_cksum
- nd_na_flags_reserved
- ND_NA_FLAG_ROUTER
- ND_NA_FLAG_SOLICITED
- ND_NA_FLAG_OVERRIDE

The following definitions are associated with the nd_redirect structure:

- ND_REDIRECT
- nd_rd_type
- nd_rd_code
- nd_rd_cksum
- nd_rd_reserved

The following definitions are associated with the nd_opt_hdr structure:

- ND_OPT_SOURCE_LINKADDR
- ND_OPT_TARGET_LINKADDR
- ND_OPT_PREFIX_INFORMATION
- ND_OPT_REDIRECTED_HEADER
- ND_OPT_MTU

The following definitions are associated with nd_opt_prefix_info structure:

- ND_OPT_PI_FLAG_ONLINK

- ND_OPT_PI_FLAG_AUTO

The following definitions are associated with the mld_hdr structure:
- MLD_LISTENER_QUERY
- MLD_LISTENER_REPORT
- MLD_LISTENER_REDUCTION
- mld_type
- mld_code
- mld_cksum
- mld_maxdelay
- mld_reserved

The following definitions are associated with the icmp6_router_renum structure:
- ICMP6_ROUTER_RENUMBERING
- rr_type
- rr_code
- rr_cksum
- rr_seqnum
- ICMP6_RR_FLAGS_TEST
- ICMP6_RR_FLAGS_REQRESULT
- ICMP6_RR_FLAGS_FORCEAPPLY
- ICMP6_RR_FLAGS_SPECSITE
- ICMP6_RR_FLAGS_PREVDONE

The following definitions are associated with the rr_pco_match structure:
- RPM_PCO_ADD
- RPM_PCO_CHANGE
- RPM_PCO_SETGLOBAL

The following definitions are associated with the rr_pco_use structure:
- ICMP6_RR_PCOUSE_RAFLAGS_ONLINK
- ICMP6_RR_PCOUSE_RAFLAGS_AUTO
- ICMP6_RR_PCOUSE_FLAGS_DECRVLTIME
- ICMP6_RR_PCOUSE_FLAGS_DECRPLTIME
- nd_ns_reserved

The following definitions are associated with the rr_result structure:
- ICMP6_RR_RESULT_FLAGS_OOB
- ICMP6_RR_RESULT_FLAGS_FORBIDDEN

netinet/in.h

The netinet/in.h header file contains definitions for the internet protocol family.

The following structure definition is supported for IPv6:
- struct ip6_mtuinfo{};

The following functions are supported for IPv6:

- bind2addrsel()
- inet6_is_srcaddr()
- inet6_rth_space()
- inet6_rth_init()
- inet6_rth_add()
- inet6_rth_reverse()
- inet6_rth_segments()
- inet6_rth_getaddr()
- inet6_opt_init()
- inet6_opt_append()
- inet6_opt_finish()
- inet6_opt_set_val()
- inet6_opt_next()
- inet6_opt_find()
- inet6_opt_get_val()

The following macros are supported for IPv6:
IN6_IS_ADDR_LINKLOCAL
IN6_IS_ADDR_LOOPBACK
IN6_IS_ADDR_MC_GLOBAL
IN6_IS_ADDR_MC_LINKLOCAL
IN6_IS_ADDR_MC_NODELOCAL
IN6_IS_ADDR_MC_ORGLOCAL
IN6_IS_ADDR_MC_SITELOCAL
IN6_IS_ADDR_MULTICAST
IN6_IS_ADDR_SITELOCAL
IN6_IS_ADDR_UNSPECIFIED
IN6_IS_ADDR_V4COMPAT
IN6_IS_ADDR_V4MAPPED

Structures:

```
struct ip_mreq{
     struct in_addr imr_multiaddr;
     struct in_addr imr_interface;
};
```

Socket options:

- MCAST_INCLUDE
- MCAST_EXCLUDE
- IP_BLOCK_SOURCE
- IP_UNBLOCK_SOURCE
- IP_ADD_SOURCE_MEMBERSHIP
- IP_DROP_SOURCE_MEMBERSHIP
- IPV6_ADDR_PREFERENCES
- MCAST_JOIN_GROUP
- MCAST_LEAVE_GROUP
- MCAST_BLOCK_SOURCE
- MCAST_UNBLOCK_SOURCE
- MCAST_JOIN_SOURCE_GROUP
- MCAST_LEAVE_SOURCE_GROUP

Structure: Multicast filter support is accessed by defining feature test macro _OPEN_SYS_SOCKET_EXT3. The feature test also exposes symbols in sys/socket.h

```
struct ip_mreq{}
struct ip_mreq_source {};
struct group_req {};
struct group_source_req {};
setipv4sourcefilter()
getipv4sourcefilter()
setsourcefilter()
getsourcefilter()
```

netinet/ip6.h

The netinet/ip6.h header file defines structures and constants for IPv6 header options.

The following structures are exposed with this header file:

- ip6_hdr
- ip6_hbh
- ip6_dest
- ip6_rthdr
- ip6_rthdr0
- ip6_frag
- ip6_opt
- ip6_opt_jumbo
- ip6_opt_nsap
- ip6_opt_tunnel
- ip6_opt_router

The following definitions are associated with the ip6_hdr structure:

- ip6_vcf
- ip6_flow
- ip6_plen
- ip6_nxt
- ip6_hlim
- ip6_hops
- ip6_src
- ip6_dst

The following definitions are associated with the extension header structure:

- IP6F_OFF_MASK
- IP6F_RESERVED_MASK
- IP6F_MORE_FRAG

The following definitions are associated with the option header structure:

- IP6OPT_TYPE
- IP6OPT_TYPE_SKIP
- IP6OPT_TYPE_DISCARD
- IP6OPT_TYPE_FORCEICMP
- IP6OPT_TYPE_ICMP

- IP6OPT_MUTABLE
- IP6OPT_PAD1
- IP6OPT_PADN
- IP6OPT_JUMBO
- IP6OPT_NSAP_ADDR
- IP6OPT_TUNNEL_LIMIT
- IP6OPT_ROUTER_ALERT
- IP6OPT_JUMBO_LEN
- IP6_ALERT_MLD
- IP6_ALERT_RSVP
- IP6_ALERT_AN

netinet/tcp.h

The netinet/tcp.h header contains definitions for the Internet Transmission Control Protocol (TCP) .

new

The <new> header file defines several types and functions that control allocation and freeing of storage under program control.

Some of the functions declared in this header are replaceable. The implementation supplies a default version. A program can, however, define a function with the same signature to replace the default version at link time. The replacement version must satisfy the requirements of the function.

```
namespace std {
 typedef void (*new_handler)();
 class bad_alloc;
 class nothrow_t;
 extern const nothrow_t nothrow;
//      FUNCTIONS
 new_handler set_new_handler(new_handler ph) throw();
};
//      OPERATORS
void operator delete(void *p) throw();
void operator delete(void *, void *) throw();
void operator delete(void *p, const std::nothrow_t&) throw();
void operator delete[](void *p) throw();
void operator delete[](void *, void *) throw();
void operator delete[](void *p, const std::nothrow_t&) throw();
void *operator new(std::size_t n) throw(std::bad_alloc);
void *operator new(std::size_t n, const std::nothrow_t&) throw();
void *operator new(std::size_t n, void *p) throw();
void *operator new[](std::size_t n) throw(std::bad_alloc);
void *operator new[](std::size_t n, const std::nothrow_t&) throw();
void *operator new[](std::size_t n, void *p) throw();
```

The <new> header file supercedes the new.h header, which remains for compatibility as a wrapper to <new>.

`bad_alloc`

```
class bad_alloc : public exception {
    };
```

The class describes an exception thrown to indicate that an allocation request did not succeed. The value returned by what() is an implementation-defined C string. None of the member functions throw any exceptions.

```
new_handler
typedef void (*new_handler)();
```

The type points to a function suitable for use as a new handler.

```
nothrow
extern const nothrow_t nothrow;
```

The object is used as a function argument to match the parameter type nothrow_t.

```
nothrow_t
class nothrow_t {};
```

The class is used as a function parameter to operator new to indicate that the function should return a null pointer to report an allocation failure, rather than throw an exception.

new.h

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header <new>. However, new.h remains for compatibility as a wrapper for TARGET releases of z/OS V1R2 and later.

For compilations with a TARGET release before z/OS V1R2, the new.h header file declares the set_new_handler() function, which is used for z/OS C++ exception handling (`try`, `throw`, and `catch`). This header file also declares array and non-array version of the allocation operator `new` and the deallocation operator `delete`.

nlist.h

The nlist.h header file declares the nlist() function.

nl_types.h

The nl_types.h header file defines the following types:

nl_item	int used as manifest constant by nl_langinfo()
nl_catd	pointer to a catalog descriptor structure

The header also contains these constants:

NL_SETD NL_CAT_LOCALE

The following functions are prototyped:

catclose() catgets() catopen()

No feature test macro is required for nl_item.

To expose the other definitions in this header, compile with the _XOPEN_SOURCE feature test macro defined.

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this topic. For more information, see “Internationalization: Locales and Character Sets” in *z/OS XL C/C++ Programming Guide*.

poll.h

The poll.h header file contains definitions for the poll() function.

pthread.h

The pthread.h header file contains function declarations and mappings for threading interfaces and defines a number of constants used by those functions. The header includes the sched.h header. When _UNIX03_THREADS is defined, pthread.h also includes the time.h header. For _OPEN_THREADS applications, pthread.h defines the timespec structure.

There is a lot of overlap in the namespaces identified by the _OPEN_THREADS and _UNIX03_THREADS feature test macros. There are, however, behavioral differences between functions of the same name exposed by _OPEN_THREADS (POSIX.4a Draft 6) and by _UNIX03_THREADS (Single UNIX Specification, Version 3). See the individual function descriptions for specific details.

_OPEN_THREADS 1

pthread_attr_destroy()

pthread_mutexattr_getkind_np()
pthread_security_np()
pthread_tag_np()

_OPEN_SYS_MUTEX_EXT

pthread_condattr_getpshared()
pthread_condattr_setpshared()

The pthread.h header defines the following constants:

__COND_DEFAULT
__DETACHED
__MEDIUM_WEIGHT
__MUTEX_NONRECXRSIVE
__UNDETACHED
PRIO_INHERIT
PTHREAD_INHERIT_SCHED
PTHREAD_INTR_CONTROLLED
PTHREAD_INTR_ENABLE
PTHREAD_PROCESS_PRIVATE
PTHREAD_SCOPE_GLOBAL
SCHED_FIFO
SCHED_RR
__COND_NODEBUG
__HEAVY_WEIGHT
__MUTEX_NODEBXG
__MUTEX_RECXRSIVE
NO_PRIO_INHERIT
PTHREAD_DEFAULT_SCHED
PTHREAD_INTR_ASYNCHRONOUS
PTHREAD_INTR_DISABLE
PTHREAD_ONCE_INIT
PTHREAD_PROCESS_SHARED
PTHREAD_SCOPE_LOCAL
SCHED_OTHER
PRIO_PROTECT

Furthermore, pthread.h defines these macros:

PTHREAD_MUTEX_DEFAULT
PTHREAD_MUTEX_NORMAL
PTHREAD_MUTEX_RECURSIVE
__THDQ_LENGTH
PTHREAD_MUTEX_ERRORCHECK
PTHREAD_MUTEX_INITIALIZER
PTHREAD_RWLOCK_INITIALIZER

_OPEN_THREADS 2

PTHREAD_CANCEL_ENABLE
PTHREAD_CANCEL_DEFERRED
PTHREAD_CANCEL_DISABLE
PTHREAD_CANCEL_ASYNCHRONOUS

pwd.h

The pwd.h header file declares functions that access the user database through a password structure. The header file also defines the passwd structure.

_POSIX_SOURCE

getpwnam() getpwuid()

_XOPEN_SOURCE_EXTENDED 1

endpwent() getpwent() setpwent()

re_comp.h

The re_comp.h header file contains regular expression matching functions for re_comp().

Note:

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use regcomp(), regexec(), regerror() and regfree() functions and the header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

Applications conforming to Single UNIX Specification, Version 3 must not include the <re_comp.h> header file.

regex.h

The regex.h header file contains definitions for the following regular expression functions.

regcomp() regerror() regexec() regfree()

The regex.h header file declares the regex_t type, which can store a compiled regular expression.

The regex.h header file declares the following macros:
- Values of the *cflags* parameter of the regcomp() function: REG_EXTENDED, REG_ICASE, REG_NEWLINE, REG_NOSUB
- Values of the *eflags* parameter of the regexec() function: REG_NOTBOL, REG_NOTEOL
- Values of the *errcode* parameter of the regerror() function: REG_*.

regexp.h

The regexp.h header file contains regular expression declarations.

Note:

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use regcomp(), regexec(), regerror() and regfree() functions and the header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

Applications conforming to Single UNIX Specification, Version 3 must not include the <regexp.h> header file.

resolv.h

The resolv.h header file contains the __res_state structure and the definitions to support the IP Address Resolution functions commonly called the Resolver. It contains the prototypes for the following functions — dn_comp(), dn_expand(), dn_find(), dn_skipname(), res_init(), res_mkquery(), res_query(), res_querydomain(), res_search(), and res_send() — which are used to communicate with a Domain Name Server (DNS).

rexec.h

The rexec.h header file declares the rexec() and rexec_af() functions.

sched.h

The sched.h header file declares functions to manipulate and examine process execution scheduling.

_UNIX03_SOURCE

sched_yield()

When compiled with SUSV3 thread support (_UNIX03_THREADS or _XOPEN_SOURCE 600), sched.h defines the following symbols:

SCHED_FIFO	SCHED_OTHER	SCHED_RR

and the sched_param structure.

search.h

The search.h header file contains definitions for searching tables.

setjmp.h

The setjmp.h header file contains function declarations for longjmp() and setjmp(), which use the system stack to affect the program state. It also defines one buffer type, `jmp_buf`, that the setjmp() and longjmp() functions use to save and restore the program state.

_POSIX_SOURCE: setjmp.h declares functions siglongjmp() and sigsetjmp() and defines a buffer type `sigjmp_buf` used by siglongjmp() and sigsetjmp().

_XOPEN_SOURCE_EXTENDED 1: setjmp.h declares the functions _longjmp() and _setjmp().

signal.h

The signal.h header file defines the following values.

- Functions:

raise()
signal()

- Macros:

SIG_DFL
SIG_ERR
SIG_IGN
SIG_PROMOTE

- Signals:

SIGABND
SIGABRT
SIGFPE
SIGILL
SIGINT
SIGIOERR
SIGSEGV
SIGTERM
SIGUSR1
SIGUSR2

- The type `sig_atomic_t`, which is the largest integer type the processor can load or store automatically in the presence of asynchronous interrupts.

The following functions are supported only in a POSIX program. You must specify the POSIX(ON) runtime option for these functions.

kill()
sigaction()
__sigactionset()
sigaddset()
sigdelset()
sigemptyset()
sigfillset()
sigismember()
siglongjmp()
sigpending()
sigprocmask()
sigsuspend()
sigtimedwait()
sigwait()
sigwaitinfo()

The following values are available in z/OS UNIX only:

- Signals:

SIGALRM
SIGCHLD
SIGCLD
SIGCONT
SIGHUP
SIGIO
SIGKILL
SIGPIPE
SIGQUIT
SIGSTOP
SIGTHCONT
SIGTHSTOP
SIGTRACE
SIGTRAP
SIGTSTP
SIGTTIN
SIGTTOU

- The structures `sigaction`, `__sigactionset_t`, `__sigactionset_s`, `sigset_t`, and `pid_t`.
- *options* arguments for sigprocmask(): SIG_BLOCK, SIG_UNBLOCK, and SIG_SETMASK.
- Flags for the `sa_flags` field, available in z/OS UNIX only: SA_NOCLDSTOP and _SA_OLD_STYLE.

_XOPEN_SOURCE_EXTENDED 1:

- Signals:

SIGBUS
SIGPOLL
SIGPROF
SIGSYS
SIGURG
SIGXCPU
SIGXFSZ
SIGVTALRM
SIGWINCH

- Functions:

bsd_signal()
killpg()
sigaltstack()
sighold()
sigignore()
siginterrupt()
sigpause()
sigrelse()
sigset()
sigstack()

Note: bsd_signal() has been marked obsolescent in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sigaction() function is preferred for portability.

_OPEN_THREADS 2:

- Functions:

  pthread_sigmask()

_UNIX03_THREADS:

- pthread_kill()

spawn.h

The spawn.h header file contains spawn() constants and inheritance structure.

spc.h

Restriction: This header file is not supported in AMODE 64.

This header file is supported only for z/OS C applications.

The spc.h header file contains declarations for the functions available in the system programming environment, as described in "using the System Programming C Facility" in *z/OS XL C/C++ Programming Guide*. The functions are:

edcxregs
edcxusr
edcxusr2
__xhotc()
__xhotl()
__xhott()
__xhotu()
__xregs()
__xsacc()
__xsrvc()
__xusr()
__xusr2()
__24malc()
__4kmalc()

The spc.h header file also declares these functions, used for the allocation of storage and writing of strings, (which are described in Chapter 3, "Library functions," on page 89):

calloc()
free()
malloc()
realloc()
sprintf()

stdalign.h

The stdalign.h header file defines macros that are associated with alignment, which is introduced in the C11 (ISO/IEC 9899:2011) standard:

alignas
alignof
__alignas_is_defined
__alignof_is_defined

stdarg.h

The stdarg.h header file defines macros used to access arguments in functions with variable-length argument lists:

va_arg()
va_copy()
va_start()
va_end()

The stdarg.h header file also defines the structure `va_list`.

stdbool.h

The <stdbool.h> header defines the following macros:

bool expands to _Bool

__bool_true_false_are_defined
expands to 1

false expands to 0

true expands to 1

Restriction: This header is not supported for C++ applications.

stddef.h

The stddef.h header file contains definitions of the commonly used pointers, variables, and types, from the `typedef` statements, as listed below:

`ptrdiff_t`
The signed long type of the result of subtracting two pointers.

`size_t` `typedef` for the type of the value returned by *sizeof*.

`wchar_t`
`typedef` for a wide-character constant.

max_align_t
An object type whose alignment is as great as is supported in all contexts.

stddef.h defines the macros NULL and `offsetof`. NULL is a pointer that never points to a data object. The `offsetof` macro expands to the number of bytes between a structure member and the start of the structure. The `offsetof` macro has the form `offsetof(`*`structure_type`*`, `*`member`*`)`

stdefs.h

The stdefs.h header file contains the same information as found in <stddef.h>.

stdint.h

The stdint.h header defines integer types, limits of specified width integer types, limits of other integer types and macros for integer constant expressions.

Note: For the exact width integer types, minimum width integer types and limits of specified width integer types we support *bit sizes N* with the values 8, 16, 32, and 64.

The following exact width integer types are defined.
- int*N*_t
- uint*N*_t

The following minimum-width integer types are defined.
- int_least*N*_t
- uint_least*N*_t

The following fastest minimum-width integer types are defined. These types are the fastest to operate with among all integer types that have at least the specified width.

- int_fast*N*_t
- uint_fast*N*_t

The following greatest-width integer types are defined. These types hold the value of any signed/unsigned integer type.

Note: Requires long long to be available.

- intmax_t
- uintmax_t

The following integer types capable of holding object pointers are defined.

- intptr_t
- uintptr_t

Object-like macros for limits of integer types: Additional object-like macros provided by the stdint.h header are described.

Note: For the exact width integer limits, minimum width integer limits and limits of specified width integer types we support *bit sizes N* with the values 8, 16, 32, and 64.

Macros for limits of exact width integer types:

- INT*N*_MAX
- INT*N*_MIN
- UINT*N*_MAX

Macros for limits of minimum width integer types:

- INT_LEAST*N*_MAX
- INT_LEAST*N*_MIN
- UINT_LEAST*N*_MAX

Macros for limits of fastest minimum width integer types:

- INT_FAST*N*_MAX
- INT_FAST*N*_MIN
- UINT_FAST*N*_MAX

Macros for limits of greatest width integer types:

Note: Requires long long to be available.

- INTMAX_MAX
- INTMAX_MIN
- UINTMAX_MAX

Macros for limits of pointer integer types:

- INTPTR_MAX
- INTPTR_MIN
- UINTPTR_MAX

Macros for limits of ptrdiff_t:

- PTRDIFF_MAX
- PTRDIFF_MIN

Macros for limits of sig_atomic_t:

- SIG_ATOMIC_MAX
- SIG_ATOMIC_MIN

Macro for limit of size_t:

- SIZE_MAX

Macros for limits of wchar_t:

- WCHAR_MAX
- WCHAR_MIN

Macros for limits of wint_t:

- WINT_MAX
- WINT_MIN

Function-like macros for integer constants: Additional function-like macros provided by the stdint.h header are described.

Note: For the following macro for minimum width integer constants, we support *bit sizes N* with the values 8, 16, 32, and 64.

Macros for minimum width integer constants:

- INTN_C(value)
- UINTN_C(value)

Example:

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

 int main(void)
 {
   uint32_t a = UINT32_C(1234);
   printf("%u\n",a );

 }

Output

1234
```

Example of how the compiler expands the macro:

```
|     uint32_t a = UINT32_C(1234);
+     uint32_t a = 1234U;
```

Macros for greatest width integer constants:

Note: Requires long long to be available.

- INTMAX_C(value)
- UINTMAX_C(value)

Example:

```
/* long long required */
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

 int main(void)
 {
   intmax_t a = INTMAX_C(45268724);
   printf("%jd\n",a );

 }
```

```
Output

45268724
```

Example of how the compiler expands the macro with the LP64 compiler option:

```
| intmax_t a = INTMAX_C(45268724);
+ intmax_t a = 45268724L;
```

Otherwise the compiler expands to:

```
| intmax_t a = INTMAX_C(45268724);
+ intmax_t a = 45268724LL;
```

stdio.h

The stdio.h header file declares functions that deal with standard input and output. One of these functions, fdopen(), is supported only in a POSIX program.

The stdio.h header file also declares these functions:

clearerr() clrmemf() fclose() fdelrec() feof()
ferror() fflush() fgetc() fgetpos() fgets()
fldata() flocate() fopen() fprintf() fputc()
fputs() fread() freopen() fscanf() fseek()
fseeko() fsetpos() ftell() ftello() fupdate()
fwrite() getc() getchar() gets() perror()
printf() putc() putchar() puts() remove()
rename() rewind() scanf() setbuf() setvbuf()
sprintf() sscanf() svc99() tmpfile() tmpnam()
ungetc() vfprintf() vprintf() vsprintf()

Defined types in stdio.h

The `FILE` type is defined in stdio.h. Stream functions use a pointer to the `FILE` type to get access to a given stream. The system uses the information in the `FILE` structure to maintain the stream. The C standard streams `stdin`, `stdout`, and `stderr` are also defined in stdio.h.

The type `fpos_t` is defined in stdio.h for use with fgetpos() and fsetpos().

The types `__S99parms`, `__S99rbx_t`, and `__S99emparms_t` are defined in stdio.h for use with the svc99() function.

The type `fldata_t` is defined in stdio.h for use with the fldata() function.

The types `__amrc_type` and `__amrc2_type` are defined in stdio.h for use in determining error information when I/O functions fail.

Macros defined in stdio.h

You can use these macros as constants in your programs, but you should not alter their values.

`BUFSIZ` Specifies the buffer size to be used by the setbuf() library function when you are allocating buffers for stream I/O. This value is the expected size of the user's buffer supplied to setbuf(). If a larger buffer is required, for example, if blocksize is larger than BUFSIZ, or if special buffer attributes are required, z/OS XL C/C++ applications will not use the user's buffer.

`EOF` The value returned by an I/O function when the End Of File (EOF) (or in some cases, an error) is found.

`FOPEN_MAX`
The maximum number of files that can be open simultaneously.

`FILENAME_MAX`
The maximum number of characters in a filename. Can be used in the size specification of an array (for example, to hold the filename returned by fldata()).

`L_tmpnam`
The size of the longest temporary name that can be generated by the tmpnam() function.

`L_ctermid`
Maximum size of a character array for ctermid() output. This macro is supported only in a POSIX program.

NULL A pointer which never points to a data object.

`TMP_MAX`
The minimum number of unique file names that can be generated by the tmpnam() function.

The macros `SEEK_CUR`, `SEEK_END`, and `SEEK_SET` expand to integral constant expressions and can be used as the third argument to fseek().

The macros `_IOFBF`, `_IOLBF`, and `_IONBF` expand to integral constant expressions with distinct values suitable for use as the third argument to the setvbuf() function.

The following macros expand to integer constant expressions suitable for interpreting values returned by fldata(), in the `fldata_t` structure.

__APPEND
__BINARY
__BLOCKED
__DISK
__DUMMY
__ESDS
__ESDS_PATH
__HFS
__HIPERSPACE
__KSDS
__KSDS_PATH
__MEMORY
__MSGFILE
__NORLS
__NOTVSAM
__OTHER
__PRINTER
__READ
__RECORD
__RLS
__RSDS
__TAPE
__TDQ
__TERMINAL
__TEXT
__UPDATE
__WRITE

The following macros expand to integral constant expressions suitable for use as the fourth argument to the flocate() function.

__KEY_EQ
__KEY_EQ_BWD
__KEY_FIRST
__KEY_GE
__KEY_LAST
__RBA_EQ
__RBA_EQ_BWD

The following macros expand to integral constant expressions suitable for use as the argument to the function clrmemf().

__CURRENT
__CURRENT_LOWER
__LOWER

The following macros expand to integral constant expressions suitable for use to determine the last operation reported in the `__amrc_type` structure. All these macros are described in *z/OS XL C/C++ Programming Guide*.

stdio_ext.h

The stdio_ext.h header file contains prototypes and related definitions for the set of stdio extensions that allows access to the internal portions of the `FILE` structure.

stdlib.h

The stdlib.h header file contains declarations for the following functions:

abort()
abs()[1,3]
alloca()[1]
atexit()
atof()
atoi()
atol()
bsearch()
calloc()
cds()[1]
clearenv()
cs()[1]
csid()
div()[3]
exit()
fetch()[2]
fetchep()[2]
free()
getenv()
labs()
ldiv()
llabs()
lldiv()
__librel()
malloc()
mblen()
mbstowcs()
mbtowc()
__moservices()
qsort()
rand()
realloc()
release()[2]
rpmatch()
setenv()
srand()
strtod()
strtol()
strtoll()
strtoul()
strtoull()
system()
unatexit()
wcsid()
wcstombs()

wctomb()	strtod32()[4]	strtod64()[4]	strtod128()[4]

_UNIX03_SOURCE

unsetenv()

[1] Built-in function.

[2] Not supported under C++ applications.

[3] Special Behavior for C++: For C++ applications, the functions abs() and div() are also overloaded for the type long.

[4] The __STDC_WANT_DEC_FP__ feature test macro is required to expose decimal floating-point functionality.

Two type definitions are added to stdlib.h for the Compare and Swap functions cs() and cds(). The structures defined are `__cs_t` and `__cds_t`.

The type `size_t` is declared in the header file. It is used for the type of the value returned by `sizeof`. The type `wchar_t` is declared and used for a wide character constant. For more information on the types `size_t` and `wchar_t`, see “stddef.h” on page 65.

The stdlib.h declares `div_t` and `ldiv_t`, which define the structure types that are returned by div() and ldiv().

The stdlib.h file also contains definitions for the following macros:

NULL The NULL pointer constant (also defined in stddef.h).

EXIT_SUCCESS
Used by the atexit() function.

EXIT_FAILURE
Used by the atexit() function.

RAND_MAX
Expands to an integer representing the largest number that the `RAND` function can return.

MB_CUR_MAX
Expands to an integer representing the maximum number of bytes in a multibyte character. This value is dependent on the current locale.

If MB_CUR_MAX is set to 1, multibyte functions will behave as if all multibyte characters are one byte long; wide-character functions are *not* supported and full DBCS support is *not* provided. If MB_CUR_MAX is 4, all DBCS support provided by the library is enabled.

string.h

The string.h header file declares the string manipulation functions and their built-in versions:

No feature test macro required.

memchr()[1]
memcmp()[1]
memcpy()[1]
memmove()
memset()[1]
strcat()[1]
strchr()[1]
strcmp()[1]
strcoll()
strcpy()[1]
strcspn()
strerror()
strlen()[1]
strncat()[1]
strncmp()[1]
strncpy()[1]
strpbrk()
strrchr()[1]
strspn()
strstr()
strtok()
strxfrm()

_UNIX03_SOURCE

strerror_r

[1] Built-in function.

_XOPEN_SOURCE

memccpy()

_XOPEN_SOURCE_EXTENDED 1

strdup()

The string.h header file also defines the macro NULL and the type `size_t`. For more information see “stddef.h” on page 65.

strings.h

The strings.h header file contains definitions for string operations.

stropts.h

The stropts.h header file declares the following functions:

fattach()
fdetach()
getmsg()
getpmsg()
ioctl()
isastream()
putmsg()
putpmsg()

syslog.h

The syslog.h header file contains definitions for system error logging.

sys/acl.h

The sys/acl.h header enables users to manipulate ACLs. It also declares the following functions:

acl_create_entry()
acl_delete_entry()
acl_delete_fd()
acl_delete_file()
acl_first_entry()
acl_free()
acl_from_text()
acl_get_entry()
acl_get_fd()
acl_get_file()
acl_init()
acl_set_fd()

acl_set_file() acl_sort() acl_to_text() acl_update_entry()
acl_valid()

sys/__cpl.h

The sys/__cpl.h header contains definition for the __cpl() function. It also defines the following constants:

Table 8. Symbolic Constants defined in sys/__cpl.h

Symbolic Constant	Description
CPL_QUERY	Request data from available Coupling Facilities
CPL_CFSIZER	Request a structure size
CPL_CFSIZER_W_LVL	Request a structure size with the level of the CF

sys/file.h

The sys/file.h header file defines file manipulation constants.

sys/__getipc.h

The sys/__getipc.h header file contains definitions to get interprocess communication information.

sys/ioctl.h

The sys/ioctl.h header file contains system I/O definitions and structures.

sys/ipc.h

The sys/ipc.h header file contains definitions for the interprocess communication access structure.

sys/layout.h

The sys/layout.h header file contains declarations for supporting bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

sys/mman.h

The sys/mman.h header file contains memory management declarations.

sys/__messag.h

The sys/__messag.h header file contains definitions for the __console() and __console2() functions.

sys/mntent.h

This header file is protected by the _OPEN_SYS feature test macro.

The sys/mntent.h header file declares the w_getmntent() function and it defines the structures `mnte3`, `mnte2`, and `w_mntent`, along with some related constants.

sys/modes.h

The sys/modes.h header file contains several macro definitions:

- Defined constant masks and bits for values of type `mode_t`, such as the `st_mode` field of the `stat` struct
- A defined constant mask for the `st_genvalue` field of the `stat` struct
- Function-like macros for testing values of the `st_mode` field of the `stat` struct.

Under z/OS XL C support, these definitions are included in sys/stat.h to make sys/stat.h conform with POSIX.

sys/msg.h

The sys/msg.h header file contains definitions for message queue structures.

sys/ps.h

The sys/ps.h header file declares the w_getpsent() function that provides process data and defines the structure `w_psproc` along with some related constants.

It requires the `_OPEN_SOURCE 1` feature test macro.

sys/resource.h

The sys/resource.h header file contains definitions for XSI resource operations, including declarations, constants, and structures used by the following functions:

- getpriority()
- getrlimit()
- getrusage()
- setpriority()
- setrlimit()

sys/select.h

The sys/select.h header file contains definitions for select types.

sys/sem.h

The sys/sem.h header file contains definitions for the semaphore facility.

sys/server.h

The sys/server.h header file contains definitions for using WorkLoad Manager services.

sys/shm.h

The sys/shm.h header file contains definitions for the shared memory facility.

sys/socket.h

The sys/socket.h header file contains sockets definitions.

The structure sockaddr_storage is exposed by defining the feature test macro _OPEN_SYS_SOCK_IPV6 or _OPEN_SYS_SOCK_EXT3.

sys/stat.h

The sys/stat.h header file declares the following functions related to z/OS UNIX files and their access:

chaudit()
chmod()
creat()
fchaudit()
fchmod()
fstat()
lstat()
mkdir()
mkfifo()
mknod()
__mount()
mount()
__open_stat()
stat()
umask()
umount()

sys/statfs.h

The sys/statfs.h header file declares the w_statfs() function that provides file system status and the `w_statfs` structure. It requires the _OPEN_SYS feature test macro.

sys/statvfs.h

The sys/statvfs.h header file contains definitions for file system status.

sys/time.h

The sys/time.h header file contains definitions for time types.

sys/timeb.h

The sys/timeb.h header file contains additional definitions for date and time.

sys/times.h

The sys/times.h header file declares the times() function that gets processor times for use by processes. It requires the _POSIX_SOURCE feature test macro.

sys/ttydev.h

The sys/ttydev.h header file defines constants used by the terminal I/O functions.

sys/types.h

The sys/types.h header file defines a collection of *typedef* symbols and structures.

Table 9. sys/types.h: _OE_SOCKETS or _ALL_SOURCE

u_char	unsigned char
u_int	unsigned int
ushort	unsigned short
u_short	unsigned short
u_long	unsigned long

Table 10. sys/types.h: _OE_SOCKETS or _XOPEN_SOURCE_EXTENDED 1

in_addr_t	Internet address
ip_addr_t	Internet address

Table 10. sys/types.h: _OE_SOCKETS or _XOPEN_SOURCE_EXTENDED 1 (continued)

caddr_t	Used for message data pointer

Table 11. sys/types.h: _OPEN_THREADS

pthread_t	Identify a thread
pthread_attr_t	Identify a thread attribute object
pthread_mutex_t	Mutexes
pthread_mutexattr_t	Identify a mutex attribute object
pthread_cond_t	Condition variables
pthread_condattr_t	Identify a condition attribute object
pthread_key_t	Thread-specific data keys
pthread_once_t	Dynamic package initialization

Table 12. sys/types.h: _POSIX_SOURCE

dev_t	Device numbers
gid_t	Group IDs
ino_t	File serial numbers
mode_t	Some file attributes
nlink_t	Link counts
off_t	File sizes, long
pid_t	Process IDs and process group ids
size_t	unsigned long
ssize_t	Signed long
uid_t	user IDs
time_t	Time values
clock_t	Time values, int
sigset_t	Signal set
cc_t	cc_t
tty control chars	
speed_t	tty baud rate
tcflag_t	tty modes
mtm_t	Mount requests
rdev_t	Device numbers

Table 13. sys/types.h: _XOPEN_SOURCE

key_t	Interprocess communications, long

Table 14. sys/types.h: _XOPEN_SOURCE 500

blksize_t	Block sizes
blkcnt_t	File block counts
fsblkcnt_t	Filesystem block counts
fsfilcnt_t	File serial numbers
suseconds_t	Time values in range [-1,1,000,000]

Table 15. sys/types.h: _XOPEN_SOURCE_EXTENDED 1

id_t	General identifier, can contain a pid_t or a gid_t
useconds_t	Microseconds
sa_family_t	Address family
in_port_t	AF_INET port

sys/uio.h

The sys/uio.h header file contains definitions for vector I/O operations.

sys/un.h

The sys/un.h header file contains definitions for UNIX-domain sockets.

sys/__ussos.h

The sys/__ussos.h header file contains the _SET_THLIIPADDR() macro, which sets a client's IP address for security facility authorization (SAF).

sys/utsname.h

The sys/utsname.h header file declares the utsname structure and the uname() function, which returns the name of the current operating system. It requires the _POSIX_SOURCE feature test macro.

sys/wait.h

The sys/wait.h header file declares the following functions, used for holding processes.

_POSIX_SOURCE:

wait()	waitpid()

_XOPEN_SOURCE_EXTENDED 1:

waitid()	wait3()

Note: wait3() has been withdrawn in Single UNIX Specification, Version 3.

sys/__wlm.h

The sys/__wlm.h header file contains definitions for WorkLoad Manager functions.

tar.h

The tar.h header file contains definitions for the tar utility.

terminat.h

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header <exception>. However, terminat.h remains for compatibility as a wrapper for TARGET releases of z/OS V1R2 and later.

For compilations with a TARGET release before z/OS V1R2, the terminat.h header file, which is used for z/OS XL C++ exception handling, declares the terminate() and set_terminate() functions.

termios.h

The termios.h header file contains constants, prototypes, and typedef definitions of POSIX terminal I/O functions. It includes the __termcp structure, and declares the following functions:

cfgetispeed() cfgetospeed() cfsetispeed() cfsetospeed() tcdrain()
tcflow() tcflush() tcgetattr() __tcgetcp() tcgetsid()
tcsendbreak() tcsetattr() __tcsetcp() __tcsettables()

These functions are supported only in a POSIX program.

The termios.h header file also contains constants, prototypes and typedef definitions for the w_ioctl() function.

tgmath.h

The header tgmath.h includes the headers math.h and complex.h and defines a number of type-generic macros. This requires the compiler that is designed to support C99.

Use of the macro invokes a function whose corresponding real type and type domain are determined by the arguments for the generic parameters. If there is more than one real floating type argument, usual arithmetic conversions are applied to the real floating type arguments so that they have compatible types. Then,

- If any argument has type _Decimal128, the type determined is _Decimal128.
- Otherwise, if any argument has type _Decimal64, the type determined is _Decimal64.
- Otherwise, if any argument has type _Decimal32, the type determined is _Decimal32.
- Otherwise, if any argument has type long double, the type determined is long double.
- Otherwise, if any argument has type double or is of integer type, the type determined is double.
- Otherwise, if none of the above the type determined is float.

All the functions in math.h and complex.h have their corresponding type generic macros in this header where if for a function in math.h, there is a corresponding c prefixed function in complex.h, then the corresponding type generic macro has the same name as the one in math.h. The macros are:

acos acosh asin asinh atan atan2
atanh carg cbrt ceil cimag conj
copysign cos cosh cproj creal erf
erfc exp exp2 expm1 fabs fdim
floor fma fmax fmin fmod frexp
hypot ilogb ldexp lgamma llrint llround
log log10 log1p log2 logb lrint
lround nearbyint nextafter nexttoward pow remainder
remquo rint round scalbln scalbn sin
sinh sqrt tan tanh tgamma trunc
quantize() samequantum()

[1] The following type-generic macros are not supported for decimal-floating point types: carg(), cimag(), conj(), cproj(), creal().

Restrictions:
- This header does not support the _FP_MODE_VARIABLE feature test macro.
- This header is not supported for C++ applications.

For example:

> The macro `exp(int` *`n`*`)` invokes the function `exp(int` *`n`*`)`
>
> The macro `acosh(float` *`f`*`)` invokes the function `acoshf(float` *`f`*`)`
>
> The macro `log(float complex` *`fc`*`)` invokes the complex function `clogf(float complex fc)`
>
> The macro `pow(double complex` *`dc`*`, float` *`f`*`)` invokes `cpow(double complex` *`dc`*`, float` *`f`*`)`

)

time.h

The time.h header file declares the time and date functions:

asctime() clock() ctime() difftime() gmtime()
localtime() mktime() strftime() strptime() time()
tzset()[1]

[1] These functions are supported only in a POSIX program.

The time.h header file also provides:
- A structure `timespec` containing the following members:
  ```
  time_tv_sec;           seconds
  long tv_nsec;          nanoseconds
  ```
- A structure tm containing the components of a calendar time. See Table 16 on page 80 for a list of the members of the tm structure. This structure is used by the functions `asctime()`, `gmtime()`, `localtime()`, `mktime()`, `strftime()`, and `strptime()`.
- A macro `CLOCKS_PER_SEC` equal to the number per second of the value returned by the clock() function.
- Types `clock_t`, `time_t`, and `size_t`.
- The NULL pointer constant. For more information on NULL and the type `size_t`, see “stddef.h” on page 65.
-

  The macro CLK_TCK, which is the number of clock ticks per second, is kept for historical reasons. It was used in connection with the return value of the clock() function. CLK_TCK has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use sysconf(_SC_CLK_TCK) instead of the CLK_TCK macro.

  However, if it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Table 16. Fields of tm Structure

Field	Description
tm_sec	Seconds (0-60)
tm_min	Minutes (0-59)
tm_hour	Hours (0-23)
tm_mday	Day of month (1-31)
tm_mon	Month (0-11; January = 0)
tm_year	Year (current year minus 1900)
tm_wday	Day of week (0-6; Sunday = 0)
tm_yday	Day of year (0-365; January 1 = 0)
tm_isdst	Zero if Daylight Saving Time is not in effect; positive if Daylight Saving Time is in effect; negative if the information is not available.

The time functions are affected by the current locale selected. The LC_CTYPE category affects the behavior of the strftime(), strptime(), and wcsftime() functions. The LC_TOD category affects the behavior of the gmtime(), mktime(), and localtime() functions.

typeinfo

The typeinfo header file defines several types associated with the type-identification operator typeid, which yields information about both static and dynamic types.

```
namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
    };
```

```
type_info
```

The class describes type information generated within the program by the implementation. Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoded values, and collating order for types are all unspecified and may differ between program executions.

An expression of the form typeid x is the only way to construct a (temporary) typeinfo object. The class has only a private copy constructor. Since the assignment operator is also private, you cannot copy or assign objects of class typeinfo either.

```
class type_info {
public:
    virtual ~type_info();
    bool operator==(const type_info& rhs) const;
    bool operator!=(const type_info& rhs) const;
    bool before(const type_info& rhs) const;
    const char *name() const;
private:
    type_info(const type_info& rhs);
    type_info& operator=(const type_info& rhs);
    };
```

```
type_info::operator!=
bool operator!=(const type_info& rhs) const;

The function returns !(*this == rhs).

type_info::operator==

bool operator==(const type_info& rhs) const;

The function returns a nonzero value if *this and rhs represent the
same type.

type_info::before

bool before(const type_info& rhs) const;

The function returns a nonzero value if *this precedes rhs in the
collating order for types.

type_info::name

const char *name() const;

The function returns a C string which specifies the name of the type.
```

bad_cast

```
class bad_cast : public exception {
    };
```

The class describes an exception thrown to indicate that a dynamic cast expression, of the form:

```
 dynamic_cast<type>(expression)
```

generated a null pointer to initialize a reference. The value returned by what() is an implementation-defined C string. None of the member functions throw any exceptions.

bad_typeid

```
class bad_typeid : public exception {
    };
```

The class describes an exception thrown to indicate that a typeid operator encountered a null pointer. The value returned by what() is an implementation-defined C string. None of the member functions throw any exceptions.

typeinfo.h

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header <typeinfo>. While this header represents function that did not previously exist on the z/OS and OS/390 operating systems, it is being provided now for compatibility as a wrapper to <typeinfo>.

The typeinfo.h header file contains definitions for types associated with the type-identification operator typeid, which yields information about both static and dynamic types.

uchar.h

This header defines typedefs and macros associated with extended character data types.

The following typedefs are defined:

char16_t char32_t mbstate_t size_t

The following object-like macros are defined:

__STDC_UTF_16__ __STDC_UTF_32__

The uchar.h header file also declares functions that deal with conversions between multibyte characters and char16_t/char32_t. The following functions are declared:

mbrtoc16() mbrtoc32() c16rtomb() c32rtomb()

ucontext.h

The ucontext.h header file contains the prototypes and definitions needed by the following functions:

getcontext() setcontext() makecontext() swapcontext()

uheap.h

The uheap.h header file contains the prototypes and definitions needed by the following functions:

__ucreate() __umalloc() __ufree() __uheapreport()

ulimit.h

The ulimit.h header file contains definitions for ulimit commands.

unexpect.h

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header <exception>. However, unexpect.h remains for compatibility as a wrapper for TARGET releases of z/OS V1R2 and later.

For compilations with a TARGET release before z/OS V1R2, the unexpect.h header file, which is used for z/OS XL C++ exception handling, declares the `unexpected()` and `set_unexpected()` functions.

unistd.h

The unistd.h header file declares a number of implementation-specific functions:

__atoe() __atoe_l() __check_resource_auth_np()
__convert_id_np() __etoa() __etoa_l() __isPosixOn()

__smf_record()
__wsinit()

XPLINK

__a2e_l()
__a2e_s()
__e2a_l()
__e2a_s()

There are also a large number of POSIX and UNIX functions declared, shown below with the minimum feature test macro needed to expose them:

access()
alarm()
chdir()
chown()
close()
ctermid()
dup()
dup2()
execl()
execle()
execlp()
execv()
execve()
execvp()
_exit()
fork()
fpathconf()
getcwd()
getegid()
geteuid()
getgid()
getgroups()
getlogin()
getpgrp()
getpid()
getppid()
getuid()
isatty()
link()
lseek()
pathconf()
pause()
pipe()
read()
rmdir()
setgid()
setpgid()
setsid()
setuid()
sleep()
sysconf()
tcgetpgrp()
tcsetpgrp()
ttyname()
unlink()
write()

__certificate()
__getlogin1()
__login()
__pid_affinity()

POSIX1_SOURCE = 2

fchown()
fsync()
ftruncate()
readlink()
setegid()
setgeuid()
symlink()

POSIX_C_SOURCE = 2

optarg
opterr
optind
optopt

External Variables

_XOPEN_SOURCE

chroot()
confstr()
crypt()
cuserid()
encrypt()
getopt()
getpass()
nice()
swab()

_XOPEN_SOURCE = 500

brk()
fchdir()
getdtablesize()
gethostid()
gethostname()
getlogin_r()
getpagesize()
getpgid()
getsid()
getwd()
lchown()
lockf()
pread()
pwrite()
sbrk()
setpgrp()
setregid()
setreuid()
sync()
truncate()
ttyname_r()
ualarm()
usleep()
vfork()

The unistd.h header file also defines many symbols to represent configuration variables and implementation features provided. Some of these are used at compile time, while others are used to interrogate the system at run time, using sysconf(), confstr(), pathconf(), or fpathconf().

utime.h

The utime.h header file declares the `utimbuf` structure and the utime() function, which is used to set file access and modification times.

The utime() function is supported only in a POSIX program.

utmpx.h

The utmpx.h header file contains user accounting database definitions.

varargs.h

The varargs.h header file contains definitions for handling variable argument lists.

Note:

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the <stdarg.h> header to support variable argument list functionality compatible with IEEE Std 1003.1-2001.

Applications conforming to Single UNIX Specification, Version 3 must not include the header file.

variant.h

The variant.h header file declares the getsyntx() function, which returns LC_SYNTAX characters. It also contains the declaration of the variant structure:

```
struct variant {
      char   *codeset;          /* code set of the current locale */
      char    backslash;        /* encoding of \   */
      char    right_bracket;    /* encoding of ]   */
      char    left_bracket;     /* encoding of [   */
      char    right_brace;      /* encoding of }   */
      char    left_brace;       /* encoding of {   */
      char    circumflex;       /* encoding of ^   */
      char    tilde;            /* encoding of ~   */
      char    exclamation_mark; /* encoding of !   */
      char    number_sign;      /* encoding of #   */
      char    vertical_line;    /* encoding of |   */
      char    dollar_sign;      /* encoding of $   */
      char    commercial_at;    /* encoding of @   */
      char    grave_accent;     /* encoding of `   */
};

   struct variant *getsyntx(void);
```

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this topic. For still more information, see “Internationalization: Locales and Character Sets” in *z/OS XL C/C++ Programming Guide*.

wchar.h

The wchar.h header file contains the declaration for the supported subset of the ISO/C Multibyte Support extensions introduced in ISO/IEC 9899:1990/ Amendment 1:1993(E) extensions. The following functions are declared in wchar.h:

btowc()
fgetwc()
fgetws()
fputwc()
fputws()
fwide()
fwprintf()
fwscanf()
getwc()
getwchar()
mbrlen()
mbrtowc()
mbsinit()
mbsrtowcs()
putwc()
putwchar()
swprintf()
swscanf()
ungetwc()
vfwprintf()
vfwscanf()
vswprintf()
vswscanf()
vwprintf()
vwscanf()
wcrtomb()
wcscat()
wcschr()
wcscmp()
wcscoll()
wcscpy()
wcscspn()
wcsftime()
wcslen()
wcsncat()
wcsncmp()
wcsncpy()
wcspbrk()
wcsrchr()
wcsrtombs()
wcsspn()
wcsstr()
wcstod()
wcstok()
wcstol()
wcstoll()
wcstoul()
wcstoull()
wcswidth()
wcsxfrm()
wctob()
wcwidth()
wmemchr()
wmemcpy()
wmemcmp()
wmemmove()
wmemset()
wprintf()
wscanf()
wcstod32()[1]
wcstod64()[1]
wcstod128()[1]

[1] The __STDC_WANT_DEC_FP__ feature test macro is required to expose decimal floating-point functionality.

wmemchr(), wmemcpy(), wmemcmp(), and wmemset() are also available as their built-in versions.

You don't need to include stdio.h and stdarg.h to use the header file.

The header file wchar.h contains definitions of the following types:

`mbstate_t`
Conversion-state information needed when converting between sequences of multibyte characters and wide characters.

`size_t` `typedef` for the type of the value returned by *sizeof*.

`wchar_t`
`typedef` for a wide-character constant.

`win_t` An integral type unchanged by integral promotions that can hold any value corresponding to members of the extended character set, as well as WEOF (see below).

`FILE` The `FILE` structure type is defined in both stdio.h and wchar.h. Stream functions use a pointer to the `FILE` type to get access to a given stream. The system uses the information in the `FILE` structure to maintain the stream. The C standard streams `stdin`, `stdout`, and `stderr` are also defined in stdio.h.

`va_list`
This type is defined in both stdarg.h and wchar.h.

The header file wchar.h also contains definitions of the following constants:

NULL A pointer that never points to a data object.

WEOF Expands to a constant expression of type `wint_t`, whose value does not correspond to any member of the extended character set. It indicates End Of File (EOF).

WCHAR_MIN
Defines the lower limit of the wchar_t type.

WCHAR_MAX
Defines the upper limit of the wchar_t type.

You can perform wide-character input/output on the streams described in the ISO/IEC 9899:1990 standard, subclause 7.9.2. This standard expands the definition of a stream to include an *orientation* for both text and binary streams. For more information about DBCS orientation, see the section on Double-Byte Characters Sets in *z/OS XL C/C++ Programming Guide*.

The wide-character string functions are also declared in wcstr.h for compatibility with previous releases of C/370™, although wcstr.h may be withdrawn in the future.

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this topic. For still more information, see the "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

wcstr.h

The wcstr.h header file declares the following multibyte functions:

wcscat() wcschr() wcscmp() wcscpy() wcscspn()
wcslen() wcsncat() wcsncmp() wcsncpy() wcspbrk()
wcsrchr() wcsspn() wcswcs()

wcstr.h also defines the types `size_t`, NULL, `wchar_t`, and `wint_t`.

The wide-character string functions are also declared in wchar.h for compatibility with previous releases of C/370. wcstr.h may be withdrawn in future releases of the z/OS XL C/C++ product.

wcstr.h is a non-standard header provided for compatibility with previous releases of C/370. Functions in wcstr.h are exposed by compiling with LANGLVL(EXTENDED). The wcstr.h header may be withdrawn in future releases of the z/OS XL C/C++ product. The wide character functions in wcstr.h are also declared in the wchar.h header, which is the standard interface.

wctype.h

The wctype.h header declares functions that deal with wide character properties. The following are declared as functions and are also defined as macros:

iswalnum() iswalpha() iswblank() iswcntrl() iswctype()
iswdigit() iswgraph() iswlower() iswprint() iswpunct()
iswspace() iswupper() iswxdigit() towlower() towupper()
wctype()

The following are declared as prototypes only:

towctrans() wctrans() wctype()

The wctype.h header defines the types `wctrans_t`, `wctype_t` and `wint_t`. The wctype.h defines the macro WEOF, which expands to a constant expression of type `wint_t`, whose value does not correspond to any member of the extended character set. The macro WEOF indicates End Of File (EOF).

wordexp.h

The wordexp.h header file contains definitions for word expansion types.

xti.h

The xti.h header file declares the following under the _XOPEN_SOURCE_EXTENDED 1 feature test macro:

Table 17. Symbolic Constants defined in xti.h

Symbolic Constant	Description
TBADADDR	Incorrect addr format
TBADOPT	Incorrect option format
TACCES	Incorrect permissions
TBADF	Illegal transport fd
TNOADDR	Could not allocate addr
TOUTSTATE	Out of state
TBADSEQ	Bad call sequence number
TSYSERR	System error
TLOOK	Event requires attention
TBADDATA	Illegal amount of data
TBUFOVFLW	Buffer not large enough
TFLOW	Flow control
TNODATA	No data
TNODIS	Discon_ind not found on queue
TNOUDERR	unitdata error not found
TBADFLAG	Bad flags
TNOREL	No ord rel found on queue
TNOTSUPPORT	Primitive not supported
TSTATECHNG	State currently changing
TNOSTRUCTYPE	unknown struct-type requested
TBADNAME	Invalid transport name
TBADQLEN	Qlen is zero
TADDRBUSY	Address in use
TINDOUT	Outstanding connect indications
TPROVMISMATCH	Transport provider mismatch
TRESQLEN	Resfd specified to accept w/qlen>0
TRESADDR	Resfd not bound to same addr as fd
TQFULL	Incoming connection queue full
TPROTO	XTI protocol error
T_LISTEN	Connection indication received
T_CONNECT	Connect confirmation received
T_DATA	Normal data received
T_EXDATA	Expedited data received
T_DISCONNECT	Disconnect received
T_UDERR	Datagram error indication
T_ORDREL	Orderly release indication
T_GODATA	Sending normal data is possible
T_GOEXDATA	Sending expedited data is possible
T_EVENTS	Event mask

Table 17. Symbolic Constants defined in xti.h (continued)

Symbolic Constant	Description
T_MORE	More data
T_EXPEDITED	Expedited data
T_NEGOTIATE	Set opts
T_CHECK	Check opts
T_DEFAULT	Get default opts
T_SUCCESS	Successful
T_FAILURE	Failure
T_CURRENT	Current opts
T_PARTSUCCESS	Partial success
T_READONLY	Read-only
T_NOTSUPPORT	Not supported
T_BIND	S

Chapter 3. Library functions

This topic describes the z/OS XL C/C++ Runtime Library functions, including the built-in library functions used by the z/OS XL C/C++ compilers.

Names

Identifiers (function names, macros, types) defined by the various standards in the headers are reserved. Also reserved are:

- Identifiers that begin with an underscore and either an uppercase letter or another underscore.
- Identifiers that end with "_t".

Do not use these reserved identifiers for any purpose other than those defined in the documentation.

All identifiers other than the ISO C identifiers comprise the *user's name space*. You are free to use any of these names. However, a number of names in the z/OS XL C/C++ Runtime Library encroach on the user's name space. This is a result of our desire to provide names that are meaningful and easy to remember, or to support industry-defined names, for example: fetchep() or pthread_cancel(). The header files cause these names to be renamed into reserved names and these in turn are mapped onto the external entry point names that usually are operating-system specific.

If you want to use names in the z/OS XL C/C++ Runtime Library which are in the user's name space as defined, just include the appropriate header. If you cannot include the appropriate header because it would bring in other names that collide with your own private names, but you still want to use some of the functions defined there, you can refer to these functions by their reserved internal names. These reserved names are unique, not longer than 8 characters, and usually start with a double underscore.

The IBM z/OS XL C/C++ compiler automatically maps all underscores and lowercase letters in external identifiers in source code to '@' characters and uppercase characters in the object deck. Thus, to refer to the fetchep() function without including the stdlib.h header, you can use its reserved internal name __ftchep(), which is then automatically mapped to the external entry point `@@FTCHEP`. For C++ functions, you must ensure C linkage by declaring the functions as `extern "C"`.

Functions that are mapped this way have the external entry point listed in the function description in this part under the heading, "External Entry Point".

See also the following section s in *z/OS XL C/C++ Language Reference* for more information about external names:

- "#pragma csect"
- "#pragma map"
- "External Name Mapping"

See also the following section s in *z/OS XL C/C++ User's Guide*:

- "Prelinking a C Application"
- The LONGNAME compiler option

See also “Naming Conventions” in “Using Environment Variables”, in *z/OS XL C/C++ Programming Guide* for details about external names.

Unsupported functions and external variables in AMODE 64

All examples have been tested to work in 31-bit mode. Some examples might not work in 64-bit mode (AMODE 64). As examples are updated for AMODE 64, a statement of AMODE 64 support will be added to the description of the example.

The following functions are not supported in AMODE 64:
- advance()
- brk()
- compile()
- __console()
- __csplist
- ctdli()
- fortrc()__openMvsRel()
- __pcblist
- pthread_quiesce_and_get_np()
- re_comp()
- re_exec()
- regcmp()
- regex()
- sbrk()
- sock_debug_bulk_perf0()
- sock_do_bulkmode()
- step()
- tinit()
- tsched()
- tsetsubt()
- tsyncro()
- tterm()
- valloc()

The following external variables are not supported in AMODE 64:
- __loc1
- loc1
- loc2
- locs

Standards

Each function description begins with a table to indicate the standards/extensions, language support, and dependencies. See the table below for more details:

Standards / Extensions	C or C++	Dependencies
ISO C	C only	POSIX(ON)
ISO C Amendment	C++ only	OS/390 V2R6

Standards / Extensions	C or C++	Dependencies
POSIX.1	both	OS/390 V2R7
POSIX.1a		OS/390 V2R8
POSIX.2		OS/390 V2R9
POSIX.4a		OS/390 V2R10
POSIX.4b		z/OS V1R1
BSD 4.3		z/OS V1R2
XPG4		z/OS V1R3
XPG4.2		z/OS V1R4
SAA		z/OS V1R5
C Library		z/OS V1R6
Language Environment		z/OS V1R7
z/OS UNIX		z/OS V1R8
Single UNIX Specification, Version 2		z/OS V1R9
ISO/ANSI C++		AMODE 64
RFC2292		
RFC2553		
RFC3678		
ANSI/IEEE Standard P754		
C99		
Single UNIX Specification, Version 3		
C/C++ DFP		
C++ TR1 C99		

By indicating a standard, we refer to the origin of the function, not necessarily the compliance. For example, functions that are enriched by features from XPG4 have XPG4 listed.

These are the standards referred to:

- Standards/extensions
  1. *ISO C* refers to ISO/IEC 9899:1990(E).
  2. ISO C Amendment refers to a subset of the ISO/IEC 9899:1990/Amendment 1:1993(E).
  3. POSIX
     - *POSIX.1* refers to ISO/IEC 9945-1:1990/IEEE POSIX 1003.1-1990.
     - *POSIX.1a* refers to a subset of IEEE POSIX 1003.1a, Draft 7, May 1992.
     - *POSIX.2* refers to IEEE Portable Operating System Interface (POSIX) Part 2, P1003.2 draft 12.
     - *POSIX.4a* refers to a subset of IEEE POSIX 1003.4a, Draft 6, Feb. 26,1992.
  4. *XPG4* refers to X/Open Common Applications Environment Specification, System Interfaces and Headers, Issue 4.
  5. *XPG4.2* refers to X/Open Common Applications Environment Specification, System Interfaces and Headers, Issue 4, Version 2.

6. *ISO/ANSI C++* refers to the ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)).
7. RFC2553 refers to the Basic Socket Interface Extensions for IPv6 (draft-ietf-ipngwg-rfc2253bis-05.txt, dated February 2002).

   Note: Not all of the support described in this draft is available on z/OS.
8. RFC2292 refers to the Advanced Sockets API for IPv6 (draft-ietf-ipngwg-rfc2292bis-06.txt, dated February 25, 2002).

   Note: Not all of the support described in this draft is available on z/OS.
9. C99 refers to ISO/IEC 9899:1999(E).
10. Single UNIX Specification, Version 2 refers to IEEE Std 1003.1-1997.
11. Single UNIX Specification, Version 3 refers to IEEE Std 1003.1-2001.
12. *Extensions* refers to one of the following:
    a. *SAA* refers to the IBM Systems Application Architecture® Common Programming Interface (SAA CPI) Level 2 definition of the C language.
    b. *C Library* refers to the functions that are extensions to the runtime library, before the Language Environment product.
    c. *Language Environment* refers to functions that are extensions to the conventional standards.
    d. *z/OS UNIX* refers to functions that provide z/OS UNIX support beyond the defined standards.
13. C/C++ DFP refers to:
    a. ISO/IEC TR24732 -- Extensions for the programming language C to support decimal floating point arithmetic.
    b. ISO/IEC TR24733 -- Extensions for the programming language C++ to support decimal floating point arithmetic.
14. C++ TR1 C99 refers to ISO/IEC DTR 19768 - Draft Technical Report on C++ library Extensions, chapter 8, C compatibility.

- Language support

  C or C++ refers to whether the function is supported for the z/OS XL C compiler, the z/OS XL C++ compiler, or both.
- Dependencies

  Some functions have the following dependencies identified. If the dependencies are not met, then the function fails, and returns an errno of EMVSNORTL. Functions defined by the standards that cannot fail, will cause abnormal termination and return Language Environmen condition CEE5001.

  – POSIX(ON) *required* refers to whether the enclave can run with the POSIX semantics.

    POSIX is an application characteristic that is maintained at the enclave level. After you have established the characteristic during enclave initialization, you cannot change it.

    When you set POSIX to ON, you can use functions that are unique to POSIX, such as pthread_create().

    One of the effects of POSIX(ON) is the enablement of POSIX signal handling semantics, which interact closely with the z/OS Language Environment condition handling semantics. Where ambiguities exist between ANSI and POSIX semantics, the POSIX runtime setting indicates that the POSIX semantics will be followed.

These standards do have some overlap, as illustrated in Figure 1.

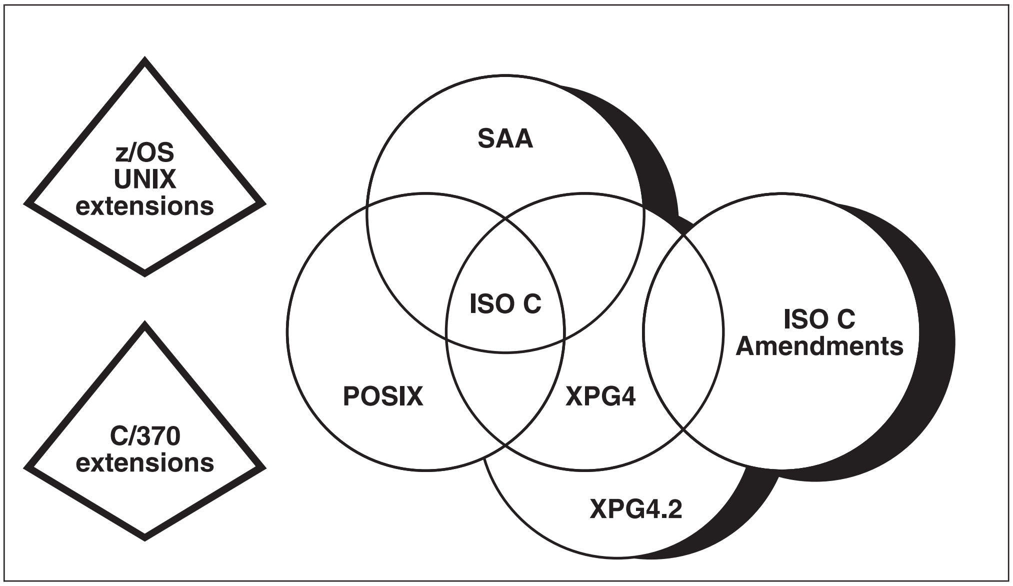

Figure 1. Overlap of C Standards and Extensions

The C library contains several functions that are extensions to the SAA CPI Level 2 definition. These library functions are available only if the LANGLVL(EXTENDED) compile-time option is in effect. As indicated, some of the *stub* routines for the extensions are available if you specify LANGLVL(ANSI). They are made available for compatibility with Version 1; they may not be available in the future. (Within runtime libraries, a *stub routine* is a routine that contains the minimum lines of code required to locate a given routine at run time.)

Many of the symbols that are defined in headers are “protected” by a feature test macro. For information on the relationships between feature test macros and the standards, see “Feature test macros” on page 3.

Using C include files from C++

If you need to use an old C header file in a C++ program, use `extern`, like this:

```
extern "C" {
  #include "myhdr.include"
}
```

Built-in functions

Built-in functions are ones for which the compiler generates inline code at compile time. Every call to a built-in function eliminates a runtime call to the function having the same name in the dynamic library.

Built-in functions are used by application code, while it is running, without reference to the dynamic library. Although built-in functions increase the size of a generated application slightly, this should be offset by the improved performance resulting from reducing the overhead of the dynamic calls. Built-in functions can be used with the System Programming C (SPC) Facilities to generate free-standing C applications.

Restriction: The SPC facility is not supported in AMODE 64.

Table 18 shows all of the built-in functions. In the listing of library functions, each built-in function is labelled as such.

Table 18. Built-in Library Functions

abs()	alloca()	cds()	cs()	decabs()
decchk()	decfix()	fabs()	fortrc()	memchr()
memcmp()	memcpy()	memset()	strcat()	strchr()
strcmp()	strcpy()	strlen()	strncat()	strncmp()
strncpy()	strrchr()	tsched()	wmemchr()	wmemcmp()
wmemcpy()	wmemset()			

The built-in versions of these functions are accessed by preprocessor macros defined in the standard header files. They are not used unless the appropriate header file (such as `decimal.h`, `math.h`, `stdlib.h`, `string.h` or `wchar.h`) is included in the source file.

The built-in versions of functions wmemchr(), wmemcmp(), wmemcpy(), and wmemset() are only available under ARCH(7) when LP64 is not used.

Your program will use the built-in version of a standard function only if you include the associated standard header file. However, decfix(), decabs(), and decchk() are implemented only as built-in functions. They are not available without including the header file.

If you are using the standard header file, but want to use the function in the dynamic library instead of the built-in function, you can force a call to the dynamic library by putting parentheses around the function name in your source code:

```
(memcpy)(buf1, buf2, len)
```

The built-in functions are documented in Using hardware built-in functions in *z/OS XL C/C++ Programming Guide*.

If you will never use the built-in version, you can also use `#undef` with the function name. For example, `#undef memcpy` causes all calls to `memcpy` in the compilation unit to make a dynamic call to the function rather than using the built-in version.

IEEE binary floating-point

Starting with OS/390 V2R6 (including the Language Environment and C/C++ components), support has been added for IEEE binary floating-point (IEEE floating-point) as defined by the ANSI/IEEE Standard 754-1985, IEEE Standard for Binary Floating-Point Arithmetic.

Notes:

1. You must have OS/390® Release 6 or higher to use the IEEE Binary Floating-Point instructions. In Release 6, the base control program (BCP) is enhanced to support the new IEEE Binary Floating-Point hardware in the IBM S/390® Generation 5 Server. This enables programs running on OS/390 Release 6 to use the IEEE Binary Floating-Point instructions and 16 floating-point registers.In addition, the BCP provides simulation support for all the new floating-point hardware instructions. This enables applications that make light use of IEEE Binary Floating-Point, and can tolerate the overhead of software simulation, to execute on OS/390 V2R6 without requiring an IBM S/390 Generation 5 Server.

2. The terms *binary floating point* and *IEEE binary floating point* are used interchangeably. The abbreviations BFP and HFP, which are used in some function names, refer to binary floating point and hexadecimal floating point respectively.
3. Under Hexadecimal Floating-Point format, the rounding mode is set to round toward 0. Under IEEE Binary Floating-Point format, the rounding mode is to round toward the nearest integer.

The z/OS XL C/C++ compiler provides a FLOAT option to select the format of floating-point numbers produced in a compile unit. The FLOAT option allows you to select either IEEE Binary Floating-Point or hexadecimal floating-point format. For details on the z/OS XL C/C++ support, see the description of the FLOAT option in *z/OS XL C/C++ User's Guide*. In addition, two related sub-options have been introduced, ARCH(3) and TUNE(3). The two sub-options support the new G5 processor architecture, and IEEE binary floating-point data. Refer to the ARCHITECTURE and TUNE compiler options in *z/OS XL C/C++ User's Guide* for details.

The C/C++ runtime library interfaces, which formerly supported only hexadecimal floating-point format, have been changed in OS/390 V2R6 to support both IEEE Binary Floating-Point and hexadecimal floating-point formats. These interfaces are documented in the z/OS XL C/C++ Runtime Library Reference.

The primary documentation for the IEEE Binary Floating-Point support is contained in *z/Architecture Principles of Operation* and *z/OS XL C/C++ User's Guide*.

IEEE binary floating point support provides interoperability and portability between platforms. It is anticipated that the support will be most commonly used for new and ported applications and in emerging environments, such as Java. Customers should not migrate existing applications that use hexadecimal floating point to binary floating point, unless there is a specific reason.

IBM does not recommend mixing floating-point formats in an application. However, for applications which must handle both formats, the C/C++ runtime library does offer some support. Reference information for IEEE Binary Floating-Point can also be found in *z/OS XL C/C++ Language Reference*.

IEEE decimal floating-point

Starting with z/OS V1R9 (including the Language Environment and C/C++ components), support has been added for IEEE decimal floating-point as defined by the ANSI/IEEE Standard P754/D0.15.3, IEEE Standard for Floating-Point Arithmetic.

Note:

1. You must have z/OS V1R9 or higher to use IEEE decimal floating-point, the hardware must have the Decimal Floating Point Facility installed and the __STDC_WANT_DEC_FP__ feature test macro must be defined.
2. The abbreviation DFP refers to IEEE Decimal Floating-Point.
3. IEEE decimal floating-point is not supported in a CICS environment.

   The z/OS XL C/C++ compiler provides a DFP option to include support for IEEE Decimal Floating-Point numbers. For details on the z/OS XL C/C++ support, see the description of the DFP option in *z/OS XL C/C++ User's Guide*. New C/C++ runtime library interfaces, which support IEEE Decimal Floating Point numbers have been added for z/OS V1R9 and other existing interfaces have been updated to support DFP. These interfaces are documented in the *z/OS XL C/C++ Runtime Library Reference*. The primary documentation for the IEEE decimal floating-point support is contained in *z/Architecture Principles of Operation* and *z/OS XL C/C++ User's Guide*. Reference information for IEEE floating-point can also be found in *z/OS XL C/C++ Language Reference*.

4. When one or more input values for a Decimal Floating Point (DFP) library function are not in the preferred Densely Packed Decimal (DPD) encoding, it is not defined whether or not the output values are converted to the preferred DPD coding. Applications should not rely on the current behavior of library functions regarding the DPD recoding of output values.

External variables

The POSIX 1003.1 and X/Open CAE Specification 4.2 (XPG4.2) require that the C system header files define certain external variables. Additional variables are defined for use with POSIX or XPG4.2 functions. If you define one of the POSIX or XPG4 feature test macros and include one of these headers, the external variables will be defined in your program. These external variables are treated differently compared with other global variables in a multithreaded environment (values are thread-specific) and across a call to a fetched module (values are propagated).

To access the global variable values the following must be specified during C/C++ compiles and z/OS bind:

Non-XPLINK (non-thread-safe)
C code must be compiled with the RENT or DLL option (C++ code needs no additional options). The SCEEOBJ autocall library must be specified during the bind.

Non-XPLINK (thread-safe)
No additional options are required for either C or C++. The _SHARE_EXT_VARS feature test macro, or the necessary _SHR_ prefixed feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented below under each external variable).

XPLINK (non-thread-safe)
No additional options (besides XPLINK) are required for either C or C++. The C runtime library side-deck, member CELHS003 of the SCEELIB data set, must be included during the bind. (c89/cc/c++ automatically include this side-deck when the XPLINK link edit option (for example, c89 -Wl,XPLINK ...) is used.)

XPLINK (thread-safe)
No additional options (besides XPLINK) are required for either C or C++. The C runtime library side-deck, member CELHS003 of the SCEELIB dataset, must be included during the bind.

The _SHARE_EXT_VARS feature test macro, or the necessary _SHR_ prefixed feature test macros must be used. Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

LP64 (non-thread-safe)
No additional options (besides LP64) are required for either C or C++. The C runtime library side-deck, member CELQS003 of the SCEELIB dataset, must be included during the bind.

The _SHARE_EXT_VARS feature test macro, or the necessary _SHR_ prefixed feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

LP64 (thread-safe)

No additional options (besides LP64) are required for either C or C++. The C runtime library side-deck, member CELQS003 of the SCEELIB dataset, must be included during the bind. (c89/cc/c++ automatically include this side-deck when the LP64 link edit option (for example, c89 -Wl, LP64 ...) is used.)

The _SHARE_EXT_VARS feature test macro, or the necessary _SHR_ prefixed feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

errno

When a runtime library function fails, the function may do any of the following to identify the error:

- Set errno to a documented value.
- Set errno to a value that is not documented. You can use strerror() or perror() to get the message associated with the errno.
- Not set errno.
- Clear errno.

See also **errno.h**.

daylight

Daylight savings time flag set by tzset(). Note that other time zone sensitive functions such as ctime(), localtime(), mktime(), and strftime() implicitly call tzset().

Note: Use the `__dlght()` function to access the thread-specific value of `daylight`. See also **time.h**.

getdate_err

The variable is set to the value below when an error occurs in the getdate() function.

1. The DATEMSK environment variable is NULL or undefined.
2. The template file cannot be opened for reading.
3. Failed to get file status information.
4. The template file is not a regular file.
5. An error was encountered while reading the template file.
6. Memory allocation failed (not enough memory available).
7. No line in the template file matches the input specification.
8. Non-valid input specification. For example, February 31; or a time that can not be represented in a time_t (representing the time is seconds since Epoch - midnight, January 1, 1970 (UTC)).
9. Unable to determine current time.

Any changes to errno are unspecified.

Note: This value is unique for z/OS UNIX.

The getdate64() interface affects the same pointer to the thread-specific value of getdate_err and uses the same getdate_err values as the getdate() interface.

Note: Use the**__gderr()** function to access the thread-specific value of `getdate_err`. The getdate64() function affects the same pointer to the thread-specific value of getdate_err as the getdate() function does.

See also **time.h**.

h_errno

An integer which holds the specific error code when the network name server encounters an error. The network name server is used by the gethostbyname() and gethostbyaddr() functions.

Note: Use the**__h_errno()** function to access the thread-specific value of `h_errno`. See also **netdb.h**.

Note: This variable is kept for historical reasons. However, it is used only in connection with the functions gethostbyaddr() and gethostbyname(), which are obsolescent in Single UNIX Specification, Version 3, so that the h_errno variable may also be withdrawn in the future.

__loc1

Restriction: This external variable is not supported in AMODE 64

A global character pointer which is set by the regex() function to point to the first matched character in the input string. Use the **____loc1()** function to access the thread-specific value of `__loc1`.

Note:

This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the <regex.h> header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3. See also **libgen.h**.

loc1

Restriction: This external variable is not supported in AMODE 64.

A pointer to characters matched by regular expressions used by step(). The value is not propagated across a call to a fetched module.

Note:

This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the <regex.h> header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions. See also **regexp.h**.

loc2

Restriction: This external variable is not supported in AMODE 64

A pointer to characters matched by regular expressions used by step(). The value is not propagated across a call to a fetched module.

Note:

This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the <regex.h> header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions. See also **regexp.h**.

locs

Restriction: This external variable is not supported in AMODE 64

Used by advance() to stop regular expression matching in a string. The value is not propagated across a call to a fetched module. See also **regexp.h**.

Note:

This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the <regex.h> header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

optarg

Character pointer used by getopt() for options parsing variables.

Note: Use the**__opargf()** function to access the thread-specific value of `optarg`.

Note: This variable has been removed from stdio.h by Single UNIX Specification, Version 3 and is exposed for Version 3 only in unistd.h . See also **stdio.h** and **unistd.h**.

opterr

Error value used by getopt().

Note: Use the **__operrf()** function to access the thread-specific value of `opterr`.

Note: This variable has been removed from stdio.h by Single UNIX Specification, Version 3 and is exposed for Version 3 only in unistd.h. See also **stdio.h** and **unistd.h**.

optind

Integer pointer used by getopt() for options parsing variables.

Note: Use the**__opindf()** function to access the thread-specific value of `optind`.

Note: This variable has been removed from stdio.h by Single UNIX Specification, Version 3 and is exposed for Version 3 only in unistd.h. See also **stdio.h** and **unistd.h**.

optopt

Integer pointer used by getopt() for options parsing variables.

Note: Use the**__opoptf()** function to access the thread-specific value of `optopt`.

Note: This variable has been removed from stdio.h by Single UNIX Specification, Version 3 and is exposed for Version 3 only in unistd.h. See also **stdio.h** and **unistd.h**.

signgam

Storage for sign of lgamma(). This function defaults to thread-specific. See also **math.h**.

stderr

Standard Error stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard error file. There is no multithreaded function. See also **stdio.h**.

stdin

Standard Input stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard input file. There is no multithreaded function. See also **stdio.h**.

stdout

Standard Output stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard output file. There is no multithreaded function. See also **stdio.h**.

t_errno

An integer which holds the specific error code when a failure occurs in one of the X/Open Transport Interface (XTI) functions. Use the **__t_errno()** function to access the thread-specific value of `t_errno`.

Note: Use the**__t_errno()** function to access the thread-specific value of `t_errno`. See also **xti.h**.

timezone

Long integer difference from UTC and standard time as set by tzset(). Note that other time zone sensitive functions such as ctime(), localtime(), mktime(), and strftime() implicitly call tzset().

Note: Use the __tzone() function to access the thread-specific value of `timezone`. See also **time.h**.

tzname

Character pointer to unsized array of timezone strings used by tzset() and ctime(). The *tzname variable contains the Standard and Daylight Savings time zone names. If the TZ environment variable is present and correct, tzname will be set from TZ. Otherwise tzname will be set from the LC_TOD locale category. See the tzset() function for a description. There is no multithreaded function. See also **time.h**.

The __restrict__ macro

The restrict keyword is being made available in the form of a macro named __restrict__ which can be used for coding before the availability of a compiler that is designed to support C99. Once the compiler support is available, only a recompile will be necessary. Applications need to include <features.h> before using the __restrict__ macro.

The __noreturn__ macro

The _Noreturn keyword is being made available in the form of a macro named __noreturn__ which can be used for coding before the availability of a compiler that is designed to support C11. Once the compiler support is available, only a recompile will be necessary. Applications need to include <features.h> before using the __noreturn__ macro.

abort() — Stop a program

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 C11 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

__noreturn__ void abort(void);
```

General description

Causes an abnormal program termination and returns control to the host environment. The abort() function flushes all buffers and closes all open files. Be aware that abnormal termination will *not* run the atexit() list functions.

If the abort() function is called and the user has a handler for SIGABRT, then SIGABRT is raised; however, SIGABRT is raised again when the handler associated with the default action is returned. The code path only passes through the user's handler once, even if the handler is reset. The same thing occurs if SIGABRT is ignored; abnormal termination occurs.

The abort() function will not result in program termination if SIGABRT is caught by a signal handler, and the signal handler does not return. You can avoid returning by “jumping” out of the handler with setjmp() and longjmp(). In z/OS XL C programs, you can jump out of the handler with sigsetjmp() and siglongjmp().

For more information see the process termination sections in the chapter “Using Runtime User Exits” in *z/OS XL C/C++ Programming Guide*.

Special behavior for POSIX C: To obtain access to the special POSIX behavior for abort(), the POSIX runtime option must be set ON.

Calls to abort() raise the SIGABRT signal, using pthread_kill(), so that the signal is directed to the same thread. A SIGABRT signal generated by abort() cannot be blocked.

Under POSIX, the handler can use siglongjmp() to restore the environment at a place in the code where a sigsetjmp() was previously issued. In this way, an application can avoid the process for termination.

Special behavior for C++: If abort() is called from a z/OS XL C++ program, the program will be terminated immediately, without leaving the current block. Functions passed to atexit(), and destructors for static and local (automatic) objects, will not be called.

By default, the z/OS XL C++ function terminate() calls abort().

Returned value

The abnormal termination return code for z/OS is 2000.

Example

CELEBA01

```
/* CELEBA01

   This example tests for successful opening of the file myfile.
   If an error occurs, an error message is printed and the program
   ends with a call to the abort() function.

 */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
   FILE *stream;
   unlink("myfile.dat");
   if ((stream = fopen("myfile.dat", "r")) == NULL)
   {
      printf("Could not open data file\n");
      abort();

      printf("Should not see this message\n");
   }
}
```

abs(), absf(), absl() — Calculate integer absolute value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	

Format

```
#include <stdlib.h>

int abs(int n);
long abs(long n);                   /* C++ only */

#include <math.h>

double abs(double n);               /* C++ only */
float abs(float n);                 /* C++ only */
long double abs(long double n);     /* C++ only */
float absf(float n);
long double absl(long double n);
```

DFP:

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  abs(_Decimal32 x);   /* C++ only */
_Decimal64  abs(_Decimal64 x);   /* C++ only */
_Decimal128 abs(_Decimal128 x);  /* C++ only */
```

C++ TR1 C99:

```
#define _TR1_C99
#include <inttypes.h>
intmax_t abs(intmax_t n);

#define _TR1_C99
#include <stdlib.h>
long long abs(long long n);
```

General description

The functions abs(), absf(), and absl() return the absolute value of an argument *n*.

For the integer version of abs(), the minimum allowable integer is `INT_MIN+1`. (`INT_MIN` is a macro that is defined in the `limits.h` header file.) For example, with the z/OS XL C/C++ compiler, `INT_MIN+1` is -2147483648.

For the double, float, and long double versions of abs(), the minimum allowable values are `DBL_MIN+1`, `FLT_MIN+1`, and `LDBL_MIN+1`, respectively. (The floating-point macro constants are defined in the `float.h` header file.)

If the value entered cannot be represented as an integer, the abs(), absf(), and absl() functions return the same value.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Special behavior for C++: For C++ applications, abs() is also overloaded for the types long, float, and long double.

Returned value

The returned value is the absolute value, if the absolute value is possible to represent.

Otherwise the input value is returned.

There are no errno values defined.

Example

CELEBA02

```
/* CELEBA02

   This example calculates the absolute value of an integer
   x and assigns it to y.

 */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    int x = -4, y;

    y = abs(x);
    printf("The absolute value of %d is %d.\n", x, y);
}
```

Output

```
The absolute value of    -4 is    4.
```

- “labs() — Calculate long absolute value” on page 935

accept() — Accept a new connection on a socket

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int accept(int socket, struct sockaddr *__restrict__ address,
           socklen_t *__restrict__address_len);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int accept(int socket, struct sockaddr *address, int *address_len);
```

General description

The accept() call is used by a server to accept a connection request from a client. When a connection is available, the socket created is ready for use to read data from the process that requested the connection. The call accepts the first connection on its queue of pending connections for the given socket *socket*. The accept() call creates a new socket descriptor with the same properties as *socket* and returns it to the caller. If the queue has no pending connection requests, accept() blocks the caller unless *socket* is in nonblocking mode. If no connection requests are queued and *socket* is in nonblocking mode, accept() returns -1 and sets the error code to EWOULDBLOCK. The new socket descriptor cannot be used to accept new connections. The original socket, *socket*, remains available to accept more connection requests.

Parameter
Description

socket The socket descriptor.

address The socket address of the connecting client that is filled in by accept()

before it returns. The format of *address* is determined by the domain that the client resides in. This parameter can be NULL if the caller is not interested in the client address.

address_len
: Must initially point to an integer that contains the size in bytes of the storage pointed to by *address*. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in sockaddr is truncated to the length supplied on input. If *address* is NULL, *address_len* is ignored.

The *socket* parameter is a stream socket descriptor created with the socket() call. It is usually bound to an address with the bind() call. The listen() call marks the socket as one that accepts connections and allocates a queue to hold pending connection requests. The listen() call places an upper boundary on the size of the queue.

The *address* parameter is a pointer to a buffer into which the connection requester's address is placed. The *address* parameter is optional and can be set to be the NULL pointer. If set to NULL, the requester's address is not copied into the buffer. The exact format of *address* depends on the addressing domain from which the communication request originated. For example, if the connection request originated in the AF_INET domain, *address* points to a **sockaddr_in** structure, or if the connection request originated in the AF_INET6 domain, *address* points to a **sockaddr_in6** structure. The **sockaddr_in** and **sockaddr_in6** structures are defined in **netinet/in.h**. , The *address_len* parameter is used only if the address is not NULL. Before calling accept(), you must set the integer pointed to by *address_len* to the size of the buffer, in bytes, pointed to by *address*. On successful return, the integer pointed to by *address_len* contains the actual number of bytes copied into the buffer. If the buffer is not large enough to hold the address, up to *address_len* bytes of the requester's address are copied. If the actual length of the address is greater than the length of the supplied **sockaddr**, the stored address is truncated. The **sa_len** member of the store structure contains the length of the untruncated address.

Notes:

1. This call is used only with SOCK_STREAM sockets. There is no way to screen requesters without calling accept(). The application cannot tell the system the requesters from which it will accept connections. However, the caller can choose to close a connection immediately after discovering the identity of the requester.
2. The accept() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2113 for details.

A socket can be checked for incoming connection requests using the select() call.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, accept() returns a nonnegative socket descriptor.

If unsuccessful, accept() returns -1 and sets errno to one of the following values:

Error Code
Description

EAGAIN
If during an accept call that changes identity, the UID of the new identity is already at MAXPROCUID, the accept call fails.

EBADF
The *socket* parameter is not within the acceptable range for a socket descriptor.

EFAULT
Using *address* and *address_len* would result in an attempt to copy the address into a portion of the caller's address space into which information cannot be written.

EINTR
A signal interrupted the accept() call before any connections were available.

EINVAL
listen() was not called for socket descriptor *socket*.

EIO There has been a network or transport failure.

EMFILE
An attempt was made to open more than the maximum number of file descriptors allowed for this process.

EMVSERR
Two consecutive accept calls that cause an identity change are not allowed. The original identity must be restored (close() the socket that caused the identity change) before any further accepts are allowed to change the identity

ENFILE
The maximum number of file descriptors in the system are already open.

ENOBUFS
Insufficient buffer space is available to create the new socket.

ENOTSOCK
The *socket* parameter does not refer to a valid socket descriptor.

EOPNOTSUPP
The socket type of the specified socket does not support accepting connections.

EWOULDBLOCK
The socket descriptor *socket* is in nonblocking mode, and no connections are in the queue.

Example

The following are two examples of the accept() call. In the first, the caller wishes to have the requester's address returned. In the second, the caller does not wish to have the requester's address returned.

```
int clientsocket;
int s;
struct sockaddr clientaddress;
int address_len;
int accept(int s, struct sockaddr *addr, int *address_len);
/* socket(), bind(), and listen()
have been called */
```

```
/* EXAMPLE 1: I want the address now */
address_len = sizeof(clientaddress);
clientsocket = accept(s, &clientaddress, &address_len);
/* EXAMPLE 2: I can get the address later using getpeername() */
clientsocket = accept(s, (struct sockaddr *) 0,
(int *) 0);
```

accept_and_recv() — Accept connection and receive first message

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

X/Open:

```
#define _OPEN_SYS_SOCK_EXT2
#include <sys/socket.h>

int accept_and_recv(int socket, int *accept_socket,
                    struct sockaddr *remote_address,
                    socklen_t *remote_address_len,
                    struct sockaddr *local_address,
                    socklen_t *local_address_len,
                    void *buffer, size_t buffer_len);
```

General description

The accept_and_recv() function extracts the first connection on the queue of pending connections. It either reuses the specified socket (if **accept_socket* is not -1) or creates a new socket with the same socket type, protocol, and address family as the listening socket (if **accept_socket* is -1). It then returns the first block of data sent by the peer and returns the local and remote socket addresses associated with the connection.

The function takes the following arguments:

Parameter
Description

socket Specifies a socket that was created with socket(), has been bound to an address with bind(), and has issued a successful call to listen().

accept_socket
Pointer to an `int` which specifies the socket on which to accept the incoming connection. The socket must not be bound or connected. Use of this parameter lets the application reuse the accepting socket. It is possible that the system may choose to reuse a different socket than the one the

application specified by this argument. In this case, the system will set **accept_socket* to the socket actually reused.

A value of -1 for **accept_socket* indicates that the accepting socket should be assigned by the system and returned to the application in this parameter. It is recommended that a value of -1 be used on the first call to accept_and_recv(). For more details, see "Usage notes" on page 110.

remote_address
: Either a NULL pointer or a pointer to a `sockaddr` structure where the address of the connecting socket will be returned.

remote_address_len
: Points to a `socklen_t`. On input, this specifies the length of the supplied `sockaddr` structure. On output, this contains the length of the stored address.

local_address
: Either a NULL pointer or a pointer to a `sockaddr` structure where the address of the local socket will be returned.

local_address_len
: Points to a `socklen_t`. On input, this specifies the length of the supplied `sockaddr` structure. On output, this contains the length of the stored address.

buffer
: Either a NULL pointer, or a pointer to a buffer where the message should be stored. If this is a NULL pointer, no receive is performed, and accept_and_recv() completes when the incoming connection is received.

buffer_len
: Specifies the length in bytes of the buffer pointed to by the *buffer* argument.

If **accept_socket* is not -1, the incoming connection will be accepted on the socket specified by **accept_socket*. The system may choose to reuse a different socket. If it does, the system will change **accept_socket* to reflect the socket actually used.

If *remote_address* is not a NULL pointer, the address of the peer for the accepted connection is stored in the `sockaddr` structure pointed to by *remote_address*, and the length of this address is stored in the object pointed to by *remote_address_len*. If the actual length of the address is greater than the length of the supplied socket address structure, the stored address will be truncated.

If *local_address* is not a NULL pointer, the address of the local socket associated with this connection is stored in the `sockaddr` structure pointed to by *local_address*, and the length of this address is stored in the object pointed to by *local_address_len*. If the actual length of the address is greater than the length of the supplied socket address structure, the stored address will be truncated.

Nonblocking mode is not supported for this function. If `O_NONBLOCK` is set on the socket file descriptor, the function will return with -1 and errno will be set to `EOPNOTSUPP`.

If the listen queue is empty of connection requests, accept_and_recv() will not return until an incoming connection is received.

If *buffer* is not NULL, accept_and_recv will not return until the first block of data on the connection has been received, otherwise accept_and_recv() returns 0 after the connection is established.

Note: The accept_and_recv() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Usage notes

1. On the first call to accept_and_recv(), it is recommended that the application set the socket pointed to by *accept_socket* to -1. This will cause the system to assign the accepting socket. The application then passes the assigned value into the next call to accept_and_recv() (by setting *accept_socket* = *socket_ptr*).

   To take full advantage of the performance improvements offered by the accept_and_recv() function, a process/thread model different from the one where a parent accepts in a loop and spins off child process threads is needed. The parent/process thread is eliminated. Multiple worker processes/threads are created, and each worker process/thread then executes the accept_and_recv() function in a loop. The performance benefits of accept_and_recv() include fewer buffer copies, recycled sockets, and optimal scheduling.

Returned value

If successful, accept_and_recv() returns the number of bytes (zero or more) stored in the buffer pointed to by the *buffer* argument. Zero can be returned when buffer is NULL or when the client closes the socket without sending any data.

A partial success is achieved with *accept_socket being assigned, a return value of -1 and errno set to one of the following values:

Error Code
  Description

EINTRNODATA
  The accept_and_recv() function was interrupted by a signal that was caught after a valid connection was established, but before the first block of data arrived.

EWOULDBLOCK
  A new connection was established, but the SO_RCVTIMEO timeout value was reached before data was available.

If unsuccessful, accept_and_recv() sets *accepted_socket to -1, returns -1 and sets errno to one of the following values:

Error Code
  Description

EBADF
  One of two errors occurred:
  1. *socket* is not a valid descriptor.
  2. *accept_socket* does not point to a valid descriptor.

ECONNABORTED
  A connection has been aborted.

ECONNRESET
  A connection was forcibly closed by a peer.

EFAULT
The data buffer pointed to by *accept_socket*, *remote_address*, *remote_address_len*, *local_address*, *local_address_len*, or *buffer* was not valid.

EINTR
The accept_and_recv() function was interrupted by a signal that was caught before a valid connection was established.

EINVAL
The *socket* is not accepting connections.

EIO An I/O error occurred.

EISCONN
The *accept_socket* is either bound or connected already.

EMFILE
`OPEN_MAX` descriptors are already open in the calling process.

ENOBUFS
No buffer space is available.

ENOMEM
There was insufficient memory available to complete the operation.

ENOREUSE
Socket reuse is not supported.

ENOSR
There were insufficient STREAMS resources available for the operation to complete.

ENOTSOCK
The *socket* argument does not refer to a socket, or *accept_socket* does not point to a socket.

EOPNOTSUPP
One of errors occurred:

1. The type of the socket does not support accepting connections.
2. `O_NONBLOCK` is set for the socket and nonblocking is not supported for this function.

access() — Determine whether a file can be accessed

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int access(const char *pathname, int how);
```

General description

Determines how an HFS file can be accessed. When checking to see if a process has appropriate permissions, access() looks at the *real* user ID (UID) and group ID (GID), not the effective IDs.

pathname is the name of the file whose accessibility you want to test. The *how* argument indicates the access modes you want to test. The following symbols are defined in the unistd.h header file for use in the *how* argument:

F_OK Tests whether the file exists.

R_OK Tests whether the file can be accessed for reading.

W_OK
Tests whether the file can be accessed for writing.

X_OK Tests whether the file can be accessed for execution.

You can take the bitwise inclusive-OR of any or all of the last three symbols to test several access modes at once. If you are using F_OK to test for the file's existence, you cannot use OR with any of the other symbols.

Returned value

If the specified access is permitted, access() returns 0.

If the given file cannot be accessed in the specified way, access() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The process does not have appropriate permissions to access the file in the specified way, or does not have search permission on some component of the *pathname* prefix.

EINVAL
The value of *how* is incorrect.

ELOOP
A loop exists in the symbolic links.

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters. The **PATH_MAX** value is determined using pathconf().

ENOENT
There is no file named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR
Some component of the *pathname* prefix is not a directory.

EROFS
The argument *how* has specified write access for a file on a read-only file system.

Returned value for POSIX C

The following errno values behave differently when a program is running with POSIX(ON):

Error Code
Description

ELOOP
A loop exists in the symbolic links. This error is issued if the number of symbolic links detected in the resolution is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX**, when _POSIX_NO_TRUNC (defined in the unistd.h header file) is in effect. The **PATH_MAX** and **NAME_MAX** values are determined using pathconf().

Example

CELEBA03

```
/* CELEBA03

   The following example determines how a file is accessed.

 */
#define _POSIX_SOURCE
#include <stdio.h>
#undef _POSIX_SOURCE
#include <unistd.h>

main() {
  char path[]="/";

  if (access(path, F_OK) != 0)
    printf("'%s' does not exist!\n", path);
  else {
    if (access(path, R_OK) == 0)
      printf("You have read access to '%s'\n", path);
    if (access(path, W_OK) == 0)
      printf("You have write access to '%s'\n", path);
    if (access(path, X_OK) == 0)
      printf("You have search access to '%s'\n", path);
  }
}
```

Output: From a non-superuser:

```
You have read access to '/'
You have search access to '/'
```

acl_create_entry() — Add a new extended ACL entry to the ACL

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_create_entry(lacl_t *acl_p, acl_entry_t entry_p, int version);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_create_entry() function creates a new extended ACL entry in the ACL pointed to by the contents of the pointer argument *acl_p*. The contents of the acl_entry are specified by *entry_p*. ACL working storage is allocated as needed. The first call to acl_get_entry() following the call to acl_create_entry() will obtain the first extended ACL entry in the ACL, as ordered by the system.

The version tells the function the version of ACL entry. See “sys/acl.h” on page 72 for ACL entry mapping.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_create_entry() function returns -1 and sets errno to the corresponding value:

Error Code
  Description

EINVAL
  Argument *acl_p* does not point to a pointer to an ACL structure. Argument *entry_d* does not point to a valid extended ACL entry.

ENOMEM
  The ACL working storage requires more memory than is available.

Related information

- “sys/acl.h” on page 72

acl_delete_entry() — Delete an extended ACL entry from the ACL

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_delete_entry(lacl_t acl_d, acl_entry_t entry_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_delete_entry() function removes the extended ACL entry indicated by *entry_d* in the ACL pointed to by argument *acl_d*. The first call to acl_get_entry() following the call to acl_delete_entry() will obtain the first extended ACL entry in the ACL, as ordered by the system.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_delete_entry() function returns -1 and sets errno to the corresponding value:

Error Code
 Description

EINVAL
 Argument *acl_d* does not point to a pointer to an ACL structure. Argument *entry_d* does not point to a valid extended ACL entry or not within the given ACL structure.

Related information

- "sys/acl.h" on page 72

acl_delete_fd() — Delete an ACL by file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int     acl_delete_fd (int fd, int type_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_delete_fd() function deletes the *type_d* ACL. That means that all extended ACL entries are deleted for *type_d* ACL. A file/dir subject must match the owner of the directory/file or the subject must have appropriate privileges.

The effective UID of the process must match the owner of the directory/file or the process must have appropriate privileges. If the *type_d* is the directory/file default and the object referred to by *fd* is not a directory, then the function will fail. An attempt to delete an ACL from a file that does not have that ACL is not considered an error.

Upon successful completion, the acl_delete_fd() will delete the type ACL associated with the file referred by argument *fd*. If unsuccessful, the type ACL associated with the file object referred by argument *fd* will not be changed.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_delete_fd() function returns -1 and sets errno to the corresponding value:

Error Code
  Description

EBADF
  The *fd* argument is not a valid file descriptor.

EINVAL
  Argument *type_d* is not a valid ACL type.

ENOTDIR
  The type specifies directory/file default ACL and the argument *fd* does not refer to a directory object.

EACCES
  The process does not have appropriate privilege to delete the type ACL.

Related information

- “sys/acl.h” on page 72
- “acl_delete_file() — Delete an ACL by file name”

acl_delete_file() — Delete an ACL by file name

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int     acl_delete_file (const char *path_p, int type_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_delete_file() function deletes the *type_d* ACL. That means that all extended ACL entries are deleted for *type_d* ACL. A file/directory always has base ACL entries so they cannot be deleted. The effective UID of the process must match the owner of the directory/file or the process must have appropriate privileges.

If the type_d is the directory/file default and the object referred to by *fd* is not a directory, then the function will fail. An attempt to delete an ACL from a file that does not have that ACL is not considered an error.

Upon successful completion, the acl_delete_file() will delete the type ACL associated with the file referred by argument *path_p*. If unsuccessful, the type ACL associated with the file object referred by argument *path_p* will not be changed.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_delete_file() function returns -1 and sets errno to the corresponding value:

Error Code
Description

EACCES
Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.

EINVAL
Argument *type_d* is not a valid ACL type.

ENAMETOOLONG
The length of the path name argument exceeds PATH_MAX, or a path name component is longer than NAME_MAX and {_POSIX_NO_TRUNC} is in effect for that file. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX. PATH_MAX and NAME_MAX values can be determined by using pathconf().

ENOENT
The named object does not exist or the *path_p* argument points to an empty string.

ENOTDIR
The type specified was directory/file default but the argument *path_p* is not a directory or a component of the path prefix is not a directory.

acl_first_entry() — Return to beginning of ACL working storage

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int     acl_first_entry (lacl_t acl_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

A call to acl_first_entry() sets the internal ACL entry offset descriptor for the *acl_d* argument such that a subsequent call to acl_get_entry() using the same *acl_d* argument obtains the first extended ACL entry in the ACL.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_init() function returns -1 and sets errno to the corresponding value:

Error Code
 Description

EINVAL
 Argument *acl_d* does not point to an ACL structure.

Related information

acl_free() — Release memory allocated to an ACL data object

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int     acl_free (lacl_t acl_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_free() function frees any releasable memory currently allocated to the ACL data object identified by *acl_d*. Use of the object reference pointed to by *acl_d* after the memory has been released is undefined.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_free() function returns -1 and sets errno to the corresponding value:

Error Code
Description

EINVAL
The value of the *acl_d* argument is not valid.

Related information

- “sys/acl.h” on page 72

acl_from_text() — Create an ACL from text

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int  acl_from_text (const char *buf_p, short OpType, acl_all_t ptr, char **ret);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_from_text() function converts the text form of an ACL referred to by *buf_p* into the acl_t form of an ACL. It parses both the extended and base ACL entries.

If successful, the structure that *ptr* points to will be updated with ACL entries for the 3 types of ACLs. The structure members that *ptr* points to must either be NULL or point to a valid *acl_t* structure. If the structure member is not NULL, ACL entries contained in *buf_p* will be merged in. New storage for those structure members may be allocated as needed and in that case passed-in storage will be freed, so structure members may point to a different storage than the one originally supplied.

If ptr is NULL, the acl_from_text will fail. If the *buf_p* has no ACL entries (such as empty string, only empty lines, etc), acl_from_text() will fail with errno set to EINVAL and *ret* will point to the null terminator in *buf_p*.

Working storage is allocated for the individual ACLs structures as needed and need to be freed using acl_free().

If the function is unsuccessful due to error encountered in parsing, ret will contain the address of beginning of extended/base ACL entry where the error was found in *buf_p* and errno will be set to EINVAL. Otherwise *ret* will be NULL.

The text form of the ACL referred to by buf_p may be incomplete or may be a non-valid ACL as defined by acl_valid(). The *buf_p* must be null terminated. The first call to acl_get_entry() following the call to acl_from_text() obtains the first entry in the ACL as ordered by the system.

For OpType =ACL_DELETE, the extended ACL entries will be updated with the flag bit to be removed from the ACL when acl_set_fd() or acl_set_file() is called. The base ACL entries are parsed but not put into the structure that ptr points to since you cannot delete base ACL entries.

The *buf_p* cannot have a mixture of ACL entry delimiters (newline and comma). All ACL entries in the buf must use the same delimiter, either a newline or comma. For a mixture of delimiters, acl_from_text() will fail with errno set to EINVAL and ret parameter will point to the delimiter in error.

acl_all_t :

index 0
access acl

index 1
file default acl

index 2
directory default acl

Valid text input format based on OpType:

tag fdefault, default (access if nothing is specified)

type user, group, other

id uid, gid, username, groupname

perm rwx (or '-' for no permission), octal (0-7) , +/^ (where + is turn on and ^ is turn off)

Pound sign (#) is used to designate a comment. When the input is separated by commas, everything past # is treated as a comment. When the input is separated by a newline, everything after # till the newline is considered a comment. Comments are ignored and are not stored in the buffer.

```
ACL_ADD  tag:type:id:perm // extended ACL entry
   type::perm     // base ACL entry
ACL_MODIFY same as ACL_ADD
ACL_DELETE tag:type:id  // extended ACL entry
```

Note: The extended ACL entries must have the type (group or user) and the id (uid/gid). The base ACL entries do not have a value for the id field. The id field or the lack of one is what distinguishes the base ACL entry from the extended ACL entry. The base ACL entries do not have the tag fields since they only apply to access ACL.

The acl_from_text() allows for trailing ACL entry separator (newline or comma). For relative permission settings, only one of '+' or '^' is allowed per ACL entry. When using relative permissions you must have at least one of r, w, or x. For example: +rw or ^rwx.

Returned value

Upon successful completion, the function returns a zero.

If any of the following conditions occur, the acl_from_text() function returns -1 and sets errno to the corresponding value:

Error Code
Description

EINVAL
Argument *buf_p* cannot be translated into an ACL.

ENOMEM
The ACL working storage requires more memory than is available.

E2BIG The number of base ACL entries exceeded allowable 3.

The ret will contain the address in *buf_p* where the error was found.

Related information

- “sys/acl.h” on page 72
- “acl_free() — Release memory allocated to an ACL data object” on page 118

acl_get_entry() — Get an ACL entry

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int     acl_get_entry (lacl_t acl_d, acl_entry_t *entry_p);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_get_entry() function obtains a descriptor to the next extended ACL entry of the ACL indicated by argument *acl_d*. Upon successful execution, the acl_get_entry() function returns a descriptor for the extended ACL entry via entry_p. Argument *acl_d* must refer to a valid acl_t structure.

The first call to acl_get_entry() following a call to acl_first_entry(), acl_from_text(), acl_get_fd(), acl_get_file(), acl_set_fd(), acl_set_file(), or acl_valid() obtains the first extended ACL entry in the ACL, as ordered by the system. Subsequent calls to acl_get_entry() obtain successive extended ACL entries, until the last entry is obtained. After the last extended ACL entry has been obtained from the *acl_d* the value NULL is returned via *entry_p*.

To determine if ACL has any base ACL entries, check acl_d->lacl_base, which gives the number of base ACL entries present. Then the process can access the base ACL entries directly in the acl_d. (For example: acl_d->lacl_base_entries[0].acle_type is the type field of the first base ACL entry.)

Returned value

If the function successfully obtains a pointer to the extended ACL entry, the function returns a value of one. If the last extended ACL entry in the ACL has already been returned by a previous call to acl_get_entry() or if ACL has no extended ACL entries, the function returns a value of zero.

If any of the following conditions occur, the acl_get_entry() function returns -1 and sets errno to the corresponding value:

Error Code
Description

EINVAL
Argument *acl_d* does not point to an ACL structure.

Related information

- "sys/acl.h" on page 72
- "acl_init() — Initialize ACL working storage" on page 125

acl_get_fd() — Get ACL by file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int   acl_get_fd (int fd, acl_type_t type_d, lacl_t acl_d, int *num);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_get_fd() function retrieves an ACL based on *type_d* argument for an object associated with the file descriptor *fd*. The ACL is retrieved into the supplied working storage pointed to by *acl_d*. For the *type_d* = ACL_ACCESS, acl_get_fd() will get both the base ACL entries and extended ACL entries. (The base ACL entries only apply to the ACL_ACCESS ACL.)

The working storage should be allocated using the acl_init() function. If the buffer is not big enough, the acl_get_fd() will fail with errno=E2BIG and *num* will be filled with the number of ACLs in the ACL pointed to by fd. The user can get a bigger acl_t structure buffer using the num value and reissue the acl_get_fd().

If the object associated with the file descriptor does not have the specified ACL, then an ACL containing zero ACL entries will be returned. If the argument *fd* refers to an object other than a directory and the value of *type_d* is a directory/file default, then the function will fail.

The first call to acl_get_entry() following the call to acl_get_fd() obtains the first extended ACL entry in the ACL as ordered by the system.

The result of acl_get_fd() can be used to set that same ACL using acl_set_fd() or acl_set_file() using OpType = ACL_ADD.

Returned value

Upon successful completion, the function returns zero.

If any of the following conditions occur, the acl_get_fd() function returns a value of NULL and sets errno to the corresponding value:

Error Code
Description

EACCES
The required access to the file referred to by *fd* is denied.

EBADF
The fd argument is not a valid file descriptor.

EINVAL
Argument *type_d* is not a valid ACL type. Argument *acl_d* does not point to an ACL structure.

ENOTDIR
The type specified was directory/file default but the argument *fd* does not refer to a directory.

E2BIG
The supplied buffer is too small for all extended ACL entries. *num* value has the number of ACL entries that need to fit in the buffer.

Related information

- “sys/acl.h” on page 72
- “acl_free() — Release memory allocated to an ACL data object” on page 118

acl_get_file() — Get ACL by file name

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int  acl_get_file (const char *path_p, acl_type_t type_d, lacl_t acl_d, int *num);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_get_file() function retrieves an ACL based on *type_d* argument for an object associated with the object via file name. The ACL is retrieved into the specified working storage pointed to by *acl_d*. For the *type_d* = ACL_ACCESS, acl_get_file() will get both the base ACL entries and extended ACL entries. The base ACL entries only apply to the ACL_ACCESS ACL.

The working storage should be allocated using the acl_init() function. If the buffer is not big enough, the acl_get_fd() will fail with errno=E2BIG and *num* will be filled with the number of ACLs in the ACL pointed to by *fd*. The user can get a bigger acl_t structure buffer using the num value and reissue the acl_get_fd().

If the object associated with the file descriptor does not have the specified ACL, then an ACL containing zero ACL entries will be returned. If the argument *fd* refers to an object other than a directory and the value of *type_d* is a directory/file default, then the function will fail.

The first call to acl_get_entry() following the call to acl_get_fd() obtains the first extended ACL entry in the ACL as ordered by the system. The result of acl_get_fd() can be used to set that same ACL using acl_set_fd() or acl_set_file() using OpType = ACL_ADD.

Returned value

Upon successful completion, the function returns zero.

If any of the following conditions occur, the acl_get_file() function returns a value of NULL and sets errno to the corresponding value:

Error Code
Description

EACCES
Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.

EINVAL
Argument *type_d* is not a valid ACL type. Argument *acl_d* does not point to an ACL structure.

ENAMETOOLONG
The length of the path name argument exceeds PATH_MAX, or a path name component is longer than NAME_MAX and {_POSIX_NO_TRUNC} is in effect for that file. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX. PATH_MAX and NAME_MAX values can be determined by using pathconf().

ENOENT
The named object does not exist or the *path_p* argument points to an empty string.

ENOTDIR
The type specified was directory/file default but the argument *path_p* is not a directory or a component of the path prefix is not a directory.

E2BIG The supplied buffer is too small for all extended ACL entries. Num value has the number of ACL entries that need to fit in the buffer.

acl_init() — Initialize ACL working storage

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

lacl_t   acl_init (int count);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_init() function allocates and initializes working storage for an ACL of at least *count* extended ACL entries. A pointer to the working storage is returned. The working storage allocated to contain the ACL must be freed by a call to acl_free(). The working storage contains an ACL with no ACL entries. The count must be greater than 0.

The acl_init() function initializes fields in the *lacl_t* it returns. When those fields are destroyed (for example, using memset or overwriting storage), the results are unpredictable. To re-use the buffer, acl_entry_delete() all extended ACL entries and set lacl_base = 0 or acl_free() the existing buffer and acl_init() for a new one.

Returned value

Upon successful completion, the function returns a pointer to the working storage.

If any of the following conditions occur, the acl_init() function returns NULL and sets errno to the corresponding value:

Error Code
 Description

ENOMEM
 The *lacl_t* to be returned requires more memory than is available.

EINVAL
 The count is less than or equal to zero.

Related information

- “sys/acl.h” on page 72
- “acl_free() — Release memory allocated to an ACL data object” on page 118

acl_set_fd() — Set an ACL by file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int     acl_set_fd (int fd, acl_type_t type_d, lacl_t acl_d, short OpType,
  acl_entry_t *entry_p);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_set_fd() function associates the type_d ACL with the object referred to by *fd*. The effective UID of the subject must match the owner of the object or the subject must have appropriate privileges.

If the *type_d* is the directory/file default and the object referred to by *fd* is not a directory, then the function will fail.

The acl_set_fd() function will succeed only if the ACL is valid as defined by the acl_valid() function.

Upon successful completion, acl_set_fd() will set the ACL of the object. For type_d = ACL_ACCESS, acl_set_fd() will also set the base ACL entries. The base ACL entries only apply to ACl_ACCESS ACL type, so for any other type the base ACL entries are ignored.

The *OpType* determines whether the ACL is updated or replaced.

OpType
Action

ACL_ADD
replace the whole ACL with the given extended and base ACL entries

ACL_MODIFY
update the ACL with the given extended and/or base ACL entries (if individual extended ACL entries are marked for deletion, than ACL_MODIFY removes them)

ACL_DELETE
delete from the ACL the specified extended ACL entries; marks the individual extended ACL entries for deletion (cannot delete base ACL entries)

If *Optype* is ACL_MODIFY, the setting will modify the existing extended ACL entries and add new ones if they do not exist. Both ACL entry's mask and value are used to determine ACL entry's permission to set.

If *OpType* is ACL_ADD, the existing ACL is replaced by the new one. Only extended ACL entry's value is used to determine permissions to set. The object's previous ACL will no longer be in effect. If the object had no ACL, a new one is added for both ACL_MODIFY and ACL_ADD.

Similarly, for OpType = ACL_ADD, base ACL entries are replaced with the new values specified (mask field is ignored). All three base ACL entries (ACL_USER, ACL_GROUP, and ACL_OTHER) must be specified. For OpType = ACL_MODIFY, the base ACL entries are modified with the specified values (both mask and value fields are used).

For Optype = ACL_MODIFY only the base ACL entries to be changed need to be specified. The Optype = ACL_DELETE does not apply to base ACL entries since they cannot be removed. Every file always has base ACL entries.

If the acl_set_fd() is unsuccessful, the ACL of the object referred to by argument *fd* is not changed.

The ordering of entries within ACL referred to by *acl_d* may be changed. The first call to acl_get_entry() following the call to acl_set_fd() obtains the first extended ACL entry in the ACL as ordered by the system.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_set_file() function returns a value of -1 and sets errno to the corresponding value:

Error Code
Description

EACCES
Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.

E2BIG The ACL has more extended ACL entries than is allowed.

ENOENT
The named object does not exist or the *path_p* argument points to an empty string.

EINVAL
Argument *acl_d* does not point to a valid ACL structure.

ENOSPC
The directory or file system that would contain the new ACL cannot be extended or the file system is out of space.

ENOTDIR
The *type_d* specified was directory/file default but the argument *path_p* does not refer to a directory.

ENAMETOOLONG
The length of the path name argument exceeds PATH_MAX, or a path name component is longer than NAME_MAX and {_POSIX_NO_TRUNC} is in effect for that file. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX. PATH_MAX and NAME_MAX values can be determined by using pathconf().

EMVSERR
Other internal RACF® error (more information in errno2)

The function will return -2 and set errno to EINVAL if the base ACL entry is not unique or is not a valid type or for ACL_ADD, there are less than 3 base ACL entries. The *entry_p* will be NULL.

The function will return -3 and set errno to EINVAL if the extended ACL entry is not unique or is not a valid type. The *entry_p*, if not NULL, will point to the extended ACL entry in error.

acl_set_file() — Set an ACL by file name

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int     acl_set_file (char *path_p, acl_type_t type_d, lacl_t acl_d, short OpType,
  acl_entry_t *entry_p);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_set_file() function associates the type_d ACL with the object referred to by file name *path_p*. The effective UID of the subject must match the owner of the object or the subject must have appropriate privileges.

If the type_d is the directory/file default and the object referred to by file name *path_p* is not a directory, then the function will fail.

The acl_set_file() function will succeed only if the ACL is valid as defined by the acl_valid() function.

Upon successful completion, acl_set_file() will set the ACL of the object. For type_d = ACL_ACCESS, acl_set_file() will also set the base ACL entries. The base ACL entries only apply to ACl_ACCESS ACL type, so for any other type the base ACL entries are ignored.

The *OpType* determines whether the ACL is updated or replaced.

OpType
: **Action**

ACL_ADD
: replace the whole ACL with the given extended and base ACL entries

ACL_MODIFY
: update the ACL with the given extended and/or base ACL entries (if individual extended ACL entries are marked for deletion, then ACL_MODIFY removes them)

ACL_DELETE
: delete from the ACL the specified extended ACL entries; marks the individual extended ACL entries for deletion (cannot delete base ACL entries)

If *Optype* is ACL_MODIFY, the setting will modify the existing extended ACL entries and add new ones if they do not exist. Both ACL entry's mask and value are used to determine ACL entry's permission to set.

If *OpType* is ACL_ADD, the existing ACL is replaced by the new one. Only extended ACL entry's value is used to determine permissions to set. The object's previous ACL will no longer be in effect. If the object had no ACL, a new one is added for both ACL_MODIFY and ACL_ADD.

Similarly, for OpType = ACL_ADD, base ACL entries are replaced with the new values specified (mask field is ignored). All three base ACL entries (ACL_USER, ACL_GROUP, and ACL_OTHER) must be specified. For OpType = ACL_MODIFY, the base ACL entries are modified with the specified values (both mask and value fields are used).

For Optype = ACL_MODIFY only the base ACL entries to be changed need to be specified. The Optype = ACL_DELETE does not apply to base ACL entries since they cannot be removed. Every file always has base ACL entries.

If the acl_set_file() is unsuccessful, the ACL of the object referred to by argument *path_p* is not changed.

The ordering of entries within ACL referred to by acl_d may be changed. The first call to acl_get_entry() following the call to acl_set_file() obtains the first extended ACL entry as ordered by the system.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_set_file() function will return a value of -1 and set errno to the corresponding value:

Error Code
    Description

EACCES
    Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.

E2BIG The ACL has more extended ACL entries than are allowed.

ENOENT
    The named object does not exist or the *path_p* argument points to an empty string.

EBADF
    The *fd* argument is not a valid file descriptor.

EINVAL
    Argument *acl_d* does not point to a valid ACL structure.

ENOSPC
    The directory or file system that would contain the new ACL cannot be extended or the file system is out of space.

ENOTDIR
    The *type_d* specified was directory/file default but the argument *path_p* does not refer to a directory.

ENAMETOOLONG
    The length of the path name argument exceeds PATH_MAX, or a path name component is longer than NAME_MAX and {_POSIX_NO_TRUNC} is in effect for that file. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX. PATH_MAX and NAME_MAX values can be determined by using pathconf().

EMVSERR
    Other internal RACF error (more information in errno2)

The function will return -2 and set errno to EINVAL if the base ACL entry is not unique or is not a valid type or for ACL_ADD, there are less than 3 base ACL entries. The *entry_p* will be NULL.

The function will return -3 and set errno to EINVAL if the extended ACL entry is not unique or is not a valid type. The *entry_p*, if not NULL, will point to the extended ACL entry in error.

acl_sort() — Sort the extended ACL entries

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_sort(lacl_t acl_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_sort() function sorts the extended ACL entries in the following orders:

- ACL_USER lowest to highest uid
- ACL_GROUP lowest to highest gid

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_sort() returns -1 and sets errno to the corresponding value:

Error Code
Description

EINVAL
Argument *acl_d* does not point to a valid ACL structure.

Related information

- “sys/acl.h” on page 72

acl_to_text() — Convert an ACL to text

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

char * acl_to_text (const lacl_t acl_d, ssize_t *len_p, acl_type_t type_d,
  char delim);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_to_text() function translates the extended ACL entries in an ACL pointed to by argument *acl_d* into a NULL terminated character string. This function allocates any memory necessary to contain the string and returns a pointer to the string. The memory allocated to contain the string must be freed. If the pointer *len_p* is not NULL, then the function returns the full length of the string (not including the NULL terminator) in the location pointed to by *len_p*. The *delim* parameter determines the delimiter used to separate the ACL entries (usually newline or comma).

The mask field in the base and extended ACL entry is ignored and only the ACL entry value field is used to display the ACL entry permissions.

For *acl_d* with no extended ACL entries, acl_to_text() returns NULL. When acl_to_text() cannot convert uid/gid to username/groupname, it leaves the uid/gid in the string.

The format of the text string:

```
<acl_entry>delim<acl_entry> ... <acl_entry>
```

where acl_entry may be:

base_acl_tag::permissions
user:user_name:permissions
group:group_name:permissions
default:user_name:permissions

base_acl_entry:
user, group, or other

permissions:
rwx (with '-' for no permission)

default:
fdefault - file default
default - directory default

Returned value

Upon successful completion, the function returns a pointer to the text form of an ACL.

If any of the following conditions occur, the acl_to_text() returns NULL and sets errno to the corresponding value:

Error Code
Description

EINVAL
Argument *acl_d* does not point to a valid ACL structure. The ACL referenced by acl_d contains one or more improperly formed ACL entries, or for some other reason cannot be translated into the string form of ACL.

ENOMEM
The character string to be returned requires more memory than is available.

acl_update_entry() — Update the extended ACL entry

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_update_entry(lacl_t acl_d, acl_entry_t entry_s, acl_entry_t entry_d
   int version);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_update_entry() function updates the extended ACL entry *entry_s* with the values from *entry_d*. The version tells the function the version of ACL entry. See "sys/acl.h" on page 72 for ACL entry mapping.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_create_entry() function returns -1 and sets errno to the corresponding value:

Error Code
Description

EINVAL
Argument *entry_s* or *entry_d* do not point to a valid extended ACL entry. Argument *acl_d* does not point to a valid ACL structure.

Related information

- "sys/acl.h" on page 72

acl_valid() — Validate an ACL

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R3

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int     acl_valid (lacl_t acl_d, acl_entry_t *entry_p);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The acl_valid() function checks the access ACL, file default ACL, or directory default ACL referred to by the argument *acl_d* for validity.

The ACL_USER, ACL_GROUP, and ACL_OTHER can only exist once in base ACL entries. The ACL_OTHER only applies to base ACL entries.

The tag type (user, group) must contain valid values for the extended ACL entries. The qualifier field (uid, gid) must be unique among all extended ACL entries of the same ACL except for the extended ACL entries that are mapped for deletion (see ACL entry mapping in "sys/acl.h" on page 72 for more information). The ordering of base and/or extended ACL entries within ACL referred by the *acl_d* may be changed.

The first call to acl_get_entry() following the call to acl_valid() obtains the first extended ACL entry in the ACL as ordered by the system.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the location referred to by *entry_p* will be undefined and the acl_valid() function returns -1 and sets errno to the corresponding value:

Error Code
Description

EINVAL
Argument *acl_d* does not point to an ACL structure.

If any of the following conditions occur, the acl_valid() function will set the location referred to by entry_p to one of the ACL entries in error, return -2 and set errno to the appropriate value.

Error Code
Description

EINVAL
The ACL contains extended ACL entries that are not unique or is not a valid ACL entry type.

If any of the following conditions occur, the acl_valid() function will return -3 and set errno to the appropriate value.

Error Code
Description

EINVAL
The ACL contains base ACL entries that are not unique or is not a valid ACL entry type. Only one base ACL entry of the same tag type (ACL_USER, ACL_GROUP, ACL_OTHER) may exist.

acos(), acosf(), acosl() — Calculate arccosine

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double acos(double x);
float acos(float x);                  /* C++ only */
long double acos(long double x);      /* C++ only */
float acosf(float x);
long double acosl(long double x);
```

General description

Calculates the arccosine of *x*, expressed in radians, in the range 0 to pi.

The value of *x* must be between -1 and 1 inclusive.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Special behavior for C/370: If *x* is less than -1 or greater than 1, the function sets errno to EDOM and returns 0. If the correct value would cause underflow, zero is returned and the value ERANGE is stored in errno.

Special behavior for XPG4.2: If successful, the function returns the arccosine of *x*, in the range [0,pi] radians.

If the value of *x* is not in the range [-1,1], the function returns 0.0 and sets errno to the following value. No other errors will occur.

Error Code
Description

EDOM
The value *x* is not in the range [-1,1].

Special behavior for IEEE: If successful, the function returns the arccosine of the argument *x*.

If *x* is less than -1 or greater than 1, the function sets errno to EDOM and returns NaNQ (Not a Number Quiet). No other errors will occur.

Example

CELEBA04

```
/* CELEBA04

   This example prompts for a value for x.
   It prints an error message if x is greater than 1 or
   less than -1; otherwise, it assigns the arccosine of
   x to y.

 */
#include <stdio.h>
#include <stdlib.h>
#include <math.h>
#define MAX  1.0
#define MIN -1.0
```

```
int main(void)
{
  double x, y;

  printf( "Enter x\n" );
  scanf( "%lf", &x );

                  /* Output error if not in range */
  if ( x > MAX )
    printf( "Error: %f too large for acos\n", x );
  else if ( x < MIN )
    printf( "Error: %f too small for acos\n", x );
  else {
    y = acos( x );
    printf( "acos( %f ) = %f\n", x, y );
  }
}
```

Output

Expected result if 0.4 is entered:

```
Enter x
acos( 0.400000 ) = 1.159279
```

acosh(), acoshf(), acoshl() — Calculate hyperbolic arccosine

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double acosh(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float acoshf(float x);
long double acoshl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>
float acosh(float x);
long double acosh(long double x);
```

General description

The acosh functions compute the (nonnegative) arc hyperbolic cosine of *x*. A domain error occurs for arguments less than 1.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
acosh	X	X

Function	Hex	IEEE
acoshf	X	X
acoshl	X	X

Returned value

If successful, acosh() returns the hyperbolic arccosine of its argument *x*.

If the value of *x* is less than 1.0, then the function returns 0.0 and sets errno to EDOM.

Special behavior for IEEE: If successful, the function returns the hyperbolic arccosine of its argument *x*.

If *x* is less than 1.0, the function sets errno to EDOM and returns NaNQ.

advance() — Pattern match given a compiled regular expression

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2	both	

Format

```
#define _XOPEN_SOURCE
#include <regexp.h>

int advance(const char *string, const char *expbuf);

extern char *loc2, *locs;
```

General description

Restriction: This function is not supported in AMODE 64.

The advance() function attempts to match an input string of characters with the compiled regular expression which was obtained by an earlier call to compile().

The first parameter *string* is a pointer to a string of characters to be checked for a match.

expbuf is the pointer to the regular expression which was previously obtained by a call to compile().

The external variable *loc2* will point to the next character in *string* after the last character that matched the regular expression.

The external variable *locs* can be optionally set to point to some point in the input regular expression string to cause the advance() function to exit its back up loop.

Note: The external variables *cirf*, *sed*, and *nbra* are reserved.

During the pattern matching operation, when advance() encounters a * or \{\} sequence in the regular expression, it will advance its pointer to the string to be matched as far as possible and will recursively call itself trying to match the rest of the string to the rest of the regular expression. As long as there is no match, advance() will back up along the string until it finds a match or reaches the point in the string that initially matched the * or \{\}. It is sometime desirable to stop this backing up before the initial point in the string is reached. If the external character pointer *locs* is equal to the point in the string at some time during the back up process, advance() will break out of the loop that backs up and will return 0 (a failure indication).

Notes:

1. The application must provide the proper serialization for the compile(), step(), and advance() functions if they are run under a multithreaded environment.
2. The compile(), step(), and advance() functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions fnmatch(), glob(), regcomp() and regexec(), which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

Returned value

If the initial substring of *string* matches the regular expression in *expbuf*, advance() returns nonzero.

If there is no match, advance() returns 0.

If there is a match, advance() sets an external character pointer, *loc2*, as a side effect. The variable *loc2* points to the next character in *string* after the last character that matched the regular expression.

__ae_correstbl_query() — Return coded character set ID type (ASCII and EBCDIC)

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R2

Format

```
#include <_Nascii.h>

__argument_t __ae_correstbl_query(void *search_argument, int src_arg_type,
                                  _AE_correstbl_t **ebcdic_entry_ptr,
                                  _AE_correstbl_t **ascii_entry_ptr);
```

General description

The __ae_correstbl_query() function is a method by which the user can obtain coded character set id (CCSID), type, and correspondence information from the EBCDIC/ASCII Correspondence and CCSID/Codeset Name Lookup Table, CEL4CTBL.

The user must provide the following:

Argument
    Description

***search_argument**
    A Codeset Name or CCSID search argument.

src_arg_type
    Specifies whether *search_argument* is a Codeset Name or a CCSID, using one of the defined values from <_Nascii.h>:

- _AE_CODESET_SRCH_ARG
- _AE_CCSID_SRCH_ARG

****ebcdic_entry_ptr**
    The address of an _AE_correstbl_t pointer for storing the EBCDIC table entry.

****ascii_entry_ptr**
    The address of an _AE_correstbl_t pointer for storing the ASCII table entry.

The function will then populate the supplied pointers with the address of _AE_correstbl_t structures containing the requested codeset's table entry as well as the address of the corresponding codeset's entry. However, not every EBCDIC codeset in the table has a corresponding ASCII encoding and vice versa. When a corresponding codeset does not exist, the pointer value returned in that argument is zero.

For consistency, the first _AE_correstbl_t pointer address argument will be populated with the EBCDIC entry address, and the second _AE_correstbl_t pointer will be populated with the ASCII entry address, regardless of which was the requested codeset and which was the corresponding codeset.

The __argument_t return value for __ae_correstbl_query() indicates the EBCDIC or ASCII type of the provided codeset.

Returned value

If successful, __ae_correstbl_query() returns either:

- _AE_EBCDIC_TYPE, when the requested entry is EBCDIC.
- _AE_ASCII_TYPE, when the requested entry is ASCII.

If unsuccessful, because the correspondence table cannot be loaded or the provided Codeset Name or CCSID is not valid, __ae_correstbl_query() returns _AE_UNKNOWN_TYPE.

aio_cancel() — Cancel an asynchronous I/O request

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3	both	OS/390 V2R7

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_cancel(int fildes, struct aiocb *aiocbp);
```

General description

The aio_cancel() function attempts to cancel one or more asynchronous I/O requests currently outstanding against file descriptor *fildes*. The *aiocbp* argument points to an *aiocb* structure for a particular request to be canceled or is NULL to cancel all outstanding cancelable requests against *fildes*.

Normal asynchronous notification occurs for asynchronous I/O operations that are successfully canceled. The associated error status is set to ECANCELED and the return status is set to -1 for the canceled requests.

For requests that cannot be canceled, the normal asynchronous completion process takes place when their I/O completes. In this case the *aiocb* is not modified by aio_cancel().

An asynchronous operation is cancelable if it is currently blocked or becomes blocked. Once an outstanding request can be completed it is allowed to complete. For example, an aio_read() will be cancelable if there is no data available at the time that aio_cancel() is called.

fildes must be a valid file descriptor, but when *aiocbp* is not NULL *fildes* does not have to match the file descriptor with which the asynchronous operation was initiated. For maximum portability, though, it should match.

The aio_cancel() function always waits for the request being canceled to either complete or be canceled. When control returns from aio_cancel(), the program may safely free the original request's aiocb and buffer. If a signal was specified on the original request, the signal handler for that request's I/O complete notification may run before, during, or after control returns from aio_cancel(), so coordination may be necessary between the signal handler and the caller of aio_cancel(). This is particularly unpredictable when aio_cancel() is called from a different thread than the original request, unless the original thread no longer exists.

Canceling all requests on a given descriptor does not stop new requests from being made or otherwise effect the descriptor. The program may start again or close the descriptor depending on why it issued the cancel.

An individual request can only be canceled once. Subsequent attempts to explicitly cancel the same request will fail with EALREADY.

Returned value

aio_cancel() returns one of the following values:

- AIO_CANCELED if the requested operations were canceled.
- AIO_NOTCANCELED if at least one of the requested operations cannot be canceled because it is in progress.

  In this case, the state of the other operations, if any, referenced in the call to aio_cancel() is not indicated by the return value of aio_cancel(). The application can determine the status of these operations by using aio_error().
- AIO_ALLDONE if all of the operations have already completed. This is returned when there are no outstanding requests found that match the criteria specified. This is also the result returned when a file associated with *fildes* does not support the asynchronous I/O function because there are no outstanding requests to be found that match the criteria specified.
- -1 if there was an error. aio_cancel() sets errno to one of the following values:

  Error Code
  Description

  EALREADY
  The operation to be canceled is already being canceled.

EBADF
The *fildes* argument is not a valid file descriptor.

aio_error() — Retrieve error status for an asynchronous I/O operation

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3	both	OS/390 V2R7

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_error(const struct aiocb *aiocbp);
```

General description

The aio_error() function returns the error status associated with the *aiocb* structure referenced by the *aiocbp* argument. The error status for an asynchronous I/O operation is the errno value that would be set by the corresponding read(), or write() operation. If the operation has not yet completed, then the error status will be equal to EINPROGRESS.

Returned value

If the asynchronous I/O operation has completed successfully, aio_error() returns 0.

If the asynchronous I/O operation has completed unsuccessfully, aio_error() returns the error status as described for read(), or write().

If the asynchronous I/O operation has not yet completed, then EINPROGRESS is returned.

aio_error() does not set errno.

When the errno is returned is not EINPROGRESS and not zero, the errno2 set by either read() or write() can be retrieved by using the __errno2() function.

aio_read() — Asynchronous read from a socket

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3	both	OS/390 V2R7

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_read(struct aiocb *aiocbp);
```

General description

The aio_read() function initiates an asynchronous read operation as described by the *aiocb* structure (the asynchronous I/O control block).

The *aiocbp* argument points to the `aiocb` structure. This structure contains the following members:

aio_fildes
file descriptor

aio_offset
file offset

aio_buf
location of buffer

aio_nbytes
length of transfer

aio_reqprio
request priority offset

aio_sigevent
signal number and value

aio_lio_opcode
operation to be performed

The operation reads up to *aio_nbytes* from the socket or file associated with *aio_fildes* into the buffer pointed to by *aio_buf*. The call to aio_read() returns when the request has been initiated or queued to the file or device (even when the data cannot be delivered immediately).

Asynchronous I/O is currently only supported for sockets. The *aio_offset* field may be set but it will be ignored.

With a stream socket an asynchronous read may be completed when the first packet of data arrives and the application may have to issue additional reads, either asynchronously or synchronously, to get all the data it wants. A datagram socket has message boundaries and the operation will not complete until an entire message has arrived.

The *aiocbp* value may be used as an argument to aio_error() and aio_return() functions in order to determine the error status and return status, respectively, of the asynchronous operation. While the operation is proceeding, the error status retrieved by aio_error() is EINPROGRESS; the return status retrieved by aio_return() however is unpredictable.

If an error condition is encountered during the queueing, the function call returns without having initiated or queued the request.

When the operation completes asynchronously the program can be notified by a signal as specified in the *aio_sigevent* structure. It is significantly more efficient to receive these notifications with sigwaitinfo() or sigtimedwait() than to let them drive a signal handler. At this time the return and error status will have been updated to reflect the outcome of the operation. The sigevent structure's notification function fields are not supported. If a signal is not desired the program can occasionally poll the aiocb with aio_error() until the result is no longer EINPROGRESS.

Be aware that the operation may complete, and the signal handler may be delivered, before control returns from the call to aio_read(). Even when the operation does complete this quickly the return value from the call to aio_read() will be zero, reflecting the queueing of the I/O request not the results of the I/O itself.

An asynchronous operation may be canceled with aio_cancel() before its completion. Canceled operations complete with an error status of ECANCELED and any specified signal will be delivered. Due to timing, the operation may still complete naturally, either successfully or unsuccessfully, before it can be canceled by aio_cancel().

If the file descriptor of this operation is closed, the operation will be deleted if it has not completed or is not just about to complete. Signals specified for deleted operations will not be delivered. Close() will wait for asynchronous operations in progress for the descriptor to be deleted or completed.

You may use aio_suspend() to wait for the completion of asynchronous operations.

Sockets must be in blocking state or the operation may fail with EWOULDBLOCK.

If the control block pointed by *aiocbp* or the buffer pointed to by *aio_buf* becomes an illegal address before the asynchronous I/O completion, then the behavior of aio_read() is unpredictable.

If the thread that makes the aio_read() request terminates before the I/O completes the *aiocb* structure will still be updated with the return and error status, and any specified signal will be delivered to the process in which the thread was running. If thread related storage was used on the request the results are quite unpredictable.

Simultaneous asynchronous operations using the same *aiocbp*, asynchronous operations using a non-valid *aiocbp*, or any system action, that changes the process memory space while asynchronous I/O is outstanding to that address range, will produce unpredictable results

Simultaneous aio_read() operations on the same socket should not be done in general. With stream sockets, the I/O complete notifications may not be delivered in the same order as the bytes to which they refer, and so the byte stream may appear out of order. With UDP sockets, each datagram will complete one aio_read() operation, but you should not use multiple aio_reads for UDP sockets because this can cause significantly more system overhead as data arrives than a single outstanding request would.

There are several sockets oriented extensions to asynchronous I/O available with the BPX1AIO callable service, such as asynchronous accept(), asynchronous accept_and_recv(), asynchronous forms of all five pairs of read and write type operations, and receiving I/O completion notifications via an ECB, exit program, or through a message queue. The <aio.h> header contains all the structure fields, constants, and prototypes necessary to use BPX1AIO from a C program. These extensions are exposed when the _AIO_OS390 feature test macro is defined. The BPX1AIO stub resides in SYS1.CSSLIB and must be bound with your program. For a more detailed description of asynchronous I/O services, see BPX1AIO in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

The *aio_lio_opcode* field is set to LIO_READ by the function aio_read().

_POSIX-PRIORITIZED_IO is not supported. The *aio_reqprio* field may be set but it will be ignored.

_POSIX_SYNCHRONIZED_IO is not supported.

Returned value

If successful, aio_read() returns 0 to the calling process.

If unsuccessful, aio_read() returns -1 and sets errno to one of the following values:

Error Code
    Description

EAGAIN
    The requested asynchronous I/O operation was not queued due to system resource limitations.

ENOSYS
    The file associated with *aio_fildes* does not support the aio_read() function.

Each of the following conditions may be detected synchronously at the time of the call to aio_read(), or asynchronously. If any of the conditions below are detected synchronously, aio_read() returns -1 and sets the errno to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation will be set to the corresponding value.

Error Code
    Description

EBADF
    The *aio_fildes* argument is not a valid file descriptor open for reading.

EINVAL
    aio_sigevent contains an non-valid value.

EWOULDBLOCK
    The file associated with *aio_fildes* is in nonblocking state and there is no data available.

In the case where the aio_read() function successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operations is set to -1, and the error status of the asynchronous operation will be set to the error status normally set by the read() function call, or to the following value:

Error Code
Description

ECANCELED
The requested I/O was canceled before the I/O completed due to an explicit call to aio_cancel().

aio_return() — Retrieve status for an asynchronous I/O operation

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3	both	OS/390 V2R7

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_return(const struct aiocb *aiocbp);
```

General description

The aio_return() function returns the return status associated with the *aiocb* structure referenced by the *aiocbp* argument. The return status for an asynchronous I/O operation is the value that would be set by the corresponding read() or write() operation. While the operation is proceeding, the error status retrieved by aio_error() is EINPROGRESS; the return status retrieved by aio_return() however is unpredictable. The aio_return() function may be called to retrieve the return status of a given asynchronous operation; once aio_error() has returned with 0.

Returned value

If the asynchronous I/O operation has completed successfully, aio_return() returns the status as described for read() or write().

If the asynchronous I/O operation has not yet completed, then the return status is unpredictable.

aio_return() does not set errno.

Related information

- "aio.h" on page 17
- "aio_error() — Retrieve error status for an asynchronous I/O operation" on page 146
- "aio_read() — Asynchronous read from a socket" on page 147
- "aio_suspend() — Wait for an asynchronous I/O request"

aio_suspend() — Wait for an asynchronous I/O request

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3	both	OS/390 V2R7

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_suspend(const struct aiocb *const list[],
                int nent, const struct timespec *timeout);
```

General description

The aio_suspend() function suspends the calling thread when the *timeout* is a NULL pointer until at least one of the asynchronous I/O operations referenced by the *list* argument has completed, or until a signal interrupts the function. Or, if *timeout* is not NULL, it is suspended until the time interval specified by *timeout* has passed. If the time interval indicated in the *timespec* structure pointed to by *timeout* passes before any of the I/O operations referenced by *list*, then aio_suspend() returns with an error. If any of the *aoicb* structures in the list correspond to completed asynchronous I/O operations (that is, the error status for the operation is not equal to EINPROGRESS) at the time of the call, the function returns without suspending the calling thread.

The *list* argument is an array of pointers to asynchronous I/O control blocks (AIOCBs). The *nent* argument indicates the number of elements in the array. Each *aiocb* structure pointed to will have been used in initiating an asynchronous I/O request. This array may contain NULL pointers, which are ignored. If this array contains pointers that refer to *aiocb* structures that have not been used in submitting asynchronous I/O or *aiocb* structures that are not valid, the results are unpredictable.

Returned value

If successful, aio_suspend() returns 0.

If unsuccessful, aio_suspend() returns -1. The application may determine which asynchronous I/O completed by scanning the associated error and return status using aio_error() or aio_return(), respectively. aio_suspend() sets errno to one of the following values:

Error Code
Description

EAGAIN
No asynchronous I/O indicated in the list referenced by *list* completed in the time interval indicated by *timeout*.

EINTR
A signal interrupted the aio_suspend() function. Note that, since each asynchronous I/O operation may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited.

ENOSYS
z/OS UNIX System Services does not support the aio_suspend() function.

Usage notes

1. The AIOCBs represented by the list of AIOCB pointers must reside in the same storage key as the key of the invoker of aio_suspend. If the AIOCB Pointer List or any of the AIOCBs represented in the list are not accessible by the invoker an EFAULT may occur.
2. AIOCB pointers in the list with a value of zero will be ignored.
3. A timeout value of zero (seconds+nanoseconds) means that the aio_suspend() call will not wait at all. It will check for any completed asynchronous I/O requests. If none are found it will return with a EAGAIN. If at least one is found aio_suspend() will return with success.
4. A timeout value of a *timespec* with the tv_sec field set with INT_MAX, as defined in <limits.h>, will cause the aio_suspend service to wait until a asynchronous I/O request completes or a signal is received.

   If the Macro _AIO_OS390 is defined then the following may also apply.
5. The number of pointers to AIOCBs that use application supplied event control block (ECB) pointers for invocations of asynchronous I/O is limited to 253. There is no limit when not using the _AIO_OS390 Feature Test Macro. See *z/OS UNIX System Services Programming: Assembler Callable Services Reference* under the BPX1AIO for information on supplying user-defined ECBs in the AIOCB data area.
6. The AIOCBs passed to aio_suspend() must not be freed or reused by other threads in the process while this service is still in progress. This service may use the AIOCBs even after the asynchronous I/O completes. This restriction excludes multiple threads from doing aio_suspend() on the same AIOCB at the same time. Modifying the AIOCB during an aio_suspend() will produce unpredictable results.
7. The use of these extensions will require macros from SYS1.CSSLIB. Make sure that it is included in the SYSLIB concatenation during the compile.

aio_write() — Asynchronous write to a socket

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3	both	OS/390 V2R7

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_write(struct aiocb *aiocbp);
```

General description

The aio_write() function initiates an asynchronous write as described by the *aiocb* structure (the asynchronous I/O control block).

The *aiocbp* argument points to the `aiocb` structure. This structure contains the following members:

aio_fildes
file descriptor

aio_offset
file offset

aio_buf
location of buffer

aio_nbytes
length of transfer

aio_reqprio
request priority offset

aio_sigevent
signal number and value

aio_lio_opcode
operation to be performed

The operation will write *aio_nbytes* from the buffer pointed to by *aio_buf* to the socket or file associated with *aio_fildes*. The call to aio_write() returns when the request has been initiated or queued to the file or device (even when the data cannot be delivered immediately).

Asynchronous I/O is currently only supported for sockets. The *aio_offset* field may be set but it will be ignored.

The *aiocbp* value may be used as an argument to aio_error() and aio_return() functions in order to determine the error status and return status, respectively, of the asynchronous operation. While the operation is proceeding, the error status retrieved by aio_error() is `EINPROGRESS`; the return status retrieved by aio_return() however is unpredictable.

If an error condition is encountered during the queueing, the function call returns without having initiated or queued the request.

When the operation completes asynchronously the program can be notified by a signal as specified in the *aio_sigevent* structure. It is significantly more efficient to receive these notifications with sigwaitinfo() or sigtimedwait() than to let them drive a signal handler. At this time the return and error status will have been updated to reflect the outcome of the operation. The sigevent structure's notification function fields are not supported. If a signal is not desired the program can occasionally poll the aiocb with aio_error() until the result is no longer EINPROGRESS.

Be aware that the operation may complete, and the signal handler may be delivered, before control returns from the call to aio_read(). Even when the operation does complete this quickly the return value from the call to aio_read() will be zero, reflecting the queueing of the I/O request not the results of the I/O itself.

An asynchronous operation may be canceled with aio_cancel() before its completion. Canceled operations complete with an error status of ECANCELED and any specified signal will be delivered. Due to timing, the operation may still complete naturally, either successfully or unsuccessfully, before it can be canceled by aio_cancel().

If the file descriptor of this operation is closed, the operation will be deleted if it has not completed or is not just about to complete. Signals specified for deleted operations will not be delivered. Close() will wait for asynchronous operations in progress for the descriptor to be deleted or completed.

You may use aio_suspend() to wait for the completion of asynchronous operations.

Sockets must be in blocking state or the operation may fail with EWOULDBLOCK.

If the control block pointed by *aiocbp* or the buffer pointed to by *aio_buf* becomes an illegal address before the asynchronous I/O completion, then the behavior of aio_read() is unpredictable

If the thread that makes the aio_read() request terminates before the I/O completes, the *aiocb* structure will still be updated with the return and error status, and any specified signal will be delivered to the process in which the thread was running. If thread related storage was used on the request the results are quite unpredictable.

Simultaneous asynchronous operations using the same *aiocbp*, attempting asynchronous operations using a non-valid *aiocbp*, or any system action, that changes the process memory space while asynchronous I/O is outstanding to that address range, will produce unpredictable results.

Simultaneous aio_write() operations on the same stream socket should not be done because the data may be transmitted on the network out of order. With UDP sockets each aio_write defines a single datagram and there is no implied order of arrival in UDP. Beware, though, of sending too many datagrams. If there is network congestion or the receiver is slow you can tie up a large amount of system storage with uncontrolled aio_writes, and eventually they may start to fail with ENOBUFS.

There are several sockets oriented extensions to asynchronous I/O available with the BPX1AIO callable service, such as asynchronous accept(), asynchronous accept_and_recv(), asynchronous forms of all five pairs of read and write type operations, and receiving I/O completion notifications via an ECB, exit program, or through a message queue. The <aio.h> header contains all the structure fields, constants, and prototypes necessary to use BPX1AIO from a C program. These extensions are exposed when the _AIO_OS390 feature test macro is defined. The BPX1AIO stub resides in SYS1.CSSLIB and must be bound with your program. For a more detailed description of asynchronous I/O services, see BPX1AIO in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

The *aio_lio_opcode* field is set to LIO_WRITE by the function aio_write().

_POSIX_PRIORITIZED_IO is not supported. The *aio_reqprio* field may be set but it will be ignored.

_POSIX_SYNCHRONIZED_IO is not supported.

Returned value

If the I/O operation is successfully queued, aio_write() returns 0 to the calling process.

If the I/O operation is not queued, aio_write() returns -1 and sets errno to one of the following values:

Error Code
  Description

EAGAIN
  The requested asynchronous I/O operation was not queued due to system resource limitations.

ENOSYS
  The file associated with *aio_fildes* does not support the aio_write() function.

Each of the following conditions may be detected synchronously at the time of the call to aio_write(), or asynchronously. If any of the conditions below are detected synchronously, aio_write() returns -1 and sets the errno to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation will be set to the corresponding value.

Error Code
  Description

EBADF
  The *aio_fildes* argument is not a valid file descriptor open for writing.

EINVAL
  The *aio_nbytes* is not a valid value or *aio_sigevent* contains a value that is not valid.

EWOULDBLOCK
  The file associated with *aio_fildes* is in nonblocking state and there is no data available.

In the case where aio_write() successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation is set to the error status normally set by the write() function call, or to the following value:

Error Code
Description

ECANCELED
The requested I/O was canceled before the I/O completed due to an explicit call to aio_cancel().

alarm() — Set an alarm

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

unsigned int alarm(unsigned int seconds);
```

General description

Generates a SIGALRM signal after the number of seconds specified by the *seconds* parameter has elapsed. The SIGALRM signal delivery is directed at the calling thread.

seconds is the number of real seconds to wait before the SIGALRM signal is generated. Because of processor delays, the SIGALRM signal may be generated slightly later than this specified time. If *seconds* is zero, any previously set alarm request is canceled.

Only one such alarm can be active at a time. If you set a new alarm time, any previous alarm is canceled.

This function is supported only in a POSIX program.

Special behavior for XPG4: The fork() function clears pending alarms in the child thread. However, a new thread image created by one of the *exec* functions inherits the time left to an alarm in the old thread's image.

Special behavior for XPG4.2: alarm() will interact with the setitimer() function when the setitimer() function is used to set the ‘real’ interval timer (`ITIMER_REAL`).

alarm() does not interact with the usleep() function.

Returned value

If a prior alarm request has not yet completed, alarm() returns the number of seconds remaining until that request would have generated a SIGALRM signal.

If there are no prior alarm requests with time remaining, alarm() returns 0. Because alarm() is always successful, there is no failure return. If any failures are encountered that prevent alarm() from completing successfully, an abend is generated.

Example

CELEBA05

```
/* CELEBA05

   The following example generates a SIGALRM signal.

 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <time.h>
#include <unistd.h>

volatile int footprint=0;

void catcher(int signum) {
  puts("inside signal catcher!");
  footprint = 1;
}

main() {
  struct sigaction sact;
  volatile double count;
  time_t t;

  sigemptyset(&sact.sa_mask);
  sact.sa_flags = 0;
  sact.sa_handler = catcher;
  sigaction(SIGALRM, &sact, NULL);

  alarm(5); /* timer will pop in five seconds */

  time(&t);
  printf("before loop, time is %s", ctime(&t));
  for (count=0; (count<1e10) && (footprint == 0); count++);
  time(&t);
  printf("after loop, time is %s", ctime(&t));

  printf("the sum so far is %.0f\n", count);

  if (footprint == 0)
    puts("the signal catcher never gained control");
  else
    puts("the signal catcher gained control");
}
```

Output

```
before loop, time is Fri Jun 16 08:37:03 2006
inside signal catcher!
after loop, time is Fri Jun 16 08:37:08 2006
the sum so far is 17417558
```

alloca() — Allocate storage from the stack

Standards

Standards / Extensions	C or C++	Dependencies
	both	OS/390 V2R6

Format

```
#include <stdlib.h>

void *alloca(unsigned int size);
```

General description

The built-in alloca() function obtains memory from the stack. This eliminates the need for an explicit free() as the memory is freed when the stack is collapsed.

If the alloca() function is unable to obtain the requested storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

To avoid infringing on the user's name space, this nonstandard function is exposed only when you use the compiler option, LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Note: Storage from an alloca() is done after a setjmp() (or any variation thereof) is freed on a longjmp() (or any variation thereof) to an XPLINK-compiled function, and not freed on a longjmp() to a NOXPLINK-compiled function. See the longjmp() family of functions for more details.

Returned value

If successful, alloca() returns the address of the requested storage.

arm_bind_thread() — Bind the current thread to a given transaction

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_bind_thread(
/* [in]     */  arm_start_handle_t     start_handle,
/* [in]     */  arm_int32_t            flags,
/* [in]     */  arm_buffer4_t          *buffer4,
);
```

General description

Use arm_bind_thread() to indicate the current thread is performing processing on behalf of a given transaction, and no other transaction. This enables eWLM to collect resource usage and delay information for threads serving each class of work, and to adjust the resources given to threads to help them meet the goals assigned to those classes.

Any number of threads can bind to the same transaction at the same time. However a single thread cannot bind to more than one transaction at the same time. If a thread calls arm_bind_thread() when it is already bound to a transaction, the call is not honored and it returns a negative value to indicate an error.

A thread that calls arm_bind_thread() must call arm_unbind_thread() when it completes its processing on behalf of the transaction. (If arm_unbind_thread() is not called, then arm_stop_transaction() unbinds any threads that remain bound to the transaction. This exists for recovery purposes. Applications are expected to use arm_unbind_thread() as part of normal processing.)

start_handle
The handle returned by arm_start_transaction() for the transaction.

flags
Reserved for future use. The argument must be set to 0.

buffer4
A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

Returned value

On success, arm_bind_thread returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

Return code

The following list contains all possible return codes for the ARM function calls.

Return Code
Description

ARM_RC_APP_INPUT
User provided application id is invalid.

ARM_RC_APPL_INST_MAX
Maximum number of application instances per process is exceeded.

ARM_RC_APPL_INST_NAME
Application instance name is too long.

ARM_RC_APPL_MAX
Maximum number of registered applications is exceeded.

ARM_RC_APPL_NAME
Application name is missing or too long.

ARM_RC_AUTH_ERROR
User is not authorized to perform ARM calls.

ARM_RC_BLOCKED_MAX
Maximum number of blocked threads per transaction is exceeded.

ARM_RC_CORR_BAD_SIZE
Correlator size is not valid.

ARM_RC_CORR_EFAULT
Correlator return address is not valid.

ARM_RC_ENOMEM
Process or system is out of memory.

ARM_RC_FLAGS_EINVAL
Flags value is not valid.

ARM_RC_GRP_MAX
Maximum number of registered application groups is exceeded.

ARM_RC_GRP_NAME
Application group name is too long.

ARM_RC_HANDLE_EFAULT
Handle return address is not valid.

ARM_RC_MAXMEM
Maximum ARM services memory limit is exceeded.

ARM_RC_PARENT_CORR_INVAL
Parent correlator is not valid.

ARM_RC_PARENT_CORR_SZ
Parent correlator is too small.

ARM_RC_PARENT_CORR_VERSION
Parent correlator version is not correct.

ARM_RC_PROC_VAL_MSMTCH
Property values do not match property names.

ARM_RC_PROP_NAME
Transaction property name is too long.

ARM_RC_PROP_NAME_MAX
Too many property names are passed to ARM call.

ARM_RC_PROP_NAME_SUBBUF_MAX
Too many property name sub-buffers are passed to ARM call.

ARM_RC_PROP_VAL
Transaction property value is too long.

ARM_RC_PROP_VAL_MAX
Too many property values are passed to ARM call.

ARM_RC_PROP_VAL_SUBBUF_MAX
Too many property value sub-buffers are passed to ARM call.

ARM_RC_TIME_SUBBUF_MAX
Too many arrival time sub-buffers are passed to ARM call.

ARM_RC_TRAN_INPUT
User provided transaction type id is not valid.

ARM_RC_TRAN_MAX
Maximum number of transactions is exceeded.

ARM_RC_TRAN_STATUS_EINVAL
Invalid transaction status.

ARM_RC_TRAN_TYPE_INST_MAX
Maximum number of registered transaction type instances per process is exceeded.

ARM_RC_TRAN_TYPE_MAX
Maximum number of registered transaction types is exceeded.

ARM_RC_TRAN_TYPE_NAME
Transaction type name is missing or too long.

ARM_RC_UNKN_APPL_INST
Application instance is not found.

ARM_RC_UNKN_BLOCKED
Blocked thread is not valid for the specified transaction.

ARM_RC_UNKN_PARENT
Parent transaction is not a valid transaction.

ARM_RC_UNKN_PROC
The calling processing did not register an application instance.

ARM_RC_UNKN_TRAN
Transaction was not found for the calling process.

ARM_RC_UNKN_TRANCLASS_INST
Transaction class instance is not found.

ARM_RC_URI_NAME
URI value is too long.

ARM_RC_URI_SUBBUF_MAX
Too many URI value sub-buffers are passed to ARM call.

ARM_RC_VERSION_NAME
Application version name is too long.

arm_blocked() — Indicate the processing of a transaction is blocked

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_blocked(
/* [in]     */  arm_start_handle_t     start_handle,
/* [in]     */  arm_int32_t       flags,
/* [in]     */  arm_buffer4_t   *buffer4,
/* [out]    */  arm_block_handle_t   *block_handle
);
```

General description

Use arm_blocked() to indicate that processing of a transaction is blocked waiting for a transaction in another application to complete. This helps to identify what portion of a transaction's response time is spent in its own application and what portion is spent in downstream applications.

`start_handle`
The handle returned by arm_start_transaction() for the transaction.

`flags`
Reserved for future use. The argument must be set to 0.

`buffer4`
A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

`block_handle`
A pointer to a 64-bit area where a handle that identifies the arm_blocked() call is returned. The handle must be passed to arm_unblocked(). The handle is valid only within the caller's process.

Returned value

On success, arm_blocked returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes. On failure, the block_handle is set to a dummy value which can be used for later calls to other interfaces. Those interfaces will recognize that the block_handle contains a dummy value and return without performing any action.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_correlator_get_length() — Get the actual size of the transaction correlator

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_correlator_get_length(
/* [in]     */  arm_correlator_t   *corr_ptr,
/* [out] */  arm_correlator_length_t   **result_ptr
);
```

General description

Returns the actual size of a given correlator.

corr_ptr
Address of correlator.

result_ptr
Set to the address of the length of the correlator.

Returned value

On success, arm_correlator_get_length returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See "Return code" on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_end_application() — Undefines an ARM application

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_end_application(
/* [in/out] */  arm_appl_id_t   *application_id
/* [in]     */  arm_int32_t      flags,
/* [in]     */  arm_buffer4_t   *buffer4,
);
```

General description

Use arm_end_application() to close ARM API activity for a particular application. arm_end_application() invalidates the application handle returned by arm_init_application(), all transaction type handles associated with the application handle, and all transaction handles associated with those transaction types. Any further API calls using these handles will be rejected with a negative status return value. Information about transactions that were started and not yet stopped is discarded.

`application_id`
The handle passed to or returned by arm_init_application() for the application.

`flags`
Reserved for future use. The argument must be set to 0.

`buffer4`
A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

Returned value

On success, arm_stop_transaction returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See "Return code" on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

Related information

arm_get_correlator_max_length() — Get the max length of the transaction correlator

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_int32_t arm_get_correlator_max_length();
```

General description

Returns the size of the buffer required for the correlator returned by arm_start_transaction().

Note: The size applies only to correlators returned by arm_start_transaction(). It does not necessarily apply to parent correlators received from other applications, which may have been created by another ARM implementation and may have a different maximum size. The ARM 2.0 and ARM 3.0 standards defined the maximum size of the correlator for any implementation as 168 bytes. However the proposed ARM 4.0 standard most likely will drop this restriction and implementations will be allowed to create a correlator of any length.

Returned value

On success, arm_iget_correlator_max_length returns a positive number representing the maximum correlator length. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_get_timestamp() — Get the current timestamp

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_get_timestamp(
/* [out] */  arm_timestamp_t   *timestamp
);
```

General description

Use arm_get_timestamp() to obtain the current time. If the application wants to pass the arrival time sub-buffer to arm_start_transaction(), it must call arm_get_timestamp() to capture the arrival time in a format that is compatible with the arrival time sub-buffer.

timestamp
Area where the current time is returned. The format of the timestamp is implementation-dependent.

Returned value

On success, arm_get_timestamp returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See "Return code" on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_init_application() — Defines an ARM application

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_init_application(
/* [in]     */  arm_string_t     application_name,
/* [in]     */  arm_string_t     application_group_name,
/* [in]     */  arm_string_t     application_instance_name,
/* [in]     */  arm_int32_t      flags,
/* [in]     */  arm_buffer4_t   *buffer4,
/* [in/out] */  arm_appl_id_t   *application_id
);
```

General description

Use arm_init_application() to define an application. This function must be called before any other ARM API calls. Typically it should be called during the application's initialization.

If an application exists as multiple processes, it must call arm_init_application() in each process. This is necessary for eWLM to understand how each process contributes to the application. Multiple applications can register from within one process. This is useful if external functions are packaged in the same process.

arm_init_application() is the ARM 4.0 equivalent of ARM 2.0's arm_init function.

application_name
The name used generically to identify the application. The maximum length is 128 characters including the null string terminator.

application_group_name
The name of a group of application instances to which this instance belongs. The maximum length is 256 characters including the null string terminator. If no value is desired, a null pointer should be passed.

application_instance_name
The name of this instance of the application. The maximum length is 256 characters including the null string terminator. If no value is desired, a null pointer should be passed.

flags
One flag is defined. ARM_INIT_FLAG_ID_INPUT indicates whether the application id is an input (flag is one) or an output (flag is zero). See the application id parameter below. All other flag bits are reserved and must be zero.

buffer4
A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed, eWLM ignores it.

application_id
A pointer to a 64-bit area handle that identifies the application. The application can define its own handle and pass it as input or it can have eWLM generate a handle and return it. The choice is indicated by the flag ARM_INIT_FLAG_ID_INPUT. The handle must be passed to arm_init_transaction_type() and arm_end_application(). The handle is defined only within the caller's process.

Returned value

On success, arm_init_application returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes. On failure, the application_id is set to a dummy value which can be used for later calls to other interfaces. Those interfaces will recognize that the application_id contains a dummy value and return without performing any action.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_init_transaction_type() — Defines and initializes an ARM transaction type

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_init_transaction_type(
/* [in]     */  arm_appl_id_t   *application_id,
/* [in]     */  arm_string_t     transaction_name,
/* [in]     */  arm_int32_t      flags,
/* [in]     */  arm_buffer4_t   *buffer4,
/* [in/out] */  arm_appl_id_t   *transaction_type_id
);
```

General description

Use arm_init_transaction_type() to define a transaction classtype. A transaction type represents a type of transaction that is executed by an application. A transaction type must be defined before transactions of that type can be measured using arm_start_transaction() and arm_stop_transaction().

A transaction type consists of a transaction type name and a list of up to 20 transaction property names. Multiple transaction types with the same transaction type name and different transaction property names are allowed. It is the complete set of names that determines the uniqueness of a transaction type.

It is recommended that transaction types be defined during the application's initialization. eWLM expects transaction types to represent broad categories of work so that ordinarily there will be few of them. Detailed transaction identification should be done using the transaction-level properties.

Transaction types also can be defined as needed, during the application's processing of transactions. The ARM implementation must check whether there is an existing definition of the same type to prevent duplicates. Since this adds further overhead into mainline processing, this approach is not recommended.

Transaction classtype definitions remain valid for the life of the application (i.e. until it calls arm_end_application() or its process terminates).

arm_init_application_type() is the ARM 4.0 equivalent of ARM 2.0's arm_getid function.

application_id
The handle passed to or returned by arm_init_application() for the application associated with this transaction type.

transaction_name
The name used to identify the transaction type. The maximum length is 128 characters including the null string terminator. Classification rules in the eWLM policy can use the transaction type name to categorize transactions into eWLM service classes and report classes.

flags
One flag is defined. ARM_INIT_FLAG_ID_INPUT indicates whether the transaction type id is an input (flag is one) or an output (flag is zero). See the transaction type id parameter below. All other flag bits are reserved and must be zero.

buffer4
A pointer to a buffer that identifies one or more sub-buffers containing additional data. A null value can be specified if no additional data is required.

transaction_type_id
A pointer to a 64-bit handle that identifies the transaction type. The application can define its own handle and pass it as input or it can have eWLM generate a handle and return it. The choice is indicated by the flag ARM_INIT_FLAG_ID_INPUT. The handle must be passed to arm_start_transaction(). The handle is defined only within the caller's process. If eWLM is asked to generate a handle and the transaction type name and the transaction property names (in the user data buffer) match the names passed on a previous arm_init_transaction_type() call, the handle value that is returned will be the same as the previous call.

Returned value

On success, arm_init_application returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes. On failure, the application_id is set to a dummy value which can be used for later calls to other interfaces. Those interfaces will recognize that the application_id contains a dummy value and return without performing any action.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_start_transaction() — Mark the start of an ARM transaction

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_start_transaction(
/* [in]     */  arm_appl_id_t     *transaction_id,
/* [in]     */  arm_correlator_t     *parent_correlator_ptr,
/* [in]     */  arm_int32_t      flags,
/* [in]     */  arm_buffer4_t   *buffer4,
/* [out]    */  arm_start_handle_t     *start_handle,
/* [out]    */  arm_correlator_t   *current_correlator_ptr
);
```

General description

Use arm_start_transaction() to mark the beginning of execution of a transaction. The transaction must be identified as a member of a transaction type that was previously defined by arm_init_transaction_type(). There can be any number of transactions executing simultaneously.

transaction_id
The handle passed to or returned by arm_init_transaction_type() for the transaction type.

parent_correlator_ptr
A pointer to the parent correlator for this transaction. If there is no parent correlator, a null value should be passed.

flags
One flag bit is defined:. ARM_START_FLAG_TRACE_REQUEST requests tracing of the transaction. Currently eWLM has no support to trace transactions and ignores the flag. All other flag bits are reserved and must be zero.

buffer4
A pointer to a buffer that identifies one or more sub-buffers with additional data. A null value can be specified if no additional data is required.

start_handle
A pointer to a 64-bit area where a handle that identifies the transaction is returned. The handle must be passed to other transaction-level interfaces such as arm_stop_transaction(). The handle is valid only within the caller's process.

current_correlator_ptr
A pointer to a buffer into which eWLM will store a correlator for the transaction. The length of the buffer must be at least the length returned from the arm_get_correlator_max_length() function.

Returned value

On success, arm_init_application returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes. On failure, the application_id is set to a dummy value which can be used for later calls to other interfaces. Those interfaces will recognize that the application_id contains a dummy value and return without performing any action.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_stop_transaction() — Mark the end of an ARM transaction

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_stop_transaction(
/* [in]     */  arm_start_handle_t     start_handle,
/* [in]     */  arm_int32_t     transaction_status,
/* [in]     */  arm_int32_t      flags,
/* [in]     */  arm_buffer4_t   *buffer4,
);
```

General description

Use arm_stop_transaction() to mark the end of execution of a transaction.

If any threads are bound to the transaction, arm_stop_transaction() unbinds them. If the transaction is in a blocked state due to outstanding arm_blocked() calls, then arm_stop_transaction() considers the transaction to be unblocked at the time it is stopped. This cleanup processing exists for recovery purposes. Applications are expected to use arm_unbind_thread() and arm_unblocked() as part of normal processing.

start_handle
The handle returned by arm_start_transaction() for the transaction.

transaction_status
The completion code of the transaction.

ARM_STATUS_GOOD
Transaction successful.

ARM_STATUS_ABORT
Transaction aborted This value indicates there was a fundamental failure in the system; for example, a communications timeout or a database operation error.

ARM_STATUS_FAILED
Transaction failed. This value indicates the system worked properly but the transaction was not successful; for example, when making an airline reservation, no seats are available on the requested flight.

ARM_STATUS_UNKNOWN
Transaction status is unknown.

.

flags
Reserved for future use. The argument must be set to 0.

buffer4
A pointer to a buffer that identifies one or more sub-buffers containing additional data. A null pointer can be passed if no additional data is required. The proposed ARM4 standard defines a metric values sub-buffer for this function but eWLM does not process metrics. If a buffer is passed eWLM ignores it.

Returned value

On success, arm_end_application returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_unbind_thread() — Unbind the current thread to a given transaction

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_unbind_thread(
/* [in]     */  arm_start_handle_t     start_handle,
/* [in]     */  arm_int32_t      flags,
/* [in]     */  arm_buffer4_t   *buffer4,
);
```

General description

Use arm_unbind_thread() to indicate the current thread is no longer performing processing on behalf of a given transaction.

If arm_unbind_thread() is not called, then arm_stop_transaction() unbinds any threads that remain bound to the transaction. This exists for recovery purposes. Applications are expected to use arm_unbind_thread() as part of normal processing.

start_handle
The handle returned by arm_start_transaction() for the transaction.

flags
Reserved for future use. The argument must be set to 0.

buffer4
A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

Returned value

On success, arm_unbind_thread returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_unblocked() — Indicate the processing of a transaction is no longer blocked

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_unblocked(
/* [in]     */  arm_start_handle_t     start_handle,
/* [in]     */  arm_block_handle_t     block_handle,
/* [in]     */  arm_int32_t      flags,
/* [in]     */  arm_buffer4_t   *buffer4,
);
```

General description

Use arm_unblocked() to indicate that processing of a transaction is no longer blocked.

If arm_unblocked() is not called, then arm_stop_transaction() considers the transaction to be unblocked at the time it is stopped. This exists for recovery purposes. Applications are expected to use arm_unblocked() as part of normal processing.

start_handle
The handle returned by arm_startarm_start_transaction() for the transaction.

block_handle
The handle returned by arm_blocked().

flags
Reserved for future use. The argument must be set to 0.

buffer4
A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

Returned value

On success, arm_unblocked returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See "Return code" on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

arm_update_transaction() — Update a given transaction

Standards

Standards / Extensions	C or C++	Dependencies
	both	

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_update_transaction(
/* [in]     */  arm_start_handle_t     start_handle,
/* [in]     */  arm_int32_t      flags,
/* [in]     */  arm_buffer4_t   *buffer4,
);
```

General description

arm_update_transaction() does not perform any function in the eWLM developer's edition. A future edition of eWLM may support a version of arm_update_transaction() that can be used to log problem determination data associated with the transaction.

`start_handle`
The handle returned by arm_start_transaction() for the transaction.

`flags`
Reserved for future use. The argument must be set to 0.

`buffer4`
A pointer to a buffer that identifies one or more sub-buffers containing additional data. A null pointer can be passed if no additional data is required. The proposed ARM4 standard defines a metric values sub-buffer for this function but eWLM does not process metrics. If a buffer is passed eWLM ignores it.

Returned value

On success, arm_update_transaction returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 160 for the list of all possible return codes.

Error Code
Description

EFAULT
A parameter of this service contained an address that was not accessible to the caller.

EINVAL
A parameter of this service contained a value that was not valid.

EMVSARMERROR
An ARM error occurred. Refer to the return code for the specific error.

EPERM
The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR
An error occurred in the security product.

asctime(), asctime64() — Convert time to character string

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <time.h>

char *asctime(const struct tm *timeptr);
```

```
#define _LARGE_TIME_API
#include <time.h>

char asctime64(const struct tm *timeptr);
```

General description

Converts time stored as a structure, pointed to by *timeptr*, to a character string. The *timeptr* value can be obtained from a call to gmtime() or localtime(). Both functions return a pointer to a tm structure defined in “time.h” on page 79.

The string result that asctime() produces contains exactly 26 characters and has the format:

```
"%.3s %.3s%3d %.2d:%.2d:%.2d %d\n"
```

The following is an example of the string returned:

```
Fri Jun 16 02:03:55 2006\n\0
```

Notes:

1. The calendar time returned by a call to the time() function begins at epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.
2. The asctime() function uses a 24-hour clock format.
3. The days are abbreviated to: Sun, Mon, Tue, Wed, Thu, Fri, and Sat.
4. The months are abbreviated to: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
5. All fields have a constant width.
6. Dates with only one digit are preceded either with a zero or a blank space.

7. The newline character (\n) and the NULL character (\0) occupy the last two positions of the string.
8. The asctime(), ctime(), and other time functions can use a common, statically allocated buffer for holding the return string. Each call to one of these functions may possibly destroy the result of the previous call.

The function asctime64() will behave exactly like asctime() except it will support a structured date beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, asctime() returns a pointer to the resulting character string.

If the function is unsuccessful, it returns NULL.

Example

CELEBA06

```
/* CELEBA06

   This example polls the system clock and prints a message
   giving the current time.

 */
#include <time.h>
#include <stdio.h>

int main(void)
{
    struct tm *newtime;
    time_t ltime;

        /* Get the time in seconds */
    time(&ltime);
        /* Break it down & store it in the structure tm */
    newtime = localtime(&ltime);

        /* Print the local time as a string */
    printf("The current date and time are %s",
             asctime(newtime));
}
```

Output

```
The current date and time are Fri Jun 16 13:29:51 2006
```

asctime_r(), asctime64_r() — Convert date and time to a character string

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>

char *asctime_r(const struct tm *__restrict__ tm, char *__restrict__ buf);
#define _LARGE_TIME_API
#include <time.h>

char *asctime64_r(const struct tm *__restrict__ tm, char *__restrict__ buf);
```

General description

The asctime_r() function converts the broken-down time in the structure pointed to by *tm* into a character string that is placed in the user-supplied buffer pointed to by *buf* (which contains at least 26 bytes) and then returns *buf*.

The function asctime64_r() will behave exactly like asctime_r() except it will support a structured date beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, asctime_r() returns a pointer to a character string containing the date and time. This string is pointed to by the argument *buf*.

If unsuccessful, asctime_r() returns NULL.

There are no documented errno values.

asin(), asinf(), asinl() — Calculate arcsine

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double asin(double x);
float asin(float x);                  /* C++ only */
long double asin(long double x);      /* C++ only */
float asinf(float x);
long double asinl(long double x);
```

General description

Calculates the arcsine of *x*, in the range -pi/2 to pi/2 radians.

The value of *x* must be between -1 and 1.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

If *x* is less than -1 or greater than 1, the function sets errno to EDOM, and returns 0. Otherwise, it returns a nonzero value.

If the correct value would cause an underflow, 0 is returned and the value ERANGE is stored in errno.

Special behavior for IEEE: If successful, the function returns the arcsine of its argument *x*.

If *x* is less than -1 or greater than 1, the function sets errno to EDOM and returns NaNQ. No other errors will occur.

Example

CELEBA07

```
/* CELEBA07

   This example prompts for a value for x.
   It prints an error message if x is greater than 1 or
   less than -1; otherwise, it assigns the arcsine of
   x to y.

 */
#include <stdio.h>
#include <stdlib.h>
#include <math.h>
#define MAX  1.0
#define MIN -1.0

int main(void)
{
  double x, y;

  printf( "Enter x\n" );
  scanf( "%lf", &x );

  /* Output error if not in range */
  if ( x > MAX )
    printf( "Error: %f too large for asin\n", x );
  else if ( x < MIN )
    printf( "Error: %f too small for asin\n", x );
  else {
    y = asin( x );
    printf( "asin( %f ) = %f\n", x, y );
  }
}
```

Output

```
Enter x
 0.2 is entered
asin( 0.200000 ) = 0.201358
```

assert() — Verify condition

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <assert.h>

void assert(int expression);
```

General description

The assert() macro inserts diagnostics into a program. If the expression (which will have a scalar type) is false (that is, compares equal to 0), a diagnostic message of the form shown below is printed to stderr, and abort() is called to abnormally end the program. The assert() macro takes no action if the expression is true (nonzero).

Without a compiler that is designed to support C99, or when compiling C++ code, the diagnostic message has the following format:

```
Assertion failed: expression, file filename, line line-number.
```

With a compiler that is designed to support C99, or when compiling C++ code, the diagnostic message has the following format:

```
Assertion failed: expression, file filename, line line-number, function function-name.
```

If you define NDEBUG to any value with a `#define` directive or with the DEFINE compiler option, the C/C++ preprocessor expands all assert() invocations to `void` expressions.

Note: The assert() function is a macro. Using the `#undef` directive with the assert() macro results in undefined behavior. The assert() macro uses `__FILE__`, `__LINE__` and, with a compiler that is designed to support C99, __func__...

Returned value

assert() returns no values.

Example

CELEBA08

```
/* CELEBA08

   In this example, the assert() macro tests the string argument for a
   null string and an empty string, and verifies that the length argument
   is positive before proceeding.

 */
#include <stdio.h>
#include <assert.h>
```

```
void analyze(char *, int);
int main(void)
{
   char *string1 = "ABC";
   char *string2 = "";
   int length = 3;

   analyze(string1, length);
   printf("string1 %s is not null or empty, "
          "and has length %d \n", string1, length);
   analyze(string2, length);
   printf("string2 %s is not null or empty,"
          "and has length %d\n", string2, length);
}

void analyze(char *string, int length)
{
   assert(string != NULL);     /* cannot be NULL */
   assert(*string != '\0');    /* cannot be empty */
   assert(length > 0);         /* must be positive */
}
```

Output without a compiler that is designed to support C99

```
String1 ABC is not NULL or empty, and has length 3
Assertion failed: *string != '\0', file: CELEBA08 C       A1, line: 26
```

Output with a compiler that is designed to support C99

```
String1 ABC is not NULL or empty, and has length 3
Assertion failed: *string != '\0', file: CELEBA08 C       A1, line: 26 in function analyze
```

Related information

- "assert.h" on page 17

atan(), atanf(), atanl(), atan2(), atan2f(), atan2l() — Calculate arctangent

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double atan(double x);
float atan(float x);                  /* C++ only */
long double atan(long double x);      /* C++ only */
float atanf(float x);
long double atanl(long double x);

double atan2(double y, double x);
float atan2(float y, float x);                    /* C++ only */
```

```
long double atan2(long double y, long double x);  /* C++ only */
float atan2f(float y, float x);
long double atan2l(long double y, long double x);
```

General description

The atan() and atan2() functions calculate the arctangent of *x* and *y/x*, respectively.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Restriction: The atan2f() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

Returns a value in the range -pi/2 to pi/2 radians.

The atan2() functions return a value in the range -pi to pi radians. If both arguments of atan2() are zero, the function sets errno to EDOM, and returns 0. If the correct value would cause underflow, zero is returned and the value ERANGE is stored in errno.

Special behavior for IEEE: If successful, atan2() returns the arctangent of *y/x*.

If both arguments of atan2() are zero, the function sets errno to EDOM and returns 0. No other errors will occur.

Example

CELEBA09

```
/* CELEBA09 */
#include <math.h>
#include <stdio.h>

int main(void)
{
    double a,b,c,d;

    c = 0.45;
    d = 0.23;

    a = atan(c);
    b = atan2(c,d);

    printf("atan( %f ) = %f\n", c, a);
    printf("atan2( %f, %f ) = %f\n", c, d, b);
}
```

Output

```
atan( 0.450000 ) = 0.422854
atan2( 0.450000, 0.230000 ) = 1.098299
```

atand32(), atand64(), atand128(), atan2d32(), atan2d64(), atan2d128() - Calculate arctangent

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.10

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  atand32(_Decimal32 x);
_Decimal64  atand64(_Decimal64 x);
_Decimal128 atand128(_Decimal128 x);
_Decimal32  atan(_Decimal32 x);     /* C++ only */
_Decimal64  atan(_Decimal64 x);     /* C++ only */
_Decimal128 atan(_Decimal128 x);    /* C++ only */

_Decimal32  atan2d32(_Decimal32 y, _Decimal32 x);
_Decimal64  atan2d64(_Decimal64 y, _Decimal64 x);
_Decimal128 atan2d128(_Decimal128 y, _Decimal128 x);
_Decimal32  atan2(_Decimal32 y, _Decimal32 x);   /* C++ only */
_Decimal64  atan2(_Decimal64 y, _Decimal64 x);   /* C++ only */
_Decimal128 atan2(_Decimal128 y, _Decimal128 x); /* C++ only */
```

General description

The atan() and atan2() functions calculate the arctangent of x and *y/x*, respectively.

These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

Returns a value in the range -pi/2 to pi/2 radians.

If both arguments of atan2() are zero, the function sets errno to EDOM and returns 0. No other errors will occur.

Example

CELEBA15

```
/* CELEBA15

   This example illustrates the atand64() and atan2d64() functions.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 a,b,c,d;

    c = 0.45DD;
    d = 0.23DD;

    a = atand64(c);
    b = atan2d64(c,d);

    printf("atand64( %Df ) = %Df\n", c, a);
    printf("atan2d64( %Df, %Df ) = %Df\n", c, d, b);
}
```

atanh(), atanhf(), atanhl() — Calculate hyperbolic arctangent

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double atanh(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float atanhf(float x);
long double atanhl(long double x);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>
float atanh(float x);
long double atanh(long double x);
```

General description

The atanh() function returns the hyperbolic arctangent of its argument *x*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
atanh	X	X
atanhf	X	X
atanhl	X	X

Returned value

If successful, atanh() returns the hyperbolic arctangent of its argument *x*.

atanh() fails, returns 0.0 and sets errno to one of the following values:

Error Code
  Description

EDOM
  The *x* argument has a value greater than 1.0.

ERANGE
  The *x* argument has a value equal to 1.0.

Special behavior for IEEE: If successful, the function returns the hyperbolic arctangent of its argument *x*.

If the absolute value of *x* is greater than 1.0, atanh() sets errno to EDOM and returns NaNQ. If the value of *x* is equal to 1.0, the function sets errno to ERANGE and returns +HUGE_VAL.

_Decimal128 atanh(_Decimal128 x);     /* C++ only */
```

General description

The atanh() function returns the hyperbolic arctangent of its argument *x*.

These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, the function returns the hyperbolic arctangent of its argument x.

If the absolute value of *x* is greater than 1.0, atanh() sets errno to EDOM and returns NaNQ. If the value of *x* is equal to 1.0, the function sets errno to ERANGE and returns +HUGE_VAL_D32, +HUGE_VAL_D64 or +HUGE_VAL_D128.

Example

CELEBA16

```
/* CELEBA16

   This example illustrates the atanhd32() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal32 x, y;
   x = 0.5DF;
   y = atanhd32(x);

   printf("atanhd32(%Hf) = %Hf\n", x, y);
}
```

__atanpid32(), __atanpid64(), __atanpid128() - Calculate arctangent(x)/pi

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	z/OS V1.10

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  __atanpid32(_Decimal32 x);
_Decimal64  __atanpid64(_Decimal64 x);
_Decimal128 __atanpid128(_Decimal128 x);
```

General description

Calculates the value of arctangent(*x*)/pi.

These functions work in IEEE decimal floating-point format. See "IEEE decimal floating-point" on page 95 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

Returns the calculated value expressed in radians.

Example

CELEBA17

```
/* CELEBA17

   This example illustrates the __atanpid64() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal64 x, y;

   x = 5.0DD;
   y = __atanpid64(x);

   printf("__atanpid64(%Df) = %Df\n", x, y);
}
```

atexit() — Register program termination function

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

int atexit(void (*func)(void));
```

General description

Records a function, pointed to by *func*, that the system calls at normal program termination. Termination is a result of exit() or returning from main(), regardless of the language of the main() routine. Process termination started by _exit() or by a terminating signal under Language Environment is not included.

The functions are executed in the reverse order that they were registered. The registered function must return to ensure that all registered functions are called. The functions registered with atexit() are started before streams and files are closed. You may specify a number of functions to the limit set by the ATEXIT_MAX constant, which is defined in <limits.h>.

Under z/OS UNIX services only, when a process ends, the address space is ended; otherwise, the address space persists.

Special behavior for z/OS XL C: The C Library atexit() function has the following restrictions:

- Any function registered by a fetched module that has been released is removed from the list at the time of release(). See fetch(), fetchep(), and release() for details about fetching and releasing modules.
- Any function registered in an explicitly loaded DLL (using dllload()) that has been freed (using dllfree()) is removed from the list. But, if the DLL in question has also been implicitly loaded, then the function is NOT removed from the atexit list.
- All C Library library functions can be used in a registered routine except exit().
- When a program is running under CICS control, if an `EXEC CICS RETURN` command or an `EXEC CICS XCTL` command is issued, the atexit() list that has been previously registered is not run.
- Use of the system() library function within atexit() may result in undefined behavior.
- Use of non-C subroutines or functions in the atexit() list will result in undefined behavior.
- The atexit() list will not be run when abort() is called.

Special behavior for C++:

- All of the behaviors listed under "Special Behavior for z/OS XL C".
- Because C and C++ linkage conventions are incompatible, atexit() cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to atexit(), the compiler will flag it as an error. To use the C++ atexit() function, you must ensure that all functions registered for atexit() have C linkage by declaring them as `extern "C"`.
- You can use `try`, `throw`, and `catch` in a function registered for atexit(). However, by the time an atexit() function is driven, all stack frames will have collapsed. As a result, the only `catch` clauses available for `throw` will be the ones coded in the atexit() function. If those `catch` clauses cannot handle the thrown object, terminate() will be called.

Special behavior for XPG4.2: The maximum number of functions that can be registered is specified by the symbol ATEXIT_MAX which is defined in the limits.h header.

Returned value

If successful, atexit() returns 0.

If unsuccessful, atexit() returns nonzero.

Example

CELEBA10

```
/* CELEBA10

   This example uses the atexit() function to call the function goodbye()
   at program termination.

 */
#include <stdlib.h>
#include <stdio.h>

#ifdef __cplusplus             /* the __cplusplus macro is     */
```

```
extern "C" void goodbye(void); /* automatically defined by the  */
#else                          /* C++/MVS compiler              */
void goodbye(void);
#endif

int main(void)
{
   int rc;

   rc = atexit(goodbye);
   if (rc != 0)
      printf("Error in atexit");
   exit(0);
}

void goodbye(void)
   /* This function is called at normal program termination */
{
   printf("The function goodbye was called \
at program termination\n");
}
```

Output

```
The function goodbye was called at program termination
```

__atoe() — ISO8859-1 to EBCDIC string conversion

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <unistd.h>

int __atoe(char *string);
```

General description

The __atoe() function converts an ISO8859-1 character string *string* to its EBCDIC equivalent. The conversion is performed using the codeset page associated with the current locale. The input character string up to, but not including, the NULL is changed from an ISO8859-1 representation to that of the current locale.

The argument *string* points to the ISO8859-1 character string to be converted to its EBCDIC equivalent.

Returned value

If successful, __atoe() converts the input ISO8859-1 character string to its equivalent EBCDIC value, and returns the length of the converted string.

If unsuccessful, __atoe() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The current locale does not describe a single-byte character set.

ENOMEM
There is insufficient storage to complete the conversion process.

Note: This function may internally call iconv_open() and iconv(). The errnos returned by these functions are propagated without modification.

Related information

__atoe_l() — ISO8859-1 to EBCDIC conversion operation

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <unistd.h>

int __atoe_l(char *bufferptr, int leng);
```

General description

The __atoe_l() function converts *leng* ISO8859-1 bytes in the buffer pointed to by *bufferptr* to their EBCDIC equivalent. The conversion is performed using the codeset page associated with the current locale.

The argument *bufferptr* points to a buffer containing the ISO8859-1 bytes to be converted to their EBCDIC equivalent. The input buffer is treated as sequence of bytes, and all bytes in the input buffer are converted, including any imbedded NULLs.

Returned value

If successful, __atoe_l() converts the input IOS8859-1 bytes to their equivalent EBCDIC value, and returns the number of bytes that were converted.

If unsuccessful, __atoe_l() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The current locale does not describe a single-byte character set.

ENOMEM
There is insufficient storage to complete the conversion process.

Note: This function may internally call iconv_open() and iconv(). The errnos returned by these functions are propagated without modification.

atof() — Convert character string to double

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

double atof(const char *nptr);
```

General description

The atof() function converts the initial portion of the string pointed to by *nptr* to a 'double'. This is equivalent to

```
strtod(nptr, (char**)NULL)
```

The double value is either hexadecimal floating point or binary floating point, depending on the floating point mode of the thread invoking the atof() function. This function uses _isBF() to determine the floating point mode of the invoking thread.

See the “*fscanf* Family of Formatted Input Functions” on fscanf(), scanf(), sscanf() — Read and format data for a description of special infinity and NaN sequences recognized by z/OS formatted input functions, including atof() and strtod() in IEEE Binary Floating-Point mode.

Returned value

The atof() function returns the converted value if the value can be represented, otherwise the return value is undefined.

atoi() — Convert character string to integer

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

int atoi(const char *nptr);
```

General description

The atoi() function converts the initial portion of the string pointed to by *nptr* to a 'int'. This is equivalent to

```
(int)strtol(nptr, NULL, 10)
```

Returned value

There are no documented errno values.

Related information

atol() — Convert character string to long

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

long int atol(const char *nptr);
```

General description

The atol() function converts the initial portion of the string pointed to by *nptr* to a 'long int'. This is equivalent to

```
strtol(nptr, (char**)NULL, 10)
```

Returned value

The atol() function returns the converted value if the value can be represented, otherwise the return value is undefined.

Related information

atoll() — Convert character string to signed long long

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <stdlib.h>
long long atoll(const char *nptr);
```

Compile requirement: Use of this function requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

atoll() converts the initial portion of the string pointed to by *nptr* to a '**long long** int'. This is equivalent to strtoll(*nptr*, (char **)NULL, 10).

Returned value

If successful, atoll() returns the converted signed **long long** value, represented in the string. If unsuccessful, it returns an undefined value.

Related information

__a2e_l() — Convert characters from ASCII to EBCDIC

Standards

Standards / Extensions	C or C++	Dependencies
	both	z/OS V1R2

Format

```
#include <unistd.h>

size_t  __a2e_l(char  *bufptr, size_t  szLen)
```

General description

The __a2e_l() function converts *szLen* characters in *bufptr* from ASCII to EBCDIC, returning the number of characters converted if successful or -1 if not. Conversion occurs in place in the buffer. __a2e_l() is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned value

If successful, __a2e_l() returns the number of characters converted.

If unsuccessful, __a2e_l() returns -1 and sets errno to the following value:

Error Code
Description

EINVAL
The pointer to *bufptr* is NULL or *szLen* is a negative value.

Related information

- “unistd.h” on page 82
- “__a2e_s() — Convert string from ASCII to EBCDIC”
- “__e2a_l() — Convert characters from EBCDIC to ASCII” on page 458
- “__e2a_s() — Convert string from EBCDIC to ASCII” on page 459

__a2e_s() — Convert string from ASCII to EBCDIC

Standards

Standards / Extensions	C or C++	Dependencies
	both	z/OS V1R2

Format

```
#include <unistd.h>

size_t  __a2e_s(char  *string)
```

General description

The __a2e_s() function converts a string from ASCII to EBCIDIC, returning the string length if successful or -1 if not. Conversion occurs in place in the string. __a2e_s() is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned value

If successful, __a2e_s() returns the string length.

If unsuccessful, __a2e_s() returns -1 and sets errno to the following value:

Error Code
 Description

EINVAL
 The pointer to string is NULL.

Related information

- "unistd.h" on page 82
- "__a2e_l() — Convert characters from ASCII to EBCDIC" on page 206
- "__e2a_l() — Convert characters from EBCDIC to ASCII" on page 458
- "__e2a_s() — Convert string from EBCDIC to ASCII" on page 459

a64l() — Convert base 64 string representation to long integer

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define  _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

long a64l(const char *string);
```

General description

The a64l() function converts a string representation of a base 64 number into its corresponding long value. It scans the string from left to right with the least significant character on the left, decoding each character as a 6-bit base 64 number. If the string pointed to by *string* contains more than six characters, a64l() uses only the first six. If the first six characters of the string contain a NULL character, a64l() uses only the characters preceding the first NULL. The following characters are used to represent digits:

Character	Digit Represented
.	0
/	1
0-9	2-11
A-Z	12-37
a-z	38-63

Returned value

If successful, a64l() returns the long value resulting from conversion of the input string.

If the string pointed to by *string* is NULL, a64l() returns 0.

There are no errno values defined.

Related information

- “stdlib.h” on page 70
- “l64a() — Convert long to base 64 string representation” on page 1026
- “strtoul() — Convert string to unsigned integer” on page 1780

basename() — Return the last component of a path name

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>

char *basename(char *path);
```

General description

The basename() function takes the pathname pointed to by *path* and returns a pointer to the final component of the pathname, deleting any trailing '/' characters.

If the string consists entirely of the '/' character, basename() returns a pointer to the string “/”.

If *path* is a NULL pointer or points to an empty string, basename() returns a pointer to the string “.”. The basename() function may modify the string pointed to by path.

Examples:

```
Input String     Output String
"/usr/lib"       "lib"
"/usr/"          "usr"
"/"              "/"
```

Returned value

If successful, basename() returns a pointer to the final component of *path*.

There are no errno values defined.

Related information

- “libgen.h” on page 38
- “dirname() — Report the parent directory of a path name” on page 381

bcmp() — Compare bytes in memory

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define  _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int bcmp(const void *s1, const void *s2, size_t n);
```

General description

The bcmp() function compares the first *n* bytes of the area pointed to by *s1* with the area pointed to by *s2*.

Note: The bcmp() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The memcmp() function is preferred for portability.

Returned value

If *s1* and *s2* are identical, bcmp() returns 0. Otherwise, bcmp() returns nonzero. Both areas are assumed to be at least *n* bytes long.

If the value of *n* is zero, bcmp() returns 0.

There are no errno values defined.

Related information

- “strings.h” on page 72
- “bcopy() — Copy bytes in memory”
- “bzero() — Zero bytes in memory” on page 223
- “memcmp() — Compare bytes” on page 1062

bcopy() — Copy bytes in memory

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define  _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

void bcopy(const void *s1, void *s2, size_t n);
```

General description

The bcopy() function copies *n* bytes from the area pointed to by *s1* to the area pointed to by *s2* using the memcpy() function.

Note: The bcopy() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The memmove() function is preferred for portability.

Returned value

bcopy() returns no values.

There are no errno values defined.

Related information

- "strings.h" on page 72

- "memcpy() — Copy buffer" on page 1063
- "memmove() — Move buffer" on page 1065

bind() — Bind a name to a socket

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int bind(int socket, const struct sockaddr *address, socklen_t address_len);
```

Berkeley Sockets

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int bind(int socket, struct sockaddr *address, int address_len);
```

General description

The bind() function binds a unique local name to the socket with descriptor *socket*. After calling socket(), a descriptor does not have a name associated with it. However, it does belong to a particular address family as specified when socket() is called. The exact format of a name depends on the address family.

Parameter
Description

socket The socket descriptor returned by a previous socket() call.

address The pointer to a **sockaddr** structure containing the name that is to be bound to *socket*.

address_len
The size of *address* in bytes.

The *socket* parameter is a socket descriptor of any type created by calling socket().

The *address* parameter is a pointer to a buffer containing the name to be bound to *socket*. The *address_len* parameter is the size, in bytes, of the buffer pointed to by *address*. For AF_UNIX, this function creates a file that you later need to unlink besides closing the socket.

Socket Descriptor Created in the AF_INET Domain

If the socket descriptor *socket* was created in the AF_INET domain, the format of the name buffer is expected to be **sockaddr_in**, as defined in the include file **netinet/in.h**:

```
struct in_addr
{
        ip_addr_t s_addr;
};

 struct sockaddr_in {
     unsigned char  sin_len;
     unsigned char  sin_family;
     unsigned short sin_port;
     struct in_addr sin_addr;
     unsigned char  sin_zero[8];

};
```

The *sin_family* field must be set to AF_INET.

The *sin_port* field is set to the port to which the application must bind. It must be specified in network byte order. If *sin_port* is set to 0, the caller leaves it to the system to assign an available port. The application can call getsockname() to discover the port number assigned.

The *sin_addr.s_addr* field is set to the Internet address and must be specified in network byte order. On hosts with more than one network interface (called multihomed hosts), a caller can select the interface to which it is to bind. Subsequently, only UDP packets and TCP connection requests from this interface (which match the bound name) are routed to the application. If this field is set to the constant INADDR_ANY, as defined in **netinet/in.h**, the caller is requesting that the socket be bound to all network interfaces on the host. Subsequently, UDP packets and TCP connections from all interfaces (which match the bound name) are routed to the application. This becomes important when a server offers a service to multiple networks. By leaving the address unspecified, the server can accept all UDP packets and TCP connection requests made for its port, regardless of the network interface on which the requests arrived.

The *sin_zero* field is not used and must be set to all zeros.

Socket Descriptor Created in the AF_INET6 Domain If the socket descriptor *socket* was created in the AF_INET6 domain, the format of the name buffer is expected to be **sockaddr_in6**, as defined in the include file **netinet/in.h**. The structure is defined as follows:

```
struct sockaddr_in6 {
   uint8_t         sin6_len;
   sa_family_t     sin6_family;
   in_port_t       sin6_port;
   uint32_t        sin6_flowinfo;
   struct in6_addr  sin6_addr;
   uint32_t        sin6_scope_id;
};
```

The sin6_len field is set to the size of this structure. The SIN6_LEN macro is defined to indicate the version of the sockaddr_in6 structure being used.

The sin6_family field identifies this as a sockaddr_in6 structure. This field overlays the sa_family field when the buffer is cast to a sockaddr structure. The value of this field must be AF_INET6.

The sin6_port field contains the 16-bit UDP or TCP port number. This field is used in the same way as the sin_port field of the sockaddr_in structure. The port number is stored in network byte order.

The sin6_flowinfo field is a 32-bit field that contains the traffic class and the flow label.

The sin6_addr field is a single in6_addr structure. This field holds one 128-bit IPv6 address. The address is stored in network byte order.

The sin6_scope_id field is a 32-bit integer that identifies a set of interfaces as appropriate for the scope of the address carried in the sin6_addr field. For a link scope sin6_addr, sin6_scope_id, this would be an interface index. For a site scope sin6_addr, sin6_scope_id, this would be a site identifier.

Socket Descriptor Created in the AF_UNIX Domain

If the socket descriptor *socket* is created in the AF_UNIX domain, the format of the name buffer is expected to be **sockaddr_un**, as defined in the include file **un.h**.

```
 struct sockaddr_un {
    unsigned char  sun_len;
    unsigned char  sun_family;
             char  sun_path[108];       /* pathname */
};
```

The *sun_family* field is set to AF_UNIX.

The *sun_path* field contains the NULL-terminated pathname, and *sun_len* contains the length of the pathname.

Notes:

1. For AF_UNIX, when a bind is issued, a file is created with a mode of 660. In order to allow other users to access this file, a chmod() should be issued to modify this mode if desired.
2. For AF_UNIX, when closing sockets that were bound, you should also use unlink() to delete the file created at bind() time.
3. The pathname the client uses on the bind() must be unique.
4. The sendto() call must specify the pathname associated with the server.
5. For AF_INET or AF_INET6, the user must have appropriate privileges to bind to a port in the range from 1 to 1023.

Special Behavior for C++

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The bind() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2113 for details.

Returned value

If successful, bind() returns 0.

If unsuccessful, bind() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
Permission denied.

EADDRINUSE
The address is already in use. See the SO_REUSEADDR option described under “getsockopt() — Get the options associated with a socket” on page 777 and the SO_REUSEADDR described under the “setsockopt() — Set options associated with a socket” on page 1578 for more information.

EADDRNOTAVAIL
The address specified is not valid on this host. For example, the Internet address does not specify a valid network interface.

EAFNOSUPPORT
The address family is not supported (it is not AF_UNIX, AF_INET, or AF_INET6).

EBADF
The *socket* parameter is not a valid socket descriptor.

EINVAL
One of three conditions may apply:

- The socket is already bound to an address—for example, trying to bind a name to a socket that is already connected.
- The socket was shut down.
- An incorrect parameter was passed on the bind() invocation.

Check the parameter values passed and ensure they are specified as described above.

EIO There has been a network or transport failure.

ENOBUFS
bind() is unable to obtain a buffer due to insufficient storage.

ENOTSOCK
The descriptor is for a file, not for a socket.

EOPNOTSUPP
The socket type of the specified socket does not support binding to an address.

EPERM
The user is not authorized to bind to the port specified.

The following are for AF_UNIX only:

Error Code
Description

EACCES
A component of the path prefix denies search permission, or the requested name requires writing in a directory with a mode that denies write permission.

EDESTADDRREQ
The *address* argument is a NULL pointer.

EIO An I/O error occurred.

ELOOP
Too many symbolic links were encountered in translating the pathname in *address*.

ENAMETOOLONG
A component of a pathname exceeded **NAME_MAX** characters, or an entire pathname exceeded **PATH_MAX** characters.

ENOENT
A component of the pathname does not name an existing file or the pathname is an empty string.

ENOTDIR
A component of the path prefix of the pathname in *address* is not a directory.

EROFS
The name would reside on a read-only file system.

Example

The following are examples of the bind() call. It is a good idea to zero the structure before using it to ensure that the name requested does not set any reserved fields.

AF_INET Domain Example

The following example illustrates the bind() call binding to interfaces in the AF_INET domain. The Internet address and port must be in network byte order. To put the port into network byte order, the htons() utility routine is called to convert a short integer from host byte order to network byte order. The *address* field is set using another utility routine, inet_addr(), which takes a character string representing the dotted-decimal address of an interface and returns the binary Internet address representation in network byte order.

```
int rc;
int s;
struct sockaddr_in myname;
/* Bind to a specific interface in the Internet domain */
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = inet_addr("129.5.24.1");
/* specific interface */
myname.sin_port = htons(1024);
⋮
rc = bind(s, (struct sockaddr *) &myname,
sizeof(myname));
/* Bind to all network interfaces in the Internet domain */
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = INADDR_ANY; /* specific interface */
myname.sin_port = htons(1024);
⋮
rc = bind(s, (struct sockaddr *) &myname,
sizeof(myname));
/* Bind to a specific interface in the Internet domain.
   Let the system choose a port                         */
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = inet_addr("129.5.24.1");
/* specific interface */
myname.sin_port = 0;
⋮
rc = bind(s, (struct sockaddr *) &myname,
sizeof(myname));
```

AF_UNIX Domain Example

The following example illustrates the bind() call binding to interfaces in the AF_UNIX domain.

```
/* Bind to a name in the UNIX domain */
struct sockaddr_un myname;
char socket_name[]="/tmp/socket.for._";
⋮
memset(&myname, 0, sizeof(myname));
myname.sun_family = AF_UNIX;
strcpy(myname.sun_path,socket_name);
myname.sun_len = sizeof(myname.sun_path);
⋮
rc = bind(s, (struct sockaddr *) &myname, SUN_LEN(&myname));
```

bind2addrsel() - Bind with source address selection

Standards

Standards / Extensions	C or C++	Dependencies
RFC 5014	both	

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int bind2addrsel(int sd, const struct sockaddr *dstaddr, socklen_t dstaddrlen);
```

General description

The bind2addrsel() function binds a socket to a source address and port that is appropriate to communicate with a given destination address. The source address is selected by the TCP stack according to either the default preference flags or the flags previously expressed by the application by use of the setsockopt() IPV6_ADDR_PREFERENCES call on this socket. If the bind is successful, the application can call getsockname() to determine the address and port selected. The application can then call inet6_is_srcaddr() to determine if the bound local address meets its preferences. For more information on source address selection, see *z/OS Communications Server: IPv6 Network and Appl Design Guide*.

Argument
Description

sd The socket to bind to a stack-selected source address and port.

dstaddr
A non-NULL pointer to a sockaddr_in6 structure initialized as follows:

- Clear the entire structure for sizeof(struct sockaddr_in6).
- *sin6_family* must be set to AF_INET6.
- Set *sin6_len* to the correct length for AF_INET6.
- Set *sin6_addr* to a 128-bit IPv6 destination address with which the local node wants to communicate.
- The *sin6_scope_id* must be set if the address is link-local.

dstaddrlen
The size of the sockaddr structure passed as argument.

Returned value

If successful, bind2addrsel() returns 0.

If unsuccessful, bind2addrsel() returns -1 and sets errno to one of the following values:

Error Code
Description

EADDRNOTAVAIL
The destination address is a multicast address but the socket type is SOCK_STREAM or there are no ephemeral ports available to satisfy the bind request.

EAFNOSUPPORT
The address family specified in the address structure is not supported.

EBADF
The socket descriptor is incorrect.

EHOSTUNREACH
The destination address is not reachable because there is no route.

EINVAL
One of the input parameters was not valid.

EIO There has been a network or transport failure.

ENOBUFS
A buffer could not be obtained.

ENOTSOCK
The *sd* parameter does not refer to a valid socket descriptor.

EOPNOTSUPP
The socket domain type is not supported.

EPROTOTYPE
The socket protocol is not TCP or UDP.

brk() — Change space allocation

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int brk(void *addr);
```

General description

Restriction: This function is not supported in AMODE 64.

The brk() function is used to change the space allocated for the calling process. The change is made by setting the process's break value to addr and allocating the appropriate amount of space. The amount of allocated space increases as the break value increases. The newly-allocated space is set to 0. However, if the application first decrements and then increments the break value, the contents of the reallocated space are not zeroed.

The storage space from which the brk() and sbrk() functions allocate storage is separate from the storage space that is used by the other memory allocation functions (malloc(), calloc(), etc.). Because this storage space must be a contiguous segment of storage, it is allocated from the initial heap segment only and thus is limited to the initial heap size specified for the calling program or the largest contiguous segment of storage available in the initial heap at the time of the first brk() or sbrk() call. Since this is a separate segment of storage, the brk() and sbrk() functions can be used by an application that is using the other memory allocation functions. However, it is possible that the user's region may not be large enough to support extensive usage of both types of memory allocation.

Prior usage of the brk() function has been limited to specialized cases where no other memory allocation function performed the same function. Because the brk() function may be unable to sufficiently increase the space allocation of the process when the calling application is using other memory functions, the use of other memory allocation functions, such as mmap(), is now preferred because it can be used portably with all other memory allocation functions and with any function that uses other allocation functions. Applications that require the use of brk() and/or sbrk() should refrain from using the other memory allocation functions and should be run with an initial heap size that will satisfy the maximum storage requirements of the program. The brk() function is not supported from a multithreaded environment, it will return in error if it is invoked in this environment.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use malloc() instead of brk() or sbrk().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, brk() returns 0.

If unsuccessful, brk() returns -1 and sets errno to one of the following values:

Error Code
    Description

ENOMEM
    The requested change would allocate more space than allowed for the calling process.

bsd_signal() — BSD version of signal()

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

void (*bsd_signal(int sig, void (*func)(int)))(int);
```

General description

The bsd_signal() function provides a partially compatible interface for programs written to use the BSD form of the signal() function.

BSD signal() differs from ANSI signal() in that the **SA_RESTART** flag is set and the **SA_RESETHAND** is cleared when bsd_signal() is used. Whereas for signal() both of these flags are cleared and **_SA_OLD_STYLE** is set.

There are three functions available for establishing a signal's action, signal(), bsd_signal(), and sigaction(). The sigaction() function is the strategic way to establish a signal's action. The bsd_signal() and signal() functions are provided for compatibility with BSD and ANSI, respectively.

The argument *sig* is the signal type. See Table 48 on page 1612 for a list of the supported signal types or refer to the <signal.h> header. The argument *func* is the signal action. It may be set to **SIG_DFL**, **SIG_IGN**, or the address of a signal catching function that takes one input argument.

Special Behavior for C++

Because C and C++ linkage conventions are incompatible, bsd_signal() cannot receive a C++ function pointer as the start routine function pointer If you attempt to pass a C++ function pointer to bsd_signal(), the compiler will flag it as an error. You can pass a C or C++ function to bsd_signal() by declaring it as extern "C".

Usage notes

1. The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.
2. The bsd_signal() function has been marked obsolescent in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sigaction() function is preferred for portability.

Returned value

If successful, bsd_signal() returns the previous action established for this signal type.

If unsuccessful, bsd_signal() returns **SIG_ERR** and sets errno to one of the following values:

Error Code
Description

EINVAL
The value of the argument *sig* was not a valid signal type, or an attempt was made to catch a signal that cannot be caught, or ignore a signal that cannot be ignored.

Related information

- "signal.h" on page 63

bsearch() — Search arrays

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

void *bsearch(const void *key, const void *base, size_t num, size_t size,
              int (*compare)(const void *element1, const void *element2));
```

General description

Performs a binary search of an array of *num* elements, each of *size* bytes.

The pointer *base* points to the initial element of the array to be searched. *key* points to the object containing the value being sought. The array must be sorted in ascending key sequence, according to the comparison function. Otherwise, undefined behavior occurs.

The *compare* parameter is a pointer to a function you must supply. It compares two array elements and returns a value specifying their relationship. The bsearch() function calls this function one or more times during the search, passing the key and the pointer to one array element on each call. The function compares the elements and then returns one of the following values:

Value	**Meaning**
< 0	Object pointed to by `key` is less than the array element.
= 0	Object pointed to by `key` is equal to the array element.
> 0	Object pointed to by `key` is greater than the array element.

Special Behavior for C++

Because C++ and C linkage conventions are incompatible, bsearch() cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to bsearch(), the compiler will flag it as an error. To use the C++ bsearch() function, you must ensure that the *compare* function has C linkage by declaring it as `extern "C"`.

Returned value

If successful, bsearch() returns a pointer to a matching element of the array. If two or more elements are equal, the element pointed to is not specified.

If unsuccessful finding the *key*, bsearch() returns NULL.

Example

CELEBB01

```
/* CELEBB01

   This example performs a binary search on the argv array of pointers  o
   to the program arguments and finds the position of the argument PATH.
   It first removes the program name from argv, and then sorts the array
   alphabetically before calling bsearch().

   The functions compare1 and compare2 compare the values pointed to by
   arg1 and arg2, and they return the result to bsearch().

 */
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

#ifdef __cplusplus  /* the __cplusplus macro is   */
extern "C" {        /* automatically defined by the   */
#endif              /* C++/MVS compiler               */
   int compare1(const void *arg1, const void *arg2);
   int compare2(const void *arg1, const void *arg2);
#ifdef __cplusplus
}
#endif

int main(int argc, char *argv[])
{
   char **result;
   char *key = "PATH";
   int i;
   argv++;
   argc--;

              /* sort to ensure that the input is ordered */
   qsort((char *)argv, argc, sizeof(char *), compare1);

   result = (char**)bsearch(key, (void *)argv, argc, sizeof(char *),
                            compare2);
   if (result != NULL) {
      printf("The key <%s> was found.\n",*result);
   }
   else printf("Match not found\n");
}

int compare1(const void *arg1, const void *arg2)
{
   return (strcmp(*(char **)arg1, *(char **)arg2));
}

int compare2(const void *arg1, const void *arg2) {
   return (strcmp((char *)arg1, *(char **)arg2));
}
```

Input

```
progname Is there PATH in this sentence?
```

Output

```
The key <PATH> was found.
```

- "qsort() — Sort array" on page 1363

btowc() — Convert single-byte character to wide-character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C C99 Single UNIX Specification, Version 3	both	z/OS V1R2

Format

```
#include <wchar.h>

wint_t btowc(int c);
```

General description

The btowc() function determines whether *c* constitutes a valid (one-byte) character in the initial shift state.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, btowc() returns the wide-character representation of the character *c*.

If *c* has the value EOF or if (unsigned char)*c* does not constitute a valid (one-byte) character in the initial shift state, btowc() returns WEOF.

There are no documented errno values.

bzero() — Zero bytes in memory

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define  _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

void bzero(void *s, size_t n);
```

General description

The bzero() function places *n* zero-valued bytes in the area pointed to by *s*.

Note: The bzero() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The memset() function is preferred for portability.

Returned value

bzero() returns no values.

There are no errno values defined for bzero().

Related information

- “strings.h” on page 72

c16rtomb() — Convert a char16_t character to a multibyte character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C11	both	z/OS V2R1

Format

```
#include <uchar.h>

size_t c16rtomb(char * restrict s, char16_t c16, mbstate_t * restrict ps);
```

General description

The c16rtomb() function converts a wide character of type char16_t to a multibyte character, and returns the number of bytes stored in *s* (including any shift sequences).

If *s* is not a null pointer, the c16rtomb() function determines the number of bytes needed to represent the multibyte character that corresponds to the wide character given by *c16* (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by *s*. At most MB_CUR_MAX bytes are stored. If the *c16* is a null wide character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

If *s* is a null pointer, the c16rtomb() function is equivalent to the call `c16rtomb(buf, L'\0', ps)`, where *buf* is an internal buffer.

If *ps* is a null pointer, c16rtomb() uses its own internal object to track the shift state. Otherwise **ps* must be a valid mbstate_t object. An mbstate_t object **ps* can be initialized to the initial state by assigning 0 to it, or by calling `c16rtomb(NULL, L'\0', ps)`.

Usage notes

1. To use the c16rtomb() function, compile the source code with the LANGLVL(EXTC1X) option.
2. The result *s* for stateful multibyte encodings, such as EBCDIC MBCS, might leave out shift bytes according to the conversion state. The first DBCS character in the output sequence has only shift-out character, and the following characters have neither shift-out nor shift-in. The ending shift-in will not be produced until an SBCS character or a null wide character is encountered.
3. The c16rtomb() function only supports the CCSIDs that are provided by Unicode Services.
4. The Unicode combining characters are not supported, and will be converted to substitute character of target CCSID.
5. The result of converting multiple string alternately in one thread by using multiple mbstate_t objects (including the internal one) is undefined.

Returned value

The c16rtomb() function returns the number of bytes stored in the array object (including any shift sequences). When *c16* is not a valid wide character, an encoding error occurs. The function stores the vlaue of the macro EILSEQ in errno and returns (size_t)(-1); the conversion state is unspecified.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <uchar.h>

int main(void)
{
   char16_t in = u'a';
   mbstate_t st = 0;
   char out[MB_CUR_MAX];
   int rc, i;
   rc = c16rtomb(out, in, &st);
   if (rc < 0) {
      perror("c16rtomb() fails to convert");
      exit(-1);
   }
   printf(" c16: 0x%04x \n", in);
   printf(" return code: %d \n", rc);
   printf(" mb character: ");
   for (i=0; i<rc; i++)
```

```
      printf(" 0x%02x", out[i]);
   printf("\n");
   return 0;
}
```

Output:

```
c16: 0x0061
return code: 1
mb character: 0x81
```

Related information

c32rtomb() — Convert a char32_t character to a multibyte character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C11	both	z/OS V2R1

Format

```
#include <uchar.h>

size_t c32rtomb(char * restrict s, char32_t c32, mbstate_t * restrict ps);
```

General description

The c32rtomb() function converts a wide character of type char32_t to a multibyte character, and returns the number of bytes stored in the *s* (including any shift sequences).

If *s* is not a null pointer, the c32rtomb() function determines the number of bytes needed to represent the multibyte character that corresponds to the wide character given by *c32* (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by *s*. At most MB_CUR_MAX bytes are stored. If the *c32* is a null wide character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

If *s* is a null pointer, the c32rtomb() function is equivalent to the call `c32rtomb(buf, L'\0', ps)`, where *buf* is an internal buffer.

If *ps* is a null pointer, c32rtomb() uses its own internal object to track the shift state. Otherwise **ps* must be a valid mbstate_t object. An mbstate_t object **ps* can be initialized to the initial state by assigning 0 to it, or by calling `c32rtomb(NULL, L'\0', ps)`.

Usage notes

1. To use the c32rtomb() function, compile the source code with the LANGLVL(EXTC1X) option.
2. The result *s* for stateful multibyte encodings, such as EBCDIC MBCS, might leave out shift bytes according to the conversion state. The first DBCS character in the output sequence has only shift-out character, and the following characters have neither shift-out nor shift-in. The ending shift-in will not be produced until an SBCS character or a null wide character is encountered.
3. The c32rtomb() function only supports the CCSIDs that are provided by Unicode Services.
4. The Unicode combining characters are not supported, and will be converted to substitute character of target CCSID.
5. The result of converting multiple string alternately in one thread by using multiple mbstate_t objects (including the internal one) is undefined.

Returned value

The c32rtomb() function returns the number of bytes stored in the array object (including any shift sequences). When *c32* is not a valid wide character, an encoding error occurs. The function stores the vlaue of the macro EILSEQ in errno and returns (size_t)(-1); the conversion state is unspecified.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <uchar.h>

int main(void)
{
   char32_t in = U'a';
   mbstate_t st = 0;
   char out[MB_CUR_MAX];
   int rc, i;
   rc = c32rtomb(out, in, &st);
   if (rc < 0) {
      perror("c32rtomb() fails to convert");
      exit(-1);
   }
   printf(" c32: 0x%04x \n", in);
   printf(" return code: %d \n", rc);
   printf(" mb character: ");
   for (i=0; i<rc; i++)
      printf(" 0x%02x", out[i]);
   printf("\n");
   return 0;
}
```

Output:

```
c32: 0x00000061
return code: 1
mb character:  0x81
```

__cabend() — Terminate the process with an abend

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <ctest.h>

void  __cabend(int abendcode, int reasoncode,int clean_up);
```

General description

Causes an abnormal process termination and returns an abend code.

Note: When TRAP(OFF) is specified, __cabend() behaves as if clean_up was set to 0.

Parameter
Description

abendcode
Numeric value for the user abend code.

reasoncode
Numeric value of the reason code.

clean_up
Specifies whether normal process cleanup should be performed with the type of dump the user requires.

0 - Issue the abend without cleanup
1 - Issue the abend with cleanup honoring the TERMTHDACT
runtime option that the user has specified
2 - Issue the abend with cleanup honoring the TERMTHDACT
runtime option for system dump of the
user address space but always suppressing the CEEDUMP
3 - Issue the abend with cleanup honoring the TERMTHDACT
runtime option but always suppressing
both the system dump and the CEEDUMP
4 - Issue the abend with cleanup honoring the TERMTHDACT
runtime option for CEEDUMP but always
suppressing the system dump
5 - Issue the abend with cleanup forcing a system dump of
the user address space but not specifying the
TERMTHDACT runtime option

cabs(), cabsf(), cabsl() — Calculate the complex absolute value

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double cabs(double complex z);
float cabsf(float complex z);
long double cabsl(long double complex z);
```

General description

The cabs() family of functions compute the complex absolute value (also called norm, modules, or magnitude) of *z*.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
cabs	X	X
cabsf	X	X
cabsl	X	X

Returned value

The cabs functions return the complex absolute value.

Example

```
/*
 * This example calculates the complex absolute
 * value of complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{
   double complex z=3.5 + I*2.21;
   double res;

   res = cabs(z);
   printf("cabs(%f + I*%f) = %f\n",creal(z), cimag(z),res);
}

/*
 * Output:
 * cabs(3.5 + I*2.21) = 4.139336
 */
```

- “creal(), crealf(), creall() — Calculate the complex real part” on page 340

cacos(), cacosf(), cacosl() — Calculate the complex arc cosine

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex cacos(double complex z);
float complex cacosf(float complex z);
long double complex cacosl(long double complex z);
```

General description

The cacos() family of functions compute the complex arc cosine of *z*, with branch cuts outside the interval [-1, +1] along the real axis.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
cacos	X	X
cacosf	X	X
cacosl	X	X

Returned value

The cacos() family of functions return the complex arc cosine value, in the range of a strip, mathematically unbounded along the imaginary axis and in the interval [0, *π*] along the real axis.

Example

```
/*
 *  This example calculates the complex arc-cosine of
 *  complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{

   long double complex zl=3.5 + I*2.21;
   double complex zd=(double complex)zl;
   float complex zf=(float complex)zl;
   long double resl;
   double resd;
   float resf;
   char *func = "cacos";

   printf("Example of the %s complex function\n",func);
   resd = cacos(zd);
   resf = cacosf(zf);
   resl = cacosl(zl);
   printf("\t%s(%f + I*%f) = %f\n",func, creal(zd), cimag(zd),resd);
   printf("\t%sf(%f + I*%f) = %f\n",func, crealf(zf), cimagf(zf),resf);
   printf("\t%sl(%Lf + I*%Lf) = %Lf\n",func, creall(zl), cimagl(zl),resl);
}
```

```
Output:

Example of the cacos complex function
        cacos(3.500000 + I*2.210000) = 0.576628
        cacosf(3.500000 + I*2.209999) = 0.576627
        cacosl(3.500000 + I*2.210000) = 0.576628
```

cacosh(), cacoshf(), cacoshl() — Calculate the complex arc hyperbolic cosine

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex cacosh(double complex z);
float complex cacoshf(float complex z);
long double complex cacoshl(long double complex z);
```

General description

The cacosh() family of functions compute the complex arc hyperbolic cosine of *z*, with a branch cut at values less than 1 along the real axis.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
cacosh	X	X
cacoshf	X	X
cacoshl	X	X

Returned value

The cacosh() family of functions return the complex arc hyperbolic cosine value, in the range of a half-strip, non-negative value along the real axis and in the interval [-i *π*, +i *π*] along the imaginary axis.

Example

For an example of a similar function see cacos(), cexp() or cpow().

calloc() — Reserve and initialize storage

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

void *calloc(size_t num, size_t size);
```

General description

Reserves storage space for an array of *num* elements, each of length *size* bytes. The calloc() function then gives all the bits of each element an initial value of 0.

calloc() returns a pointer to the reserved space. The storage space to which the returned value points is aligned for storage of any type of object.

This function is also available to C applications in free-standing System Programming C (SPC) Facilities applications.

Special behavior for C++: The C++ keywords new and delete are not interoperable with calloc(), free(), malloc(), or realloc().

Returned value

If successful, calloc() returns the pointer to the area of memory reserved.

If there is not enough space to satisfy the request or if *num* or *size* is 0, calloc() returns NULL. If calloc() returns NULL because there is not enough storage, it sets errno to one of the following values:

Error Code
Description

ENOMEM
Insufficient memory is available

Example

CELEBC01

```
/* CELEBC01

   This example prompts for the number of array entries required
   and then reserves enough space in storage for the entries.

   If &calloc. is successful, the example prints out each entry;
   otherwise, it prints out an error message.

 */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
  long * array;    /* start of the array */
  long * index;    /* index variable     */
  int        i;    /* index variable     */
  int      num;    /* number of entries in the array */

  printf( "Enter the number of elements in the array\n" );
  scanf( "%i", &num );

  /* allocate num entries */
  if ( (index = array = (long *)calloc( num, sizeof( long ))) != NULL )
  {

    for ( i = 0; i < num; ++i )           /* put values in array    */
       *index++ = i;                      /* using pointer notation */

    for ( i = 0; i < num; ++i )           /* print the array out    */
      printf( "array[ %i ] = %i\n", i, array[i] );
  }
  else
  { /* out of storage */
    printf( "Out of storage\n" );
    abort();
  }
}
```

Output

```
Enter the size of the array
array[ 0 ] = 0
array[ 1 ] = 1
array[ 2 ] = 2
```

carg(), cargf(), cargl() — Calculate the argument

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double carg(double complex z);
float cargf(float complex z);
long double cargl(long double complex z);
```

General description

The carg() family of functions compute the argument (phase angle) of *z*, with a branch cut along the negative real axis.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
carg	X	X
cargf	X	X
cargl	X	X

Returned value

The carg() family of functions return the value of the argument in the interval [-*π*, +*π*].

Example

For an example of a similar function see cacos(), cexp() or cpow().

casin(), casinf(), casinl() — Calculate the complex arc sine

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex casin(double complex z);
float complex casinf(float complex z);
long double complex casinl(long double complex z);
```

General description

The casin() family of functions compute the complex arc sine of *z*, with branch cuts outside the interval [-1, +1] along the real axis.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
casin	X	X
casinf	X	X
casinl	X	X

Returned value

The casin() family of functions return the complex arc sine value, in the range of a strip, mathematically unbounded along the imaginary axis and in the interval [-π/2, + π/2] along the real axis.

Related information

casinh(), casinhf(), casinhl() — Calculate the complex arc hyperbolic sine

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#define _ISOC99_SOURCE
#include <complex.h>

double complex casinh(double complex z);
float complex casinhf(float complex z);
long double complex casinhl(long double complex z);
```

General description

The casinh() family of functions compute the complex arc hyperbolic sine of *z*, with branch cuts outside the interval [-i, +i] along the imaginary axis.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
casinh	X	X
casinhf	X	X
casinhl	X	X

Returned value

The casinh() family of functions return the complex arc hyperbolic sine value, in the range of a strip, mathematically unbounded along the real axis and in the interval [-i $\pi/2$, +i $\pi/2$] along the imaginary axis.

Example

For an example of a similar function see cacos(), cexp() or cpow().

catan(), catanf(), catanl() — Calculate the complex arc tangent

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex catan(double complex z);
float complex catanf(float complex z);
long double complex catanl(long double complex z);
```

General description

The catan() family of functions compute the complex arc tangent of *z*, with branch cuts outside the interval [-i, +i] along the imaginary axis.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
catan	X	X
catanf	X	X
catanl	X	X

Returned value

The catan() family of functions return the complex arc tangent value, in the range of a strip, mathematically unbounded along the imaginary axis and in the interval [-*π*/2, +*π*/2] along the real axis.

Example

For an example of a similar function see cacos(), cexp() or cpow().

catanh(), catanhf(), catanhl() — Calculate the complex arc hyperbolic tangent

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex catanh(double complex z);
float complex catanhf(float complex z);
long double complex catanhl(long double complex z);
```

General description

The catanh() family of functions compute the complex arc hyperbolic tangent of *z*, with branch cuts outside the interval [-1, +1] along the real axis.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
catanh	X	X
catanhf	X	X
catanhl	X	X

Returned value

The catanh() family of functions return the complex arc hyperbolic tangent value, in the range of a strip, mathematically unbounded along the real axis and in the interval [-i $\pi/2$, +i $\pi/2$] along the imaginary axis.

Example

For an example of a similar function see cacos(), cexp() or cpow().

catclose() — Close a message catalog descriptor

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <nl_types.h>

int catclose(nl_catd catd);
```

General description

The catclose() function closes the message catalog identified by catd. If a catalog is opened more than once in the same process, a use count is incremented. catclose() decrements this use count. When the use count reaches zero then the file descriptor for that catalog is closed.

Returned value

If successful, catclose() returns 0.

If unsuccessful, catclose() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
The catalog descriptor is not valid.

EINTR
catclose() was interrupted by a signal.

Related information

- "nl_types.h" on page 57
- "catgets() — Read a program message"
- "catopen() — Open a message catalog" on page 240

catgets() — Read a program message

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <nl_types.h>

char *catgets(nl_catd catd, int set_id, int msg_id, const char *s);
```

General description

The catgets() function attempts to read message msg_id, in set set_id, from the message catalog identified by catd. The catd argument is a message catalog descriptor returned from an earlier call to catopen(). The s argument points to a default message string which will be returned by catgets() if it cannot retrieve the identified message.

When message source files are processed by the gencat command, the CODESET used to create them is saved in the resulting message catalog. The catgets() function interrogates this CODESET value to see if it differs from the CODESET value of the current locale. If it does differ then catgets() uses the iconv() function to convert the message text coming from the message catalog into the codeset of the current locale. The default message string (s) is not affected by this conversion. If iconv() does not support the conversion specified by the two CODESETs then the default message string is returned.

Returned value

If the identified message is retrieved successfully, catgets() returns a pointer to an internal buffer area containing the NULL-terminated message string.

If unsuccessful, catgets() returns *s* and sets errno to one of the following values:

Error Code
    Description

EBADF
    The *catd* argument is not a valid message catalog descriptor open for reading.

EINTR
    The read operation was terminated due to the receipt of a signal, and no data was transferred.

Special behavior for z/OS UNIX Services:

Error Code
    Description

EINVAL
    May be returned for several reasons:

- The message catalog identified by catd is not a valid message catalog, or has been corrupted. Ensure that the message catalog was created using the z/OS UNIX gencat command.
- iconv() does not support the conversion between the codeset of the message catalog and that of the current locale. To check the codeset that the message catalog was created in, look for the codeset name at offset 28 into the message catalog.

ENOMSG
    The message identified by set_id and msg_id is not in the message catalog.

Related information

- “nl_types.h” on page 57
- “catclose() — Close a message catalog descriptor” on page 238
- “catopen() — Open a message catalog” on page 240

catopen() — Open a message catalog

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <nl_types.h>

nl_catd catopen(const char *name, int oflag);
```

General description

The catopen() function opens a message catalog and returns a message catalog descriptor. The name argument specifies the name of the message catalog to be opened. If name contains a "/", then name specifies a complete name for the message catalog. Otherwise, the environment variable NLSPATH is used with name substituted for %N (see the XBD specification, Chapter 6, Environment Variables). If NLSPATH does not exist in the environment, or if a message catalog cannot be found in any of the components specified by NLSPATH, then the default path of "/usr/lib/nls/msg/%L/%N" is used. The "%L" component of this default path is replaced by the setting of LC_MESSAGES if the value of oflag is NL_CAT_LOCALE, or the LANG environment variable if oflag is 0. A change in the setting of the LANG or LC_MESSAGES will have no effect on existing open catalogs.

A message catalog descriptor remains valid in a process until that process closes it, or a successful call to one of the exec functions. When a message catalog is opened the FD_CLOEXEC flag will be set. See “fcntl() — Control open file descriptors” on page 474. Portable applications must assume that message catalog descriptors are not valid after a call to one of the exec functions.

If a catalog is opened more than once in the same process, a use count is incremented. When the use count reaches zero, by using catclose() to close the catalog, then the file descriptor for that catalog is closed.

Returned value

If successful, catopen() returns a message catalog descriptor for use on subsequent calls to catgets() and catclose().

If unsuccessful, catopen() returns (nl_catd)-1 and sets errno to one of the following values:

Error Code
Description

EACCES
Search permission is denied for the component of the path prefix of the message catalog or read permission is denied for the message catalog.

EMFILE
OPEN_MAX file descriptors are currently open in the calling process.

ENAMETOOLONG
The length of the path name of the message catalog exceeds **PATH_MAX**, or a path name component is longer than **NAME_MAX**.

ENFILE
Too many files are currently open in the system.

ENOENT
The message catalog does not exist or the name argument points to an empty string.

ENOMEM
Insufficient storage space is available.

ENOTDIR
A component of the path prefix of the message catalog is not a directory.

cbrt(), cbrtf(), cbrtl() — Calculate the cube root

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double cbrt(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float cbrtf(float x);
long double cbrtl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float cbrt(float x);
long double cbrt(long double x);
```

General description

The cbrt() function calculates the real cube root of its argument *x*.

Note: The following table shows which functions work in IEEE Binary Floating-Point format and which work in hexadecimal floating-point format. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
cbrt	X	X
cbrtf	X	X
cbrtl	X	X

Returned value

The cbrt functions return x to the 1/3 power.

cbrt() does not fail.

Related information

- "math.h" on page 44

cbrtd32(), cbrtd64(), cbrtd128() — Calculate the cube root

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.11

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  cbrtd32(_Decimal32 x);
_Decimal64  cbrtd64(_Decimal64 x);
_Decimal128 cbrtd128(_Decimal128 x);

_Decimal32  cbrt(_Decimal32 x);      /* C++ only */
_Decimal64  cbrt(_Decimal64 x);      /* C++ only */
_Decimal128 cbrt(_Decimal128 x);     /* C++ only */
```

General description

The cbrt() function calculates the real cube root of its argument *x*.

Notes:

1. These functions work in IEEE decimal floating-point format. See "IEEE decimal floating-point" on page 95IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Example

```
/* CELEBC52

   This example illustrates the cbrtd64() function.

*/
```

```
#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
   _Decimal64 x, y;

   x = 1000.0DD;
   y = cbrtd64(x);

   printf("cbrtd64( %Df ) = %Df\n", x, y);
}
```

Returned value

The cbrt functions return *x* to the 1/3 power.

cbrt() does not fail.

Related information

- “math.h” on page 44

cclass() — Return characters in a character class

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <collate.h>

int cclass(char *class, collel_t **list);
```

General description

Finds all the collating elements of the class, *class*. The list is updated to point to the array of collating elements found. The list is valid until the next call to setlocale().

The function supports user-defined character classes. In C Library programs, the function also supports POSIX.2 character classes.

Returned value

If successful, cclass() returns the number of elements in the list pointed to by *list*.

If the first argument specifies a class that does not exist in the LC_CTYPE category of the current locale, cclass() returns -1.

Example

CELEBC02

```
/* CELEBC02  */
#include <stdio.h>
#include <collate.h>

int main(void)
```

```
{
   collel_t *list;      /* ptr to the digit class collation weights   */
   int       weights;   /* no. of class collation class weights found */
   int       i;

   weights = cclass("digit", &list);

   printf("weights=%d\n", weights);
   for (i=0; i<weights; i++)
      printf("*(list + %d) = %d\n", i, *(list  + i) );
}
```

ccos(), ccosf(), ccosl() — Calculate the complex cosine

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex ccos(double complex z);
float complex ccosf(float complex z);
long double complex ccosl(long double complex z);
```

General description

The ccos() family of functions compute the complex cosine of *z*.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
ccos	X	X
ccosf	X	X

Function	Hex	IEEE
ccosl	X	X

Returned value

The ccos() family of functions return the complex cosine value.

Example

For an example of a similar function see cacos(), cexp() or cpow().

ccosh(), ccoshf(), ccoshl() — Calculate the complex hyperbolic cosine

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#define _ISOC99_SOURCE
#include <complex.h>

double complex ccosh(double complex z);
float complex ccoshf(float complex z);
long double complex ccoshl(long double complex z);
```

General description

The ccosh() family of functions compute the complex hyperbolic cosine of *z*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
ccosh	X	X
ccoshf	X	X
ccoshl	X	X

Returned value

The ccosh() family of functions return the complex hyperbolic cosine value.

Example

For an example of a similar function see cacos(), cexp() or cpow().

__CcsidType() — Return coded character set ID type

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R2

Format

```
#include <_Ccsid.h>

__csType __CcsidType(__ccsid_t Ccsid);
```

General description

__CcsidType() returns a __csType value which indicates the corresponding coded character set ID type.

Returned value

If *Ccsid* is valid, __CcsidType() returns one of the following __csType values, which are defined in <_Ccsid.h>:

- _CSTYPE_EBCDIC
- _CSTYPE_ASCII
- _CSTYPE_UCS2
- _CSTYPE_UTF8
- _CSTYPE_UTF16
- _CSTYPE_UTF32

If *Ccsid* is not valid, __CcsidType() returns _CSTYPE_INVALID.

Related information

- "_Ccsid.h" on page 17

cds() — Compare double and swap

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <stdlib.h>

int cds(cds_t *oldptr, cds_t *curptr, cds_t newwords);
```

General description

The cds() built-in function compares the 8-byte value pointed to by *oldptr* to the 8-byte value pointed to by *curptr*. If they are equal, the 8-byte value *newwords* is copied into the location pointed to by *curptr*. If they are unequal, the value pointed to by *curptr* is copied into the location pointed to by *oldptr*.

To avoid infringing on the user's name space, this nonstandard function is exposed only when you use the compiler option, LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The function uses the COMPARE DOUBLE AND SWAP (CDS) instructions, which can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas. For a detailed description, see the appendixes in the *z/Architecture Principles of Operation* on number representation and instruction.

Returned value

cds() returns 0 if the 8-byte value pointed to by *oldptr* is equal to the 8-byte value pointed to by *curptr*.

Otherwise cds() returns 1.

cdump() — Request a main storage dump

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <ctest.h>

int cdump(char *dumptitle);
```

General description

1. Creates a display of the activation stack, by calling trace in the same way as the ctrace() function does.
2. Displays the Language Environment-formatted dump.
3. If the source file was compiled with `TEST(SYM)`, cdump() displays the contents of the user's variables. The output is identified with *dumptitle*. See the `CEE3DMP` Language Environment callable service in *z/OS Language Environment Programming Guide, SA38-0682*, to determine where the output is written to.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

When cdump() is invoked from a user routine, the C/C++ library issues an OS SNAP macro to obtain a dump of virtual storage. The first invocation of cdump() results in a SNAP identifier of 0. For each successive invocation, the ID is increased by one to a maximum of 256, after which the ID is reset to 0.

The output of the dump is directed to the CEESNAP data set. The DD definition for CEESNAP is as follows:

```
//CEESNAP DD SYSOUT= *
```

If the data set is not defined, or is not usable for any reason, cdump() returns a failure code of 1. This occurs even if the call to CEE3DMP is successful. For more information see "Debugging C/C++ Routines " in *z/OS Language Environment Debugging Guide*.

Returned value

If successful, cdump() returns 0.

If unsuccessful, cdump() returns nonzero.

ceil(), ceilf(), ceill() — Round up to integral value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double ceil(double x);
float ceil(float x);                    /* C++ only */
long double ceil(long double x);        /* C++ only */
float ceilf(float x);
long double ceill(long double x);
```

General description

Computes the smallest integer that is greater than or equal to *x*.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated value as a double, float, or long double value.

If there is an overflow, the function sets errno to ERANGE and returns HUGE_VAL.

Special behavior for IEEE: The ceil() functions are always successful.

Example

CELEBC04

```
/* CELEBC04

   This example sets y to the smallest integer greater than
   1.05, and then to the smallest integer greater than -1.05.

   The results are 2.0 and -1.0, respectively.

 */
#include <math.h>
#include <stdio.h>
int main(void)
{
   double y, z;
   y = ceil(1.05);       /* y = 2.0 */
   z = ceil(-1.05);      /* z = -1.0 */
   printf("y = %f\n z = %f\n", y, z);
}
```

ceild32(), ceild64(), ceild128() — Round up to integral value

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  ceild32(_Decimal32 x);
_Decimal64  ceild64(_Decimal64 x);
_Decimal128 ceild128(_Decimal128 x);
_Decimal32  ceil(_Decimal32 x); /* C++ only */
_Decimal64  ceil(_Decimal64 x); /* C++ only */
_Decimal128 ceil(_Decimal128 x); /* C++ only */
```

General description

Computes the smallest integer that is greater than or equal to *x*.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

These functions are always successful.

Example

```
/* CELEBC50

   This example illustrates the ceild32() function.

   This example sets y to the smallest integer greater than
   1.05, and then to the smallest integer greater than -1.05.

   The results are 2.0 and -1.0, respectively.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal32 y, z;

   y = ceild32(+1.05DF);      /* y = +2.0 */
   z = ceild32(-1.05DF);      /* z = -1.0 */

   printf("ceild32(+1.05) = % Hf\n"
          "ceild32(-1.05) = % Hf\n", y, z);
}
```

__certificate() — Register, deregister, or authenticate a digital certificate

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R7

Format

```
#define _OPEN_SYS
#include <unistd.h>

int __certificate(int function_code,
                  int certificate_length,
                  char *certificate,...);
```

General description

The __certificate() function allows the user to register or deregister a digital certificate with or from the userid that is associated with the current security environment, or to authenticate a security environment using a digital certificate in lieu of a userid/password combination.

The function takes at least the following arguments:

function_code
Specifies one of the following functions:

__CERTIFICATE_REGISTER
Register the passed certificate to the user. No new security environment is created, and no authentication of the user is done.

__CERTIFICATE_DEREGISTER
Deregister the passed certificate from the user. Certificate must have been previously registered to the user.

__CERTIFICATE_AUTHENTICATE
As of z/OS V1R4, authenticate the passed certificate for this caller. The certificate must have already been registered.

certificate_length
The length of the digital certificate. A zero length will cause -1 return value with errno set to EINVAL.

certificate
The certificate must be a single BER encoded X.509 certificate. PKCS7, PEM, or Base64 encoded certificates are allowed.

Note: Only a single BER encoded X.509 certificate is supported for the authenticate function.

As of z/OS V1R4, the __CERTIFICATE_AUTHENTICATE function code requires the following additional parameters to be specified o nthe function call:

buflen (size_t)
Specifies the size of the buffer pointed to by buf. Up to buflen bytes of userid (including the NULL terminator) will be copied into the buffer. Note that truncation may occur if the buffer is too small. The buffer size should be large enough for any userid on the system. A value less than 1 will cause -1 return value with errno set to EINVAL.

buf (char *)
Pointer to character buffer where _certificate() will place the userid associated with the digital certificate. A value of NULL will cause -1 return value with errno set to EINVAL.

Usage notes

1. The _certificate function is intended for servers that support the automatic registration of certificates for clients they are supporting (on the World Wide Web for example).
2. The __CERTIFICATE_REGISTER function code will associate the passed certificate with whatever user identity is present. If the task level identity is present the certificate is associated with the task. Task level security can be created by pthread_security_np(), __login() or by any other means of creating a task level ACEE. If no task level identity (ACEE) is present, the certificate will be associated with the address space identity.
3. The __certificate() function calls the z/OS z/OS UNIX System Services BPX1SEC service. For a more detailed description of the BPX1SEC service, see *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

Restrictions

A security manager supporting digital certificate registration and deregistration must be installed and operational.

Returned value

If successful, __certificate() returns 0.

If unsuccessful, __certificate() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
Permission is denied.

EINVAL
A parameter is not valid.

EMVSERR
An MVS environmental error or internal error occurred.

EMVSSAF2ERR
An error occurred in the security product. Certificate is already defined for another process or certificate is not valid or certificate does not meet required format. Also, realized when an internal error has occurred.

ENOSYS
The function is not implemented or installed.

EPERM
The operation was not permitted. Calling process may not be authorized in BPX.DAEMON facility class.

Use __errno2() to obtain a more detailed reason code (in most cases) when __certificate() fails.

cexp(), cexpf(), cexpl() — Calculate the complex exponential

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex cexp(double complex z);
float complex cexpf(float complex z);
long double complex cexpl(long double complex z);
```

General description

The cexp() family of functions compute the complex base-e exponential of *z*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
cexp	X	X
cexpf	X	X
cexpl	X	X

Returned value

The cexp() family of functions return the complex base-e exponential value.

Example

```
/*
 * This example illustrates the complex exponential
 * function
 */
#include <complex.h>
#include <stdio.h>

void main()
{
   double complex z=6.0146 + I*(-2.41958),
                  res;

   res = cexp(z);
   printf("cexp(%f + (%f)*I) = %f + (%f)*I\n",creal(z), cimag(z),creal(res),cimag(res));
}

Output:

cexp(6.014600 + (-2.419580)*I) = -307.216850 + (-270.545937)*I
```

cfgetispeed() — Determine the input baud rate

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <termios.h>

speed_t cfgetispeed(const struct termios *termptr);
```

General description

Extracts the input baud rate from the termios structure indicated by **termptr*. The termios structure contains information about a terminal. A program should first use tcgetattr() to get the termios structure, and then use cfgetispeed() to extract the speed from the structure. The program can then use cfgetispeed() to set a new baud rate in the structure and tcsetattr() to pass the changed value to the system.

Although in a z/OS UNIX application valid speeds can be set with cfsetispeed() and passed to the system with tcsetattr(), the speed has no effect on the operation of a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

Returned value

cfgetispeed() returns a code indicating the baud rate; see Table 19. These codes are defined in the termios.h header file and have an unsigned integer type.

There are no documented errno values.

Table 19. Baud Rate Codes

B0	Hang up
B50	50 baud
B75	75 baud
B110	110 baud
B134	134.5 baud
B150	150 baud
B200	200 baud
B300	300 baud
B600	600 baud
B1200	1200 baud
B1800	1800 baud
B2400	2400 baud
B4800	4800 baud
B9600	9600 baud
B19200	19,200 baud
B38400	38,400 baud

Example

CELEBC05

```
/* CELEBC05

   This example determines the speed of stdin.

 */
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>

char *see_speed(speed_t speed) {
  static char   SPEED[20];
  switch (speed) {
    case B0:       strcpy(SPEED, "B0");
                   break;
    case B50:      strcpy(SPEED, "B50");
                   break;
    case B75:      strcpy(SPEED, "B75");
                   break;
    case B110:     strcpy(SPEED, "B110");
                   break;
    case B134:     strcpy(SPEED, "B134");
                   break;
    case B150:     strcpy(SPEED, "B150");
                   break;
    case B200:     strcpy(SPEED, "B200");
```

```
                 break;
    case B300:     strcpy(SPEED, "B300");
                   break;
    case B600:     strcpy(SPEED, "B600");
                   break;
    case B1200:    strcpy(SPEED, "B1200");
                   break;
    case B1800:    strcpy(SPEED, "B1800");
                   break;
    case B2400:    strcpy(SPEED, "B2400");
                   break;
    case B4800:    strcpy(SPEED, "B4800");
                   break;
    case B9600:    strcpy(SPEED, "B9600");
                   break;
    case B19200:   strcpy(SPEED, "B19200");
                   break;
    case B38400:   strcpy(SPEED, "B38400");
                   break;
    default:       sprintf(SPEED, "unknown (%d)", (int) speed);
  }
  return SPEED;
}

main() {
  struct termios term;
  speed_t speed;

  if (tcgetattr(0, &term) != 0)
    perror("tcgetattr() error");
  else {
    speed = cfgetispeed(&term);
    printf("cfgetispeed() says the speed of stdin is %s\n",
           see_speed(speed));
  }
}
```

Output

```
cfgetispeed() says the speed of stdin is B0
```

cfgetospeed() — Determine the output baud rate

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <termios.h>

speed_t cfgetospeed(const struct termios *termptr);
```

General description

Extracts the output baud rate from the `termios` structure indicated by **termptr*. The `termios` structure contains information about a terminal. A program should first use tcgetattr() to get the `termios` structure, and then use cfgetospeed() to extract the speed from the structure. The program can then use cfgetospeed() to set a new baud rate in the structure and tcsetattr() to pass the changed value to the system.

Although in a z/OS UNIX application valid speeds can be set with cfsetospeed() and passed to the system with tcsetattr(), the speed has no effect on the operation a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

Returned value

cfgetospeed() returns a code indicating the baud rate. The codes are defined in the termios.h header file and have an unsigned integer type. Table 19 on page 255 shows the codes to set the baud rate.

There are no documented errno values.

Example

CELEBC06

```
/* CELEBC06

   This example determines the speed of stdout.

 */
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>

char *see_speed(speed_t speed) {
  static char   SPEED[20];
  switch (speed) {
    case B0:       strcpy(SPEED, "B0");
                   break;
    case B50:      strcpy(SPEED, "B50");
                   break;
    case B75:      strcpy(SPEED, "B75");
                   break;
    case B110:     strcpy(SPEED, "B110");
                   break;
    case B134:     strcpy(SPEED, "B134");
                   break;
    case B150:     strcpy(SPEED, "B150");
                   break;
    case B200:     strcpy(SPEED, "B200");
                   break;
    case B300:     strcpy(SPEED, "B300");
                   break;
    case B600:     strcpy(SPEED, "B600");
                   break;
    case B1200:    strcpy(SPEED, "B1200");
```

```
                   break;
    case B1800:    strcpy(SPEED, "B1800");

    case B2400:    strcpy(SPEED, "B2400");
                   break;
    case B4800:    strcpy(SPEED, "B4800");
                   break;
    case B9600:    strcpy(SPEED, "B9600");
                   break;
    case B19200:   strcpy(SPEED, "B19200");
                   break;
    case B38400:   strcpy(SPEED, "B38400");
                   break;
    default:       sprintf(SPEED, "unknown (%d)", (int) speed);
  }
  return SPEED;
}

main() {
  struct termios term;
  speed_t speed;

  if (tcgetattr(1, &term) != 0)
    perror("tcgetattr() error");
  else {
    speed = cfgetospeed(&term);
    printf("cfgetospeed() says the speed of stdout is %s\n",
           see_speed(speed));
  }
}
```

Output

```
cfgetospeed() says the speed of stdout is B0
```

cfsetispeed() — Set the input baud rate in the termios

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int cfsetispeed(struct termios *termptr, speed_t speed);
```

General description

Specifies a new input baud rate for the termios control structure, **termptr*. cfsetispeed() records this new baud rate in the control structure but does not actually change the terminal device file. The program must call tcsetattr() to modify the terminal device file to reflect the settings in the termios structure.

A program should first use tcgetattr() to get the termios structure. Then it should use cfsetispeed() to set the speed in termios and tcsetattr() to pass the modified termios structure to the system.

Although in a z/OS UNIX application valid speeds can be set with cfsetispeed() and passed to the system with tcsetattr(), the speed has no effect on the operation of a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

The *speed* argument indicates the new baud rate with one of the following codes, defined in the termios.h header file. The codes have an unsigned integer type. Table 19 on page 255 shows the codes to set the baud rate.

Returned value

If successful, cfsetispeed() sets the baud rate in the control structure and returns 0.

If unsuccessful, cfsetispeed() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
An unsupported value for *speed*

Example

CELEBC07

```
/* CELEBC07

   This example specifies a new input baud rate.

 */
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>

main() {
  struct termios term;

  if (tcgetattr(0, &term) != 0)
    perror("tcgetattr() error");
  else if (cfsetispeed(&term, B0) != 0)
    perror("cfsetispeed() error");
  else if (tcsetattr(0, TCSANOW, &term) != 0)
    perror("tcsetattr() error");
}
```

cfsetospeed() — Set the output baud rate in the termios

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int cfsetospeed(struct termios *termptr, speed_t speed);
```

General description

Specifies a new output baud rate for the `termios` control structure, **termptr*. cfsetospeed() records this new baud rate in the control structure, but does not actually change the terminal device file. The program must call tcsetattr() to modify the terminal device file to reflect the settings in the `termios` structure.

A program should first use tcgetattr() to get the `termios` structure. It should then use cfsetospeed() to set the speed in `termios` and tcsetattr() to pass the modified `termios` structure to the system.

Although in a z/OS UNIX application valid speeds can be set with cfsetospeed() and passed to the system with tcsetattr(), the speed has no effect on the operation of a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

The *speed* argument should be a code indicating the new baud rate. These codes are defined in the termios.h header file and have an unsigned integer type. Table 19 on page 255 shows the codes to set the baud rate.

Returned value

If successful, cfsetospeed() sets the baud rate for the structure and returns 0.

If unsuccessful, cfsetospeed() returns -1 and sets errno to one of the following values:

Error Code
    Description

EINVAL
    The value *speed* is not supported by the hardware or software.

Example

CELEBC08

```
/* CELEBC08

   This example specifies a new output baud rate.

 */
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>

main() {
  struct termios term;

  if (tcgetattr(1, &term) != 0)
    perror("tcgetattr() error");
  else if (cfsetospeed(&term, B38400) != 0)
    perror("cfsetospeed() error");
  else if (tcsetattr(1, TCSANOW, &term) != 0)
    perror("tcsetattr() error");
}
```

__chattr() — Change the attributes of a file or directory

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R2

Format

```
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __chattr(char* pathname, attrib_t *attributes, int attributes_len);
```

General description

The __chattr() function modifies the attributes that are associated with a file. It can be used to change the mode, owner, access time, modification time, change time, reference time, audit flags, general attribute flags, file tag, and file format and size. The file to be impacted is defined by the *pathname* argument.

The *attributes* argument is the address of an attrib_t structure which is used to identify the attributes to be modified and the new values desired. The attrib_t type is an f_attributes structure as defined in <sys/stat.h> for use with the __chattr() function. For proper behavior the user should ensure that this structure has been initialized to zeros before it is populated. Available elements of the f_attributes structure are defined in Table 20:

Table 20. Struct f_attributes Element Descriptions

Element	Data Type	General Description
Bit Flags Indicating Which Attributes to Change		

Table 20. Struct f_attributes Element Descriptions (continued)

Element	Data Type	General Description
att_modechg:1	int	1=Change to mode indicated
att_ownerchg:1	int	1=Change to Owner indicated
att_setgen:1	int	1=Set General Attributes
att_trunc:1	int	1=Truncate Size
att_atimechg:1	int	1=Change the Atime
att_atimetod:1	int	1=Change Atime to Cur.Time
att_mtimechg:1	int	1=Change the Mtime
att_mtimetod:1	int	1=Change Mtime to Cur.Time
att_maaudit:1	int	1=Modify auditor audit info
att_muaudit:1	int	1=Modify user audit info
att_ctimechg:1	int	1=Change the Ctime
att_ctimetod:1	int	1=Change Ctime to Cur.Time
att_reftimechg:1	int	1=Change the RefTime
att_reftimetod:1	int	1=Change RefTime to Cur.Time
att_filefmtchg:1	int	1=Change File Format
att_filetagchg:1	int	1=Change File Tag
att_seclabelchg:1	int	1=Change Seclabel
Modified Values for Indicated Attributes to Change		
att_mode	mode_t	File Mode
att_uid	int	User ID of the owner of the file
att_gid	int	Group ID of the Group of the file
att_sharelibmask:1	int	1=Shared Library Mask
att_noshareasmask:1	int	1=No Shareas Flag Mask
att_apfauthmask:1	int	1=APF Authorized Flag Mask
att_progctlmask:1	int	1=Prog. Controlled Flag Mask
att_sharelib:1	int	1=Shared Library Flag
att_noshareas:1	int	1=No Shareas Flag
att_apfauth:1	int	1=APF Authorized Flag
att_progctl:1	int	1=Program Controlled Flag
att_size	off_t	File size
att_atime	time_t	Time of last access
att_mtime	time_t	Time of last data modification
att_auditoraudit	int	Area for auditor audit info
att_useraudit	int	Area for user audit info
att_ctime	time_t	Time of last file status change
att_reftime	time_t	Reference Time
att_filefmt	char	File Format
att_filetag	struct file_tag	File Tag
att_seclabel	char	Security Label

Note: If you set att_nodelfilesmask, att_sharelibmask, att_nodelfiles, att_sharelib, att_noshareasmask, att_apfauthmask, att_progctlmask, att_noshareas, att_apfauth or att_progctl, then att_setgen must also be set. The att_setgen flag is a required indicator when setting "general" attributes.

Returned value

If successful, __chattr() returns 0.

If unsuccessful, __chattr() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The calling process did not have appropriate permissions. Possible reasons include:

- The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.
- The calling process was attempting to truncate the file, and it does not have write permission for the file.

ECICS
An attempt was made to change file tag attributes under non-OTE CICS and file tagging is not supported in that environment.

EFBIG
The calling process was attempting to change the size of a file, but the specified length is greater than the maximum file size limit for the process.

EINVAL
The attributes structure containing the requested changes is not valid.

ELOOP
A loop exists in symbolic links that were encountered during resolution of the *pathname* argument. This error is issued if more than 24 symbolic links are detected in the resolution of *pathname*.

ENAMETOOLONG
pathname is longer than 1023 characters, or a component of the *pathname* is longer than 255 characters. (File name truncation is not supported.)

ENOENT
No file named *pathname* was found.

ENOTDIR
Some component of *pathname* is not a directory.

EPERM
The operation is not permitted for one of the following reasons:

- The calling process was attempting to change the mode or the file format but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the owner but it does not have appropriate privileges.

- The calling process was attempting to change the general attribute bits but it does not have write permission for the file.
- The calling process was attempting to set a time value (not current time) but the effective UID does not match the owner of the file, and it does not have appropriate privileges.
- The calling process was attempting to set the change time or reference time to current time but it does not have write permission for the file.
- The calling process was attempting to change auditing flags but the effective UID of the calling process does not match the owner of the file and the calling process does not have appropriate privileges.
- The calling process was attempting to change the Security Auditor's auditing flags but the user does not have auditor authority.

EROFS
pathname specifies a file that is on a read-only file system.

Example

```
#define _POSIX_SOURCE 1
#define _OPEN_SYS_FILE_EXT 1
#include <stdio.h>
#include <fcntl.h>
#include <sys/stat.h>

int main(int argc, char *argv[]) {

   int fd;
   attrib_t myAtt;
   struct stat attr;
   char filename[] = "chattr.testfile";

   /* Create an empty file */
   if ( (fd = creat(filename, S_IRWXU | S_IRGRP | S_IROTH)) < 0) {
      perror("Failed to create testfile");
      exit(1);
   }
   close(fd);

   /* Clear myAtt structure */
   memset(&myAtt, 0, sizeof(myAtt));

   /* Update myAtt to request file tag change and set file tag values */
   myAtt.att_filetagchg = 1;
   myAtt.att_filetag.ft_ccsid = 12345;
   myAtt.att_filetag.ft_txtflag = 1;

   /* Change Attributes */
   if ( __chattr(filename, &myAtt, sizeof(myAtt)) != 0 ) {
      perror("Failed to change attributes for testfile");
      exit(2);
   }

   /* Verify Change */
   if ( stat(filename,&attr) !=0 ) {
      perror("Failed to acquire statistics for testfile");
      exit(3);
   }

   if ((attr.st_tag.ft_ccsid == 12345)
       && (attr.st_tag.ft_txtflag == 1)) {
      printf("File attributes changed successfully\n");
   }

}
```

Related information

chaudit() — Change audit flags for a file by path

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS 1
#include <sys/stat.h>

int chaudit(const char *pathname, unsigned int flags,
            unsigned int option);
```

General description

Changes the audit flags for a file to indicate the type of requests the security product should audit. chaudit() can change user audit flags or security auditor audit flags, depending on the *option* specified.

pathname is the name of the file for which the audit flags are to be changed.

flags is the setting for the audit flags:

AUDTREADFAIL
Audit the failing read requests.

AUDTREADSUCC
Audit the successful read requests.

AUDTWRITEFAIL
Audit the failing write requests.

AUDTWRITESUCC
Audit the successful write requests.

AUDTEXECFAIL
Audit the failing execute or search requests.

AUDTEXECSUCC
Audit the successful execute or search requests. The bitwise inclusive-OR of any or all of these can be used to set more than one type of auditing.

option indicates whether the user audit flags or the security-auditor audit flags are to be changed:

AUDT_USER (0)
Change user flags. The user must be the file owner or have appropriate authority to change the user audit flags for a file.

AUDT_AUDITOR (1)
Change security auditor audit flags. The user must have security-auditor authority to modify the security auditor audit flags for a file.

Returned value

If successful, chaudit() returns 0.

If unsuccessful, chaudit() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The calling process does not have permission to search some component of *pathname*.

EINVAL
option is not AUDT_USER or AUDT_AUDITOR.

ELOOP
A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters or a component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values are determined using pathconf().

ENOENT
There is no file named *pathname*, or *pathname* is an empty string.

ENOTDIR
A component of the path prefix is not a directory.

EPERM
The effective user ID (UID) of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS
pathname specifies a file that is on a read-only file system.

Example

CELEBC09

```
/* CELEBC09

   This example changes the audit flags.

 */

#define _OPEN_SYS
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _OPEN_SYS
#include <stdio.h>
```

```
main() {
  int fd;
  char fn[]="chaudit.file";

  if ((fd = creat(fn, S_IRUSR|S_IWUSR)) < 0)
    perror("creat() error");
  else {
    close(fd);
    if (chaudit(fn, AUDTREADFAIL, AUDT_USER) != 0)
      perror("chaudit() error");
    unlink(fn);
  }
}
```

chdir() — Change the working directory

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int chdir(const char *pathname);
```

General description

Makes *pathname* your new working directory.

Returned value

If successful, chdir() changes the working directory and returns 0.

If unsuccessful, chdir() does not change the working directory, returns -1, and sets errno to one of the following values:

Error Code
Description

EACCES
The process does not have search permission on one of the components of *pathname*.

ELOOP
A loop exists in symbolic links. This error is issued if the number of

symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values are determined using pathconf().

ENOENT
pathname is an empty string, or the specified directory does not exist.

ENOTDIR
Some component of *pathname* is not a directory.

Example

CELEBC10

```
/* CELEBC10 */
#define _POSIX_SOURCE
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  if (chdir("/tmp") != 0)
    perror("chdir() to /tmp failed");
  if (chdir("/chdir/error") != 0)
    perror("chdir() to /chdir/error failed");
}
```

Output

```
chdir() to /chdir/error failed: No such file or directory
```

__check_resource_auth_np() — Determine access to MVS resources

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <unistd.h>

int __check_resource_auth_np( char *principal_uuid,
                              char *cell_uuid,
                              char *userid,
                              char *security_class,
                              char *entity_name,
                              int access_type);
```

General description

The __check_resource_auth_np() function is used to check the access a user has to an MVS resource.

For authorization to use this function, the caller must have read permission to the BPX.SERVER Facility class, or if BPX.SERVER is not defined, the caller must be a superuser (UID=0).

The user identity can be specified in several forms. The identities are scanned in the order below, and the access check will be made with the first identity that is found:
- userid
- principal UUID and if known, a cell UUID
- caller's thread-level (task) security context, if one exists
- caller's process-level (address space) security context

Note:
- When no identity is specified by the caller and the caller's task has an ACEE created with pthread_security_np()for a SURROGATE (non-password) client, both the task and address space level ACEEs are used in determining the type of access permitted to a resource.
- The __check_resource_auth_np() function supports the general resources only. In particular, the security_class parameter can not specify DATASET. For system using RACF, the class name specified must be in the RACF class descriptor table.

The parameters supported are:

principal_uuid
Specifies a 36-byte principal UUID. A value of NULL indicates that no principal UUID is specified.

cell_uuid
Specifies a 36-byte cell UUID. A value of NULL indicates that no cell UUID is specified.

userid Specifies a user ID. A value of NULL indicates that no user ID is specified. The *userid* must be 1-8 characters in length.

security_class
Specifies the name of a class of resources. The access check will be made on a resource in this security class. The *security_class* must be 1-8 characters in length.

entity_name
Specifies the name of a resource profile name. The access check will be made on the resource specified by the resource profile name. The *entity_name* must be 1-246 characters in length.

access Specifies a numeric value that identifies the type of access to check for. Possible access values are:

__READ_RESOURCE
check if the specified user has read access to the resource.

__UPDATE_RESOURCE
check if the specified user has update access to the resource.

__CONTROL_RESOURCE
check if the specified user has control access to the resource.

__ALTER_RESOURCE
check if the specified user has alter access to the resource.

Returned value

If successful, __check_resource_auth_np() returns 0.

If unsuccessful, __check_resource_auth_np() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
One of the following errors was detected:
- Aaccess_type specified is undefined.
- Userid was not 1 to 8 characters in length.
- Security_class was not 1 to 8 characters in length.
- Eentity_name was not 1 to 246 characters in length.

EMVSERR
An MVS internal or environmental error occurred.

EMVSSAF2ERR
One of the following errors was detected:
- Received an unexpected return code for the security product.
- The security product detected an error in the input parameters.
- An internal error occurred in the security product.

ENOSYS
One of the following errors was detected:
- No security product is installed on the system.
- The security product does not have support for this function.

EPERM
One of the following errors was detected:
- The caller is not permitted to use this service.
- Do not have the access_type specified to the resource.
- Not permitted in address spaces where a load from an unauthorized library has been performed.

ESRCH
One of the following errors was detected:
- No mapping exists between a UUID and Userid.
- The resource specified is not defined to the security product.
- The DCEUUIDS class is not active.
- The userid is not defined to the security product.

CheckSchEnv() — Check WLM scheduling environment

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

int CheckSchEnv(const char *sched_env,
                const char *system_name);
```

General description

The CheckSchEnv() function provides the ability for an application to connect to check the WLM scheduling environment.

***sched_env**
: Points to a 16 byte character string that represents the WLM scheduling environment to be queried. If the environment name is less than 16 characters, the name should be right padded with blanks.

***sys_name**
: Points to a 8 bytes character string that represents the system name to be queried. If the system name is less than 8 characters, the name should be right padded with blanks.

Returned value

If successful, CheckSchEnv() returns 0.

If unsuccessful, CheckSchEnv() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EFAULT
: An argument of this function contained an address that was not accessible to the caller.

EINVAL
: An argument of this function contained an incorrect value.

EMVSSAF2ERR
: An error occurred in the security product.

EMVSWLMERROR
: The WLM check scheduling environment failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
: The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

chmod() — Change the mode of a file or directory

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int chmod(const char *pathname, mode_t mode);
```

General description

Changes the mode of the file or directory specified in *pathname*.

The *mode* argument is created with one of the following symbols defined in the sys/stat.h header file.

Any mode flags that are not defined will be turned off, and the function will be allowed to proceed.

S_IRGRP
Read permission for the file's group.

S_IROTH
Read permission for users other than the file owner.

S_IRUSR
Read permission for the file owner.

S_IRWXG
Read, write, and search or execute permission for the file's group. S_IRWXG is the bitwise inclusive-OR of S_IRGRP, S_IWGRP, and S_IXGRP.

S_IRWXO
Read, write, and search or execute permission for users other than the file owner. S_IRWXO is the bitwise inclusive-OR of S_IROTH, S_IWOTH, and S_IXOTH.

S_IRWXU
Read, write, and search, or execute, for the file owner; S_IRWXG is the bitwise inclusive-OR of S_IRUSR, S_IWUSR, and S_IXUSR.

S_ISGID
Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is set to the group ID of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.

S_ISUID
Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.

S_ISVTX
The sticky bit indicating shared text. Keep loaded as an executable file in storage.

S_IWGRP
Write permission for the file's group.

S_IWOTH
Write permission for users other than the file owner.

S_IWUSR
Write permission for the file owner.

S_IXGRP
Search permission (for a directory) or execute permission (for a file) for the file's group.

S_IXOTH
Search permission for a directory, or execute permission for a file, for users other than the file owner.

S_IXUSR
Search permission (for a directory) or execute permission (for a file) for the file owner.

Special behavior for XPG4.2: If a directory is writable and the mode bit S_ISVTX is set on the directory, a process may remove or rename files within that directory only if one or more of the following is true:

- The effective user ID of the process is the same as that of the owner ID of the file.
- The effective user ID of the process is the same as that of the owner ID of the directory.
- The process has appropriate privileges.

A process can set mode bits only if the effective user ID of the process is the same as the file's owner or if the process has appropriate privileges (superuser authority). chmod() automatically clears the S_ISGID bit in the file's mode bits if all these conditions are true:

- The calling process does not have appropriate privileges, that is, superuser authority (UID=0).
- The group ID of the file does not match the group ID or supplementary group IDs of the calling process.

- One or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set to 1.

Returned value

If successful, chmod() marks for update the `st_ctime` field of the file and returns 0.

If unsuccessful, chmod() returns -1 and sets errno to one of the following values:

Error Code
    Description

EACCES
    The process does not have search permission on some component of the *pathname* prefix.

ELOOP
    A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).

ENAMETOOLONG
    pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values are determined using pathconf().

ENOENT
    There is no file named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR
    Some component of the *pathname* prefix is not a directory.

EPERM
    The effective user ID (UID) of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges (superuser authority).

EROFS
    pathname is on a read-only file system.

Example

CELEBC11

```
/* CELEBC11

   This example changes the permission from the file owner to the file's
   group.

 */
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  char fn[]="./temp.file";
  FILE *stream;
  struct stat info;

  if ((stream = fopen(fn, "w")) == NULL)
    perror("fopen() error");
  else {
    fclose(stream);
    stat(fn, &info);
    printf("original permissions were: %08x\n", info.st_mode);
    if (chmod(fn, S_IRWXU|S_IRWXG) != 0)
      perror("chmod() error");
    else {
      stat(fn, &info);
      printf("after chmod(), permissions are: %08x\n", info.st_mode);
    }
    unlink(fn);
  }
}
```

Output

```
original permissions were: 030001b6
after chmod(), permissions are: 030001f8
```

chown() — Change the owner or group of a file or directory

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int chown(const char *pathname, uid_t owner, gid_t group);
```

General description

Changes the owner or group (or both) of a file. *pathname* is the name of the file whose owner or group you want to change. *owner* is the user ID (UID) of the new owner of the file. *group* is the group ID (GID) of the new group for the file.

If _POSIX_CHOWN_RESTRICTED is defined in the unistd.h header file, a process can change the group of a file only if one of these is true:

1. The process has appropriate privileges.
2. Or all of the following are true:

a. The effective user ID of the process is equal to the user ID of the file owner.
b. The *owner* argument is equal to the user ID of the file owner or `(uid_t)-1`,
c. The *group* argument is either the effective group ID or a supplementary group ID of the calling process.

If *pathname* is a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, chown() clears the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file mode and returns successfully.

If *pathname* is not a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, chown() clears the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file.

When chown() completes successfully, it marks the `st_ctime` field of the file to be updated.

Special behavior for XPG4.2: If *owner* or *group* is specified as `(uid_t)-1` or `(gid_t)-1` respectively, the corresponding ID of the file is unchanged.

Returned value

If successful, chown() updates the owner, group, and change time for the file and returns 0.

If unsuccessful, chown() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The process does not have search permission on some component of the *pathname* prefix.

EINTR
Added for XPG4.2: The chown() function was interrupted by a signal which was caught.

EINVAL
owner or *group* is not a valid user ID (UID) or group ID (GID).

EIO **Added for XPG4.2:** An I/O error occurred while reading or writing to the file system.

ELOOP
A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT
There is no file named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR
Some component of the *pathname* prefix is not a directory.

EPERM
The effective user ID of the calling process does not match the owner of the file, or the calling process does not have appropriate privileges, that is, superuser authority (UID=0).

EROFS
pathname is on a read-only file system.

Example

CELEBC12

```
/* CELEBC12

   This example changes the owner and group of a file.

 */
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/stat.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  char fn[]="./temp.file";
  FILE *stream;
  struct stat info;

  if ((stream = fopen(fn, "w")) == NULL)
    perror("fopen() error");
  else {
    fclose(stream);
    stat(fn, &info);
    printf("original owner was %d and group was %d\n", info.st_uid,
           info.st_gid);
    if (chown(fn, 25, 0) != 0)
      perror("chown() error");
    else {
      stat(fn, &info);
      printf("after chown(), owner is %d and group is %d\n",
             info.st_uid, info.st_gid);
    }
    unlink(fn);
  }
}
```

Output

```
original owner was 0 and group was 0
after chown(), owner is 25 and group is 0
```

chpriority() — Change the scheduling priority of a process

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SOURCE 2
#include <sys/resource.h>

int chpriority(int which, id_t who, int prioritytype, int priority);
```

General description

The chpriority() function changes the scheduling priority of a process, process group or user.

Processes are specified by the values of the *which* and *who* arguments. The *which* argument may be one of the following values: PRIO_PROCESS, PRIO_PGRP, or PRIO_USER, indicating that the *who* argument is to be interpreted as a process ID, a process group ID, or a user ID, respectively. A 0 (zero) value for the *who* argument specifies the current process, process group or user ID.

If more than one process is specified, the chpriority() function changes the priorities of all of the specified processes.

The default priority is 0; negative priorities cause more favorable scheduling. The range of legal priority values is -20 to 19. If the CPRIO_ABSOLUTE value is specified for the *prioritytype* argument and the priority value specified to chpriority() is less than the system's lowest supported priority value, the system's lowest supported value is used; if it is greater than the system's highest supported value, the system's highest supported value is used. If the CPRIO_RELATIVE value is specified on the *prioritytype* argument, request for values above or below the legal limits result in the priority value being set to the corresponding limit.

The changing of a process's scheduling priority value has the equivalent effect of a process's nice value, since they both represent the process's relative CPU priority. For example, changing one's scheduling priority value using the chpriority() function to its maximum value (19) has the equivalent effect of increasing one's nice value to its maximum value 2*{NZERO}-1, and will be reflected on the nice(), getpriority(), chpriority(), and setpriority() functions.

Only a process with appropriate privilege can lower its priority. In addition to lowering the priority value, a process with appropriate privilege has the ability to change the priority of any process regardless of the process's saved set-user-ID value.

Returned value

If successful, chpriority() returns 0.

If unsuccessful, chpriority() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The priority is being changed to a lower value and the current process does not have the appropriate privilege.

EINVAL
The value of the *which* argument was not recognized, or the value of the *who* argument is not a valid process ID, process group ID or user ID, or the value of the *prioritytype* argument was not recognized.

ENOSYS
The system does not support this function.

EPERM
A process was located, but the save set-user-ID of the executing process does not match the saved set-user-ID of the process whose priority is to be changed.

ESRCH
No process could be located using the *which* and *who* argument values specified.

chroot() — Change root directory

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2	both	

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

int chroot(const char *path);
```

General description

The *path* argument points to a path name naming a directory. The chroot() function causes the named directory to become the root directory, that is the starting point for path searches for path names beginning with /. The process's working directory is unaffected by chroot(). Only a superuser can request chroot().

The dot-dot entry in the root directory is interpreted to mean the root directory. Thus, dot-dot cannot be used to access files outside the subtree rooted at the root directory.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, chroot() changes the root directory, and returns 0.

If unsuccessful, chroot() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EACCES
: Search permission is denied for a component of *path*

ELOOP
: A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of path name is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).

ENAMETOOLONG
: Path name is longer that **PATH_MAX** characters, or some component of path name is longer that **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values are determined using pathconf().

ENOENT
: A component of *path* does not name an existing directory or *path* is an empty string.

ENOTDIR
: A component of the *path* name is not a directory.

EPERM
: The effective user ID does not have appropriate privileges.

cimag(), cimagf(), cimagl() — Calculate the complex imaginary part

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double cimag(double complex z);
float cimagf(float complex z);
long double cimagl(long double complex z);
```

General description

The cimag() family of functions compute the imaginary part of *z*.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
cimag	X	X
cimagf	X	X
cimagl	X	X

Returned value

The cimag() family of functions return the imaginary part value (as a real).

Example

For an example of a similar function see cacos(), cexp() or cpow().

clearenv() — Clear environment variables

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1a Language Environment	both	

Format

POSIX - C only:

```
#define _POSIX1_SOURCE 2
#include <env.h>

int clearenv(void);
```

Non-POSIX:

```
#include <stdlib.h>

int clearenv(void);
```

General description

Clears all environment variables from the environment table and frees the associated storage.

clearenv() also resets all behavior modified by z/OS XL C/C++ specific environment variables back to their defaults. For example, if a binary file was opened, then it would support seeking by byte offsets, regardless of record format. If the file is a Variable Record format MVS DASD file, then clearing the environment variable causes seeking by encoded values the next time it is opened.

To avoid infringing on the user's name space, the non-POSIX version of this function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

For details about environment variables, see “Using Environment Variables” in *z/OS XL C/C++ Programming Guide*.

Special behavior for POSIX C: clearenv() can change the value of the pointer `environ`. Therefore, a copy of that pointer made before a call to clearenv() may no longer be valid after the call to clearenv().

Returned value

If successful, clearenv() returns 0.

If unsuccessful, clearenv() returns nonzero and sets errno to one of the following values:

Error Code
    Description

ENOMEM
    The process requires more space than is available.

Example

CELEBC13

```
/* CELEBC13

   This C/MVS example needs to be run with POSIX(ON).
   It clears the process environment variable list.

 */
#define _POSIX_SOURCE 1
#include <env.h>
#include <stdio.h>

extern char **environ;
```

```
int count_env() {
  int num;

  for (num=0; environ[num] != NULL; num++);
  return num;
}

main() {
  printf("before clearenv(), there are %d environment variables\n",
         count_env());
  if (clearenv() != 0)
    perror("clearenv() error");
  else {
    printf("after clearenv(), there are %d environment variables\n",
           count_env());
    setenv("var1", "value1", 1);
    setenv("var-two", "Value Two", 1);
    printf("after setenv()'s, there are %d environment variables\n",
           count_env());
    if (clearenv() != 0)
      perror("clearenv() error");
    else
      printf("after clearenv(), there are %d environment variables\n",
             count_env());
  }
}
```

Output

```
before clearenv(), there are 9 environment variables
after clearenv(), there are 0 environment variables
after setenv()'s, there are 2 environment variables
after clearenv(), there are 0 environment variables
```

CELEBC14

```
/* CELEBC14

   This example is for a non-POSIX environment, and thus will work under
   C++/MVS.

 */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
   char *x;

   /* set 3 environment variables to "Y" */
   setenv("_EDC_ANSI_OPEN_DEFAULT","Y",1);
   setenv("_EDC_BYTE_SEEK","Y",1);
   setenv("_EDC_COMPAT","3",1);

   /* query the setting of _EDC_BYTE_SEEK */
   x = getenv("_EDC_BYTE_SEEK");

   if (x != NULL)
      printf("_EDC_BYTE_SEEK = %s\n",x);
   else
      printf("_EDC_BYTE_SEEK is undefined\n");

/* clear the environment variable table */
   clearenv();

   /* query the setting of _EDC_BYTE_SEEK */
   x = getenv("_EDC_BYTE_SEEK");
   if (x != NULL)
      printf("_EDC_BYTE_SEEK = %s\n",x);
   else
      printf("_EDC_BYTE_SEEK is undefined\n");
}
```

Output

```
     _EDC_BYTE_SEEK = Y
     _EDC_BYTE_SEEK is undefined
```

clearerr() — Reset error and end of file (EOF)

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

void clearerr(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

void clearerr_unlocked (FILE *stream);
```

General description

Resets the error indicator and EOF indicator for the stream that `stream` points to. Generally, the indicators for a stream remain set until your program calls clearerr() or rewind().

clearerr_unlocked() is functionally equivalent to clearerr() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

clearerr() returns no values.

Example

CELEBC15

```
/* CELEBC15

   This example reads a data stream and then checks that a read
   error has not occurred.

 */
#include <stdio.h>

int main(void)
{
   char string[100];
   FILE *stream;
   int eofvalue;

   stream = fopen("myfile.dat", "r");

   /* scan an input stream until an end-of-file character is read */
   while (!feof(stream))
      fscanf(stream,"%s",&string[0]);

   /* print EOF value: will be nonzero */
   eofvalue=feof(stream);
   printf("feof value=%i\n",eofvalue);

   /* print EOF value-after clearerr, will be equal to zero */
   clearerr(stream);
   eofvalue=feof(stream);
   printf("feof value=%i\n",eofvalue);
}
```

clock() — Determine processor time

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <time.h>

clock_t clock(void);
```

General description

Approximates the processor time used by the program, since the beginning of an implementation-defined time period that is related to the program invocation. To measure the time spent in a program, call the clock() function at the start of the program, and subtract its returned value from the value returned by subsequent calls to clock(). Then, to obtain the time in seconds, divide the value returned by clock() by `CLOCKS_PER_SEC`.

If you use the system() function in your program, do not rely on clock() for program timing, because calls to system() may reset the clock.

In a multithread POSIX C application, if you are creating threads with a function that is based on a POSIX.4a draft standard, the clock() function is thread-scoped.

Returned value

If the time is available and can be represented, clock() returns the calculated time.

If unsuccessful, clock() returns (clock_t)-1. clock() may return -1 when running with STIMER REAL TQE present on MVS/ESA Version 3 Release 1 Modification 2 (or earlier) system.

Special behavior for XPG4: If _XOPEN_SOURCE or _XOPEN_SOURCE_EXTENDED are defined when your application is compiled, CLOCKS_PER_SEC is defined as 1000000. Also, in this case, the following C/370 pragma in the <time.h> header is used to compile your application:

```
#pragma map ( clock(), "@@OCLCK")
```

Because of this pragma, when your application executes, it will attempt to access an XPG4 version of clock() which returns a clock_t value in units of 1000000 CLOCKS_PER_SEC. The XPG4 version of clock() is only available if POSIX(ON) is specified for execution of your application.

If _XOPEN_SOURCE or _XOPEN_SOURCE_EXTENDED are defined when you compile your program AND your application is run with POSIX(OFF), clock() will return `(clock_t)-1`.

If neither _XOPEN_SOURCE or _XOPEN_SOURCE_EXTENDED are defined when you compile your application, the historical C/370 value of CLOCKS_PER_SEC will be used and clock() calls in your application will be mapped to the historical C/370 version of clock() which returns a clock_t value in historical C/370 CLOCKS_PER_SEC units whether your application executes with POSIX(ON) or POSIX(OFF).

Example

```
/*  This example prints the time elapsed since the program was invoked.  */
#include <time.h>
#include <stdio.h>

double time1, timedif;   /* use doubles to show small values */

int main(void)
{
    time1 = (double) clock();            /* get initial time */
    time1 = time1 / CLOCKS_PER_SEC;      /*    in seconds    */
⋮
    /* call clock a second time */
    timedif = ( ((double) clock()) / CLOCKS_PER_SEC) - time1;
    printf("The elapsed time is %f seconds\n", timedif);
}
```

clog(), clogf(), clogl() — Calculate the complex natural logarithm

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex clog(double complex z);
float complex clogf(float complex z);
long double complex clogl(long double complex z);
```

General description

The clog() family of functions compute the complex natural (base-e) logarithm of *z*, with a branch cut along the negative real axis.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
clog	X	X
clogf	X	X
clogl	X	X

Returned value

The clog() family of functions return the complex natural logarithm value, in the range of a strip, mathematically unbounded along the real axis and in the interval [-i *π*, +i *π*] along the imaginary axis.

Example

For an example of a similar function see cacos(), cexp() or cpow().

Related information

- "complex.h" on page 19
- "cexp(), cexpf(), cexpl() — Calculate the complex exponential" on page 253

close() — Close a file

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int close(int fildes);
```

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int close(int socket);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <unistd.h>

int close(int socket);
```

General description

Closes a file descriptor, *fildes*. This frees the file descriptor to be returned by future open() calls and other calls that create file descriptors. The *fildes* argument must represent a hierarchical file system (HFS) file.

When the last open file descriptor for a file is closed, the file itself is closed. If the file's link count is 0 at that time, its space is freed and the file becomes inaccessible.

When the last open file descriptor for a pipe or FIFO file is closed, any data remaining in the pipe or FIFO file is discarded.

close() unlocks (removes) all outstanding record locks that a process has on the associated file.

Behavior for sockets: close() call shuts down the socket associated with the socket descriptor *socket*, and frees resources allocated to the socket. If *socket* refers to an open TCP connection, the connection is closed. If a stream socket is closed when there is input data queued, the TCP connection is reset rather than being cleanly closed.

Parameter	Description
socket	The descriptor of the socket to be closed.

Note: All sockets should be closed before the end of your process. You should issue a shutdown() call before you issue a close() call for a socket.

For AF_INET and AF_INET6 stream sockets (SOCK_STREAM) using SO_LINGER socket option, the socket does not immediately end if data is still present when a close is issued. The following structure is used to set or unset this option, and it can be found in **sys/socket.h**.

```
struct linger {
   int l_onoff;      /* zero=off, nonzero=on */
   int l_linger;     /* time is seconds to linger */
};
```

If the l_onoff switch is nonzero, the system attempts to deliver any unsent messages. If a linger time is specified, the system waits for *n* seconds before flushing the data and terminating the socket.

For AF_UNIX, when closing sockets that were bound, you should also use unlink() to delete the file created at bind() time.

Special behavior for XPG4.2: If a STREAMS-based *fildes* is closed and the calling process was previously registered to receive a SIGPOLL signal for events associated with that STREAM, the calling process will be unregistered for events associated with the STREAM. The last close() for a STREAM causes the STREAM associated with *fildes* to be dismantled. If O_NONBLOCK is not set and there have been no signals posted for the STREAM, and if there is data on the module's write queue, close() waits for an unspecified time (for each module and driver) for any output to drain before dismantling the STREAM. The time delay can be changed using an I_SETCLTIME ioctl() request. If the O_NONBLOCK flag is set, or if there are any pending signals, close() does not wait for output to drain, and dismantles the STREAM immediately.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. See "open() — Open a file" on page 1152 for more information.

If *fildes* refers to the master side of a pseudoterminal, a SIGHUP signal is sent to the process group, if any, for which the slave side of the pseudoterminal is the controlling terminal.

If *fildes* refers to the slave side of a pseudoterminal, a zero-length message will be sent to the master.

If *fildes* refers to a socket, close() causes the socket to be destroyed. If the socket is connection-oriented and the SO_LINGER option is set for the socket and the socket has untransmitted data, then close() will block for up to the current linger interval until all data is transmitted.

Returned value

If successful, close() returns 0.

If unsuccessful, close() returns -1 and sets errno to one of the following values:

Error Code
  Description

EAGAIN
  The call did not complete because the specified socket descriptor is currently being used by another thread in the same process.

  For example, in a multithreaded environment, close() fails and returns EAGAIN when the following sequence of events occurs (1) thread is blocked in a read() or select() call on a given file or socket descriptor and (2) another thread issues a simultaneous close() call for the same descriptor.

EBADF
fildes is not a valid open file descriptor, or the *socket* parameter is not a valid socket descriptor.

EBUSY
The file cannot be closed because it is blocked.

EINTR
close() was interrupted by a signal. The file may or may not be closed.

EIO **Added for XPG4.2:** An I/O error occurred while reading from or writing to the file system.

ENXIO
fildes does not exist. The minor number for the file is incorrect.

Example

```
#define _POSIX_SOURCE
#include <fcntl.h>
#include <unistd.h>
#include <stdio.h>
#include <string.h>

main() {
  int fd;
  char out[20]="Test string";
  if ((fd = creat("./myfile", S_IRUSR | S_IWUSR)) < 0)
    perror("creat error");
  else {
    if (write(fd, out, strlen(out)+1) == -1)
    perror("write() error");

    if (fd = 0) perror("write() error");
    close(fd);
  }
}
```

closedir() — Close a directory

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <dirent.h>

int closedir(DIR *dir);
```

General description

Closes the directory indicated by *dir*. It frees the buffer that readdir() uses when reading the directory stream.

Returned value

If successful, closedir() returns 0.

If unsuccessful, closedir() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
dir does not refer to an open directory stream.

EINTR
closedir() was interrupted by a signal. The directory may or may not be closed.

Example

CELEBC18

```
/* CELEBC18

   This example closes a directory.

 */
#define _POSIX_SOURCE
#include <dirent.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  DIR *dir;
  struct dirent *entry;
  int count;

  if ((dir = opendir("/")) == NULL)
    perror("opendir() error");
  else {
    count = 0;
    while ((entry = readdir(dir)) != NULL) {
      printf("directory entry %03d: %s\n", ++count, entry->d_name);
    }
    closedir(dir);
  }
}
```

Output

```
directory entry 001: .
directory entry 002: ..
directory entry 003: bin
directory entry 004: dev
directory entry 005: etc
directory entry 006: lib
directory entry 007: tmp
directory entry 008: u
directory entry 009: usr
```

closelog() — Close the control log

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <syslog.h>

void closelog(void);
```

General description

The closelog() function closes the log file.

Returned value

closelog() neither accepts an input nor returns a result. The system control log is closed for this process.

No errors are defined.

Related information

clrmemf() — Clear memory files

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>

int clrmemf(int level);
```

General description

Removes memory files created by the current program and any program that was called using a non-POSIX system() call. clrmemf() can remove memory files regardless of whether they are open or not.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The argument *level* indicates which memory files are to be removed. The level can be one of the following:

__LOWER
Removes memory files that were created in other programs and called from this program using system().

__CURRENT
Removes only the memory files created at the current level.

__CURRENT_LOWER
Removes all the memory files created by the current program and by all the programs called at the current level.

Special behavior for multiple shared PICI C environments: Only files created by the C environment from which the clrmemf() function is called will be cleared.

Returned value

If successful, clrmemf() returns 0.

If unsuccessful, clrmemf() returns nonzero.

Example

```
/*
   In this example, when Program2 calls clrmemf()(__CURRENT) only
   A3.FILE and A4.FILE will be removed.
```

```
 */
/*****  Program1  *****/
⋮
   fp1 = fopen ("A1.FILE", "w,type=memory(hiperspace)");
   fp2 = fopen ("A2.FILE", "w,type=memory(hiperspace)");
   system("Program2");
⋮
/*****  Program2  *****/
⋮
   fp3 = fopen("A3.FILE","w,type=memory");
   fp4 = fopen("A4.FILE","w,type=memory");
   system("Program3");
⋮
   clrmemf(__CURRENT);
⋮
/*****  Program3  *****/
⋮
   fp5 = fopen("A5.FILE","w,type=memory");
   fp6 = fopen("A6.FILE","w,type=memory");
⋮
```

__cnvblk() — Convert block

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

void __cnvblk(char bits[8], char bytes[64], int flag);
```

General description

The __cnvblk() function maps an 8 character array, *bits*, of bits to or from a 64 character array, *bytes*, of bytes depending on the value of *flag*.

If the value of *flag* is 0, __cnvblk() sets all bytes in the *bytes* array to 0x00 for which the corresponding bits in the *bits* array have value 0, and it sets all bytes in the *bytes* array to 0x01 for which the corresponding bits in the *bits* array have value 1.

If the value of *flag* is **not** 0, __cnvblk() sets all bits in the *bits* array to 0 for which corresponding bytes in the *bytes* array have value 0x00, and it sets all bits in the *bits* array to 1 for which the corresponding bytes in the *bytes* array have value 0x01.

This function may be used to prepare input to setkey() or encrypt() functions and to map results back to 8 bit characters.

Returned value

If the value of *flag* is zero, __cnvblk() functions without error checking.

If the value of *flag* is nonzero, __cnvblk() checks for errors, and if found, sets errno to one of the following values:

Error Code
Description

EINVAL
The value of a byte in the array *bytes* is not 0x00 or 0x01.

Note: Because __cnvblk() returns no values, applications wishing to check for errors should set errno to 0, call __cnvblk(), then test errno and, if it is nonzero, assume an error has occurred.

Related information

collequiv() — Return a list of equivalent collating elements

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <collate.h>

int collequiv(collel_t c, collel_t **list);
```

General description

Finds all the collating elements whose primary weight is the same as the primary weight of c. It then updates the list to point to the first element of the array in which all the found elements are stored. The list of elements is valid until the next call to setlocale(), with categories LC_ALL, LC_COLLATE, or LC_CTYPE.

Another call to collequiv() may override the current list.

For information about the effect of setlocale() and locale.h, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

Returned value

If successful, collequiv() returns the number of collating elements found.

If the value of *c* is not in the valid range of collating elements in the current locale, collequiv() returns -1.

Notes:

1. If the collating element passed is specified with the weight of IGNORE in the LC_COLLATE category, the list returned will contain all the characters specified as IGNORE.
2. The list will only contain characters defined in the charmap file in the current locale.

Example

CELEBC22

```
/* CELEBC22

   This example prints the collating elements that have an
   equivalent weight as the collating element passed in
   argv[1].

 */
#include "stdio.h"
#include "locale.h"
#include "collate.h"
#include "stdlib.h"
#include "wctype.h"
#include "wchar.h"

main(int argc, char *argv[]) {
   collel_t e, *rp;
   int i;

   setlocale(LC_ALL, "");
   if ((e = strtocoll(argv[1])) == (collel_t)-1) {
      printf("'%s' collating element not defined\n", argv[1]);
      exit(1);
   }
   if ((i = collequiv(e, &rp)) == -1) {
      printf("Invalid collating element '%s'\n", argv[1]);
      exit(1);
   }
   for (; i-- > 0; rp++) {
      if (ismccollel(*rp))
         printf("'%s' ", colltostr(*rp));
      else if (iswprint(*rp))
         printf("'%lc' ", *rp);
      else
         printf("'%x' ", *rp);
   }
}
```

collorder() — Return list of collating elements

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <collate.h>

int collorder(collel_t **list);
```

General description

Finds the number of collating elements in the collate order list and sets a pointer to the list. The list returned is valid until another call to setlocale().

Notes:

1. Collating elements specified with the weight of IGNORE in the LC_COLLATE category are defined as having the lowest weight.
2. The list will only contain characters defined in the charmap file in the current locale.

Example

CELEBC23

```
/* CELEBC23

   This example creates a list of all the collating elements using
   the &collo. function.

 */
#include <stdio.h>
#include <locale.h>
#include <collate.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
   collel_t e, *rp;
   int i;

   setlocale(LC_ALL, "TEXAN.IBM-1024");
   i = collorder(&rp);
   for (; i-- > 0; rp++) {
      if (ismccollel(*rp))
         printf("'%s' ", colltostr(*rp));
      else if (iswprint(*rp))
         printf("'%lc' ", *rp);
      else
         printf("'%x' ", *rp);
   }
}
```

- “strtocoll() — Return collating element for string” on page 1763

collrange() — Calculate the range list of collating elements

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <collate.h>

int collrange(collel_t start, collel_t end, collel_t **list);
```

General description

Finds a list of collating elements whose primary weights are between the *start* and *end* points, inclusive. The number returned is the number of elements in the list, whose pointer is returned.

This value will be zero if the end point collates earlier than the *start* point. The list returned is valid until the next call to setlocale().

Returned value

If successful, collrange() returns the number of elements in the list, whose pointer is returned.

If either *start* or *end* are out of range, collrange() returns -1.

Notes:
1. Collating elements specified with the weight of IGNORE in the LC_COLLATE category are defined having the lowest weight. Therefore, such elements can only be specified as the starting collating element.
2. The list will only contain characters defined in the charmap file in the current locale.

Example

CELEBC24

```
/* CELEBC24

   This example prints the collating elements in the range
   between the start and end points passed in
   argv[1] and argv[2], using the
   &collrap. function.

 */
#include <stdio.h>
#include <locale.h>
#include <collate.h>
```

```
#include <stdlib.h>
#include <wctype.h>
#include <wchar.h>

main(int argc, char *argv[]) {
   collel_t s, e, *rp;
   int i;

   setlocale(LC_ALL, "TEXAN.IBM-1024");
   if ((s = strtocoll(argv[1])) == (collel_t)-1) {
      printf("'%s' collating element not defined\n", argv[1]);
      exit(1);
   }
   if ((e = strtocoll(argv[2])) == (collel_t)-1) {
      printf("'%s' collating element not defined\n", argv[2]);
      exit(1);
   }
   if ((i = collrange(s, e, &rp)) == -1) {
      printf("Invalid range for '%s' to '%s'\n", argv[1], argv[2]);
      exit(1);
   }
   for (; i-- > 0; rp++) {
      if (ismccollel(*rp))
         printf("'%s' ", colltostr(*rp));
      else if (iswprint(*rp))
         printf("'%lc' ", *rp);
      else
         printf("'%x' ", *rp);
   }
}
```

colltostr() — Return a string for a collating element

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <collate.h>

char *colltostr(collel_t c);
```

General description

Converts `c` to the string of the collating element. The colltostr() function is the inverse of strtocoll().

An application program can use the returned array from collrange() or collequiv(), calling ismccollel() on each element, only calling colltostr() if ismccollel() is true for the element. The string returned is valid until another call to setlocale().

Returned value

If a value is passed representing a single character or a value that is not in range, colltostr() returns NULL.

Example

CELEBC25

```
/* CELEBC25

   This example prints all the collating elements in the
   collating sequence, using the &colltop. function to get the
   string for the multi-character collating elements.

 */

#include <collate.h>
#include <locale.h>
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
   collel_t e, *rp;
   int i;

   setlocale(LC_ALL, "");
   i = collorder(&rp);
   for (; i-- > 0; rp++) {
      if (ismccollel(*rp))
         printf("'%s' ", colltostr(*rp));
      else if (iswprint(*rp))
         printf("'%lc' ", *rp);
      else
         printf("'%x' ", *rp);
   }
}
```

compile() — Compile regular expression

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2	both	

Format

```
#define INIT declarations
#define GETC() getc_code
#define PEEK() peek_code
#define UNGETC() ungetc_code
#define RETURN(ptr) return_code
#define ERROR(val) error_code

#define _XOPEN_SOURCE
#include <regexp.h>

char *compile(char *instring, char *expbuf, const char *endbuf, int eof);
```

General description

Restriction: This function is not supported in AMODE 64.

The compile() function takes as input a simple regular expression and produces a compiled expression that can be used with the step() and advance() functions.

The first parameter *instring* is never used explicitly by compile(). It is a pointer to a character string defining a source regular expression. It is useful for programs that pass down different pointers to input characters. Programs which invoke functions to input characters or have characters in an external array can pass down **(char *)0** for this parameter.

expbuf is a pointer to the place where the compiled regular expression will be placed.

endbuf points to one more than the highest address where the compiled regular expression may be placed. If the compiled expression cannot fit in (*endbuf*-*expbuf*) bytes, a call to ERROR(50) is made. (See "Returned Value" below.)

eof is the character which marks the end of the regular expression.

The z/OS UNIX services implementation of the compile() function does **not** accept internationalized simple expressions as input. Internationalized simple expressions (for example, [[=*c*=]] (an equivalence class)) may yield unpredictable results.

Programs must have the following five macros declared before the **#include <regexp.h>** statement. The macros GETC(), PEEKC() and UNGETC() operate on the regular expression given as input to compile().

GETC()
: This macro returns the value of the next character (byte) in the regular expression pattern. Successive calls to GETC() should return successive characters of the regular expression.

PEEK()
This macro returns the next character (byte) in the regular expression pattern. Immediate successive calls to PEEK() should return the same byte, which should also be the next character returned by GETC().

UNGETC(*c*)
This macro causes the argument *c* to be returned by the next call to GETC(). No more than one character is ever needed and this character is guaranteed to be the last character read by GETC(). The value of the macro UNGETC() is always ignored.

RETURN(*ptr*)
This macro is used on normal exit of the compile() function. The value of the argument *ptr* is a pointer to the character after the last character of the compiled regular expression.

ERROR(*val*)
This macro is the abnormal return from compile(). The argument *val* is an error number. (See "Returned Value" below for meanings.) This call should never return.

Notes:

1. z/OS UNIX services do not provide any default macros if the above user macros are not provided.
2. Each program that includes the **<regexp.h>** must have a **#define** statement for INIT. It is used for dependent declarations and initializations. For example, it can be used to set a variable to point to the beginning of the regular expression so that this variable can be used in the declarations for GETC(), PEEK(), and UNGETC().
3. The external variables *cirf*, *sed*, and *nbra* are reserved.
4. The application must provide the proper serialization for the compile(), step(), and advance() functions if they are run under a multithreaded environment.

Simple regular expressions

A Simple Regular Expression (SRE) specifies a set of character strings. The simplest form of regular expression is a string of characters with no special meaning. A small set of special characters, known as metacharacters, do have special meaning when encountered in patterns.

Expression
Meaning

c
The character *c* where *c* is not a special character.

\c
The character *c* where *c* is any special character. For example, `a\.e` is equivalent to `a.e`.

^
The beginning of the string being compared

$
The dollar symbol matches the end of the string.

.
The period symbol matches any one character.

[*string*]
A string within square brackets specifies any of the characters in *string*. Thus, `[abc]`, if compared to other strings, would match any which contained a, b, or c.

The] (right bracket) can be used alone within a pair of brackets, but only if it immediately follows either the opening left bracket or if it immediately follows [^.

Ranges may be specified as *c*–*c*. The hyphen symbol, within square brackets, means "through". It fills in the intervening characters according to the collating sequence. For example, [a–z] is equivalent to [abc...xyz]. If the end character in the range is lower in collating sequence to the start character, then only the range start and range end characters are accepted in the search pattern. For example, [9–1] is equivalent to [91]. Note that ranges in Simple Regular Expressions are only valid if the LC_COLLATE category is set to the C locale.

The – (hyphen) can be used by itself, but only if it is the first or last character in the expression. For example, the expression []*a-f*] matches either the] or one of the characters `a` through *f*.

[^*string*]
The caret symbol, when inside square brackets, negates the characters within the square brackets. Thus, `[^abc]`, if compared to other strings, would *fail* to match any which contains even one a, b, or c.

Note: Characters **.**, *, [, and \ (period, asterisk, left square bracket, and backslash, respectively) have special meaning, except when they appear within square brackets ([]), or are preceded by \.

* The asterisk symbol indicates 0 or more of any preceding characters. For example, (`a*e`) will match any of the following: `e, ae, aae, aaae, ....` The longest leftmost match is chosen.

rx The occurrence of regular expression *r* followed by the occurrence of regular expression *x*.

\{*m*\} \{*m*,\} \{*m*,*u*\}
Integer values enclosed in \{\} indicate the number of times to apply the preceding regular expression. *m* is the minimum number and *u* is the maximum number. *u* must be less than 256. If you specify only *m*, it indicates the exact number of times to apply the regular expression.

\{*m*,\} is equivalent to \{*m*,*255*\}. They both match *m* or more occurrences of the expression. The * (asterisk) operation is equivalent to \{0,\}.

The maximum number of occurrences is matched.

\(*r***\)** The regular expression *r*. The \(and \) sequences are ignored.

\n When \n (where 1 <= *n* <= 9) appears in a concatenated regular expression, it stands for the regular expression *x*, where *x* is the *n*th regular expression enclosed in \(and \) sequences that appeared earlier in the concatenated regular expression. For example, in the pattern \\(*c*\\)*onc*\\(*ate*\\)*n*\2, the \2 is equivalent to *ate*, giving *concatenate*.

The character ^ at the beginning of an expression permits a successful match only immediately after a newline or at the beginning of each of the string to which a match is to be applied. The character $ at the end of an expression requires a trailing newline.

Notes:

1. The compile() function is physically embedded in the **regexp.h** header. This header will be protected from multiple invocations just like other c headers.

2. The compile(), step(), and advance() functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions fnmatch(), glob(), regcomp() and regexec(), which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

Returned value

If successful, compile() exits using the user-provided macro RETURN(*ptr*). The value of the argument *ptr* is a pointer to the character after the last character of the compiled regular expression.

If unsuccessful, compile() exits using the user-provided macro ERROR(*val*). The argument *val* is an error number identifying the error. The following error numbers are defined:

Errcode	**Description String**
11	Range endpoint too large
16	Bad number
25	\digit out of range
36	Illegal or missing delimiter
41	No remembered search string
42	\\(\\) imbalance
43	Too many \\(
44	More than two numbers given in \\{ \\}
45	} expected after \\
46	First number exceeds second in \\{ \\}
49	[ ] imbalance
50	Regular expression overflow

confstr() — Get configurable variables

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

size_t confstr(int name, char *buf, size_t len);
```

General description

The confstr() function provides a method for applications to get configuration-defined string values. Its use and purpose are similar to the sysconf() function, but it is used where string values rather than numeric values are returned.

The *name* argument represents the system variable to be queried. It may be any one of the following symbolic constants, defined in <unistd.h>:

_CS_PATH
Request the value of the **PATH** environment variable that will find all standard utilities.

_CS_POSIX_V6_ILP32_OFF32_CFLAGS
Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 32-bit types.

_CS_POSIX_V6_ILP32_OFF32_LDFLAGS
Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit types.

_CS_POSIX_V6_ILP32_OFF32_LIBS
Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int, long, pointer, and off_t types.

_CS_POSIX_V6_ILP32_OFFBIG_CFLAGS
Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

_CS_POSIX_V6_ILP32_OFFBIG_LDFLAGS
Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

CS_POSIX_V6_ILP32_OFFBIG_LIBS
Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

_CS_POSIX_V6_LP64_OFF64_CFLAGS
Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LP64_OFF64_LDFLAGS
Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LP64_OFF64_LIBS
Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LPBIG_OFFBIG_CFLAGS
Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_LPBIG_OFFBIG_LDFLAGS
Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_LPBIG_OFFBIG_LIBS
Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_WIDTH_RESTRICTED_ENVS
Request the list of names of programming environments supported by the implementation in which the widths of the blksize_t, cc_t, mode_t, nfds_t, pid_t, ptrdiff_t, size_t, speed_t, ssize_t, suseconds_t, tcflag_t, useconds_t, wchar_t, and wint_t types are no greater than the width of type long.

z/OS UNIX services use the following constant:

_CS_SHELL
Request the fully qualified name of the default shell.

If the *len* argument is not zero, and if the *name* argument has a configuration-defined value, confstr() copies that value into the buffer pointed to by the *buf* argument. If the value to be returned is longer than *len* bytes, including the . terminating NULL, then confstr() truncates the string to *len*-1 bytes and NULL-terminates the results. The application can detect that the string was truncated by comparing the value returned by confstr() with *len*.

If the *len* argument is zero, and the *buf* argument is a NULL pointer, then confstr() still returns the integer value defined below, but does not return a string. If the *len* argument is zero, but the *buf* argument is not a NULL pointer the results are unspecified.

Returned value

If *name* has a configuration-defined value, confstr() returns the size of the buffer that would be needed to hold the entire configuration-defined string value. If this return value is greater than *len*, the string returned in *buf* is truncated.

If *name* does not have a configuration-defined value, confstr() returns 0 and leaves errno unchanged.

If *name* is not valid, confstr() returns 0 and sets errno to one of the following values:

Error Code
Description

EINVAL
The value of the *name* argument is not valid.

conj(), conjf(), conjl() — Calculate the complex conjugate

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex conj(double complex z);
float complex conjf(float complex z);
long double complex conjl(long double complex z);
```

General description

The conj() family of functions compute the complex conjugate of *z* by reversing the sign of its imaginary part.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
conj	X	X
conjf	X	X
conjl	X	X

Returned value

If successful, they return the complex conjugate value.

Example

```
/*
 *  This example illustrates the complex conjugate function
 */
#include <complex.h>
#include <stdio.h>

void main()
{
   long double complex z = -2.99 - I*3.99, zres;
   zres = conjl(z);
   printf("The complex conjugate of %Lf + %Lf*I is %Lf + %Lf*I\n",creall(z), cimagl(z), zres);
}

Output
The complex conjugate of -2.990000 + -3.990000*I is -2.990000 + 3.990000*I
```

connect() — Connect a socket

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int connect(int socket, const struct sockaddr *address, socklen_t address_len);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int connect(int socket, struct sockaddr *address, int address_len);
```

General description

For stream sockets, the connect() call attempts to establish a connection between two sockets. For datagram sockets, the connect() call specifies the peer for a socket. The *socket* parameter is the socket used to originate the connection request. The connect() call performs two tasks when called for a stream socket. First, it completes the binding necessary for a stream socket (in case it has not been previously bound using the bind() call). Second, it attempts to make a connection to another socket.

Note: For the X/Open socket function, the *socket* description applies to *socket*, *address* to *address*, and *address_len* to *address_len*. **const** is added to **struct sockaddr**.

Parameter
Description

socket The socket descriptor.

address The pointer to a socket address structure containing the address of the socket to which a connection will be attempted.

address_len
The size of the socket address pointed to by *address* in bytes.

The connect() call on a stream socket is used by the client application to establish a connection to a server. The server must have a passive open pending. A server that is using sockets must successfully call bind() and listen() before a connection can be accepted by the server with accept(). Otherwise, connect() returns -1 and the error code is set to ECONNREFUSED.

If *socket* is in blocking mode, the connect() call blocks the caller until the connection is set up, or until an error is received. If *socket* is in non-blocking mode, the connect returns immediately with a return code of -1 and an errno of EINPROGRESS. The caller can test the completion of the connection setup by calling select() and testing for the ability to write to the socket.

When called for a datagram socket, connect() specifies the peer with which this socket is associated. This gives the application the ability to use data transfer calls reserved for sockets that are in the connected state. In this case, read(), write(), readv(), writev(), send(), and recv() calls are then available in addition to sendto(), recvfrom(), sendmsg(), and recvmsg() calls. Stream sockets can call connect() only once, but datagram sockets can call connect() multiple times to change their association. Datagram sockets can dissolve their association by connecting to an incorrect address, such as the NULL address (all fields zeroed).

The *address* parameter is a pointer to a buffer containing the name of the peer to which the application needs to connect. The *address_len* parameter is the size, in bytes, of the buffer pointed to by *address*.

Servers in the AF_INET domain: If the server is in the AF_INET domain, the format of the name buffer is expected to be **sockaddr_in**, as defined in the include file **netinet/in.h**.

```
struct in_addr
{
        ip_addr_t s_addr;
};

 struct sockaddr_in {
     unsigned char  sin_len;
     unsigned char  sin_family;
     unsigned short sin_port;
     struct in_addr sin_addr;
     unsigned char  sin_zero[8];

};
```

The *sin_family* field must be set to AF_INET. The *sin_port* field is set to the port to which the server is bound. It must be specified in network byte order. The *sin_zero* field is not used and must be set to all zeros.

Servers in the AF_INET6 domain: If the server is in the AF_INET6 domain, the format of the name buffer is expected to be **sockaddr_in6**, as defined in the **netinet/in.h**:

```
 struct sockaddr_in6 {
     uint8_t char    sin6_len;
     sa_family_t     sin6_family;
     in_port_t       sin6_port;
     uint32_t        sin6_flowinfo;
     struct in6_addr sin6_addr;
     uint32_t        sin6_scope_id;
];
```

The *sin6_family* must be set to AF_INET6.

Servers in the AF_UNIX domain: If the server is in the AF_UNIX domain, the format of the name buffer is expected to be **sockaddr_un**, as defined in the include file **un.h**.

```
 struct sockaddr_un {
    unsigned char  sun_len;
    unsigned char  sun_family;
             char  sun_path[108];       /* path name */
};
```

The *sun_family* field is set to AF_UNIX. The *sun_path* field contains the NULL-terminated path name, and *sun_len* contains the length of the path name.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The connect() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, connect() returns 0.

If unsuccessful, connect() returns -1 and sets errno to one of the following values:

Error Code
Description

EADDRNOTAVAIL
The specified address is not available from the local machine.

EAFNOSUPPORT
The address family is not supported.

EALREADY
The socket descriptor *socket* is marked nonblocking, and a previous connection attempt has not completed.

EBADF
The *socket* parameter is not a valid socket descriptor.

ECONNREFUSED
The connection request was rejected by the destination host.

EFAULT
Using *address* and *address_len* would result in an attempt to copy the address into a portion of the caller's address space to which data cannot be written.

EINTR
The attempt to establish a connection was interrupted by delivery of a signal that was caught. The connection will be established asynchronously.

EINVAL
The *address_len* parameter is not a valid length.

EIO There has been a network or a transport failure.

EISCONN
The socket descriptor *socket* is already connected.

ENETUNREACH
The network cannot be reached from this host.

ENOTSOCK
The descriptor refers to a file, not a socket.

EOPNOTSUPP
The *socket* parameter is not of type SOCK_STREAM.

EPERM
connect() caller was attempting to extract a user's identity and the caller's process was not verified to be a server. To be server-verified, the caller's process must have permission to the BPX.SERVER profile (or superuser

and BPX.SERVER is undefined) and have called either the __passwd() or pthread_security_np() services before calling connect() to propagate identity.

EPROTOTYPE
The protocol is the wrong type for this socket.

ETIMEDOUT
The connection establishment timed out before a connection was made.

The following are for AF_UNIX only:

Error Code
Description

EACCES
Search permission is denied for a component of the path prefix, or write access to the named socket is denied.

EIO An I/O error occurred while reading from or writing to the file system.

ELOOP
Too many symbolic links were encountered in translating the path name in *address*.

ENAMETOOLONG
A component of a path name exceeded **NAME_MAX** characters, or an entire path name exceeded **PATH_MAX** characters.

ENOENT
A component of the path name does not name an existing file or the path name is an empty string.

ENOTDIR
A component of the path prefix of the path name in *address* is not a directory.

Example

The following are examples of the connect() call. The Internet address and port must be in network byte order. To put the port into network byte order, the htons() utility routine is called to convert a short integer from host byte order to network byte order. The *address* field is set using another utility routine, inet_addr(), which takes a character string representing the dotted-decimal address of an interface and returns the binary Internet address representation in network byte order. Finally, it is a good idea to zero the structure before using it to ensure that the name requested does not set any reserved fields. These examples could be used to connect to the servers shown in the examples listed with the call, “bind() — Bind a name to a socket” on page 210.

```
int s;
struct sockaddr_in inet_server;
struct sockaddr_un unix_server;
int rc;
int connect(int s, struct sockaddr *name, int namelen);

/* Connect to server bound to a specific interface in the
Internet domain */
/* make sure the sin_zero field is cleared */
memset(&inet_server, 0, sizeof(inet_server));
inet_server.sin_family = AF_INET;
inet_server.sin_addr.s_addr = inet_addr("129.5.24.1");
/* specific interface */
```

```
inet_server.sin_port = htons(1024);
⋮
rc = connect(s, (struct sockaddr *) &inet_server,
sizeof(inet_server));

/* Connect to a server bound to a name in the UNIX domain */
/* make sure the sunix_addr, sunix_port, sunix_nodeid fields are cleared
*/
memset(&unix_server, 0, sizeof(unix_server));
unix_server.sun_family = AF_UNIX;
strncpy(unix_server.sun_path, "mysocket");
unix_server.sun_len = sizeof(unix_server.sun_len);
strncpy(mvsservername.sunix_name, "APPL    ", 8);
⋮
rc = connect(s, (struct sockaddr *)
&unix_server, sizeof(unix_server));
```

ConnectExportImport() — WLM connect for export or import use

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R9

Format

```
#include <sys/__wlm.h>

unsigned long ConnextExportImport(const char *subsystype,
                                  const char *subsysname);
```

AMODE 64:

```
#include <sys/__wlm.h>

unsigned int ConnextExportImport(const char *subsystype,
                                 const char *subsysname);
```

General description

Provides the ability for an application to connect to WLM to use the ExportWorkUnit(), UndoExportWorkUnit(), ImportWorkUnit(), and UndoImportWorkUnit() functions.

Note that if you need to use the CreateWorkUnit() function, you should use ConnectWorkMgr() instead.

The ConnectExportImport() function uses the following parameters:

**subsystype*
: Points to a NULL-terminated character string containing the subsystem type by which to identify the connector. The export and import functions do not use the string. A meaningful string should be used since it can appear in WLMDATA IPCS reports. The character string can be up to 4 bytes in length.

**subsysname*
: Points to a NULL-terminated character string containing the subsystem name by which to identify the connector. The export and import functions do not use the string. A meaningful string should be used since it can appear in WLMDATA IPCS reports. The character string can be up to 8 bytes in length.

Returned value

If successful, ConnectExportImport() returns 0.

If unsuccessful, ConnectExportImport() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EFAULT
: An argument of this function contained an address that was not accessible to the caller.

EINVAL
: An argument of this function contained a value that is not correct.

EMVSWLMERROR
: A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.

ConnectServer() — Connect to WLM as a server manager

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

unsigned long ConnectServer(const char *subsystype,
                            const char *subsysname,
                            const char *applenv,
                            int *paralleleu);
```

AMODE 64:

```
#include <sys/__wlm.h>

unsigned int ConnectServer(const char *subsystype,
                           const char *subsysname,
                           const char *applenv,
                           int *paralleleu);
```

General description

The ConnectServer function provides the ability for an application to connect to WLM as a WLM server manager to perform WLM server manager functions.

**subsystype*
: Points to a NULL-terminated character string containing the generic subsystem type (CICS, IMS, WEB, etc.). This is the primary category under which WLM classification rules are grouped. The character string can be up to 4 bytes in length.

**subsysname*
: Points to a NULL-terminated character string containing the subsystem name used for classifying work requests. The character string can be up to 8 bytes in length.

**applenv*
: Points to a NULL-terminated character string that contains the name of the application environment under which work requests are processed. The character string can be up to 32 bytes in length.

**paralleleu*
: Points to an integer which contains the maximum number of tasks within the address space which will be created to process concurrent work requests.

Returned value

If successful, ConnectServer() returns a nonzero value representing a WLM connect token.

If unsuccessful, ConnectServer() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EFAULT
: An argument of this function contained an address that was not accessible to the caller.

EINVAL
: An argument of this function contained an incorrect value.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM connect failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

ConnectWorkMgr() — Connect to WLM as a work manager

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

unsigned long ConnectWorkMgr(const char *subsystype,
                              const char *subsysname);
```

AMODE 64:

```
#include <sys/__wlm.h>

unsigned int ConnectWorkMgr(const char *subsystype,
                             const char *subsysname);
```

General description

The ConnectServer function provides the ability for an application to connect to WLM as a WLM work manager to perform WLM work manager functions.

**subsystype*
Points to a NULL-terminated character string containing the generic subsystem type (CICS, IMS, WEB, etc.). This is the primary category under which WLM classification rules are grouped. The character string can be up to 4 bytes in length.

**subsysname*
Points to a NULL-terminated character string containing the subsystem name used for classifying work requests. The character string can be up to 8 bytes in length.

Returned value

If successful, ConnectServer() returns a nonzero value representing a WLM connect token.

If unsuccessful, ConnectServer() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
An argument of this function contained an address that was not accessible to the caller.

EINVAL
An argument of this function contained an incorrect value.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM connect failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

__console() — Console communication services

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__messag.h>

int __console(struct __cons_msg *cons, char *modstr, int *concmd);
```

General description

The __console() function is used to communicate with the operator's console. The __console() function allows users to send messages to the operator's console and to wait on a modify/stop request from the console.

The parameters supported are:

cons
If the argument is not NULL, it points to a structure specifying the message that is to be sent to the operator's console. If the argument is NULL then no message is sent.

modstr
Specifies the string where __console() returns the data entered at the operator's console. If modstr is not NULL the invoker will wait until an operator MODIFY's the invoking job and specifies 'APPL=' parameter. The length of modstr should be 128-byte. See *z/OS MVS System Commands* for more information on the MODIFY console command. If the argument is NULL then the __console() function will not wait on operator console commands.

concmd
If a console command was issued against the invoking job, the __console() function will set the command type. Valid types are, _CC_modify (function received a modify request) and _CC_stop (function received a stop request).

The cons structure is defined in the <sys/__messag.h> header and has the following format.

```
    struct __cons_msg   {
      short __reserved0;
      char  __reserved1[2];
      union   {
         struct   {
            int  __msg_length;
            char *__msg;
            char __reserved2[8];
         } __f1;
      }  __format;
    };
```

__reserved0
Reserved for future use.

__reserved1[2]
Reserved for future use.

__format.__f1.__msg_length
Length of message, not including the NULL terminator.

__format.__f1.__msg
A character string containing the message to be sent to the operator console.

__format.__f1.__reserved2[8]
Reserved for future use.

Note: The length of the message must be between 1 and 17850 characters for invokers with appropriate privileges, and between 1 and 17780 for invokers without appropriate privileges. The number of lines written to the console is limited to 255. In the case of an unprivileged user, one of those lines is used for the message ID and the invoker's login name. If the message length is exceeded, no lines are written and the service returns an EINVAL. If the number of lines is exceeded, the service returns an EINVAL, but the first 255 lines are written to the console.

Returned value

If successful, __console() returns 0.

If unsuccessful, __console() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EFAULT
: One of the following errors was detected:
- All or part of the cons structure is not addressable by the caller.
- All or part of the modstr string is not addressable by the caller.

EINTR
: __console() was interrupted by a signal.

EINVAL
: The *cons* structure contains errors.

EMVSERR
: z/OS environmental or internal error has occurred.

Example

CELEBC41

```
/* CELEBC41

   This example prints a simple message to the console using the
   __console() function.

 */
#include <sys/__messag.h>
#include <errno.h>
#include <string.h>
#include <stdio.h>

int main(int argc, char** argv) {
   struct __cons_msg cmsg;
   char buf[256] = "A message on the console";
   int rc;
   int cmsg_cmd = 0;

   /* fill in the __cons_msg structure */
   cmsg.__format.__f1.__msg = buf;
   cmsg.__format.__f1.__msg_length = strlen(buf);

   rc = __console(&cmsg,NULL,&cmsg_cmd);
   if(rc == -1) {
      printf("__console() failed\n");
      printf("%s\n",strerror(errno));
   }
   else {
      printf("__console() successful. Check console for message.\n");
   }

   return 0;
}
```

Related information

- “sys/__messag.h” on page 73
- “__console2() — Enhanced console communication services”

__console2() — Enhanced console communication services

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R10

Format

```
#include <sys/__messag.h>

int __console2(struct __cons_msg2 *cons, char *modstr, int *concmd);
```

General description

The __console2() function is used to communicate with the operator console. The __console2() function allows users to send messages to the operator console with the ability to specify routing codes and message descriptor codes, wait on a modify or stop request from the console, and to delete messages from operator console using either a message ID or token.

The __console2() function parameters are as follows:

cons
Specifies the address of the structure containing the console communication information. The mapping of the structure is provided below. If this parameter is NULL, then no message is sent to the operator console and no messages are deleted from the console.

modstr
Address of a 128-byte buffer that is to be used to receive a string of EBCDIC data from the console MODIFY command. All characters that appear to the right of the “APPL=” are placed into this buffer, left justified. The data returned is folded to uppercase. If this parameter is NULL, then the __console2() function does not wait on operator console commands.

concmd
Address of a 32-bit integer where the __console2() function returns the type of command that was issued on the console. If this parameter is set to NULL, the __console2() function will fail with EFAULT. The command types are:

_CC_modify
Function received a modify request.

_CC_stop
Function received a stop request.

The console communication information is specified in a structure pointed to by the *cons* parameter. The structure contains the following fields:

__cm2_format

Specifies the format of the structure. This field must be set to one of the following:

__CONSOLE_FORMAT_2

Used to indicate structure format 2.

__CONSOLE_FORMAT_3

Used to indicate structure format 3.

__cm2_msglength

The length of the message to be written to the console. A value of zero indicates that no message is to be sent to the operator console.

Notes:

1. The length of the message must be between 1 and 17850 characters for authorized users, and between 1 and 17780 for unauthorized users. The number of lines written to the console is limited to 255. In the case of an unauthorized user, one of those lines is used for the message ID and the user ID of the user. If the message length is exceeded, no lines are written and the service returns an EINVAL error code. If the number of lines is exceeded, the service returns an EINVAL error code, but the first 255 lines are written to the console.
2. An authorized user is one with appropriate privileges, as described in the "Authorization" topic in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

__cm2_msg

Pointer to a NULL terminated string containing the message to be written to the console. A value of NULL indicates no message is to be sent to the operator console.

__cm2_routcde

Pointer to an unsigned integer array containing the routing codes to be assigned to the message. The array is terminated by a zero value. Allowable routing codes are 1 to 128 for authorized users, and 1 to 28 for unauthorized users. For more information on routing codes, see *z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO*.

Note: An authorized user is one with appropriate privileges, as described in the "Authorization" topic in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

__cm2_descr

Pointer to an unsigned integer array containing the message descriptor codes to be assigned to the message. The array is terminated by a zero value. Allowable descriptor codes are 1 to 13. Descriptor codes 1 through 6, 11, and 12 are mutually exclusive. Codes 7 through 10, and 13 can be assigned in combination with any other code. For more information on descriptor codes, see *z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO*.

__cm2_mcsflag

Specifies one or more of the following flags:

__CONSOLE_HRDCPY

Queue the message for hard copy only. The message will not be displayed on the console.

__cm2_token
Specifies a 4-byte token to be associated with this message. This field is used to identify a group of messages which can be deleted using the DOM feature of the __console2() function. The token must be unique within an address space and can be any value. A token value of zero indicates no token is specified and the message issued will not be associated with any token.

__cm2_msgid
An unsigned 32-bit integer field where the __console2() function will place the message ID associated with the message last sent to the console. This message ID can be used to delete a message when it is no longer needed by specifying it using the DOM feature of the __console2() function. A value of NULL indicates that the message ID is not to be returned.

Note: The value returned in __cm2_msgid is an internal message identifier associated with the message written to the console. The value is not text and it should not be confused with any textual part of a message that might otherwise be considered a message ID.

__cm2_dom_token
Specifies a 4-byte token which represents a message or group of messages to be deleted from the console. All messages previously issued with this token will be deleted from the console. This field is mutually exclusive with __cm2_dom_msgid. A value of zero indicates that no token is specified.

__cm2_dom_msgid
Pointer to an unsigned integer array containing message IDs to be deleted from the console. A maximum of 60 message IDs can be in the array. The array is terminated by a zero value. The array terminator is not part of the 60 message IDs. This field is mutually exclusive with __cm2_dom_token. A value of NULL indicates that no message IDs are specified.

The console communication information structure includes the following additional fields when using the __CONSOLE_FORMAT_3 format. These fields are not available when using the __CONSOLE_FORMAT_2 format.

__cm2_mod_cartptr
Pointer to the 8-byte command and response token (CART) returned by a MODIFY or STOP command.

__cm2_mod_considptr
Pointer to the 4-byte console ID returned by a MODIFY or STOP command.

__cm2_msg_cart
Specifies an 8-byte CART to be used on WTO when the message is issued.

__cm2_msg_consid
Specifies a 4-byte console ID to be used on WTO when the message is issued.

Note: All operations can be done in a single request. The order of operation is to issue messages, delete messages, and then wait for a MODIFY or STOP command.

Returned value

If successful, __console2() returns 0.

If unsuccessful, __console2() returns -1 and sets ERRNO to one of the following values:

Error Code
Description

EFAULT
The __console2() function was unable to address all or part of the *cons* structure, all of part of the routing codes array, all or part of the descriptor codes array, all or part of the array of DOM message IDs, all or part of the *modstr*, or the *concmd* parameter was NULL.

Another possible cause is that __cm2_msgid points to storage which is not accessible.

EINTR
The __console2() function was interrupted by a signal.

EINVAL
The structure pointed to by *cons* contains errors.

For example, mutually exclusive parameters were specified, a non-valid routing code was specified, a non-valid descriptor code or mutually exclusive descriptor codes were specified, or there were more than 60 entries in the array of DOM message IDs.

EMVSERR
A z/OS environmental or internal error has occurred. Use the __errno2() function to obtain diagnostic information that will help determine the cause of the problem.

EPERM
An unauthorized user specified a routing code in the range 29 through 128. Only authorized (superuser) users (UID=0) can specify routing codes in that range.

Example

CELEBC42

```
/* CELEBC42

   This example prints a simple message to the console using the
   __console2() function.  A routing and descriptor code are also
   assigned to the message.

 */
#include <sys/__messag.h>
#include <errno.h>
#include <string.h>
#include <stdio.h>

int main(int argc, char** argv) {
   struct __cons_msg2 cmsg;
   char buf[256] = "A message on the console";
   int rc;
   int cmsg_cmd;
   unsigned int cmsg_rout[2] = {1,0};
   unsigned int cmsg_desc[2] = {12,0};

   /* Fill in the __cons_msg2 struct */
   cmsg.__cm2_format = __CONSOLE_FORMAT_2;
   cmsg.__cm2_msg = buf;
   cmsg.__cm2_msglength = strlen(buf);
   cmsg.__cm2_routcde = cmsg_rout;
   cmsg.__cm2_descr = cmsg_desc;
   cmsg.__cm2_token = 0;
   cmsg.__cm2_msgid = NULL;
   cmsg.__cm2_dom_token = 0;

   rc = __console2(&cmsg,NULL,&cmsg_cmd);
   if(rc == -1) {
      printf("__console2() failed\n");
      printf("%s\n",strerror(errno));
   }
   else {
      printf("__console2() successful. Check console for message\n");
   }

   return 0;
}
```

ContinueWorkUnit() — Continue WLM work unit

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

int ContinueWorkUnit(wlmetok_t *enclavetoken);
```

General description

The ContinueWorkUnit function provides the ability for an application to create a WLM work unit that represents a continuation of the work unit associated with the current home address space.

**enclavetoken*
: Points to a data field of type wlmetok_t where the ContinueWorkUnit() function is to return the WLM work unit enclave token.

Returned value

If successful, ContinueWorkUnit() returns 0.

If unsuccessful, ContinueWorkUnit() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EFAULT
: An argument of this function contained an address that was not accessible to the caller.

EINVAL
: An argument of this function contained an incorrect value.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM create enclave failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

__convert_id_np() — Convert between DCE UUID and user ID

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <unistd.h>

int __convert_id_np(int function_code,
                    char *principal_uuid,
                    char *cell_uuid,
                    char *userid);
```

General description

The __convert_id_np() function is used to retrieve the DCE UUID associated with a userid or the userid associated with a DCE UUID.

This function is intended for DCE servers which process requests from multiple clients. For example, DCE RPC requests from clients are identified by a DCE UUID only. This function enables servers to extract the userid of the requester.

The parameters supported are:

function_code
Identifies whether extracting a userid or UUID. Possible function codes are:

__GET_USERID
Return the userid associated with the specified UUIDs.

__GET_UUID
Return the UUIDs associated with the specified userid.

principal_uuid
When __GET_USERID is specified, *principal_uuid* contains the UUID of the user for the specified userid. When __GET_UUID is specified, *principal_uuid* returns the extracted UUID for the userid specified. The caller must provide a 36-byte field for the returned *principal_uuid*.

cell_uuid
When _GET_USERID is specified, *cell_uuid* should contain the cell UUID if known. If not known, *cell_uuid* must be NULL. When __GET_UUID is specified, *cell_uuid* will return the extracted cell UUID, if it is defined for the specified userid. The caller must provide a 36-byte field for the returned *cell_uuid*.

userid When _GET_USERID is specified, *userid* will return the extracted userid for the specified UUID. The caller must provide a 9 byte field for the returned userid. When __GET_UUID is specified, *userid* contains the userid for whom the UUID should be extracted. The userid must be 1 to 8 characters in length.

Returned value

If successful, __convert_id_np() returns 0.

If unsuccessful, __convert_id_np() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
One of the following errors was detected:
- function_code specified is undefined.
- __GET_UUID was specified and userid is not in the range 1 to 8 characters long.
- __GET_USERID was specified and userid was not 9 character long

EMVSERR
An MVS environmental or internal error occurred.

EMVSSAF2ERR
One of the following errors was detected:
- Received an unexpected return code for the security product.
- The security product detected an error in the input parameters.
- An internal error occurred in the security product.

ENOSYS
One of the following errors was detected:
- No security product is installed on the system.
- The security product does not have support for this function.

ESRCH
One of the following errors was detected:
- No mapping exists between a UUID and Userid.
- No mapping exists between a Userid and UUID.
- The DCEUUIDS class is not active.

- __GET_UUID was specified and no cell UUID is defined for the userid.
- The userid is not defined to the security product.

copysign(), copysignf(), copysignl() — Copy the sign from one floating-point number to another

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	OS/390 V2R6

Format

```
#define _AIX_COMPATIBILITY
#include <math.h>
#include <float.h>

double copysign(double x, double y);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>
#include <float.h>

float copysignf(float x, float y);
long double copysignl(long double x, long  double y);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float copysign(float x, float y);
long double copysign(long double x, long double y);
```

General description

The copysign functions produce a value with the magnitude of *x* and the sign of *y*.

Restriction: The copysignf() function does not support the _FP_MODE_VARIABLE feature test macro.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
copysign	X	X
copysignf	X	X
copysignl	X	X

Returned value

The copysign functions return a value with the magnitude of *x* and the sign of *y*.

copysignd32(), copysignd64(), copysignd128() — Copy the sign from one floating-point number to another

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  copysignd32(_Decimal32 x, _Decimal32 y);
_Decimal64  copysignd64(_Decimal64 x, _Decimal64 y);
_Decimal128 copysignd128(_Decimal128 x, _Decimal128 y);

_Decimal32  copysign(_Decimal32 x, _Decimal32 y);   /C++ only */
_Decimal64  copysign(_Decimal64 x, _Decimal64 y);   /C++ only */
_Decimal128 copysign(_Decimal128 x, _Decimal128 y); /C++ only */
```

General description

The copysign functions produce a value with the magnitude of *x* and the sign of *y*.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The copysign functions return a value with the magnitude of *x* and the sign of *y*.

Example

```
/* CELEBC47

   This example illustrates the copysignd64() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
```

```
#include <stdio.h>

int main(void)
{
   _Decimal64 x = 1.2DD, y = -1.0DD , z;

   z = copysignd64(x, y);

   printf("The result of copysignd64(%Df,%Df) is %Df\n",x,y,z);
}
```

cos(), cosf(), cosl() — Calculate cosine

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double cos(double x);
float cos(float x);                 /* C++ only */
long double cos(long double x);     /* C++ only */
float cosf(float x);
long double cosl(long double x);
```

General description

Calculates the cosine of *x*. The value *x* is expressed in radians.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated value.

If *x* is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets the errno to ERANGE. If the correct value would cause an underflow, zero is returned and the value ERANGE is stored in errno.

Special behavior for XPG4.2: The following error is added:

Error Code
Description

EDOM
The argument exceeded an internal limit for the function (approximately 2^{50}).

Example

CELEBC26

```
/* CELEBC26

   This example calculates y to be the cosine of
   x.

 */
#include <math.h>
#include <stdio.h>

int main(void)
{
   double x, y;

   x = 7.2;
   y = cos(x);

   printf("cos( %lf ) = %lf\n", x, y);
}
```

Output

```
cos( 7.200000 ) = 0.608351
```

cosd32(), cosd64(), cosd128() — Calculate cosine

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  cosd32(_Decimal32 x);
_Decimal64  cosd64(_Decimal64 x);
_Decimal128 cosd128(_Decimal128 x);

_Decimal32  cos(_Decimal32 x);  /* C++ only */
_Decimal64  cos(_Decimal64 x);  /* C++ only */
_Decimal128 cos(_Decimal128 x); /* C++ only */
```

General description

Calculates the cosine of *x*. The value *x* is expressed in radians.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the calculated value.

If *x* is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets errno to EDOM.

Example

```
/* CELEBC48

   This example illustrates the cosd128() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal128 x, y;

   x = 7.2DL;
   y = cosd128(x);

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double cosh(double x);
float cosh(float x);                  /* C++ only */
long double cosh(long double x);      /* C++ only */
float coshf(float x);
long double coshl(long double x);
```

General description

Calculates the hyperbolic cosine of *x*. The value *x* is expressed in radians.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

If the result overflows, the function returns +HUGE_VAL and sets errno to ERANGE.

Example

CELEBC27

```
/* CELEBC27

   This example calculates y to be the hyperbolic cosine of x.

 */
#include <math.h>
#include <stdio.h>

int main(void)
{
   double x,y;

   x = 7.2;
   y = cosh(x);

   printf("cosh( %lf ) = %lf\n", x, y);
}
```

Output

```
cosh( 7.200000 ) = 669.715755
```

coshd32(), coshd64(), coshd128() - Calculate hyperbolic cosine

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.10

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  coshd32(_Decimal32 x);
_Decimal64  coshd64(_Decimal64 x);
_Decimal128 coshd128(_Decimal128 x);
_Decimal32  cosh(_Decimal32 x);     /* C++ only */
_Decimal64  cosh(_Decimal64 x);     /* C++ only */
_Decimal128 cosh(_Decimal128 x);    /* C++ only */
```

General description

Calculates the hyperbolic cosine of *x*. The value *x* is expressed in radians.

These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If the result overflows, the function returns +HUGE_VAL_D32, +HUGE_VAL_D64 or +HUGE_VAL_D128 and sets errno to ERANGE.

Example

CELEBC51

```
/* CELEBC51

   This example illustrates the coshd128() function.

   This example calculates y to be the hyperbolic cosine of x.
```

```
*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal128 x, y;

   x = 7.2DL;
   y = coshd128(x);

   printf("coshd128( %DDf ) = %DDf\n", x, y);
}
```

__cospid32(), __cospid64(), __cospid128() — Calculate cosine of pi *x

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  __cospid32(_Decimal32 x);
_Decimal64  __cospid64(_Decimal64 x);
_Decimal128 __cospid128(_Decimal128 x);
```

General description

Calculates the cosine of pi * *x*. The value *x* is expressed in radians.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the calculated value.

If *x* is outside the prescribed limits, the value is not calculated. Instead, the function either returns 1, or returns 0 and sets errno to ERANGE.

Example

```
/* CELEBC49

   This example illustrates the __cospid32() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal32 x, y;

   x = 1.0DF;
   y = __cospid32(x);

   printf("__cospid32(%Hf) = %Hf\n", x, y);
}
```

__cotan(), __cotanf(), __cotanl() — Calculate cotangent

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	z/OS V1R5

Format

```
#include <math.h>

double __cotan(double x);
float __cotanf(float x);
long double __cotanl(long double x);
```

General description

The __cotan functions compute the cotangent of x.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
__cotan	X	X

Function	Hex	IEEE
__cotanf	X	X
__cotanl	X	X

Returned value

The __cotan functions return the cotangent of x.

Related information

- "math.h" on page 44

__cpl() — CPL interface service

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	OS/390 V2R9

Format

```
#include <sys/__cpl.h>

int __cpl(int functioncode, int bufferlen, char *buffer);
```

General description

__cpl() is currently called by the CFSizer (Coupling Facility structure sizer) tool. An IBM customer answers a minimum set of questions from an IBM web page, about one or more IBM products and then clicks the submit button. The *submit* invokes a C *cgi* program that parses the data, calls __cpl() to Query the Coupling Facility or size one or more Coupling Facility structures and then display the results back to the web client browser.

functioncode
A value that specifies what function BPX1CPL will perform. The following function codes are defined.

CPL_QUERY (equates to value of 1)

CPL_CFSIZER (equates to a value of 2)

CPL_CFSIZER_W_LVL (equates to a value of 3)

CFlevel8 or higher is required to use the computesize function. To provide a consistent result, the code must loop through all online CFs and find the one at the highest CF level. Issuing computesize against CFs at different levels gives different sizes back to the user resulting in inconsistent results when multiple requests are issued.

bufferlen
The length of the input/output storage area (*buffer*) for BPX1CPL

buffer Storage area for input/output for BPX1CPL

__cpl() is an interface to the BPX1CPL Assembler Callable Service. For more information on parameters and behavior of BPX1CPL, please refer to *z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA23-2281*.

Returned value

If successful, __cpl() returns 0.

If unsuccessful, __cpl() returns -1 and sets errno to one of the following values:

Error Code
 Description

EFAULT
 One of the parameters contained an address that was not accessible to the caller.

EINVAL
 The *functioncode* parameter contains a value that is not correct.

EMVSCPLERROR
 A __cpl() service failed.

ENOSYS
 The __cpl() service failed because the system is not at the correct level.

EPERM
 The calling thread's address space is not permitted.

Usage notes

1. Access to __cpl() is controlled using a new RACF class profile BPX.CF. For any of these cases to run, a BPX.CF class profile must be created and access level provided.

   __cpl() is only valid on a Parallel Sysplex® enabled system with a CFlevel 8 or higher Coupling Facility. Most installations run with two or more Coupling Facilities for availability and recoverability reasons. As such, the code was designed to provide the flexibility of allowing the caller to specify a CF or if not specified, MVS will select the first CF at CFlevel 8 it finds.

cpow(), cpowf(), cpowl() — Calculate the complex power

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex cpow(double complex x, double complex y);
float complex cpowf(float complex x, float complex y);
long double complex cpowl(long double complex x, long double complex y);
```

General description

The cpow() family of functions computes the complex value of *x* to the power of *y*, with a branch cut for the first parameter along the negative real axis.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
cpow	X	X
cpowf	X	X
cpowl	X	X

Returned value

The cpow() family of functions return the complex power value.

Example

```
/*
 *  This example illustrates the complex power of complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{
   long double complex zl=-0.5 + I*0.5,  zpowl=(long double complex)3.0;
   double complex zd=(double complex)zl, zpowd=(double complex)zpowl;
   float complex zf=(float complex)zd,   zpowf=(float complex)zpowl;

   long double resl;
   double resd;
   float resf;

   printf("Illustrates the cpow function. Expected result is 0.25 in all cases\n");
   resd = cpow(zd,zpowd);
   resf = cpowf(zf,zpowf);
   resl = cpowl(zl,zpowl);
   printf("\tcpow(%f + I*%f,%f + I*%f) = %f\n",creal(zd), cimag(zd),
                                           creal(zpowd), cimag(zpowd), resd);
   printf("\tcpowf(%f + I*%f,%f + I*%f) = %f\n",crealf(zd), cimagf(zd),
                                           crealf(zpowf), cimagf(zpowf), resf);
   printf("\tcpowl(%Lf + I*%Lf,%Lf + I*%Lf) = %Lf\n",creall(zl), cimagl(zl),
                                             creall(zpowl), cimagl(zpowl), resl);
}
Output

Illustrates the cpow function. Expected result is 0.25
        cpow(-0.500000 + I*0.500000,3.000000 + I*0.000000) = 0.250000
        cpowf(-0.500000 + I*0.500000,3.000000 + I*0.000000) = 0.250000
        cpowl(-0.500000 + I*0.500000,3.000000 + I*0.000000) = 0.250000
```

Related information

- "complex.h" on page 19
- "cabs(), cabsf(), cabsl() — Calculate the complex absolute value" on page 228

cproj(), cprojf(), cprojl() — Calculate the projection

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex cproj(double complex z);
float complex cprojf(float complex z);
long double complex cprojl(long double complex z);
```

General description

The cproj() family of functions compute a projection of *z* onto the Riemann sphere: *z* projects to *z* except that all complex infinities (even those with one infinite part and one NaN part) project to positive infinity on the real axis. If *z* has an infinite part, then cproj(*z*) is equivalent to:

INFINITY +I * copysign(0.0, cimag(*z*))

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
cproj	X	X
cprojf	X	X
cprojl	X	X

Returned value

The cproj() family of functions return the value of the projection onto the Riemann sphere.

For a variable *z* of complex type, z == creal(*z*) + cimag(*z*)*I.

Special behavior for hex: On hexadecimal floating point mode, cproj(z) family of functions always returns z .

Example

```
#include <complex.h>
#include <stdio.h>

/*
 * Illustrates complex function cproj().
 *
 * NOTE:       When compiled in HEX(FLOAT), cproj(z) should
 *             always return z
 */
```

```
#define INFINITEL 1.0L/0.0L   /* An infinite number */

void InitReal ( long double complex *z, long double RealPart)
{
  union LongDoubleComplexMap {
     long double complex w;
     long double ldarray[2];
  }z1;

  z1.w = *z;
  z1.ldarray[0] = RealPart;
  *z = z1.w;
}

main() {

  long double complex z,w;
  z = 2.5 + I*(-3.999);

  printf("Ilustrates function cproj() ");

  #ifdef _BFP_
    printf ("(IEEE mode)");
  #else
    printf ("(HFP mode)");
  #endif

  printf("\n\n z = %Lf + I*%Lf\n\n",creall(z), cimagl(z));
  w = cprojl(z);
  printf(" cproj(z) = %Lf + I*%Lf\n",creall(w), cimagl(w));

  printf(" Initializing z(real) with infinity ...\n");
  InitReal(z,INFINITEL);
  printf(" z = %Lf + %Lf*I\n",creall(z),cimagl(z));

  w = cprojl(z);
  printf(" cproj(z) = %Lf + %Lf*I\n",creall(w),cimagl(w));
}
```

```
Output

Ilustrates function cproj() (IEEE mode)

 z = 2.500000 + I*-3.999000

 cproj(z) = 2.500000 + I*-3.999000
 Initializing z(real) with infinity ...
 z = INF + -3.999000*I
 cproj(z) = INF + -0.000000*I
```

creal(), crealf(), creall() — Calculate the complex real part

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double creal(double complex z);
float crealf(float complex z);
long double creall(long double complex z);
```

General description

The creal() family of functions compute the real part of *z*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
creal	X	X
crealf	X	X
creall	X	X

Returned value

The creal() family of functions return the real part value (as a real).

Example

For an example of a similar function see cacos(), cexp() or cpow().

creat() — Create a new file or rewrite an existing one

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <fcntl.h>

int creat(const char *pathname, mode_t mode);
```

General description

The function call: `creat(pathname,mode)` is equivalent to the call:

```
open(pathname, O_CREAT|O_WRONLY|O_TRUNC, mode);
```

Thus the file named by *pathname* is created, unless it already exists. The file is then opened for writing only, and is truncated to zero length. See "open() — Open a file" on page 1152 for further information.

The *mode* argument specifies the file permission bits to be used in creating the file. Here is a list of symbols that can be used for a mode:

S_IRGRP
Read permission for the file's group.

S_IROTH
Read permission for users other than the file owner.

S_IRUSR
Read permission for the file owner.

S_IRWXG
Read, write, and search, or execute permission for the file's group. S_IRWXG is the bitwise inclusive-OR of S_IRGRP, S_IWGRP, and S_IXGRP.

S_IRWXO
Read, write, and search, or execute permission for users other than the file owner. S_IRWXO is the bitwise inclusive-OR of S_IROTH, S_IWOTH, and S_IXOTH.

S_IRWXU
Read, write, and search, or execute, for the file owner; S_IRWXG is the bitwise inclusive-OR of S_IRUSR, S_IWUSR, and S_IXUSR.

S_ISGID
Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is set to the group ID of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.

S_ISUID
Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.

S_ISVTX
Indicates shared text. Keep loaded as an executable file in storage.

S_IWGRP
Write permission for the file's group.

S_IWOTH
Write permission for users other than the file owner.

S_IWUSR
Write permission for the file owner.

S_IXGRP
Search permission (for a directory) or execute permission (for a file) for the file's group.

S_IXOTH
Search permission for a directory, or execute permission for a file, for users other than the file owner.

S_IXUSR
Search permission (for a directory) or execute permission (for a file) for the file owner.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, creat() returns a file descriptor for the open file.

If unsuccessful, creat() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
One of the following error conditions exists:
- The process did not have search permission on a component in *pathname*.
- The file exists but the process did not have appropriate permissions to open the file in the way specified by the flags.
- The file does not exist, and the process does not have write permission on the directory where the file is to be created.
- O_TRUNC was specified, but the process does not have write permission on the file.

EINTR
open() was interrupted by a signal.

EISDIR
pathname is a directory, and *options* specifies write or read/write access.

ELOOP
A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLOOP.

EMFILE
The process has reached the maximum number of file descriptors it can have open.

ENAMETOOLONG

pathname is longer than PATH_MAX characters or some component of *pathname* is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, this error occurs if the length of a *pathname* string substituted for a symbolic link in the *pathname* argument exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined with pathconf().

ENFILE

The system has reached the maximum number of file descriptors it can have open.

ENOENT

O_CREAT is specified, and either the path prefix does not exist or the *pathname* argument is an empty string.

ENOSPC

The directory or file system intended to hold a new file has insufficient space.

ENOTDIR

A component of *pathname* is not a directory.

EOVERFLOW

The named file is a regular file and the size of the file cannot be represented correctly in an object of type off_t

EROFS

pathname is on a read-only file system.

Example

CELEBC28

```
/* CELEBC28

   This example creates a file.

 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  char fn[]="creat.file", text[]="This is a test";
  int fd;

  if ((fd = creat(fn, S_IRUSR | S_IWUSR)) < 0)
    perror("creat() error");
  else {
    write(fd, text, strlen(text));
    close(fd);
    unlink(fn);
  }
return(fd);
}
```

CreateWorkUnit() — Create WLM work unit

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

int CreateWorkUnit(wlmetok_t *enclavetoken,
                   server_classify_t classify,
                   char *arrival_time,
                   char *func_name);
```

General description

The CreateWorkUnit function provides the ability for an application to create a WLM work unit.

**enclavetoken*
: Points to a data field of type wlmetok_t where the CreateWorkUnit() function is to return the WLM work unit enclave token.

**classify*
: Points to a server_classify_t structure that contains the classification information for the work request macro.

**arrival_time*
: Address of a doubleword (unsigned long long) field that contains the arrival time of the work request in STCK format.

**func_name*
: Points to a NULL-terminated character string that represents the descriptive function name of the associated work request.

Returned value

If successful, CreateWorkUnit() returns a pointer to work unit enclave token of type wlmetok_t.

If unsuccessful, CreateWorkUnit() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EFAULT
: An argument of this function contained an address that was not accessible to the caller.

EINVAL
: An argument of this function contained an incorrect value.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM create failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

crypt() — String encoding function

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

char *crypt(const char *key, const char *salt);
```

General description

The crypt() function encodes the string pointed to by the *key* argument. It perturbs the Data Encryption Standard (DES) encryption algorithm with the first two characters in the string pointed to by the *salt* argument to perform this encoding. The first two *salt* characters must be chosen from the set:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . /
```

This function can be called from any thread.

Returned value

If successful, crypt() returns a pointer to a thread specific encoded string. The first two characters of the returned value are those of the *salt* argument.

Notes:

1. The return value of crypt() points to a thread-specific buffer which is overwritten each time crypt() is called from the same thread.
2. The values returned by crypt() are not portable to other X/Open-conforming systems.

If unsuccessful, crypt() returns a NULL pointer and sets errno to indicate the error.

Special behavior for z/OS UNIX Services: The crypt() function will fail if:

Error Code
Description

EINVAL
First two characters of *salt* argument are not from the *salt* set.

ENOMEM
Storage for crypt() output buffer is not available for thread from which crypt() has been invoked.

cs() — Compare and swap

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdlib.h>

int cs(cs_t *oldptr, cs_t *curptr, cs_t newword);
```

General description

The cs() built-in function compares the 4-byte value pointed to by *oldptr* to the 4-byte value pointed to by *curptr*. If they are equal, the 4-byte value, *newword*, is copied into the location pointed to by *curptr*. If they are unequal, the value pointed to by *curptr* is copied into the location pointed to by *oldptr*.

If this function is used in a multi-threading environment, then it is the users responsibility to protect the *oldptr variable*. The user can create a local variable per thread to contain this value or provide locking code to protect the global variable used. The *oldptr* variable may not reflect the *curptr* variable if the *curptr* variable changes via another thread before the user has a chance to examine *oldptr*.

To avoid infringing on the user's name space, this nonstandard function is exposed only when you use the compiler option LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The function uses the COMPARE SWAP (CS) instructions, which can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas. For a detailed description, refer to the appendixes in the *z/Architecture Principles of Operation* on number representation and instruction.

Returned value

cs() returns 0 if the 4-byte value pointed to by *oldptr* is equal to the 4-byte value pointed to by *curptr*.

If the value is not equal, cs() returns 1.

Related information

- *z/Architecture Principles of Operation*

- “cds() — Compare double and swap” on page 247

csid() — Character set ID for multibyte character

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdlib.h>

int csid(const char *c)
```

External entry point: `@@CSID`, `__csid`;

General description

Determines the character set identifier for the specified multibyte character pointed to by *c*, that begins in the initial shift state.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Returned value

If successful, csid() returns the character-set identifier for the multibyte character.

If the character is not valid, csid() returns -1.

Note: The multibyte character passed must begin in the initial shift state.

Example

CELEBC29

```
/* CELEBC29

   This example checks character set ID for a character.

 */
#include "locale.h"
#include "stdio.h"
#include "stdlib.h"

main() {
   char *string = "A";
   int   rc;

   rc = csid(string);
   printf("character '%s' is in character set id %i\n", string, rc);
}
```

Output

```
character 'A' is in character set id 0
```

csin(), csinf(), csinl() — Calculate the complex sine

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex csin(double complex z);
float complex csinf(float complex z);
long double complex csinl(long double complex z);
```

General description

The csin() family of functions compute the complex sine of *z*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
csin	X	X
csinf	X	X
csinl	X	X

Returned value

The csin() family of functions return the complex sine value.

Example

For an example of a similar function see cacos(), cexp() or cpow().

csinh(), csinhf(), csinhl() — Calculate the complex hyperbolic sine

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex csinh(double complex z);
float complex csinhf(float complex z);
long double complex csinhl(long double complex z);
```

General description

The csinh() family functions compute the complex hyperbolic sine of *z*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
csinh	X	X
csinhf	X	X
csinhl	X	X

Returned value

The csinh() family functions return the complex hyperbolic sine value.

Example

For an example of a similar function see cacos(), cexp() or cpow().

__CSNameType() — Return codeset name type

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R2

Format

```
#include <_Ccsid.h>

__csType __CSNameType(char *codesetName);
```

General description

The __CSNameType() function returns a __csType value which indicates the corresponding codeset name type.

Returned value

If *codesetName* is valid, __CSNameType() returns one of the following __csType values, which are defined in <_Ccsid.h>:

- _CSTYPE_EBCDIC
- _CSTYPE_ASCII
- _CSTYPE_UCS2
- _CSTYPE_UTF8
- _CSTYPE_UTF16
- _CSTYPE_UTF32

If *codesetName* is not valid, __CSNameType() returns _CSTYPE_INVALID.

Related information

csnap() — Request a condensed dump

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <ctest.h>

int csnap(char *dumptitle);
```

General description

Creates a display of the activation stack, including the Dynamic Storage Area (DSA), for each presently active function. Other environmental control blocks that may be required by IBM Service are also displayed. Under Language Environment, these consist of the Common Anchor Area (CAA) and the z/OS XL C/C++ CAA information. The output is identified with *dumptitle*. See the CEE3DMP Language Environment callable service in *z/OS Language Environment Programming Guide, SA38-0682*, to determine where the output is written to.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Returned value

If successful, csnap() returns 0.

If unsuccessful, csnap() returns nonzero.

Example

```
#include <ctest.h>

int main(void) {

   int rc;
   rc = csnap("Sample csnap output");
}
```

Related information

__csplist — Retrieve CSP parameters

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	C only	

Format

```
#include <csp.h>

__csplist;
```

General description

Restriction: This function is not supported in AMODE 64.

__csplist is a macro intended to be used to access the parameter list passed from Cross System Product (CSP) to your C Library program. The macro evaluates to the address of the first element of the parameter list. You can use array indexing to extract the subsequent parameters, casting each parameter to the expected type, as shown in the example below. If no parameters are passed, `__csplist[0]` equals NULL.

You must include the #pragma `runopts(plist(ims))` directive if CSP is used to invoke a z/OS XL C program.

`argc` will always be 1. See *z/OS XL C/C++ User's Guide* for information about the PLIST compiler option.

If you are expecting an integer and then a structure of type `s_type`, you should have the statements:

```
int_var = (int *) __csplist[0];
s_var   = (s_type *) __csplist[1];
```

Related information

- "csp.h" on page 20

csqrt(), csqrtf(), csqrtl() — Calculate the complex square root

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
##include <complex.h>

double complex csqrt(double complex z);
float complex csqrtf(float complex z);
long double complex csqrtl(long double complex z);
```

General description

The csqrt() family of functions compute the complex square root of *z*, with a branch cut along the negative real axis.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
csqrt	X	X
csqrtf	X	X
csqrtl	X	X

Returned value

The csqrt() family of functions return the complex square root value, in the range of the right half-plane (including the imaginary axis).

Example

For an example of a similar function see cacos(), cexp() or cpow().

Related information

- "complex.h" on page 19

ctan(), ctanf(), ctanl()— Calculate the complex tangent

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex ctan(double complex z);
float complex ctanf(float complex z);
long double complex ctanl(long double complex z);
```

General description

The ctan() family of functions compute the complex tangent of *z*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
ctan	X	X
ctanf	X	X
ctanl	X	X

Returned value

The ctan() family of functions return the complex tangent value.

Example

For an example of a similar function see cacos(), cexp() or cpow().

ctanh(), ctanhf(), ctanhl() — Calculate the complex hyperbolic tangent

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3	both	z/OS V1R7 a compiler that is designed to support C99

Format

```
#include <complex.h>

double complex ctanh(double complex z);
float complex ctanhf(float complex z);
long double complex ctanhl(long double complex z);
```

General description

The ctanh() family of functions compute the complex hyperbolic tangent of *z*.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
ctanh	X	X
ctanhf	X	X
ctanhl	X	X

Returned value

The ctanh() family of functions return the complex hyperbolic tangent value.

Example

For an example of a similar function see cacos(), cexp() or cpow().

ctdli() — Call to DL/I

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

C only:

```
#pragma runopts(env(IMS),plist(OS))
#include <ims.h>             /* or #include <cics.h> */

#define _CTDLI_PARMCOUNT     /* First arg is an explicit parameter count */
int ctdli(int parmcount, const char *function, ...);

or

#define _CTDLI_NOPARMCOUNT   /*Parameter count is implicit in varargs */
int ctdli(const char *function,...);
```

C++:

```
#include <ims.h>        /* or #include <cics.h> */

int ctdli(int parmcount, const char *function, ...);

or

#define _CTDLI_NOPARMCOUNT
int ctdli(const char *function, ...);
```

General description

Restriction: This function is not supported in AMODE 64.

Invokes DL/I facilities. The *parmcount* argument is optional. The *parmcount* value specifies the number of arguments in the variable argument list for the ctdli() call to function.

In C, when specifying a *parmcount*, use the _CTDLI_PARMCOUNT feature test macro. Otherwise, for C or C++, define _CTDLI_NOPARMCOUNT and make *function* the first argument. If the compile unit contains both types of call (sometimes passing *parmcount* and sometimes not), and if you want to avoid messages when compiling with the checkout option, define _CTDLI_NOPARMCOUNT and always cast the first argument to (const char *).

The *function* argument specifies the DL/I function you want to perform. Because the format of the ctdli() call depends on the function selected, all of the variations are not given here. For complete details on the available functions, refer to the COBOL publications.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

To invoke ctdli() from an IMS transaction, you need either the #pragma runopts(env(ims),plist(os)), or you need to specify the compiler options TARGET(IMS) and PLIST(OS).

Returned value

The Program Control Block (PCB) status field (2 bytes) is stored as an `unsigned int` and used as the returned value for ctdli().

If the PCB status field contains blanks (hex '4040'), ctdli() returns 0.

Example

```
/* The following program demonstrates the use of the ctdli() function.
   It is a skeleton of a message processing program that calls ctdli()
   to retrieve messages and data.

   Do use the TARGET(IMS) and PLIST(IMS) compile options for C++
   applications.
 */
#ifndef __cplusplus
#pragma runopts(env(ims),plist(os))
#endif

#include <stdlib.h>
#include <ims.h>
#define n     20          /* I/O area size - Application dependent  */
typedef struct {PCB_STRUCT(10)} PCB_10_TYPE;
```

```
int main(void)
{
   /* Function codes for ctdli */
   static const char func_GU[4]   = "GU  ";
   static const char func_ISRT[4] = "ISRT";

   char ssa_name[] = "ORDER   (ORDERKEY   = 666666)";

   int rc;

   char msg_seg_io_area[n];
   char db_seg_io_area[n];
   char alt_msg_seg_out[n];

   PCB_STRUCT_8_TYPE *alt_pcb;
   PCB_10_TYPE *db_pcb;
   IO_PCB_TYPE *io_pcb;

   io_pcb = (IO_PCB_TYPE *)(__pcblist)[0];
   alt_pcb = __pcblist[1];
   db_pcb = (PCB_10_TYPE *) __pcblist[2];
⋮
   /* Get first message segment from message region */
   rc = ctdli(func_GU, io_pcb, msg_seg_io_area);
⋮
   /* Get the data from the database having the specified key value */
   rc = ctdli(func_GU, db_pcb, db_seg_io_area, ssa_name);
⋮
   /* Build output message in program's I/O area */
   rc = ctdli(func_ISRT, alt_pcb, alt_msg_seg_out);
⋮
}
```

- "ims.h" on page 32

ctermid() — Generate path name for controlling terminal

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

char *ctermid(char *string);
```

General description

string points to a memory location where the ctermid() function stores the name of the current controlling terminal. The memory location must be able to hold at least L_ctermid characters, where L_ctermid is a symbol defined in the stdio.h header file.

ctermid() returns a string that can be used as a path name to refer to the controlling terminal for the current process. If *string* is not NULL, ctermid() stores the path name in the specified location and returns the value of *string*. Otherwise, ctermid() uses a location of its own and returns a pointer to that location.

The path name returned can be used to access the controlling terminal, if the process has a controlling terminal.

Returned value

ctermid() is always successful; it returns a string that can be used as a path name to refer to the controlling terminal for the current process.

There are no documented errno values.

Example

CELEBC32

```
/* CELEBC32

   This example refers to the controlling terminal for
   the current process.

 */
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

main() {
  char termid[1025];

  if (ctermid(termid) == NULL)
    perror("ctermid() error");
  else
    printf("The control terminal is %s\n", termid);
}
```

Output

```
The control terminal is /dev/tty
```

Related information

- “stdio.h” on page 68
- “unistd.h” on page 82
- “ttyname() — Get the name of a terminal” on page 1931

ctest() — Start debug tool

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <ctest.h>

int ctest(char *command);
```

General description

Invokes the Debug Tool from your application program. The parameter *command* is a character pointer to a list of valid Debug Tool commands, that ctest() uses to invoke Debug Tool.

If you choose not to compile your program with hooks, you can use well-placed ctest() function calls instead. (A *hook* is a conditional exit that transfers control to the debugger, when the code is run under the debugger.) You would create a hook when you compile with the TEST option, causing the exit to be in your generated code waiting to run. A hook has minimal effect on a program that is running without the debugger.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Returned value

If successful, ctest() returns 0.

If unsuccessful, ctest() returns nonzero.

Examples

To let the debug tool gain control of your program, issue the command: `ctest(NULL)`.

To display the call chain from within a program and then let the program continue execution, issue the function call: `ctest("list calls; go;")`. To set a breakpoint from within a ctest() call, try:

```
char *cmd = "at line 17 list my_struct; go;";
ctest(cmd);
```

Related information

- "ctest.h" on page 21

ctime(), ctime64() — Convert time to character string

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <time.h>

char *ctime(const time_t *timer);
```

```
#define _LARGE_TIME_API
#include <time.h>

char  *ctime64 (const time64_t *timer);
```

General description

Converts the calendar time pointed to by *timer* to local time in the form of a character string. A value for *timer* is usually obtained by a call to the time() function.

The ctime() function is equivalent to the function call: `asctime(localtime(timer))`

The function ctime64() will behave exactly like ctime() except it will convert a time64_t value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, ctime() returns a pointer to a date and time string. The string returned by ctime() contains exactly 26 characters and has the format:

```
   "%.3s %.3s%3d %.2d:%.2d:%.2d %d\n"
```

For example: `Mon Jul 16 02:03:55 1987\n\0`

If an error occurs, ctime() returns no value.

Notes:

1. This function is sensitive to time zone information which is provided by:
   - The TZ environmental variable when POSIX(ON) and TZ is correctly defined, or by the _TZ environmental variable when POSIX(OFF) and _TZ is correctly defined.
   - The LC_TOD category of the current locale if POSIX(OFF) or TZ is not defined.

   The time zone external variables `tzname`, `timezone`, and `daylight` declarations remain feature test protected in time.h.
2. The calendar time returned by a call to the time() function begins at epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.
3. The ctime() function uses a 24-hour clock format.
4. The days are abbreviated to: `Sun`, `Mon`, `Tue`, `Wed`, `Thu`, `Fri`, and `Sat`.
5. The months are abbreviated to: `Jan`, `Feb`, `Mar`, `Apr`, `May`, `Jun`, `Jul`, `Aug`, `Sep`, `Oct`, `Nov`, and `Dec`.
6. All fields have a constant width.
7. Dates with only one digit are padded with a blank space. Single digit time values are padded with a zero.
8. The newline character (`\n`) and the NULL character (`\0`) occupy the last two positions of the string.

9. The asctime(), ctime(), and other time functions may use a common, statically allocated buffer for holding the return string. Each call to one of these functions may destroy the result of the previous call.

When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock.

For more information about customizing a time zone to work with local time, see “Customizing a time zone” in *z/OS XL C/C++ Programming Guide*.

Error Code
Description

EOVERFLOW
The result cannot be represented.

Example

CELEBC33

```
/* CELEBC33

   This example polls the system clock by using the library
   function &ttime..
   It then prints a message giving the current date and time.

 */
#include <time.h>
#include <stdio.h>

int main(void)
{
   time_t ltime;

   time(&ltime);
   printf("the time is %s", ctime(&ltime));
}
```

Output

```
the time is Fri Jun 16 16:03:38 2006
```

ctime_r(), ctime64_r() — Convert time value to date and time character string

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>

char *ctime_r(const time_t *clock, char *buf);
```

```
#define _LARGE_TIME_API
#include <time.h>

char  *ctime64_r (const time64_t *clock, char *buf);
```

General description

The ctime_r() function converts the calendar time pointed to by *clock* to local time in exactly the same form as ctime() and puts the string into the array pointed to by *buf*. (which contains at least 26 bytes) and returns *buf*.

Unlike ctime(), the thread-safe version ctime_r() is not required to set *tzname*.

The function ctime64_r() will behave exactly like ctime_r() except it will convert a time64_t value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, ctime_r() returns a pointer to the string pointed to by *buf*.

If unsuccessful, ctime_r() returns a NULL pointer.

There are no documented errno values.

ctrace() — Request a traceback

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <ctest.h>

int ctrace(char *dumptitle);
```

General description

Requests a traceback. The output is identified with *dumptitle*. ctrace() invokes the CEE3DMP Language Environment callable service with the following options: TRACEBACK, NOFILE, NOBLOCK, NOVARIABLE, NOSTORAGE, STACKFRAME(ALL), NOCOND, NOENTRY. See the CEE3DMP Language Environment callable service in *z/OS Language Environment Programming Guide, SA38-0682*. to determine where the output is written to.

If you compile the code using the GONUMBER option, this function will display, along with the traceback, the statement numbers and the offset information.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Note: The offsets displayed by ctrace() are from the beginning of the functions, whereas by default, compiler listings show offsets from the beginning of the source file. You can override the displayed offsets with the OFFSET compile-time option.

Returned value

If successful, ctrace() returns 0.

If unsuccessful, ctrace() returns nonzero.

Example

CELEBC34

```
/* CELEBC34

   This example shows how ctrace() is used and the output produced.

 */
#include <ctest.h>
int main(void) {

    int rc;
    rc = ctrace("Sample ctrace output");
}
```

Output for C++:

```
CEE3DMP: Sample ctrace output                                Language Environment for MVS
06/16/95 6:13:31 PMPage:    1

cuserid() — Return character login of the user

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2	both	

Format

```
#define _XOPEN_SOURCE
#include <stdio.h>

char *cuserid(char *s);
```

General description

The cuserid() function generates a character representation of the name associated with the real or effective user ID of the process.

If *s* is a NULL pointer, this representation is generated in an area that may be overwritten by subsequent calls to cuserid(). A pointer to the area is returned. If *s* is not a NULL pointer, *s* is assumed to point to an array of at least {L_cuserid} bytes; the representation is deposited in this array. The symbolic constant {L_cuserid} is defined in <stdio.h> and has a value greater than 0.

Note:

This function and constant L_cuserid are kept for historical reasons. They were part of the Legacy Feature in Single UNIX Specification, Version 2, but have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use getpwuid() instead of cuserid().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If *s* is not a NULL pointer, cuserid() returns *s*.

If *s* is not a NULL pointer and the login name cannot be found, the NULL byte '\0' will be placed at **s*.

If *s* is a NULL pointer and the login name cannot be found, cuserid() returns a NULL pointer.

If *s* is a NULL pointer and the login name can be found, cuserid() returns the address of a buffer local to the calling thread containing the login name.

dbm_clearerr() — Clear database error indicator

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_clearerr(DBM *db);
```

General description

The dbm_clearerr() function clears the error condition of the database. The argument *db* is a handle to a database previously obtained by dbm_open(). Note that this does not correct any problems with the database due to previous failures. It simply allows dbm_ operations to proceed. The database may be in an inconsistent or damaged state.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the database error indicator is global to all threads using the database handle. Thus, clearing the error indicator affects all threads using the database handle.

Returned value

The return value is unspecified by X/Open.

If successful, dbm_clearerr() returns 0.

If unsuccessful, dbm_clearerr() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
Non-valid database descriptor specified.

dbm_close() — Close a database

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

void dbm_close(DBM *db);
```

General description

The dbm_close() function closes a database. The *db* argument is the database handle returned by a previous call to dbm_open().

Special behavior for z/OS UNIX Services: A dbm_close() function call removes access to the specified database handle to all threads within the process.

Returned value

dbm_close() returns no values.

dbm_delete() — Delete database record

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_delete(DBM *db, datum key);
```

General description

The dbm_delete() function deletes a record and its key from the database. The *db* argument specifies the database handle returned by a previous call to dbm_open(). The *key* argument identifies the record the program is deleting. The *key* datum must contain a `dptr` pointer to the key, and the key length in `dsize`.

After calling dbm_delete(), during a pass through the keys by dbm_firstkey() and dbm_nextkey(), the application positioning must be reset by calling dbm_firstkey(). If not, unpredictable results may occur including retrieval of the same key multiple times, or not at all.

File space is not physically reclaimed by a dbm_delete() operation. That is, the file size is not reduced. However, the space is available for reuse, subject to hashing.

Special behavior for z/OS UNIX Services: In a multithreaded environment, changes made to the database by a dbm_delete() operation affect all threads using the database handle. Thus, all other threads must also reset their positioning by using the dbm_firstkey() function before using dbm_nextkey(). A previously executed dbm_fetch() operation by **another** thread for the same *key* still has correct buffer pointers to the previous data. The dbm_delete() operation does not affect this. All other operations on other threads, such as dbm_fetch() to this (now) deleted *key* will fail.

Returned value

If successful, dbm_delete() returns 0.

If unsuccessful, dbm_delete() returns -1 and sets the error value in errno. Also, the database error indicator may be set.

dbm_error() — Check database error indicator

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_error(DBM *db);
```

General description

The dbm_error() function returns the error condition of the database. The argument *db* is a handle to a database previously obtained by dbm_open().

Special behavior for z/OS UNIX Services: In a multithreaded environment, the database error indicator is global to all threads using the database handle. Thus, the database error indicator may be set as a result of a database operation by another thread.

Returned value

dbm_error() returns 0 if the error condition is not set.

dbm_error() returns nonzero if the error condition is set.

Related information

- “ndbm.h” on page 49
- “dbm_clearerr() — Clear database error indicator” on page 365

- “dbm_store() — Store database record” on page 373

dbm_fetch() — Get database content

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

datum dbm_fetch(DBM *db, datum key);
```

General description

The dbm_fetch() function reads a record from the database. The argument *db* is a handle to a database previously obtained by dbm_open(). The argument *key* is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching. A `datum` is a structure that consists of two members, `dptr` and `dsize`. The member `dptr` is a char pointer to an array of data that is `dsize` bytes in length. (**Note:** The data is arbitrary binary data and is not NULL-terminated.)

The `dptr` is valid only until the next `dbm_` operation by this thread.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the dbm_fetch() function returns a `dptr` in the datum structure to a data area that is thread-specific. This data area is not affected by other threads operations on the database, with the exception of a dbm_close() operation, which invalidates the *datum*.

Returned value

If successful, dbm_fetch() returns the `datum` containing a pointer to the data content `dptr`, and the data length `dsize`.

If unsuccessful, dbm_fetch() returns a NULL pointer in `dptr` and returns the error value in errno. Also, the database error indicator may be set.

dbm_firstkey() — Get first key in database

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

datum dbm_firstkey(DBM *db);
```

General description

The dbm_firstkey() function returns the first key in the database. The argument *db* is a handle to a database previously obtained by dbm_open(). Since the keys are arbitrary binary data, the order of key return by dbm_firstkey() and dbm_nextkey() does not reflect any lexical ordering. In addition, the return order does not reflect record insertion ordering. All keys can be retrieved from the database by executing a loop such as:

```
for (key = dbm_firstkey(db); key.dptr !=NULL; key = dbm_nextkey(db))
```

That is, establish positioning to the beginning by use of the dbm_firstkey() function, then loop doing dbm_nextkey() function calls until a NULL `dptr` is returned in the *datum*.

The returned `dptr` is valid only until the next `dbm_` operation by this thread.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the dbm_firstkey() function returns a pointer to data that is thread-specific. In addition, each thread maintains its own positioning information for dbm_nextkey() operations. However, other threads making modifications to the database, for example using dbm_store() or dbm_delete() can cause unpredictable results for threads executing dbm_nextkey(), including keys retrieved multiple times or not at all. The application must reset positioning to the beginning using dbm_firstkey() if another thread has done a modification to the database.

Returned value

If successful, dbm_firstkey() returns the `datum` containing a pointer to the key `dptr`, and the key length `dsize`.

If unsuccessful, dbm_firstkey() returns a NULL pointer in `dptr` and returns the error value in errno. Also, the database error indicator may be set.

dbm_nextkey() — Get next key in database

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

datum dbm_nextkey(DBM * db);
```

General description

The dbm_nextkey() function returns the next key in the database. The argument *db* is a handle to a database previously obtained by dbm_open(). Since the keys are arbitrary binary data, the order of key return by dbm_firstkey() and dbm_nextkey() does not reflect any lexical ordering. In addition, the return order does not reflect record insertion ordering. All keys can be retrieved from the database by executing a loop such as:

```
for (key = dbm_firstkey(db); key.dptr !=NULL; key = dbm_nextkey(db))
```

That is, establish positioning to the beginning by use of the dbm_firstkey() function, then loop doing dbm_nextkey() function calls until a NULL `dptr` is returned in *datum*.

The returned `dptr` is valid only until the next `dbm_` operation by this thread.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the dbm_nextkey() function returns a pointer to data that is thread-specific. In addition, each thread maintains its own positioning information for dbm_nextkey() operations. However, other threads making modifications to the database, for example using dbm_store() or dbm_delete() can cause unpredictable results for threads executing dbm_nextkey(), including keys retrieved multiple times or not at all. The application must reset positioning to the beginning using dbm_firstkey() if another thread has done a modification to the database.

Returned value

If successful, dbm_nextkey() returns the `datum` containing a pointer to the key `dptr`, and the key length `dsize`.

If unsuccessful, dbm_nextkey() returns a NULL pointer in dptr and returns the error value in errno. Also, the database error indicator may be set.

dbm_open() — Open a database

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

DBM *dbm_open(const char *file, int open_flags, mode_t file_mode);
```

General description

The dbm_open() function opens a database. The *file* argument is the path name of the database, not including the filename suffix (the part after the .). The database is stored in two files. One file is a directory containing a bit map of blocks in use and has .dir as its suffix. The second file contains all the data and has .pag as its suffix. The *open_flags* argument has the same meaning as the *flags* argument of open() except that a database opened for write-only access opens the files for read and write access. The *file_mode* argument has the same meaning as the third argument of open().

The number of records that can be stored in the database is limited by the file space available for the .dir and .pag files, and by the underlying key hashing. If multiple keys hash to the same 32 bit hash value, the number of keys for that hash value is limited to the amount of data (key sizes plus content sizes plus overhead) that can be stored in a single logical block of 1024 bytes.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the dbm_ functions have both POSIX process wide and thread-specific characteristics. z/OS UNIX services provide the following multithreaded behavior:

1. A database handle returned by the dbm_open() function is a process wide resource. This means that multiple threads within the process can access the database using the same database handle.
2. Each thread using a given database handle has its own positioning information for dbm_firstkey() and dbm_nextkey() operations. This means that multiple threads can each be executing a dbm_nextkey() loop.

3. Each thread using a given database handle has its own buffering for dbm_fetch() operations. This means that a pointer to a keys content (as returned by dbm_fetch()) remains valid, even if other threads modify the database.
4. Database modifications are automatically reflected to all of the threads using the same database handle. For example, if a thread adds a key/data pair using dbm_store(), a dbm_fetch() of that key by another thread will be successful.
5. Operations which modify the database, such as dbm_store() and dbm_delete(), can cause unpredictable results to threads executing dbm_nextkey(). If a database modification is done, all threads should reset positioning using a dbm_firstkey() call before executing dbm_nextkey().
6. A dbm_close() operation removes access to the database for all threads that use the database handle.
7. Multiple dbm_open() operations, whether by a single thread, multiple threads within a process, or by multiple processes are permitted, but for read access only. No protection is provided for database modification, and modification can result in unpredictable results, including database destruction.

Returned value

If successful, dbm_open() returns a pointer to the database descriptor.

If unsuccessful, dbm_open() returns a NULL pointer and stores the error value in errno.

dbm_store() — Store database record

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_store(DBM *db, datum key, datum content, int store_mode);
```

General description

The dbm_store() function writes a record to a database. The *db* argument specifies the database handle returned by a previous call to dbm_open(). The *key* argument identifies the record the program is deleting. The *key* datum must contain a `dptr` pointer to the key, and the key length in `dsize`. The argument *content* is a datum. that describes the data record being stored. record the program is writing. The *content* datum. contains a `dptr` pointer to the data, and the data length in `dsize`.

The argument *store_mode* controls whether dbm_store() replaces a already existing record that has the same key. The *store_mode* argument may be any one of the following set of symbols defined in the <ndbm.h> include file:

DBM_INSERT
Do not add the *key* and *content* pair if the *key* already exists in the database. If the *key* doesn't already exist, add the new *key* and *content* pair.

DBM_REPLACE
Replace the *key* and *content* pair in the database with the new pair if the *key* already exists. If the *key* doesn't already exist, add the new *key* and *content* pair.

After calling dbm_store(), during a pass through the keys by dbm_firstkey() and dbm_nextkey(), the application positioning must be reset by calling dbm_firstkey(). If not, unpredictable results may occur including retrieval of the same key multiple times, or not at all.

The number of records that can be stored in the database is limited by the file space available for the .dir and .pag files, and by the underlying key hashing. If multiple keys hash to the same 32 bit hash value, the number of keys for that hash value is limited to the amount of data (key sizes plus content sizes plus overhead) that can be stored in a single logical block of 1024 bytes.

Special behavior for z/OS UNIX Services: In a multithreaded environment, changes made to the database by a dbm_store() operation affect all threads using the database handle. Thus, all other threads must also reset their positioning by using the dbm_firstkey() function before using dbm_nextkey(). A previously executed dbm_fetch() operation by **another** thread for the same *key* still has correct buffer pointers to the previous data. The dbm_store() operation does not affect this. All other operations, such as dbm_fetch() or dbm_delete(), will automatically have access to the new *key* and *content* pair.

Returned value

If successful, dbm_store() returns 0. If `DBM_INSERT` is specified, and the *key* already exists, dbm_store() returns 1.

If unsuccessful, dbm_store() returns -1 and sets errno to one of the following values. Also, the database error indicator may be set.

Error Code
Description

EFBIG
Seek/Write operation failed attempting to write new block. This errno is not part of the errno set described by X/Open for this function. You may be able to store other *key* and *content* pairs when the *key* hashes to a different value.

ENOSPC

key plus *content* plus block overhead does not fit into a block. This errno is not part of the errno set described by X/Open for this function. The *key* plus *content* underlying data lengths need be less or equal to 1012 bytes in length.

decabs() — Decimal absolute value

Standards

Standards / Extensions	C or C++	Dependencies
C Library	C only	

Format

```
#include <decimal.h>

decimal(n,p) decabs(decimal(n,p) pdec);
```

General description

The built-in function decabs() accepts a decimal type expression as an argument and returns the absolute value of the decimal argument, in the same decimal type as the argument. The function does not change the content of the argument.

The parameter *n* can be any integral value between 1 and DEC_DIG. The parameter *p* can be any integral value between 0 and DEC_PRECISION, although it must be less than or equal to *n*. DEC_DIG and DEC_PRECISION are defined inside decimal.h.

If the content of the given argument is not in native packed decimal format, behavior is undefined.

Example

CELEBD01

```
/* CELEBD01 */
#include <decimal.h>

decimal(10,2) p1, p2;
int main(void) {
    p2 = -1234.56d;
    p1 = decabs(p2);
    printf("p1 = %D(10,2), p2 = %D(10,2)\n", p1, p2);
    return(0);
}
```

Output

```
p1 = 1234.56, p2 = -1234.56
```

Related information

decchk() — Check for valid decimal types

Standards

Standards / Extensions	C or C++	Dependencies
C Library	C only	

Format

```
#include <decimal.h>

int decchk(decimal(n,p) pdec);
```

General description

The built-in function decchk() accepts a decimal type expression as an argument and returns a status value of type `int`.

The status can be interpreted as follows:

DEC_VALUE_OK
A valid decimal representation value (including the less-preferred but valid sign, A-F).

DEC_BAD_NIBBLE
The leftmost half-byte is not 0 in a decimal type number that has an even number of digits. For example, 123 is stored in decimal(2,0). If such a number is packed, then it is used.

DEC_BAD_DIGIT
Digits not allowed (not 0-9). If such a number is packed, then it is used.

DEC_BAD_SIGN
Sign not allowed (not A-F). If such a number is packed, then it is used.

The function return status can be masked to return multiple status.

The parameter *n* can be any integral value between 1 and DEC_DIG. The parameter *p* can be any integral value between 0 and DEC_PRECISION, although it must be less than or equal to *n*. DEC_DIG and DEC_PRECISION are defined inside decimal.h.

If the content of the given argument is not in native packed decimal format, the behavior is undefined.

Example

```
#include <decimal.h>

decimal(10,2) p1;
char mem2[3] = { 0x12, 0x34, 0x5c };   /* bad half-byte */
char mem3[3] = { 0x02, 0xa4, 0x5c };   /* bad digit */
char mem4[3] = { 0x02, 0x34, 0x56 };   /* bad sign */
char mem5[3] = { 0x12, 0xa4, 0x56 };   /* bad half-byte, digit and sign */
decimal(4,0) *pp2;
decimal(4,0) *pp3;
decimal(4,0) *pp4;
decimal(4,0) *pp5;
int main(void) {
    p1 = 123456.78d;
    pp2 = (decimal(4,0) *) mem2;
    pp3 = (decimal(4,0) *) mem3;
    pp4 = (decimal(4,0) *) mem4;
    pp5 = (decimal(4,0) *) mem5;

    if (decchk(p1) == DEC_VALUE_OK) {
        printf("p1 is a valid decimal representation value.\n");
    }
    if (decchk(*pp2) == DEC_BAD_NIBBLE) {
        printf("pp2 points to a bad half-byte value!\n");
    }
    if (decchk(*pp3) == DEC_BAD_DIGIT) {
        printf("pp3 points to an illegal digit!\n");
    }
    if (decchk(*pp4) == DEC_BAD_SIGN) {
        printf("pp4 points to an illegal sign!\n");
    }
    /* The wrong way ----- */
    if (decchk(*pp5) == DEC_BAD_SIGN) {
        printf("YOU SHOULD NOT GET THIS!!!!!\n");
    }
    /* The right way ----- */
    if ((decchk(*pp5) & DEC_BAD_SIGN) == DEC_BAD_SIGN) {
        printf("pp5 points to an illegal sign!\n");
    }
    return(0);
}
```

Output

```
p1 is a valid decimal representation value.
pp2 points to a bad half-byte value!
pp3 points to an illegal digit!
pp4 points to an illegal sign!
pp5 points to an illegal sign!
```

Related information

- “decfix() — Fix up a nonpreferred sign variable”

decfix() — Fix up a nonpreferred sign variable

Standards

Standards / Extensions	C or C++	Dependencies
C Library	C only	

Format

```
#include <decimal.h>

decimal(n,p) decfix(decimal(n,p) pdec);
```

General description

The built-in function decfix() accepts a decimal type expression as an argument and returns a decimal value that has the same type and same value as the argument with the correct preferred sign. The function does not change the content of the argument.

The parameter *n* can be any integral value between 1 and DEC_DIG. The parameter *p* can be any integral value between 0 and DEC_PRECISION, though it must be less than or equal to *n*. DEC_DIG and DEC_PRECISION are defined inside decimal.h.

If the content of the given argument is not in native packed decimal format, behavior is undefined.

Example

```
#include <decimal.h>

char *ptr;
char mem[3] = { 0x01, 0x23, 0x4A };
decimal(4,0) *pp;
decimal(4,0) p;
int main(void) {
    pp = (decimal(4,0) *) mem;
    p = decfix(*pp);
    ptr = (char *) p;
    printf("Before decfix : %X%X%X\n", mem[0], mem[1], mem[2]);
    printf("After  decfix : %X%X%X\n", ptr[0], ptr[1], ptr[2]);
    return(0);
}
```

Output

```
Before decfix : 1234A
After  decfix : 1234C
```

DeleteWorkUnit() — Delete a WLM work unit

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

int DeleteWorkUnit(wlmetok_t *enclavetoken);
```

General description

The DeleteWorkUnit() function provides the ability for an application to delete a WLM work unit.

******enclavetoken*

Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().

Returned value

If successful, DeleteWorkUnit() returns 0.

If unsuccessful, DeleteWorkUnit() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
An argument of this function contained an address that was not accessible to the caller.

EINVAL
An argument of this function contained an incorrect value.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM delete enclave failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

difftime(), difftime64() — Compute time difference

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

Format of the difftime() function:

```
#include <time.h>

double difftime(time64_t time2, time_t time1);
```

Format of the difftime64() function:

```
#define _LARGE_TIME_API
#include <time.h>

double difftime64(time64_t time2, time64_t time1);
```

General description

Computes the difference in seconds between *time2* and *time1*, which are calendar times returned by time().

The difftime() function returns the difference between two calendar times as a double. The return value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking difftime(). The difftime() function uses __isBFP() to determine which floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) to return on the invoking thread.

The function difftime64() will behave exactly like difftime() except it will support calendar times beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

Returns the elapsed time in seconds from *time1* to *time2* as a double.

Example

CELEBD04

```
/* CELEBD04

   This example shows a timing application using &diff..
   The example calculates how long, on average, it takes a
   user to input some data to the program.

 */
#include <time.h>
#include <stdio.h>

int main(void)
{
   time_t start, finish;
   int i, n, num;
   int answer;

   printf("11 x 55 = ? Enter your answer below\n");
   time(&start);
   scanf("%d",&answer);
   time(&finish);
   printf("You answered %s in %.0f seconds.\n",
           answer == 605 ? "correctly" : "incorrectly",
           difftime(finish,start));
}
```

Output

```
11 x 55 = ? Enter your answer below
605
You answered correctly in 20 seconds
```

dirname() — Report the parent directory of a path name

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>

char *dirname(char *path);
```

General description

The dirname() function takes a pointer to a character string that contains a path name, and returns a pointer to a string that is a path name of the parent directory of that file. Trailing '/' characters in the path are not counted as part of the path.

If *path* does not contain a '/' then dirname() returns a pointer to the string ".". If *path* is a NULL pointer or points to an empty string, dirname() returns a pointer to the string ".".

The dirname() function may modify the string pointed to by path.

Examples:

```
Input String      Output String
"/usr/lib"        "/usr"
"/usr/"           "/"
"usr"             "."
"/"               "/"
"."               "."
".."              "."
```

Returned value

If successful, dirname() returns a pointer to a string that is the parent directory of *path*.

If *path* is a NULL pointer or points to an empty string, dirname() returns a pointer to a string ".".

There are no errno values defined.

Related information

- "libgen.h" on page 38
- "basename() — Return the last component of a path name" on page 208

__discarddata() — Release pages backing virtual storage

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	OS/390 V2R10

Format

```
#include <stdlib.h>

int __discarddata(void *addr, size_t size);
```

General description

The __discarddata() function is used to release segments of real storage backing virtual storage. Segments backing virtual storage are released beginning at location *addr* for a length of *size*. For AMODE 31, the *addr* must begin on a page (4K) boundary and size must be a multiple of 4K. For AMODE 64, the *addr* must begin on a segment (1 MB) boundary and size must be a multiple of 1 MB.

Returned value

If successful, __discarddata() returns 0.

If unsuccessful, because *addr* does not begin on a page (4K) boundary or *size* is not a multiple of 4K, __discarddata() returns -1.

There are no errno values defined.

Related information

- "stdlib.h" on page 70

DisconnectServer() — Disconnect from WLM server

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

int DisconnectServer(unsigned long *conn_tkn);
```

AMODE 64

```
#include <sys/__wlm.h>

int DisconnectServer(unsigned int *conn_tkn);
```

General description

The DisconnectServer function provides the ability for an application to disconnect from WLM.

**conn_tkn*
Specifies the connect token that represents the WLM connection that is to be disconnected.

Returned value

If successful, DisconnectServer() returns 0.

If unsuccessful, DisconnectServer() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
An argument of this function contained an address that was not accessible to the caller.

EINVAL
An argument of this function contained an incorrect value.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM disconnect failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

div() — Calculate quotient and remainder

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <stdlib.h>

div_t div(int numerator, int denominator);
div_t div(long numerator, long denominator);   /* C++ only */
```

C++ TR1 C99:

```
#define _TR1_C99
#include <inttypes.h>
imaxdiv_t div(intmax_t numerator, intmax_t denominator);

#define _TR1_C99
#include <stdlib.h>
lldiv_t div(long long numerator, long long denominator);
```

General description

Calculates the quotient and remainder of the division of *numerator* by *denominator*.

Special behavior for C++: For C++ applications, div() is also overloaded for the type long.

Returned value

Returns a structure of type `div_t`, containing both the quotient `int` *quot* and the remainder `int` *rem*. This structure is defined in stdlib.h. If the returned value cannot be represented, the behavior of div() is undefined. If *denominator* is 0, the same exception will be raised as if you divided by 0. That is, you get the error CEE3209S (Fixed-point divide exception).

Related information

- "stdlib.h" on page 70
- "ldiv() — Compute quotient and remainder of integral division" on page 944

dlclose() — Close a dlopen() object

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 3	both	z/OS V1R6

Format

```
#define _UNIX03_SOURCE
#include <dlfcn.h>

int  dlclose(void *handle);
```

General description

Informs the system that the dynamic link library (DLL) referenced by a *handle* returned from a previous dlopen() invocation is no longer needed by the application. Once a DLL has been closed, an application should assume that its symbols and the symbols of any dependent DLLs are no longer available to dlsym().

Returned value

NULL is returned if the referenced DLL was successfully closed. If the DLL could not be closed, or if *handle* does not refer to an open DLL, a non-zero value will be returned.

Usage notes

1. A conforming application should use a *handle* returned from a dlopen() invocation only within a given scope, bracketed by the dlopen() and dlclose() operations. The value of a *handle* must be treated as an opaque object by the application, used only in calls to dlsym() and dlclose().
2. DLLs that are loaded explicitly, that is with dlopen(), and are not freed with a corresponding call to dlclose(), are freed automatically at enclave termination in LIFO sequence.
3. Non-local C++ static destructors defined in a DLL are executed only once, when the DLL program object is deleted from memory.
4. More detailed diagnostic information is available through dlerror(), the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.
5. This function is not available under SPC, MTF and CSP environments.

Example

The following example illustrates use of dlopen() and dlclose():

```
...
/* Open a dynamic library and then close it ... */

#include <dlfcn.h>

void *mylib;
```

```
int eret;

mylib = dlopen("mylib.so", RTLD_LOCAL | RTLD_LAZY);
...
eret = dlclose(mylib);
...
```

Related information

- "dlerror() — Get diagnostic information"
- "dlopen() — Gain access to a dynamic link library" on page 387
- "dlsym() — Obtain the address of a symbol from a dlopen() object" on page 390
- "dlfcn.h" on page 23

dlerror() — Get diagnostic information

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 3	both	z/OS V1R6

Format

```
#define _UNIX03_SOURCE
#include <dlfcn.h>

void  dlerror(void);
```

General description

Returns a null-terminated character string (with no trailing <newline>) that describes the last error that occurred while processing a DLL by dlopen(), dlsym(), or dlclose(). NULL is returned if no errors have occurred since the last invocation of dlerror().

Note: dlerror() is thread safe, so the information returned describes the last error that occurred on that thread

Returned value

A null-terminated character string is returned if successful, otherwise NULL is returned.

Usage notes

1. Messages returned by dlerror() reside in a static buffer that is overwritten on each new call to dlerror() on that thread.
2. Application code should not write to this buffer.
3. Programs wishing to preserve an error message should make their own copies of that message.
4. This function is not available under SPC, MTF and CSP environments.

Example

The following example prints out the last dynamic linking error:

```
...
#include <dlfcn.h>

char *errstr;

errstr = dlerror();
if (errstr != NULL)
printf ("A dynamic linking error occurred: (%s)\n", errstr);
...
```

Related information

- “dlclose() — Close a dlopen() object” on page 385
- “dlopen() — Gain access to a dynamic link library”
- “dlsym() — Obtain the address of a symbol from a dlopen() object” on page 390
- “dlfcn.h” on page 23

dlopen() — Gain access to a dynamic link library

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 3	both	z/OS V1R6

Format

```
#define _UNIX03_SOURCE
#include <dlfcn.h>

void  *dlopen(const char *file, int mode);
```

General description

Makes the dynamic link library (DLL) specified by *file* available to the calling program.

If the *file* argument contains a single slash ("/"), it is used as the z/OS UNIX file system path name for the DLL. If the environment variable LIBPATH is set, each directory listed will be searched for the DLL. Otherwise, the current directory will be searched.

Note: Searching for a DLL in the z/OS UNIX file system is case-sensitive.

If the *file* argument begins with two slashes ("//"), then an attempt is made to load the DLL from the caller's MVS load library search order (in order: STEPLIB/JOBLIB, LPA, Link List). The DLL name must be eight characters or less, and is converted to uppercase.

If the *file* argument doesn't begin with one or two slashes ("/" or "//"), and doesn't contain a single slash ("/") anywhere in the name, then it is ambiguous as to where the DLL resides.

- If the POSIX(ON) runtime option is specified, then the z/OS UNIX file system is searched first for the DLL, and if not found, the MVS load library is searched.
- If the POSIX(OFF) runtime option is specified, then the MVS load library is searched first for the DLL, and if not found, the z/OS UNIX file system is searched.

Under the CICS environment, the search sequence for DLL load modules is the same as that used for dynamically loaded CICS modules. Loading DLLs from the z/OS UNIX file system is not supported under CICS.

For more information about how DLLs are loaded and how the search sequence is used, see the topic about loading DLLs in *z/OS Language Environment Programming Guide*.

A successful call returns a handle which the caller may use on subsequent calls to dlsym() and dlclose(). The value of this handle should not be interpreted in any way by the caller.

Only a single copy of a DLL is brought into the address space, even if invoked multiple times for the same DLL, and even if different values of the *file* parameter are used to reference the same DLL.

The *mode* parameter describes how dlopen() operates on a file with respect to the processing of dependent DLLs and the scope of visibility of the symbols provided within *file*. If a *file* is specified in multiple invocations, *mode* is interpreted at each invocation. The *mode* is a bitwise-OR of the values specified.

Mode Values

When a DLL is loaded, it may contain implicit references to symbols in another "dependent" DLL, whose addresses are not known until that DLL is loaded. These implicit references must be relocated before the symbols can be accessed, which means loading the DLL containing the references. The *mode* parameter governs when these relocations (and loads) take place and may have the following values:

Value Description

RTLD_LAZY
: When possible, the loading of dependent DLLs, and resolution of symbols contained therein, may be deferred until the first reference to one of those symbols. This is the default behavior.

  Note: Once *RTLD_NOW* has been specified, all relocations will have been completed causing additional *RTLD_NOW* operations to be redundant and any further *RTLD_LAZY* operations irrelevant.

RTLD_NOW
: Load all dependent DLLs for the DLL being loaded and resolve all symbols before returning. This may include zero or more levels of nested dependent DLLs, all of which are loaded at this time.

RTLD_GLOBAL
: Allows symbols in the DLL being loaded to be visible when resolving symbols through the global symbol object that was opened with dlopen(*NULL*,*0*). All dependent DLLs are always implicitly loaded as if RTLD_GLOBAL had been specified. This is the default behavior.

RTLD_LOCAL
: Prevents symbols in the DLL being loaded to be visible when resolving symbols through the global symbol object that was opened with dlopen(*NULL*,*0*). All dependent DLLs of this DLL continue to be implicitly loaded as if RTLD_GLOBAL had been specified.

  If a subsequent call is made for this same DLL with a *mode* of *RTLD_GLOBAL*, then the DLL will maintain the *RTLD_GLOBAL* status regardless of any previous or future specification of *RTLD_LOCAL*, as long as the DLL remains loaded (see dlclose()).

If the value of *file* is NULL, dlopen() returns a "global symbol object" *handle*. This object will provide access (via dlsym()) to the symbols exported from:

- The main application, and dependent DLLs for the main application that were loaded at program start-up, and
- The set of DLLs loaded using dlopen() with the *RTLD_GLOBAL* flag. This set of DLLs can change dynamically as other DLLs are opened and closed.

Symbols introduced by the call to dlopen() for a DLL, and available through dlsym(), are those which are exported by the DLL. Typically such symbols will be those identified by a #pragma export in C, or with the EXPORTALL compile option. For details on how to specify exported data and functions, for C/C++ as well as other languages, see the topic about building a simple DLL in *z/OS Language Environment Programming Guide*

Returned value

NULL is returned if:

- *file* cannot be found or opened for reading
- *file* is not in correct DLL executable format
- an error occurred during the process of loading *file*, or relocating its symbolic references
-

Usage notes

1. For details on how to create and use DLLs, see *z/OS Language Environment Programming Guide*.
2. The AMODE of the application must be the same as the AMODE of the DLL.
3. Non-local C++ static constructors defined in a DLL are executed only once, when the DLL program object is physically loaded into memory.
4. More detailed diagnostic information is available through dlerror(), the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.
5. This function is not available under SPC, MTF and CSP environments.

Example

The following example illustrates use of dlopen() and dlclose():

```
...
/* Open a dynamic library and then close it ... */

#include <dlfcn.h>

void *mylib;
int eret;

mylib = dlopen("mylib.so", RTLD_LOCAL | RTLD_LAZY);
...
eret = dlclose(mylib);
...
```

Related information

- "dlsym() — Obtain the address of a symbol from a dlopen() object"
- "dlfcn.h" on page 23

dlsym() — Obtain the address of a symbol from a dlopen() object

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 3	both	z/OS V1R6

Format

```
#define _UNIX03_SOURCE
#include <dlfcn.h>

void  *dlsym(void *__restrict__ handle, const char *__restrict__ name);
```

General description

Obtains the address of a symbol defined within a dynamic link library (DLL) made accessible through a dlopen() call. The *handle* argument is the value returned from a call to dlopen() (which has not been released by a call to dlclose()), and *name* is the symbol's name as a character string.

The DLL that was loaded by dlopen() will be searched for the named symbol. If the symbol is not found in that DLL, then the dependent DLLs of that DLL will be searched, followed by any dependents of those, and continuing in a breadth-first manner until the named symbol is found or all dependent DLLs have been searched. This search order determines how duplicate symbols in different DLLs will be found, although the order in which dependent DLLs at the same level are searched is indeterminate.

Also note that a search of dependent DLLs by dlsym() will not result in unloaded dependent DLLs being loaded. Only the dependent DLLs loaded as part of the call to dlopen() will be searched. If the full set of dependent DLLs need to be available to subsequent calls to dlsym(), make sure the DLL is opened with the *RTLD_NOW* load flag. It is indeterminate which dependent DLLs are loaded when *RTLD_LAZY* is specified

The only exception to this is the global symbol object obtained via a dlopen(*NULL*,*0*) call, in which case all DLLs (excluding those opened with *RTLD_LOCAL*) are searched in the order in which they were loaded.

Returned value

NULL is returned:

- If *handle* does not refer to a valid DLL opened by dlopen(),
- or the named symbol (*name*) cannot be found within any of the DLLs associated with *handle*.

Usage notes

1. The named symbol can be either an exported data item or function.
2. DLLs are enclave level resources. See *z/OS XL C/C++ Programming Guide* for more information about the use of DLLs in a multi-threaded environment.
3. C++ symbol names should be passed to dlsym() in mangled form; dlsym() does not perform any name mangling on behalf of the calling application.
4. More detailed diagnostic information is available through dlerror(), the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.
5. This function is not available under SPC, MTF and CSP environments.

Example

The following example shows how dlopen() and dlsym() can be used to access either function or data objects. For simplicity, error checking has been omitted.

```
void    *handle;
int     *iptr, (*fptr)(int);

/* open the needed object */
handle = dlopen("/usr/home/me/libfoo.so", RTLD_LOCAL | RTLD_LAZY);

/* find the address of function and data objects */
fptr = (int (*)(int))dlsym(handle, "my_function");
iptr = (int *)dlsym(handle, "my_object");

/* invoke function, passing value of integer as a parameter */
(*fptr)(*iptr);
```

Related information

dllfree() — Free the supplied dynamic link library

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <dll.h>

int dllfree(dllhandle *dllHandle);
```

General description

Frees the supplied dynamic link library (DLL). It also deletes the DLL from memory if the handle was the last handle accessing the DLL.

Returned value

dllfree() returns one of the following values and set errno if the return code is not 0:

Value	Meaning
0	Successful
1	The `dllHandle` supplied is NULL or `dllhandle` is inactive.
2	There are no DLLs to be deleted.
3	DLL is not physically deleted because there is another `dllHandle` for this DLL or there is an implicit reference to the DLL.
4	Delete of DLL failed.
5	No match is found for input `dllHandle`.
6	Not supported under this environment.
7	C++ destructors are currently running for this DLL. A dllfree() is already in progress.
8	The handle passed to dllfree() was obtained from dlopen().

Usage notes

1. This function is deprecated; use dlclose() instead.
2. This function is not available under SPC, MTF and CSP environments.
3. If a DLL is loaded implicitly, it cannot be deleted with dllfree(). For more information on the implicit use of DLLs, see *z/OS XL C/C++ Programming Guide*.
4. DLLs that are loaded explicitly, that is with dllload(), and are not freed with a corresponding call to dllfree(), are freed automatically at enclave termination in LIFO sequence.
5. C++ destructors are executed only once, when the DLL load module is physically deleted.
6. More detailed diagnostic information is available through the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain. The default action is to issue an error message to the Language Environment message file.

Example

CELEBDL4

```
/* CELEBDL4

   The following example shows how to use dllfree() to free the
   dllhandle for the DLL stream.

 */
#include <stdio.h>
#include <dll.h>
#include <stdlib.h>

int main() {
    dllhandle *handle;
    char *name="stream";
    int (*fptr1)(int);
    int (*fptr)(int);
    int *ptr_var1;
    int *ptr_var;
    int rc=0;

    handle = dllload(name); /* call to stream DLL */
    if (handle == NULL) {
       perror("failed on call to stream DLL");
       exit(-1);
    }

    fptr1 = (int (*)(int)) dllqueryfn(handle,"f1");
    /* retrieving f1 function */
    if (fptr == NULL) {
       perror("failed on retrieving f1 function");
       exit(-2);
    }

    ptr_var = dllqueryvar(handle,"var1");
    /* retrieving var1 variable */
    if (ptr_var1 == NULL) {
       perror("failed on retrieving var1 variable");
       exit(-3);
    }

    rc = fptr(*ptr_var1); /* execute DLL function f1 */
    *ptr_var++;           /* increment value of var1 */

    rc = dllfree(handle); /* freeing handle to stream DLL */
    if (rc != 0) {
       perror("failed on dllfree call");
    }
    return (0);
}

dllload() — Load the dynamic link library and connect it to the application

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <dll.h>

dllhandle *dllload(const char *dllName);
```

General description

Note: This function is deprecated; use dlopen() instead.

Loads the dynamic link library (DLL) into memory (if it has not been previously loaded) and connects it to the application. The function that called the DLL receives a handle that uniquely identifies the requested DLL for subsequent explicit requests for that DLL.

A different handle is returned for each successful call to dllload(). A DLL is physically loaded only once, even though there may be many calls to dllload(). C++ constructors are run only once.

The `dllName` identifies the DLL load module to be loaded. It must be a character string terminated with the NULL character. The DLL module must be a member of a PDS or an alias to it.

Note: The `AMODE` of the application must be the same as the `AMODE` of the DLL load module.

This function is not available under SPC, MTF and CSP environments.

The dllName identifies the DLL load to be loaded. It must be a character string, terminated with the NULL character. The DLL module must be a member of a PDS or an alias to it.

If the file argument contains a single slash ('/'), it is used as the z/OS UNIX file system path name for the DLL. If the environment variable LIBPATH is set, each directory listed will be searched for the DLL. Otherwise, the current directory will be searched.

Note: Searching for a DLL in the z/OS UNIX file system is case-sensitive.

If the file argument begins with two slashes ('//'), then an attempt is made to load the DLL from the caller's MVS load library search order (in order: STEPLIB/JOBLIB, LPA, Link List). The DLL name must be eight characters or less, and is converted to uppercase. Note that qualified DLL names are not supported and the MVS load library search order is used (for example, update or use STEPLIB to specify any number of qualifiers to be included in the search).

If the file argument doesn't begin with one or two slashes ('/' or //"), and doesn't contain a single slash ('/') anywhere in the name, then it is ambiguous as to where the DLL resides.

- If the POSIX(ON) runtime option is specified, then the z/OS UNIX file system is searched first for the DLL, and if not found, the MVS load library is searched.
- If the POSIX(OFF) runtime option is specified, then the MVS load library is searched first for the DLL, and if not found, the z/OS UNIX file system is searched.

Under CICS environment, the search sequence for DLL load modules is the same as that used for dynamically loaded CICS modules. Loading DLLs from the z/OS UNIX file system is not supported under CICS.

For more information about how DLLs are loaded and how the search sequence is used, see the topic about loading DLLs in *z/OS Language Environment Programming Guide*.

Returned value

If successful, dllload() returns a unique handle that identifies the DLL.

If unsuccessful, dllload() returns NULL and may set errno to one of the following values:

Error Code
Description

ELEFENCE
The DLL contains a member language not supported on this version of the operating system.

ENOEXEC
The new process image file has the appropriate access permission but is not in the proper format.

Note: Reason codes further qualify the errno. For most of the reason codes, see *z/OS UNIX System Services Messages and Codes*.

For ENOEXEC, the reason codes are:

Reason Code	Explanation
X'xxxx0C27'	The target z/OS UNIX file system file is not in the correct format to be an executable file.
X'xxxx0C31'	The target z/OS UNIX file system file is built at a level that is higher than that supported by the running system.

Usage notes

1. More detailed diagnostic information is available through the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

Example

CELEBDL1

```
/* CELEBDL1

   The following example shows how to invoke dllload() functions
   from a simple C application.

 */
#include <stdio.h>
#include <dll.h>

main() {
    dllhandle *handle;
    char *name="stream";

    handle = dllload(name);
    if (handle == NULL) {
       perror("failed on dllload of stream DLL");
       exit(-1);
    }
}
```

dllqueryfn() — Obtain a pointer to a dynamic link library function

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <dll.h>

void (*dllqueryfn(dllhandle *dllHandle, const char *funcName))();
```

General description

Note: This function is deprecated; use dlsym() instead.

Obtains a pointer to a dynamic link library (DLL) function (funcName). It uses the dllHandle returned from a previous successful call to dllload() for input. funcName represents the name of an exported function from the DLL. It must be a character string terminated with the NULL character.

This function is not available under the SPC, MTF, and CSP environments.

Returned value

If successful, dllqueryfn() returns a pointer to a function, *funcName*, that can be used to invoke the desired function in a DLL.

If unsuccessful, dllqueryfn() returns NULL and sets errno.

Usage notes

1. More detailed diagnostic information is available through the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

Example

CELEBDL2

```
/* CELEBDL2

   The following example shows how to use dllqueryfn() to obtain
   a pointer to a function, f1 that is in DLL load module stream.

 */
#include <stdio.h>
#include <dll.h>

main() {
    dllhandle *handle;
    char *name="stream";
    int (*fptr1)();
    handle = dllload(name);
    if (handle == NULL) {
       perror("failed on dllload of stream DLL");
       exit(-1);
    }

    fptr1 = (int (*)()) dllqueryfn(handle,"f1");
    if (fptr1 == NULL) {
       perror("failed on retrieving f1 function");
       exit (-2);
    }
}
```

- "dllqueryvar() — Obtain a pointer to a dynamic link library variable"

dllqueryvar() — Obtain a pointer to a dynamic link library variable

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <dll.h>

void* dllqueryvar(dllhandle *dllHandle, const char *varName);
```

General description

Obtains a pointer to a dynamic link library (DLL) variable (*varName*). It uses the *dllHandle* returned from a previous successful call to dllload() for input. *varName* represents the name of an exported variable from the DLL. It must be a character string terminated with the NULL character.

This function is not available under SPC, MTF and CSP environments.

Returned value

If successful, dllqueryvar() returns a pointer to a variable in the storage of the DLL.

If unsuccessful, dllqueryvar() returns NULL and sets errno.

Usage notes

1. More detailed diagnostic information is available through the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

Example

CELEBDL3

```
/* CELEBDL3

   The following example shows how to use dllqueryvar() to obtain a
   pointer to a variable, var1, that is in DLL load module stream.

 */
#include <stdio.h>
#include <dll.h>

int main() {
    dllhandle *handle;
    char *name="stream";
    int (*fptr1)(int);
    int *ptr_var1;
    int rc=0;

    handle = dllload(name);
    if (handle == NULL) {
       perror("failed on dllload of stream DLL");
       exit(-1);
    }

    fptr1 = (int (*)(int)) dllqueryfn(handle,"f1");
    /* retrieving f1 function */
    if (fptr1 == NULL) {
       perror("failed on retrieving f1 function");
       exit(-2);
    }

    ptr_var1 = dllqueryvar(handle,"var1");
    if (ptr_var1 == NULL) {
       perror("failed on retrieving var1 variable");
       exit(-3);
    }
}
```

dn_comp() — Resolver domain name compression

Standards

Standards / Extensions	C or C++	Dependencies
BSD 4.3	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_comp(const char *exp_dn, u_char *comp_dn, int length,
            u_char **dnptrs, u_char **lastdnptr);
```

General description

The dn_comp() function compresses the domain name *exp_dn* and stores it in *comp_dn*. The size of the compressed name is returned or -1 if there were errors. The size of the array pointed to by *comp_dn* is given by *length*. The compression uses an array of pointers *dnptrs* to previously-compressed names in the current message. The first pointer points to the beginning of the message and the list ends with NULL. The limit to the array is specified by *lastdnptr*.

A side effect of dn_comp() is to update the list of pointers for labels inserted into the message as the name is compressed. If *dnptr* is NULL, names are not compressed. If *lastdnptr* is NULL, the list of labels is not updated.

Note: The dn_comp() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2113 for details.

Returned value

If successful, dn_comp() returns the size of the compressed name.

If unsuccessful, dn_comp() returns -1 to report the error, when the name to be compressed was not found before the end of the buffer was reached.

There are no documented errno values.

dn_expand() — Resolver domain name expansion

Standards

Standards / Extensions	C or C++	Dependencies
BSD 4.3	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_expand(const u_char *msg, const u_char *eomorig,
              const u_char *comp_dn, char *exp_dn, int length);
```

General description

The dn_expand() function expands the compressed domain name *comp_dn* to a full domain name. The compressed name is contained in a query or reply message; *msg* is a pointer to the beginning of the message. The expanded name is placed in the buffer indicated by *exp_dn* which is of size *length*. The size of the expanded name is returned or -1 if there was an error.

Note: The dn_expand() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, dn_expand() returns the size of the expanded name.

If unsuccessful, dn_expand() returns -1 to report the error, when the name to be expanded was not found before the end of the buffer was reached.

There are no documented errno values.

Related information

- "res_send() — Send resolver query for domain name servers" on page 1443

dn_find() — Resolver domain name find

Standards

Standards / Extensions	C or C++	Dependencies
BSD 4.3	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_find(u_char *exp_dn, u_char *msg, u_char **dnptrs, u_char **lastdnptr);
```

General description

The dn_find() function will search for the expanded name *exp_dn* in the list of previously compressed names *dnptrs*.

dnptrs is the pointer to the first name in the list, not the pointer to the start of the message. The limit to the array is specified by *lastdnptr*.

Note: The dn_find() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, dn_find() returns the offset of the expanded name *exp_dn* found in the message.

If unsuccessful, dn_find() returns -1 to report the error, when the name was not found before the end of the list was reached.

There are no documented errno values.

Related information

dn_skipname() — Resolver domain name skipping

Standards

Standards / Extensions	C or C++	Dependencies
BSD 4.3	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_skipname(const u_char *comp_dn, u_char *eom);
```

General description

The dn_skipname() function skips the compressed domain name *comp_dn* and returns the position in the answer buffer that follows the *comp_dn* compressed domain name. If the information supplied in *comp_dn* is not a compressed domain name, -1 is returned to report the error.

Note: The dn_skipname() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, dn_skipname() returns the position in the answer buffer that follows the *comp_dn* compressed domain name.

If unsuccessful, dn_skipname() returns -1 to report the error, when the name to be skipped was not found before the end of the buffer was reached.

There are no documented errno values.

drand48() — Pseudo-random number generator

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

double drand48(void);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0). These functions have been extended so that the returned value will be in the proper floating-point format (hexadecimal or IEEE) based on the floating-point mode of the invoking thread.

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The drand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

```
X(n+1) = (aX(n) + c)mod(2**48)      n>=0
```

The initial values of X, a, and c are:

```
X(0) = 1
a   = 5deece66d (base 16)
c   = b         (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The value, X(n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function. Likewise, the values of a and c, may be changed by calling the lcong48() function. Thereafter, whenever the seed48() or srand48() function is called to change X(n), the initial values of a and c are also reestablished.

Special behavior for z/OS UNIX Services: You can make the drand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, and the drand48() function is called from thread t, the drand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread t. The sequence of values for a thread is generated according to the linear congruential formula:

```
   X(t,n+1) = (a(t)X(t,n) + c(t))mod(2**48)      n>=0
```

The initial values of X(t), a(t) and c(t) for the thread t are:

```
   X(t,0) = 1
   a(t)   = 5deece66d (base 16)
   c(t)   = b         (base 16)
```

C/370 provides storage which is specific to the thread t to save the most recent 48-bit integer value of the sequence, X(t,i), generated by the drand48(), lrand48() or mrand48() function. The value, X(t,n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function from the thread t. Likewise, the values of a(t) and c(t) for thread t may be changed by calling the lcong48() function from the thread. Thereafter, whenever the seed48() or srand48() function is called from the thread t to change X(t,n), the initial values of a(t) and c(t) are also reestablished.

Returned value

drand48() transforms the generated 48-bit value, X(n+1), to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the drand48 family and rand48() is called on thread t, drand48() transforms the generated 48-bit value, X(t,n+1), to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

dup() — Duplicate an open file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int dup(int fildes);
```

General description

Returns a new file descriptor that is the lowest numbered available descriptor. The new file descriptor refers to the same open file as *fildes* and shares any locks that may be associated with *fildes*.

The following operations are equivalent:

```
fd = dup(fildes);
fd = fcntl(fildes,F_DUPFD,0);
```

For further information, see "fcntl() — Control open file descriptors" on page 474.

Note: When *fildes* is an XTI endpoint, the lowest numbered available file descriptor must not exceed 65535.

Returned value

If successful, dup() returns a new file descriptor.

If unsuccessful, dup() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EMFILE
The process has already reached its maximum number of open file descriptors.

Example

CELEBD05

```
/* CELEBD05

   This example duplicates an open file descriptor, using dup().

 */
#define _POSIX_SOURCE
#include <errno.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

void print_inode(int fd) {
 struct stat info;
 if (fstat(fd, &info) != 0)
   fprintf(stderr,"fstat() error for fd %d: %s\n",fd,strerror(errno));
 else
   printf("The inode of fd %d is %d\n", fd, (int) info.st_ino);
}

main() {
  int fd;
  if ((fd = dup(0)) < 0)
    perror("&dupf error");
  else {
    print_inode(0);
    print_inode(fd);
    puts("The file descriptors are different but");
    puts("they point to the same file.");
    close(fd);
  }
}
```

Output

```
The inode of fd 0 is 30
The inode of fd 3 is 30
The file descriptors are different but
they point to the same file.
```

dup2() — Duplicate an open file descriptor to another

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int dup2(int fd1, int fd2);
```

General description

Returns a file descriptor with the value *fd2*. *fd2* now refers to the same file as *fd1*, and the file that was previously referred to by *fd2* is closed. The following conditions apply:

- If *fd2* is less than 0 or greater than OPEN_MAX, dup2() returns -1 and sets errno to EBADF.
- If *fd1* is a valid file descriptor and is equal to *fd2*, dup2() returns *fd2* without closing it; F_CLOEXEC is not cleared.
- If *fd1* is not a valid file descriptor, dup2() fails and does not close *fd2*.
- If a file descriptor does not already exist, dup2() can be used to create one, a duplicate of *fd1*. F_CLOEXEC is cleared in fd2.

Note: If *fd1* is an XTI endpoint, *fd2* must not exceed 65535.

Returned value

If successful, dup2() returns *fd2*.

If unsuccessful, dup2() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fd1 is not a valid file descriptor, or *fd2* is less than 0 or greater than **OPEN_MAX**.

EINTR
dup2() was interrupted by a signal.

Example

CELEBD06

```
/* CELEBD06

   This example duplicates an open file descriptor, using dup2().

 */

#define _POSIX_SOURCE
#include <errno.h>
#include <fcntl.h>
```

```
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

void print_inode(int fd) {
 struct stat info;
 if (fstat(fd, &info) != 0)
   fprintf(stderr,"fstat() error for fd %d: %s\n",fd,strerror(errno));
 else
   printf("The inode of fd %d is %d\n", fd, (int) info.st_ino);
}

main() {
  int fd;
  char fn[]="dup2.file";

  if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    print_inode(fd);
    if ((fd = dup2(0, fd)) < 0)
      perror("dup2() error");
    else {
      puts("After dup2()...");
      print_inode(0);
      print_inode(fd);
      puts("The file descriptors are different but they");
      puts("point to the same file which is different than");
      puts("the file that the second fd originally pointed to.");
      close(fd);
    }
    unlink(fn);
  }
}
```

Output

```
The inode of fd 3 is 3031
After dup2()...
The inode of fd 0 is 30
The inode of fd 3 is 30
The file descriptors are different but they
point to the same file which is different than
the file that the second fd originally pointed to.
```

dynalloc() — Allocate a data set

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <dynit.h>

int dynalloc(__dyn_t *dyn_parms);
```

General description

The dynalloc() function dynamically allocates a MVS data set using the MVS SVC 99 service and by building an SVC 99 parameter list based on parameters specified in *dyn_parms*. The dynalloc() function corresponds to verb code 1 for SVC 99. To use other SVC 99 verb codes, see “svc99() — Access supervisor call” on page 1788.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile your application with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED). any relevant information in the header is also exposed.

The request block extension and the error message parameter list can be used to process the messages returned by SVC99 when an error occurs. To use this feature you must allocate and initialize these structures using the processes described in *z/OS MVS Programming: Authorized Assembler Services Guide*. You must also make them available to the dynalloc() function by assigning their addresses to __rbx or __emsgparmlist.

Because additional fields have been added to the `__dyn_t` structure, you should recompile existing source code with the latest dynit.h header file to access the new fields.

Some values, such as *ddname* and *dsname*, will be converted to uppercase internally when they are used by the dynalloc() function.

To dynamically allocate an MVS data set, you should:
- Invoke the dyninit() function with a variable of type __dyn_t.
- Assign values to the appropriate fields in the variable that will satisfy the svc99() request.
- Invoke the dynalloc() function with this variable.

Table 21 on page 409 describes the elements that are part of the `__dyn_t` structure, organized as defined in the structure.

Note: For more complete information about the `__dyn_t` structure elements, their usage and restrictions, see the description of SVC 99, the SVC 99 extension block, and the text unit keys and values in *z/OS MVS Programming: Authorized Assembler Services Guide* and *z/OS MVS JCL Reference*.

Table 21. Description of __dyn_t Structure Elements

Element	Text Unit Key	Text Unit Value	Type	Description
__ddname	DALDDNAM	0001	char *	ddname (maximum length of 8)[1]. If 8 question marks (????????) are specified, it means that the request expects a system-generated ddname returned.
__dsname	DALDSNAM	0002	char *	Fully qualified data-set name (maximum length of 44)[1].
__sysout	DALSYSOU	0018	char	The class of the system output data set (for example, SYSOUT=A). Values are: alphabetic character, or the macro __DEF_CLASS, to specify the default class.
__sysoutname	DALSPGNM	0019	char *	Program name for sysout. The __sysout field must be specified with this field (maximum length of 8)[1].
__member	DALMEMBR	0003	char *	Member of a partitioned data set to be allocated (maximum length of 8)[1].
__status	DALSTATS	0004	char	Data set status. Values are: __DISP_OLD, __DISP_NEW, __DISP_MOD, and __DISP_SHR, which are defined in dynit.h.
__normdisp	DALNDISP	0005	char	Specifies the normal disposition of a data set. Values are: __DISP_CATLG, __DISP_UNCATLG, __DISP_DELETE, and __DISP_KEEP, which are defined in dynit.h.
__conddisp	DALCDISP	0006	char	Specifies the conditional disposition of a data set. Values are: __DISP_CATLG, __DISP_UNCATLG, __DISP_DELETE, and __DISP_KEEP, which are defined in dynit.h.
__unit	DALUNIT	0015	char *	Unit name of the device that the data set will (or does, if it already exists) reside on (maximum length of 8)[1].
__volser	DALVLSER	0010	char *	Volume serial number of the device a data set will (or does, if it already exists) reside on (maximum length of 6)[1].

Table 21. Description of __dyn_t Structure Elements (continued)

Element	Text Unit Key	Text Unit Value	Type	Description
__dsorg	DALDSORG	003C	char	Data set organization of a data set. Values are: **__DSORG_unknown** Unknown **__DSORG_VSAM** VSAM **__DSORG_GS** Graphics **__DSORG_PO** Partitioned organization **__DSORG_POU** Partitioned organization unmovable **__DSORG_DA** Direct access **__DSORG_DAU** Direct access unmovable **__DSORG_PS** Physical sequential **__DSORG_PSU** Physical sequential unmovable.
__alcunit	DALCYL, DALTRK	0008, 0007	char	Unit of space allocation for a data set. Values are: __CYL and __TRK. To specify allocation units in blocks, use the field __avgblk.
__primary	DALPRIME	000A	int	Primary space allocation for a data set.
__secondary	DALSECND	000B	int	Secondary space allocation for a data set.
__dirblk	DALDIR	000C	int	Number of directory blocks for a partitioned data set.
__avgblk	DALBLKLN	0009	int	Specifies the unit of space allocation to be blocks and sets the average block length.

Table 21. Description of __dyn_t Structure Elements (continued)

Element	Text Unit Key	Text Unit Value	Type	Description
__recfm		0049	short	Record format of a data set. The following macros in dynit.h can be added together to determine the __recfm value: **_M_** Machine-code printer-control characters **_A_** ASA printer-control characters **_S_** Standard fixed, spanned variable **_B_** Blocked **_D_** Variable ASCII records **_V_** Variable **_F_** Fixed **_U_** Undefined **_FB_** Fixed blocked **_VB_** Variable blocked **_FBS_** Fixed blocked standard **_VBS_** Variable blocked standard. For example, to specify a recfm of FBA, set: _recfm = _FB_ + _A_
__blksize	DALBLKSZ	0030	short	Block size of a data set.
__lrecl	DALLRECL	0042	unsigned short	Record length of a data set.
__volrefds	DALLVLRDS	0014	char *	Fully qualified name of a cataloged data set to be used as a model for obtaining volume serial information (maximum length of 44)[1].
__dcbrefds	DALDCBDS	002C	char *	Fully qualified name of a cataloged data set to be used as a model for obtaining DCB information (maximum length of 44)[1].
__dcbrefdd	DALLDCBDD	002D	char *	ddname of a data set to be used as a model for obtaining DCB information (maximum length of 9)[1]. For more information, see *z/OS MVS Programming: Authorized Assembler Services Guide*.
__misc_flags			unsigned char	Specifies the attributes. See “Example” on page 414 for instructions on how to specify the flags shown below using a logical | (OR).
__CLOSE	DALCLOSE	001C	unsigned char	(Flag) Deallocate data set when file is closed.
__RELEASE	DALRLSE	000D	unsigned char	(Flag) Release unused space when file is closed.
__CONTIG	DALSPRFRM	000E	unsigned char	(Flag) Allocate space contiguously.
__ROUND	DALROUND	000F	unsigned char	(Flag) Allocate space in whole cylinders when blocks are requested.
__TERM	DALTERM	0028	unsigned char	(Flag) Time-sharing terminal is to be used as I/O device.

Table 21. Description of __dyn_t Structure Elements (continued)

Element	Text Unit Key	Text Unit Value	Type	Description
__DUMMY_DSN	DALDUMMY	0024	unsigned char	(Flag) Dummy data set is to be allocated.
__HOLDQ	DALSHOLD	0059	unsigned char	(Flag) Hold queue routing for sysout data set.
__PERM	DALPERMA	0052	unsigned char	(Flag) Set permanent allocation attribute.
__password	DALPASSW	0050	char *	Password for a password-protected data set. The dsname field must be specified with this field (maximum length of 8)[1].
__miscitems			char * __ptr32 * __ptr32	For all other text unit keys not available in __dyn_t, this pointer will let you specify an array of text unit strings. If you specify this field, you must turn the high bit on the last item (as in svc99()). Use the bitwise inclusive-OR (|) operand with the last item and the hexadecimal value 0x80000000.
__infocode			short	Returns the information code returned by the MVS dynamic allocation functions. For more information, see *z/OS MVS Programming: Authorized Assembler Services Guide*.
__errcode			short	Returns the error code returned by the MVS dynamic allocation functions. For more information, see *z/OS MVS Programming: Authorized Assembler Services Guide*.
__storclass	DALSTCL	8004	char *	Specifies the storage class of system managed storage.
__mgntclass	DALMGCL	8005	char *	Specifies the management class of a data set.
__dataclass	DALDACL	8006	char *	Specifies the data class of a data set.
__recorg	DALRECO	800B	char	Specifies the record organization of a VSAM data set. Values are: __KS, __ES, __RR, __LS.
__keyoffset	DALKEYO	800C	short	Specifies the key offset. The position of the first byte of the key in records of the specified VSAM data set.
__keylength	DALKYLEN	0040	short	Specifies the length in bytes of the keys used in the data set.
__refdd	DALREFD	800D	char *	Specifies the name of the JCL DD statement from which the attributes are to be copied. For more information, see *z/OS MVS Programming: Authorized Assembler Services Guide*.
__like	DALLIKE	800F	char *	Specifies the name of the model data set from which the attributes are to be copied.
__dsntype	DALDSNT	8012	char	Specifies the type attributes of a data set. Valid types include __DSNT_BASIC, __DSNT_EXTPREF, __DSNT_EXTREQ, __DSNT_HFS, __DSNT_LARGE, __DSNT_LIBRARY, __DSNT_PDS, and __DSNT_PIPE.

Table 21. Description of __dyn_t Structure Elements (continued)

Element	Text Unit Key	Text Unit Value	Type	Description
__pathname	DALPATH	8017	char *	Pathname (maximum length is 255)[1]. See *z/OS V2R2.0 UNIX System Services User's Guide* for the pathname format.
__pathopts	DALPOPT	8018	int	Specifies file options for the HFS file. Values are: __PATH_OCREAT, __PATH_OAPPEND, __PATH_OEXCL, __PATH_ONOCTTY, __PATH_OTRUNC, __PATH_ONONBLOCK, __PATH_ORDONLY, __PATH_OWRONLY, __PATH_ORDWR. For information about the file options, see *z/OS MVS JCL Reference*. For information about DYNALLOC, see *z/OS MVS Programming: Authorized Assembler Services Guide*.
__pathmode	DALPMDE	8019	int	Specifies the file access attributes for the HFS file. Values are: __PATH_SIRUSR, __PATH_SIWUSR, __PATH_SIXUSR, __PATH_SIRWXU, __PATH_SIRGRP, __PATH_SIWGRP, __PATH_SIXGRP, __PATH_SIRWXG, __PATH_SIROTH, __PATH_SIWOTH, __PATH_SIXOTH, __PATH_SIRWXO, __PATH_SISUID, __PATH_SISGID. For information on the file attributes, refer to *z/OS MVS JCL Reference*. For information on DYNALLOC, refer to *z/OS MVS Programming: Authorized Assembler Services Guide*.
__pathndisp	DALPNDS	801A	char	Specifies the normal HFS file disposition desired. It is either __DISP_KEEP or __DISP_DELETE
__pathcdisp	DALPCDS	801B	char	Specifies the abnormal HFS file disposition desired. It is either __DISP_KEEP or __DISP_DELETE
__rbx			__S99rbx_t * __ptr32	For users who make use of the Request Block Extension.
__emsgparmlist			__S99emparms_t * __ptr32	For users who want to process associated messages with the dynamic allocation.
__rls	DALRLS	801C	char	Specifies the type of record level sharing (RLS) being done for a specific data set. The valid values are __RLS_NRI, __RLS_CR and __RLS_CRE. See *z/OS XL C/C++ Programming Guide* and *z/OS DFSMS Using Data Sets* for a description of these VSAM RLS/TVS access modes.

[1] If an element exceeds its maximum allowable length, it is truncated to that length.

Special behavior for POSIX C: For POSIX C programs, allocations established by the dynalloc() function persist neither after an `exec` nor in the child process after fork().

Special behavior for enhanced ASCII: When compiled ASCII, there is one input element in the `__dyn_t` structure that must contain EBCDIC text strings and there is a consideration to note with respect to retrieval of error messages related to a dynamic allocation failure. On input, any character data provided in __miscitems must be specified in the EBCDIC codeset. The __dynalloc() function does not decode the text units and convert the character data. The text units are passed directly to the system. When __emsgparmlist is specified, indicating intent to retrieve error messages using the IEFDB476 service, it should be noted that all error messages returned by the service will be in the EBCDIC codeset.

Note: The dynalloc() function has a dependency on the level of the enhanced ASCII extensions. See "Enhanced ASCII support" on page 2113 for details.

Special behavior for AMODE 64: The definitions in the `__dyn_t` structure are changed to require three of its pointer elements to be 32 bits wide. This is because the system services that work with these control structures require 31-bit addressable storage. The __miscitems are additional text units that are not already supported by elements of the `__dyn_t` structure. These are propagated by the dynalloc() function directly to into an SVC 99 call. The __rbx is propagated by the dynalloc() function directly into an SVC 99 call. The __emsgparmlist address is designed to be passed as a parameter to the IEFDB476 service, which is an AMODE 31 service, to retrieve messages associated with a dynamic allocation failure. The `__dyn_t` structure itself can be in 64-bit addressable storage. The `__dyn_t` structure must be initialized using the dyninit() macro defined in dyninit.h to ensure the proper "hidden" version indicator is used. Improper initialization of the `__dyn_t` structure will result in undefined behavior.

Returned value

If successful under MVS, the dynalloc() function returns 0.

If SVC 99 is not supported on your system, or if a text string passed to SVC 99 cannot be built from a field in *dyn_parms*, a negative value is returned.

The value -1 is returned if there is not sufficient storage to process all the text units. Otherwise, the return code is the value returned from SVC 99, and the error and information codes are found in those fields in *dyn_parms*.

For example, if you pass NULL to the dynalloc() function, the return code is nonzero.

For more information about return codes, see *z/OS MVS Programming: Authorized Assembler Services Guide*.

Example

CELEBD07

```
/* CELEBD07

   This example dynamically allocates a data set.

 */
#include <dynit.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define ZERO 0

int main () {
   __dyn_t ip;

   dyninit(&ip);

   ip.__ddname = "mydd";                /* MYDD DD                */
   ip.__dsname = "PLIXXX.MY.DATASET";   /* DSN='PLIXXX.MY.DATASET' */
   ip.__status = __DISP_NEW;              /* DISP=(NEW,CATLG)        */
   ip.__normdisp = __DISP_CATLG;
   ip.__alcunit = __CYL;                /* SPACE=(CYL,(2,1)),      */
   ip.__primary = 2;
   ip.__secondary = 1;
   ip.__dirblk = 1;
   ip.__misc_flags = __RELEASE & __CONTIG;  /*       RLSE,CONTIG)  */
   ip.__dsorg = __DSORG_PO;             /* DCB=(DSORG=PO,          */
   ip.__recfm = _F_ + _B_ + _A_;        /*        RECFM=FBA,   */
   ip.__lrecl = 121;                    /*      LRECL=121,         */
   ip.__blksize = 12100;                /*      BLKSIZE=12100)     */

   if (dynalloc(&ip) != ZERO)
   {
       printf("Dynalloc failed with error code %d, info code %d\n",
               ip.__errcode, ip.__infocode);
   }
}

```

General description

Dynamically deallocates a z/OS data set in accordance with the attributes defined in *dyn_parms*.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The only fields in __dyn_t that are used by dynfree() are:

```
char *__ddname
char *__dsname
char *__member
char *__pathname
char __normdisp
char __pathndisp
char **__miscitems
```

If any other fields are specified, they will be ignored. For more information on the __dyn_t structure, see Table 21 on page 409

To dynamically deallocate a data set on z/OS, you should:
- Invoke dyninit() with a variable of type __dyn_t
- Assign values to the appropriate fields that will satisfy the svc99() request
- Invoke dynfree() with this variable.

Note: The dynfree() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful under z/OS, dynfree() returns 0.

If unsuccessful, dynfree() returns nonzero. dynfree() returns -1 if there is not sufficient storage to process all the text units.

Example

```
/*
   This example dynamically deallocates a data set.
 */
#include <dynit.h>

int main(void) {
⋮
  __dyn_t ip;
⋮
  dyninit(ip);
  ip.__ddname = "mydd";
⋮
  dynfree(&ip);
}
```

Related information

dyninit() — Initialize __dyn_t structure

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <dynit.h>

int dyninit(__dyn_t *dyn_parms);
```

General description

Initializes the __dyn_t structure that is used to build the parameter lists that are passed to the dynalloc() function and the dynfree() function. If you do not initialize the __dyn_t structure using dyninit(), undefined behavior may result.

The __dyn_t structure is defined in the dynit.h header file. A description of the elements is found in "dynalloc() — Allocate a data set" on page 407.

Returned value

If successful under MVS, dyninit() returns 0.

If unsuccessful, dyninit() returns nonzero.

Example

CELEBD09

```
/* CELEBD09

   This example initializes a __dyn_t
    structure, called ip.

 */
#include <stdio.h>
#include <string.h>
#include <dynit.h>

main() {
  char dsn[]="USER.TEST.DATASET";
  __dyn_t ip;
  int ret;

  dyninit(&ip);
  ip.__ddname   = "TEST";
  ip.__dsname   = dsn;
  ip.__status   = __DISP_NEW;
  ip.__normdisp = __DISP_DELETE;
  ip.__alcunit  = __TRK;
  ip.__primary  = 1;
  ip.__unit     = "SYSDA  ";

  if ((ret = dynalloc(&ip)) != 0)
    printf("dynalloc() ret=%d, error code %04x, info code %04x\n",
           ret, ip.__errcode, ip.__infocode);

  else {
    dyninit(&ip);
    ip.__ddname   = "TEST";

    if ((ret = dynfree(&ip)) != 0)
      printf("dynfree() ret=%d, error code %04x, info code %04x\n",
             ret, ip.__errcode, ip.__infocode);

    else puts("success!");
  }
}
```

ecvt() — Convert double to string

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *ecvt(double x, int ndigit, int *__restrict__ decpt, int *__restrict__ sign);
```

General description

The ecvt() function converts double floating-point argument values to floating-point output strings. The ecvt() function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using __isBFP().

z/OS XL C/C++ formatted output functions, including the ecvt() function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See "*fprintf* Family of Formatted Output Functions" on fprintf(), printf(), sprintf() — Format and write data for a description of the special infinity and NaN output sequences.

The ecvt() function converts *x* to a NULL-terminated string of *ndigit* digits (where *ndigit* is reduced to an unspecified limit determined by the precision of a double) and returns a pointer to the string. The high-order digit is nonzero, unless the value is 0. The low-order digit is rounded. The position of the radix character relative to the beginning of the string is stored in the integer pointed to by *decpt* (negative means left of the returned digits). The radix character is not included in the returned string. If the sign of the result is negative, the integer pointed to by *sign* is nonzero, otherwise it is 0.

The function returns a pointer to a buffer used only by the calling thread which may be overwritten by subsequent calls to ecvt(), "fcvt() — Convert double to string" on page 485 and "gcvt() — Convert double to string" on page 683.

If the converted value is out of range or is not representable, the function returns NULL.

Note: This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sprintf() function is preferred for portability.

Returned value

If successful, ecvt() returns the character equivalent of *x* as specified above.

If unable to allocate the return buffer, or the conversion fails, ecvt() returns NULL.

encrypt() — Encoding function

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

void encrypt(char block[64], int edflag);
```

General description

The encrypt() function uses an array of 16 48-bit keys produced by the setkey() function to encode bytes specified by the *block* argument according to the Data Encryption Standard (DES) encryption algorithm or to decode argument bytes according to the DES decryption algorithm.

The *block* argument of encrypt() is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. The array is modified in place using keys produced by setkey(). If *edflag* is 0, the argument is encoded using the DES encryption algorithm. If *edflag* is 1 the argument is decoded using the DES decryption algorithm.

Special behavior for z/OS UNIX Services: The encrypt() function is thread-specific. Thus, for each thread from which the encrypt() function is called by a threaded application, the setkey() function must first be called from the thread to establish a DES key array for the thread.

Returned value

encrypt() returns no values.

Special behavior for z/OS UNIX Services: encrypt() will set errno to one of the following values:

Error Code
Description

EINVAL
64 byte input array contains bytes with values other than 0x00 or 0x01.

ENOMEM
If setkey() has not been called or failed to produce a DES key array for the thread from which encrypt() is called.

ENOSYS
If DES key array exists for thread from which encrypt() is called to decode data.

Note: Because encrypt() returns no values, applications wishing to check for errors should set errno to 0, call encrypt(), then test errno and, if it is nonzero, assume an error has occurred.

endgrent() — Group database entry functions

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <grp.h>

void endgrent(void),
struct group *getgrent (void);
void setgrent(void);
```

General description

The getgrent() function returns a pointer to the broken-out fields of a line in the group database, mapped by the **group** structure defined in the <grp.h> header file. Repeated calls to getgrent() return a pointer to the next **group** structure in the database, until End Of File (EOF), at which point a NULL pointer is returned. setgrent() interrupts this sequential search and rewinds the user database to the beginning, such that the next getgrent() returns a pointer to the first **group** structure. Use of setgrent() is optional after an End Of File (EOF), as the next getgrent() after end of file again returns a pointer to the first **group** structure. endgrent() is optionally used to close the user database when searching is complete.

The setgrent() function effectively rewinds the group database to allow repeated searches.

The endgrent() function may be called to close the group database when processing is complete.

Returned value

When first called, getgrent() returns a pointer to the next group structure in the group database. Upon subsequent calls it returns a pointer to a group structure, or it returns a NULL pointer on either End Of File (EOF) or an error. The return value may point to static data that is overwritten by each call.

There are no documented errno values.

endhostent() — Close the host information data set

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void endhostent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void endhostent();
```

General description

The endhostent() function closes the local host tables, which contains information about known hosts.

You can use the **X_SITE** environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization. For more information on these local host tables or the environment variables, see *z/OS Communications Server: IP Configuration Guide*.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

endnetent() — Close network information data sets

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void endnetent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void endnetent();
```

General description

The endnetent() function closes the *tcpip*.HOSTS.ADDRINFO data set. The *tcpip*.HOSTS.ADDRINFO data set contains information about known networks.

You can use the **X_ADDR** environment variable to specify a data set other than *tcpip*.HOSTS.ADDRINFO. For more information on these data sets and environment variables, see *z/OS Communications Server: IP Configuration Guide, SC27-3650*.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

endprotoent() — Work with a protocol entry

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void endprotoent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void endprotoent();
```

General description

The endprotoent() function closes the */etc/protocol* or the *tcpip*.ETC.PROTO data set, which contains information about the networking protocols (IP, ICMP, TCP, and UDP).

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Related information

endpwent() — User database functions

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <pwd.h>

void endpwent(void),
struct passwd *getpwent(void);
void setpwent(void);
```

General description

The getpwent() function returns a pointer to the broken-out fields of a line in the user database, mapped by the *passwd* structure defined in the <pwd.h> header file. Repeated calls to getpwent() return a pointer to the next *passwd* structure in the database, until End Of File (EOF), at which point a NULL pointer is returned. setpwent() interrupts this sequential search and rewinds the user database to the beginning, such that the next getpwent() returns a pointer to the first *passwd* structure. Use of setpwent() is optional after an End Of File (EOF), as the next getpwent() after end of file again returns a pointer to the first *passwd* structure. endpwent() is optionally used to close the user database when searching is complete.

The setpwent() function effectively rewinds the user database to allow repeated searches.

The endpwent() function may be called to close the user database when processing is complete.

Returned value

When first called, getpwent() returns a pointer to the next *passwd* structure in the user database. Upon subsequent calls it returns a pointer to a *passwd* structure, or it returns a NULL pointer on either End Of File (EOF) or an error. The return value may point to static data that is overwritten by each call.

There are no documented errno values for endpwent() and setpwent(). For getpwent(), if unsuccessful, getpwemt() sets errno to one of the following values:

Error Code
Description

EMVSSAF2ERR
The system authorization facility (SAF) or RACF Get GMAP service had an error.

EMVSSAFEXTRERR
The SAF or RACF RACROUTE EXTRACT service had an error.

Related information

endservent() — Close network services information data sets

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void endservent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void endservent();
```

General description

The endservent() function closes the */etc/services* or the *tcpip*.ETC.SERVICES data set, which contains information about network services. Example services are name server, File Transfer Protocol (FTP), and telnet.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Related information

- “netdb.h” on page 49
- “getservbyname() — Get a server entry by name” on page 770
- “getservbyport() — Get a service entry by port” on page 772

- “setservent() — Open the network services information data set” on page 1576

endutxent() — Close the utmpx database

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

void endutxent(void);
```

General description

The endutxent() function closes the utmpx database for the current thread. The database may be opened by getutxent(), getutxid(), getutxline(), or pututxline().

Because the endutxent() function processes thread-specific data the endutxent() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

Programs must not reference the data passed back by getutxline(), getutxid(), getutxent(), or pututxline() after endutxent() has been called (the storage has been freed.)

After getuxline(), getutxent(), getutxid(), or pututxline(), the utmpx database is open. No other process can do pututxline() to this utmpx database until this process issues endutxent() or __utmpxname() to close the utmpx database, or this process ends. You can cause all z/OS UNIX user logins/logouts to hang if you fail to exit() or issue endutxent() or __utmpxname(), and you have the main /etc/utmpx database open in your process. endutxent() resets the name of the next utmpx file to open back to the default. If you want to do additional utmpx operations using a nonstandard utmpx file name, you must reissue __utmpxname() after closing the utmpx database with endutxent().

Returned value

endutxent() returns no values.

erand48() — Pseudo-random number generator

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

double erand48(unsigned short int x16v[3]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0). These functions have been extended so that the returned value will be in the proper floating-point format (hexadecimal or IEEE) based on the floating-point mode of the invoking thread.

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The erand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

```
X(n+1) = (aX(n) + c)mod(2**48)     n>=0
```

The erand48() function uses storage provided by the argument array, *x16v*[3], to save the most recent 48-bit integer value in the sequence, X(i). The erand48() function uses *x16v*[0] for the low-order (rightmost) 16 bits, *x16v*[1] for the middle-order 16 bits, and *x16v*[2] for the high-order 16 bits of this value.

The initial values of a, and c are:

```
a   = 5deece66d (base 16)
c   = b         (base 16)
```

The values a and c, may be changed by calling the lcong48() function. The initial values of a and c are restored if either the seed48() or srand48() function is called.

Special behavior for z/OS UNIX Services: You can make the erand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested and the erand48() function is called from thread t, the erand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread according to the linear congruential formula:

```
X(t,n+1) = (a(t)X(t,n) + c(t))mod(2**48)     n>=0
```

The erand48() function uses storage provided by the argument array, *x16v*[3], to save the most recent 48-bit integer value in the sequence, X(t,i). The erand48() function uses *x16v*[0] for the low-order (rightmost) 16 bits, *x16v*[1] for the middle-order 16 bits, and *x16v*[2] for the high-order 16 bits of this value.

The initial values of a(t) and c(t) on the thread t are:

```
a(t)   = 5deece66d (base 16)
c(t)   = b         (base 16)
```

The values a(t) and c(t) may be changed by calling the lcong48() function from the thread t. The initial values of a(t) and c(t) are restored if either the seed48() or srand48() function is called from the thread.

Returned value

erand48() saves the generated 48-bit value, X(n+1), in storage provided by the argument array, *x16v*[3]. erand48() transforms the generated 48-bit value to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the drand48 family and erand48() is called on thread `t`, erand48() saves the generated 48-bit value, X(t,n+1), in storage provided by the argument array, *x16v*[3]. erand48() transforms the generated 48-bit value to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

erf(), erfc(), erff(), erfl(), erfcf(), erfcl() — Calculate error and complementary error functions

Standards

Standards / Extensions	C or C++	Dependencies
SAA XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

SAA:

```
#include <math.h>

double erf(double x);
double erfc(double x);
```

Compiler option: LANGLVL(EXTENDED), LANGLVL(SAA), or LANGLVL(SAA2)

XPG4:

```
#define _XOPEN_SOURCE
#include <math.h>

double erf(double x);
double erfc(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float erff(float x);
long double erfl(long double x);
float erfcf(float x);
long double erfcl(long double x)
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float erf(float x);
long double erf(long double x);
float erfc(float x);
long double erfc(long double x);
```

General description

Calculates the error and complementary error functions:

$$2\pi^{-1/2} \int_{0}^{x} e^{-t^2} dt$$

Because the erfc() function calculates the value of `1.0 - erf(x)`, it is used in place of erf() for large values of *x*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	SPC	Hex	IEEE
erf	X	X	X
erff		X	X
erfl		X	X
erfc	X	X	X
erfcf		X	X
erfcl		X	X

Returned value

Both erf() and erfc() return the calculated value.

If the correct value would cause underflow, 0 is returned and the value of the macro ERANGE is stored in errno. A range error is returned if *x* is too large.

Special behavior for IEEE: erf() and erfc() are always successful.

Requirements

This function is exposed by specifying on the compile step either the specific option LANGLVL(LONGLONG) or the general option LANGLVL(EXTENDED).

Example

CELEBE01

```
/* CELEBE01

  This example uses &erf. and &erfc. to compute the error
   function of two numbers.
```

```
 */
#include <stdio.h>
#include <math.h>

double smallx, largex, value;

int main(void)
{
   smallx = 0.1;
   largex = 10.0;

   value = erf(smallx);         /* value = 0.112463 */
   printf("Error value for 0.1: %f\n", value);

   value = erfc(largex);        /* value = 2.088488e-45 */
   printf("Error value for 10.0: %e\n", value);
}
```

Output

```
Error value for 0.1: 0.112463
Error value for 10.0: 2.088488e-45
```

erfd32(), erfd64(), erfd128(), erfcd32(), erfcd64(), erfcd128() - Calculate error and complementary error functions

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.10

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  erfd32(_Decimal32 x);
_Decimal64  erfd64(_Decimal64 x);
_Decimal128 erfd128(_Decimal128 x);
_Decimal32  erf(_Decimal32 x);      /* C++ only */
_Decimal64  erf(_Decimal64 x);      /* C++ only */
_Decimal128 erf(_Decimal128 x);     /* C++ only */

_Decimal32  erfcd32(_Decimal32 x);
_Decimal64  erfcd64(_Decimal64 x);
_Decimal128 erfcd128(_Decimal128 x);
_Decimal32  erfc(_Decimal32 x);     /* C++ only */
_Decimal64  erfc(_Decimal64 x);     /* C++ only */
_Decimal128 erfc(_Decimal128 x);    /* C++ only */
```

General description

Calculates the error and complementary error functions:

$$2\pi^{-1/2} \int_{0}^{x} e^{-t^2} dt$$

Because the erfc() function calculates the value of 1.0 - erf(*x*), it is used in place of erf() for large values of *x*.

These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

erf() and erfc() are always successful.

Example

CELEBE12

```
/* CELEBE12

   This example illustrates the erfd32() and erfcd32() functions.

*/

#define __STDC_WANT_DEC_FP__
#include <stdio.h>
#include <math.h>

_Decimal32 smallx, largex, value;

int main(void)
{
   smallx = 0.1DF;
   largex = 10.0DF;

   value = erfd32(smallx);
   printf("Error value for 0.1: %Hf\n", value);

   value = erfcd32(largex);
   printf("Error value for 10.0: %He\n", value);
}
```

__err2ad() — Return address of reason code of last failure

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
int *__err2ad(void);
```

General description

The __err2ad() function returns the address of the errno2. The errno2 may be set by the z/OS XL C/C++ runtime library, z/OS UNIX callable services or other callable services.

__err2ad() provides assistance in diagnosing problems by allowing an application to reset the errno2 value prior to calling a function.

For more information about __errno2(), see *z/OS XL C/C++ Runtime Library Reference*.

Returned value

__err2ad() is always successful.

Related information

- "__errno2() — Return reason code information"

__errno2() — Return reason code information

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
int __errno2(void);
```

General description

The __errno2() function can be used when diagnosing application problems. This function enables z/OS XL C/C++ application programs to access additional diagnostic information, errno2 (errnojr), associated with errno. The errno2 may be set by the z/OS XL C/C++ runtime library, z/OS UNIX callable services or other callable services. The errno2 is intended for diagnostic display purposes only and it is not a programming interface. The __errno2() function is not portable.

Note: Not all functions set errno2 when errno is set. In the cases where errno2 is not set, the __errno2() function may return a residual value. You may use the __err2ad() function to clear errno2 to reduce the possibility of a residual value being returned.

Returned value

The __errno2() function is always successful. The returned value is intended for diagnostic display purposes only.

The returned value may input to the BPXMTEXT utility to produce detailed information about the reported error if available.

For more information about the return value, see the *z/OS UNIX System Services Command Reference*, *z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA23-2281*, and *z/OS Language Environment Debugging Guide*.

Example

CELEBE02

```
/* CELEBE02

   The following example's output only occurs
   if the buffer is flushed.

 */
#include <errno.h>
#include <stdio.h>
int   main(void) {
   FILE *f;
   f = fopen("notafile","r");
   if (f==NULL) {
      perror("fopen() failed");
      printf("__errno2 = %08x\n", __errno2());
   }
   return(0);
}
```

```
Sample output of routine using __errno2(), CELEBE02:

fopen() failed: EDC5129I No such file or directory. __errno2 = 05620062
```

CELEBE08

```
#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>
#include <stdlib.h>

int main(void){
  FILE *fp;
  /* add errno2 to perror message */
  setenv("_EDC_ADD_ERRNO2", "1", 1);
  fp = fopen("testfile.dat", "r");
  if (fp == NULL)
    perror("fopen() failed");
   return 0;
}

Sample output of routine using _EDC_ADD_ERRNO2, CELEBE08:

fopen() failed: EDC5129I No such file or directory. (errno2=0x05620062)
```

CELEBE09

```
#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>

int main(void){
  FILE *f;
  f = fopen("testfile.dat", "r");
  if (f == NULL){
    perror("fopen() failed");
    printf("__errno2 = %08x\n", __errno2());
  }

  /* reset errno2 to zero */
  *__err2ad() = 0x0;
  printf("__errno2 = %08x\n", __errno2());

  f = fopen("testfile.dat", "r");
  if (f == NULL){
    perror("fopen() failed");
    printf("__errno2 = %08x\n", __errno2());
  }

  return 0;
}
```

For more information about _EDC_ADD_ERRNO2 , see *z/OS XL C/C++ Programming Guide*. For more information about __err2ad() , see *z/OS XL C/C++ Runtime Library Reference*.

__etoa() — EBCDIC to ISO8859-1 string conversion

Standards

Standards / Extensions	**C or C++**	**Dependencies**
z/OS UNIX	both	

Format

```
#include <unistd.h>

int __etoa(char *string);
```

General description

The __etoa() function converts an EBCDIC character string *string* to its ISO8859-1 equivalent. The conversion is performed using the codeset page associated with the current locale. The input character string up to, but not including, the NULL character is changed from the current locale to an ISO8859-1 representation.

The argument *string* points to the EBCDIC character string to be converted to its ISO8859-1 equivalent.

Returned value

If successful, __etoa() converts the input EBCDIC string to its equivalent ISO8859-1 value, and returns the length of the converted string.

If unsuccessful, __etoa() returns -1 and sets errno to one of the following values. (This function internally may call iconv_open() and iconv(). The errnos returned by these functions are propagated without modification.)

Error Code
Description

EINVAL
The current locale does not describe a single-byte character set.

ENOMEM
There is insufficient storage to complete the conversion process.

Related information

- “sys/msg.h” on page 74
- “unistd.h” on page 82

__etoa_l() — EBCDIC to ISO8859-1 conversion operation

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <unistd.h>

int __etoa_l(char *bufferptr, int leng);
```

General description

The __etoa_l() function converts *leng* EBCDIC bytes in the buffer pointed to by *bufferptr* to their ISO8859-1 equivalent. The conversion is performed using the codeset page associated with the current locale.

The argument *bufferptr* points to a buffer containing the EBCDIC bytes to be converted to their ISO8859-1 equivalent. The input buffer is treated as a sequence of bytes, and all bytes in the input buffer are converted, including any imbedded NULLs.

Returned value

If successful, __etoa_l() converts the input EBCDIC bytes to their equivalent ISO8859-1 value, and returns the number of bytes converted.

If unsuccessful, __etoa_l() returns -1 and sets errno to one of the following values. (This function may internally call iconv_open() and iconv(). The errnos returned by these functions are propagated without modification.)

Error Code
  Description

EINVAL
  The current locale does not describe a single-byte character set.

ENOMEM
  There is insufficient storage to complete the conversion process.

Related information

- “sys/msg.h” on page 74
- “unistd.h” on page 82

exec functions

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>
extern char **environ;

int execl(const char *path, const char *arg, ..., NULL);
int execle(const char *path, const char *arg, ..., NULL, char *const envp[]);
int execlp(const char *file, const char *arg, ..., NULL);
int execv(const char *path, char *const argv[]);
int execve(const char *path, char *const argv[], char *const envp[]);
int execvp(const char *file, char *const argv[]);
```

Note: Although POSIX.1 does not require that the unistd.h include file be included, it is recommended that you include it for portability.

General description

All exec functions run a new program by replacing the current process image with a new process image obtained from a file in the HFS (hierarchical file system).

For information on specifying names for MVS data sets and HFS files, see *z/OS XL C/C++ Programming Guide*.

A successful exec function never returns control because the calling process is overwritten with the new process.

The argument *path* is a string giving the absolute or relative path name of a file. This file contains the image of the process to be run.

file is a string that is used in determining the path name of the file containing the image of the process to be run. If *file* contains a slash character (/), it is assumed to be the absolute or relative path name of the file. If *file* does not contain a slash, the system searches for the given file name under the list of directories given by the PATH environment variable. The system checks under directories in the order they appear in the PATH variable, and executes the first file whose name matches the *file* string. The file must reside in the HFS.

The exec functions use the following environment variables:

STEPLIB

Supports the creation and propagation of a STEPLIB environment to the new process image. The following are the accepted values for the STEPLIB environment variable and the actions taken for each value:

- STEPLIB=NONE. No Steplib DD is to be created for the new process image.

- STEPLIB=CURRENT. The TASKLIB, STEPLIB or JOBLIB DD data set allocations that are active for the calling task at the time of the call to exec() are propagated to the new process image, if they are found to be cataloged. Uncataloged data sets are not propagated to the new process image.
- STEPLIB=Dsn1:Dsn2:,...DsnN. The specified data sets, Dsn1:Dsn2:...DsnN, are built into a STEPLIB DD in the new process image.

  Note: The actual name of the DD is not STEPLIB, but is a system-generated name that has the same effect as a STEPLIB DD. The data sets are concatenated in the order specified. The specified data sets must follow standard MVS data set naming conventions. Data sets found to be in violation of this standard are ignored. If the data sets do follow the standard, but:
  - The caller does not have the proper security access to a data set
  - A data set is uncataloged or is not in load library format

  then the data set is ignored. Because the data sets in error are ignored, the executable file may run without the proper STEPLIB environment. If a data set is in error due to improper security access, a X'913' abend is generated. The dump for this abend can be suppressed by your installation.

If the STEPLIB environment variable is not specified, the exec() default behavior is the same as if STEPLIB=CURRENT were specified.

If the program to be invoked is a set-user-ID or set-group-ID file and the user-ID or group-ID of the file is different from that of the current process image, the data sets to be built into the STEPLIB environment for the new process image must be found in the system sanction list for set-user-id and set-group-id programs. Only those data sets that are found in the sanction list are built into the STEPLIB environment for the new process image. For detailed information regarding the sanction list, and for information on STEPLIB performance considerations, see *z/OS UNIX System Services Planning, GA32-0884*.

_BPX_JOBNAME

Used to change the jobname of the new process image. The jobname change is allowed only if the invoker has appropriate privileges and is running in an address space created by fork. If these conditions are not met, the environment variable is ignored. Accepted values are strings of 1–8 alphanumeric characters. Incorrect specifications are ignored.

_BPX_ACCT_DATA

Used to change the account data of the new process image. Rules for specifying account data:
- Up to 142 actual account data characters are allowed, including any commas
- Sub-parameters must be separated by commas.
- There is no restriction on the character set.
- If the account data is greater than 142 characters, the data is ignored.

_BPXK_JOBLOG

The _BPXK_JOBLOG environment variable can be used to specify that WTO messages are to be written to an open HFS job log file. The following are the allowable values:

Value Description

nn Job log messages are to be written to open file descriptor nn.

STDERR
Job log messages are to be written to the standard error file descriptor, 2.

None Job log messages are not to be written. This is the default.

The file that is used to capture messages can be changed at any time by calling the oe_env_np service (BPX1ENV) and specifying _BPXK_JOBLOG with a different file descriptor.

Message capturing is turned off if the specified file descriptor is marked for close on a fork or exec.

Message capturing is process-related. All threads under a given process share the same job log file. Message capturing may be initiated by any thread under that process.

Multiple processes in a single address space can each have different files active as the JOBLOG file; some or all of them can share the same file; and some processes can have message capturing active while others do not.

Only files that can be represented by file descriptors may be used as job log files; MVS data sets are not supported.

Message capturing will be propagated on a fork() or spawn(). In the case where a file descriptor was specified, the physical file must be the same for message capturing to continue in the forked or spawned process. If STDERR was specified, the file descriptor may be re-mapped to a different physical file.

Message capturing may be overridden on exec() or spawn() by specifying the _BPXK_JOBLOG environment variable as a parameter to the exec() or spawn().

Message capturing will only work in forked (BPXAS) address spaces.

Note: This is not true joblog support, messages that would normally go to the JESYSMSG data set are captured, but messages that go to JESMSGLG are not captured.

Special behavior for XPG4: If this file is not a valid executable object, the execlp() and execvp() functions invoke **/bin/sh** with the invoker's path name and the rest of the input arguments. It is similar to invoking:

```
execl("/bin/sh",
      "sh",
      "--",
      fully_expanded_pathname,
      arg1, arg2, ..., argn,
      NULL
     );
```

where arg1, arg2, ..., argn are the caller's arguments to execlp() or execvp(), and fully_expanded_pathname is the path name of the shell script found by searching the directories in the current PATH.

arg, ..., NULL is a series of pointers to NULL-terminated character strings specifying arguments for the process being invoked. If the new process is a main(), these strings are stored in an array, and a pointer to the array is passed in the *argv* parameter. The first argument is required, and it should point to a string containing the name of the file that is associated with the process that exec is starting. A NULL pointer must follow the last argument string pointer.

argv[ ] is a pointer to an array of pointers to NULL-terminated character strings. There must be a NULL pointer after the last character string to mark the end of the array. These strings are used as arguments for the process being invoked. *argv*[0] should point to a string containing the name of a file associated with the process being started by exec. *envp*[] is a pointer to an array of pointers to NULL-terminated character strings. There must be a NULL pointer after the last character string to mark the end of the array. The strings of *envp* provide the environment variables for the new process.

All the forms of exec functions provide a way to locate the file containing the new process you want to run and a collection of arguments that should be passed to the new process. Each form of exec has its own method for specifying this information.

Some exec calls explicitly pass an environment using an *envp* argument. In versions where an environment is not passed explicitly—execl(), execlp(), execv(), and execvp()—the system uses the entire environment of the caller. The caller's environment is assumed to be the *environment variables* that the *external variable **environ* points to.

The variable **ARG_MAX**, obtained from z/OS UNIX services by an invocation of `sysconf(`*`_SC_ARG_MAX`*`)`, specifies the maximum number of bytes that can be used for arguments and environment variables passed to the process being invoked. The number of bytes includes the NULL terminator on each string.

A process started by an exec function has all of the open file descriptors that were present in the caller, except for those files opened with the close-on-exec flag FD_CLOEXEC. See “fcntl() — Control open file descriptors” on page 474 for more information about this flag. In file descriptors that remain open, all attributes remain unchanged (including file locks).

Directory streams that are open in the calling process image are closed in the new process image.

The state of conversion descriptors and message catalog descriptors is undefined.

Signals set to be ignored in the caller, `SIG_IGN`, are set to be ignored in the new process image. Be careful to take care of signals that are being ignored. Although sigaction() specifying a handler is not passed by, `SIG_IGN` is. Blocking of signals is also passed by. All other signals are set to the default action, `SIG_DFL`, in the new process image, no matter how the caller handled such signals.

The real user ID (UID), real group ID (GID), and supplementary group IDs of the new process are the same as those of the caller. If the set-user-ID mode bit of the program file is on, the effective user ID of the new process is set to the file's owner. Similarly, if the set-group-ID mode bit of the program file is on, the effective group ID of the new process is set to the file's group. The effective user ID of the new process image is saved as the saved set-user-ID, and the effective group ID of the new process image is saved as the saved set-group-ID.

Any shared memory segments attached to the calling process image will not be attached to the new process image, see “shmat() — Shared memory attach operation” on page 1598. Any shared memory segments attached to the calling process image will be detached (that is, the value of shm_nattch decremented by one). If this is the last thread attached to the shared memory segment and a shmctl() RMID has been issued, the segment will be removed from the system.

Special behavior for XPG4.2: Interval timers are preserved across an exec.

The new process also inherits the following from the caller:
- Controlling terminal (**XPG4.2**)
- Nice value (see "nice() — Change priority of a process" on page 1145) (**XPG4**)
- semadj values (see "semop() — Semaphore operations" on page 1488) (**XPG4**)
- Process ID
- Parent process ID
- Process group ID
- Resource limits (see "setrlimit() — Control maximum resource consumption" on page 1573 and "ulimit() — Get or set process file size limits" on page 1942) (**XPG4.2**)
- Session membership
- Time left until an alarm clock signal
- Working directory
- Root directory
- File mode creation mask
- File size limit (see "ulimit() — Get or set process file size limits" on page 1942) (**XPG4**)
- Process signal mask
- Pending signals
- tms_utime, tms_stime, tms_cutime, and tms_cstime. See "times() — Get process and child process times" on page 1879 for more about these qualities.

A successful exec function automatically opens the specified program file, and updates the access time st_atime for that file. The program file is closed automatically after the program has been read from the file. The precise time of this close operation is undefined.

Special behavior for z/OS UNIX Services:

1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
   - If the calling process is in Ptrace debug mode, a prior loaded copy is not reused.
   - If the calling process is not in Ptrace debug mode, but the only prior loaded usable copy found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.
2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller's MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the loadhfs service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the HFS, and the following restriction exists for sticky bit programs that have the set-user-ID or set-group-ID attribute:

   If the program is found in the MVS program search order, the MVS program name must have a BPX.STICKYSUG.program_name resource profile defined in the RACF FACILITY class. See the*z/OS UNIX System Services Planning* book for details on defining the resource profile. Failure to follow this restriction will cause the abend EC6 with code xxxxE055.

3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one 'business unit of work' entity for system accounting and management purposes.

Note: If you are expecting this function to take advantage of the z/OS UNIX magic number support, the Language Environment runtime option to POSIX(ON) must have been set when the process was initialized. Attempting to use magic number support with a process initialized with POSIX(OFF) may produce undesirable effects. See *z/OS UNIX System Services Planning, GA32-0884* and *z/OS V2R2.0 UNIX System Services User's Guide, SA23-2279* for details and uses of the z/OS UNIX magic number.

Returned value

If successful, an exec function never returns control because the calling process is overwritten with the new process.

If unsuccessful, an exec function returns -1 and sets errno to one of the following values:

Error Code
Description

E2BIG The combined argument list and environment list of the new process has more bytes than the system-defined length. See "sysconf() — Determine system configuration options" on page 1798 for information about the system-defined length.

EACCES
The process did not have appropriate permissions to run the specified file, for one of these reasons:

- The process did not have permission to search a directory named in your *path*.
- The process did not have execute permission for the file to be run.
- The system cannot run files of this type.

EFAULT
A bad address was received as an argument of the call, or the user exit program checked.

Consult Reason Code to determine the exact reason the error occurred. The following reason code can accompany the return code: JRExecParmErr and JRExitRtnError.

EINVAL
The new process image file has the appropriate permission and has a recognized format, but the system does not support execution of a file with this format.

ELOOP
A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of the *path* or *file* argument is greater than POSIX_SYMLOOP (a value defined in the limits.h header file)

ELEMULTITHREAD
The exec function was invoked from a multithreaded environment.

EMVSSAF2ERR
The executable file is a set-user-ID or set-group-ID file, and the file owner's UID or GID is not defined to RACF.

ENAMETOOLONG
All or part of the file name is too long. This can happen if:

- A *path* or *file* argument exceeds the value of **PATH_MAX**, or an element of your *path* exceeds **PATH_MAX**.
- Any *pathname* component is greater than **NAME_MAX**, and _POSIX_NO_TRUNC is in effect.
- The length of a path name string substituted for a symbolic link in the *path* argument exceeds **PATH_MAX**.

The **PATH_MAX** and **NAME_MAX** values are determined with pathconf().

ENOENT
One or more *pathname* components in *path* or *file* does not exist. This error is also issued if *path* or *file* is a NULL string.

ENOEXEC
The new process image file has the appropriate access permission but has an unrecognized format. This errno can be returned from any one of the exec family of functions, except for execlp() and execvp().

Note: Reason codes further qualify the errno. For most of the reason codes, see *z/OS UNIX System Services Messages and Codes*.

For ENOEXEC, the reason codes are:

Reason Code	Explanation
X'xxxx0C27'	The target HFS file is not in the correct format to be an executable file.
X'xxxx0C31'	The target HFS file is built at a level that is higher than that supported by the running system.

ENOMEM
The new process requires more memory than is permitted by the operating system.

ENOTDIR
A directory component of *path* or *file* is not really a directory.

Example

CELEBE03

```
/* CELEBE03

   This example runs a program, using the execl() function.

 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/wait.h>            /*FIX: used be <wait.h>*/
#include <sys/types.h>
#include <unistd.h>

main() {
  pid_t pid;
  int status;
```

```
   if ((pid = fork()) == 0) {
     execl("/bin/false", NULL);
     perror("The execl() call must have failed");
     exit(255);
   }
   else {
     wait(&status);
     if (WIFEXITED(status))
       printf("child exited with status of %d\n", WEXITSTATUS(status));
     else
       puts("child did not exit successfully\n");
   }
 }
```

Output

```
child exited with status of 1
```

__noreturn__ void exit(int status);
```

General description

The exit() function:

1. Calls all functions registered with the atexit() function, and destroys C++ objects with static storage duration, all in last-in-first-out (LIFO) order. C++ objects with static storage duration are destroyed in the reverse order of the completion of their constructor. (Automatic objects are not destroyed as a result of calling exit().)

   Functions registered with atexit() are called in the reverse order of their registration. A function registered with atexit(), before an object obj1 of static storage duration is initialized, will not be called until obj1's destruction has completed. A function registered with atexit(), after an object obj2 of static storage duration is initialized, will be called before obj2's destruction starts.
2. Flushes all buffers, and closes all open files.
3. All files opened with tmpfile() are deleted.
4. Returns control to the host environment from the program.

Process termination in _exit() is equivalent to program termination in exit().

The argument *status* can have a value from 0 to 255 inclusive or be one of the macros EXIT_SUCCESS or EXIT_FAILURE. The value of EXIT_SUCCESS is defined in `stdlib.h` as 0; the value of EXIT_FAILURE is 8.

This function is also available to C applications in a stand-alone Systems Programming C (SPC) Environment.

In a POSIX C program, exit() returns control to the kernel with the value of *status*. The kernel then performs normal process termination.

POSIX-level thread cleanup routines are *not* executed. These includes cleanup routines created with pthread_cleanup_push() and destructor routines created with pthread_key_create().

Special behavior for C++: If exit() is called in a z/OS XL C++ program, the program terminates without leaving the current block, and therefore destructors are not called for local (automatic) variables. Destructors for initialized static objects will be called in the reverse order of the completion of their constructors.

Functions registered with atexit() are called in the reverse order of their registration. A function registered with atexit(), before an object obj1 of static storage duration is initialized, will not be called until obj1's destruction has completed. A function registered with atexit(), after an object obj2 of static storage duration is initialized, will be called before obj2's destruction starts.

Returned value

exit() returns no values.

exit() returns control to its host environment, with the returned value `status`.

For example, if program A invokes program B using a call to the system() function, and program B calls the exit() function, then program B returns to its host environment, which is program A.

Example

```
/* This example flushes all buffers, closes any open files, and ends the
   program if it cannot open the file myfile.
 */
#include <stdio.h>
#include <stdlib.h>

FILE *stream;

int main(void)
{
⋮
   if ((stream = fopen("myfile.dat", "r")) == NULL)
   {
      printf("Could not open data file\n");
      exit(EXIT_FAILURE);
      }
}
```

_exit() — End a process and bypass the cleanup

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

void _exit(int status);
```

General description

Ends the current process and makes an exit status value for the process available to the system.

The argument *status* specifies a return status for the process that is ending. Ending the process has the following results:

- _exit() closes all open file descriptors and directory streams in the caller.
- If the caller's parent is currently suspended because of wait() or waitpid(), the low-order 8 bits of *status* become available to the parent. For a discussion on accessing those 8 bits, refer to “waitpid() — Wait for a specific child process to end” on page 1997.
- If the caller's parent is not currently suspended because of wait() or waitpid(), _exit() saves the *status* value so that it can be returned to the parent if the parent calls wait() or waitpid().
- A SIGCHILD signal is sent to the parent process.
- If the process calling _exit() is a controlling process, the SIGHUP signal is sent to each process in the foreground process group of the controlling terminal belonging to the caller.
- If the process calling _exit() is a controlling process, _exit() disassociates the associated controlling terminal from the session. A new controlling process can then acquire the terminal.
- Exiting from a process does not end its child processes directly. The SIGHUP signal may end children in some cases. Children that survive when a process ends are assigned a new parent process ID. The new parent process ID is always 1, indicating the root ancestor of all processes.
- If a process ends and orphans a process group and if a member of that group is stopped, each member of the group is sent a SIGHUP signal, followed by a SIGCONT signal.
- All threads are ended, and their resources cleaned up. (*Threads* are MVS tasks that call a z/OS UNIX callable service.) POSIX-level thread cleanup routines are *not* executed. These include cleanup routines created with pthread_cleanup_push() and destructor routines created with pthread_key_create().

These results occur whenever a process ends. _exit() does not cause C runtime library cleanup to be performed; therefore, stream buffers are not necessarily flushed.

Note: If _exit() is issued from a TSO/E address space, it ends the calling task and all its subtasks.

Special behavior for C++: If _exit() is called in a C++ program, the program terminates without leaving the current block, and destructors are not called for local (automatic) variables. In addition, unlike exit(), destructors for global (static) variables are not called.

Returned value

_exit() is always successful and returns no values.

No value is stored in errno for this function.

Example

CELEBE05

```
/* CELEBE05

   This example ends a process.

 */
#define _POSIX_SOURCE
```

```
#include <unistd.h>
#include <stdio.h>

main() {
  puts("Remember that stream buffers are not automatically");
  puts("flushed before _exit()!");
  fflush(NULL);
  _exit(0);
}
```

Output

```
Remember that stream buffers are not automatically
flushed before _exit()!
```

_Exit() — Terminate a process

Standards

Standards / Extensions	C or C++	Dependencies
C99 C11 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <stdlib.h>

__noreturn__ void _Exit(int status);
```

General description

When running POSIX(OFF), the _Exit() function is equivalent to exit() with the exception that it does not run atexit() registered routines or signal handlers registered using signal().

When running POSIX(ON), the _Exit() function is equivalent to _exit().

Returned value

The _Exit() function does not return to its caller.

- “_exit() — End a process and bypass the cleanup” on page 445

exp(), expf(), expl() — Calculate exponential function

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double exp(double x);
float exp(float x);                   /* C++ only */
long double exp(long double x);       /* C++ only */
float expf(float x);
long double expl(long double x);
```

General description

Calculates the exponent of *x*, defined as *e**x*, where *e* equals 2.17128128....

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Returned value

If successful, the function returns the calculated value.

If an overflow occurs, the function returns HUGE_VAL. If an underflow occurs, it returns 0. Both overflow and underflow set errno to ERANGE.

Example

CELEBE06

```
/* CELEBE06

   This example calculates y as the exponential function of x.

 */
#include <math.h>
#include <stdio.h>

int main(void)
{
   double x, y;
   x = 5.0;
   y = exp(x);

   printf("exp( %f ) = %f\n", x, y);
}
```

Output

```
exp( 5.000000 ) = 148.413159
```

expd32(), expd64(), expd128() — Calculate exponential function

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  expd32(_Decimal32 x);
_Decimal64  expd64(_Decimal64 x);
_Decimal128 expd128(_Decimal128 x);
_Decimal32  exp(_Decimal32 x);     /* C++ only */
_Decimal64  exp(_Decimal64 x);     /* C++ only */
_Decimal128 exp(_Decimal128 x);    /* C++ only */
```

General description

Calculates the exponent of x, defined as e***x*, where e equals 2.17128128....

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE binary floating-point" on page 94 for more information

Returned value

If successful, the function returns the calculated value.

If an overflow occurs, the function returns HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128. If an underflow occurs, it returns 0. Both overflow and underflow set errno to ERANGE.

Example

```
/* CELEBE11

   This example illustrates the expd64() function.

*/
```

```
#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal64 x, y;

   x = 5.0DD;
   y = expd64(x);

   printf("expd64(%Df) = %Df\n", x, y);
}
```

expm1(), expm1f(), expm1l() — Exponential minus one

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double expm1(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float expm1f(float x);
long double expm1l(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float expm1(float x);
long double expm1(long double x);
```

General description

The expm1() functions calculate the function:

e^x -1.0

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
expm1	X	X
expm1f	X	X
expm1l	X	X

Returned value

If successful, expm1() returns the above function calculated on *x*.

If unsuccessful, expm1() may fail as follows:

- If *x* is negative and exceeds an internally defined large value, expm1() functions will return -1.0.
- If the value of the function overflows, expm1() functions will return HUGE_VAL or HUGE_VALF or HUGE_VALL as appropriate, and set errno to ERANGE.

Related information

expm1d32(), expm1d64(), expm1d128() — Exponential minus one

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.11

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  expm1d32(_Decimal32 x);
_Decimal64  expm1d64(_Decimal64 x);
_Decimal128 expm1d128(_Decimal128 x);

_Decimal32  expm1(_Decimal32 x);      /* C++ only */
_Decimal64  expm1(_Decimal64 x);      /* C++ only */
_Decimal128 expm1(_Decimal128 x);     /* C++ only */
```

General description

The expm1() functions calculate the function:

e^x -1.0

Notes:

1. These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, expm1() returns the above function calculated on *x*.

If unsuccessful, expm1() may fail as follows:

- If x is negative and exceeds an internally defined large value, expm1() functions will return -1.0.
- If the value of the function overflows, expm1() functions will return HUGE_VAL_D32 or HUGE_VAL_D64 or HUGE_VAL_D128 as appropriate, and set errno to ERANGE.

Example

```
/* CELEBE13

   This example illustrates the expm1d32() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
   _Decimal32 x, y;

   x = 2.5DF;
   y = expm1d32(x);

   printf("expm1d32(%Hf) = %Hf\n", x, y);
}
```

ExportWorkUnit() — WLM export service

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R9

Format

```
#include <sys/__wlm.h>

int ExportWorkUnit(wlmetok_t *enclavetoken,
                   wlmxtok_t *exporttoken,
                   unsigned long *conntoken);
```

AMODE 64:

```
#include <sys/__wlm.h>

int ExportWorkUnit(wlmetok_t *enclavetoken,
                   wlmxtok_t *exporttoken,
                   unsigned int *conntoken);
```

General description

Exports an enclave to all systems in a parallel sysplex, enabling dispatchable units on other systems to join the enclave.

The ExportWorkUnit() function uses the following parameters:

**enclavetoken*
: Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().

**exporttoken*
: Points to a data field of type wlmxtok_t where the ExportWorkUnit() function is to return the WLM work unit export token.

**conntoken*
: Specifies the connect token that represents the connection to WLM.

Returned value

If successful, ExportWorkUnit() returns 0.

If unsuccessful, ExportWorkUnit() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EFAULT
: An argument of this function contained an address that was not accessible to the caller.

EINVAL
: An argument of this function contained a value that is not correct.

EMVSSAF2ERR
: An error occurred in the security product.

EMVSWLMERROR
: A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
: The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class, if the BPX.WLMSERVER class is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

exp2(), exp2f(), exp2l() — Calculate the base-2 exponential

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double exp2(double x);
float exp2f(float x);
long double exp2l(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float exp2(float x);
long double exp2(long double x);
```

General description

The exp2 functions compute the base-2 exponential of *x*.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
exp2	X	X
exp2f	X	X
exp2l	X	X

Returned value

The exp2 functions return 2 to the power *x*.

Related information

- “math.h” on page 44

exp2d32(), exp2d64(), exp2d128() — Calculate the base-2 exponential

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.11

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  exp2d32(_Decimal32 x);
_Decimal64  exp2d64(_Decimal64 x);
_Decimal128 exp2d128(_Decimal128 x);

_Decimal32  exp2(_Decimal32 x);      /* C++ only */
_Decimal64  exp2(_Decimal64 x);      /* C++ only */
_Decimal128 exp2(_Decimal128 x);     /* C++ only */
```

General description

The exp2() functions compute the base-2 exponential of *x*.

Notes:

1. These functions work in IEEE decimal floating-point format. See "IEEE decimal floating-point" on page 95IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The exp2() functions return 2 to the power *x*.

Example

```
/* CELEBE14

   This example illustrates the exp2d128() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
   _Decimal128 x, y;

   x = 4.785DL;
   y = exp2d128(x);

   printf("exp2d128(%DDf) = %DDf\n", x, y);
}
```

Related information

extlink_np() — Create an external symbolic link

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <unistd.h>

int extlink_np(const char *ename, const char *elink);
```

General description

Creates the external symbolic link file named by *elink* with the object specified by *ename*. The *ename* is not resolved, and refers to an object outside the HFS (hierarchical file system). The variable *elink* is the name of the external symbolic link file created, and *ename* is the name of the object contained within that file.

Returned value

If successful, extlink_np() returns 0.

If unsuccessful, extlink_np() returns -1, does not affect any file it names, and sets errno to one of the following values:

Error Code
Description

EACCES
A component of the *elink* path prefix denies search permission.

EEXIST
The file named by *elink* already exists.

EINVAL
elink has a slash as its last component, which indicates that the preceding component will be a directory. An external link cannot be a directory.

ELOOP
A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of the *elink* argument is greater than POSIX_SYMLOOP.

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined with pathconf().

ENOTDIR
A component of the path prefix of *elink* is not a directory.

ENOSPC
The new external link cannot be created because there is no space left on the file system to contain it.

EROFS
The file named by *elink* cannot be created on a read-only file system.

Example

CELEBE07

```
/* CELEBE07

   This example creates an external symbolic link.
```

```
 */
#include <stdio.h>
#include <fcntl.h>
#include <errno.h>
#include <unistd.h>
#include <stdlib.h>
#include <sys/stat.h>
#include <sys/types.h>

main( argc, argv )
  int   argc ;
  char  *argv ;
{
  int   i_rc ;
  int   i_fd ;
  char  ac_mvsds[] = "SYS1.LINKLIB" ;
  char  ac_mvsdsextsymlnk[] = "sys1.linklib.extsymlink" ;

  i_rc = unlink( ac_mvsdsextsymlnk ) ;

  if (( i_rc == -1 ) && ( errno == ENOENT )) {
  }
  else
  {
    perror( "unlink() error" ) ;
    return( -1 ) ;
  }

  printf( "Before extlink_np() call ...\n" ) ;
  system( "ls -il sys1.*" ) ;

  i_rc = extlink_np( ac_mvsds, ac_mvsdsextsymlnk ) ;

  if ( i_rc == -1 )
  {
    perror( "extlink_np() error" ) ;
    return( -1 ) ;
  }

  printf( "After extlink_np() call ...\n" ) ;
  system( "ls -il sys1.*" ) ;

  i_rc = unlink( ac_mvsdsextsymlnk ) ;
}
```

ExtractWorkUnit() — Extract enclave service

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R8

Format

```
#include <sys/__wlm.h>

int ExtractWorkUnit(wlmetok_t *enclavetoken);
```

General description

The ExtractWorkUnit() function will allow the task to retrieve the enclaves token for the purpose of performance management.

The ExtractWorkUnit() function uses the following parameter:

**enclavetoken*
: Points to a data field of type wlmetok_t where the ExtractWorkUnit() function is to return the WLM work unit token to which the current process is joined.

Returned value

If successful, ExtractWorkUnit() returns 0.

If unsuccessful, ExtractWorkUnit() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EFAULT
: An argument of this service contained an address that was not accessible to the caller.

EINVAL
: The Functioncode parm contains a value that is not correct or the function parmlist data is incorrect.

EMVSSAF2ERR
: An error occurred in the security product. Consult the reason code, which can be retrieved using the __errno2() function.

EMVSWLMERROR
: A WLM service failed. Consult the reason code, which can be retrieved using the __errno2() function.

EPERM
: Do not have appropriate permissions and privilege.

ESRCH
: A WLM_EXTRACT_WORKUNIT request was issued but the WLM enclave token was not returned.

__e2a_l() — Convert characters from EBCDIC to ASCII

Standards

Standards / Extensions	C or C++	Dependencies
	both	z/OS V1R2

Format

```
#include <unistd.h>

size_t  __e2a_l(char  *bufptr, size_t  szLen)
```

General description

The __e2a_l() function converts *szLen* characters in *bufptr* between IBM-1047 and ISO8859-1, returning the number of characters converted if successful or -1 if not. Conversion occurs in place in the buffer. __e2a_l() is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned value

If successful, __e2a_l() returns the number of characters converted.

If unsuccessful, __e2a_l() returns -1 and sets errno to the following value:

Error Code
Description

EINVAL
The pointer to *bufptr* is NULL or *szLen* is a negative value.

Related information

Standards

Standards / Extensions	C or C++	Dependencies
	both	z/OS V1R2

Format

```
#include <unistd.h>

size_t  __e2a_s(char  *string)
```

General description

The __e2a_s() function converts a string between IBM-1047 and ISO8859-1, returning the string length if successful or -1 if not. Conversion occurs in place in the string. __e2a_s() is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned value

If successful, __e2a_s() returns the string length.

If unsuccessful, __e2a_s() returns -1 and sets errno to the following value:

Error Code
Description

EINVAL
The pointer to string is NULL.

fabs(), fabsf(), fabsl() — Calculate floating-point absolute value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double fabs(double x);
float fabs(float x);                  /* C++ only */
long double fabs(long double x);      /* C++ only */
float fabsf(float x);
long double fabsl(long double x);
```

General description

The fabs() functions calculate the absolute value of a floating-point argument.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Returns the absolute value of the float input.

Example

```
/* This example calculates y as the absolute value of x. */
#include <math.h>

int main(void)
```

```
{
   double x, y;

   x = -5.6798;
   y = fabs(x);

   printf("fabs( %f ) = %f\n", x, y);
}
```

Output

```
fabs( -5.679800 ) = 5.679800
```

Related information

fabsd32(), fabsd64(), fabsd128() — Calculate floating-point absolute value

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  fabsd32(_Decimal32 x);
_Decimal64  fabsd64(_Decimal64 x);
_Decimal128 fabsd128(_Decimal128 x);
_Decimal32  fabs(_Decimal32 x);    /* C++ only */
_Decimal64  fabs(_Decimal64 x);    /* C++ only */
_Decimal128 fabs(_Decimal128 x);   /* C++ only */
```

General description

The fabs() functions calculate the absolute value of a decimal floating-point argument.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See “IEEE binary floating-point” on page 94 for more information

Returned value

Returns the absolute value of the decimal floating-point input.

Example

```
/* CELEBF75

   This example illustrates the fabsd128() function.

*/
```

```
#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
  _Decimal128 x, y;

  x = -5.6798DL;
  y = fabsd128(x);

  printf("fabsd128(%DDf) = %DDf\n", x, y);
}
```

fattach() — Attach a STREAMS-based file descriptor to a file in the file system name space

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int fattach(int fildes, const char *path);
```

General description

The fattach() function attaches a STREAMS-based file descriptor to a file, effectively associating a path name with *fildes*. The *fildes* argument must be a valid open file descriptor associated with a STREAMS file. The *path* argument points to a path name of an existing file. The process must have appropriate privileges, or must be the owner of the file named by *path* and have write permission. A successful call to fattach() causes all path names that name the file named by *path* to name the STREAMS file associated with *fildes*, until the STREAMS file is detached from the file. A STREAMS file can be attached to more than one file and can have several path names associated with it.

The attributes of the named STREAMS file are initialized as follows: the permissions, user ID, group ID, and times are set to those of the file named by *path*, the number of links is set to 1, and the size and device identifier are set to those of the STREAMS file associated with *fildes*. If any attributes of the named STREAMS file are subsequently changed (for example, by chmod()), neither the attributes of the underlying file nor the attributes of the STREAMS file to which *fildes* refers are affected.

File descriptors referring to the underlying file, opened before an fattach() call, continue to refer to the underlying file.

Returned value

If successful, fattach() returns 0.

If unsuccessful, fattach() returns -1 and sets errno to one of the following values.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for fattach() to attach a STREAMS-based file descriptor to a file. It will always return -1 with errno set to indicate the failure. See “open() — Open a file” on page 1152 for more information.

Error Code
Description

EACCES
Search permission is denied for a component of the path prefix, or the process is the owner of *path* but does not have write permissions on the file named by *path*.

EBADF
The *fildes* argument is not a valid open file descriptor.

EBUSY
The file named by *path* is currently a mount point or has a STREAMS file attached to it.

EINVAL
The *fildes* argument does not refer to a STREAMS file.

ELOOP
Too many symbolic links were encountered in resolving *path*.

ENAMETOOLONG
The size of *path* exceeds **PATH_MAX**, or a component of *path* is longer than **NAME_MAX**, or path name resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.

ENOENT
A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR
A component of the path prefix is not a directory.

EPERM
The effective user ID of the process is not the owner of the file named by *path* and the process does not have appropriate privilege.

__fbufsize() — Retrieve the buffer size of an open stream

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>
#include <stdio_ext.h>

size_t __fbufsize(FILE *stream);
```

General description

The __fbufsize() function retrieves the buffer size, in bytes, of the specified stream.

Returned value

The __fbufsize() function returns the size of the buffer in bytes. Otherwise, the __fbufsize() function returns 0. If an error has occurred, __fbufsize() returns 0 and sets errno to nonzero.

An application wishing to check for error situations should set errno to 0, then call __fbufsize(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
    Description

EBADF
    The stream specified by *stream* is not valid.

Example

CELEBF87

```
/* CELEBF87

   This example determines the size of the I/O buffer
   for an open stream.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
   FILE *f;
   int bufsize = 0;
   char filename[FILENAME_MAX] = "myfile.dat";

   f = fopen(filename,"wb");
   if (f == NULL) {
      perror("fopen failed\n");
      return;
   }

   bufsize = __fbufsize(f);

   printf("The buffer size for %s is %d\n",filename,bufsize);

   return;
}
```

Output

```
The buffer size for myfile.dat is 4096
```

Related information

__fchattr() — Change the attributes of a file or directory by file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R2

Format

```
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __fchattr(int filedes, attrib_t *attributes, int attributes_len);
```

General description

The __fchattr() function modifies the attributes that are associated with a file. It can be used to change the mode, owner, access time, modification time, change time, reference time, audit flags, general attribute flags, file tag, and file format and size. The file to be impacted is defined by its file descriptor with the *filedes* argument.

The *attributes* argument is the address of an attrib_t structure which is used to identify the attributes to be modified and the new values desired. The attrib_t type is an f_attributes structure as defined in <sys/stat.h> for use with the __fchattr() function. For proper behavior, the user should ensure that this structure has been initialized to zeros before it is populated. The f_attributes structure is defined as indicated in Table 20 on page 261.

The f_attributes structure is defined in <sys/stat.h> for use with the __fchattr() function.

Returned value

If successful, __fchattr() returns 0.

If unsuccessful, __fchattr() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The calling process did not have appropriate permissions. Possible reasons include:

- The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.

- The calling process was attempting to truncate the file, and it does not have write permission for the file.

EBADF
The *filedes* parameter is not a valid file descriptor.

ECICS
An attempt was made to change file tag attributes under non-OTE CICS and file tagging is not supported in that environment.

EFBIG
The calling process was attempting to change the size of a file but the specified length is greater than the maximum file size limit for the process.

EINVAL
The attributes structure containing the requested changes is not valid.

EPERM
The operation is not permitted for one of the following reasons:

- The calling process was attempting to change the mode or the file format but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the owner but it does not have appropriate privileges.
- The calling process was attempting to change the general attribute bits but it does not have write permission for the file.
- The calling process was attempting to set a time value (not current time) but the effective UID does not match the owner of the file, and it does not have appropriate privileges.
- The calling process was attempting to set the change time or reference time to current time but it does not have write permission for the file.
- The calling process was attempting to change auditing flags but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the Security Auditor's auditing flags but the user does not have auditor authority.

EROFS
pathname specifies a file that is on a read-only file system.

Related information

- “sys/stat.h” on page 75
- “__chattr() — Change the attributes of a file or directory” on page 261
- “__lchattr() — Change the attributes of a file or directory when they point to a symbolic or external link” on page 936

fchaudit() — Change audit flags for a file by descriptor

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/stat.h>

int fchaudit(int fildes, unsigned int flags, unsigned int option);
```

General description

Changes the audit flags of a file. The parameter *fildes* is the file descriptor for the open file whose audit flags are to be changed. *flags* specifies what the audit flags should be changed to:

AUDTREADFAIL
Audit failing read requests.

AUDTREADSUCC
Audit successful read requests.

AUDTWRITEFAIL
Audit failing write requests.

AUDTWRITESUCC
Audit successful write requests.

AUDTEXECFAIL
Audit failing execute or search requests.

AUDTEXECSUCC
Audit successful execute or search requests. The bitwise inclusive-OR of any or all of these can be used to set more than one type of auditing.

The parameter *option* specifies whether the user audit flags or the security auditor audit flags should be changed:

AUDT_USER (0)
User audit flags are changed. The user must be the file owner or have appropriate authority to change the user audit flags for a file.

AUDT_AUDITOR (1)
Security-auditor audit flags are changed. The user must have security auditor authority to change the security auditor audit flags for a file.

Returned value

If successful, fchaudit() returns 0.

If unsuccessful, fchaudit() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EINVAL
option does not contain a 0 or 1.

EPERM
The effective user ID (UID) of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS
fildes is associated with a file that is on a read-only file system.

Example

CELEBF02

```
/* CELEBF02

   The following program changes the audit flags of a file.

 */
#define _OPEN_SYS
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#include <stdio.h>

main() {
  int fd;
  char fn[]="fchaudit.file";

  if ((fd = creat(fn, S_IRUSR|S_IWUSR)) < 0)
    perror("creat() error");
  else {
    if (fchaudit(fd, AUDTREADSUCC, AUDT_USER) != 0)
      perror("fchaudit() error");
    close(fd);
    unlink(fn);
  }
}
```

fchdir() — Change working directory

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int fchdir(int fildes);
```

General description

The fchdir() function has the same effect as *chdir*() except that the directory that is to be new current working directory is specified by the file descriptor *fildes*.

Returned value

If successful, fchdir() changes the working directory and returns 0.

If unsuccessful, fchdir() does not change the working directory, returns -1, and sets errno to one of the following values:

Error Code
Description

EACCES
Search permission is denied for the directory referenced by *fildes*.

EBADF
The *fildes* arguments is not an open file descriptor.

ENOTDIR
The open file descriptor *fildes* does not refer to a directory.

Related information

- "unistd.h" on page 82
- "chdir() — Change the working directory" on page 267
- "chroot() — Change root directory" on page 279

fchmod() — Change the mode of a file or directory by descriptor

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1a XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX1_SOURCE 2
#include <sys/stat.h>

int fchmod(int fildes, mode_t mode);
```

General description

Sets the S_ISUID, S_ISGID, and file permission bits of the open file identified by *fildes*, its file descriptor.

The *mode* argument is created with one of the symbols defined in the sys/stat.h header file. For more information on these symbols, refer to "chmod() — Change the mode of a file or directory" on page 272.

Returned value

If successful, fchmod() marks for update the `st_ctime` field of the file and returns 0.

If unsuccessful, fchmod() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EPERM
The effective user ID (UID) does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS
The file resides on a read-only file system.

Example

CELEBF03

```
/* CELEBF03

   This example changes a file permission.

 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  char fn[]="temp.file";
  int  fd;
  struct stat info;

  if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    stat(fn, &info);
    printf("original permissions were: %08x\n", info.st_mode);
    if (fchmod(fd, S_IRWXU|S_IRWXG) != 0)
      perror("fchmod() error");
    else {
      stat(fn, &info);
      printf("after fchmod(), permissions are: %08x\n", info.st_mode);
    }
    close(fd);
    unlink(fn);
  }
}
```

Output

```
original permissions were: 03000080
after fchmod(), permissions are: 030001f8
```

Related information

fchown() — Change the owner or group by file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1a XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int fchown(int fildes, uid_t owner, gid_t group);
```

General description

Changes the owner or group (or both) of a file. *fildes* is the file descriptor for the file. *owner* is the user ID (UID) of the new owner of the file. *group* is the group ID of the new group for the file.

If _POSIX_CHOWN_RESTRICTED is defined in the unistd.h header file, a process can change the group of a file only if one of the following conditions is true:

1. The process has appropriate privileges.

   Or
2. All of the following are true:
   1. The effective user ID of the process is equal to the user ID of the file owner.
   2. The *owner* argument is equal to the user ID of the file owner or `(uid_t)-1`,
   3. The *group* argument is either the effective group ID or a supplementary group ID of the calling process.

If *fildes* points to a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set when fchown() returns successfully, it clears the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file mode.

If the file referred to by *fildes* is not a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file are cleared.

When fchown() completes successfully, it marks the `st_ctime` field of the file to be updated.

Returned value

If successful, fchown() updates the change time for the file and returns 0.

If unsuccessful, fchown() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EPERM
Either the effective user ID does not match the owner of the file, or the calling process does not have appropriate privileges, and POSIX_CHOWN_RESTRICTED indicates that such privilege is required.

EROFS
The file resides on a read-only system.

Example

CELEBF04

```
/* CELEBF04

   This example changes the owner ID and group ID.

 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <unistd.h>
#include <sys/stat.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  char fn[]="temp.file";
  FILE *stream;
  int  fd;
  struct stat info;

  if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    stat(fn, &info);
    printf("original owner was %d and group was %d\n", info.st_uid,
           info.st_gid);
    if (fchown(fd, 25, 0) != 0)
      perror("fchown() error");
    else {
      stat(fn, &info);
      printf("after fchown(), owner is %d and group is %d\n",
             info.st_uid, info.st_gid);
    }
    close(fd);
    unlink(fn);
  }
}
```

Output

```
original owner was 0 and group was 500
after fchown(), owner is 25 and group is 0
```

fclose() — Close file

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdio.h>

int fclose(FILE *stream);
```

General description

Flushes a stream, and then closes the file associated with that stream. Afterwards, the function releases any buffers associated with the stream. To *flush* means that unwritten buffered data is written to the file, and unread buffered data is discarded.

A pointer to a closed file *cannot* be used as an input value to the freopen() function.

Notes:

1. The storage pointed to by the FILE pointer is freed by the fclose() function. An attempt to use the FILE pointer to a closed file is not valid. This restriction is true even when fclose() fails.
2. If an application has locked a (FILE *) object (with flockfile() or ftrylockfile()), it is responsible for relinquishing the locked (FILE *) object (with funlockfile()) before calling fclose(). Failure to relinquish a locked (FILE *) object may cause deadlock (or looping).

Returned value

If successful closing the stream, fclose() returns 0.

If a failure occurs in flushing buffers or in outputting data, fclose() returns EOF. An attempt will still be made to close the file.

Special behavior for XPG4

fclose() sets errno to one of the following values:

Error Code
Description

EAGAIN
The O_NONBLOCK flag is set and output cannot be written immediately.

EBADF
The underlying file descriptor is not valid.

EFBIG
Writing to the output file would exceed the maximum file size or the process's file size supported by the implementation.

EINTR
The fclose() function was interrupted by a signal before it had written any output.

EIO The process is in a background process group and is attempting to write to its controlling terminal, but TOSTOP (defined in the termio.h include file) is set, the process is neither ignoring nor blocking SIGTTOU signals, and the process group of the process is orphaned.

ENOSPC
There is no free space left on the output device

ENXIO
A request was made of a nonexistent device, or the request was outside the device.

EPIPE fclose() is trying to write to a pipe or FIFO that is not open for reading by any process. This error also generates a SIGPIPE signal.

Example

```
/* This example opens a file myfile.dat for reading as a stream and then
   closes the file.
 */
#include <stdio.h>

int main(void)
{
   FILE *stream;

   stream = fopen("myfile.dat", "r");
⋮
   if (fclose(stream))   /* Close the stream. */
      printf("fclose error\n");
}
```

fcntl() — Control open file descriptors

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <fcntl.h>

int fcntl(int fildes, int action, ...);
```

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <unistd.h>
#include <fcntl.h>

int fcntl(int socket, int cmd, ...);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <unistd.h>
#include <fcntl.h>

int fcntl(int socket, int cmd, ...);
```

General description

The fcntl() function performs various actions on open file descriptors.

The argument *fildes* is a file descriptor for the file you want to manipulate. *action* is a symbol indicating the action you want to perform on *fildes*. These symbols are defined in the <fcntl.h> header file. If needed, "`...`" indicates a third argument. The type of the third argument depends on *action*, and some actions do not need an additional argument.

Behavior for sockets: The operating characteristics of sockets can be controlled with the fcntl() call. The operations to be controlled are determined by *cmd*. The *arg* parameter is a variable with a meaning that depends on the value of the *cmd* parameter.

Parameter	**Description**
socket	The socket descriptor.
cmd	The command to perform.
arg	The data associated with *cmd*.

The *action* argument can be one of the following symbols:

F_CLOSFD
Closes a range of file descriptors. A third `int` argument must be specified to indicate the upper limit for the range of the file descriptors to be closed, while *fildes* specifies the lower limit. If -1 is specified for the third argument, all file descriptors greater than or equal to the lower limit are closed.

F_DUPFD
Duplicates the file descriptor. A third `int` argument must be specified. fcntl() returns the lowest file descriptor greater than or equal to this third argument that is not already associated with an open file. This file descriptor refers to the same file as *fildes* and shares any locks. The flags

FD_CLOEXEC and FD_CLOFORK are turned off in the new file descriptor, so that the file is kept open if an exec function is called.

Note: If *fildes* is an XTI endpoint, there must be at least one available file descriptor greater than or equal to the third argument and less than 65536.

F_DUPFD2

Duplicates the file descriptor. A third `int` argument must be specified to indicate which file descriptor to use as the duplicate. This file descriptor is closed if already open and then used as the new file descriptor. The new file descriptor refers to the same file as *fildes* and shares any locks. The flag FD_CLOEXEC is turned off in the new file descriptor, so that the file is kept open if an exec function is called.

Note:

1. If the third argument refers to the same file descriptor as *fildes*, the file descriptor is not closed and is FD_CLOEXEC is not turned off.
2. If *fildes* is an XTI endpoint, the third argument must not exceed the limit of 65535.

F_GETFD

Obtains the file descriptor flags for *fildes*. fcntl() returns these flags as its result. For a list of supported file descriptor flags, see "File flags" on page 480.

F_SETFD

Sets the file descriptor flags for *fildes*. You must specify a third `int` argument, giving the new file descriptor flag settings. fcntl() returns 0 if it successfully sets the flags.

F_GETFL

Obtains the file status flags and file access mode flags for *fildes*. fcntl() returns these flags as its result. For a list of supported file status and file access mode flags, see "File flags" on page 480.

Usage of the F_GETFL action will return the setting of O_LARGEFILE status flag when fcntl() has been enabled to operate on large files

Behavior for sockets: This command gets the status flags of socket descriptor *socket*. With the `_OPEN_SYS` feature test macro you can query the FNDELAY flag. With the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro you can query the O_NDELAY flag. The FNDELAY and O_NDELAY flags mark *socket* as being in nonblocking mode. If data is not present on calls that can block, such as read(), readv(), and recv(), the call returns with -1, and the error code is set to EWOULDBLOCK.

F_SETFL

Sets the file status flags for *fildes*. You must specify a third `int` argument, giving the new file descriptor flag settings. fcntl() does not change the file access mode, and file access bits in the third argument are ignored. fcntl() returns 0 if it successfully sets the flags.

Behavior for sockets: This command sets the status flags of socket descriptor *socket*. With the `_OPEN_SYS` feature test macro you can set the FNDELAY flag. With the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro you can set the O_NDELAY flag.

F_GETLK

Obtains locking information for a file. See "File locking" on page 481

F_SETLK

Sets or clears a file segment lock. See "File locking" on page 481

F_SETLKW

Sets or clears a file segment lock; but if a shared or exclusive lock is blocked by other locks, fcntl() waits until the request can be satisfied. See "File locking" on page 481

F_GETOWN

Behavior for sockets: Obtains the PID for the filedes and returns this value. The value returned will be either the process ID or the process group ID that is associated with the socket. If it is a positive integer, it specifies a process ID. If it is a negative integer (other than -1), it specifies a process group ID.

F_SETOWN

Behavior for sockets: Sets either the process ID or the process group ID that is to receive either the SIGIO or SIGURG signals for the socket associated with filedes. The SIGURG signal is generated as a result of receiving out-of-band data. Refer to send(), sendto(), sendmsg(), and recv(), recvfrom() and recvmsg() for more information on sending and receiving out-of-band data.

You must specify a third int argument, giving the PID requested. This value can be either a positive integer, specifying a process ID, or a negative integer (other than -1), specifying a process group ID. The difference between specifying a process ID or a process group ID is that in the first case only a single process will receive the signal, while in the second case all processes in the process group will receive the signal.

F_SETTAG

Sets the file tag for the file referred to by file descriptor *fildes*.

The third argument *ftag* is the address of a populated file_tag structure.

If the *ftag* argument supplied to fcntl(F_SETTAG) does not have the ft_deferred bit set ON, fcntl() will immediately set the file's File Tag with the provided *ftag*'s ft_ccsid and ft_txtflag values.

If the *ftag* argument supplied to fcntl(F_SETTAG) has the ft_deferred bit set ON, fcntl() will not set the file's File Tag until first write to the file. The CCSID used to tag the file will be the current Program CCSID at the time of first write, regardless of the *ftag* ft_ccsid value, however the ft_txtflag value will be used.

If the ft_ccsid of the specified file_tag differs from the Program CCSID, automatic file conversion will occur, provided:

- The ft_txtflag is set to ON.
- Environment variable _BPXK_AUTOCVT is ON or ALL; or if _BPXK_AUTOCVT is unset, the BPXPRMxx member AUTOCVT is either ON or ALL.

Restriction: When _BPXK_AUTOCVT is ON, automatic conversion can only take place between IBM-1047 and ISO8859-1 code sets. Other CCSID pairs are not supported for automatic text conversion. To request automatic conversion for any CCSID pairs that Unicode service supports, set _BPXK_AUTOCVT to ALL.

If AUTOCVT(OFF) and _BPXK_AUTOCVT=OFF, the file will be tagged with the specified file_tag's ft_ccsid and ft_txtflag values, but automatic conversion will not occur. See the "Using Environment Variables" chapter in *z/OS XL C/C++ Programming Guide* for more information about the _BPXK_AUTOCVT environment variable.

If the *ftag* argument supplied to fcntl(F_SETTAG) has the ft_deferred bit set ON, pipes and FIFOs are tagged from the write end with the Program CCSID of the first writer.

F_CONTROL_CVT

Controls or queries the conversion status of the open file referred to by file descriptor *fildes*. Conversion control is generally used to provide CCSID information for untagged files or untagged programs.

Character set conversion between a program and a file, pipe or other I/O stream can be enabled or changed with F_CONTROL_CVT. A pair of CCSID's is specified or defaulted, one for the program and one for the data. As the program reads and writes data, the system will convert from one CCSID to the other.

The third f_cnvrt argument is the required address of an f_cnvrt structure. This structure is defined in <fcntl.h> and includes the following members:

Table 22. Struct f_cnvrt Element Descriptions

Element	Data Type	Description
pccsid	short	The Program CCSID - This is output from query and input to setting conversion ON. A value of 0 on input indicates to use the previously set value or the current Program CCSID.
fccsid	short	The File CCSID - This is output from query and input to setting conversion ON. A value of 0 on input indicates to use the CCSID from the File Tag as stored in the file, specified on mount, or set by a prior call.

Table 22. Struct f_cnvrt Element Descriptions (continued)

Element	Data Type	Description
cvtcmd	int	Conversion Control Command. The following conversion controls are available: • Query Conversion - Returns whether or not conversion is in effect and the Program and File CCSIDs being used. On input, *cvtcmd* is set to QUERYCVT, and on output, it is changed to either SETCVTON, SETCVTOFF, or SETCVTALL to indicate that conversion is currently ON, OFF, or ALL respectively. The current CCSIDs are also returned in their respective positions in the f_cnvrt structure. • Set Conversion OFF - Turns OFF any conversion that may be in effect. On input, *cvtcmd* is set to SETCVTOFF and the rest of the f_cnvrt is ignored. There is no output. A program can use this to override an automatic conversion that might be established by the environment within which it is invoked. If conversion is currently in effect, the CCSIDs being used will be remembered while conversion is turned OFF, so that the prior conversion may be resumed without the program having to remember what the prior CCSIDs were. • Set Conversion ON - Turns on enhanced ASCII conversion environment and optionally specifies the CCSIDs to use in place of the Program or File CCSIDs that are currently in effect. On input, *cvtcmd* is set either to SETCVTON to unconditionally turn on Enhanced ASCII, or to SETAUTOCVTON to turn on it only if _BPXK_AUTOCVT=ON or AUTOCVT(ON) was specified in BPXPRMxx. In this case, automatic conversion can only take place between IBM-1047 and ISO8859-1 code sets. Other CCSID pairs are not supported for automatic text conversion. A value of 0 for the Program CCSID indicates that the current Program CCSID be used. A value of 0 for the file CCSID indicates that no change should be made to the File CCSID. This does not affect the stored File Tag or the current Program CCSID. It only changes the values being used to control conversion on this data stream. • Set Conversion ALL - Turns on Unicode conversion environment and optionally specifies the CCSIDs to use in place of the Program or File CCSIDs that are currently in effect. On input, *cvtcmd* can be set either to SETCVTALL to unconditionally turn on Unicode conversion, or to SETAUTOCVTALL to turn on it only if _BPXK_AUTOCVT=ALL or AUTOCVT(ALL) was specified in BPXPRMxx. SETCVTALL or SETAUTOCVTALL has no effect after the first read or write of the file. In this case, automatic conversion can take place between any code sets that Unicode service supports. A value of 0 for the Program CCSID indicates that the current Program CCSID be used. A value of 0 for the file CCSID indicates that no change should be made to the File CCSID. This does not affect the stored File Tag or the current Program CCSID. It only changes the values being used to control conversion on this data stream.

The call fails if a conversion table is not installed for the resulting CCSID pair.

Attention: Flipping the autoconversion mode off and on, or changing the CCSID values when file conversion and/or tagging takes place, or setting the CCSIDs to values that are not compatible with the program or file, can be quite unpredictable.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

File flags

There are several types of flags associated with each open file. Flags for a file are represented by symbols defined in the <fcntl.h> header file.

The following *file descriptor* flags can be associated with a file:

FD_CLOEXEC
If this flag is 1, the file descriptor is closed if the process executes one of the exec function calls. If it is 0, the file remains open.

FD_CLOFORK
If this flag is 1 when a fork occurs, the file descriptor will be closed for the child process. If it is 0, the file remains open for the child.

The following *file status* flags can be associated with a file:

O_APPEND
Append mode. If this flag is 1, every write operation on the file begins at the end of the file.

O_ASYNCSIG
If this flag is 1, then asynchronous I/O will be used for the file.

O_NONBLOCK
No blocking. If this flag is 1, read and write operations on the file return with an error status if they cannot perform their I/O immediately. If this flag is 0, read and write operations on the file wait (or "block") until the file is ready for I/O. For more details, see "read() — Read from a file or socket" on page 1376 and "write() — Write data on a file or socket" on page 2085.

O_SYNC
Force synchronous update. If the flag is 1, every write() operation on the file is written to permanent storage. That is, the file system buffers are forced to permanent storage. (See "fsync() — Write changes to direct-access storage" on page 655.) If this flag is 0, update operations on the file will not be completed until the data has been written to permanent storage. On return from a function that performs a synchronous update, the program is assured that all data for the file has been written to permanent storage.

The following *file access mode* flags can be associated with a file:

O_RDONLY
The file is opened for reading only.

O_RDWR
The file is opened for reading and writing.

O_WRONLY
The file is opened for writing only.

Two masks can be used to extract flags:

O_ACCMODE
Extracts file access mode flags.

O_GETFL
Extracts file status flags and file access mode flags.

File locking

A process can use fcntl() to lock out other processes from a part of a file, so that the process can read or write to that part of the file without interference from others. File locking can ensure data integrity when several processes have a file accessed concurrently. File locking can only be performed on file descriptors that refer to regular files. Locking is not permitted on file descriptors that refer to directories, FIFOs, pipes, character special files, or any other type of files.

A structure that has the type `struct flock` (defined in the <fcntl.h> header file) controls locking operations. This structure has the following members:

`short l_type`
Indicates the type of lock, using one of the following symbols (defined in the <fcntl.h> header file):

F_RDLCK
Indicates a *read lock*, also called a *shared lock*. The process can read the locked part of the file, and other processes cannot obtain write locks for that part of the file in the meantime. More than one process can have a read lock on the same part of a file simultaneously.

To establish a read lock, a process must have the file accessed for reading.

F_WRLCK
Indicates a *write lock*, also called an *exclusive lock*. The process can write on the locked part of the file, and no other process can establish a read lock or write lock on that same part or on an overlapping part of the file. A process cannot put a write lock on part of a file if there is already a read lock on an overlapping part of the file. To establish a write lock, a process must have accessed the file for writing.

F_UNLCK
Unlocks a lock that was set previously. An unlock (F_UNLCK) request in which l_len is non-zero and the offset of the last byte of the requested segment is the maximum value for an object of type off_t, when the process has an existing lock in which l_len is 0 and which includes the last byte of the requested segment, is treated as a request to unlock from the start of the requested segment with an l_len equal to 0. Otherwise, an unlock (F_UNLCK) request attempts to unlock only the requested segment.

`short l_whence`
One of three symbols used to determine the part of the file that is affected by this lock. These symbols are defined in the <unistd.h> header file and are the same as symbols used by lseek():

SEEK_CUR
The current file offset in the file

SEEK_END
The end of the file

SEEK_SET
The start of the file.

`off_t l_start`
Gives the byte offset used to identify the part of the file that is affected by this lock. The part of the file affected by the lock begins at this offset from

the location given by l_whence. For example, if l_whence is SEEK_SET and l_start is 10, the locked part of the file begins at an offset of 10 bytes from the beginning of the file.

off_t l_len
Gives the size of the locked part of the file in bytes. If l_len is 0, the locked part of the file begins at the position specified by l_whence and l_start, and extends to the end of the file. If l_len is positive, the area affected starts at l_start and end at l_start+ l_len-1. If l_len is negative, the area affected starts at l_start+ l_len and end at l_start-1. Locks may start and extend beyond the current end of a file, but cannot extend before the beginning of the file. A lock can be set to extend to the largest possible value of the file offset for that file by setting l_len to 0. If such a lock also has l_start set to 0 and l_whence is set to SEEK_SET, the whole file is locked.

pid_t l_pid
Specifies the process ID of the process that holds the lock. This is an output field used only with F_GETLK actions.

You can set locks by specifying F_SETLK as the *action* argument for fcntl(). Such a function call requires a third argument pointing to a struct flock structure, as in this example:

```
struct flock lock_it;
lock_it.l_type = F_RDLCK;
lock_it.l_whence = SEEK_SET;
lock_it.l_start = 0;
lock_it.l_len = 100;
fcntl(fildes,F_SETLK,&lock_it);
```

This example sets up an flock structure describing a read lock on the first 100 bytes of a file, and then calls fcntl() to establish the lock. You can unlock this lock by setting l_type to F_UNLCK and making the same call. If an F_SETLK operation cannot set a lock, it returns immediately with an error saying that the lock cannot be set.

The F_SETLKW operation is similar to F_SETLK, except that it waits until the lock can be set. For example, if you want to establish an exclusive lock and some other process already has a lock established on an overlapping part of the file, fcntl() waits until the other process has removed its lock. If fcntl() is waiting in an F_SETLKW operation when a signal is received, fcntl() is interrupted. After handling the signal, fcntl() returns -1 and sets errno to EINTR.

F_SETLKW operations can encounter *deadlocks* when process A is waiting for process B to unlock a region, and B is waiting for A to unlock a different region. If the system detects that an F_SETLKW might cause a deadlock, fcntl() fails with errno set to EDEADLK.

A process can determine locking information about a file by using F_GETLK as the *action* argument for fcntl(). In this case, the call to fcntl() should specify a third argument pointing to an flock structure. The structure should describe the lock operation you want. When fcntl() returns, the structure indicated by the flock pointer is changed to show the first lock that would prevent the proposed lock operation from taking place. The returned structure shows the type of lock that is set, the part of the file that is locked, and the process ID of the process that holds the lock. In the returned structure:
- l_whence is always SEEK_SET.
- l_start gives the offset of the locked portion from the beginning of the file.

- `l_len` is the length of the locked portion.

If there are no locks that prevent the proposed lock operation, the returned structure has F_UNLCK in `l_type`, and is otherwise unchanged.

A process can have several locks on a file simultaneously but only one type of lock set on a given byte. Therefore, if a process puts a new lock on part of a file that it had locked previously, the process has only one lock on that part of the file: the type of the lock is the one specified in the most recent locking operation.

All of a process's locks on a file are removed when the process closes any file descriptor that refers to the locked file. Locks are not inherited by child processes created with fork().

All locks are advisory only. Processes can use locks to inform each other that they want to protect parts of a file, but locks do not prevent I/O on the locked parts. If a process has appropriate permissions on a file, it can perform whatever I/O it chooses, regardless of what locks are set. Therefore, file locking is only a convention, and it works only when all processes respect the convention.

Returned value

If successful, the value fcntl() returns will depend on the *action* that was specified.

If unsuccessful, fcntl() returns -1 and sets errno to one of the following values:

Error Code
Description

EAGAIN
The process tried to set a lock with F_SETLK, but the lock is in conflict with a lock already set by some other process on an overlapping part of the file.

EBADF
fildes is not a valid open file descriptor; or the process tried to set a read lock on a file descriptor open for writing only; or the process tried to set a write lock on a file descriptor open for reading only; or the *socket* parameter is not a valid socket descriptor.

In an F_DUPFD2 operation, the third argument is negative, or greater than or equal to **OPEN_MAX**, which is the highest file descriptor value allowed for the process.

EDEADLK
The system detected the potential for deadlock in a F_SETLKW operation.

EINTR
fcntl() was interrupted by a signal during a F_SETLKW operation.

EINVAL
In an F_DUPFD operation, the third argument is negative or greater than or equal to **OPEN_MAX**, the highest file descriptor value allowed for the process. The **OPEN_MAX** value can be determined using pathconf().

In a locking operation, *fildes* refers to a file with a type that does not support locking, or the `struct flock` pointed to by the third argument has an incorrect form.

If an F_CLOSFD operation, the third argument, which specifies the upper limit, is less than *filedes* but is not equal to -1.

Behavior for sockets: The *arg* parameter is not a valid flag, or the *cmd* parameter is not a valid command.

EMFILE
In an F_DUPFD operation, the process has already reached its maximum number of file descriptors, or there are no available file descriptors greater than the specified third argument.

ENOLCK
In an F_SETLK or F_SETLKW operation, the specified file has already reached the maximum number of locked regions allowed by the system.

EOVERFLOW
One of the values to be returned cannot be represented correctly.

The cmd argument is F_GETLK, F_SETLK or F_SETLKW and the smallest or, if l_len is nonzero, the largest offset of any byte in the requested segment cannot be represented correctly in an object of type `off_t`.

EPERM
The operation was F_CLOSFD, but all the requested file descriptors were not closed.

Examples

CELEBF06

```
/* CELEBF06

   This example illustrates one use of fcntl().
   The example will compile only with C/MVS.

 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>

void catcher(int signum) {
  puts("inside catcher...");
}

main() {
  int p[2], flags;
  struct sigaction sact;
  char c;

  if (pipe(p) != 0)
    perror("pipe() error");
  else {
    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGALRM, &sact, NULL);

    alarm(10);

    if (read(p[0], &c, 1) == -1)
      perror("first read() failed");

    if ((flags = fcntl(p[0], F_GETFL)) == -1)
      perror("first fcntl() failed");
    else if (fcntl(p[0], F_SETFL, flags | O_NONBLOCK) == -1)
```

```
      perror("second fcntl() failed");
    else {
      alarm(10);

      if (read(p[0], &c, 1) == -1)
        perror("second read() failed");

      alarm(0);
    }
    close(p[0]);
    close(p[1]);
  }
}
```

Output

```
inside catcher...
first read() failed: Interrupted function call
second read() failed: Resource temporarily unavailable
```

Sockets example:

```
#define _OPEN_SYS
int s;
int rc;
int flags;
⋮
/* Place the socket into nonblocking mode */
rc = fcntl(s, F_SETFL, FNDELAY);

/* See if asynchronous notification is set */
flags = fcntl(s, F_GETFL, 0);
if (flags & FNDELAY)
   /* it is set */
else
   /* it is not */
```

fcvt() — Convert double to string

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *fcvt(double x, int ndigit, int *__restrict__ decpt, int *__restrict__ sign);
```

General description

The fcvt() function converts double floating-point argument values to floating-point output strings. The fcvt() function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using __isBFP().

z/OS XL C/C++ formatted output functions, including the fcvt() function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See "*fprintf* Family of Formatted Output Functions" on fprintf(), printf(), sprintf() — Format and write data for a description of the special infinity and NaN output sequences.

The fcvt() function converts *x* to a NULL-terminated string which has *ndigit* digits to the right of the radix point (where the total number of digits in the output string is restricted by the precision of a double) and returns a pointer to the string. The function behaves identically to "ecvt() — Convert double to string" on page 418 in all respects other than the number of digits in the return value.

Note: This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sprintf() function is preferred for portability.

Returned value

If successful, fcvt() returns the character equivalent of *x* as specified above.

If unable to allocate the return buffer, or the conversion fails, fcvt() returns NULL.

fdelrec() — Delete a VSAM record

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>

int fdelrec(FILE *stream);
```

```
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fdelrec_unlocked(FILE *stream);
```

General description

Removes the record previously read by fread() from the VSAM file associated with *stream*. The fdelrec() function can only be used after an fread() call has been performed and before any other operation on that file pointer. For example, if you need to acquire the file position using ftell() or fgetpos(), you can do it either before the fread() or after the fdelrec(). An fread() after an fdelrec() will retrieve the next record.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The fdelrec() function can be used with *key sequenced data sets* (KSDS), KSDS PATHs, and *relative record data set* (RRDS) opened in an update mode (that is, `rb+/r+b`, `wb+/w+b`, or `ab+/a+b`), with `type=record`.

VSAM does not support deletions from ESDSs.

fdelrec_unlocked() is functionally equivalent to fdelrec() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fdelrec() returns 0.

If unsuccessful, fdelrec() returns nonzero.

Example

```
/* This example shows how a VSAM record is deleted using the fdelrec()
   function.
 */
#include <stdio.h>
   FILE *stream;
   char buf[80];
   int num_read;
   int rc;
   stream = fopen("DD:MYCLUS", "rb+,type=record");
⋮
   num_read = fread(buf, 1, sizeof(buf), stream);
   rc = fdelrec(stream);
⋮
```

fdetach() — Detach a name from a STREAMS-based file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int fdetach(const char *path);
```

General description

The fdetach() function detaches a STREAMS-based file from the file to which it was attached by a previous call to fattach(). The *path* argument points to the path name of the attached STREAMS file. The process must have appropriate privileges or be the owner of the file. A successful call to fdetach() causes all path names that named the attached STREAMS file to again name the file to which the STREAMS file was attached. All subsequent operations on *path* will operate on the underlying file and not on the STREAMS file.

All open file descriptions established while the STREAMS file was attached to the file referenced by *path*, will still refer to the STREAMS file after the fdetach() has taken effect.

If there are no open file descriptors or other references to the STREAMS file, then a successful call to fdetach() has the same effect as performing the last close() on the attached file.

Returned value

If successful, fdetach() returns 0.

If unsuccessful, fdetach() returns -1 and sets errno to one of the following values.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for fdetach() to detach a file from a STREAMS-based file descriptor. See “open() — Open a file” on page 1152 for more information.

Error Code
Description

EACCES
Search permission is denied on a component of the path prefix.

EINVAL
The *path* argument names a file that is not currently attached.

ELOOP
Too many symbolic links were encountered in resolving *path*.

ENAMETOOLONG
The size of a path name exceeds **PATH_MAX**, or a path name component is longer than **NAME_MAX**, or path name resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.

ENOENT
A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR
A component of the path prefix is not a directory.

EPERM
The effective user ID is not the owner of *path* and the process does not have appropriate privileges.

fdim(), fdimf(), fdiml() — Calculate the positive difference

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R5

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double fdim(double x, double y);
float fdimf(float x, float y);
long double fdiml(long double x, long  double y);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float fdim(float x, float y);
long double fdim(long double x, long double y);
```

General description

The fdim functions compute the positive difference between *x* and *y*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
fdim	X	X
fdimf	X	X
fdiml	X	X

Restriction: The fdimf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

The fdim functions return the positive difference between *x* and *y*.

Related information

- "math.h" on page 44

fdimd32(), fdimd64(), fdimd128() — Calculate the positive difference

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  fdimd32(_Decimal32 x, _Decimal32 y);
_Decimal64  fdimd64(_Decimal64 x, _Decimal64 y);
_Decimal128 fdimd128(_Decimal128 x, _Decimal128 y);
_Decimal32  fdim(_Decimal32 x, _Decimal32 y);     /* C++ only */
_Decimal64  fdim(_Decimal64 x, _Decimal64 y);     /* C++ only */
_Decimal128 fdim(_Decimal128 x, _Decimal128 y);   /* C++ only */
```

General description

The fdim functions compute the positive difference between *x* and *y*.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE binary floating-point" on page 94 for more information

Returned value

The fdim functions return the positive difference between *x* and *y*.

Example

```
/* CELEBF76

   This example illustrates the fdimd32() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal32 x = 56789.70DF, y = 56790.00DF, z;

   z = fdimd32(y, x);

   printf("The result of fdim32(%Hf, %Hf)\n is %Hf\n", y, x, z);
   return 0;
}
```

fdopen() — Associate a stream with an open file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <stdio.h>

FILE *fdopen(int fildes, const char *options);
```

General description

Associates a stream with an open file descriptor. A *stream* is a pointer to a FILE structure that contains information about a file. A stream permits user-controllable buffering and formatted input and output. For a discussion of the z/OS UNIX services implementation of buffering, see *z/OS XL C/C++ Programming Guide*.

The specified *options* must be permitted by the current mode of the file descriptor. For example, if the file descriptor is open-read-only (O_RDONLY), the corresponding stream cannot be opened write-only (w).

These options are the same as for an fopen() operation.

Special behavior for XPG4.2: The values for options are changed to include binary streams.

Mode Description

r or rb
Open for reading.

w or wb
Open for writing.

a or ab
Open for appending.

r+ or rb+ or r+b
Open for update (reading and writing).

w+ or wb+ or w+b
Open for update (reading and writing).

a+ or ab+ or a+b
Open for update at End Of File (EOF) (reading and writing).

All these options have the same behavior as the corresponding fopen() options, except that w, wb, w+, wb+ and w+b do not truncate the file.

The file position indicator of the new stream is the file offset associated with the file descriptor. The error indicator and end of file (EOF) indicator for the stream are cleared.

Returned value

If successful, fdopen() returns a FILE pointer to the control block for the new stream.

If unsuccessful, fdopen() returns NULL and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EINVAL
The specified mode is incorrect or does not match the mode of the open file descriptor.

Example

CELEBF08

```
/* CELEBF08

   This example associates stream with the file descriptor fd which is
   open for the file fdopen.file.
   The association is made in write mode.

 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>

main() {
  char fn[]="fdopen.file";
  FILE *stream;
  int  fd;
  if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    if ((stream = fdopen(fd, "w")) == NULL) {
      perror("fdopen() error");
      close(fd);
    }
    else {
      fputs("This is a test", stream);
      fclose(stream);
    }}}
```

feclearexcept() — Clear the floating-point exceptions

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feclearexcept (int excepts);
```

General description

feclearexcept() clears the supported floating-point exceptions represented by *excepts*.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
feclearexcept		X

Returned value

If successful, feclearexcept() returns 0 if the argument passed is 0 or if all the exceptions are successfully cleared.

Related information

-

fe_dec_getround() — Get the current rounding mode

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <fenv.h>

int fe_dec_getround(void);
```

General description

The fe_dec_getround function gets the current rounding mode for decimal floating-point operations.

The following rounding modes are defined for decimal floating-point, and are located in fenv.h:

FE_DEC_DOWNWARD
rounds towards minus infinity

FE_DEC_TONEAREST
rounds to nearest

FE_DEC_TOWARDZERO
rounds toward zero

FE_DEC_UPWARD
rounds toward plus infinity

FE_DEC_TONEARESTFROMZERO
rounds to nearest, ties away from zero

_FE_DEC_AWAYFROMZERO
rounds away from zero

_FE_DEC_TONEARESTTOWARDZERO
rounds to nearest, ties toward zero

_FE_DEC_PREPAREFORSHORTER
rounds to prepare for shorter precision

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, returns the value of the current rounding mode for decimal floating-point operations.

If there is no such rounding mode or the current rounding mode can't be determined returns -1.

Example

```
/* CELEBF77

   sample program that issues fe_dec_getround()/setround()

   This program calls fe_dec_getround() to get the DFP rounding mode.
   Then it will compare the returned value with FE_DEC_TONEAREST
   rounding mode. If not the same, it will call fe_dec_setround() to
   set the rounding mode to the desired value FE_DEC_TONEAREST.
 */

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <stdlib.h>
#include <stdio.h>

int main(int argc, char *argv[]){
   int r;
   if ((r = fe_dec_getround()) == -1){
     perror("fe_dec_getround");
     exit (-1);
   }
   printf("The Decimal floating point rounding mode is %d\n", r);
   if (r != FE_DEC_TONEAREST){
     printf("The DFP rounding mode is not FE_DEC_TONEAREST.\n");
     if (fe_dec_setround(FE_DEC_TONEAREST) == -1){
       perror("fe_dec_setround");
       exit (-1);
     }
   }
   printf("The DFP rounding mode has been set to FE_DEC_TONEAREST.\n");
   return 0;
}
```

Related information

- “fenv.h” on page 28
- “fe_dec_setround() — Set the current rounding mode”

fe_dec_setround() — Set the current rounding mode

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <fenv.h>

int fe_dec_setround(int round);
```

General description

The fe_dec_setround function establishes the rounding mode for decimal floating-point operations represented by its argument *round*. If the argument is not equal to the value of a valid rounding mode, the rounding mode is not changed.

The following rouding modes are defined for decimal floating-point, and are located in fenv.h:

FE_DEC_DOWNWARD
rounds towards minus infinity

FE_DEC_TONEAREST
rounds to nearest

FE_DEC_TOWARDZERO
rounds toward zero

FE_DEC_UPWARD
rounds toward plus infinity

FE_DEC_TONEARESTFROMZERO
rounds to nearest, ties away from zero

_FE_DEC_AWAYFROMZERO
rounds away from zero

_FE_DEC_TONEARESTTOWARDZERO
rounds to nearest, ties toward zero

_FE_DEC_PREPAREFORSHORTER
rounds to prepare for shorter precision

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, returns a zero value.

If the argument is not equal to a valid rounding mode, returns -1. The following errnos are defined:

Error Code
Definition

EINVAL
The rounding mode specified is not a valid Decimal Floating Point rounding mode.

EMVSERR
The function was unable to set the specified rounding mode due to an internal error.

Example

```
/* CELEBF77

   sample program that issues fe_dec_getround()/setround()

   This program calls fe_dec_getround() to get the DFP rounding mode.
   Then it will compare the returned value with FE_DEC_TONEAREST
   rounding mode. If not the same, it will call fe_dec_setround() to
   set the rounding mode to the desired value FE_DEC_TONEAREST.
 */

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <stdlib.h>
```

```
#include <stdio.h>

int main(int argc, char *argv[]){
   int r;
   if ((r = fe_dec_getround()) == -1){
     perror("fe_dec_getround");
     exit (-1);
   }
   printf("The Decimal floating point rounding mode is %d\n", r);
   if (r != FE_DEC_TONEAREST){
     printf("The DFP rounding mode is not FE_DEC_TONEAREST.\n");
     if (fe_dec_setround(FE_DEC_TONEAREST) == -1){
       perror("fe_dec_setround");
       exit (-1);
     }
   }
   printf("The DFP rounding mode has been set to FE_DEC_TONEAREST.\n");
   return 0;
}
```

fegetenv() — Store the current floating-point environment

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fegetenv(fenv_t *envp);
```

General description

fegetenv() stores the current floating-point environment in the object pointed to by *envp*.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
fegetenv		X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. If the hardware has the Decimal Floating-Point Facility installed, this function will store the decimal floating-point rounding mode.

3. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, fegetenv() returns 0 upon completion of the store.

Related information

- “fenv.h” on page 28

fegetexceptflag() — Store the states of floating-point status flags

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fegetexceptflag(fexcept_t *flagp, int excepts);
```

General description

fegetexceptflag() stores an implementation defined representation of the states of floating-point status flags indicated by *excepts* in the object pointed to by *flagp*.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
fegetexceptflag		X

Returned value

If successful, fegetexceptflag() returns 0 upon completion of the store.

Related information

-

fegetround() — Get the current rounding mode

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fegetround(void);
```

General description

fegetround() gets the current rounding mode.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
fegetround		X

Note: This function will not return or update decimal floating-point rounding mode bits. The *fe_dec_getround()* and *fe_dec_setround()* functions can be used to get and set the current rounding mode for decimal floating-point operations.

Returned value

If successful, fegetround() returns the value of the rounding mode macro representing the current rounding mode. Otherwise, returns a negative value if there is no such rounding mode macro or the current rounding mode is not determinable.

Related information

- “fe_dec_getround() — Get the current rounding mode” on page 494
- “fe_dec_setround() — Set the current rounding mode” on page 495

feholdexcept() — Save the current floating-point environment

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feholdexcept(fenv_t *envp);
```

General description

feholdexcept() saves the current floating-point environment in the object pointed to by *envp*, clears the floating-point status flags, and then installs a non-stop (continue on floating-point exceptions) mode, if available, for all floating-point exceptions.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
feholdexcept		X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. If the hardware has the Decimal Floating-Point Facility installed, this function will save the decimal floating-point rounding mode.
3. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, feholdexcept() returns 0 when the non-stop floating-point exception handling was successfully installed.

Related information

- "fenv.h" on page 28
- "fegetenv() — Store the current floating-point environment" on page 497
- "fesetenv() — Set the floating-point environment" on page 504

feof() — Test end of file (EOF) indicator

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

int feof(FILE *stream);
```

```
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int feof_unlocked (FILE *stream);
```

General description

Indicates whether the EOF flag is set for the given stream pointed to by *stream*.

The EOF flag is set when the user attempts to read past the EOF. Thus, a read of the last character in the file does not turn the flag on. A subsequent read attempt reaches the EOF.

For HFS files, a simultaneous reader cannot see the extensions automatically. Use clearerr() is required to reset the EOF flag.

If the file has a simultaneous writer that extends the file, the flag can be turned on by the reader before the file is extended. After the extension becomes visible to the reader, a subsequent read will get the new data and set the flag appropriately (see fflush()). For example, if the read does not read past the EOF, the flag is turned off. If a file does not have a simultaneous writer that is extending the file, it is not possible to read past EOF.

A successful repositioning in a file (with fsetpos(), rewind(), fseek()) or a call to clearerr() resets the EOF flag. For a terminal file, when the EOF flag is set, subsequent reads will continue to deliver no data until the EOF flag is cleared. This can be accomplished by calling clearerr() or rewind().

The terminal can only read past the EOF after the rewind() function or the clearerr() function is called. The EOF flag is cleared by calling rewind(), fsetpos(), fseek(), or clearerr() for this stream.

feof_unlocked() is functionally equivalent to feof() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If and only if the EOF flag is set for *stream*, feof() returns nonzero.

Otherwise, feof() returns 0.

Example

CELEBF09

```
/* CELEBF09

   This example scans the input stream until it reads an EOF character.

 */
#include <stdio.h>
#include <stdlib.h>
```

```
main() {

      FILE *stream;
      int rc;
      stream = fopen("myfile.dat","r");

/* myfile.dat contains 3 characters "abc" */
      while (1) {
         rc = fgetc(stream);
         if (rc == EOF) {
            if (feof(stream)) {
               printf("at EOF\n");
               break;
            }
            else {
               printf("error\n");
               break;
            }
         }
         else
            printf("read %c\n",rc);
      }
}
```

Output

```
read a
read b
read c
at EOF
```

Related information

- “stdio.h” on page 68
- “clearerr() — Reset error and end of file (EOF)” on page 284

feraiseexcept() — Raise the supported floating-point exceptions

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feraiseexcept(int excepts);
```

General description

feraiseexcept() raises the supported floating-point exceptions represented by *excepts*. The order in which these floating-point exceptions are raised is unspecified.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
feraiseexcept		X

Returned value

If successful, feraiseexcept() returns 0 if the argument passed is 0 or if all the exceptions are successfully raised.

Related information

-

ferror() — Test for read and write errors

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

int ferror(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int ferror_unlocked (FILE *stream);
```

General description

Tests for an error in reading from or writing to the specified *stream*. If an error occurs, the error indicator for the *stream* remains set until you close the *stream*, call rewind(), or call clearerr().

If a non-valid parameter is given to an I/O function, z/OS XL C/C++ does not turn the error flag on. This case differs from one where parameters are not valid in context with one another.

ferror_unlocked() is functionally equivalent to ferror() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, ferror() returns a nonzero value to indicate an error for the stream pointed to by *stream*.

If unsuccessful, ferror() returns 0.

Example

CELEBF10

```
/* CELEBF10

   This example puts data out to a stream and then checks that
   a write error has not occurred.

 */
#include <stdio.h>

int main(void)
{
   FILE *stream;
   char *string = "Important information";
   stream = fopen("myfile.dat","w");

   fprintf(stream, "%s\n", string);
   if (ferror(stream))
   {
      printf("write error\n");
      clearerr(stream);
   }
   if (fclose(stream))
      printf("fclose error\n");
}
```

Related information

- “stdio.h” on page 68
- “clearerr() — Reset error and end of file (EOF)” on page 284

fesetenv() — Set the floating-point environment

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8pd

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fesetenv(const fenv_t *envp);
```

General description

fesetenv() establishes the floating-point environment represented by the object pointed to by *envp*. The argument *envp* points to an object set by a call to fegetenv() or feholdexcept(), or equal to a floating-point environment macro. fesetenv() merely installs the state of the floating-point status flags represented through *envp* and does not raise these floating-point exceptions.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	**Hex**	**IEEE**
fesetenv		X

Notes:

1. If the hardware has the Decimal Floating-Point Facility installed, this function can be used to set the decimal floating-point rounding mode.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, fesetenv() returns 0 if the settings are restored.

If unsuccessful, fesetenv() returns -1 and sets one of the following errno values:

Error Code
Description

EINVAL
The rounding mode specified is not a valid Decimal Floating Point rounding mode.

EMVSERR
The function was unable to set the specified rounding mode due to an internal error.

Related information

- "fenv.h" on page 28
- "fegetenv() — Store the current floating-point environment" on page 497
- "feholdexcept() — Save the current floating-point environment" on page 499

fesetexceptflag() — Set the floating-point status flags

Standards

Standards / Extensions	**C or C++**	**Dependencies**
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fesetexceptflag(const fexcept_t *flagp, int excepts);
```

General description

fesetexceptflag() sets the floating-point status flags indicated by *excepts* to the states stored in the object pointed to by *flagp*. The value of *flagp* should be set by fegetexceptflag(), whose second argument represents the floating-point exceptions indicated by the argument *excepts*. This function does not raise floating-point exceptions, but only sets the state of the flags.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
fesetexceptflag		X

Returned value

If successful, fesetexceptflag() returns 0 if *excepts* is 0 or if all selected exceptions are successfully set.

Related information

-

fesetround() — Set the current rounding mode

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fesetround(int round);
```

General description

fesetround() establishes the rounding mode represented by *round*. If the argument is not equal to the value of a rounding mode macro, the rounding mode is not changed.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
fesetround		X

Note: This function will not return or update decimal floating-point rounding mode bits. The *fe_dec_getround()* and *fe_dec_setround()* functions can be used to get and set the current rounding mode for decimal floating-point operations.

Returned value

If successful, fesetround() returns 0 when *round* is set to a rounding mode.

- "fe_dec_setround() — Set the current rounding mode" on page 495

fetch() — Get a load module

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	C	

Format

```
#include <stdlib.h>

void (*fetch(const char *name))();
```

General description

Dynamically loads the load module specified by *name* into memory. The load module can then be invoked from a z/OS XL C program. The name or the alias by which the fetchable load module is identified in the load module library must appear in a fetch() library function call.

To avoid infringing on the user's name space, this nonstandard function has two names. One name, the external entry point name, is prefixed with two underscore characters, and the other name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters __fetch()) or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED), any relevant information in the header is also exposed.

You cannot fetch a module that contains a main(). If you do, fetch() will not return a usable pointer. Use of the pointer will result in undefined behavior. To call these types of modules, use the system() library function. Alternatively, when creating the module, you can reset the entry point so that the linkage is provided by z/OS XL C.

When non-reentrant modules have been fetched multiple times, you should release them in the reverse order; otherwise the load modules may not be deleted immediately.

You can fetch modules written in C and C++. For C modules, the source of the fetched module must, in general, contain `#pragma linkage(..., fetchable)` (the exception is described below). To fetch a C++ module, the routine must be declared extern "C", and must be declared in a **`#pragma linkage`**`(..., fetchable)` directive. See also "fetchep() — Share writable static" on page 519 for more information about the need for `#pragma linkage`.

Note: For C or C++ modules that are compiled with the XPLINK option and are to be fetched, #pragma linkage(..., fetchable) is required. They cannot use the technique of resetting the entry point. If an application tries to fetch() an XPLINK routine that did not specify FETCHABLE, then an error will be returned.

XPLINK programs can fetch non-XPLINK programs, and vice versa. The function descriptor returned by fetch() will contain glue code to support a stack swap and parameter list conversion if necessary. Calls to a fetched routine that do not cross an XPLINK linkage boundary will not incur any glue code overhead.

If the fetched module is compiled as a DLL it can import variables and functions from other DLL modules, but it cannot export variables or functions.

Nested fetching is supported. That is, a fetched module can also invoke the fetch() library function to dynamically load a separate fetchable module.

Multiple fetching is also supported. Fetching a module more than once will result in separate fetch pointers. If the module is marked "reentrant", multiple fetches will not reload the module into storage. Under MVS, you can place the reentrant module into the Extended Link Pack Area or the Link Pack Area (ELPA/LPA) to save time on the load. Although multiple copies of the reentrant module are not brought into storage, each fetch returns a separate pointer. If a module is not reentrant, multiple fetches cause multiple loads into storage. Be aware that if you fetch() a non-reentrant module multiple times, the module may not get deleted by release() until all fetch instances have been released. Also, you should keep in mind that multiple loads of a non-reentrant module can be costly in terms of storage.

Writable statics are, in general, process-scoped. The exception is that, when a thread calls a fetched module, the writable statics are changed for that thread only, that is, thread-scoped.

Under MVS, fetchable (or dynamically loaded) modules must be link-edited and accessible using the standard system search. MVS supports fetching of non-reentrant, serially reusable, and reentrant modules.

Under POSIX, however, the fetchable, dynamically loaded modules cannot be in the HFS (Hierarchical File System). Note also, that the POSIX and XPG4 external variables are propagated. Refer to *z/OS XL C/C++ Programming Guide* for more information on external variables.

Unless your program is naturally reentrant, each reentrant module has a different copy of writable static. Follow these steps to allow the fetching of your reentrant module that has writable static:

1. Compile the module to be fetched with the RENT compile-time option.
2. Using the object module created in step 1, generate a fetchable member. You must specify the entry point as the function you are fetching unless you have included a **`#pragma linkage(...,`** `FETCHABLE)` directive.

See Figure 2 on page 509 for the program flow of a fetchable module. (FECB refers to a Fetch Control Block, which is a z/OS XL C internal control block used by fetch().)

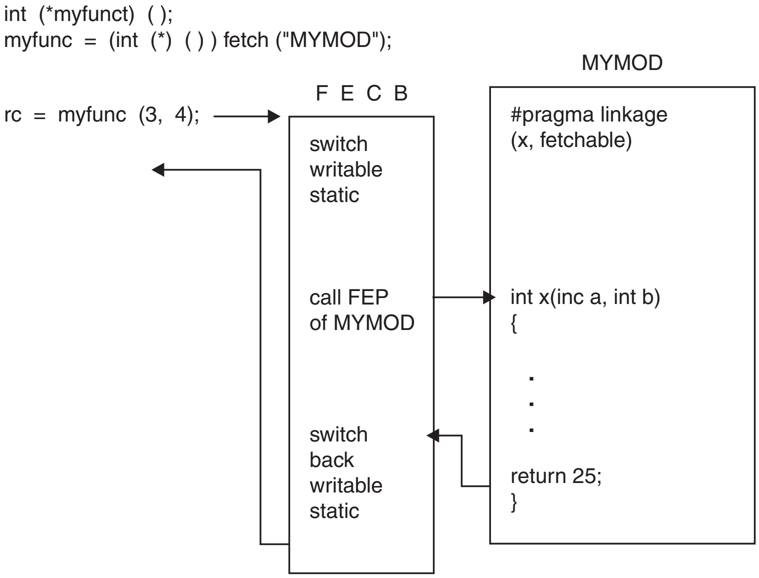

Figure 2. Program Flow of a Fetchable Module

To dynamically fetch a set of functions with shared writable static, you can use the library function fetchep(). See “fetchep() — Share writable static” on page 519 for more details.

Both the module being fetched and the module invoking the fetch() library function can be reentrant.

You can fetch modules without specifying the directive, `#pragma linkage(..., FETCHABLE)`, in the fetched module. If you do, then using the fetch pointer will result in calling the entry point for that module. When you link the module, you must reset the entry point. In addition, you cannot have any writable static.

It follows that fetching a reentrant C module containing writable statics requires that you use the `#pragma linkage(... FETCHABLE)` preprocessor directive in the fetched module.

If the entry point linkage is not a C linkage, you must use a `pragma linkage` with a function pointer defined by a *typedef*. The following sample excerpt would set up a COBOL linkage for a COBOL routine.

```
typedef int COBOL_FUNC ();
#pragma linkage (COBOL_FUNC, COBOL)
⋮
COBOL_FUNC * fetch_ptr;
fetch_ptr = (COBOL_FUNC *) fetch(module);    /* loads fetched module */
fetch_ptr(args);         /* sets up the proper linkage for the call */
```

Once the module is fetched, calling the fetched function is similar to making an interlanguage call.

fetch() also supports `AMODE` switching: when the function call is made, `AMODE` will be switched; upon return, the `AMODE` will be restored. Beware of calling fetched modules with `AMODE=24` that try to access variables or the library above the line.

Notes:

1. You cannot call functions through a function pointer that crosses load module boundaries, except through fetchep(). (See “fetchep() — Share writable static” on page 519 for more information.) For example, you cannot pass the address of a function to a fetched routine and invoke it from the fetched routine because the z/OS C writable static will not be swapped.
2. If you need to access code that has to run in a restricted addressing mode (such as a AMODE 24), you can package the code into a module to be fetched. The module can then be linked using the restricted addressing mode, but fetched from a program with an unrestricted addressing mode.
3. A program that invokes fetch() many times without releasing all of the load modules may run out of memory.

Link considerations: When linking the function to be fetched, you must link in the necessary libraries and specify the entry point as the function you are fetching unless you have included this directive: `#pragma linkage(..., FETCHABLE)`.

When linking the main() z/OS C function, you must specify the necessary libraries to use the functions you are fetching. For example, if you are fetching a COBOL function, specify the COBOL library. This requirement does *not* apply to Language Environment.

When running main(), specify the runtime libraries you will need for main(), as well as the functions you will fetch. This requirement does *not* apply to Language Environment.

Special behavior for C++: A z/OS XL C++ program cannot call fetch(). If you attempt to call fetch() from a z/OS XL C++ program, the compiler will issue an error message. There are three alternatives to fetch() under z/OS XL C++:

- You can replace fetch() with DLL (dynamic link library) calls.
- You can provide a C DLL module to fetch modules, as shown in examples CELEBF52 and CELEBF53. See “Examples.”
- A z/OS XL C++ program may statically call a z/OS XL C function that, in turn, fetches another module.

Returned value

If successful, fetch() returns a pointer to a stub that will call the entry point to the fetched load module.

If the load fails, fetch() returns NULL and may set errno to one of the following values:

Error Code
  Definition

ELEFENCE
  The DLL contains a member language not supported on this version of the operating system.

Examples

Examples of using the fetch() function with C: The following example demonstrates how to compile, link, and run a program that fetches a function in another object module that contains the directive:
`pragma linkage(...., FETCHABLE)`.

Begin with the main program.

```
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)();  /* pointer to a function returning an int */

int main(void)
{
    int result;
    funcPtr add;

    printf("fetch module\n");
    add = (funcPtr) fetch("f1a");            /* load module F1A      */

    if (add == NULL) {
        printf("ERROR: fetch failed\n");
    }
    else {
        printf("execute fetched module\n");
        result = (*add)(1,2);                /* execute module F1A   */

        printf("1 + 2 == %d\n", result);
    }
}
```

Then the fetched function:

```
#pragma linkage(func1, fetchable)

int func1(int a, int b)
{
   printf("in fetched module\n");

   return(a+b);
}
```

Next, JCL to compile, link, and run under MVS:

```
>
//F1A      EXEC EDCC,INFILE='userid.TEST.SOURCE(F1A)'
//         OUTFILE='userid.TEST.OBJ(F1A),DISP=SHR',
//         CPARM='NOSEQ,NOMARGIN,RENT'
//F1B      EXEC EDCPL,INFILE='userid.TEST.OBJ(F1A)'
//         OUTFILE='userid.TEST.LOAD(F1A),DISP=SHR'
//F1       EXEC EDCCLG,INFILE='userid.TEST.SOURCE(F1)'
//GO.STEPLIB DD
//           DD  DSN=userid.TEST.LOAD,DISP=SHR
```

This example demonstrates the use of fetch() with COBOL and how to compile, link, and run the program.

```
/* cob1 */
#include <stdlib.h>
#include <stdio.h>

typedef void funcV();           /* function returning void            */
#pragma linkage(funcV, COBOL)   /* establish Cobol linkage            */

int main(void)
{
    int var1 = 1;
    int var2 = 2;
    funcV *add;

    printf("fetch module\n");
    add = (funcV *) fetch("cob1a");           /* load module COB1A    */
    if (add == NULL)
    {
        printf("ERROR: fetch failed\n");
    }
    else
    {
        printf("execute fetched module\n");
        (*add)(&var1, &var2);                 /* execute module COB1A */

        printf("1 + 2 == %d\n", var1);
    }
}
```

Here is the fetched COBOL subroutine COB1A.

```
 IDENTIFICATION DIVISION.
 PROGRAM-ID.  COB1A.
****************************************************************
*   This subroutine receives 2 integer parameters.             *
*   The first is added to the second and the result is stored  *
*   back into the first.                                       *
****************************************************************
 ENVIRONMENT DIVISION.
 DATA DIVISION.

 WORKING-STORAGE SECTION.

 LINKAGE SECTION.
 01  VAR1                    PIC S9(9) COMP.

//GO.STEPLIB DD
//           DD DSNAME=userid.TEST.LOAD,DISP=SHR
```

Examples of alternatives to fetch() under C++: This example shows how to use DLL as an alternative to fetch(). Here, myfunc() is the function to be dynamically loaded using DLL, and main() invokes DLL.

CELEBF52

```
// CELEBF52-part 1 of 2-other file is CELEBF53.

// This example shows how to use DLL as an alternative to fetch().

// C++ program that invokes myfunc using DLL

#include <stdlib.h>
#include <stdio.h>
#include <dll.h>

extern "C" {           // needed to indicate C linkage
  typedef int (*funcPtr)(); // pointer to a function returning an int
}

int main (void)
{
  dllhandle *dllh;
  funcPtr   fptr;

  if ((dllh = dllload( "celebf53" )) == NULL) {
     perror( "failed to load celebf53" );
     exit( -1 );
  }
  if ((fptr = (funcPtr) dllqueryfn( dllh, "myfunc" )) == NULL) {
     perror( "failed to retrieve myfunc" );
     exit( -2 );
  }
  if ( fptr() != 0 ) {
     perror( "failed to execute myfunc" );
```

```
      exit( -3 );
   }
   if ( dllfree( dllh ) != 0 ) {
      perror( "failed to free celebf53" );
      exit( -4 );
   }
   return( 0 );
}
```

CELEBF53

```
/* CELEBF53-part 2 of 2-other file is CELEBF52.

   This example shows how to use DLL as an alternative to fetch().

 */

/*

  C function dynamically loaded using DLL

 */

#include <stdio.h>

int myfunc (void)
{
  printf( "Hello world\n" );
  return( 0 );
}
```

The following example shows how a C++ program can dynamically call a function in a C DLL module, to fetch other C modules.

CELEBF54

```
// CELEBF54-part 1 of 3-other files are CELEBF55, CELEBF56.
// This example shows how a C++ program can dynamically call a function
// in a C DLL module, to fetch other C modules

// C++ program that dynamically calls a function in a C DLL module

#include <stdio.h>
#include <stdlib.h>
#include <dll.h>
#include <iostream.h>

extern "C" {           // needed to indicate C linkage
  typedef int (*funcPtr)(); // pointer to a function returning an int
}

int main (void)
{
  dllhandle *dllh;
  funcPtr   fptr;

  if ((dllh = dllload( "mydll" )) == NULL) {
     perror( "failed to load mydll" );
     exit( -1 );
  }
  if ((fptr = (funcPtr) dllqueryfn( dllh, "fwrap" )) == NULL) {
     perror( "failed to retrieve fwrap" );
     exit( -2 );
  }
  if ( fptr() != 0 ) {
     perror( "failed to execute fwrap" );
     exit( -3 );
  }
  if ( dllfree( dllh ) != 0 ) {
     perror( "failed to free mydll" );
     exit( -4 );
  }
  return( 0 );
}
```

CELEBF55

```
/* CELEBF55-part 2 of 3-other files are CELEBF54, CELEBF56.
   This example shows how a C++ program can dynamically call a function
   in a C DLL module, to fetch other C modules

   fwrap function used in a DLL module-it fetches mymod, which
   contains myfunc
 */
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)();   /* pointer to a function returning an int */

int fwrap (void)
{
  funcPtr   fptr;

  if ((fptr = (funcPtr) fetch( "mymod" )) == NULL) {
     perror( "failed to fetch mymod" );
     return( -1 );
  }
  else
     return(fptr());
}
```

CELEBF56

```
/* CELEBF56-part 3 of 3-other files are CELEBF54, CELEBF55.
   This example shows how a C++ program can dynamically call a function
   in a C DLL module, to fetch other C modules
 */

/*    C function to be fetched   */

#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int myfunc (void)
{
  printf( "in fetched module\n" );
  return( 0 );
}
```

The following example shows how to statically call a C function that in turn fetches other functions. Here, myfunc() is the function to be fetched, fetcher() is a C function that fetches myfunc(), and main() is a function that statically calls fetcher().

CELEBF57

```
// CELEBF57-part 1 of 3-other files are CELEBF58, CELEBF59.
// This example shows how to statically call a C function that
// fetches other functions.

// C++ statically calling a C program that uses fetch()

#include <iostream.h>
```

```
extern "C" {          //  needed to indicate C linkage
  int fetcher (void);
}

int main (void)
{
  cout << "The fetcher says: ";
  fetcher();
  cout << "and returns";
  return( 0 );
}
```

CELEBF58

```
/* CELEBF58-part 2 of 3-other files are CELEBF57, CELEBF59.
   This example shows how to statically call a C function that fetches
   other functions.
 */

/*
   C function that fetches mymod which contains myfunc
 */
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)();   /* pointer to a function returning an int */

int fetcher (void)
{
  funcPtr fptr;

  if ((fptr = (funcPtr) fetch( "mymod" )) == NULL) {
     perror( "failed to fetch mymod" );
     return( -1 );
  }
  else {
     fptr();               /* invoke fetched function */
     return( 0 );
  }
}
```

CELEBF59

```
/* CELEBF59-part 3 of 3-other files are CELEBF57, CELEBF58.
   This example shows how to statically call a C function that fetches
   other functions.
 */

/*    C function to be fetched    */

#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int myfunc (void)
{
  printf( "Hello world " );
  return( 0 );
}
```

Although fetching and using DLL are functionally comparable, there is one subtle difference. Fresh copies of static and global variables are allocated each time a module is fetched, but not each time a DLL load of the same module is done.

The following example shows that, when a module is fetched multiple times, fresh copies of static and global variables are allocated.

CELEBF60

```
/* CELEBF60-part 1 of 2-other file is CELEBF61.
   This example shows how copies of variables are allocated when multiple
   fetches are done.
 */

/*
   C program fetching mymod multiple times--mymod contains myfunc.
 */
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)(int); /*pointer to a function returning an int*/

int main (void)
{
  funcPtr fptr1, fptr2;

  if ((fptr1 = (funcPtr) fetch( "mymod" )) == NULL) {
     perror( "failed to fetch mymod" );
     return( -1 );
  }
  if ( fptr1(100) != 0 ) {
     perror( "failed to execute myfunc" );
     exit( -2 );
  }
  if ((fptr2 = (funcPtr) fetch( "mymod" )) == NULL) {
     perror( "failed to fetch mymod" );
     return( -3 );
  }
  if ( fptr2(100) != 0 ) {
     perror( "failed to execute myfunc" );
     exit( -4 );
  }
  return( 0 );
}
```

CELEBF61

```
/* CELEBF61-part 2 of 2-other file is CELEBF60.
   This example shows how copies of variables are allocated when multiple
   fetches are done.
 */

/*     C module mymod    */
#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int globvar = 5;

int myfunc (int x)
{
  globvar += x;
  printf( "%d\n", globvar );
  return( 0 );
}
```

Running this example would produce the following results:

```
105
105
```

The following example shows that fresh copies of static and global variables are not allocated for multiple DLL loads of the same module.

CELEBF62

```
// CELEBF62-part 1 of 2-other file is CELEBF63.
// This example shows how copies of variables are allocated when
// multiple DLL loads are done.

// C++ program doing multiple DLL loads of the same module

#include <stdlib.h>
#include <stdio.h>
#include <dll.h>

extern "C" {                    //needed to indicate C linkage
  typedef int (*funcPtr)(int); //pointer to a function returning an int
}

int main (void)
{
  dllhandle *dllh1, *dllh2;
  funcPtr fptr;

  if ((dllh1 = dllload( "mydll" )) == NULL) {
     perror( "failed to load mydll" );
     exit( -1 );
  }
  if ((fptr = (funcPtr) dllqueryfn( dllh1, "myfunc" )) == NULL) {
     perror( "failed to retrieve myfunc" );
     exit( -2 );
  }
  if ( fptr(100) != 0 ) {
     perror( "failed to execute myfunc" );
     exit( -3 );
  }
  if ((dllh2 = dllload( "mydll" )) == NULL) {
     perror( "failed to load mydll" );
     exit( -4 );
  }
  if ((fptr = (funcPtr) dllqueryfn( dllh2, "myfunc" )) == NULL) {
     perror( "failed to retrieve myfunc" );
     exit( -5 );
  }
  if ( fptr(100) != 0 ) {
     perror( "failed to execute myfunc" );
     exit( -6 );
  }
  if ( dllfree( dllh1 ) != 0 ) {
     perror( "failed to free mydll" );
     exit( -7 );
  }
  return( 0 );
}
```

CELEBF63

```
/* CELEBF63-part 2 of 2-other file is CELEBF62.
   This example shows how copies of variables are allocated when multiple
   DLL loads are done.
 */

/* C function invoked using DLL */

#include <stdio.h>
#include <stdlib.h>

int globvar = 5;
int myfunc (int);

int myfunc (int x)
{
  globvar += x;
  printf( "%d\n", globvar );
  return( 0 );
}
```

Running this example would produce the following results:

```
105
205
```

fetchep() — Share writable static

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	C only	

Format

```
#include <stdlib.h>

void ( *fetchep( void ( *entry_point)()))();
```

General description

Dynamically fetches a set of functions with shared writable static variables. fetchep() is used to register an entry point. It returns a pointer that may be passed across the fetch boundary and used as if it were the original entry point. Therefore, you can create more than one entry point from a fetched module. A call to the new entry point will use the same writable static as the original fetch pointer uses on each invocation.

fetchep() is called within a fetched module but not from the same level as the fetch() call. If fetchep() is called in the root program that is not a fetched module, fetchep() returns a fetch pointer that will use the root program's writable static (if any exists).

If the *entry_point* given as input to fetchep() is a function address external to the current module or is an non-valid function address, use of the resulting pointer returned from the call will result in undefined behavior.

If writable static is required, then this directive must be used:

```
#pragma linkage(entry_point, FETCHABLE)
```

In addition, the steps for fetching a reentrant module must be followed as described in "fetch() — Get a load module" on page 507. If writable static is *not* required, the C module using fetchep() need not contain the directive: #pragma linkage(..., FETCHABLE).

You can release the new fetch pointer without any effect on the original or any other fetch pointer created from the original fetch pointer. If the original fetched function is released, however, all the fetch pointers created using the fetchep() function will also be released. Trying to use a fetch pointer once it has been released or its origin has been released will result in undefined behavior.

To avoid infringing on the user's name space, this nonstandard function has two names. One name, the external entry point name, is prefixed with two underscore characters, and the other name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

Note: The external entry point name for fetchep() is __ftchep(), **NOT** __fetchep().

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters __ftchep(), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Examples

These examples and diagram demonstrate the program flow of a call to fetch() and subsequent calls to fetchep().

```
/* The module that calls fetch()    */
#include <stdlib.h>
typedef int (*FUNC_T)();

int main(void) {
FUNC_T (*myfunc)();
FUNC_T myfunc1;
FUNC_T myfunc2;
FUNC_T myfunc3;

myfunc = (FUNC_T (*)())fetch("MYMOD");
myfunc1 = myfunc(0);
myfunc2 = myfunc(1);
myfunc3 = myfunc(2);
}
```

```
/*
   The following code is the fetched module.
   Please see fetch() for information on how to compile and link the
   above.
 */

/*   inside MYMOD   */
#include <stdlib.h>
typedef int (*FUNC_T)();
int k;              /* global variable to share within MYMOD */
#pragma linkage(x, fetchable)
FUNC_T x(int a)
{
  switch(a)
    {
    case 0:
       return (FUNC_T)fetchep((void(*)())func1);
    case 1:
       return (FUNC_T)fetchep((void(*)())func2);
    case 2:
       return (FUNC_T)fetchep((void(*)())func3);
    }
{

int func1(int a, int b)
```

```
{
k = 6;
⋮
}

int func2(int a, int b)
{
k = 4;
⋮
}

int func3(int a, int b)
{
k = 5;
⋮
}
```

fetestexcept() — Test the floating-point status flags

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fetestexcept(int excepts);
```

General description

fetestexcept() determines which of a specified subset of floating-point exception flags are currently set. *excepts* specifies the floating-point status flags to be queried.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
fetestexcept		X

Returned value

If successful, fetestexcept() returns the value of the bitwise OR for the floating-point exception macros corresponding to the currently set floating-point exceptions included in *excepts*.

feupdateenv() — Save the currently raised floating-point exceptions

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feupdateenv(const fenv_t *envp);
```

General description

feupdateenv() saves the currently raised floating-point exceptions in its automatic storage, installs the floating-point environment represented by the object pointed to by *envp*, and then raises the saved floating-point exceptions. *envp* should point to an object set by feholdexcept() or fegetenv(), or equal a floating-point environment macro.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
feupdateenv		X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. If the hardware has the Decimal Floating-Point Facility installed, this function can update the decimal floating-point rounding mode.
3. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, feupdateenv() returns 0 if the settings have been restored.

If unsuccessful, feupdateenv() returns -1 and sets one of the following errno values:

Error Code
Description

EINVAL
The rounding mode specified is not a valid Decimal Floating Point rounding mode.

EMVSERR
The function was unable to set the specified rounding mode due to an internal error.

fflush() — Write buffer to file

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

int fflush(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fflush_unlocked(FILE *stream);
```

General description

Flushes the stream pointed to by *stream*. If *stream* is NULL, it flushes all open streams.

The fflush() function is affected by the ungetc() and ungetwc() functions. Calling these functions causes fflush() to back up the file position when characters are pushed back. For details, see the ungetc() and ungetwc() functions respectively. If desired, the _EDC_COMPAT environment variable can be set at open time such that fflush() discards any pushed-back characters and leaves the file position where it was when the first ungetc() or ungetwc() function call was issued.

If fflush() is used after ungetwc() has pushed a wide char on a text stream, the position will be backed up by one wide character from the position the file was at when the ungetwc() was issued. For a wide-oriented binary stream, the position will be backed up based on the number of bytes used to represent the wide char in the ungetc buffer. For this reason, attempting to use ungetwc() on a character when the destination is a binary wide-oriented stream that was never read in the first place results in undefined behavior for fflush(). Note that the _EDC_COMPAT environment variable also changes the behavior of fflush() after ungetwc(), and will cause any wide char pushed-back to be discarded and the position left at the point where the ungetwc() was issued. For details on the _EDC_COMPAT environment variable, see the “Environment Variables” in *z/OS XL C/C++ Programming Guide*.

If fflush() fails, the position is left at the point in the file where the first ungetc() or ungetwc() function call was issued. All pushed-back characters are discarded.

Note: The system automatically flushes buffers when you close the stream or when a program ends normally without closing the stream.

The buffering mode and the file type can have an effect on when output data is flushed. For more information, see “Buffering of C Streams” in *z/OS XL C/C++ Programming Guide*.

stream remains open after the fflush() call. Because a read operation cannot immediately follow or precede a write operation, the fflush() function can be used to allow exchange between these two modes. The fflush() function can also be used to refresh the buffer when working with a reader and a simultaneous writer/updater.

fflush_unlocked() is functionally equivalent to fflush() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

The fflush() function has no effect for files opened with `type=blocked`.

Returned value

If successful in flushing the buffer, fflush() returns 0.

If unsuccessful, fflush() returns EOF. When flushing all open files, a failure to flush any of the files causes EOF to be returned. However, flushing will continue on any other open files that can be flushed successfully.

Example

CELEBF15

```
/* CELEBF15

   This example flushes a stream buffer.
   It tests for the returned value of 0 to see if the flushing was
   successful.

 */
#include <stdio.h>

int retval;
int main(void)
{
   FILE *stream;
   stream = fopen("myfile.dat", "w");

   retval=fflush(stream);
   printf("return value=%i",retval);
}
```

ffs() — Find first set bit in an integer

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define  _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int ffs(int i);
```

General description

The ffs() function finds the first bit set (beginning with the least significant bit) and returns the index of that bit. Bits are numbered starting at one (the least significant bit).

Returned value

If successful, ffs() returns the index of the first bit set.

If *i* is 0, ffs() returns 0.

There are no errno values defined.

fgetc() — Read a character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

int fgetc(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fgetc_unlocked(FILE *stream);
```

General description

Reads a single-byte unsigned character from the input stream pointed to by *stream* at the current position, and increases the associated file pointer so that it points to the next character.

The fgetc() function is not supported for files opened with `type=record` or `type=blocked`.

fgetc() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fgetc_unlocked() is functionally equivalent to fgetc() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fgetc() returns the character read as an integer.

If unsuccessful, fgetc() returns EOF to indicate an error or an EOF condition. Use feof() or ferror() to determine whether the EOF value indicates an error or the end of the file.

Note: EOF is only reached when an attempt is made to read "past" the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBF16

```
/* CELEBF16

   This example gathers a line of input from a stream.
   It tests to see if the file can be opened.
   If the file cannot be opened &perror. is called.

 */
#include <stdio.h>
#define  MAX_LEN  80

int main(void)
{
   FILE *stream;
   char buffer[MAX_LEN + 1];
   int i, ch;

   if ((stream = fopen("myfile.dat","r")) != NULL) {
     for (i = 0; (i < (sizeof(buffer)-1) &&
           ((ch = fgetc(stream)) != EOF) && (ch != '\n')); i++)
        printf("character is %d\n",ch);
        buffer[i] = ch;

     buffer[i] = '\0';

     if (fclose(stream))
        perror("fclose error");
   }
   else
     perror("fopen error");
}
```

fgetpos() — Get file position

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

int fgetpos(FILE * __restrict__stream, fpos_t * __restrict__pos);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fgetpos_unlocked(FILE * __restrict__stream, fpos_t * __restrict__pos);
```

General description

The fgetpos() function stores the current value of the file pointer associated with *stream* into the object pointed to by *pos*. The value pointed to by *pos* can be used later in a call to fsetpos() to reposition the stream pointed to by *stream*.

Both the fgetpos() and fsetpos() function save state information for wide-oriented files. The value stored in *pos* is unspecified, and it is usable only by fsetpos().

The position returned by the fgetpos() function is affected by the ungetc() and ungetwc() functions. Each call to these functions causes the file position indicator to be backed up from the position where the ungetc() or ungetwc() function was issued. For details on how the ungetc() function affects the fgetpos() function behavior, see “ungetc() — Push character onto input stream” on page 1958. For details on how the ungetwc() function affects the fgetpos() function behavior for a wide-oriented stream, see “ungetwc() — Push a wide character onto a stream” on page 1961.

Multivolume data sets performance: Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftell() and fseek() functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: The fgetpos() function implicitly supports operating on large files. Defining the _LARGE_FILES feature test macro is not required to use this function on large files.

Usage notes

1. The _EDC_COMPAT environment variable can be set at open time such that the fgetpos() function will ignore any pushed-back characters. For further details on _EDC_COMPAT, see the environment variables topic in *z/OS XL C/C++ Programming Guide*.
2. The fgetpos_unlocked() function is functionally equivalent to the fgetpos() function with the exception that it is not threadsafe. The fgetpos() function can

safely be used in a multithreaded application if, and only if, iit is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() functions.

Returned value

If successful, the fgetpos() function returns 0.

If unsuccessful, the fgetpos() function returns nonzero and sets errno to nonzero.

Special behavior for XPG4.2: The fgetpos() function returns -1 and sets errno to ESPIPE if the underlying file type for the stream is a PIPE or a socket.

Example

CELEBF17

```
/* CELEBF17

   This example opens the file myfile.dat for reading.
   The current file pointer position is stored into the variable pos.

 */
#include <stdio.h>

int main(void)
{
   FILE *stream;
   int retcode;
   fpos_t pos;

   stream = fopen("myfile.dat", "rb");

   /* The value returned by fgetpos can be used by fsetpos()
      to set the file pointer if 'retcode' is 0            */

   if ((retcode = fgetpos(stream, &pos)) == 0)
      printf("Current position of file pointer found\n");
   fclose(stream);
}
```

fgets() — Read a string from a stream

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

char *fgets(char * __restrict__string, int n, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

char *fgets_unlocked(char * __restrict__string, int n, FILE * __restrict__stream);
```

General description

Reads bytes from a stream pointed to by *stream* into an array pointed to by *string*, starting at the position indicated by the file position indicator. Reading continues until the number of characters read is equal to *n*-1, or until a newline character (`\n`), or until the end of the stream, whichever comes first. The fgets() function stores the result in *string* and adds a NULL character (\0) to the end of the string. The *string* includes the newline character, if read.

The fgets() function is not supported for files opened with `type=record` or `type=blocked`.

fgets() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fgets_unlocked() is functionally equivalent to fgets() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fgets() returns a pointer to the *string* buffer.

If unsuccessful, fgets() returns NULL to indicate failure.

If *n* is less than or equal to 0, it indicates a domain error; errno is set to EDOM to indicate the cause of the failure.

When *n* equals 1, it indicates a valid result. It means that the string buffer has only room for the NULL terminator; nothing is physically read from the file. (Such an operation is still considered a read operation, so it cannot immediately follow a write operation unless there is an intervening flush or reposition operation first.)

If *n* is greater than 1, fgets() will only fail if an I/O error occurs or if EOF is reached, and no data is read from the file.

The ferror() and feof() functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read "past" the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

If EOF is reached after data has already been read into the string buffer, fgets() returns a pointer to the string buffer to indicate success. A subsequent call would result in NULL being returned since EOF would be reached without any data being read.

Example

CELEBF18

```
/* CELEBF18

   This example gets a line of input from a data stream.
   It reads no more than MAX_LEN - 1 characters, or up
   to a new-line character, from the stream.

 */
#include <stdio.h>
#define  MAX_LEN  100

int main(void)
{
   FILE *stream;
   char line[MAX_LEN], *result;

   stream = fopen("myfile.dat","r");

   if ((result = fgets(line,MAX_LEN,stream)) != NULL)
       printf("The string is %s\n", result);

   if (fclose(stream))
       printf("fclose error\n");
}
```

fgetwc() — Get next wide character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment XPG4 XPG4.2C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <wchar.h>

wint_t fgetwc(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t fgetwc_unlocked(FILE *stream);
```

General description

Obtains the next multibyte character from the input stream pointed to by *stream*, converts it to a wide character, and advances the associated file position indicator for the stream (if defined).

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with fgetwc() results in undefined behavior. This happens because fgetwc() processes a whole multibyte character and does not expect to be "within" such a character. In addition, fgetwc() expects state information to be set already. Because functions like fgetc() and fputc() do not obey such rules, their results fail to meet the assumptions made by fgetwc().

fgetwc() has the same restriction as any read operation for read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fgetwc_unlocked() is functionally equivalent to fgetwc() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fgetwc() returns the next wide character that corresponds to the multibyte character from the input stream pointed to by *stream*.

If the stream is at EOF, the EOF indicator for the stream is set and fgetwc() returns WEOF.

If a *read* error occurs, the error indicator for the stream is set and fgetwc() returns WEOF. If an *encoding* error occurs (an error converting the multibyte character into a wide character), the value of the macro EILSEQ (illegal sequence) is stored in errno and WEOF is returned.

The ferror() and feof() functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read "past" the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBF19

```
/* CELEBF19 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
   FILE    *stream;
   wint_t   wc;

   if ((stream = fopen("myfile.dat", "r")) == NULL) {
      printf("Unable to open file\n");
      exit(1);
   }

   errno = 0;
   while ((wc = fgetwc(stream)) != WEOF)
      printf("wc=0x%X\n", wc);

   if (errno == EILSEQ) {
      printf("An invalid wide character was encountered.\n");
      exit(1);
   }

   fclose(stream);
}
```

fgetws() — Get a wide-character string

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <wchar.h>

wchar_t *fgetws(wchar_t * __restrict__wcs, int n, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wchar_t *fgetws_unlocked(wchar_t * __restrict__wcs,
                         int n, FILE * __restrict__stream);
```

General description

Reads at most one less than the number of the wide characters specified by *n*, from the stream pointed to by *stream*, into the array pointed to by *wcs*. No additional wide characters are read after a newline wide character (which is retained) or after the EOF. A NULL wide character is written immediately after the last wide character read into the array.

The fgetws() function advances the file position unless there is an error, when the file position is undefined.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with fgetws() results in undefined behavior. This happens because fgetws() processes a whole multibyte character and does not expect to be "within" such a character. In addition, fgetws() expects state information to be set already. Because functions like fgetc() and fputc() do not obey such rules, their results fail to meet the assumptions made by fgetws().

fgetws() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fgetws_unlocked() is functionally equivalent to fgetws() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fgetws() returns the new value of *wcs*.

If EOF is encountered and no wide characters have been read into the array, the contents of the array remain unchanged and fgetws() returns a NULL pointer.

If a read error or an encoding error occurs during the operation, the array contents are indeterminate and fgetws() returns a NULL pointer. An *encoding* error is one that occurs when a wide character is converted to a multibyte character. If it occurs, errno is set to EILSEQ and fgetws() returns NULL.

If *n* is less than or equal to 0, it indicates a domain error; errno is set to EDOM to indicate the cause of the failure.

When *n* equals 1, it indicates a valid result. It means that the string buffer has only room for the NULL terminator; nothing is physically read from the file. (Such an operation is still considered a read operation, so it cannot immediately follow a write operation unless there is an intervening flush or reposition operation first.)

If *n* is greater than 1, fgets() will only fail if an I/O error occurs or if EOF is reached, and no data is read from the file. To find out which error has occurred, use either the feof() or the ferror() function. If EOF is reached after data has already been read into the string buffer, fgetws() returns a pointer to the string buffer to indicate success. A subsequent call would result in NULL being returned because EOF would be reached without any data being read.

The ferror() and feof() functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBF20

```
/* CELEBF20 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
   FILE    *stream;
   wchar_t  wcs[100];
   wchar_t  *ptr;

  if ((stream = fopen("myfile.dat", "r")) == NULL) {
      printf("Unable to open file\n");
      exit(1);
   }

   errno = 0;
   ptr = fgetws(wcs, 100, stream);

   if (ptr == NULL) {
      if (errno == EILSEQ) {
         printf("An invalid wide character was encountered.\n");
         exit(1);
      }
      else if (feof(stream))
         printf("end of file reached\n");
      else
         perror("read error");
   }

   printf("wcs=\"%ls\"\n", wcs);

   fclose(stream);
}
```

fileno() — Get the file descriptor from an open stream

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1a XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#define _POSIX_SOURCE
#include <stdio.h>

int fileno(const FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fileno_unlocked(const FILE *stream);
```

General description

Returns the file descriptor number associated with a specified z/OS XL C/C++ I/O stream. The argument *stream* points to a FILE structure controlling a z/OS XL C/C++ I/O stream.

The unistd.h header file defines the following macros, which are constants that map to the file descriptors of the standard streams:

STDIN_FILENO
Standard input, stdin (value 0)

STDOUT_FILENO
Standard output, stdout (value 1)

STDERR_FILENO
Standard error, stderr (value 2)

Note that stdin, stdout, and stderr are macros, not constants.

fileno_unlocked() is functionally equivalent to fileno() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fileno() returns the file descriptor number associated with an open HFS stream (that is, one opened with fopen() or freopen()). MVS data sets are not supported, so fileno() of an MVS data set returns -1.

If unsuccessful, fileno() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
One of the following error conditions exists:
- *stream* points to a closed stream
- *stream* is an incorrect *stream* pointer
- *stream* points to a stream associated with an MVS data set.

Example

CELEBF21

```
/* CELEBF21

   This example illustrates one use of fileno().

 */
#define _POSIX_SOURCE
#include <errno.h>
#include <stdio.h>

main() {
  FILE *stream;
  char hfs_file[]="./hfs_file", mvs_ds[]="//mvs.ds";

  printf("fileno(stdin) = %d\n", fileno(stdin));

  if ((stream = fopen(hfs_file, "w")) == NULL)
    perror("fopen() error for HFS file");
  else {
    printf("fileno() of the HFS file is %d\n", fileno(stream));
    fclose(stream);
    remove(hfs_file);
  }

  if ((stream = fopen(mvs_ds, "w")) == NULL)
    perror("fopen() error for MVS data set");
  else {
    errno = 0;
    printf("fileno() returned %d for MVS data set,\n",fileno(stream));
    printf(" errno=%s\n", strerror(errno));
    fclose(stream);
    remove(mvs_ds);
  }
}
```

Output

```
fileno(stdin) = 0
fileno() of the HFS file is 3
fileno() returned -1 for the MVS data set,
errno=Bad file descriptor
```

finite() — Determine the infinity classification of a floating-point number

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	OS/390 V2R6

Format

```
#define _AIX_COMPATIBILITY
#include <math.h>

int finite(x)
double x;
```

General description

The finite() function determines the infinity classification of floating-point number *x*.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

finite() returns nonzero if the *x* parameter is a finite number, that is, if *x* is not +-, INF, NaNQ, or NaNS.

finite() does not return errors or set bits in the floating-point exception status, even if a parameter is a NaNS.

Special behavior for hex: finite() always returns 1 when it is called from HFP mode.

Related information

__flbf() — Determine if a stream is line buffered

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	None

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __flbf(FILE *stream);
```

General description

The __flbf() function determines if the specified stream is line buffered.

Returned value

The __flbf() function returns nonzero if the stream is line buffered. Otherwise, the __flbf() function returns 0. If an error has occurred, __flbf() returns 0 and sets errno to nonzero.

An application wishing to check for error situations should set errno to 0, then call __flbf(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
Description

EBADF
The stream specified by *stream* is not valid.

Example

CELEBF84

```
/* CELEBF84

   This example flushes all the line-buffered files.

*/

#include <stdio.h>
#include <stdio_ext.h>
#include <string.h>

#define BUF_SIZE 128

int main(void)
{
   char lbuf[BUF_SIZE]; /* line buffer */
   char fbuf[BUF_SIZE]; /* full buffer */
   char *tagstr = "This file was modified!";
   FILE *lfp;
   FILE *ffp;

   lfp = fopen("newlfile.dat", "a+");
   if(lfp == NULL){
      perror("Open file failed!\n");
      return -1;
   }
   if(setvbuf(lfp, lbuf, _IOLBF, sizeof(lbuf)) != 0){ /* set lbuf to line-buffered */
      perror("Format line-buffered failed!\n");
      fclose(lfp);
      return -1;
   }

   if (__flbf(lfp)) printf("newlfile.dat is line-buffered\n");
   else printf("newlfile.dat is not line-buffered\n");

   if(fwrite(lfp,strlen(tagstr), 1, lfp) != 1){ /* write tag string to line buffer*/
      perror("Write line buffer failed!\n");
      fclose(lfp);
      return -1;
   }
   printf("Write to the line buffered file succeeded\n");

   ffp = fopen("newffile.dat", "a+");
   if(ffp == NULL){
      perror("Open file failed!\n");
      fclose(lfp);
      return -1;
   }
   if(setvbuf(ffp, fbuf, _IOFBF, sizeof(fbuf)) != 0){ /* set fbuf to full-buffered */
```

```
      perror("Format full-buffered failed!\n");
      fclose(ffp);
      return -1;
   }

   if (__flbf(ffp)) printf("newffile.dat is line-buffered\n");
   else printf("newffile.dat is not line-buffered\n");

   if(fwrite(tagstr, strlen(tagstr), 1, ffp) != 1){ /* write tag string to full buffer */
      perror("Write full buffer failed!\n");
      fclose(lfp);
      fclose(ffp);
      return -1;
   }
   printf("Write to the full buffered file succeeded\n");
   _flushlbf(); /* flush line buffered files */
   printf("Only line buffered files are flushed...\n");
   fclose(lfp);
   fclose(ffp);
   return 0;
}
```

Output

```
newlfile.dat is line-buffered
Write to the line buffered file succeeded
newffile.dat is not line-buffered
Write to the full buffered file succeeded
Only line buffered files are flushed...
```

Related information

fldata() — Retrieve file information

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>

int fldata(FILE *file, char *filename, fldata_t *info);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fldata_unlocked(FILE *file, char *filename, fldata_t *info);
```

General description

Retrieves information about an open stream pointed to by *file*. It returns the file name in *filename* and other information in the structure *info*. The file name returned in *filename* is the name specified in fopen() or freopen(). If the file is opened with a *ddname* (for example, `fopen("DD:A","w")`)), then the *filename* field will contain the *ddname* used to open the file, prefixed with `dd:`. If the file is a DASD data set or a memory file, the field `__dsname` contains the dsname. If the file is an HFS file, the field __dsname contains the path name. For all other files, it is NULL.

After a failure, the contents of the information structure are indeterminate.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

For full details about *filename* considerations, see one of the "Opening Files" section s in *z/OS XL C/C++ Programming Guide*.

If *fldata* is the first reference to a standard stream, a call to the fldata() function opens the stream.

See Table 23.

Note:

A file name of NULL indicates that no file name will be returned.

FILENAME_MAX is recommended for the size of the file name buffer.

The table "Elements Returned in fldata_t Data Structure" (below) describes the fields in the fldata_t data structure. For further details, see *z/OS XL C/C++ Programming Guide*.

fldata_unlocked() is functionally equivalent to fldata() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Special behavior for POSIX C: Under z/OS UNIX services, if there had been an exec to an application that invokes fldata(), the standard streams are opened at the time of the exec. Thus fldata() does not attempt to open them again.

Returned value

If successful, fldata() returns 0.

If unsuccessful, fldata() returns nonzero.

Table 23. Elements Returned in fldata_t Data Structure

Element	Data Type	General Description
__recfmF:1	unsigned int	Indicates whether it has fixed-length records.
__recfmV:1	unsigned int	Indicates whether it has variable-length records.
__recfmU:1	unsigned int	Indicates whether it has undefined-length records.
__recfmS:1	unsigned int	Indicates whether it has either standard (if fixed-length) or spanned (if variable-length) records.
__recfmBlk:1	unsigned int	Indicates whether it has blocked records.
__recfmASA:1	unsigned int	Indicates whether it has ASA print-control characters.

Table 23. Elements Returned in fldata_t Data Structure (continued)

Element	Data Type	General Description
__recfmM:1	unsigned int	Indicates whether it has machine print-control codes.
__dsorgPO:1	unsigned int	Indicates whether it is a partitioned data set.
__dsorgPDSmem:1	unsigned int	Indicates whether a file is a member.
__dsorgPDSdir:1	unsigned int	Indicates whether a file is a PDS or PDSE directory.
__dsorgPS:1	unsigned int	Indicates whether it is a sequential data set.
__dsorgConcat:1	unsigned int	Indicates whether it is a sequentially concatenated file.
__dsorgMem:1	unsigned int	Indicates whether it is a memory file.
__dsorgHiper:1	unsigned int	Indicates whether it is a memory file in hiperspace.
__dsorgTemp:1	unsigned int	Indicates whether it is a temporary file created by tmpfile().
__dsorgVSAM:1	unsigned int	Indicates whether it is a VSAM file.
__dsorgHFS:	unsigned int	Indicates whether it is an HFS file.
__openmode:2	unsigned int	Values are __TEXT, __BINARY, __RECORD, __BLOCKED.
__modeflag:4	unsigned int	Values are __APPEND, __READ, __UPDATE, __WRITE. These macros can be added together to determine the value; for example, a file opened with mode a+ will have the value __APPEND + __UPDATE.
__dsorgPDSE:1	unsigned int	Indicates whether a file is a PDSE.
__vsamRLS:3	unsigned int	Returned values are __NORLS, __RLS, __TVS.
__recfmB:1	unsigned int	Indicates whether it was allocated with blocked records
__reserve2:3	unsigned int	Reserved bits.
__device	char	Returned values are __DISK, __TERMINAL, __PRINTER, __TAPE, __TDQ, __DUMMY, __OTHER, __MEMORY, __MSGFILE, __HFS, __HIPERSPACE, __MSGRTN.
__blksize	unsigned long	Total block size of the file, including all control information needed in the block.
__maxreclen	unsigned long	Maximum length of the data in the record, including ASA control characters, if present.
__vsamtype	unsigned short	Returned values are __NOTVSAM, __ESDS, __KSDS, __RRDS, __ESDS_PATH, __KSDS_PATH. **Note:** Valid only if __dsorgVSAM is set.
__vsamkeylen	unsigned long	Length of VSAM key (if any). **Note:** Valid only if __dsorgVSAM is set.
__vsamRKP	unsigned long	Key position. **Note:** Valid only if __dsorgVSAM is set.

Table 23. Elements Returned in fldata_t Data Structure (continued)

Element	Data Type	General Description
__access_method	uint8_t	Identifies the access method used for the data set. Values include: __AM_UNSPEC __AM_BSAM __AM_QSAM **Note:** Valid only if __dsorgPS or __dsorgPO is set.
__noseek_to_seek	uint8_t	Identifies the reason noseek was changed to seek. Values include: __AM_BSAM_NOSWITCH __AM_BSAM_UPDATE __AM_BSAM_BSAMWRITE __AM_BSAM_FBS_APPEND __AM_BSAM_LRECLX __AM_BSAM_PARTITIONED_DIRECTORY __AM_BSAM_PARTITIONED_INDIRECT **Note:** Valid only if __dsorgPS or __dsorgPO is set.
__dsname	char *	The contents of this field is determined by the following: • If the file is a DASD data set, memory file, or an HFS file, then __dsname contains the real file name of file opened by ddname • If you open by ddname, and the ddname is a concatenation of PDS or PDSE data sets, then __dsname contains the data set name of the first PDS or PDSE. This is because your are only opening the directory of the first PDS or PDSE. • If you open by ddname(member) and the ddname is a concatenation of PDS or PDSE data sets, then __dsname contains the data set name of the first PDS or PDSE containing the member. Otherwise this field is NULL. The char *__dsname field is allocated internally by the library functions and must be saved before the next call to the fldata() function.
__reserve4	unsigned long	Reserved.

Note: The numeric values for the macro names can be found in stdio.h. The meaning of the __noseek_to_seek values are described in topic about using the __amrc structure in *z/OS XL C/C++ Programming Guide*.

Example

```
#include <stdio.h>

int main(void)
{
    FILE *stream;
    char filename[100];
    fldata_t fileinfo;
    int rc;

    stream = fopen("myfile.dat","rb+");
⋮
    rc = fldata(stream, filename, &fileinfo);
    if (rc != 0)
       printf("fldata failed\n");
    else
       printf("filename is %s\n",filename);
}
```

flocate() — Locate a VSAM record

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>

int flocate(FILE *stream, const void *key, size_t key_len, int options);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int flocate_unlocked(FILE *stream, const void *key, size_t key_len, int options);
```

General description

Moves the VSAM file position indicator associated with the stream pointed to by *stream*, according to the rest of the arguments specified.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

key points to a key used for positioning.

key_len specifies the length of the search key. The *key_len* argument value must always be nonzero, except for `__KEY_FIRST` and `__KEY_LAST`.

KSDS, KSDS PATH, and ESDS PATH

The *key* can point to a field of any storage type except `register`. Typically it points to a character string whose length is *key_len*. The *key_len* must be less than or equal to the key length of the data set. If *key_len* is the same as the file's key length, a full key search is automatically used; otherwise, a generic search is used. A generic key search is one in which the search key is a leading portion of the key field. The record positioned to is the first of the records having the same generic key.

ESDS The *key* points to a relative byte address that may be stored as 4 or 8 byte value. *key_len* is either 4 or 8.

RRDS The *key* points to a relative record number stored as an `unsigned long int`. *key_len* is either 4 or 8.

options specifies the position options described in Table 24.

Table 24. Position Options Parameter for flocate()

__KEY_FIRST	Positions to the first record in the file. Subsequent reads are in the forward direction. *key* and *key_len* are ignored.
__KEY_LAST	Positions to the last record in the file. Subsequent reads are in backward order. *key* and *key_len* are ignored. Only applies to VSAM files opened in record mode.
__KEY_EQ	Positions to the first record with the specified key. Subsequent reads are in the forward direction.
__KEY_EQ_BWD	Positions to the first record with the specified key. Subsequent reads are in backward order. Using this option requires a full key search. Key_len must be equal to the key length as defined for the data set. Only applies to VSAM files opened in record mode.
__KEY_GE	Positions to the first record with a key greater than or equal to the specified key.
__RBA_EQ	Positions to the record with the specified RBA. Subsequent reads are in the forward direction. You cannot use __RBA_EQ with an alternative index path. Using this option with RRDS is *not* recommended. The underlying VSAM utilities do not support seeking to an RBA in an RRDS file. The flocate() function attempts to convert the RBA to a Relative Record Number by dividing the value by the LRECL of the file and using the equivalent __KEY_EQ. Using this option with KSDS is *not* recommended because the RBA of a given record may change over time, because of inserts, deletions, or updates of other records.
__RBA_EQ_BWD	Positions to the record with the specified RBA. Subsequent reads are in backward order. You cannot use __RBA_EQ_BWD with an alternative index path. Using this option with RRDS is not recommended. The underlying VSAM utilities do not support seeking to an RBA in an RRDS file. The flocate() function attempts to convert the RBA to a Relative Record Number by dividing the value by the LRECL of the file and using the equivalent __KEY_EQ_BWD. Using this option with KSDS is *not* recommended because the RBA of a given record may change over time, because of inserts, deletions, or updates of other records. Only applies to VSAM files opened in record mode.

Table 24. Position Options Parameter for flocate() (continued)

_KEY_EQ_BWD	Positions to the first record with the specified key. Subsequent reads are in backward order. Using this option requires a full key search. key_len must be set equal to the key length as defined for the data set. Only applies to VSAM files opened in record mode.

Notes:

1. When you are trying to use flocate() in a path to a nonunique key, the resulting position will be at the first physical record of the duplicate key set.
2. flocate() releases all record locking.
3. Writes to VSAM data sets are not affected by preceding calls to flocate().
4. If a record was not found, you must successfully relocate to another position before reading or writing (using the flocate() function). The exception to this is that a write that follows a failed flocate() will succeed if the file was opened for initial loading, but no records have been written to it yet.

flocate_unlocked() is functionally equivalent to flocate() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Considerations for VSAM extended addressability data sets: flocate() accepts key lengths of 4 or 8 when relative byte address (RBA) values are used for positioning. A key length of 8 is required only when the working with a VSAM extended addressability data set, because when the address grows past the 4GB boundary, the key needs to be large enough to hold the value.

When using the value 4GB-1 as the key to flocate(), the key length must be 8 and the data type used must be 8 bytes in size (for example, X' 00000000FFFFFFFF') . If the key length is 4, flocate() treats the key as -1(EOF).

Returned value

If successful, flocate() returns 0.

If a record was not found or the position is beyond the EOF, flocate() returns EOF.

Example

```
#include <stdio.h>

int main(void)
{
   FILE *stream;
   int   vsam_rc;
   char *key = "RECORD 27";

   stream = fopen("DD:MYCLUS", "rb+,type=record");
   vsam_rc = flocate(stream, key, 9, __KEY_EQ);
⋮
}
```

flockfile()— stdio locking

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 3	both	z/OS V1R8

Format

```
#define _UNIX03_SOURCE
#include <stdio.h>

void flockfile(FILE *file);
```

General description

This function provides explicit application-level locking of stdio (FILE*) objects. The flockfile() family of the functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

The flockfile() function acquires ownership of a (FILE*) object for the thread, waiting if necessary, and increases the internal lock count. If the thread has previously been granted ownership, the internal lock count is increased.

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS Consideration: The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For example, fopen() opens a file and open() opens the same file, and then fdopen() creates a FILE * object. In this case, locking the first FILE * does not prevent the second FILE * from also being locked and used.

Returned value

None.

Notes:

1. Because the flockfile() function returns void, no error information can be returned.
2. It is the application's responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (FILE *) object is closed, or a thread is terminated, before relinquishing all locked (FILE *) objects.

floor(), floorf(), floorl() — Round down to integral value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double floor(double x);
float floor(float x);                  /* C++ only */
long double floor(long double x);      /* C++ only */
float floorf(float x);
long double floorl(long double x);
```

General description

Calculates the largest integer that is less than or equal to *x*.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated integral value expressed as a double, float, or long double value. The result cannot have a range error.

Example

CELEBF24

```
/* CELEBF24

   This example assigns y the value of the largest integer that is less
   than or equal to 2.8, and it assigns z the value of the largest integer
   that is less than or equal to -2.8.

 */
#include <math.h>
#include <stdio.h>

int main(void)
{
   double y, z;

   y = floor(2.8);
   z = floor(-2.8);
   printf("floor(  2.8 ) = %f\n", y);
   printf("floor( -2.8 ) = %f\n", z);
}
```

Output

```
floor(  2.8 ) = 2.000000
floor( -2.8 ) = -3.000000
```

floord32(), floord64(), floord128() — Round down to integral value

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  floord32(_Decimal32 x);
_Decimal64  floord64(_Decimal64 x);
_Decimal128 floord128(_Decimal128 x);
_Decimal32  floor(_Decimal32 x);      /* C++ only */
_Decimal64  floor(_Decimal64 x);      /* C++ only */
_Decimal128 floor(_Decimal128 x);     /* C++ only */
```

General description

Calculates the largest integer that is less than or equal to *x*.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the calculated integral value expressed as a _Decimal32, _Decimal64, or _Decimal128 value. The result cannot have a range error.

Example

```
/* CELEBF78

   This example illustrates the floord64() function.

   This example assigns y the value of the largest integer that is less
   than or equal to 2.8, and it assigns z the value of the largest
   integer that is less than or equal to -2.8.

*/
```

```
#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal64 y, z;

   y = floord64(+2.8DD);
   z = floord64(-2.8DD);

   printf("floord64(+2.8) = %+Df\n", y);
   printf("floord64(-2.8) = %+Df\n", z);
}
```

_flushlbf() — Flush all open line-buffered files

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	None

Format

```
#include <stdio.h>
#include <stdio_ext.h>

void _flushlbf(void);

#define _OPEN_SYS_UNLOCKEKD 1
#include <stdio.h>
#include <stdio_ext.h>

void _flushlbf_unlocked(void);
```

General description

The _flushlbf() function flushes all open line-buffered streams.

The _flushlbf() function is affected by the ungetc() and ungetwc() functions. Calling this function causes _flushlbf() to back up the file position when characters are pushed back. For details, see "ungetc() — Push character onto input stream" on page 1958 and "ungetwc() — Push a wide character onto a stream" on page 1961. If needed, the _EDC_COMPAT environment variable can be set at open time such that _flushlbf() discards any pushed-back characters and leaves the file position where it was when the first ungetc() or ungetwc() function call was issued.

If the _flushlbf() function is used after the ungetwc() function pushed a wide char on a text stream, the position will be backed up by one wide character from the position of the file when the ungetwc() function was issued. For a wide-oriented binary stream, the position will be backed up based on the number of bytes that are used to represent the wide char in the ungetc buffer. For this reason, attempting to use ungetwc() on a character when the destination is a binary wide-oriented stream that was never read in the first place results in undefined behavior for _flushlbf(). Note that the _EDC_COMPAT environment variable also changes the behavior of _flushlbf() after ungetwc(), and will cause any wide char pushed-back to be discarded and the position left at the point where the ungetwc() was issued. For details about the _EDC_COMPAT environment variable, see *Environment Variables* in *z/OS XL C/C++ Programming Guide*.

If _flushlbf() fails, the position is left at the point in the file where the first ungetc() or ungetwc() function call was issued. All pushed-back characters are discarded.

Note:

1. The system automatically flushes buffers when you close the stream or when a program ends normally without closing the stream.
2. The _flushlbf() function has no effect on line-buffered text files, because z/OS XL C/C++ writes all records to the system as they are completed. All incomplete new records remain in the buffer.

The buffering mode and the file type can have an effect on when output data is flushed. For more information, see *Buffering of C Streams* in *z/OS XL C/C++ Programming Guide*.

All streams remain open after the _flushlbf() call. Because a read operation cannot immediately follow or precede a write operation, the _flushlbf() function can be used to allow exchange between these two modes. The _flushlbf() function can also be used to refresh the buffer when working with a reader and a simultaneous writer or updater.

The _flushlbf_unlocked() function is equivalent to the _flushlbf() function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application whether the user has locked all open line-buffered files or not.

When flushing all open line-buffered files, a failure to flush any of the files will leave it unchanged. However, flushing will continue on any other open line-buffered files that can be flushed successfully.

Returned value

The _flushlbf() function returns no values.

Example

CELEBF84

```
/* CELEBF84

   This example flushes all the line-buffered files.

*/

#include <stdio.h>
#include <stdio_ext.h>
#include <string.h>

#define BUF_SIZE 128

int main(void)
{
   char lbuf[BUF_SIZE]; /* line buffer */
   char fbuf[BUF_SIZE]; /* full buffer */
   char *tagstr = "This file was modified!";
   FILE *lfp;
   FILE *ffp;
```

```
    lfp = fopen("newlfile.dat", "a+");
    if(lfp == NULL){
       perror("Open file failed!\n");
       return -1;
    }
    if(setvbuf(lfp, lbuf, _IOLBF, sizeof(lbuf)) != 0){ /* set lbuf to line-buffered */
       perror("Format line-buffered failed!\n");
       fclose(lfp);
       return -1;
    }

    if (__flbf(lfp)) printf("newlfile.dat is line-buffered\n");
    else printf("newlfile.dat is not line-buffered\n");

    if(fwrite(lfp,strlen(tagstr), 1, lfp) != 1){ /* write tag string to line buffer*/
       perror("Write line buffer failed!\n");
       fclose(lfp);
       return -1;
    }
    printf("Write to the line buffered file succeeded\n");

    ffp = fopen("newffile.dat", "a+");
    if(ffp == NULL){
       perror("Open file failed!\n");
       fclose(lfp);
       return -1;
    }
    if(setvbuf(ffp, fbuf, _IOFBF, sizeof(fbuf)) != 0){ /* set fbuf to full-buffered */
       perror("Format full-buffered failed!\n");
       fclose(ffp);
       return -1;
    }

    if (__flbf(ffp)) printf("newffile.dat is line-buffered\n");
    else printf("newffile.dat is not line-buffered\n");

    if(fwrite(tagstr, strlen(tagstr), 1, ffp) != 1){ /* write tag string to full buffer */
       perror("Write full buffer failed!\n");
       fclose(lfp);
       fclose(ffp);
       return -1;
    }
    printf("Write to the full buffered file succeeded\n");
    _flushlbf(); /* flush line buffered files */
    printf("Only line buffered files are flushed...\n");
    fclose(lfp);
    fclose(ffp);
    return 0;
}
```

Output

```
newlfile.dat is line-buffered
Write to the line buffered file succeeded
newffile.dat is not line-buffered
Write to the full buffered file succeeded
Only line buffered files are flushed...
```

fma(), fmaf(), fmal() — Multiply then add

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double fma(double x, double y, double z);
float fmaf(float x, float y, float z);
long double fmal(long double x, long double y, long double z);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float fma(float x, float y, float z);
long double fma(long double x, long double y, long double z);
```

General description

The fma() family of functions compute (*x* * *y*) + *z*, rounded as one ternary operation: they compute the value to infinite precision and round once to the resulting format according to the rounding mode characterized by the value of **FLT_ROUNDS**.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
fma	X	X
fmaf	X	X
fmal	X	X

Restriction: The fmaf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

If successful, they return the rounded value of (*x* * *y*) + *z* as one ternary operation.

fmad32(), fmad64(), fmad128() — Multiply then add

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.11

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  fmad32(_Decimal32 x, _Decimal32 y, _Decimal32 z);
_Decimal64  fmad64(_Decimal64 x, _Decimal64 y, _Decimal64 z);
_Decimal128 fmad128(_Decimal128 x, _Decimal128 y, _Decimal128 z);

_Decimal32  fma(_Decimal32 x, _Decimal32 y, _Decimal32 z);     /* C++ only */
_Decimal64  fma(_Decimal64 x, _Decimal64 y, _Decimal64 z);     /* C++ only */
_Decimal128 fma(_Decimal128 x, _Decimal128 y, _Decimal128 z);    /* C++ only */
```

General description

The fma() family of functions compute (*x* * *y*) + *z* rounded as one ternary operation: they compute the value to infinite precision and round once to the resulting format according to the current rounding mode.

Notes:

1. These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, they return the rounded value of (*x* * *y*) + *z* as one ternary operation.

Example

```
/* CELEBF82

   This example illustrates the fmad64() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
   _Decimal64 w, x, y, z;

   x = 2.5DD;
   y = 6.7DD;
   z = 1.0DD;
   w = fmad64(x,y,z);

   printf("fmad64( %Df, %Df, %Df ) = %Df\n", x, y, z, w);
}

fmod(), fmodf(), fmodl() — Calculate floating-point remainder

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double fmod(double x, double y);
float fmod(float x, float y);                          /* C++ only */
long double fmod(long double x, long double y);  /* C++ only */
float fmodf(float x, float y);
long double fmodl(long double x, long double y);
```

General description

Calculates the floating-point remainder of *x*/*y*. The absolute value of the result is always less than the absolute value of *y*. The result will have the same sign as *x*.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Restriction: The fmodf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

If *y* is 0, or the result would overflow, then the function returns 0. Errno remains unchanged.

Special behavior for IEEE

If successful, the function returns the floating-point remainder of *x*/*y*.

If *y* is 0, the function sets errno to EDOM and returns NaNQ. No other errors will occur.

Example

CELEBF25

```
/* CELEBF25

   This example computes z as the remainder of x/y; here x/y is -3 with a
   remainder of -1.

 */
#include <math.h>
```

```
#include <stdio.h>

int main(void)
{
   double x, y, z;

   x = -10.0;
   y = 3.0;
   z = fmod(x,y);      /* z = -1.0 */

   printf("fmod( %f, %f) = %lf\n", x, y, z);
}
```

Output

```
fmod( -10.000000, 3.000000) = -1.000000
```

fmodd32(), fmodd64(), fmodd128() — Calculate floating-point remainder

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.11

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  fmodd32(_Decimal32 x, _Decimal32 y);
_Decimal64  fmodd64(_Decimal64 x, _Decimal64 y);
_Decimal128 fmodd128(_Decimal128 x, _Decimal128 y);

_Decimal32  fmod(_Decimal32 x, _Decimal32 y);     /* C++ only */
_Decimal64  fmod(_Decimal64 x, _Decimal64 y);     /* C++ only */
_Decimal128 fmod(_Decimal128 x, _Decimal128 y);    /* C++ only */
```

General description

Calculates the floating-point remainder of *x*/*y*. The absolute value of the result is always less than the absolute value of *y*. The result will have the same sign as *x*.

Notes:

1. These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, the function returns the floating-point remainder of *x/y*.

If *y* is 0, the function sets errno to EDOM and returns NaNQ. No other errors will occur.

Example

```
/* CELEBF83

   This example illustrates the fmodd32() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
   _Decimal32 x, y, z;

   x = -10.0DF;
   y = 3.0DF;
   z = fmodd32(x, y);

   printf("fmodd32( %Hf, %Hf ) = %Hf\n", x, y, z);
}

fmtmsg() — Display a message in the specified format

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <fmtmsg.h>

int fmtmsg(long classification, const char *label, int severity,
           const char *text, const char *action, const char *tag);
```

General description

The fmtmsg() function can be used to display messages in a specified format instead of the traditional printf() function.

Based on a message's classification component, fmtmsg() writes a formatted message either to standard error, to the console, or to both.

A formatted message consists of up to five components as defined below. The component classification is not part of a message displayed to the user, but defines the source of the message and directs the display of the formatted message.

classification

Contains identifiers from the following groups of major classifications and subclassifications. Any one identifier from a subclass may be used in combination with a single identifier from a different subclass. Two or more identifiers from the same subclass should not be used together, with the exception of identifiers from the display subclass. (Both display subclass identifiers may be used so that messages can be displayed to both standard error and the system console).

Major Classifications
Identifies the source of the condition. Identifiers are: **MM_HARD** (hardware), **MM_SOFT** (software), and **MM_FIRM** (firmware).

Message Source Subclassifications
Identifies the type of software in which the problem is detected. Identifiers are: **MM_APPL** (application), **MM_UTIL** (utility), and **MM_OPSYS** (operating system).

Display Subclassifications
Indicates where the message is to be displayed. Identifiers are: **MM_PRINT** to display the message on the standard error stream, **MM_CONSOLE** to display the message on the system console. One or both identifiers may be used.

Status Subclassifications
Indicates whether the application will recover from the condition. Identifiers are: **MM_RECOVER** (recoverable) and **MM_NRECOV** (non-recoverable).

An additional identifier, **MM_NULLMC**, indicates that no classification component is supplied for the message.

label Identifies the source of the message. The format is two fields separated by a colon. The first field is up to 10 bytes, the second is up to 14 bytes. The constant **__MM_MXLABELLN** defines the maximum length of *label*.

severity
Indicates the seriousness of the condition. Identifiers for the levels of severity are:

MM_HALT
indicates that the application has encountered a severe fault and is halting. Produces the string “HALT”.

MM_ERROR
indicates that the application has detected a fault. Produces the string “ERROR”.

MM_WARNING
indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the string “WARNING”.

MM_INFO
provides information about a condition that is not in error. Produces the string “INFO”.

MM_NOSEV
indicates that no severity level is supplied for the message.

Other provides an unknown severity. Produce the string “SV=n”, where n is the *severity* value specified.

text Describes the error condition that produced the message. The character string is not limited to a specific size. If the character string is empty, then the text produced is unspecified.

action Describes the first step to be taken in the error-recovery process. The fmtmsg() function precedes the action string with the prefix: “TO FIX:”. The action string is not limited to a specific size.

tag An identifier that references on-line documentation for the message. Suggested usage is that tag includes the label and a unique identifying number. A sample tag is “XSI:cat:146”. The constant **__MM_MXTAGLN** defines the maximum length of *tag*.

The MSGVERB environment variable (for message verbosity) tells fmtmsg() which message components it is to select when writing messages to standard error. The value of MSGVERB is a colon-separated list of optional keywords. Valid keywords are: label, severity, text, action, and tag. If MSGVERB contains a keyword for a component and the component's value is not the component's NULL value, fmtmsg() includes that component in the message when writing the message to standard error. If MSGVERB does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If MSGVERB is not defined, if its value is the NULL string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, fmtmsg() selects all components.

MSGVERB affects only which components are selected for display to standard error. All message components are included in console messages.

Returned value

fmtmsg() returns one of the following values:

Value **Description**

MM_OK
The function succeeded.

MM_NOCON
The function was unable to generate a console message, but otherwise succeeded.

MM_NOMSG
The function was unable to generate a message on standard error, but otherwise succeeded.

MM_NOTOK
The function failed completely.

Examples

The following is an example of fmtmsg():

```
fmtmsg(MM_PRINT, "XSI:cat", MM_ERROR, "illegal option",
"refer to cat in user's reference manual", "XSI:cat:001")

       produces a complete message in the specified message format:

XSI:cat: ERROR: illegal option
TO FIX: refer to cat in user's reference manual XSI:cat:001
```

The following is another example when the environment variable MSGVERB is set.

```
export MSGVERB=severity:text:action

fmtmsg(MM_PRINT, "XSI:cat", MM_ERROR, "illegal option",
"refer to cat in user's reference manual", "XSI:cat:001")
```

```
    produces a complete message in the specified message format:

ERROR: illegal option
TO FIX: refer to cat in user's reference manual
```

fnmatch() — Match file name or path name

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <fnmatch.h>

int fnmatch(const char *pattern, const char *string, int flags);
```

General description

The fnmatch() function matches patterns as described in the **XCU** specification, **Section 2.13.1**, **Patterns Matching a Single Character**, and **Section 2.13.2**, **Patterns Matching Multiple Characters**. It checks the string specified by the *string* argument to see if it matches the pattern specified by the *pattern* argument.

The *flags* argument modifies the interpretation of *pattern* and *string*. It is the bitwise inclusive-OR of zero or more of the flags defined in the header <fnmatch.h>. If the FNM_PATHNAME flag is set in *flags*, then a slash character in *string* will be explicitly matched by a slash in *pattern*; it will not be matched by either the asterisk or question-mark special characters, nor by a bracket expression. If FNM_PATHNAME is set and either of these characters would match a slash, the function returns FNM_ESLASH. If the FNM_PATHNAME flag is not set, the slash character is treated as an ordinary character.

If FNM_NOESCAPE is not set in *flags*, a backslash character (\) in *pattern* followed by any other character will match that second character in *string*. In particular, \\ will match a backslash in *string*. If FNM_NOESCAPE is set, a backslash character will be treated as an ordinary character.

If FNM_PERIOD is set in *flags*, then a leading period in *string* will match a period in *pattern*; as described by rule 2 in the **XCU** specification, **Section 2.13.3**, **Patterns Used for Filename Expansion**, where the location of “leading” is indicated by the value of FNM_PATHNAME:

- If FNM_PATHNAME is set, a period is “leading” if it is the first character in *string* or if it immediately follows a slash.
- If FNM_PATHNAME is not set, a period is “leading” only if it is the first character of *string*.

If FNM_PERIOD is not set, then no special restrictions are placed on matching a period. If FNM_PERIOD is set, and a pattern wildcard would match a leading period as defined by the above rules, then the function returns FNM_EPERIOD.

Returned value

If *string* matches the pattern specified by *pattern*, fnmatch() returns 0.

If there is no match, fnmatch() returns FNM_NOMATCH, which is defined in the header <fnmatch.h>.

If an error occurs, fnmatch() returns another nonzero value. See the discussion above for the various possible nonzero returns.

fopen() — Open a file

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdio.h>

FILE *fopen(const char *__restrict__filename, const char *__restrict__mode);
```

General description

The fopen() function opens the file specified by *filename* and associates a stream with it. The *mode* variable is a character string specifying the type of access requested for the file. The *mode* variable contains one positional parameter followed by optional keyword parameters. The positional parameters are described in Table 25 on page 566 and Table 26 on page 567.

The positional parameters must be passed as lowercase characters.

The keyword parameters can be passed in mixed case. They must be separated by commas. Only one instance of a keyword can be specified.

The file name passed to fopen() often determines the type of file that is opened. A set of file-naming rules exist, which allow you to create an application that references both MVS and HFS files specifically. For details on how fopen() determines the type of file from the *filename* and *mode* strings, see the topics about opening files in *z/OS XL C/C++ Programming Guide*.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Named pipes in multithreaded environment: Do not use fopen() to open named pipes in multithreaded environment. If used, a deadlock will occur. See *z/OS XL C/C++ Programming Guide* for a detailed explanation.

File mode

Restriction: When running with POSIX(OFF) and specifying a mode parameter that includes `t`, for example, `rt`, `rt+`, `r+t`, `wt`, `wt+`, `w+t`, `at`, `at+` or `a+t`, the fopen() request will fail with a message indicating a non-valid mode was specified.

Table 25. Values for the Positional Parameter

File Mode	General Description
r	Open a text file for reading. (The file must exist.)
w	Open a text file for writing. If the `w` mode is specified for a ddname that has DISP=MOD, the behavior is the same as if `a` had been specified. Otherwise, if the file already exists, its contents are destroyed.
a	Open a text file in append mode for writing at the end of the file. fopen() creates the file if it does not exist.
r+	Open a text file for both reading and writing. (The file must exist.)
w+	Open a text file for both reading and writing. If the `w+` mode is specified for a ddname that has DISP=MOD, the behavior is the same as if `a+` had been specified. Otherwise, if the file already exists, its contents are destroyed.
a+	Open a text file in append mode for reading or updating at the end of the file. fopen() creates the file if it does not exist.
rb	Open a binary file for reading. (The file must exist.)
wb	Open an empty binary file for writing. If the `wb` mode is specified for a ddname that has DISP=MOD, the behavior is the same as if `ab` had been specified. Otherwise, if the file already exists, its contents are destroyed.
ab	Open a binary file in append mode for writing at the end of the file. fopen() creates the file if it does not exist.
rt	Open a text file for reading. (The file must exist.)
wt	Open a text file for writing. If the file already exists, its contents are destroyed.
at	Open a text file in append mode for writing at the end of the file. fopen() creates the file if it does not exist.
r+b *or* rb+	Open a binary file for both reading and writing. (The file must exist.)
w+b *or* wb+	Open an empty binary file for both reading and writing. If the `w+b` (or `wb+`) mode is specified for a ddname that has DISP=MOD, the behavior is the same as if `ab+` had been specified. Otherwise, if the file already exists, its contents are destroyed.
a+b *or* ab+	Open a binary file in append mode for reading or updating at the end of the file. fopen() creates the file if it does not exist.
r+t *or* rt+	Open a text file for both reading and writing. (The file must exist.)

Table 25. Values for the Positional Parameter (continued)

File Mode	General Description
w+t *or* wt+	Open a text file for both reading and writing. If the file already exists, its contents are destroyed.
a+t *or* at+	Open a text file in append mode for reading or updating at the end of the file. fopen() creates the file if it does not exist.

Attention: Use the `w`, `w+`, `wb`, `w+b`, and `wb+` parameters with care; data in existing files of the same name will be lost.

Text files contain printable characters and control characters organized into lines. Each line ends with a newline character. The system may insert or convert control characters in an output text stream. For example, `\r` written to an MVS DASD text file will be treated as if `\n` (newline) was written.

Note: When compared, data output to a text stream may not be equal to data input from the same text stream.

Binary files contain a series of characters. For binary files, the system does not translate control characters on input or output. Under z/OS XL C/C++, some types of files are always treated as binary files, even when opened in text mode.

In such cases, a control character is written to the file as binary data. On input, the control character will be read back as it was written. See the topic about the byte stream model in *z/OS XL C/C++ Programming Guide* for more information.

z/OS XL C/C++ has *Record I/O* and *Blocked I/O* file extensions. These files are binary in nature—no data interpretation—and require additional qualifiers: `type=record` and `type=blocked`. See the topics about writing to record I/O files and writing to blocked I/O files in *z/OS XL C/C++ Programming Guide* for more information.

When you open a file with `a`, `a+`, `ab`, `a+b`, or `ab+` mode, all write operations take place at the end of the file. Although you can reposition the file pointer using fseek(), fsetpos(), or rewind(), the write functions move the file pointer back to the end of the file before they carry out any output operation. This action prevents you from overwriting existing data.

When you specify the update mode (using `+` in the second or third position), you can both read from and write to the file. However, when switching between reading and writing, you must include an intervening positioning function such as fseek(), fsetpos(), rewind(), or fflush(). Output may immediately follow input if the EOF was detected.

Table 26. Keyword Parameters for File Mode

Parameter	Description
`abend=`*value*	Controls whether the runtime library should attempt to recover from an abend issued during OS I/O operations against the stream being opened. The *value* can be **abend** or **recover**. See *z/OS XL C/C++ Programming Guide* for more information.
`acc=`*value*	Indicator of the direction of the access of the VSAM data set. The *value* can be **fwd** or **bwd**.

Table 26. Keyword Parameters for File Mode (continued)

Parameter	Description
`acc=bwd`	Sets the file position indicator to the last record. The access direction may be changed by a call to flocate().
`asis`	Indicates that the file name is not to be converted to uppercase but used as is. This option is the default under POSIX. It is also the default for HFS file names (see *z/OS XL C/C++ Programming Guide* for more information).
`blksize=`*value*	Specifies the maximum length, in bytes, of a physical block of records. To check whether your `blksize` parameter is valid and is within its limits, see the appropriate topic in *z/OS XL C/C++ Programming Guide* for the type of file you are opening.
`byteseek`	Indicator to allow byte seeks for a binary file. For more information, see the ftell() and fseek() functions.
`lrecl=`*value*	Specifies the length, in bytes, for fixed-length records and the maximum length for variable-length records. To check whether your `lrecl` parameter is valid and is within its limits, see the appropriate topic in *z/OS XL C/C++ Programming Guide* for the type of file you are opening.
`noseek`	Indicates that the stream may not use any of the reposition functions. This may improve performance.
`password=`*xxxxxxx*	Specifies the password for a VSAM data set.
`recfm=A`	ASA print-control characters
`recfm=F`	Fixed-length, unblocked
`recfm=FA`	Fixed-length, ASA print-control characters
`recfm=FB`	Fixed-length, blocked
`recfm=FM`	Fixed-length, machine print-control codes
`recfm=FS`	Fixed-length, unblocked, standard
`recfm=FBA`	Fixed-length, blocked, ASA print-control characters
`recfm=FBM`	Fixed-length, blocked, machine print-control codes
`recfm=FBS`	Fixed-length, unblocked, standard ASA print-control characters
`recfm=FSA`	Fixed-length, unblocked, standard, ASA print-control characters
`recfm=FSM`	Fixed-length, unblocked, standard, machine print-control codes
`recfm=FBSA`	Fixed-length, blocked, standard, ASA print-control characters
`recfm=FBSM`	Fixed-length, blocked, standard, machine print-control codes
`recfm=U`	Undefined-length
`recfm=UA`	Undefined-length, ASA print control characters
`recfm=UM`	Undefined-length, machine print control codes
`recfm=V`	Variable, unblocked
`recfm=VA`	Variable, ASA print-control characters
`recfm=VB`	Variable, blocked
`recfm=VM`	Variable, machine print-control codes
`recfm=VS`	Variable, unblocked, spanned
`recfm=VBA`	Variable, blocked, ASA print-control characters

Table 26. Keyword Parameters for File Mode (continued)

Parameter	Description
`recfm=VBM`	Variable, blocked, machine print-control codes
`recfm=VBS`	Variable, blocked, spanned
`recfm=VSA`	Variable, unblocked, spanned, ASA print-control characters
`recfm=VSM`	Variable, unblocked, spanned, machine print-control codes
`recfm=VBSA`	Variable, blocked, spanned, ASA print-control characters
`recfm=VBSM`	Variable, blocked, spanned, machine print-control codes
`recfm=*`	Existing file attributes are used if file is opened in write mode. **Note:** Using `recfm=*` is only valid for existing DASD data sets. It is ignored in all other cases.
`recfm=+`	Identical to `recfm=*` with the following exceptions: • If there is no record format for the existing DASD data set, defaults are assigned as if the data set did not exist. • When append mode is used, the fopen() fails. See *z/OS XL C/C++ Programming Guide* for more information about fopen() default attributes.
`samethread`	This parameter specifies that I/O operations against the stream are restricted to the thread in which the stream was opened. The library will not lock the stream in a multithread environment. Use of this keyword can improve performance when the stream does not need to be accessed on different threads.
space	Space attributes for MVS data sets. Within the parameter, you cannot have any imbedded blanks. Where: **u** unit type of space requested **p** primary amount of space requested **s** secondary amount of space requested **d** number of directory space requested See the topic about fopen() and freopen() parameters in *z/OS XL C/C++ Programming Guide* for more information about the syntax of this parameter.
`type=blocked`	This parameter specifies that the file is to be opened for sequential blocked I/O. The file must be opened as a binary file; otherwise, fopen() fails. Read and write operations are done with the fread() and fwrite() functions.
`type=memory`	This parameter identifies this file as a memory file that is accessible only from C programs.
`type=memory(hiperspace)`	If you are using MVS/ESA, you can specify the HIPERSPACE suboption to open a hiperspace memory file. **Restriction:** For AMODE 64 applications, `type=memory(hiperspace)` is treated as `type=memory`.
`type=record`	This parameter specifies that the file is to be opened for sequential record I/O. The file must be opened as a binary file; otherwise, fopen() fails. Read and write operations are done with the fread() and fwrite() functions. This is the default fopen() mode for accessing VSAM clusters.

Returned value

If successful, fopen() returns a pointer to the object controlling the associated stream.

If unsuccessful, fopen() returns a NULL pointer.

fopen() generally fails if parameters are mismatched.

Special behavior for large files for HFS: The following is a possible value of errno:

Error Code
Description

EOVERFLOW
The named file is a regular file and the size of the file cannot be represented correctly in an object of type `off_t`.

Example

CELEBF26

```
/* CELEBF26

   This example attempts to open two files for reading, myfile.dat
   and myfile2.dat.

 */
#include <stdio.h>

int main(void)
{
   FILE *stream;

   /* The following call opens a text file for reading */

   if ((stream = fopen("myfile.dat", "r")) == NULL)
      printf("Could not open data file for reading\n");

   /* The following call opens:
              the file myfile2.dat,
              a binary file for reading and writing,
              whose record length is 80 bytes,
              and maximum length of a physical block is 240 bytes,
              fixed-length, blocked record format
              for sequential record I/O.
   */

   if ( (stream = fopen("myfile2.dat", "rb+, lrecl=80,\
      blksize=240, recfm=fb, type=record")) == NULL )
      printf("Could not open data file for read update\n");
}
```

fork() — Create a new process

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <sys/types.h>
#include <unistd.h>

pid_t fork(void);
```

Note: Although POSIX.1 does not require that the <sys/types.h> include file be included, XPG4 has it as an optional header. Therefore, it is recommended that you include it for portability.

General description

Creates a new process. The new process (the *child process*) is an exact duplicate of the process that calls fork() (the *parent process*), except for the following:

- The child process has a unique process ID (PID) that does not match any active process group ID.
- The child has a different parent process ID, that is, the process ID of the process that called fork().
- The child has its own copy of the parent's file descriptors. Each file descriptor in the child refers to the same open file description as the corresponding file descriptor in the parent.
- The child has its own copy of the parent's open directory streams. Each child's open directory stream can share directory stream positioning with the corresponding parent's directory stream.
- The following elements in the tms structure are set to 0 in the child:

  ```
  tms_utime
  tms_stime
  tms_cutime
  tms_cstime
  ```

  For more information about these elements, see "times() — Get process and child process times" on page 1879.
- The child does not inherit any file locks previously set by the parent.
- The child process has no alarms set (similar to the results of a call to alarm() with an argument value of 0).
- The child has no pending signals.
- The child process has only a single thread. That thread is a copy of the thread in the parent that called fork(). The child process has a different thread ID. If the parent process was multithreaded (invoked pthread_create() at least once), the child process can only safely invoke async-signal-safe functions before it invokes an exec() family function. (This restriction also applies to any process created as the result of the child invoking fork() before it invokes an exec() family function

because the child process is still considered multithreaded.) The child process does not inherit pthread attributes or pthread security environment. See Table 27 for a list of async-signal-safe functions.

In all other respects, the child is identical to the parent. Because the child is a duplicate, it contains the same call to fork() that was in the parent. Execution begins with this fork() call, which returns a value of 0; the child then proceeds with normal execution.

The child address space inherits the following address space attributes of the parent address space:
- Region size
- Time limit

If the parent process is multithreaded, it is the responsibility of the application to ensure that the application data is in a consistent state when the fork() occurs. For example, mutexes that are used to serialize updates to application data may need to be locked before the fork() and unlocked afterwards.

For more information on fork(), refer to *z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA23-2281*.

You can use MVS memory files from a z/OS UNIX program. However, use of the fork() function from the program removes access from a hiperspace memory file for the child process. Use of an exec function from the program clears a memory file when the process address space is cleared.

The child process that results from a fork() in a multithreaded environment can only invoke async-signal-safe functions.

An async-signal-safe function is defined as a function that may be invoked, without restriction, from signal-catching functions. All supported async-signal-safe functions are listed in Table 27.

fchmod()	pause()	sleep()	wait()
fchown()	pipe()	signal()	waitpid()
fcntl()	poll()	sigpause()	write()
fork()			

Interoperability restriction: For POSIX resources, fork() behaves as just described. But in general, MVS resources that existed in the parent do *not* exist in the child. This is true for open streams in MVS data sets and assembler-accessed MVS facilities, such as STIMERS. In addition, MVS allocations (through JCL, SVC99, or ALLOCATE) are not passed to the child process.

Special behavior for z/OS UNIX Services:

1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
   - If the calling process is in Ptrace debug mode, a prior loaded copy is not reused.
   - If the calling process is not in Ptrace debug mode, but the only prior loaded usable copy found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.
2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller's MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the loadhfs service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the HFS.
3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one ‘business unit of work’ entity for system accounting and management purposes.

Returned value

If successful, fork() returns 0 to the child process and the process ID of the newly created child to the parent process.

If unsuccessful, fork() fails to create a child process, returns -1 to the parent, and sets errno to one of the following values:

Error Code
    Description

EAGAIN
    There are insufficient resources to create another process, or the process has already reached the maximum number of processes you can run.

ELEMSGERR
    Language Environment message file not available.

ELEMULTITHREAD
    Application contains a language that does not support fork() in a

multithreaded environment, or the multithreaded fork() is being attempted while running in a Language Environment preinitialization (CEEPIPI) environment.

ELENOFORK
Application contains a language that does not support fork().

ENOMEM
The process requires more space than is available.

Example

CELEBF27

```
/* CELEBF27

   This example creates a new child process.

 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <sys/wait.h>

main() {
  pid_t pid;
  int status;

  if ((pid = fork()) < 0)
    perror("fork() error");
  else if (pid == 0) {
    puts("This is the child.");
    printf("Child's pid is %d and my parent's is %d\n",
           (int) getpid(), (int) getppid());
    exit(42);
  }
  else {
    puts("This is the parent.");
    printf("Parent's pid is %d and my child's is %d\n",
           (int) getpid(), (int) pid);
    puts("I'm waiting for my child to complete.");
    if (wait(&status) == -1)
      perror("wait() error");
    else if (WIFEXITED(status))
           printf("The child exited with status of %d\n",
                  WEXITSTATUS(status));
         else
           puts("The child did not exit successfully");
  }
}
```

Output

```
This is the parent.
This is the child.
Child's pid is 1114120 and my parent's is 2293766
Parent's pid is 2293766 and my child's is 1114120
I'm waiting for my child to complete.
The child exited with status of 42
```

fortrc() — Return FORTRAN return code

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <stdlib.h>

int fortrc(void);
```

External entry point: `@@FORTRC`, `__fortrc`

General description

Restriction: This function is not supported in AMODE 64.

The fortrc() function returns the value specified on the FORTRAN RETURN statement issued by the last FORTRAN routine called from the C program.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The FORTRAN routine called must be identified to C as a FORTRAN routine using the following preprocessor directive:

```
#pragmalinkage(identifier,FORTRAN,RETURNCODE).
```

The function fortrc() should be called immediately after a call to the FORTRAN routine *identifier* or else results are unpredictable.

If you do not include `stdlib.h` in your source code or you use the compile-time option LANGLVL(ANSI), then you must use `_ _fortrc` to call the function.

fp_clr_flag() — Reset floating-point exception status flag

Standards

Standards / Extensions	C or C++	Dependencies
	both	OS/390 V2R6

Format

```
#include <float.h>
#include <fpxcp.h>

void fp_clr_flag(mask)
fpflag_t mask;
```

General description

The fp_clr_flag() function resets the exception status flags defined by the *mask* parameter to 0 (false). The remaining flags in the exception status remain unchanged.

Note: This function works only in IEEE Binary Floating-Point. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

The **fpxcp.h** file defines the following names for the flags indicating floating-point exception status:

FP_INVALID
Invalid operation summary

FP_OVERFLOW
Overflow

FP_UNDERFLOW
Underflow

FP_DIV_BY_ZERO
Division by 0

FP_INEXACT
Inexact result

Users can reset multiple exception flags using the fp_clr_flag() function by OR-ing the names of individual flags. For example, the following resets both the overflow and inexact flags.

```
fp_clr_flag(FP_OVERFLOW | FP_INEXACT)
```

Returned value

fp_clr_flag() returns no values.

Related information

- “float.h” on page 29
- “fpxcp.h” on page 32
- “fp_raise_xcp() — Raise a floating-point exception” on page 577

- "fp_read_flag() — Return the current floating-point exception status" on page 578
- "__isBFP() — Determine application floating-point format" on page 904

fp_raise_xcp() — Raise a floating-point exception

Standards

Standards / Extensions	C or C++	Dependencies
	both	OS/390 V2R6

Format

```
#include <fpxcp.h>

int fp_raise_xcp(mask)
fpflag_t mask;
```

General description

The fp_raise_xcp() function causes floating-point exceptions defined by the *mask* parameter to be raised immediately.

If the exceptions defined by the *mask* parameter are enabled and the program is running in serial mode, the signal for floating-point exceptions, SIGFPE, is raised.

Note: This function works only in IEEE Binary Floating-Point. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

The **fpxcp.h** file defines the following names for the flags indicating floating-point exception status:

FP_INVALID
Invalid operation summary

FP_OVERFLOW
Overflow

FP_UNDERFLOW
Underflow

FP_DIV_BY_ZERO
Division by 0

FP_INEXACT
Inexact result

Users can cause multiple exceptions using fp_raise_xcp() by OR-ing the names of individual flags. For example, the following causes both overflow and division by 0 exceptions to occur.

```
fp_raise_xcp(FP_OVERFLOW | FP_DIV_BY_ZERO)
```

If more than one exception is included in the mask variable, the exceptions are raised in the following order:

1. Non-valid operation
2. Division by zero
3. Underflow
4. Overflow

5. Inexact result

Thus, if the user exception handler does not disable further exceptions, one call to the fp_raise_xcp() function can cause the exception handler to be entered many times.

Returned value

If successful, fp_raise_xcp() returns 0.

If unsuccessful, fp_raise_xcp() returns nonzero.

Related information

- "fpxcp.h" on page 32
- "fp_clr_flag() — Reset floating-point exception status flag" on page 576

fp_read_flag() — Return the current floating-point exception status

Standards

Standards / Extensions	C or C++	Dependencies
	both	OS/390 V2R6

Format

```
#include <float.h>
#include <fpxcp.h>

fpflag_t fp_read_flag()
```

General description

The fp_read_flag() function returns the current floating-point exception status.

These functions aid in determining both when an exception has occurred and the exception type. These functions can be called explicitly around blocks of code that may cause a floating-point exception.

According to the IEEE Standard for Binary Floating-Point Arithmetic, the following types of floating-point operations must be signaled when detected in a floating-point operation:
- Non-valid operation
- Division by zero
- Overflow
- Underflow
- Inexact

A non-valid operation occurs when the result cannot be represented (for example, a square root operation on a number less than 0).

The IEEE Standard for Binary Floating-Point Arithmetic states: "For each type of exception, the implementation shall provide a status flag that shall be set on any occurrence of the corresponding exception when no corresponding trap occurs. It shall be reset only at the user's request. The user shall be able to test and to alter the status flags individually, and should further be able to save and restore all five at one time.”

Floating-point operations can set flags in the floating-point exception status but cannot clear them. Users can clear a flag in the floating-point exception status using an explicit software action such as the fp_clr_flag (0) subroutine.

Note: This function works only in IEEE Binary Floating-Point. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

The **fpxcp.h** file defines the following names for the flags indicating floating-point exception status:

FP_INVALID
non-valid operation summary

FP_OVERFLOW
Overflow

FP_UNDERFLOW
Underflow

FP_DIV_BY_ZERO
Division by 0

FP_INEXACT
Inexact result

Returned value

fp_read_flag() returns the current floating-point exception status. The flags in the returned exception status can be tested using the flag definitions above. You can test individual flags or sets of flags.

fp_read_rnd() — Determine rounding mode

Standards

Standards / Extensions	C or C++	Dependencies
	both	OS/390 V2R6

Format

```
#define _AIX_COMPATIBILITY 1
#include <float.h>

fprnd_t fp_read_rnd(void);
```

General description

For an application running in binary floating-point mode, the fp_read_rnd() function returns the current rounding mode indicated by the rounding mode field of the floating-point control (FPC) register. For an application running in hexadecimal floating-point mode, fp_read_rnd() returns 0.

Note: This function will not return or update decimal floating-point rounding mode bits.

Returned value

For an application running in IEEE Binary Floating-Point mode, fp_read_rnd() returns the following:

Value **Rounding Mode**

_FP_RND_RZ
Round toward 0

_FP_RND_RN
Round to nearest

_FP_RND_RP
Round toward +infinity

_FP_RND_RM
Round toward -infinity

For an application running in hexadecimal floating-point mode, fp_read_rnd() returns 0.

Related information

- “float.h” on page 29
- “fp_swap_rnd() — Swap rounding mode”
- “__isBFP() — Determine application floating-point format” on page 904

fp_swap_rnd() — Swap rounding mode

Standards

Standards / Extensions	C or C++	Dependencies
	both	OS/390 V2R6

Format

```
#define _AIX_COMPATIBILITY 1
#include <float.h>

fprnd_t fp_swap_rnd(RoundMode)
fprnd_t RoundMode
```

General description

For an application running in IEEE Binary Floating-Point mode, the fp_swap_rnd() function returns the current rounding mode specified by the rounding mode field of the floating-point control (FPC) register and sets the rounding mode field in the FPC register based on the value of *RoundMode* as follows:

Value **Rounding Mode**

_FP_RND_RZ
Round toward 0

_FP_RND_RN
Round to nearest

_FP_RND_RP
Round toward +infinity

_FP_RND_RM
Round toward -infinity

Notes:

1. When processing IEEE Binary Floating-Point values, the z/OS XL C/C++ runtime library math functions require IEEE rounding mode of round to nearest. The z/OS XL C/C++ runtime library takes care of setting round to nearest rounding mode while executing math functions and restoring application rounding mode before returning to the caller.
2. This function will not return or update decimal floating-point rounding mode bits.

Returned value

For an application running in hexadecimal floating-point mode, fp_swap_rnd() returns 0.

For an application running in IEEE Binary Floating-Point mode, fp_swap_rnd() returns the previous (changed from) rounding mode as follows:

Value **Rounding Mode**

_FP_RND_RZ
Round toward 0

_FP_RND_RN
Round to nearest

_FP_RND_RP
Round toward +infinity

_FP_RND_RM
Round toward -infinity

Related information

- “float.h” on page 29
- “fp_read_rnd() — Determine rounding mode” on page 579
- “__isBFP() — Determine application floating-point format” on page 904

fpathconf() — Determine configurable path name variables

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

long fpathconf(int fildes, int varcode);
```

General description

Determines the value of a configuration variable (*varcode*) associated with a particular file descriptor (*fildes*).

fpathconf() works exactly like pathconf(), except that it takes a file descriptor as an argument rather than taking a path name.

The *varcode* argument can be any one of a set of symbols defined in the unistd.h header file. Each symbol stands for a configuration variable. These are the possible symbols:

_PC_LINK_MAX
Represents **LINK_MAX**, the maximum number of links the file can have. If *pathname* is a directory, fpathconf() returns the maximum number of links that can be established to the directory itself.

_PC_MAX_CANON
Represents **MAX_CANON**, the maximum number of bytes in a terminal canonical input line. *pathname* must refer to a character special file for a terminal.

_PC_MAX_INPUT
Represents **MAX_INPUT**, the minimum number of bytes for which space will be available in a terminal input queue. This input space is the maximum number of bytes that a portable application will allow an end user to enter before the application actually reads the input. *pathname* must refer to a character special file for a terminal.

_PC_NAME_MAX
Represents **NAME_MAX**, the maximum number of characters in a file name (not including any terminating NULL character if the file name is stored as a string). This limit refers only to the file name itself, that is, the last component of the file's path name. fpathconf() returns the maximum length of file names.

_PC_PATH_MAX
Represents **PATH_MAX**, the maximum number of characters in a complete path name (not including any terminating NULL if the path name is stored as a string). fpathconf() returns the maximum length of a relative path name.

_PC_PIPE_BUF
Represents **PIPE_BUF**, the maximum number of bytes that can be written to a pipe as one unit. If more than this number of bytes is written to a pipe, the operation can take more than one physical write operation and can require more than one physical read operation to read the data on the other end of the pipe. If *pathname* is a FIFO special file, fpathconf() returns the value for the file itself. If *pathname* is a directory, fpathconf() returns the value for any FIFOs that exist or can be created under the directory. If *pathname* is any other kind of file, an errno of EINVAL (see description below) will be returned.

_PC_CHOWN_RESTRICTED
Represents _POSIX_CHOWN_RESTRICTED defined in the unistd.h header file. This symbol indicates that the use of chown() is restricted; see the callable service chown() for more details. If *pathname* is a directory, fpathconf() returns the value for any kind of file under the directory, but not for subdirectories of the directory.

_PC_NO_TRUNC
Represents _POSIX_NO_TRUNC defined in the unistd.h header file. This symbol indicates that an error should be generated if a file name is longer than **NAME_MAX**. If *pathname* refers to a directory, the value returned by fpathconf() applies to all files under that directory.

_PC_VDISABLE
Represents _POSIX_VDISABLE defined in the unistd.h header file. This symbol indicates that terminal special characters can be disabled using this character value, if it is defined. See the callable service tcsetattr() for details. *pathname* must refer to a character special file for a terminal.

_PC_ACL
Returns 1 if an access control mechanism is supported by the security product for the file identified by the file descriptor.

_PC_ACL_ENTRIES_MAX
Returns the maximum number of ACL entries in an ACL for the file or directory identified by the file descriptor.

Returned value

If a particular variable has no limit, fpathconf() returns -1 but does not change errno.

If successful, fpathconf() returns the value of the variable requested in *varcode*.

If unsuccessful, fpathconf() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EINVAL
varcode is not a valid variable code, or the given variable cannot be associated with the specified file.

- If *varcode* refers to **MAX_CANON**, **MAX_INPUT**, or _POSIX_VDISABLE, and *pathname* does not refer to a character special file, fpathconf() returns -1 and sets errno to EINVAL.
- If *varcode* refers to **NAME_MAX**, **PATH_MAX**, or POSIX_NO_TRUNC, and *pathname* does not refer to a directory, fpathconf() returns the requested information.
- If *varcode* refers to PC_PIPE_BUF and *pathname* refers to a pipe or a FIFO, the value returned applies to the referenced object itself. If *pathname* refers to a directory, the value returned applies to any FIFOs that exist or can be created within the directory. If *pathname* refers to any other type of file, the function sets errno to EINVAL.

Example

CELEBF29

```
/* CELEBF29

   This example uses fpathconf() with __PC_NAME_MAX to determine the value
   of the NAME_MAX configuration variable.

 */
#define _POSIX_SOURCE
#include <errno.h>
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  long result;
  char fn[]="temp.file";
  int  fd;

  if ((fd = creat(fn, S_IRUSR)) < 0)
    perror("creat() error");
  else {
    errno = 0;
    puts("examining NAME_MAX limit for current working directory's");
    puts("filesystem:");
    if ((result = fpathconf(fd, _PC_NAME_MAX)) == -1)
      if (errno == 0)
        puts("There is no limit to NAME_MAX.");
      else perror("fpathconf() error");
    else
      printf("NAME_MAX is %ld\n", result);
    close(fd);
    unlink(fn);
  }
}
```

Output

```
examining NAME_MAX limit for current working directory's
file system:
NAME_MAX is 255
```

fpclassify() — Classifies an argument value

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int fpclassify (real-floating x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int fpclassify([real-floating|decimal-floating] x);

#define _TR1_C99
#include <math.h>

int fpclassify(real-floating x);
```

General description

This macro or function template classifies its argument value as NaN, infinite, normal, subnormal or zero based on the type of its argument. If the argument is represented in a format wider than its semantic type, then it is converted to its semantic type and then it is classified.

Function	Hex	IEEE
fpclassify	X	X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

fpclassify() returns:

- FP_NAN if the argument is Not-a-Number.
- FP_INFINITE if the argument is plus or minus infinity.
- FP_ZERO if the argument is of value zero.
- FP_SUBNORMAL if the argument is too small to be represented in the normal format.
- FP_NORMAL if none of the above.

Special behavior in hex:

- FP_ZERO if the argument is of value zero.
- FP_NORMAL if the argument is a normalized number.
- FP_SUBNORMAL if the argument is an unnormalized number.

Related information

- “math.h” on page 44

__fpending() — Retrieve number of bytes pending for write

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>
#include <stdio_ext.h>

size_t __fpending(FILE *stream);

#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

size_t __fpending_unlocked(FILE *stream);
```

General description

The __fpending() function retrieves the number of bytes pending to be written in the output buffer associated with the specified binary stream. When the stream is opened for text processing, the __fpending() function retrieves the number of characters pending to be written.

The __fpending_unlocked() function is equivalent to the __fpending() function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the flockfile() or ftrylockfile() function.

The __fpending() function cannot be used on buffers in read mode or opened read-only.

Usage notes

1. If __fpending() is called when the stream is currently reading, __fpending() returns 0 and sets errno to a nonzero value.
2. If __fpending() is called on a data set opened `type=record`, __fpending() returns 0 and sets errno to a nonzero value.
3. For text data sets, any newline characters representing record boundaries written to the buffer will be included in the returned value.

Returned value

The __fpending() functions return the number of bytes or characters pending to be written in the current buffer, depending on the type of stream. Otherwise, the __fpending() functions return 0. If an error has occurred, __fpending() functions return 0 and set errno to nonzero.

When the stream is wide-oriented text, the __fpending() functions return a value measured in wide characters.

An application wishing to check for error situations should set errno to 0, then call __fpending(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
Description

EBADF
The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
   FILE *f;
   char filename[FILENAME_MAX] = "myfile.dat";
   char data[128] = "There are 34 bytes in this buffer\n";
   int datalen = strlen(data);
   size_t n = 0;

   f = fopen(filename,"wb+");
   if (f == NULL) {
      perror("fopen() failed\n");
      return;
   }

   if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
   if (__freadable(f)) printf("Reading is allowed on the open stream\n");

   n = fputs(data,f);
   if (n == EOF) {
      perror("fputs() failed\n");
      return;
   }

   n = __fpending(f);
   printf("There are %d bytes in the buffer pending to be written\n", n);

   if (__fwriting(f)) printf("The last operation on the stream was a write\n");

   rewind(f);

   n = fgetc(f);

   n = __freadahead(f);
   printf("There are %d bytes remaining to be read from the buffer\n", n);

   if (__freading(f)) printf("The last operation on the stream was a read\n");

   return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

fprintf(), printf(), sprintf() — Format and write data

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	z/OS V1.8

Format

```
#include <stdio.h>

int fprintf(FILE *__restrict__stream, const char *__restrict__format-string, ...);
int printf(const char *__restrict__format-string, ...);
int sprintf(char *__restrict__buffer, const char *__restrict__format-string, ...);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fprintf_unlocked(FILE *__restrict__stream,
                     const char *__restrict__format-string, ...);
int printf_unlocked(const char *__restrict__format-string, ...);
```

General description

These three related functions are referred to as the fprintf family.

The fprintf() function formats and writes output to a *stream*. It converts each entry in the *argument list*, if any, and writes to the stream according to the corresponding format specification in the *format-string*. The fprintf() function cannot be used with a file that is opened using `type=record` or `type=blocked`.

The printf() function formats and writes output to the standard output stream `stdout`. printf() cannot be used if `stdout` has been reopened using `type=record` or `type=blocked`.

The sprintf() function formats and stores a series of characters and values in the array pointed to by *buffer*. Any *argument-list* is converted and put out according to the corresponding format specification in the *format-string*. If the strings pointed to by *buffer* and *format* overlap, behavior is undefined.

fprintf() and printf() have the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

The *format-string* consists of ordinary characters, escape sequences, and conversion specifications. The ordinary characters are copied in order of their appearance. Conversion specifications, beginning with a percent sign (%) or the sequence (%n$) where n is a decimal integer in the range [1,NL_ARGMAX], determine the output format for any *argument-list* following the *format-string*. The *format-string* can contain multibyte characters beginning and ending in the initial shift state. When the *format-string* includes the use of the optional prefix *ll* to indicate the size expected is a long long datatype then the corresponding value in the argument list should be a long long datatype if correct output is expected.

fprintf_unlocked() is functionally equivalent to fprintf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

printf_unlocked() is functionally equivalent to printf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

The *format-string* is read from left to right. When the first format specification is found, the value of the first *argument* after the *format-string* is converted and output according to the format specification. The second format specification causes the second *argument* after the *format-string* to be converted and output, and so on through the end of the *format-string*. If there are more arguments than there are format specifications, the extra arguments are evaluated and ignored. The results are undefined if there are not enough arguments for all the format specifications. The format specification is illustrated below.

Format Specification for fprintf(), printf(), and sprintf()

                                             ├─vL──┤
                                             └─Lv──┘
```

Each field of the format specification is a single character or number signifying a particular format option. The *type* character, which appears after the last optional format field, determines whether the associated argument is interpreted as a character, a string, a number, or pointer. The simplest format specification contains only the percent sign and a *type* character (for example, %s).

Percent sign: If a percent sign (%) is followed by a character that has no meaning as a format field, the character is simply copied to `stdout`. For example, to print a percent sign character, use %%.

Flag characters: The *flag* characters in Table 28 are used for the justification of output and printing of thousands' grouping characters, signs, blanks, decimal-points, octal and hexadecimal prefixes, the semantics for `wchar_t` precision unit and the separator for vector data type output conversion. Notice that more than one *flag* can appear in a format specification. This is an optional field.

Table 28. Flag Characters for fprintf Family

Flag	Meaning	Default
'	**Added for XPG4:**The integer portion of the result of a decimal conversion(%i,%d,%u, %f,%g or %G) will be formatted with the thousands' grouping characters.	No grouping.
-	Left-justify the result within the field width.	Right-justify.
+	Prefix the output value with a sign (+ or -) if the output value is of a signed type.	Sign appears only for negative signed values (-).

Table 28. Flag Characters for fprintf Family (continued)

Flag	Meaning	Default
blank(' ')	Prefix the output value with a blank if the output value is signed and positive. The `+` flag overrides the *blank* flag if both appear, and a positive signed value will be output with a sign.	No blank.
#	When used with the `o`, `x`, or `X` formats, the `#` flag prefixes any nonzero output value with 0, 0x, or 0X, respectively. For `o` conversion, it increases the precision, if and only if necessary, to force the first digit of the result to be a zero (if the value and precision are both 0, a single 0 will be printed)	No prefix.
	When used with the `f`, `e`, or `E` formats, the `#` flag forces the output value to contain a decimal-point in all cases. The decimal-point is sensitive to the LC_NUMERIC category of the same current locale.	Decimal-point appears only if digits follow it.
	When used with the `g` or `G` formats, the `#` flag forces the output value to contain a decimal-point in all cases and prevents the truncation of trailing zeros.	Decimal-point appears only if digits follow it; trailing zeros are truncated.
	When used with the `ls` or `S` format, the `#` flag causes precision to be measured in wide characters.	Precision indicates the maximum number of bytes to be output.
0	When used with the `d`, `i`, `o`, `u`, `x`, `X`, `e`, `E`, `f`, `g`, or `G` formats, the `0` flag causes leading `0`'s to pad the output to the field width. The `0` flag is ignored if precision is specified for an integer or if the `-` flag is specified.	Space padding.
`,` `;` `:` `_`	Indicates the separator character between each two components in the vector data type conversion. Only one separator character can be specified.	The default value for the separator character is a space (' '), unless the `c` format is being used. For the `c` format, there is no separator at all if no separator character is specified.

The code point for the # character varies between the EBCDIC encoded character sets. The definition of the # character is based on the current LC_SYNTAX category. The default C locale expects the # character to use the code point for encoded character set IBM-1047.

When the LC_SYNTAX category is set using setlocale(), the format strings passed to the printf() functions must use the same encoded character set as is specified for the LC_SYNTAX category.

The `#` flag should not be used with `c`, `lc`, `C`, `d`, `i`, `u`, `s`, or `p` conversion specifier.

Output width: The *width* argument is a nonnegative decimal integer controlling the minimum number of characters printed. If the number of characters in the output value is less than the specified *width*, blanks are added on the left or the right (depending on whether the – flag is specified) until the minimum width is reached.

The width never causes a value to be truncated; if the number of characters in the output value is greater than the specified *width*, or *width* is not given, all characters of the value are output (subject to the *precision* specification).

The *width* specification can be an asterisk (*); if it is, an argument from the argument list supplies the value. The *width* argument must precede the value being formatted in the argument list. This is an optional field.

If *format-string* contains the %n$ form of conversion specification, *width* can be indicated by the sequence *m$, where m is a decimal integer in the range [1,NL_ARGMAX] giving the position of an integer argument in the argument list containing the field width.

Output precision: The *precision* argument is a nonnegative decimal integer preceded by a period. It specifies the number of characters to be output, or the number of decimal places. Unlike the *width* specification, the *precision* can cause truncation of the output value or rounding of a floating-point value.

Be aware that the rounding of floating-point values may not always occur as expected based on the decimal value of the number. This is because the internal binary representation cannot always be an exact representation of the decimal value, so the rounding may occur on an inexact value. This is true of both OS/390 hexadecimal and IEEE 754 binary floating- point formats.

The *precision* argument can be an asterisk (*); if it is, an argument from the argument list supplies the value. The *precision* argument must precede the value being formatted in the argument list. The *precision* field is optional.

If *format-string* contains the %n$ form of conversion specification, *precision* can be indicated by the sequence *m$, where m is a decimal integer in the range [1,NL_ARGMAX] giving the position of an integer argument in the argument list containing the field precision.

The interpretation of the *precision* value and the default when the *precision* is omitted depend upon the *type*, as shown in Table 29.

Table 29. Precision Argument in fprintf Family

Type	Meaning	Default
d i o u x X	*Precision* specifies the minimum number of digits to be output. If the number of digits in the argument is less than *precision*, the output value is padded on the left with zeros. The value is not truncated when the number of digits exceeds *precision*.	Default *precision* is 1. If *precision* is 0, or if the period (.) appears without a number following it, the *precision* is set to 0. When *precision* is 0, conversion of the value zero results in no characters.

Table 29. Precision Argument in fprintf Family (continued)

Type	Meaning	Default
e E f F	*Precision* specifies the number of digits to be output after the decimal-point. The last digit output is rounded. The decimal-point is sensitive to the LC_NUMERIC category of the current locale.	Default *precision* is 6. If *precision* is 0 or the period appears without a number following it, no decimal-point is output.
a A	For non decimal floating-point numbers, *precision* specifies the number of hexadecimal digits to be output after the decimal-point character. For decimal floating-point numbers, precision determines the style of formatting to be used.	For non decimal floating-point numbers, default *precision* is 6. If *precision* is 0, no decimal-point is output. For decimal floating-point numbers, precision is determined by the quantum of the decimal floating-point number. Refer to Table 30 on page 594 for more details.
g G	*Precision* specifies the maximum number of significant digits output.	All significant digits are output.
c	No effect.	The character is output.
C lc	No effect.	The wide character is output.
s	*Precision* specifies the maximum number of characters to be output. Characters in excess of *precision* are not output.	Characters are output until a NULL character is encountered.
S ls	*Precision* specifies the maximum number of bytes to be output. Bytes in excess of *precision* are not output; however, multibyte integrity is always preserved.	`wchar_t` characters are output until a NULL character is encountered.

Optional prefix: The optional prefix characters used to indicate the size of the argument expected or size of a single component in a vector data type output conversion are explained:

Prefix	Meaning
h	Specifies that the `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a short or unsigned short argument (the argument will have been promoted according to the integer promotions, but its value shall be converted to short or unsigned short before printing); or that a following `n` conversion specifier applies to a pointer to a short argument.
hh	Specifies that the `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a signed char or unsigned char argument (the argument will have been promoted according to the integer promotions, but its value shall be converted to signed char or unsigned char before printing); or that a following `n` conversion specifier applies to a pointer to a signed char argument.
l	(ell) Specifies that the `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a long or unsigned long argument; that a following `n` conversion specifier applies to a pointer to a long argument; that the `c` conversion specifier applies to a wint_t argument; that the `s` conversion specifier applies to a pointer to a wchar_t argument. It has no effect on the `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier.

ll (ell-ell) Specifies that the `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a long long or unsigned long long argument; or that the `n` conversion specifier applies to a pointer to a long long argument.

j Specifies that the `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to an intmax_t or uintmax_t argument; or that the `n` conversion specifier applies to a pointer to an intmax_t argument.

t Specifies that the `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a ptrdiff_t or the corresponding unsigned type argument; or that the `n` conversion specifier applies to a pointer to a ptrdiff_t argument.

z Specifies that the `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a size_t or the corresponding signed integer type argument; or that the `n` conversion specifier applies to a pointer to a signed integer type corresponding to a size_t argument.

D Specifies that the `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to an _Decimal64 argument.

DD Specifies that the `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to an _Decimal128 argument.

H Specifies that the `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to an _Decimal32 argument.

L Specifies that the `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to a long double argument.

v Specifies that a following `c`, `d`, `i`, `u`, `o`, `x`, or `X` conversion specifier applies to a `vector signed char`, `vector unsigned char`, or `vector bool char` parameter. It consumes one argument and interprets the data as a series of sixteen 1-byte components.

vh, hv Specifies that a following `d`, `i`, `u`, `o`, `x`, or `X` conversion specifier applies to a `vector signed short`, `vector unsigned short`, or `vector bool short` parameter. It consumes one argument and interprets the data as a series of eight 2-byte integer components.

vl, lv Specifies that a following `d`, `i`, `u`, `o`, `x`, or `X` conversion specifier applies to a `vector signed int`, `vector unsigned int`, or `vector bool int` parameter. It consumes one argument and interprets the data as a series of four 4-byte integer components.

vll, llv Specifies that a following `d`, `i`, `u`, `o`, `x`, or `X` conversion specifier applies to a `vector signed long long`, `vector unsigned long long`, or `vector bool long long` parameter. It consumes one argument and interprets the data as a series of two 8-byte integer components.

vL, Lv specifies that a following `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to a `vector double` parameter. It consumes one argument and interprets the data as a series of two 8-byte floating point components.

Conversion specifier: Table 30 explains the meaning of the type characters used in the precision argument.

Table 30. Type Characters and their Meanings

Conversion specifier	Argument	Output Format
d, i	Integer	Signed decimal integer.
u	Integer	Unsigned decimal integer.

Table 30. Type Characters and their Meanings (continued)

Conversion specifier	Argument	Output Format
o	Integer	Unsigned octal integer.
x	Integer	Unsigned hexadecimal integer, using abcdef.
X	Integer	Unsigned hexadecimal integer, using ABCDEF.
f, F	Double	Signed value having the form [-]*dddd.dddd*, where *dddd* is one or more decimal digits. The number of digits before the decimal-point depends on the magnitude of the number. The number of digits after the decimal-point is equal to the requested precision. The decimal-point is sensitive to the LC_NUMERIC category of the current locale.
e	Double	Signed value having the form [-]*d.dddd*`e`[*sig n*]*ddd*, where *d* is a single-decimal digit, *dddd* is one or more decimal digits, *ddd* is 2 or more decimal digits, and *sign* is + or -. A double argument representing an infinity or NaN is converted in the style of an f or F conversion specifier.
E	Double	Identical to the `e` format, except that `E` introduces the exponent, not `e`.
g	Double	Signed value output in `f` or `e` format. The `e` format is used only when the exponent of the value is less than -4 or greater than or equal to the *precision*. Trailing zeros are truncated, and the decimal-point appears only if one or more digits follow it. A double argument representing an infinity or NaN is converted in the style of an f or F conversion specifier.
G	Double	Identical to the `g` format, except that `E` introduces the exponent (where appropriate), not *e*.
D(n,p)	Decimal type argument.	Fixed-point value consisting of a series of one or more decimal digits possibly containing a decimal-point.
c C or lc	Character Wide Character	Single character. The argument of wchar_t type is converted to an array of bytes representing a multibyte character as if by call to wctomb().
s S or ls	String Wide String	Characters output up to the first NULL character (`\0`) or until *precision* is reached. The argument is a pointer to an array of wchar_t type. Wide characters from the array are converted to multibyte characters up to and including a terminating NULL wide character. Conversion takes place as if by a call to wcstombs(), with the conversion state described by the mbstate_t object initialized to 0. The result written out will not include the terminating NULL character. If no precision is specified, the array contains a NULL wide character. If a precision is specified, its sets the maximum number of characters written, including shift sequences. A partial multibyte character cannot be written.
n	Pointer to integer	Number of characters successfully output so far to the *stream* or buffer; this value is stored in the integer whose address is given as the argument.
p	Pointer	Pointer to void converted to a sequence of printable characters. Refer to the individual system reference guides for the specific format.

Table 30. Type Characters and their Meanings (continued)

Conversion specifier	Argument	Output Format
a, A	Double _Decimal32 _Decimal64 _Decimal128	A double argument representing a floating-point number is converted to the “[-]0xh.hhhhp±d” format, where there is one hexadecimal digit (non-zero when the argument is a normalized floating-point number; otherwise unspecified) before the decimal-point character and the number of hexadecimal digits after it is equal to the precision. If the precision is missing and FLT_RADIX is a power of 2, then the precision will be sufficient for an exact representation of the value. If the precision is missing and FLT_RADIX is not a power of 2, then the precision will be sufficient to distinguish values of type double, except that trailing zeros may be omitted. If the precision is zero and the “#” flag is not specified, no decimal-point will appear. The letters “abcdef” are used for the a conversion and the letters “ABCDEF” for the A conversion. The A conversion specifier produces a number with letters “X” and “P” instead of letters “x” and “p”. The exponent always contains at least one digit, and only as many more digits as necessary to represent the decimal exponent of 2. If the value is zero, the exponent is zero. A double argument representing an infinity or NaN is converted in the style of an f or F conversion specifier. If precision is zero, results can be different for Hexadecimal floating point format and IEEE floating point format. For Hexadecimal floating point, a decimal point will not appear in the output. For IEEE floating point, a decimal point will appear. If an H, D, or DD modifier is present and the precision is missing, then for a decimal floating type argument, either the f or e style formatting is used based on the following criteria: • f style formatting is used when the quantum is less than or equal to 0 but greater than or equal to -(n+5). The quantum of a number can be determined by calling the quantexp() functions. The number of digits (n) in the digit-sequence includes trailing zeros only and ignores the decimal point. For example: **0.000005** contains 1 digit in the digit sequence, n = 1 **0.0000050** contains 2 digits in the digit sequence, n = 2 **12.30** contains 4 digits in the digit sequence, n = 4 The precision is equal to -quantum. • e style formatting is used when the quantum does not satisfy the f style criteria. The precision is equal to n-1, except if the argument is equal to 0 then the digit-sequence in the exponent-part is equal to the quantum. For example: **0.0000000** produces 0e-07 **-1870** produces -1.87e+03 \If the precision is present and at least as large as the precision of the decimal floating type, the conversion is as if the precision were missing. If the precision is present and less than the precision of the decimal floating type, the input is first rounded according to the current rounding direction to the number of digits specified by the precision . The result is then converted as if the precision were missing. The "quantum" when referring to a finite decimal floating-point number is defined as the "magnitude of a value of one in the rightmost digit position of the significand". For example, pennies and dollars can be represented respectively as 1 * 10 with a quantum of -2 and 0, or, 1*10^-2 and 1*10^0. For more information on the term quantum, see *z/Architecture Principles of Operation*.

Special behavior for XPG4:

- If the %n$ conversion specification is found, the value of the nth *argument* after the *format-string* is converted and output according to the conversion specification. Numbered arguments in the argument list can be referenced from *format-string* as many times as required.
- The *format-string* can contain either form of the conversion specification, that is, % or %n$ but the two forms cannot be mixed within a single *format-string* except that %% can be mixed with the %n$ form. When numbered conversion specifications are used, specifying the 'nth' argument requires that the first to (n-1)th arguments are specified in the *format-string*.

Floating-point and the fprintf family of formatted output functions: The fprintf family functions match `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifiers to floating-point arguments for which they produce floating-point number substrings in the output stream. The fprintf family functions have been extended to determine the floating-point format, hexadecimal floating-point or IEEE Binary Floating-Point, of types `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` by using __isBFP().

The fprintf family functions convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences.

- The special output sequence for infinity values is a plus or minus sign, then the character sequence INF followed by a white space character (space, tab, or newline), a NULL character (`\0`) or EOF.
- The special output sequence for NaN values is a plus or minus sign, then the character sequence NANS for a signalling NaN or NANQ for a quiet NaN, then a NaN ordinal sequence, and then a a white space character (space, tab, or newline), a NULL character (`\0`) or EOF.

  For binary floating point NANs: A NaN ordinal sequence is a left-parenthesis character, “(”, followed by a digit sequence representing an integer n, where 1 <= n <= INT_MAX-1, followed by a right-parenthesis character, “)”. The integer value, n, is determined by the fraction bits of the NaN argument value as follows:

  1. For a signalling NaN value, NaN fraction bits are reversed (left to right) to produce bits (right to left) of an even integer value, 2*n. Then formatted output functions produce a (signalling) NaN ordinal sequence corresponding to the integer value n.
  2. For a quiet NaN value, NaN fraction bits are reversed (left to right) to produce bits (right to left) of an odd integer value, 2*n-1. Then formatted output functions produce a (quiet) NaN ordinal sequence corresponding to the integer value n.

  For decimal floating point NANs: A NaN ordinal sequence is a left parenthesis character, "(", followed by a decimal digit sequence of up to 6 digits for a _Decimal32 output number, up to 15 digits for a _Decimal64 output value, or up to 33 digits for a _Decimal128 output value, followed by a right parenthesis, ")". If the NaN ordinal sequence is omitted, NaN ordinal sequence "(0)" is assumed. If the NaN ordinal sequence is shorter than 6, 15, or 33 digits, it will be padded on the left with "0" digits so that the length becomes 6, 15, or, 33 digits for _Decimal32, _Decimal64, and _Decimal128 values respectively.

  For decimal floating point numbers, the digits are not reversed, and both odd or even NaN ordinal sequences can be specified for either a Quiet NAN or Signalling NAN.

The C99 standard does not distinguish between the quiet NaN and signaling NaN values. An argument representing a NaN (Not a Number) is to be displayed as [-]nan or [-]nan(n-char-sequence); where the implementation decides the representation. For the `A`, `E`, `F`, and `G` conversion specifiers, NaN values are displayed as the uppercase versions of the aforementioned character string representations. To get this behavior set the environment variable _EDC_C99_NAN to YES.

Some compatibility with NaN sequences output by AIX formatted output functions can be achieved by setting a new environment variable, _AIX_NAN_COMPATIBILITY, which z/OS formatted output functions recognize, to one of the following (string) values:

Value Output function

1 Formatted output functions which produce special NaN output sequences omit the NaN ordinal output sequence (1). This results in output NaN sequences of plus or minus sign followed by NANS or NANQ instead of plus or minus sign followed by NANS(1) or NANQ(1). All other NaN ordinal sequences are explicitly output.

ALL Formatted output functions which produce special NaN output sequences omit the NaN ordinal output sequence for all NaN values. This results in output NaN sequences of plus or minus sign followed by NANS or NANQ instead of plus or minus sign followed by NANS(n) or NANQ(n) for all NaN values.

Note: _AIX_NAN_COMPATIBILITY does not affect the formatting of DFP NAN values. It affects only the formatting of BFP NAN values.

Vector types and the fprintf family of formatted output functions: The fprintf family functions support character, integer, and floating-point vector data types in the output conversion specification. The vector value is displayed in the following general form:

```
Value1Cvalue2C...CValueN
```

where C is a separator character optionally defined in flag characters, and there can be 2, 4, 8, or 16 output values depending on the optional prefix v, vh, hv, vl, lv, vll, llv, vL, or Lv. Each value is formatted according to the conversion specifier.

The sprintf() function is available to C applications in a stand-alone System Programming C (SPC) Environment.

Usage notes

1. FLOAT(HEX) normalizes differently than FLOAT(IEEE). FLOAT(HEX) produces output in 0x0.hhhhhp+/-dd format, not in the 0x1.hhhhhhp+/-dd format.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, fprintf(), printf(), and sprintf() return the number of characters output. The ending NULL character is not counted.

If unsuccessful, they return a negative value.

Example

CELEBF30

```
/* CELEBF30

   This example prints data using &printf. in a variety of
   formats.

 */
#include <stdio.h>

int main(void)
{
   char ch = 'h', *string = "computer";
   int count = 234, hex = 0x10, oct = 010, dec = 10;
   double fp = 251.7366;
   unsigned int a = 12;
   float b = 123.45;
   int c;
   void *d = "a";

   printf("the unsigned int is %u\n\n",a);

   printf("the float number is %g, and %G\n\n",b,b);

   printf("RAY%n\n\n",&c);

   printf("last line prints %d characters\n\n",c);

   printf("Address of d is %p\n\n",d);

   printf("%d   %+d    %06d     %X    %x     %o\n\n",
      count, count, count, count, count, count);

   printf("1234567890123%n4567890123456789\n\n", &count);

   printf("Value of count should be 13; count = %d\n\n", count);

   printf("%10c%5c\n\n", ch, ch);

   printf("%25s\n%25.4s\n\n", string, string);

   printf("%f    %.2f    %e    %E\n\n", fp, fp, fp, fp);

   printf("%i    %i     %i\n\n", hex, oct, dec);
}
```

Output

```
the unsigned int is 12

the float number is 123.45 and 123.45

RAY

last line prints 3 characters

Address of d is DD72F9

234   +234    000234     EA    ea     352

12345678901234567890123456789

Value of count should be 13; count = 13

         h    h
```

```
                 computer
                     comp

251.736600    251.74    2.517366e+02    2.517366E+02

16    8     10
```

CELEBF31

```
/* CELEBF31
   The following example illustrates the use of printf() to print
   fixed-point decimal data types.
   This example works under C only, not C++.
 */
#include <stdio.h>
#include <decimal.h>

decimal(10,2) pd01 = -12.34d;
decimal(12,4) pd02 = 12345678.9876d;
decimal(31,10) pd03 = 123456789013579246801.9876543210d;

int main(void) {
  printf("pd01 %%D(10,2)      = %D(10,2)\n", pd01);
  printf("pd02 %%D( 12 , 4 )  = %D( 12 , 4 )\n", pd02);

  printf("pd01 %%010.2D(10,2) = %010.2D(10,2)\n", pd01);
  printf("pd02 %%20.2D(12,4)  = %20.2D(12,4)\n", pd02);
  printf("\n Give strange result if the specified size is wrong!\n");
  printf("pd03 %%D(15,3)      = %D(15,3)\n\n", pd03);
}
```

Output

```
pd01 %D(10,2)      = -12.34
pd02 %D( 12 , 4 )  = 12345678.9876
pd01 %010.2D(10,2) = -000012.34
pd02 %20.2D(12,4)  =          12345678.98

Give strange result if the specified size is wrong!
pd03 %D(15,3)      = -123456789013.579
```

CELEBF32

```
/* CELEBF32
   This example illustrates the use of sprintf() to format and print
   various data.
 */
#include <stdio.h>

char buffer[200];
int i, j;
double fp;
char *s = "baltimore";
char c;

int main(void)
{
   c = 'l';
   i = 35;
   fp = 1.7320508;

   /* Format and print various data */
   j = sprintf(buffer, "%s\n", s);
   j += sprintf(buffer+j, "%c\n", c);
   j += sprintf(buffer+j, "%d\n", i);
   j += sprintf(buffer+j, "%f\n", fp);
   printf("string:\n%s\ncharacter count = %d\n", buffer, j);
}
```

Output

```
string:
Baltimore
l
35
1.732051

character count = 24
```

CELEBF90

```
/* CELEBF90
   The following example illustrates the use of printf() to print
   vector data types.
 */
#include <stdio.h>

vector signed char s8 =
                {'a','b',' ','d','e','f','g','h',
                 'i','j','k','l','m','!','o','p'};
vector unsigned short u16 = {1,2,3,4,5,6,7,8};
vector signed int s32 = {1, 2, 3, 99};
vector unsigned long long u64 = {1, 2};
vector double d64 = {0.1, 1.2};

int main(void)
{
   printf("s8 = %vc\n", s8);
   printf("s8 = %,vc\n", s8);
   printf("u16 = %vhu\n", u16);
   printf("s32 = %,2lvd\n", s32);
   printf("u64 = %vllu\n", u64);
   printf("d64 = %vLf\n", d64);
}
```

Output

```
s8 = ab defghijklm!op
s8 = a,b, ,d,e,f,g,h,i,j,k,l,m,!,o,p
u16 = 1 2 3 4 5 6 7 8
s32 =  1, 2, 3,99
u64 = 1 2
d64 = 0.100000 1.200000
```

__fpurge() — Discard pending data in a stream

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	None

Format

```
#include <stdio.h>
#include <stdio_ext.h>

void __fpurge(FILE *stream);

#define _OPEN_SYS_UNLOCKEKD 1
#include <stdio.h>
#include <stdio_ext.h>

void __fpurge_unlocked(FILE *stream);
```

General description

The _fpurge() function requests that any pending data in the stream be discarded.

After a call to __fpurge(), if stream is currently reading, any data that has been read from the system but not yet presented to the application will be discarded. Similarly, any data that has been pushed back into the steam with ungetc() will also be discarded.

After a call to __fpurge(), if stream is currently writing, any data that the application has requested to be written, but has not yet been flushed to an output device will be discarded. Any data that is written to the buffer after a call to __fpurge() is destined to be written out, to the block where the discarded data was originally intended to be placed, either explicitly via fflush() or implicity once the buffer is full.

The __fpurge_unlocked() function is equivalent to the __fpurge() function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the flockfile() or ftrylockfile() function.

Usage note

The __fpurge() function is allowed to be called on UNIX files only. Calling this function on any other type of file will not cause pending data in the buffer to be discarded. The function will return and result in errno being set to a nonzero value.

Returned value

The _fpurge() function returns no values.

An application wishing to check for error situations should set errno to 0, then call __fpurge(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
Description

EBADF
The stream specified by *stream* is not valid.

Example

CELEBF86

```
/* CELEBF86

   This example purges pending data in the I/O buffer.

*/

#include <stdio.h>
#include <errno.h>
#include <stdio_ext.h>

void main(int argc,char** argv){
   char *bufflush="data will be written into file";
   char *bufpurge="data will be not written into file";
   FILE *fp=fopen("./myfile","a");
   if(NULL==fp){
      perror("failed to open file\n");
      exit(0);
   }
   fwrite(bufflush,strlen(bufflush),1,fp);
   fflush(fp);
   fwrite(bufpurge,strlen(bufpurge),1,fp);
   errno=0;
   __fpurge(fp);
   if(errno!=0)
      perror("call __fpurge() failed\n");
   fclose(fp);
}
```

Output

```
The file "myfile" contains the text - data will be written into file
```

fputc() — Write a character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language environment	both	

Format

```
#include <stdio.h>

int fputc(int c, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fputc_unlocked(int c, FILE *stream);
```

General description

Converts *c* to an `unsigned char` and then writes *c* to the output stream pointed to by *stream* at the current position and advances the file position appropriately. The fputc() function is identical to *putc* but is always a function, because it is not available as a macro.

If the stream is opened with one of the append modes, the character is appended to the end of the stream regardless of the current file position.

The fputc() function is not supported for files opened with `type=record` or `type=blocked`.

fputc() has the same restriction as any write operation for a read immediately following a write, or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fputc_unlocked() is functionally equivalent to fputc() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fputc() returns the character written.

If unsuccessful, fputc() returns EOF.

Example

CELEBF34

```
/* CELEBF34

   This example writes the contents of buffer to a file called
   myfile.dat.
   Because the output occurs as a side effect within the second
   expression of the for statement, the statement body is null.

 */
#include <stdio.h>
#define NUM_ALPHA  26

int main(void)
{
  FILE * stream;
  int i;
  int ch;
  char buffer[NUM_ALPHA + 1] = "abcdefghijklmnopqrstuvwxyz";

  if (( stream = fopen("myfile.dat", "w"))!= NULL )
  {
    /* Put buffer into file */
    for ( i = 0; ( i < sizeof(buffer) ) &&
           ((ch = fputc( buffer[i], stream)) != EOF ); ++i );
    fclose( stream );
  }
  else
    printf( "Error opening myfile.dat\n" );
}
```

fputs() — Write a string

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language environment	both	

Format

```
#include <stdio.h>

int fputs(const char * __restrict__string, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fputs_unlocked(const char * __restrict__string, FILE * __restrict__stream);
```

General description

Writes the string pointed to by *string* to the output stream pointed to by *stream*. It does not write the terminating `\0` at the end of the string.

For a text file, truncation may occur if the record is too long. *Truncation* means that excess characters are discarded after the record is full, up to a control character that ends the line (\n). Characters after the \n start at the next record. For more information, see the section on “Truncation” in *z/OS XL C/C++ Programming Guide*.

fputs() is not supported for files opened with `type=record` or `type=blocked`.

fputs() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fputs_unlocked() is functionally equivalent to fputs() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fputs() returns the number of bytes written.

If unsuccessful, fputs() returns EOF.

Example

CELEBF35

```
/* CELEBF35

   This example writes a string to a stream.

 */
#include <stdio.h>
#define NUM_ALPHA  26

int main(void)
{
  FILE * stream;
  int num;

  /* Do not forget that the '\0' char occupies one character */
  static char buffer[NUM_ALPHA + 1] = "abcdefghijklmnopqrstuvwxyz";

  if ((stream = fopen("myfile.dat", "w")) != NULL )
  {
     /* Put buffer into file */
     if ( (num = fputs( buffer, stream )) != EOF )
     {
       /* Note that fputs() does not copy the \0 character */
       printf( "Total number of characters written to file = %i\n", num );
       fclose( stream );
     }
     else   /* fputs failed */
       printf( "fputs failed" );
  }
  else
     printf( "Error opening myfile.dat" );
}
```

fputwc() — Output a wide-character

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment	both	

Format

Non-XPG4:

```
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wchar_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t fputwc_unlocked(wchar_t wc, FILE *stream);
```

XPG4:

```
#define _XOPEN_SOURCE
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wint_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t fputwc_unlocked(wchar_t wc, FILE *stream);
```

XPG4 and MSE:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wchar_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t fputwc_unlocked(wchar_t wc, FILE *stream);
```

General description

Converts the wide character specified by *wc* to a multibyte character and writes it to the output stream pointed to by *stream*, at the position indicated by the associated file position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests or if the stream was opened with append mode, the character is appended to the output stream.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. Using non-wide-character functions with fputwc() results in undefined behavior.

fputwc() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fputwc_unlocked() is functionally equivalent to fputwc() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then the compiler assumes that your program is using the XPG4 variety of the fputwc() function, unless you also define the _MSE_PROTOS feature test macro. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the fputwc() function is:

```
wint_t fputwc(wint_t wc, FILE *stream);
```

The difference between this variety and the MSE variety of the fputwc() function is that the first parameter has type wint_t rather than type wchar_t.

Returned value

If successful, fputwc() returns the wide character written.

If a write error occurs, the error indicator for the stream is set and WEOF is returned. If an encoding error occurs during conversion from wide character to a multibyte character, the value of the macro EILSEQ is stored in errno and WEOF is returned.

Example

CELEBF36

```
/* CELEBF36 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
   FILE    *stream;
   wchar_t *wcs = L"This test string should not cause a WEOF condition";
   int     i;
   int     rc;

   if ((stream = fopen("myfile.dat", "w")) == NULL) {
      printf("Unable to open file.\n");
      exit(1);
   }

   for (i=0; wcs[i] != L'\0'; i++) {
      errno = 0;
      if ((rc = fputwc(wcs[i], stream)) == WEOF) {
         printf("Unable to fputwc() the wide character.\n");
         printf("wcs[%d] = 0x%lx\n", i, wcs[i]);
         if (errno == EILSEQ)
            printf("An invalid wide character was encountered.\n");
         exit(1);
      }
   }

   fclose(stream);
}
```

fputws() — Output a wide-character string

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <wchar.h>

int fputws(const wchar_t * __restrict__wcs, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fputws_unlocked(const wchar_t * __restrict__wcs, FILE * __restrict__stream);
```

General description

Converts the wide-character string pointed to by *wcs* to a multibyte character string and writes it to the stream pointed to by *stream*, as a multibyte character string. The terminating NULL byte is not written.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. Using non-wide-character functions with fputws() results in undefined behavior.

fputws() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fputws_unlocked() is functionally equivalent to fputws() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fputws() returns a nonnegative value.

If a *stream* error occurs, fputws() returns -1 and the error indicator for the stream is set.

If an *encoding* error occurs, fputws() returns -1 and the value of the macro EILSEQ is stored in errno. An encoding error is one that occurs when converting a wide character to a multibyte character.

Example

CELEBF37

```
/* CELEBF37 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
   FILE    *stream;
   wchar_t *wcs = L"This test string should not return -1";
   int     rc;

   if ((stream = fopen("myfile.dat", "w")) == NULL) {
      printf("Unable to open file.\n");
      exit(1);
   }

   errno = 0;
   rc = fputws(wcs, stream);

   if (rc == EOF) {
      printf("Unable to complete fputws() function.\n");
      if (errno == EILSEQ)
         printf("An invalid wide character was encountered.\n");
      exit(1);
   }

   fclose(stream);
}
```

Related information

- “stdio.h” on page 68
- “wchar.h” on page 85

fread() — Read items

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language environment	both	

Format

```
#include <stdio.h>

size_t fread(void * __restrict__buffer, size_t size, size_t count, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

size_t fread_unlocked(void * __restrict__buffer, size_t size,
                      size_t count, FILE * __restrict__stream);
```

General description

Reads up to *count* items of *size* length from the input stream pointed to by *stream* and stores them in the given *buffer*. The file position indicator advances by the number of bytes read.

If there is an error during the read operation, the file position indicator is undefined. If a partial element is read, the element's value is undefined.

When you are using fread() for record I/O, set *size* to 1 and *count* to the maximum expected length of the record, to obtain the number of bytes. Only one record is read, regardless of *count*, when using record I/O.

When you are using fread() for blocked I/O, set *size* to 1 and *count* to the maximum expected length of the block, to obtain the number of bytes. Only one block is read, regardless of *count*, when using blocked I/O.

fread() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fread_unlocked() is functionally equivalent to fread() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

fread() returns the number of complete items successfully read.

If *size* or *count* is 0, fread() returns 0, and the contents of the array and the state of the stream remain unchanged. For record I/O and blocked I/O, it is possible that the number of complete items can be less than *count*. However, this result does not necessarily indicate that an error has occurred.

If the Physical File System does not support simple reads from directories, fread() will return 0 if it is used for a directory. Users should use Opendir() and readdir() instead.

The ferror() and feof() functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBF38

```
/* CELEBF38

   This example attempts to read NUM_ALPHA characters from the
   file myfile.dat.
   If there are any errors with either &fread. or &fopen., a
   message is printed.

 */
#include <stdio.h>
#define NUM_ALPHA  26

int main(void)
{
  FILE * stream;
  int num;       /* number of characters read from stream */

  /* Do not forget that the '\0' char occupies one character too! */
  char buffer[NUM_ALPHA + 1];
  buffer[NUM_ALPHA] = '\0';

  if (( stream = fopen("myfile.dat", "r"))!= NULL )
  {
    num = fread( buffer, sizeof( char ), NUM_ALPHA, stream );
    if (num == NUM_ALPHA) {  /* fread success */
      printf( "Number of characters read = %i\n", num );
      printf( "buffer = %s\n", buffer );
      fclose( stream );
    }
    else {  /* fread failed */
      if ( ferror(stream) )         /* possibility 1 */
        printf( "Error reading myfile.dat" );
      else if ( feof(stream)) {     /* possibility 2 */
        printf( "EOF found\n" );
        printf( "Number of characters read %d\n", num );
        printf( "buffer = %.*s\n", num, buffer);
      }
    }
  }
  else
    printf( "Error opening myfile.dat" );
}
```

__freadable() — Determine if a stream is open for reading

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __freadable(FILE *stream);
```

General description

The __freadable() function determines if the specified stream has been opened for reading.

Returned value

The __freadable() function returns nonzero if the stream is opened for reading. Otherwise, the __freadable() function returns 0. If an error has occurred, __freadable() function returns 0 and sets errno to nonzero.

An application wishing to check for error situations should set errno to 0, then call __freadable(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
    Description

EBADF
    The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
   FILE *f;
   char filename[FILENAME_MAX] = "myfile.dat";
   char data[128] = "There are 34 bytes in this buffer\n";
   int datalen = strlen(data);
   size_t n = 0;

   f = fopen(filename,"wb+");
   if (f == NULL) {
      perror("fopen() failed\n");
      return;
   }

   if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
   if (__freadable(f)) printf("Reading is allowed on the open stream\n");

   n = fputs(data,f);
   if (n == EOF) {
      perror("fputs() failed\n");
      return;
   }
   n = __fpending(f);
   printf("There are %d bytes in the buffer pending to be written\n", n);

   if (__fwriting(f)) printf("The last operation on the stream was a write\n");

   rewind(f);

   n = fgetc(f);

   n = __freadahead(f);
   printf("There are %d bytes remaining to be read from the buffer\n", n);

   if (__freading(f)) printf("The last operation on the stream was a read\n");

   return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

Related information

__freadahead() — Retrieve number of bytes remaining in input buffer

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>
#include <stdio_ext.h>

size_t __freadahead(FILE *stream);

#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

size_t __freadahead_unlocked(FILE *stream);
```

General description

The __freadahead() function retrieves the number of bytes remaining to be read in the input buffer that is associated with the specified binary stream. When the stream is opened for text processing, __fpending retrieves the number of characters pending to be written.

The __freadahead_unlocked() function is equivalent to the __freadahead() function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the flockfile() or ftrylockfile() function.

Usage notes

1. If __freadahead() is called when the stream is currently writing, __freadahead() returns 0 and sets errno to a nonzero value.
2. If __freadahead() is called on a data set opened `type=record`, __freadahead() returns 0 and sets errno to a nonzero value.
3. For text data sets, any newline characters representing record boundaries will be included in the returned value.

Returned value

The __freadahead() functions return the number of bytes or characters remaining to be read in the current buffer, depending on the type of stream. Otherwise, the __freadahead() functions return 0. If an error has occurred, __freadahead() functions return 0 and set errno to nonzero.

When the stream is wide-oriented text, the __freadahead() function returns a value measured in wide characters.

An application wishing to check for error situations should set errno to 0, then call __freadahead(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
Description

EBADF
The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
   FILE *f;
   char filename[FILENAME_MAX] = "myfile.dat";
   char data[128] = "There are 34 bytes in this buffer\n";
   int datalen = strlen(data);
   size_t n = 0;

   f = fopen(filename,"wb+");
   if (f == NULL) {
      perror("fopen() failed\n");
      return;
   }

   if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
   if (__freadable(f)) printf("Reading is allowed on the open stream\n");

   n = fputs(data,f);
   if (n == EOF) {
      perror("fputs() failed\n");
      return;
   }

   n = __fpending(f);
   printf("There are %d bytes in the buffer pending to be written\n", n);

   if (__fwriting(f)) printf("The last operation on the stream was a write\n");

   rewind(f);

   n = fgetc(f);

   n = __freadahead(f);
   printf("There are %d bytes remaining to be read from the buffer\n", n);

   if (__freading(f)) printf("The last operation on the stream was a read\n");

   return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

__freading() — Determine if last operation on stream is a read operation

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __freading(FILE *stream);
```

```
#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

int __freading_unlocked(FILE *stream);
```

General description

The __freading() function determines if the last operation on the specified stream is a read operation or if the specified stream is open for read-only.

The __freading_unlocked() function is equivalent to the __freading() function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

The __freading() functions return nonzero when the last operation is a read operation or the stream is open for read-only. Otherwise, the __freading() functions return 0. If an error has occurred, __freading() functions return 0 and set errno to nonzero.

An application wishing to check for error situations should set errno to 0, then call __freading(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
Description

EBADF
The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
   FILE *f;
   char filename[FILENAME_MAX] = "myfile.dat";
   char data[128] = "There are 34 bytes in this buffer\n";
   int datalen = strlen(data);
   size_t n = 0;

   f = fopen(filename,"wb+");
   if (f == NULL) {
      perror("fopen() failed\n");
      return;
   }

   if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
   if (__freadable(f)) printf("Reading is allowed on the open stream\n");

   n = fputs(data,f);
   if (n == EOF) {
      perror("fputs() failed\n");
      return;
   }

   n = __fpending(f);
   printf("There are %d bytes in the buffer pending to be written\n", n);

   if (__fwriting(f)) printf("The last operation on the stream was a write\n");

   rewind(f);

   n = fgetc(f);

   n = __freadahead(f);
   printf("There are %d bytes remaining to be read from the buffer\n", n);

   if (__freading(f)) printf("The last operation on the stream was a read\n");

   return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

free() — Free a block of storage

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

void free(void *ptr);
```

General description

Frees a block of storage pointed to by *ptr*. The *ptr* variable points to a block previously reserved with a call to calloc(), malloc(), realloc(), or strdup(). The number of bytes freed is the number of bytes specified when you reserved (or reallocated, in the case of realloc()), the block of storage. If *ptr* is NULL, free() simply returns without freeing anything. Since *ptr* is passed by value free() will not set *ptr* to NULL after freeing the memory to which it points.

This function is also available to C applications in a stand-alone System Programming C (SPC) Environment.

Note: Attempting to free a block of storage not allocated with calloc(), malloc(), realloc(), strdup(), or previously freed storage, can affect the subsequent reserving of storage and lead to an abend.

Special behavior for C++: Under C++, you cannot use free() with an item that was allocated using the C++ new keyword.

Returned value

free() returns no values.

Example

```
/* This example illustrates the use of calloc() to allocate storage for x
   array elements and then calls free() to free them.
 */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
  long * array;    /* start of the array */
  long * index;    /* index variable     */
  int    i;        /* index variable     */
  int  num;        /* number of entries of the array */

  printf( "Enter the size of the array\n" );
  scanf( "%i", &num );

  /* allocate num entries */
  if ( (index = array = (long *)calloc( num, sizeof( long ))) != NULL )
  {
⋮
   /*  do something with the array  */
    free( array );                        /* deallocates array  */
  }
  else
  { /* Out of storage */
    printf( "Error: out of storage\n" );
    abort();
  }
}
```

freeaddrinfo() — Free addrinfo storage

Standards

Standards / Extensions	C or C++	Dependencies
RFC2553 Single UNIX Specification, Version 3	both	z/OS V1R4

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <sys/socket.h>
#include <netdb.h>

void *freeaddrinfo(struct addrinfo *ai);
```

SUSV3

```
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>

void *freeaddrinfo(struct addrinfo *ai);
```

General description

The freeaddrinfo() function frees one or more addrinfo structures returned by getaddrinfo(), along with any additional storage associated with those structures. If the ai_next field of the structure is not null, the entire list of structures is freed.

Returned value

No return value is defined.

freopen() — Redirect an open file

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdio.h>

FILE *freopen(const char *__restrict__filename, const char *__restrict__mode,
              FILE *__restrict__stream);
```

General description

Closes the file currently associated with *stream* and pointed to by *stream*, opens the file specified by the *filename*, and then associates the stream with it.

The freopen() function opens the new file with the type of access requested by the *mode* argument. The *mode* argument is used as in the fopen() function. See "fopen() — Open a file" on page 565 for a description of the *mode* parameter.

You can also use the freopen() function to redirect the standard stream files `stdin`, `stdout`, and `stderr` to files that you specify. The file pointer input to the freopen() function must point to a valid open file. If the file pointer has been closed, the behavior is undefined.

You could use the following freopen() call to redirect `stdout` to a memory file `a.b`:

```
freopen("a.b","wb,type=memory",stdout);
```

If *filename* is an empty string, freopen() closes the file and reuses the original file name. For details on how the file name and open mode is interpreted, see *z/OS XL C/C++ Programming Guide*.

A standard stream can be opened by default to a type of file not available to a general fopen(). This is true for standard streams under CICS, and also true for the default stderr, when running a non-POSIX Language Environment application.

The following statement uses freopen() to have `stdin` use binary mode instead of text mode:

```
fp = freopen("", "rb", stdin);
```

You can use the same empty string method to change the mode from binary back to text. This method is not allowed for:

- The default CICS data queues used by the standard streams under CICS
- The Language Environment Message File (MSGFILE), which is the default for `stderr`
- z/OS UNIX files.
- -CELQPIPI MSGRTN file, which is the default for stderr if MSGRTN service routine is specified.

Note: Using the empty string method is included in the SAA C definition, but not in the ANSI C standard.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, freopen() returns the value of *stream*, the same value that was passed to it, and clears both the error and EOF indicators associated with the stream.

A failed attempt to close the original file is ignored.

If an error occurs in reopening the requested file, freopen() closes the original file, and returns a NULL pointer value.

Special behavior for large z/OS UNIX files: The following is the possible value of errno:

Error Code
Description

EOVERFLOW
The named file is a regular file and the size of the file cannot be represented correctly in an object of type off_t.

Example

This example illustrates the z/OS XL C extension that allows you to change characteristics of a file by reopening it.

```
#include <stdio.h>

int main(void)
{
   FILE *stream, *stream2;

   stream = fopen("myfile.dat","r");
   stream2 = freopen("", "w+", stream);
}
```

This example closes the `stream` data stream and reassigns its stream pointer:

```
#include <stdio.h>

int main(void)
{
   FILE *stream, *stream2;

   stream = fopen("myfile.dat","r");
   stream2 = freopen("myfile2.dat", "w+", stream);
}
```

Note: `stream` and `stream2` will have the same value.

frexp(), frexpf(), frexpl() — Extract mantissa and exponent of the floating-point value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double frexp(double x, int *expptr);
float frexp(float x, int *expptr);              /* C++ only */
long double frexp(long double x, int *expptr);   /* C++ only */
float frexpf(float x, int *expptr);
long double frexpl(long double x, int *expptr);
```

General description

Breaks down the floating-point value *x* into a component *m* for the normalized fraction component and another term *n* for the exponent, such that the absolute value of *m* is greater than or equal to 0.5 and less than 1.0 or equal to 0, and $x = m * 2^n$. The function stores the integer exponent *n* at the location to which *expptr* points.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Restriction: The frexpf() and frexpl() functions do not support the _FP_MODE_VARIABLE feature test macro.

Returned value

Returns the normalized fraction *m*. If *x* is 0, the function returns 0 for both the fraction and exponent. The fraction has the same sign as the argument *x*. The result of the function cannot have a range error.

Example

CELEBF41

```
/* CELEBF41

   This example decomposes the floating-point value of x, 16.4, into its
   normalized fraction 0.5125, and its exponent 5.
   It stores the mantissa in y and the exponent in n.

 */

#include <math.h>
```

```
#include <stdio.h>

int main(void)
{
   double x, m;
   int n;

   x = 16.4;
   m = frexp(x, &n);

   printf("The fraction is %lf and the exponent is %d\n", m, n);
}
```

Output

```
The mantissa is 0.512500 and the exponent is 5
```

Related information

frexpd32(), frexpd64(), frexpd128() — Extract mantissa and exponent of the decimal floating-point value

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  frexpd32(_Decimal32 x, int *expptr);
_Decimal64  frexpd64(_Decimal64 x, int *expptr);
_Decimal128 frexpd128(_Decimal128 x, int *expptr);

_Decimal32  frexp(_Decimal32 x, int *expptr);   /* C++ only */
_Decimal64  frexp(_Decimal64 x, int *expptr);   /* C++ only */
_Decimal128 frexp(_Decimal128 x, int *expptr);  /* C++ only */
```

General description

Breaks down the decimal floating-point value *x* into a component *m* for the normalized fraction component and another term *n* for the exponent, such that the absolute value of *m* is greater than or equal to 0.1 and less than 1.0 or equal to 0, and $x = m * 10^{n}$. The function stores the integer exponent *n* at the location to which *expptr* points.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the normalized fraction m. If *x* is 0, the function returns 0 for both the fraction and exponent. The fraction has the same sign as the argument *x*. The result of the function cannot have a range error.

Example

```
/* CELEBF81

   This example illustrates the frexpd64() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal64 x, m;
   int n;

   x = 164.5DD;
   m = frexpd64(x, &n);

   printf("The fraction of %Df is %Df and the exponent is %d\n",
          x, m, n);
}
```

fscanf(), scanf(), sscanf() — Read and format data

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 C/C++ DFP Language environment	both	z/OS V1R8

Format

```
#include <stdio.h>

int fscanf(FILE *__restrict__stream, const char *__restrict__format-string, ...);
int scanf(const char *__restrict__format-string, ...);
int sscanf(const char *__restrict__buffer, const char *__restrict__format, ...);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>
```

```
int fscanf_unlocked(FILE *__restrict__stream,
                    const char *__restrict__format-string, ...);
int scanf_unlocked(const char *__restrict__format-string, ...);
```

General description

These three related functions are referred to as the fscanf family.

Reads data from the current position of the specified *stream* into the locations given by the entries in the argument list, if any. The argument list, if it exists, follows the format string. The fscanf() function cannot be used for a file opened with `type=record` or `type=blocked`.

The scanf() function reads data from the standard input stream `stdin` into the locations given by each entry in the argument list. The argument list, if it exists, follows the format string. scanf() *cannot* be used if `stdin` has been reopened as a `type=record` or `type=blocked` file.

The sscanf() function reads data from *buffer* into the locations given by *argument-list*. Reaching the end of the string pointed to by *buffer* is equivalent to fscanf() reaching EOF. If the strings pointed to by *buffer* and *format* overlap, behavior is undefined.

fscanf() and scanf() have the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

For all three functions, each entry in the argument list must be a pointer to a variable of a type that matches the corresponding conversion specification in *format-string*. If the types do not match, the results are undefined.

For all three functions, the *format-string* controls the interpretation of the argument list. The *format-string* can contain multibyte characters beginning and ending in the initial shift state.

The format string pointed to by *format-string* can contain one or more of the following:

- White space characters, as specified by isspace(), such as blanks and newline characters. A white space character causes fscanf(), scanf(), and sscanf() to read, but not to store, all consecutive white space characters in the input up to the next character that is not white space. One white space character in *format-string* matches any combination of white space characters in the input.
- Characters that are not white space, except for the percent sign character (%). A non-white space character causes fscanf(), scanf(), and sscanf() to read, but not to store, a matching non-white space character. If the next character in the input stream does not match, the function ends.
- Conversion specifications which are introduced by the percent sign (%) or the sequence (%n$) where n is a decimal integer in the range [1,NL_ARGMAX]. A conversion specification causes fscanf(), scanf(), and sscanf() to read and convert characters in the input into values of a conversion specifier. The value is assigned to an argument in the argument list.

All three functions read *format-string* from left to right. Characters outside of conversion specifications are expected to match the sequence of characters in the input stream; the matched characters in the input stream are scanned but not stored. If a character in the input stream conflicts with *format-string*, the function ends, terminating with a "matching" failure. The conflicting character is left in the input stream as if it had not been read.

When the first conversion specification is found, the value of the first *input field* is converted according to the conversion specification and stored in the location specified by the first entry in the argument list. The second conversion specification converts the second input field and stores it in the second entry in the argument list, and so on through the end of *format-string*.

fscanf_unlocked() is functionally equivalent to fscanf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

scanf_unlocked() is functionally equivalent to scanf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

An *input field* is defined as:

- All characters until a white space character (space, tab, or newline) is encountered
- All characters until a character is encountered that cannot be converted according to the conversion specification
- All characters until the field *width* is reached.

If there are too many arguments for the conversion specifications, the extra arguments are evaluated but otherwise ignored. The results are undefined if there are not enough arguments for the conversion specifications.

Syntax of Conversion Specification for fscanf(), scanf(), and sscanf()

```

```

Each field of the conversion specification is a single character or a number signifying a particular format option. The *conversion specifier*, which appears after the last optional format field, determines whether the input field is interpreted as a character, a string, or a number. The simplest conversion specification contains only the percent sign and a *conversion specifier* (for example, `%s`).

Each field of the format specification is discussed in detail below.

Other than conversion specifiers, you should avoid using the percent sign (`%`), except to specify the percent sign: `%%`. Currently, the percent sign is treated as the start of a conversion specifier. Any unrecognized specifier is treated as an ordinary sequence of characters. If, in the future, z/OS XL C/C++ permits a new conversion specifier, it could match a section of your format string, be interpreted incorrectly, and result in undefined behavior. See Table 32 on page 630 for a list of conversion specifiers.

Flag characters: The *flag* characters in Table 31 are used for assignment-suppressing and separator for vector type input conversion. Notice that more than one *flag* can appear in a format specification. This is an optional field.

Table 31. Flag Characters for fscanf Family

Flag	Meaning	Default
*	Suppresses assignment of the next input field, which is interpreted as a field of the specified conversion specifier. The field is scanned but not stored.	

Table 31. Flag Characters for fscanf Family (continued)

Flag	Meaning	Default
, ; : _	Indicates the separator character between each two components in the vector data type conversion. Only one separator character can be specified.	The default value for the separator character is a space (' '), unless the c format is being used. For the c format, there is no separator at all if no separator character is specified.

width is a positive decimal integer controlling the maximum number of characters to be read. No more than *width* characters are converted and stored at the corresponding *argument*.

Fewer than *width* characters are read if a white space character (space, tab, or newline), or a character that cannot be converted according to the given format occurs before *width* is reached.

Optional prefix: The optional prefix characters used to indicate the size of the argument expected or size of a single value in a vector data type input conversion are explained:

Prefix	Meaning
h	Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to short or unsigned short.
hh	Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to signed char or unsigned char.
l	(ell) Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to long or unsigned long; the following a, A, e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to double; and the following c, s, or [conversion specifier applies to an argument with type pointer to wchar_t.
ll	(ell-ell) Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to long long or unsigned long long.
j	Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to intmax_t or uintmax_t.
t	Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to ptrdiff_t or the corresponding unsigned type.
z	Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to size_t or the corresponding signed integer type.
D	Specifies that the e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to _Decimal64 float.
DD	Specifies that the e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to _Decimal128 float.
H	Specifies that the e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to _Decimal32 float.

L Specifies that the `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to an argument with type pointer to long double.

v Specifies that a following `c`, `d`, `i`, `u`, `o`, `x`, or `X` conversion specifier applies to an argument with type pointer to `vector signed char`, `vector unsigned char`, or `vector bool char`.

vh, hv Specifies that a following `d`, `i`, `u`, `o`, `x`, or `X` conversion specifier applies to an argument with type pointer to `vector signed short`, `vector unsigned short`, or `vector bool short`.

vl, lv Specifies that a following `d`, `i`, `u`, `o`, `x`, or `X` conversion specifier applies to an argument with type pointer to `vector signed int`, `vector unsigned int`, or `vector bool int`.

vll, llv Specifies that a following `d`, `i`, `u`, `o`, `x`, or `X` conversion specifier applies to an argument with type pointer to `vector signed long long`, `vector unsigned long long`, or `vector bool long long`.

vL, Lv specifies that a following `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to an argument with type pointer to `vector double`.

Conversion specifier: Table 32 explains the valid conversion specifiers and their meanings are in.

Table 32. Conversion Specifiers in fscanf Family

Conversion Specifier	Type of Input Expected	Type of Argument
d	Decimal integer	Pointer to `int`
o	Octal integer	Pointer to `unsigned int`
x X	Hexadecimal integer	Pointer to `unsigned int`
i	Decimal, hexadecimal, or octal integer	Pointer to `int`
u	Unsigned decimal integer	Pointer to `unsigned int`
e E f F g G	Floating-point value consisting of an optional sign (+ or -); a series of one or more decimal digits possibly containing a decimal-point; and an optional exponent (e or E) followed by a possibly signed integer value	Pointer to `float`
a A	Matches an optionally signed floating-point number, infinity, or NaN, whose format is the same as expected for the subject sequence of strtod(). In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to float.	Pointer to `float`
D(n,p)	Fixed-point value consisting of an optional sign (+ or -); a series of one or more decimal digits possibly containing a decimal-point.	Pointer to decimal
c	Sequence of one or more characters as specified by field width; white space characters that are ordinarily skipped are read when `%c` is specified. No terminating null is added.	Pointer to `char` large enough for input field.

Table 32. Conversion Specifiers in fscanf Family (continued)

Conversion Specifier	Type of Input Expected	Type of Argument
C or lc	The input is a sequence of one or more multibyte characters as specified by the field width, beginning in the initial shift state. Each multibyte character in the sequence is converted to a wide character as if by a call to the mbrtowc() function. The conversion state described by the mbstate_t object is initialized to zero before the first multibyte character is converted. The corresponding argument is a pointer to the initial element of an array of `wchar_t` large enough to accept the resulting sequence of wide characters. No NULL wide character is added.	`C` or `lc` uses a pointer to `wchar_t`.
s	Like `c`, a sequence of bytes of type `char` (signed or unsigned), except that white space characters are not allowed, and a terminating null is always added.	Pointer to character array large enough for input field, plus a terminating NULL character (`\0`) that is automatically appended.
S or ls	A sequence of multibyte characters that begins and ends in the initial shift state. Each multibyte character in the sequence is converted to a wide character as if by a call to the mbrtowc() function, with the conversion state described by the mbstate_t object initialized to zero before the first multibyte character is converted. The corresponding argument is a pointer to the initial array of `wchar_t` large enough to accept the sequence and the terminating NULL wide character, which is added automatically.	`S` or `ls` uses a pointer to `wchar_t` string.
n	No input read from *stream* or buffer.	Pointer to `int`, into which is stored the number of characters successfully read from the *stream* or buffer up to that point in the call to either fscanf() or to scanf().
p	Pointer to `void` converted to series of characters. For the specific format of the input, see the individual system reference guides.	Pointer to `void`.

Table 32. Conversion Specifiers in fscanf Family (continued)

Conversion Specifier	Type of Input Expected	Type of Argument
[	A non-empty sequence of bytes to be matched against a set of expected bytes (the *scanset*), which form the conversion specification. White space characters that are ordinarily skipped are read when %[is specified. Consider the following situations: [^*bytes*]. In this case, the scanset contains all bytes that do not appear between the circumflex and the right square bracket. []abc] *or* [^]abc.] In both these cases the right square bracket is included in the scanset (in the first case:]abc and in the second case, *not*]abc) [a–z] In EBCDIC The – is in the scanset, the characters b through y are *not* in the scanset; in ASCII The – is *not* in the scanset, the characters b through y are. The code point for the square brackets ([and]) and the caret (^) vary among the EBCDIC encoded character sets. The default C locale expects these characters to use the code points for encoded character set Latin-1 / Open Systems 1047. Conversion proceeds one byte at a time: there is no conversion to wide characters.	Pointer to the initial byte of an array of char, signed char, or unsigned char large enough to accept the sequence and a terminating byte, which will be added automatically.
l[	If an l length modifier is present, input is a sequence of multibyte characters that begins and ends in the initial shift state. Each multibyte character in the sequence is converted to a wide character as if by a call to the mbrtowc() function, with the conversion state described by the mbstate_t object initialized to zero before the first multibyte character is converted. The corresponding argument is a pointer to the initial array of wchar_t large enough to accept the sequence and the terminating NULL wide character, which is added automatically.	l[uses a pointer to wchar_t string

When the LC_SYNTAX category is set using setlocale(), the format strings passed to the fscanf(), scanf(), or sscanf() functions must use the same encoded character set as is specified for the LC_SYNTAX category.

To read strings not delimited by space characters, substitute a set of characters in square brackets ([ ]) for the s (string) conversion specifier. The corresponding input field is read up to the first character that does not appear in the bracketed character set. If the first character in the set is a logical not (¬), the effect is reversed: the input field is read up to the first character that does appear in the rest of the character set.

To store a string without storing an ending NULL character (\0), use the specification %*a*c, where *a* is a decimal integer. In this instance, the c conversion specifier means that the argument is a pointer to a character array. The next *a* characters are read from the input stream into the specified location, and no NULL character is added.

The input for a *%x* conversion specifier is interpreted as a hexadecimal number.

All three functions, fscanf(), scanf(), and sscanf() scan each input field character by character. It might stop reading a particular input field either before it reaches a space character, when the specified *width* is reached, or when the next character cannot be converted as specified. When a conflict occurs between the specification and the input character, the next input field begins at the first unread character. The conflicting character, if there is one, is considered unread and is the first character of the next input field or the first character in subsequent read operations on the input stream.

Special behavior for XPG4.2:

- When the %n$ conversion specification is found, the value of the *input field* is converted according to the conversion specification and stored in the location specified by the nth argument in the argument list. Numbered arguments in the argument list can only be referenced once from *format-string*.
- The *format-string* can contain either form of the conversion specification, that is, % or %n$ but the two forms cannot be mixed within a single *format-string* except that %% or %* can be mixed with the %n$ form.

Floating-point and the fscanf family of formatted input functions: The fscanf family functions match `e`, `E`, `f`, `F`, `g` or `G` conversion specifiers to floating-point number substrings in the input stream. The fscanf family functions convert each input substring matched by an `e`, `E`, `f`, `F`, `g` or `G` conversion specifier to a float, double or long double value depending on a size modifier preceding the `e`, `E`, `f`, `F`, `g` or `G` conversion specifier.

The floating-point value produced is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the fscanf family function. The fscanf family functions use __isBFP() to determine the floating-point mode of invoking threads.

Many z/OS XL C/C++ formatted input functions, including the fscanf family, recognize special infinity and NaN floating-point number input sequences when the invoking thread is in IEEE Binary Floating-Point mode as determined by __isBFP().

- The special sequence for infinity input is an optional plus or minus sign, then the character sequence INF, where the individual characters may be uppercase or lowercase, and then a white space character (space, tab, or newline), a NULL character (`\0`) or EOF.
- The special sequence for NaN input is an optional plus or minus sign, then the character sequence NANS for a signalling NaN or NANQ for a quiet NaN, where the individual characters may be uppercase or lowercase, then an optional NaN ordinal sequence, and then a a white space character (space, tab, or newline), a NULL character (`\0`) or EOF.

  For binary floating point NANs: A NaN ordinal sequence is a left-parenthesis character, “(”, followed by a digit sequence representing an integer n, where 1 <= n <= INT_MAX-1, followed by a right-parenthesis character, “)”. If the NaN ordinal sequence is omitted, NaN ordinal sequence (1) is assumed. The integer value, n, corresponding to a NaN ordinal sequence determines what IEEE Binary Floating-Point NaN fraction bits are produced by formatted input functions.

For a signalling NaN, these functions produce NaN fraction bits (left to right) by reversing the bits (right to left) of the even integer value 2*n.

For a quiet NaN they produce NaN fraction bits (left to right) by reversing the bits (right to left) of the odd integer value 2*n-1.

For decimal floating point NANs: A NaN ordinal sequence is a left parenthesis character, "(", followed by a decimal digit sequence of up to 6 digits for a _Decimal32 output number, up to 15 digits for a _Decimal64 output value, or up to 33 digits for a _Decimal128 output value, followed by a right parenthesis, ")". If the NaN ordinal sequence is omitted, NaN ordinal sequence "(0)" is assumed. If the NaN ordinal sequence is shorter than 6, 15, or 33 digits, it will be padded on the left with "0" digits so that the length becomes 6, 15, or, 33 digits for _Decimal32, _Decimal64, and _Decimal128 values respectively.

For decimal floating point numbers, the digits are not reversed, and both odd or even NaN ordinal sequences can be specified for either a Quiet NAN or Signalling NAN.

Vector types and the fscanf family of formatted input functions: The fscanf family functions support character, integer, and floating-point vector data types in the input conversion specification. The vector value to be scanned is in the following general form:

```
Value1Cvalue2C...CValueN
```

where C is a separator character optionally defined in flag characters, and there can be 2, 4, 8, or 16 components depending on the optional prefix v, vh, hv, vl, lv, vll, llv, vL, or Lv. Each value is scanned according to the conversion specifier. If the conversion fails in the middle of a vector value, the successful elements will be saved to the vector argument and the other elements in the vector argument will remain unchanged.

Usage note

To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

All three functions, fscanf(), scanf(), and sscanf() return the number of input items that were successfully matched and assigned. The returned value does not include conversions that were performed but not assigned (for example, suppressed assignments). The functions return EOF if there is an input failure before any conversion, or if EOF is reached before any conversion. Thus a returned value of 0 means that no fields were assigned: there was a matching failure before any conversion. Also, if there is an input failure, then the file error indicator is set, which is not the case for a matching failure.

The ferror() and feof() functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Examples

CELEBF42

```
/* CELEBF42

   This example scans various types of data

 */
#include <stdio.h>

int main(void)
{
   int i;
   float fp;
   char c, s[81];

   printf("Enter an integer, a real number, a character "
          "and a string : \n");
   if (scanf("%d %f %c %s", &i, &fp, &c, s) != 4)
      printf("Not all of the fields were assigned\n");
   else
   {
      printf("integer = %d\n", i);
      printf("real number = %f\n", fp);
      printf("character = %c\n", c);
      printf("string = %s\n",s);
   }
}
```

Output

If input is: `12 2.5 a yes`, then output would be:

```
Enter an integer, a real number, a character and a string:
integer = 12
real number = 2.500000
character = a
string = yes
```

CELEBF43

```
/* CELEBF43
   This example converts a hexadecimal integer to a decimal integer.
   The while loop ends if the input value is not a hexadecimal integer.
 */
#include <stdio.h>

int main(void)
{
   int number;

   printf("Enter a hexadecimal number or anything else to quit:\n");
   while (scanf("%x",&number))
      {
      printf("Hexadecimal Number = %x\n",number);
      printf("Decimal Number     = %d\n",number);
      }
}
```

Output

If input is: `0x231 0xf5e 0x1 q`, then output would be:

```
Enter a hexadecimal number or anything else to quit:
Hexadecimal Number = 231
Decimal Number     = 561
Hexadecimal Number = f5e
Decimal Number     = 3934
Hexadecimal Number = 1
Decimal Number     = 1
```

CELEBF44

```
/* CELEBF44
   The next example illustrates the use of scanf() to input fixed-point
   decimal data types. This example works under C only, not C++.
 */
#include <stdio.h>
#include <decimal.h>

decimal(15,4) pd01;
decimal(10,2) pd02;
decimal(5,5) pd03;

int main(void) {
  printf("\nFirst time :-------------------------------\n");
  printf("Enter three fixed-point decimal number\n");
  printf("  (15,4) (10,2) (5,5)\n");
  if (scanf("%D(15,4) %D(10,2) %D(5,5)", &pd01, &pd02, &pd03) != 3) {
    printf("Error found in scanf\n");
  } else {
    printf("pd01 = %D(15,4)\n", pd01);
    printf("pd02 = %D(10,2)\n", pd02);
    printf("pd03 = %D(5,5)\n", pd03);
  }
  printf("\nSecond time :------------------------------\n");
  printf("Enter three fixed-point decimal number\n");
  printf("  (15,4) (10,2) (5,5)\n");
  if (scanf("%D(15,4) %D(10,2) %D(5,5)", &pd01, &pd02, &pd03) != 3) {
    printf("Error found in scanf\n");
  } else {
    printf("pd01 = %D(15,4)\n", pd01);
    printf("pd02 = %D(10,2)\n", pd02);
    printf("pd03 = %D(5,5)\n", pd03);
  }
  return(0);
}
```

Output

```
First time :-------------------------------
Enter three fixed-point decimal number
  (15,4) (10,2) (5,5)
12345678901.2345 -987.6 .24680
pd01 = 12345678901.2345
pd02 = -987.60
pd03 = 0.24680

Second time :------------------------------
Enter three fixed-point decimal number
  (15,4) (10,2) (5,5)
123456789013579.24680 123.4567890 987
pd01 = 12345678901.3579
pd02 = 123.45
pd03 = 0.98700
```

CELEBF46

```
/* CELEBF46
   The next example opens the file myfile.dat for reading and then scans
   this file for a string, a long integer value, a character, and a
   floating-point value.
 */
#include <stdio.h>
#define  MAX_LEN  80

int main(void)
{
   FILE *stream;
   long l;
   float fp;
   char s[MAX_LEN + 1];
   char c;

   stream = fopen("myfile.dat", "r");

   /* Put in various data. */
   fscanf(stream, "%s", &s[0]);
   fscanf(stream, "%ld", &l);
   fscanf(stream, "%c", &c);
   fscanf(stream, "%f", &fp);

   printf("string = %s\n", s);
   printf("long double = %ld\n", l);
   printf("char = %c\n", c);
   printf("float = %f\n", fp);
}
```

Output

If `myfile.dat` contains `abcdefghijklmnopqrstuvwxyz 343.2`, then the expected output is:

```
string = abcdefghijklmnopqrstuvwxyz
long double = 343
char = .
float = 2.000000
```

CELEBS32

```
/* CELEBS32
   This example uses sscanf() to read various data from the string
   tokenstring, and then displays the data.
 */
#include <stdio.h>
#define  SIZE  81

int main(void)
{
char *tokenstring = "15 12 14";
int i;
float fp;
char s[SIZE];
char c;

   /* Input various data                           */
   printf("No. of conversions=%d\n",
      sscanf(tokenstring, "%s %c%d%f", s, &c, &i, &fp));

   /* If there were no space between %s and %c,       */
   /* sscanf would read the first character following */
   /* the string, which is a blank space.            */

   /* Display the data */
   printf("string = %s\n",s);
   printf("character = %c\n",c);
   printf("integer = %d\n",i);
   printf("floating-point number = %f\n",fp);
}
```

Output

You would see this output from example CELEBS32.

```
No. of conversions = 4
string = 15
character = 1
integer = 2
floating-point number = 14.000000
```

CELEBF91

```
/* CELEBF91
   The following example illustrates the use of sscanf()
   to input vector data types.
 */
#include <stdio.h>

int main (void)
{
   vector signed char s8;
   vector unsigned short u16;
   vector signed int s32;
   vector unsigned long long u64;
   vector double d64;

   sscanf("ab defghijklm,op", "%vc", &s8);
   printf("s8 = %vc\n", s8);

   sscanf("a,b, ,d,e,f,g,h,i,j,k,l,m,!,o,p", "%,vc", &s8);
   printf("s8 = %,vc\n", s8);

   sscanf("1 2 3 4 5 6 7 8", "%vhu", &u16);
   printf("u16 = %vhu\n", u16);

   Sscanf(" 1, 2, 3,99", "%,2lvd", &s32);
   printf("s32 = %,2lvd\n", s32);

   sscanf("1 2", "%vllu", &u64);
   printf("u64 = %vllu\n", u64);

   sscanf("0.1 1.2", "%vLf\n", &d64);
   printf("d64 = %vLf\n", d64);
}
```

Output

```
s8 = ab defghijklm!op
s8 = a,b, ,d,e,f,g,h,i,j,k,l,m,!,o,p
u16 = 1 2 3 4 5 6 7 8
s32 =  1, 2, 3,99
u64 = 1 2
d64 = 0.100000 1.200000
```

fseek() — Change file position

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

int fseek(FILE *stream, long int offset, int origin);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fseek_unlocked(FILE *stream, long int offset, int origin);
```

General description

The fseek() function changes the current file position associated with *stream* to a new location within the file. The next operation on the stream takes place at the new location. On a stream opened for update, the next operation can be either a reading or a writing operation.

The *origin* must be one of the following constants defined in stdio.h:

Origin Definition

SEEK_SET
Beginning of file

SEEK_CUR
Current position of file pointer

SEEK_END
End of file

If successful, the fseek() function clears the EOF indicator, even when *origin* is SEEK_END, and cancels the effect of any preceding ungetc() or ungetwc() function on the same stream.

If the call to the fseek() function or the fsetpos() function is not valid, the call is treated as a flush and the ungetc characters are discarded.

Behavior for binary streams: ANSI states that binary streams use relative byte offsets for both the ftell() and fseek() functions. Under z/OS XL C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the default behavior is to use encoded offsets for the ftell() function and the fseek() function using an origin of SEEK_SET.

Encoded offsets restrict you to seeking only to those positions that are recorded by a previous ftell() function call or to position 0. If you want to use relative-byte offsets for these types of files, you can either open the file with the BYTESEEK fopen() function option or set the _EDC_BYTE_SEEK environment variable before opening.

With relative-byte offsets, you can calculate your own offsets. If the offset exceeds the EOF, your file is extended with NULLs, except for z/OS UNIX files, for which the file is only extended with NULLs if you subsequently write new data. This is true also under POSIX, using z/OS UNIX files, where the file is only extended with NULLs if you subsequently write new data.

Attempting to reposition to before the start of the file causes the fseek() function to fail.

Regardless of whether encoded or relative offsets are returned by the ftell() function, you can specify relative offsets when using SEEK_CUR and SEEK_END.

If the new position is before the start of the file, the fseek() function fails. If the relative offset is positioned beyond the EOF, the file is padded with NULLs, except in the case of POSIX, using z/OS UNIX files, where padding does not occur until a subsequent write of new data.

Behavior for text streams: For text streams, the ftell() function returns an encoded offset. When seeking with an origin of SEEK_SET, you are restricted to seeking only to 0 or to positions returned by a previous ftell() function call.

Attempting to calculate your own position is not supported, and might result in a non-valid position and the failure of the fseek() function.

When you are using SEEK_CUR or SEEK_END, the offset is a relative byte offset. Attempting to seek to before the start of the file or past the EOF results in failure.

Behavior for record I/O: For files opened for record I/O using the `type=record` open mode parameter, the ftell() function returns the relative record number. For the origins of SEEK_SET, SEEK_CUR, and SEEK_END, the offset is a relative record number.

Attempting to seek to before the first record or past the EOF results in failure.

Behavior for blocked I/O: For files opened for blocked I/O using the `type=blocked` open mode parameter, the ftell() function returns the relative block number. For the origins of SEEK_SET, SEEK_CUR, and SEEK_END, the offset is a relative block number.

Attempting to seek to before the first block or past the EOF results in failure.

Behavior for wide-oriented streams: All of the above restrictions apply for wide-oriented streams of any type.

Multivolume data sets performance: Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftell() and fseek() functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: For AMODE 31 C/C++ applications, the fseek() function accepts a signed 4-byte offset and therefore cannot be used to directly or relatively position to offsets beyond 2 GB - 1. To avoid repositioning limitations, AMODE 31 C/C++ applications should define the _LARGE_FILES feature test macro before any headers are included and replace the fseek() function with the fseeko() function. For AMODE 64 C/C++ applications, there are no restrictions on using the fseek() function with large files. The AMODE 64 version automatically accepts a signed 8-byte offset.

Usage notes

1. Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if your update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe.
2. If you specify SEEK_CUR, any characters pushed back by the ungetc() or ungetwc() functions will have backed up the current position of the file pointer—which is the starting point of the seek. The seek will discard any pushed-back characters before repositioning, but the starting point will still be affected. For more information about calling the fseek() function after an ungetc() or ungetwc() function call, see “ungetc() — Push character onto input stream” on page 1958 and “ungetwc() — Push a wide character onto a stream” on page 1961.
3. The _EDC_COMPAT environment variable causes fseek() to ignore the effects of the ungetc() or ungetwc() functions. For more details, see the topic about environment variables in *z/OS XL C/C++ Programming Guide*.
4. The fseek_unlocked() function is functionally equivalent to the fseek() function with the exception that it is not threadsafe. The fseek() function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful in moving the pointer, the fseek() function returns 0.

If unsuccessful, or on devices that cannot seek, such as terminals and printers, the fseek() function returns nonzero.

Special behavior for XPG4.2: If unsuccessful, the fseek() function returns -1 and sets errno to one of the following values:

Error Code
Description

EOVERFLOW
The resulting file offset would be a value which cannot be represented correctly in an object of type long.

Note: Environment variable _EDC_EOVERFLOW can be used to control behavior of the fseek() function with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, the fseek() function will continue to be able to position beyond a location that the ftell() function can return. When _EDC_EOVERFLOW is set to YES, the fseek() function will check if the new position can be returned by the ftell() function.

ESPIPE
The underlying file type for the stream is a PIPE or a socket.

Example

```
/* This example opens a file myfile.dat for reading.
   After performing input operations (not shown), it moves the file
   pointer to the beginning of the file.
 */
#include <stdio.h>

int main(void)
{
   FILE *stream;
   int result;

   if (stream = fopen("myfile.dat", "r"))
   { /* successful */

   if (fseek(stream, 0L, SEEK_SET));  /* moves pointer to   */
                                   /* the beginning of the file */
   { /* if not equal to 0
             then error ...    */
   }
   else {
       /* fseek() successful  */
   }
}
```

fseeko() — Change file position

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment	both	OS/390 V2R10

Format

```
#define _XOPEN_SOURCE 500
#include <stdio.h>

int fseeko(FILE *stream, off_t offset, int origin);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fseeko_unlocked(FILE *stream, off_t offset, int origin);
```

General description

The fseeko() function changes the current file position associated with *stream* to a new location within the file. The next operation on the stream takes place at the new location. On a stream opened for update, the next operation can be either a reading or a writing operation.

The *origin* must be one of the following constants defined in stdio.h:

Origin Definition

SEEK_SET
Beginning of file

SEEK_CUR
Current position of file pointer

SEEK_END
End of file

If successful, the fseeko() function clears the EOF indicator, even when the origin is SEEK_END, and cancels the effect of any preceding ungetc() or ungetwc() function on the same stream.

If the call to the fseeko() function or the fsetpos() function is not valid, the call is treated as a flush and the ungetc characters are discarded.

Behavior for binary streams: ANSI states that binary streams use relative byte offsets for both the ftello() and fseeko() functions. Under z/OS XL C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the default behavior is to use encoded offsets for the ftello() function and the fseeko() function using an origin of SEEK_SET.

Encoded offsets restrict you to seeking only to those positions that are recorded by a previous ftello() function call or to position 0. If you want to use relative-byte offsets for these types of files, you can either open the file with the BYTESEEK fopen() function option or set the _EDC_BYTE_SEEK environment variable before opening.

With relative-byte offsets, you can calculate your own offsets. If the offset exceeds the EOF, your file is extended with NULLs, except for z/OS UNIX files, for which the file is only extended with NULLs if you subsequently write new data. This is true also under POSIX, using z/OS UNIX files, where the file is only extended with NULLs if you subsequently write new data.

Attempting to reposition to before the start of the file causes the fseeko() function to fail.

Regardless of whether encoded or relative offsets are returned by the ftello() function, you can specify relative offsets when using SEEK_CUR and SEEK_END.

If the new position is before the start of the file, the fseeko() function fails. If the relative offset is positioned beyond the EOF, the file is padded with NULLs, except in the case of POSIX, using z/OS UNIX files, where padding does not occur until a subsequent write of new data.

Behavior for text streams: For text streams, the ftello() function returns an encoded offset. When seeking with an origin of SEEK_SET, you are restricted to seeking only to 0 or to positions returned by a previous ftello() function call.

Attempting to calculate your own position is not supported, and might result in a non-valid position and the failure of the fseeko() function.

When you are using SEEK_CUR or SEEK_END, the offset is a relative byte offset. Attempting to seek to before the start of the file or past the EOF results in failure.

Behavior for record I/O: For files opened for record I/O using the `type=record` open mode parameter, the ftello() function returns the relative record number. For the origins of SEEK_SET, SEEK_CUR, and SEEK_END, the offset is a relative record number.

Attempting to seek to before the first record or past the EOF results in failure.

Behavior for blocked I/O: For files opened for blocked I/O using the `type=blocked` open mode parameter, the ftello() function returns the relative block number. For the origins of SEEK_SET, SEEK_CUR, and SEEK_END, the offset is a relative block number.

Attempting to seek to before the first block or past the EOF results in failure.

Behavior for wide-oriented streams: All of the above restrictions apply for wide-oriented streams of any type.

Multivolume data sets performance: Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftello() and fseeko() functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: For AMODE 31 C/C++ applications, the fseeko() function accepts a signed 4-byte offset and therefore cannot be used to directly or relatively position to offsets beyond 2 GB - 1. To avoid repositioning limitations, AMODE 31 C/C++ applications should define the _LARGE_FILES feature test macro before any headers are included. For AMODE 64 C/C++ applications, there are no restrictions on using the fseeko() function with large files. The AMODE 64 version automatically accepts a signed 8-byte offset.

Usage notes

1. Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if your update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe.
2. If you specify SEEK_CUR, any characters pushed back by the ungetc() or ungetwc() functions will have backed up the current position of the file pointer—which is the starting point of the seek. The seek will discard any pushed-back characters before repositioning, but the starting point will still be affected. For more information about calling the fseeko() function after an

ungetc() or ungetwc() function call, see “ungetc() — Push character onto input stream” on page 1958 and “ungetwc() — Push a wide character onto a stream” on page 1961.

3. The _EDC_COMPAT environment variable causes fseeko() to ignore the effects of the ungetc() or ungetwc() functions. For more details, see the topic about environment variables in *z/OS XL C/C++ Programming Guide*.
4. The fseeko_unlocked() function is functionally equivalent to the fseeko() function with the exception that it is not threadsafe. The fseek() function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, fseeko() returns 0, which means it successfully moved the pointer.

If unsuccessful, fseeko() returns nonzero and sets errno to one of the following values.

On devices that cannot seek, such as terminals and printers, the fseeko() function returns nonzero.

Error Code
  Description

EBADF
  The file descriptor underlying stream is not an open file descriptor.

EOVERFLOW
  The current file offset cannot be represented correctly in an object of type off_t.

ESPIPE
  The file descriptor underlying stream is associated with a pipe or FIFO.

Example

```
/* This example opens a file myfile.dat for reading.
   After performing input operations (not shown), it moves the file
   pointer to the beginning of the file.
 */
#define _LARGE_FILES 1
#include <stdio.h>

int main(void)
{
   FILE *stream;
   int result;

   if (stream = fopen("/myfile.dat", "r"))

   { /* successful */

   if (fseeko(stream, 0LL, SEEK_SET));  /* moves pointer to   */
                                       /* the beginning of the file */
   { /* if not equal to 0
             then error ...    */
   }
   else {
       /* fseeko() successful  */
   }
}
```

__fseterr() — Set stream in error

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>
#include <stdio_ext.h>

void __fseterr(FILE *stream);
```

General description

The __fseterr() function sets the specified stream in error.

Returned value

The __fseterr() function returns no values.

An application wishing to check for error situations should set errno to 0, then call __fseterr(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
    Description

EBADF
    The stream specified by *stream* is not valid.

Example

CELEBF88

```
/* CELEBF88

   This example sets a stream in error.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
   FILE *f;
   char filename[FILENAME_MAX] = "myfile.dat";

   f = fopen(filename,"wb");
   if (f == NULL) {
      perror("fopen failed\n");
      return;
   }

   if (ferror(f)) printf("The error indicator is set for the open stream\n");
   else printf("The error indicator is not set for the open stream\n");

   __fseterr(f);

   if (ferror(f)) printf("The error indicator is set for the open stream\n");
   else printf("The error indicator is not set for the open stream\n");

   return;
}
```

Output

```
The error indicator is not set for the open stream
The error indicator is set for the open stream
```

__fsetlocking() — Set locking type

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	None

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __fsetlocking(FILE *stream, int type);
```

General description

The __fsetlocking() function allows the type of locking on an open stream to be controlled or queried by the application.

If *type* is FSETLOCKING_INTERNAL, subsequent stdio functions perform implicit locking around every operation on the given stream. This is the default system behavior.

If *type* is FSETLOCKING_BYCALLER, subsequent stdio functions assume that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If only one thread is accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, you can use the flockfile(), funlockfile(), and ftrylockfile() functions to provide the appropriate serialization.

If *type* is FSETLOCKING_QUERY, the __fsetlocking() function returns the current locking type of the stream without changing it.

Usage notes

1. The _fsetlocking() function acts upon FILE* objects. It is possible to have the same physical file represented by multiple FILE* objects that are not recognized as being equivalent. For example, fopen() opens a file in thread A and sets the locking type as FSETLOCKING_INTERNAL. Then fopen() opens the same file in another thread B and sets the locking type as FSETLOCKING_BYCALLER. If both threads begin to write to their FILE* objects, the results are unpredictable.
2. The __fsetlocking() function impacts the behavior of all other stream operation functions. Using __fsetlocking() to modify the locking type while any of these stream operation functions are executing might produce undesirable behaviors, including hang conditions. You must make sure that __fsetlocking() is used only when no other functions are acting upon the stream.

Returned value

The __fsetlocking() function returns the locking type in effect before the call to __fsetlocking().

The __fsetlocking() function returns -1 if the stream or the locking type is not valid and sets errno to nonzero.

Error Code
  Description

EBADF
  The stream specified by *stream* is not valid.

EINVAL
  The locking type is not valid.

Example

CELEBF85

```
/* CELEBF85

   This example sets LOCKING_TYPE as locking type to a stream.

   It checks that the fopen() function is successful and that
   locking type is setted to the stream and queried from the stream.

*/

#include <stdio.h>
#include <stdio_ext.h>

int main(void)
{
   FILE *stream;
   int locktype;
   int nwrite;
   int buflen;
   char buf[5]="1234";

   if((stream = fopen("myfile.dat", "w+b")) != NULL )
   {
      locktype = __fsetlocking(stream,FSETLOCKING_BYCALLER);
      locktype = __fsetlocking(stream,FSETLOCKING_QUERY);
      if(locktype == FSETLOCKING_BYCALLER){
         printf("__fsetlocking succeeds! \
         Lock type is FSETLOCKING_BYCALLER\n");
      }
      buflen = strlen(buf);
      flockfile(stream);
      nwrite = fwrite(buf, 1, buflen, stream);
      if(nwrite < buflen){
         printf("fwrite did not return expected number of bytes\n");
      }
      funlockfile(stream);
   }
   return(0);
}
```

Output

```
__fsetlocking succeeds! Lock type is FSETLOCKING_BYCALLER
```

fsetpos() — Set file position

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

int fsetpos(FILE *stream, const fpos_t *pos);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fsetpos_unlocked(FILE *stream, const fpos_t *pos);
```

General description

The fsetpos() function moves the file position associated with *stream* to a new location within the file according to the value of the object pointed to by *pos*. The value of *pos* must be obtained by a call to the fgetpos() function. If successful, the fsetpos() function clears the EOF indicator, and cancels the effect of any previous ungetc() or ungetwc() function on the same stream.

If the call to the fsetpos() function is not valid, the call is treated as a flush, and the ungetc characters are discarded.

The fsetpos() function handles the double-byte character set (DBCS) state information for wide-oriented files. An fsetpos() function call to a position that no longer exists results in an error.

For text streams, the DBCS shift state is recalculated from the start of the record, which has a performance implication. The fsetpos() function repositions to the start of a multibyte character.

For binary streams, the DBCS shift state is set to the state saved by the fsetpos() function. If the record has been updated in the meantime, the shift state might be incorrect.

After the fsetpos() function call, the next operation on a stream in update mode can be an input or output operation.

Multivolume data sets performance: Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftell() and fseek() functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: The fsetpos() function implicitly supports operating on large files. Defining the _LARGE_FILES feature test macro is not required to use this function on large files.

Usage notes

1. Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if the update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe. For information about wide-oriented streams, see *z/OS XL C/C++ Programming Guide*.
2. The fsetpos_unlocked() function is functionally equivalent to the fsetpos() function with the exception that it is not threadsafe. The fsetpos() function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful in changing the current position of the file, the fsetpos() function returns 0.

If unsuccessful, the fsetpos() function returns nonzero and sets errno.

Special behavior for XPG4.2: If unsuccessful, the fsetpos() function returns -1 and sets errno to one of the following values:

Error Code
  Description

ESPIPE
  The underlying file type for the stream is a PIPE or a socket.

Example

```
/* This example opens a file called myfile.dat for reading.
   After performing input operations (not shown), it moves the file
   pointer to the beginning of the file and rereads the first byte.
 */
#include <stdio.h>

int main(void)
{

   FILE *stream;
   int retcode;
   fpos_t pos, pos1, pos2, pos3;
   char ptr[20];  /* existing file 'myfile.dat' has 20 byte records */

   /* Open file, get position of file pointer, and read first record */

   stream = fopen("myfile.dat", "rb");
   fgetpos(stream,&pos);
   pos1 = pos;
   if (!fread(ptr,sizeof(ptr),1,stream))
       printf("fread error\n");

   /* Perform a number of read operations.  The value of 'pos'
      changes if 'pos' is passed to fgetpos()                  */
⋮
   /* Re-set pointer to start of file and re-read first record  */

   fsetpos(stream,&pos1);
   if (!fread(ptr,sizeof(ptr),1,stream))
       printf("fread error\n");

   fclose(stream);
}
```

fstat() — Get status information about a file

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int fstat(int fildes, struct stat *info);
```

General description

Gets status information about the file specified by the open file descriptor *fildes* and stores it in the area of memory indicated by the *info* argument. The status information is returned in a `stat` structure, as defined in the sys/stat.h header file. The elements of this structure are described in “stat() — Get file information” on page 1720.

Note: Environment variable _EDC_EOVERFLOW can be used to control behavior of fstat() with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, fstat() will not set EOVERFLOW when the file size can not be represented correctly in structure pointed to by info. When _EDC_EOVERFLOW is set to YES, fstat() will check for an overflow condition.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, fstat() returns 0.

If unsuccessful, fstat() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EINVAL
info contains a NULL.

EIO **Added for XPG4.2:** An I/O error occurred while reading from the file system.

EOVERFLOW

The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by info.

Note: The fstat() function might fail with error code EOVERFLOW if large file support is not enabled. The environment variable _EDC_EOVERFLOW controls this behavior. If _EDC_EOVERFLOW is set to YES the new behavior will take place. The default for _EDC_EOVERFLOW is NO.

Example

CELEBF47

```
/* CELEBF47

   This example gets status information for the file called temp.file.
```

```
 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <time.h>

main() {
  char fn[]="temp.file";
  struct stat info;
  int fd;

  if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    if (fstat(fd, &info) != 0)
      perror("fstat() error");
    else {
      puts("fstat() returned:");
      printf("  inode:   %d\n",   (int) info.st_ino);
      printf(" dev id:   %d\n",   (int) info.st_dev);
      printf("   mode:   %08x\n",       info.st_mode);
      printf("  links:   %d\n",         info.st_nlink);
      printf("    uid:   %d\n",   (int) info.st_uid);
      printf("    gid:   %d\n",   (int) info.st_gid);
      printf("created:   %s",           ctime(&info.st_createtime));
    }
    close(fd);
    unlink(fn);
  }
}
```

Output

```
fstat() returned:
  inode:   3057
 dev id:   1
   mode:   03000080
  links:   1
    uid:   25
    gid:   500
created:   Fri Jun 16 16:03:16 2006
```

fstatvfs() — Get file system information

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/statvfs.h>

int fstatvfs(int fildes, struct statvfs *fsinfo);
```

General description

The fstatvfs() function obtains information about the file system containing the file referenced by *fildes* and stores it in the area of memory pointed to by the *fsinfo* argument.

The information is returned in a `statvfs` structure, as defined in the sys/statvfs.h header file. The elements of this structure are described in "statvfs() — Get file system information" on page 1724. If fstatvfs() successfully determines this information, it stores it in the area indicated by the *fsinfo* argument. The size of the buffer determines how much information is stored; data that exceeds the size of the buffer is truncated.

Returned value

If successful, fstatvfs() returns 0.

If unsuccessful, fstatvfs() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EINTR
A signal was caught during the execution of the function.

EIO An I/O error has occurred while reading the file system.

Example

```
#include <sys/statvfs.h>
#include <stdio.h>

main()
{
  char fn[]="temp.file";
  int fd;
  struct statvfs buf;

  if ((fd = creat(fn,S_IWUSR)) < 0)
    perror("creat() error");
  else {
    if (fstatvfs(fd, &buf) == -1)
      perror("fstatvfs() error");
    else {
      printf("each block is %d bytes big\n", buf.f_bsize);
      printf("there are %d blocks available\n", buf.f_bavail);
      printf("out of a total of %d in bytes,\n", buf.f_blocks);
      printf("that's %.0f bytes free out of a total of %.0f\n",
           ((double)buf.f_bavail * buf.f_bsize),
           ((double)buf.f_blocks * buf.f_bsize));
    }
    close(fd);
    unlink(fn);
  }
}
```

Output

```
each block is 4096 bytes big
there are 2089 blocks available
out of a total of 2400 in bytes,
that's 8556544 bytes free out of a total of 9830400

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int fsync(int fildes);
```

General description

Transfers all data for the file indicated by the open file descriptor *fildes* to the storage device associated with *fildes*. fsync() does not return until the transfer has completed, or until an error is detected.

Returned value

If successful, fsync() returns 0.

If unsuccessful, fsync() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EINVAL
The file is not a regular file.

Example

CELEBF48

```
/* CELEBF48 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <stdlib.h>

#define mega_string_len 250000

main() {
  char *mega_string;
  int  fd, ret;
  char fn[]="fsync.file";

  if ((mega_string = (char*) malloc(mega_string_len)) == NULL)
    perror("malloc() error");
  else if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    memset(mega_string, 's', mega_string_len);
    if ((ret = write(fd, mega_string, mega_string_len)) == -1)
      perror("write() error");
    else {
      printf("write() wrote %d bytes\n", ret);
      if (fsync(fd) != 0)
        perror("fsync() error");
      else if ((ret = write(fd, mega_string, mega_string_len)) == -1)
        perror("write() error");
      else
        printf("write() wrote %d bytes\n", ret);
    }
    close(fd);
    unlink(fn);
  }
}
```

Output

```
write() wrote 250000 bytes
write() wrote 250000 bytes
```

ftell() — Get current file position

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

long int ftell(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

long int ftell_unlocked(FILE *stream);
```

General description

The ftell() function obtains the current value of the file position indicator for the stream pointed to by *stream*.

Behavior for binary streams: ANSI states that the ftell() function returns relative byte offsets from the beginning of the file for binary files. Under z/OS XL C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the ftell() function returns an encoded offset.

If you want to use relative-byte offsets for these types of files, you can either open the file with the BYTESEEK fopen() function option or set the _EDC_BYTE_SEEK environment variable before opening.

Behavior for text streams: The ftell() function returns an encoded offset for text streams.

Behavior for record I/O: For files opened for record I/O using the `type=record` open mode parameter, the ftell() function returns the relative record offset of the current file position from the beginning of the file. All offset values are given in terms of records.

Behavior for blocked I/O: For files opened for blocked I/O using the `type=blocked` open mode parameter, the ftell() function returns the relative block offset of the current file position from the beginning of the file. All offset values are given in terms of blocks.

Multivolume data sets performance: Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftell() and fseek() functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: For AMODE 31 C/C++ applications, the ftell() function accepts a signed 4-byte offset and therefore cannot be used to directly or relatively position to offsets beyond 2 GB - 1. To avoid repositioning limitations, AMODE 31 C/C++ applications should define the _LARGE_FILES feature test macro before any headers are included and replace the ftell() function with the ftello() function. For AMODE 64 C/C++ applications, there are no restrictions on using the ftell() function with large files. The AMODE 64 version automatically accepts a signed 8-byte offset.

Usage note

The ftell_unlocked() function is functionally equivalent to the ftell() function with the exception that it is not threadsafe. The ftell() function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, the ftell() function returns the calculated value.

If unsuccessful, the ftell() function returns -1 and sets errno to a positive value.

Special behavior for XPG4.2: If unsuccessful, the ftell() function returns -1 and sets errno to one of the following values:

Error Code
  Description

EOVERFLOW
  For ftell(), the current file offset cannot be represented correctly in an object of type long.

  Note: Environment variable _EDC_EOVERFLOW can be used to control behavior of the ftell() function with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, the ftell() function will not set EOVERFLOW when the file offset cannot be represented correctly. When _EDC_EOVERFLOW is set to YES, the ftell() function will check for an overflow condition.

ESPIPE
  The underlying file type for the stream is a PIPE or a socket.

Example

```
/* This example opens the file myfile.dat for reading.
   The current file pointer position is stored in the variable pos.
 */
#include <stdio.h>

int main(void)
{
   FILE *stream
   long int pos;

   stream = fopen("myfile.dat", "rb");

   /* The value returned by ftell can be used by fseek()
      to set the file pointer if 'pos' is not -1       */
   if ((pos = ftell(stream)) != EOF)
      printf("Current position of file pointer found\n");
   fclose(stream);
}
```

ftello() — Get current file position

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment	both	OS/390 V2R10

Format

```
#define _XOPEN_SOURCE 500
#include <stdio.h>

off_t ftello(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

off_t ftello_unlocked(FILE *stream);
```

General description

The ftello() function obtains the current value of the file position indicator for the stream pointed to by *stream*.

Behavior for binary streams: ANSI states that the ftello() function returns relative byte offsets from the beginning of the file for binary files. Under z/OS XL C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the ftello() function returns an encoded offset.

If you want to use relative-byte offsets for these types of files, you can either open the file with the BYTESEEK fopen() function option or set the _EDC_BYTE_SEEK environment variable before opening.

Behavior for text streams: The ftello() function returns an encoded offset for text streams.

Behavior for record I/O: For files opened for record I/O using the `type=record` open mode parameter, the ftello() function returns the relative record offset of the current file position from the beginning of the file. All offset values are given in terms of records.

Behavior for blocked I/O: For files opened for blocked I/O using the `type=blocked` open mode parameter, the ftello() function returns the relative block offset of the current file position from the beginning of the file. All offset values are given in terms of blocks.

Multivolume data sets performance: Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftello() and fseeko() functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: For AMODE 31 C/C++ applications, the ftello() function accepts a signed 4-byte offset and therefore cannot be used to directly or relatively position to offsets beyond 2 GB - 1. To avoid repositioning limitations, AMODE 31 C/C++ applications should define the _LARGE_FILES feature test macro before any headers are included. For AMODE 64 C/C++ applications, there are no restrictions on using the ftello() function with large files. The AMODE 64 version automatically accepts a signed 8-byte offset.

Usage notes

1. The ftello_unlocked() function is functionally equivalent to the ftello() function with the exception that it is not threadsafe. The ftello() function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, the ftello() function returns the calculated value.

If unsuccessful, the ftello() function returns (off_t)-1 and sets errno to one of the following values:

Error Code
: **Description**

EBADF
: The file descriptor underlying stream is not an open file descriptor.

EOVERFLOW
: The current file offset cannot be represented correctly in an object of type off_t.

ESPIPE
: The file descriptor underlying stream is associated with a pipe or FIFO.

Example

```
/* This example opens the file myfile.dat for reading.
   The current file pointer position is stored in the variable
   pos.
 */
#define _LARGE_FILES 1
#include <stdio.h>

int main(void)
{
   FILE *stream
```

```
    off_t pos;

   stream = fopen("/myfile.dat", "rb");

    /* The value returned by ftello() can be used by fseeko()
       to set the file pointer if 'pos' is not -1       */

    if ((pos = ftello(stream)) != -1LL)
       printf("Current position of file pointer found\n");
    fclose(stream);
 }
```

ftime() — Set the date and time

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/timeb.h>

int ftime(struct timeb *tp);
```

General description

The ftime() function sets the time and millitm members of the timeb structure pointed to by *tp* to contain seconds and milliseconds, respectively, of the current time in seconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

Note: The ftime() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The time() function is preferred for portability.

Returned value

If successful, ftime() returns 0.

If overflow occurs, ftime() returns -1.

ftok() — Generate an interprocess communication (IPC) key

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/ipc.h>

key_t ftok(const char *path, int id);
```

General description

The ftok() function returns a key based on *path* and *id* that is usable in subsequent calls to msgget(), semget(), and shmget(). The *path* argument must be the path name of an existing file that the process is able to stat().

The ftok() function returns the same key value for all paths that name the same file, when called with the same *id* value. If a different *id* value is given, or a different file is given, a different key is returned. Only the low-order 8-bits of *id* are significant, and must be nonzero.

Returned value

If successful, ftok() returns a key.

If unsuccessful, ftok() returns -1 and sets errno to one of the following values:

Error Code
    Description

EACCES
    Search permission is denied for a component of the path prefix.

[1] Overflow occurs when the current time in seconds since 00:00:00 UTC, January 1, 1970 exceeds the capacity of the *time* member of the timeb structure pointed to by *tp*. The *time* member is type time_t.

EINVAL
The low-order 8-bits of *id* are zero.

ELOOP
Too many symbolic links were encountered in resolving path.

ENAMETOOLONG
One of the following error conditions exists:
- The length of the *path* argument exceeds **PATH_MAX** or a path name component is longer than **NAME_MAX**.
- The path name resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.

ENOENT
A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR
A component of the path prefix is not a directory.

Related information

- "sys/ipc.h" on page 73
- "msgget() — Get message queue" on page 1105
- "semget() — Get a set of semaphores" on page 1485

ftruncate() — Truncate a file

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1a XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int ftruncate(int fildes, off_t length);
```

General description

The ftruncate() function truncates the file indicated by the open file descriptor *fildes* to the indicated *length*. *fildes* must be a regular file that is open for writing. If the file size exceeds *length*, any extra data is discarded. If the file size is smaller than length, bytes between the old and new lengths are read as zeros. A change to the size of the file has no impact on the file offset.

Special behavior for XPG4.2: If the ftruncate() function would cause the file size to exceed the soft file size limit for the process, ftruncate() will fail and a SIGXFSZ signal will be generated for the process.

If successful, the ftruncate() function marks the `st_ctime` and `st_mtime` fields of the file.

If unsuccessful, the ftruncate() function leaves the file unchanged.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, the ftruncate() function returns 0.

If unsuccessful, the ftruncate() function returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EFBIG
The length argument was greater than the maximum file size.

EINTR
Added for XPG4.2: A signal was caught during execution.

EINVAL
fildes does not refer to a regular file, it is opened read-only, or the length specified is incorrect.

EIO **Added for XPG4.2:** An I/O error occurred while reading from or writing to a file system.

EROFS
The file resides on a read-only file system.

Example

CELEBF49

```
/* CELEBF49 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <stdlib.h>

#define string_len 1000

main() {
  char *mega_string;
  int  fd, ret;
  char fn[]="write.file";
  struct stat st;

  if ((mega_string = (char*) malloc(string_len)) == NULL)
```

```
    perror("malloc() error");
  else if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    memset(mega_string, '0', string_len);
    if ((ret = write(fd, mega_string, string_len)) == -1)
      perror("write() error");
    else {
      printf("write() wrote %d bytes\n", ret);
      fstat(fd, &st);
      printf("the file has %ld bytes\n", (long) st.st_size);
      if (ftruncate(fd, 1) != 0)
        perror("ftruncate() error");
      else {
        fstat(fd, &st);
        printf("the file has %ld bytes\n", (long) st.st_size);
      }
    }
    close(fd);
    unlink(fn);
  }
}
```

Output

```
write() wrote 1000 bytes
the file has 1000 bytes
the file has 1 bytes
```

ftrylockfile() — stdio locking

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 3	both	z/OS V1R8

Format

```
#define _UNIX03_SOURCE
#include <stdio.h>

int ftrylockfile(FILE *file);
```

General description

This function provides explicit application-level locking of stdio (FILE*) objects. The flockfile() family of functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

If the (**FILE***) object specified by the ftrylockfile() function is available, ownership is granted to the thread for the (FILE*) object and the internal lock count is increased. If the thread has previously been granted ownership, the internal lock count is increased. If another thread has been granted ownership, ftrylockfile() does not grant ownership to the calling thread and returns a non-zero value. ftrylockfile() is a non-blocking version of flockfile().

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS consideration: The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For example, fopen() opens a file and open() opens the same file, and then fdopen() creates a FILE * object. In this case, locking the first FILE * does not prevent the second FILE * from also being locked and used.

Returned value

The ftrylockfile() function returns zero for success and non-zero to indicate that the lock cannot be acquired.

Error Code
Definition

EBADF
The input (**FILE ***) object is not valid.

EBUSY
The input (**FILE ***) object is locked by another thread.

Note: It is the application's responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (FILE *) object is closed, or a thread is terminated, before relinquishing all locked (FILE *) objects.

ftw() — Traverse a file tree

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <ftw.h>

int ftw(const char *path,
        int (*fn)(const char *, const struct stat *, int),
        int ndirs);
```

General description

The ftw() function recursively descends the directory hierarchy rooted in *path*. For each object in the hierarchy, ftw() calls the function pointed to by *fn*, passing it a pointer to a NULL-terminated string containing the name of the object, a pointer to a *stat* structure containing information about the object, and an integer. Possible values of the integer, defined in the <ftw.h> header, are:

FTW_D
for a directory

FTW_DNR
for a directory that cannot be read

FTW_F
for a file

FTW_SL
for a symbolic link

FTW_NS
for an object other than a symbolic link on which stat() could not be successfully executed. If the object is a symbolic link, and stat() failed, it is unspecified whether ftw() passes FTW_SL or FTW_NS to the user-supplied function.

If the integer is FTW_DNR, descendants of that directory will not be processed. If the integer is FTW_NS, the stat structure will contain undefined values. An example of an object that would cause FTW_NS to be passed to the function pointed to by *fn* would be a file in a directory with read but without execute (search) permission.

The ftw() function visits a directory before visiting any of its descendants.

The ftw() function uses at most one file descriptor for each level in the tree.

The argument *ndirs* should be in the range of 1 to OPEN_MAX.

The tree traversal continues until the tree is exhausted, an invocation of *fn* returns a nonzero value, or some other error, other than [EACCES], is detected within ftw().

The *ndirs* argument specifies the maximum number of directory streams or file descriptors or both available for use by ftw() while traversing the tree. When ftw() returns it closes any directory streams and file descriptors it uses not counting any opened by the application-supplied *fn* function.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If the tree is exhausted, ftw() returns 0. If the function pointed to by *fn* returns a nonzero value, ftw() stops its tree traversal and returns whatever value was returned by the function pointed to by *fn()*.

If ftw() detects an error, it returns -1 and sets errno to one of the following values. All other errnos returned by ftw() are unchanged.

Error Code
Description

EACCES
Search permission is denied for any component of *path* or read permission is denied for *path*.

EINVAL
The value of the *ndirs* argument is not valid.

ELOOP
Too many symbolic links were encountered.

ENAMETOOLONG
One of the following error conditions exists:

- Path name resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX.
- The length of *path* exceeds PATH_MAX, or a path name component is longer than PATH_MAX.

ENOENT
A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR
A component of *path* is not a directory.

funlockfile() — stdio unlocking

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 3	both	z/OS V1R8

Format

```
#define _UNIX03_SOURCE
#include <stdio.h>

void funlockfile(FILE *file);
```

General description

This function provides explicit application-level unlocking of stdio (FILE*) objects. The flockfile() family of functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

The funlockfile() function reduces the internal lock count. When the count is reduced to zero, the funlockfile() function relinquishes the ownership granted to the thread, of a (FILE *) object. If a call to funlockfile() is made by a thread which has not been granted ownership of a (FILE *) object, the call is ignored and the lock count is not reduced

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS consideration: The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For example, fopen() opens a file and open() opens the same file, and then fdopen() creates a FILE * object. In this case, locking the first FILE * does not prevent the second FILE * from also being locked and used.

Returned value

None.

Notes:

1. Because the funlockfile() function returns void, no error information can be returned. If an invalid (FILE *) object is input, it will be ignored.
2. It is the application's responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (FILE *) object is closed, or a thread is terminated, before relinquishing all locked (FILE *) objects.

fupdate() — Update a VSAM record

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>

size_t fupdate(const void *buffer, size_t size, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

size_t fupdate_unlocked(const void *buffer, size_t size, FILE *stream);
```

General description

Replaces the last record read from the VSAM cluster pointed to by *stream*, with the contents of *buffer* for a length of *size*. See "Performing VSAM I/O Operations" in *z/OS XL C/C++ Programming Guide* for details.

The fupdate() function can be used *only* with a VSAM data set opened in update mode (`rb+/r+b`, `ab+/a+b`, or `wb+/w+b`) with the `type=record` option.

The fupdate() function can only be used after an fread() call has been performed and before any other operation on that file pointer. For example, if you need to acquire the file position using ftell() or fgetpos(), you can do it either before the fread() or after the fupdate(). An fread() after an fupdate() retrieves the next updated record.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

fupdate_unlocked() is functionally equivalent to fupdate() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

KSDS or KSDS PATH: The size of the record can be changed by a call to fupdate(). If the size is greater than the existing record size but less than or equal to the maximum record length of the file, a call to fupdate() will lengthen the record up to the maximum record length of the file. If the size is greater than the maximum record length of the file, the record is truncated and errno is set. If the size is less than or equal to the existing record length, all size bytes of the record are written, and no padding or overlaying occurs. The records will be shortened and not partially updated.

ESDS, ESDS PATH, or RRDS: The size of a record cannot be changed by a call to fupdate(). If you call fupdate() with *size* smaller than the size of the existing record, *size* bytes of the record are updated; the remaining bytes are unchanged, and the record length remains unchanged.

The key of reference (the prime key if opened as a cluster, the alternative index key if opened as a path) cannot be changed by an update. If a data set is opened as a path, the prime key cannot be changed by an update. For RRDS files, the `buffer` must be an RRDS record structure, which includes an `rrds_key`.

Returned value

If successful, fupdate() returns the size of the updated record.

If the update operation is not successful, fupdate() returns 0.

Example

CELEBF50

```
/* CELEBF50 */
#include <stdio.h>
```

```
int main(void)
{
   FILE *stream;
   struct record { char name[20];
                   char address[40];
                   int age;
                 } buffer;
   int vsam_rc, numread;

   stream = fopen("DD:MYCLUS", "rb+,type=record");
   numread = fread(&buffer, 1, sizeof(buffer), stream);
   /*  ... Update fields in the record ...  */
   vsam_rc = fupdate(&buffer, sizeof(buffer), stream);
}
```

fwide() — Set stream orientation

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment ISO/ANSI C++ C99 Single UNIX Specification, Version 3 Language Environment	both	z/OS V1R7

Format

```
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

int fwide(FILE *stream, int mode);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fwide_unlocked(FILE *stream, int mode);
```

General description

fwide() determines the orientation of the stream pointed to by *stream*. If *mode* is greater than 0, the function attempts to make the stream wide-oriented. If *mode* is less than 0, the function attempts to make the stream byte-oriented. Otherwise, *mode* is 0 and the function does not alter the orientation of the stream, rather the function returns the current orientation of the stream.

If the orientation of the stream has already been determined, fwide() will not change it.

Streams opened as `type=record` or `type=blocked` do not have orientation.

VSAM data sets and CICS transient data queues do not have orientation. Use of fwide() against streams referring to VSAM data sets or CICS transient data queues will be unsuccessful.

An application wishing to check for error situations should set errno to 0, then call fwide(), then check errno. If errno is non-zero assume an error has occurred.

fwide_unlocked() is functionally equivalent to fwide() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Special considerations for C++: The interaction of fwide() and a C++ I/O stream is undefined.

Usage notes

1. The runtime library does not prevent using byte-oriented I/O functions on a wide-oriented stream, using wide-oriented I/O functions on a byte-oriented stream, or any other mixed orientation usage. The behavior of an application doing so is undefined. As a result, the orientation of a stream reported by fwide() might not be consistent with the I/O functions that are being used. The stream orientation first set using fwide() itself, or through the first I/O operation on the stream is what will be returned. For example, if fwide() is used to set the orientation as byte-oriented, but only wide-oriented I/O functions are used on the stream, the orientation of the stream remains byte-oriented even though no mixing of I/O functions has occurred.

Returned value

If successful, fwide() returns a value greater than 0 if the stream has wide-orientation after the call. It returns a value less than 0 if the stream has byte-orientation, or 0 if the stream has no orientation after the call.

When unsuccessful, fwide() returns 0 and sets errno to one of the following:

EBADF – The stream specified by stream was not valid.

EINVAL – The stream specified by stream was opened as `type=record` or `type=blocked`, or the stream refers to a VSAM data set or CICS transient data queue.

fwprintf(), swprintf(), wprintf() — Format and write wide characters

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

Non-XPG4:

```
#include <wchar.h>

int fwprintf(FILE * __restrict__ stream, const wchar_t * __restrict__ format, ...);
int swprintf(wchar_t * __restrict__ wcs, size_t n, const wchar_t * __restrict__ format, ...);
int wprintf(const wchar_t * __restrict__ format, ...);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fwprintf_unlocked(FILE * __restrict__ stream, const wchar_t * __restrict__ format, ...);
int wprintf_unlocked(const wchar_t * __restrict__ format, ...);
```

XPG4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int fwprintf(FILE * __restrict__ stream, const wchar_t * __restrict__ format, ...);
int swprintf(wchar_t *__restrict__ wcs, size_t n, const wchar_t * __restrict__ format, ...);
int wprintf(const wchar_t * __restrict__ format, ...);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fwprintf_unlocked(FILE * __restrict__ stream, const wchar_t * __restrict__ format, ...);
int wprintf_unlocked(const wchar_t * __restrict__ format, ...);
```

General description

The fwprintf(), swprintf() and wprintf() functions are equivalent to fprintf(), sprintf() and printf(), respectively, except for the following:

- For swprintf(), the argument *wcs* specifies an array of type `wchar_t` into which the generated output is to be written, rather than an array of type char.
- The argument *format* specifies an array of type `wchar_t` that describes how subsequent arguments are converted for output, rather than an array of type char.
- %c without an `l` prefix means an int arg is to be converted to `wchar_t`, as if mbtowc() were called, and then written.
- %c with `l` prefix means a `wint_t` is converted to `wchar_t` and then written.
- %s without an `l` prefix means a character array containing a multibyte character sequence is to be converted to an array of `wchar_t` and then written. The conversion will take place as if mbrtowc() were called repeatedly.
- %s with `l` prefix means an array of `wchar_t` will be written. The array is written up to but not including the terminating NULL character, unless the precision specifies a shorter output.

For swprintf(), a NULL wide character is written at the end of the wide characters written; the NULL wide character is not counted as part of the returned sum. If copying takes place between objects that overlap, the behavior is undefined.

fwprintf_unlocked() family is functionally equivalent to fwprintf() family with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the fwprintf(), swprintf() or wprintf() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Note: The fwprintf() and wprintf() functions have a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, fwprintf(), wprintf(), and swprintf() return the number of wide characters written, not counting the terminating NULL wide character.

If unsuccessful, a negative value is returned.

If *n* or more wide characters were requested to be written, swprintf() returns a negative value and sets errno to indicate the error.

Related information

__fwritable() — Determine if a stream is open for writing

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __fwritable(FILE *stream);
```

General description

The __fwritable() function determines if the specified stream has been opened for writing.

Returned value

The __fwritable() function returns nonzero if the stream is opened for writing. Otherwise, the __fwritable() function returns 0. If an error has occurred, __fwritable() returns 0 and sets errno to nonzero.

An application wishing to check for error situations should set errno to 0, then call __fwritable(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
  Description

EBADF
  The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
   FILE *f;
   char filename[FILENAME_MAX] = "myfile.dat";
   char data[128] = "There are 34 bytes in this buffer\n";
   int datalen = strlen(data);
   size_t n = 0;

   f = fopen(filename,"wb+");
   if (f == NULL) {
      perror("fopen() failed\n");
      return;
   }

   if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
   if (__freadable(f)) printf("Reading is allowed on the open stream\n");

   n = fputs(data,f);
   if (n == EOF) {
      perror("fputs() failed\n");
      return;
   }

   n = __fpending(f);
   printf("There are %d bytes in the buffer pending to be written\n", n);

   if (__fwriting(f)) printf("The last operation on the stream was a write\n");

   rewind(f);

   n = fgetc(f);

   n = __freadahead(f);
   printf("There are %d bytes remaining to be read from the buffer\n", n);

   if (__freading(f)) printf("The last operation on the stream was a read\n");

   return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

Related information

fwrite() — Write items

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

size_t fwrite(const void * __restrict__buffer, size_t size, size_t count, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

size_t fwrite_unlocked(const void * __restrict__buffer, size_t size,
                       size_t count, FILE * __restrict__stream);
```

General description

Writes up to *count* items of size *size* from the location pointed to by *buffer* to the stream pointed to by *stream*.

When you are using fwrite() for record I/O output, set *size* to 1 and *count* to the length of the record to be written. You can only write one record at a time when you are using record I/O. Any string longer than the record length is truncated at the record length. A flush or reposition is required before a subsequent read.

When you are using fwrite() for blocked I/O output, set *size* to 1 and *count* to the length of the block to be written. You can only write one block at a time when you are using blocked I/O. Any string longer than the block length is truncated at the block length.

Because fwrite() may buffer output before writing it out to the stream, data from prior fwrite() calls may be lost where a subsequent call to fwrite() causes a failure when the buffer is written to the stream.

fwrite() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

fwrite_unlocked() is functionally equivalent to fwrite() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

fwrite() returns the number of items that were successfully written.

This number can be smaller than *count* only if a write error occurred.

Example

CELEBF51

```
/* CELEBF51

   This example writes NUM long integers to a stream in binary
   format.
   It checks that the &fopen. function is successful and that
   100 items are written to the stream.

 */
#include <stdio.h>
#define  NUM  100

int main(void)
{
   FILE *stream;
   long list[NUM];
   int numwritten, number;

   if((stream = fopen("myfile.dat", "w+b")) != NULL )
   {
     for (number = 0; number < NUM; ++number)
       list[number] = number;
     numwritten = fwrite(list, sizeof(long), NUM, stream);
     printf("number of long characters written is %d\n",numwritten);
   }
   else
     printf("fopen error\n");
}
```

__fwriting() — Determine if last operation on stream is a write operation

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __fwriting(FILE *stream);
```

```
#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

int __fwriting_unlocked(FILE *stream);
```

General description

The __fwriting() function determines if the last operation on the specified stream is a write operation or if the specified stream is open for write-only or append-only.

The __fwrite_unlocked() function is equivalent to the __fwriting() function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

The __fwriting() functions return nonzero when the last operation was a write operation or the stream is open for write-only or append-only. Otherwise, the __fwriting() function returns 0. If an error has occurred, the __fwriting() functions return 0 and set errno to nonzero.

An application wishing to check for error situations should set errno to 0, then call __fwriting(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
    Description

EBADF
    The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
   FILE *f;
   char filename[FILENAME_MAX] = "myfile.dat";
   char data[128] = "There are 34 bytes in this buffer\n";
   int datalen = strlen(data);
   size_t n = 0;

   f = fopen(filename,"wb+");
   if (f == NULL) {
      perror("fopen() failed\n");
      return;
   }

   if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
   if (__freadable(f)) printf("Reading is allowed on the open stream\n");
   n = fputs(data,f);
   if (n == EOF) {
      perror("fputs() failed\n");
      return;
   }

   n = __fpending(f);
   printf("There are %d bytes in the buffer pending to be written\n", n);

   if (__fwriting(f)) printf("The last operation on the stream was a write\n");

   rewind(f);

   n = fgetc(f);

   n = __freadahead(f);
   printf("There are %d bytes remaining to be read from the buffer\n", n);

   if (__freading(f)) printf("The last operation on the stream was a read\n");

   return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

fwscanf(), swscanf(), wscanf() — Convert formatted wide-character input

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment ISO/ANSI C++ C99 Single UNIX Specification, Version 3 Language Environment	both	z/OS V1R7

Format

Non-XPG4:

```
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

int fwscanf(FILE *__restrict__ stream,
     const wchar_t *__restrict__ format, ... );

int swscanf(const wchar_t * __restrict__ wcs,
     const wchar_t * __restrict__ format, ...);

int wscanf(const wchar_t *__restrict__ format, ... );

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fwscanf_unlocked(FILE *__restrict__ stream,
     const wchar_t *__restrict__ format, ... );
int wscanf_unlocked(const wchar_t *__restrict__ format, ... );
```

XPG4 and swscanf():

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int swscanf(const wchar_t *wcs, const wchar_t *format, ...);
```

General description

The fwscanf(), swscanf(), and wscanf() functions are equivalent to fscanf(), scanf(), and sscanf() respectively, except for the following:

- The argument *wcs* specifies an array of type wchar_t from which the input is to be obtained, rather than an array of type char.
- The *format* argument specifies an array of type wchar_t that describes the admissible input sequences and how they are to be converted for assignment, rather than an array of type char.
- %c with no *l* prefix means one or more (depending on precision) wchar_t is converted to multibyte characters and copied to the character array pointed to by the corresponding argument.
- %c with the *l* prefix means one or more (depending on precision) wchar_t is copied to the array of wchar_t pointed to by the corresponding argument.
- %s with no *l* prefix means a sequence of non-white wchar_t will be converted and copied, including the terminating NULL character, to the character array pointed to by the corresponding argument.
- %s with the *l* prefix means an array of wchar_t will be copied, including the terminating NULL wide-character, to the array of wchar_t pointed to by the corresponding argument.
- %[with no *l* prefix means a sequence of non-white wchar_t will be converted and copied, including the terminating NULL character, to the character array pointed to by the corresponding argument.
- %[with the *l* prefix means an array of wchar_t will be copied, including the terminating NULL wide-character, to the array of wchar_t pointed to by the corresponding argument.

Note: Reaching the end of a wide-character string is equivalent to reaching the end of a char string for the fscanf() and scanf() functions. If copying takes place between objects that overlap, the behavior is undefined.

fwscanf_unlocked() family is functionally equivalent to fwscanf() family with the exception that they are not thread-safe. These functions can safely be used in a multithreaded application if and only if they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Special behavior for XPG4 and swscanf(): If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the swscanf() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If successful, they either return the number of input items assigned, which can be fewer than provided for, or 0 in the event of an early matching failure. If an input failure occurs before any conversion, EOF is returned.

gai_strerror() — Address and name information error description

Standards

Standards / Extensions	C or C++	Dependencies
RFC2553 Single UNIX Specification, Version 3	both	z/OS V1R4

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netdb.h>

char *gai_strerror(int ecode);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <netdb.h>
const char *gai_strerror(int ecode);
```

General description

The gai_strerror() function returns a pointer to a text string describing the error value returned by a failure return from either the getaddrinfo() or getnameinfo() function. If the *ecode* is not one of the EAI_xxx values from the <netdb.h> header, then gai_strerror() returns a pointer to a string indicating an unknown error.

Subsequent calls to gai_strerror() will overwrite the buffer containing the text string.

Returned value

When successful, gai_strerror() returns a pointer to a string describing the error. Upon failure, gai_strerror() will return NULL and set errno to one of the following:

Error Code
Description

ENOMEM
Insufficient memory to allocate buffer for text string describing the error.

Related information

- "getaddrinfo() — Get address information" on page 684
- "getnameinfo() — Get name information" on page 738
- "netdb.h" on page 49

gamma() — Calculate gamma function

Standards

Standards / Extensions	C or C++	Dependencies
SAA XPG4 XPG4.2	both	

Format

```
#include <math.h>

double gamma(double x);
```

Compiler option: LANGLVL(SAA), LANGLVL(SAAL2), or LANGLVL(EXTENDED)

General description

gamma() provides the same function as lgamma(), including the use of *signgam*. Use of lgamma() instead of gamma() is suggested by XPG4.2.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use lgamma() instead of gamma().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Related information

- "math.h" on page 44
- "lgamma(), lgammaf(), lgammal() — Log gamma function" on page 964
- "__signgam() — Return signgam reference" on page 1648

gcvt() — Convert double to string

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *gcvt(double x, int ndigit, char *buf);
```

General description

The gcvt() function converts double floating-point argument values to floating-point output strings. The gcvt() function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using __isBFP().

z/OS XL C/C++ formatted output functions, including the gcvt() function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See "*fprintf* Family of Formatted Output Functions" on fprintf(), printf(), sprintf() — Format and write data for a description of the special infinity and NaN output sequences.

The gcvt() function converts *x* to a NULL-terminated string (similar to the %g format of "fprintf(), printf(), sprintf() — Format and write data" on page 588) in the array pointed to by *buf* and returns *buf*. It produces *ndigit* significant digits (limited to an unspecified value determined by the precision of a double) in %f if possible, or %e (scientific notation) otherwise. A minus sign is included in the returned string if *value* is less than 0. A radix character is included in the returned string if *value* is not a whole number. Trailing zeros are suppressed where *value* is not a whole number. The radix character is determined by the current locale. If "setlocale() — Set locale" on page 1552 has not been called successfully, the default locale, "POSIX", is used. The default locale specifies a period (.) as the radix character. The LC_NUMERIC category determines the value of the radix character within the current locale.

Note: This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sprintf() function is preferred for portability.

Returned value

If successful, gcvt() returns the character equivalent of *x* as specified above.

If unsuccessful, gcvt() returns NULL.

getaddrinfo() — Get address information

Standards

Standards / Extensions	C or C++	Dependencies
RFC2553	both	z/OS V1R4

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <sys/socket.h>
#include <netdb.h>

int getaddrinfo(const char *nodename,
                const char *servname,
                const struct addrinfo *hints,
                struct addrinfo **res);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>
int getaddrinfo(const char *__restrict__ nodename,
           const char *__restrict__ servname,
           const struct addrinfo *__restrict__ hints,
           struct addrinfo **__restrict__ res);
```

General description

The getaddrinfo() function translates the name of a service location (for example, a host name) and/or service name and returns a set of socket addresses and associated information to be used in creating a socket with which to address the specified service.

The *nodename* and *servname* arguments are either pointers to null-terminated strings or null pointers. One or both of these two arguments must be specified as a non-null pointer.

The format of a valid name depends on the protocol family or families. If a specific family is not given and the name could be interpreted as valid within multiple supported families, the function attempts to resolve the name in all supported families. When no errors are detected, all successful results will be returned.

If the *nodename* argument is not null, it can be a descriptive name or it can be an address string. If the specified address family is AF_INET, AF_INET6, or AF_UNSPEC, valid descriptive names include host names. If the specified address family is AF_INET or AF_UNSPEC, address strings using standard dot notation as specified in inet_addr() are valid. If the specified address family is AF_INET6 or AF_UNSPEC, standard IPv6 text forms described in inet_pton() are valid. In addition, scope information can be appended to the descriptive name or the address string using the format *nodename%scope* information. Scope information can be either an interface name or the numeric representation of an interface index suitable for use on this system.

If *nodename* is not null, the requested service location is named by *nodename*; otherwise, the requested service location is local to the caller.

If *servname* is null, the call returns network-level addresses for the specified *nodename*. If *servname* is not null, it is a null-terminated character string identifying the requested service. This can be either a descriptive name or a numeric representation suitable for use with the address family or families. If the specified address family is AF_INET, AF_INET6, or AF_UNSPEC, the service can be specified as a string specifying a decimal port number.

If the argument *hints* is not null, it refers to a structure containing input values that may direct the operation by providing options and by limiting the returned information to a specific socket type, address family and/or protocol. In the hints structure every member other than *ai_flags*, *ai_family*, *ai_socktype*, and *ai_protocol* must be zero or a null pointer. A value of AF_UNSPEC for *ai_family* means that the caller will accept any protocol family. A value of zero for *ai_socktype* means that the caller will accept any socket type. A value of zero for ai_protocol means that the caller will accept any protocol. If hints is a null pointer, the behavior must be as if it referred to a structure containing the value zero for the *ai_flags*, *ai_socktype*, and *ai_protocol* fields, and AF_UNSPEC for the *ai_family* field.

The *ai_flags* member to which the hints argument points can be set to 0 or be the bitwise inclusive OR of one or more of the following values:
- AI_PASSIVE
- AI_CANONNAME
- AI_NUMERICHOST
- AI_NUMERICSERV
- AI_V4MAPPED
- AI_ALL
- AI_ADDRCONFIG
- AI_EXTFLAGS

If the AI_PASSIVE bit is set in the *ai_flags* member of the hints structure, then the caller plans to use the returned socket address structure in a call to bind(). In this case, if the *nodename* argument is a null pointer, then the IP address portion of the socket address structure will be set to INADDR_ANY for an IPv4 address or IN6ADDR_ANY_INIT for an IPv6 address. If the AI_PASSIVE bit is not set in the *ai_flags* member of the hints structure, then the returned socket address structure will be ready for a call to connect() (for a connection-oriented protocol) or either connect(), sendto(), or sendmsg() (for a connectionless protocol). In this case, if the *nodename* argument is a null pointer, then the IP address portion of the socket address structure will be set to the loopback address.

If the AI_CANONNAME bit is set in the *ai_flags* member of the hints structure, then upon successful return the *ai_canonname* member of the first addrinfo structure in the linked list will point to a null-terminated string containing the canonical name of the specified nodename.

If the AI_NUMERICHOST bit is set in the *ai_flags* member of the hints structure, then a non-null *nodename* string must be a numeric host address string. Otherwise an error code of EAI_NONAME is returned. This flag prevents any type of name resolution service (for example, the DNS) from being called.

If the AI_NUMERICSERV flag is specified then a non-null *servname* string must be a numeric port string. Otherwise an error code EAI_NONAME is returned. This flag prevents any type of name resolution service (for example, NIS+ from being invoked.

If the AI_V4MAPPED flag is specified along with the AF field with the value of AF_INET6, or a value of AF_UNSPEC when IPv6 is supported on the system, then the caller will accept IPv4-mapped IPv6 addresses. When the AI_ALL flag is not also specified and no IPv6 addresses are found, then a query is made for IPv4 addresses. If any IPv4 addresses are found, they are returned as IPv4-mapped IPv6 addresses.

If the AF field does not have a value of AF_INET6 or the AF field contains AF_UNSPEC but IPv6 is not supported on the system, this flag is ignored.

When the AF field has a value of AF_INET6 and AI_ALL is set, the AI_V4MAPPED flag must also be set to indicate that the caller will accept all addresses (IPv6 and IPv4-mapped IPv6 addresses). When the AF field has a value of AF_UNSPEC when the system supports IPv6 and AI_ALL is set, the caller accepts IPv6 addresses and either IPv4 (if AI_V4MAPPED is not set) or IPv4-mapped IPv6 (if AI_V4MAPPED is set) addresses. A query is first made for IPv6 addresses and if successful, the IPv6 addresses are returned. Another query is then made for IPv4 addresses and any found are returned as IPv4 addresses (if AI_V4MAPPED was not set) or as IPv4-mapped IPv6 addresses (if AI_V4MAPPED was set). If the AF field does not have the value of AF_INET6, or the value of AF_UNSPEC when the system supports IPv6, the flag is ignored.

If the AI_ADDRCONFIG flag is specified then a query for IPv6 address records should occur only if the node has at least one IPv6 source address configured. A query for IPv4 address records will always occur, whether or not any IPv4 addresses are configured. The loopback address is not considered for this case as valid as a configured sources address.

If the AI_EXTFLAGS flag is specified then getaddrinfo() will look for the values stored in the extended flags field called *ai_eflags* in the addrinfo structure. The flags stored in the *ai_eflags* field are only meaningful if the AI_EXTFLAGS flag is set in the *ai_flags* field of the addrinfo data structure. By default, AI_EXTFLAGS is not set in the *ai_flags* field. If AI_EXTFLAGS is set in the *ai_flags* field, and the *ai_eflags* extended flags field is 0 (zero) or undefined, then AI_EXTFLAGS is ignored. The *ai_eflags* field can be set to any of the following:

- IPV6_PREFER_SRC_HOME - prefer home address as source
- IPV6_PREFER_SRC_COA - prefer care-of address as source
- IPV6_PREFER_SRC_TMP - prefer temporary address as source
- IPV6_PREFER_SRC_PUBLIC - prefer public address as source
- IPV6_PREFER_SRC_CGA - prefer CGA address as source
- IPV6_PREFER_SRC_NONCGA - prefer a non-CGA address as source

These flags can be combined into a flag set to express complex address preferences, but some can result in a contradictory flag set. For example, the following flags are mutually exclusive:

- IPV6_PREFER_SRC_HOME and IPV6_PREFER_SRC_COA
- IPV6_PREFER_SRC_TMP and IPV6_PREFER_SRC_PUBLIC
- IPV6_PREFER_SRC_CGA and IPV6_PREFER_SRC_NONCGA

All of the information returned by getaddrinfo() is dynamically allocated: the addrinfo structures, and the socket address structures and canonical node name strings pointed to by the addrinfo structures. To return this information to the system the function freeaddrinfo() is called.

Usage notes

1. If the caller handles only TCP and not UDP, for example, then the *ai_protocol* member of the hints structure should be set to IPPROTO_TCP when getaddrinfo() is called.
2. If the caller handles only IPV4 and not IPv6, then the *ai_family* member of the hints structure should be set to AF_INET when getaddrinfo() is called.
3. Scope information is only pertinent to IPv6 link-local addresses. It is ignored for resolved IPv4 addresses and IPv6 addresses that are not link-local addresses.

Returned value

When successful, getaddrinfo() returns 0 and a pointer to a linked list of one or more addrinfo structures through the res argument. The caller can process each addrinfo structure in this list by following the ai_next pointer, until a null pointer is encountered. In each returned addrinfo structure the three members *ai_family*, *ai_socktype*, and *ai_protocol* are the corresponding arguments for a call to the socket() function. In each addrinfo structure the *ai_addr* member points to a filled-in socket address structure whose length is specified by the *ai_addrlen* member. Upon failure, getaddrinfo() returns a non-zero error code. The error codes are as follows:

Error Code
Description

EAI_AGAIN
The name specified by the Node_Name or Service_Name parameter could not be resolved within the configured time interval, or the resolver address space has not been started. The request can be retried later.

EAI_BADEXTFLAGS
The extended flags parameter had an incorrect setting.

EAI_BADFLAGS
The flags parameter had an incorrect setting.

EAI_FAIL
An unrecoverable error occurred.

EAI_FAMILY
The family parameter had an incorrect setting.

EAI_MEMORY
A memory allocation failure occurred during an attempt to acquire an Addr_Info structure.

EAI_NONAME
One of the following conditions occurred:

1. The name does not resolve for the specified parameters. At least one of the Name or Service operands must be specified.
2. The request name parameter is valid, but it does not have a record at the name server.

EAI_SERVICE
The service that was passed was not recognized for the specified socket type.

EAI_SOCKTYPE
The intended socket type was not recognized.

EAI_SYSTEM
A system error occurred.

For more information about the above return codes, see *z/OS Communications Server: IP and SNA Codes*.

getc(), getchar() — Read a character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdio.h>

int getc(FILE *stream);
int getchar(void);
```

General description

Reads a single character from the current *stream* position and advances the *stream* position to the next character. The getchar() function is identical to getc(stdin).

The getc() and fgetc() functions are identical. However, getc() and getchar() are provided in a highly efficient macro form. For performance purposes, it is recommended that the macro forms be used rather than the functional forms or fgetc(). By default, stdio.h provides the macro versions of these functions.

However, to get the functional forms, do one or more of the following:
- For C only: do *not* include stdio.h.
- Specify `#undef`, for example, `#undef getc`
- Surround the call statement by parentheses, for example, `(getc)`

getc() and getchar() are not supported for files opened with `type=record` or `type=blocked`.

getc() and getchar() have the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

If the application is not multithreaded, then setting the _ALL_SOURCE_NO_THREADS feature test macro may improve performance of the application, because it allows use of the inline version of this function.

Special behavior for POSIX: In a multithreaded C application that uses POSIX(ON), in the presence of the feature test macro, _OPEN_THREADS, these macros are in an #undef status because they are not thread-safe.

Note: Because the getc() macro reevaluates its input argument more than once, you should never pass a stream argument that is an expression with side effects.

Returned value

getc() and getchar() return the character read.

A returned value of EOF indicates either an error or an EOF condition. If a read error occurs, the error indicator is set. If an EOF is encountered, the EOF indicator is set.

Use ferror() or feof() to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBG02

```
/* CELEBG02

   This example gets a line of input from the stdin stream.
   You can also use getc(stdin) instead of &getchar. in the for
   statement to get a line of input from stdin.

 */
#include <stdio.h>

#define LINE 80

int main(void)
{
  char buffer[LINE+1];
  int i;
  int ch;

  printf( "Please enter string\n" );

  /* Keep reading until either:
     1. the length of LINE is exceeded  or
     2. the input character is EOF  or
     3. the input character is a new-line character
   */

  for ( i = 0; ( i < LINE ) && (( ch = getchar()) != EOF) &&
               ( ch !='\n' ); ++i )
    buffer[i] = ch;

  buffer[i] = '\0';  /* a string should always end with '\0' ! */

  printf( "The string is %s\n", buffer );
}
```

Output

```
Please enter string
hello world
The string is hello world
```

getc_unlocked(), getchar_unlocked(), putc_unlocked(), putchar_unlocked() — Stdio with explicit client locking

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 3	both	z/OS V1R8

Format

```
#define _UNIX03_SOURCE
#include <stdio.h>

int getc_unlocked(FILE *stream);
int getchar_unlocked(void);
int putc_unlocked(int c, FILE *stream);
int putchar_unlocked(int c);
```

General description

Versions of the functions getc(), getchar(), putc(), and putchar() respectively named getc_unlocked(), getchar_unlocked(), putc_unlocked(), and putchar_unlocked() are functionally equivalent to the original versions, with the exception that they are not thread-safe. These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call to the flockfile() or ftrylockfile() functions.

getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked are provided in a highly efficient macro form. For performance purposes, it is recommended that the macro forms be used rather than the functional forms. By default, stdio.h provides the macro versions of these functions.

However, to get the functional forms, do one or more of the following:
- Surround the call statement by parentheses, for example, (getc_unlocked)
- Specify #undef, for example, #undef getc_unlocked
- For C only: do *not* include stdio.h.

getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked are not supported for files that are opened with type=record or type=blocked.

getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked have the same restrictions as any read or write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Note: Because the macro forms of these functions reevaluate their input arguments more than once, you must not pass an argument that is an expression with side effects.

Returned value

See “getc(), getchar() — Read a character” on page 688 and “putc(), putchar() — Write a character” on page 1347.

Related information

getclientid() — Get the identifier for the calling application

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>
#include <sys/types.h>

int getclientid(int domain, struct clientid *clientid);
```

General description

The getclientid() function call returns the identifier by which the calling application is known to the TCP/IP address space. The *clientid* can be used in the givesocket() and takesocket() calls. However, this function is supplied for use by existing programs that depend on the address space name returned. Even for these programs it is recommended that the name be saved for its later use and the __getclientid() function be issued to reconstruct the clientid structure for use by givesocket() and takesocket().

Parameter
Description

domain The address domain requested.

clientid The pointer to a *clientid* structure to be filled.

The clientid structure is filled in by the call and returned as follows:

The clientid structure:

```
struct clientid {
   int domain;
   union  {
     char name[8];
     struct {
       int NameUpper;
       pid_t pid;
     } c_pid;
   } c_name;
```

```
          char subtaskname[8];

          struct  {
            char type;
            union  {
               char specific[19];
               struct  {
                 char unused[3];
                 int SockToken;
               } c_close;
            } c_func;
          } c_reserved;
       };
```

Element
Description

domain
The input *domain* value returned in the domain field of the clientid structure.

c_name.name
The application program's address space name, left-justified and padded with blanks.

subtaskname
The calling program's task identifier.

c_reserved
Specifies binary zeros.

Returned value

If successful, getclientid() returns 0.

If unsuccessful, getclientid() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
Using the *clientid* parameter as specified would result in an attempt to access storage outside the caller's address space, or storage not modifiable by the caller.

Related information

- “sys/socket.h” on page 74
- “sys/types.h” on page 75
- “__getclientid() — Get the PID identifier for the calling application”

__getclientid() — Get the PID identifier for the calling application

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>
#include <sys/types.h>

int __getclientid(int domain, struct clientid *clientid);
```

General description

The __getclientid() function call returns the process identifier (PID) by which the calling application is known to the TCP/IP address space. The *clientid* is used in the givesocket() and takesocket() calls. Use the __getclientid() function call to transfer sockets between the caller and the selected application. The __getclientid() function provides improved performance and integrity over the getclientid() function for applications that use the output of __getclientid() as input clientids for givesocket() and takesocket().

Parameter
Description

domain The address domain requested.

clientid The pointer to a *clientid* structure to be filled.

The clientid structure:

```
      struct clientid {
         int domain;
         union  {
           char name[8];
           struct {
             int NameUpper;
             pid_t pid;
           } c_pid;
         } c_name;
         char subtaskname[8];

         struct  {
           char type;
           union  {
              char specific[19];
              struct  {
                char unused[3];
                int SockToken;
              } c_close;
           } c_func;
         } c_reserved;
      };
```

Element
Description

domain The input *domain* value returned in the domain field of the clientid structure.

c_pid.pid
Is the label in the *clientid* structure that is filled in by the function call to the PID of the requester (caller of __getclientid()). It should be left as set because it is used by the takesocket() and givesocket() functions.

subtaskname
Blanks

c_reserved
Binary zeros

Returned value

If successful, __getclientid() returns 0.

If unsuccessful, __getclientid() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
Using the *clientid* parameter as specified would result in an attempt to access storage outside the caller's address space, or storage not modifiable by the caller.

getcontext() — Get user context

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

int getcontext(ucontext_t *ucp);
```

General description

The getcontext() function initializes the structure pointed to by *ucp* to the current user context of the calling process. The **ucontext_t** type that *ucp* points to defines the user context and includes the contents of the calling process's machine registers, the signal mask, and the current execution stack. A subsequent call to setcontext() restores the saved context and returns control to a point in the program corresponding to the getcontext() call. Execution resumes as if the getcontext() call had just returned. The return value from getcontext() is the same regardless of whether the return is from the initial invocation or using a call to setcontext().

The context created by getcontext() may be modified by the makecontext() function. Refer to makecontext for details.

getcontext() is similar in some respects to sigsetjmp() (and setjmp() and _setjmp()). The getcontext()–setcontext() pair, the sigsetjmp()–siglongjmp() pair, the setjmp()–longjmp() pair, and the _setjmp()–_longjmp() pair cannot be intermixed. A context saved by getcontext() should be restored only by setcontext().

Note: Some compatibility exists with siglongjmp(), so it is possible to use siglongjmp() from a signal handler to restore a context created with getcontext(), but it is not recommended.

Portable applications should not modify or access the **uc_mcontext** member of **ucontext_t**. A portable application cannot assume that context includes any process-wide static data, possibly including errno. Users manipulating contexts should take care to handle these explicitly when required.

This function is supported only in a POSIX program.

The **<ucontext.h>** header file defines the **ucontext_t** type as a structure that includes the following members:

```
mcontext_t       uc_mcontext     A machine-specific representation
                                 of the saved context.
ucontext_t      *uc_link         Pointer to the context that will
                                 be resumed when this context returns.
sigset_t         uc_sigmask      The set of signals that are blocked
                                 when this context is active.
stack_t          uc_stack        The stack used by this context.
```

Special behavior for C++: If getcontext() and setcontext() are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. This applies to both z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of getcontext() and setcontext() in conjunction with try(), catch(), and throw() is also undefined.

Do not issue getcontext() in a C++ constructor or destructor, since the saved context would not be usable in a subsequent setcontext() or swapcontext() after the constructor or destructor returns.

Special behavior for XPLINK-compiled C/C++: Restrictions concerning setjmp.h and ucontext.h:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **jmp_buf**, **sigjmp_buf** or **ucontext_t** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **jmp_buf**, **sigjmp_buf** or **ucontext_t** data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.
3. When __XPLINK__ is defined, the Language Environment V2R10 and later headers define a larger **jmp_buf**, **sigjmp_buf** or **ucontext_t**area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Language Environment V2R10 and later headers define a shorter **jmp_buf**, **sigjmp_buf** or **ucontext_t** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short **jmp_buf**, **sigjmp_buf** or **ucontext_t** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

If successful, getcontext() returns 0.

If unsuccessful, getcontext() returns -1.

There are no errno values defined.

Example

This example saves the context in main with the getcontext() statement. It then returns to that statement from the function `func` using the setcontext() statement. Since getcontext() always returns 0 if successful, the program uses the variable `x` to determine if getcontext() returns as a result of setcontext() or not.

```
/* This example shows the usage of getcontext() and setcontext().    */

#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>
#include <ucontext.h>

void func(void);

int  x = 0;
ucontext_t context, *cp = &context;

int main(void) {

  getcontext(cp);
  if (!x) {
    printf("getcontext has been called\n");
    func();
  }
  else {
    printf("setcontext has been called\n");
  }

}

void func(void) {

  x++;
  setcontext(cp);

}
```

Output

```
getcontext has been called
setcontext has been called
```

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R10

Format

```
#define _OPEN_SYS_EXT 1
#include <sys/ps.h>

int __get_cpuid(char *buff);
```

General description

Retrieves the current CPU ID in the form of a string containing the readable part of the serial number concatenated with the model number. The variable *buff* is a character string of 11 bytes in length. It is a work area to build the unique cpuid.

Returned value

Always returns the serial and model number.

getcwd() — Get path name of the working directory

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

char *getcwd(char *buffer, size_t size);
```

General description

Determines the path name of the working directory and stores it in *buffer*.

size The number of characters in the *buffer* area.

buffer The name of the buffer that will be used to hold the path name of the working directory. *buffer* must be big enough to hold the working directory name, plus a terminating NULL to mark the end of the name.

Returned value

If successful, getcwd() returns a pointer to the buffer.

If unsuccessful, getcwd() returns a NULL pointer and sets errno to one of the following values:

Error Code
: **Description**

EACCES
The process did not have read or search permission on some component of the working directory's path name.

EINVAL
size is less than or equal to zero.

EIO An input/output error occurred.

ENOENT
A component of the working directory's path name does not exist.

ENOTDIR
A directory component of the working directory's path name is not really a directory.

ERANGE
size is greater than 0, but less than the length of the working directory's path name, plus 1 for the terminating NULL.

Example

CELEBG03

```
/* CELEBG03

   This example determines the working directory.

 */
#define _POSIX_SOURCE
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  char cwd[256];

  if (chdir("/tmp") != 0)
    perror("chdir() error()");
  else {
    if (getcwd(cwd, sizeof(cwd)) == NULL)
      perror("getcwd() error");
    else
      printf("current working directory is: %s\n", cwd);
  }
}
```

Output

```
current working directory is: /tmp
```

getdate(), getdate64() — Convert user format date and time

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <time.h>

struct tm *getdate(const char *string);

extern int getdate_err;
#define _LARGE_TIME_API
#include <time.h>

struct tm *getdate64(const char *string);
```

General description

The getdate() function converts definable date and/or time specifications pointed to by *string* into a tm structure. The tm structure declaration is in the header <time.h>.

Templates are used to parse and interpret the input string. The templates are contained in text files created by the process and identified using the environment variable DATEMSK. The DATEMSK variable should be set to indicate the full path name of the file that contains the templates. The first line in the template that matches the input specification is used for the interpretation and conversion into the internal time format.

The following field descriptors are supported:

%% same as %.

%a abbreviated weekday name

%A full weekday name

%b abbreviated month name

%B full month name

%c locale's appropriate date and time representation

%C Century number [00,99]; leading zeros are permitted but not required. Used in conjuction with %y

%d day of month (01-31; the leading 0 is optional)

%D date as %m/%d/%y

%e same as %d

%h same as %b

%H hour (00-23; the leading 0 is optional)

%I hour (01-12; the leading 0 is optional)

%m month number (00-11; the leading 0 is optional)

%M minute (00-59; the leading 0 is optional)

%n same as `\n`

%p locale's equivalent of either AM or PM

%r locale's 12 hour time representation. In the POSIX locale this is equivalent to %I:%M:%S %p

%R time as %H:%M

%S Seconds [00,60]. The range goes to 60 (rather than stopping at 59) to allow positive leap seconds to be expressed. Since leap seconds cannot be predicted by any algorithm, leap second data must come from some external source.

%t same as `\t` (tab)

%T time as %H:%M:%S

%w weekday number (0-6; 0 indicates Sunday)

%x locale's date representation. In the POSIX locale this is equivalent to %m/%d/%y.

%X locale's time representation. In the POSIX locale this is equivalent to %H:%M:%S.

%y year within century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999 inclusive); values in the range 00-68 refer to years in the twenty-first century (2000 to 2068 inclusive). 31-bit supports values in the range 00-37 and 64-bit supports values in the range 00-68.

%Y

year as ccyy (1969-9999)

31-bit the upper bound for %Y is 2037.

64-bit the upper bound for %Y is 9999.

%Z time zone name or no characters if no time zone exists. If the time zone supplied for %Z is not the time zone getdate() expects, a non-valid input specification error will result. The getdate() function calculates an expected time zone based on time and date information supplied to it.

The match between the template and input specification performed by getdate() is case insensitive.

The month and weekday names can consist of any combination of uppercase or lowercase letters. The process can request that the input date and time specification be in a specific language by setting the `LC_TIME` category (see setlocale()).

Leading 0's are not necessary for the descriptors that allow leading 0's. However, at most two digits are allowed for those descriptors, including leading 0's. Extra white space in either the template file or in *string* is ignored.

The field descriptors %c, %x, and %X will not be supported if they include unsupported field descriptors.

The following rules apply for converting the input specification into a tm structure:

- If only weekday is given, today is assumed if the given day is equal to the current day and next week if it is less,
- If only the month is given, the current month is assumed if the given month is equal to the current month and next year if it is less and no year is given (the first day of the month is assumed if no day is given),
- If no hour, minute, and second are given, the current hour, minute and second are assumed,
- If no date is given, today is assumed if the given hour is greater than the current hour and tomorrow is assumed if it is less.

Notes:

1. When converting an input specification into a tm structure, the getdate() function assumes current time and date values for missing fields as indicated in the previous list. The function treats these values as local time, based on the customization of time zone data.
2. When neither the TZ (POSIX) nor _TZ (non-POSIX) environment variable is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see "Customizing a time zone" in *z/OS XL C/C++ Programming Guide*.

If a field descriptor in the template file is not one of the supported field descriptors, then the following behaviors exist when the descriptor is encountered:

1. In an ASCII application, it is ignored (treated as non-matching) and processing continues to the next template.
2. In an EBCDIC application, it causes the function to return unsuccessful with getdate_err being set to the value 8.

The function getdate64() will behave exactly like getdate() except it will convert definable date or time specifications pointed to by string into a *tm* structure of calendar times beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, getdate() returns a pointer to a tm structure.

If unsuccessful, getdate() returns a NULL pointer and sets the external variable `getdate_err` to a value indicating the error.

The tm structure to which getdate() returns a pointer is not shared with any other functions. Also, the getdate() function produces a tm structure unique to the thread on which it runs.

As is true for all external variables, C/370 allocates storage for the `getdate_err` external variable in writable static storage which is shared among all threads. Thus, `getdate_err` is not intrinsically "thread-safe".

C/370 allocates storage on a per thread basis for an analog of `getdate_err`. The __gderr() function returns a pointer to this storage. It is recommended that multithread applications and applications running from a DLL use the __gderr()

function rather than getdate_err if getdate() returns a NULL pointer to determine in a thread-safe manner why getdate() was unsuccessful.

The __gderr() is defined as follows:

```
#include <time.h>

int *__gderr(void);
```

The __gderr() function returns a pointer to the thread-specific value of getdate_err. The getdate64() function affects the same pointer to the thread-specific value of getdate_err as the getdate() function does.

The following is a list of getdate_err settings and their description:

1 The DATEMSK environment variable is NULL or undefined.

2 The template file cannot be opened for reading.

3 Failed to get file status information.

4 The template file is not a regular file.

5 An error was encountered while reading the template file.

6 Memory allocation failed (not enough memory available).

7 No line in the template file matches the input specification.

8 Non-valid input specification. For example, February 31; or a time that can not be represented in a time_t (representing the time is seconds since Epoch - midnight, January 1, 1970 (UTC)).

9 Unable to determine current time.

Note: This value is unique for z/OS UNIX services.

getdtablesize() — Get the file descriptor table size

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int getdtablesize(void);
```

General description

The getdtablesize() function is equivalent to getrlimit() with the RLIMIT_NOFILE option.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use getrlimit() instead of getdtablesize().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

getdtablesize() returns the current soft limit as if obtained from a call to getrlimit().

There are no errno values defined.

getegid() — Get the effective group ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

gid_t getegid(void);
```

General description

Finds the effective group ID (GID) of the calling process.

Returned value

Returns the effective group ID (GID). It is always successful.

There are no documented errno values.

Example

CELEBG04

```
/* CELEBG04

   This example finds the group ID.

 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>

main() {
  printf("my group id is %d\n", (int) getgid());
}
```

Output

```
my group id is 500
```

Related information

- "setgid() — Set the group ID" on page 1537

getenv() — Get value of environment variables

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

char *getenv(const char *varname);
```

General description

Searches the table of environment variables for an entry corresponding to *varname* and returns a pointer to a buffer containing the current string value of *varname*.

Special behavior for POSIX: Under POSIX, the value of the `char **environ` pointer is honored and used by getenv(). You can declare and use this pointer. Under POSIX(OFF) this is not the case: the table start cannot be modified.

Returned value

If successful, getenv() returns a pointer to a buffer containing the current string value of *varname*. You should copy the string that is returned because a subsequent call to getenv() will overwrite it.

If the *varname* is not found, getenv() returns a NULL pointer. The returned value is NULL if the given variable is not currently defined.

Example

CELEBG05

```
/* CELEBG05

   In this example, *pathvar points to the value of the PATH
   environment variable.
   In a POSIX environment, this variable would be from the CENV
   group ID.

 */
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
   char *pathvar;

   pathvar = getenv("PATH");
   printf("pathvar=%s",pathvar);
}
```

__getenv() — Get an environment variable

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <stdlib.h>

char  *__getenv(const char *varname);
```

General description

__getenv() returns a unique character pointer for each environmental variable. For single-threaded applications, this eliminates the need to copy the string returned by previous __getenv() calls.

This function should not be used by multithreaded applications. Updates to the environmental variable on another thread may invalidate the address returned by __getenv() before the application copies the returned value.

The format of an environment variable is made up of three parts that are combined to form:

name=value

Where:

1. The first part, *name*, is a character string that represents the name of the environment variable. It is this part of the environment variable that __getenv() tries to match with *varname*.
2. The second part, =, is a separator character (since the equal sign is used as a separator character it cannot appear in the *name*).
3. The third part, *value*, is a NULL-terminated character string that represents the value that the environment variable, *name*, is set to. This is the part of the environment variable that __getenv() returns a pointer to.

There are several ways to establish a set of environment variables.

- Set at program initialization time from the Language Environment runtime option ENVAR.
- Set at program initialization time from a data set.
- If the program was invoked with a system() call, they can be inherited from the calling enclave.
- In the z/OS UNIX environment they can also be inherited from the parent process if the program was invoked with one of the exec functions.
- During the running of a program they can be set with the setenv() function or the putenv() function.

For a list of the environment variables that z/OS UNIX services support, see the chapter "Using Environment Variables" in *z/OS XL C/C++ Programming Guide*.

Special behavior for POSIX: Under POSIX, the value of the `char **environ` pointer is honored and used by getenv(). You can declare and use this pointer. Under POSIX(OFF) this is not the case: the table start cannot be modified.

Note: The __getenv() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, __getenv() returns a pointer to the string containing the value of the environment variable specified by *varname*.

If unsuccessful, __getenv() returns a NULL pointer. The returned value is NULL if the given variable is not currently defined or if the system does not support environment variables.

geteuid() — Get the effective user ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

uid_t geteuid(void);
```

General description

Finds the effective user ID (UID) of the calling process.

Returned value

Returns the effective user ID of the calling process. It is always successful.

There are no documented errno values.

Example

CELEBG06

```
/* CELEBG06

   This example returns information for your user ID.

 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>
#include <unistd.h>

main() {
  struct passwd *p;
  uid_t  uid;

  if ((p = getpwuid(uid = geteuid())) == NULL)
    perror("getpwuid() error");
  else {
    puts("getpwuid() returned the following info for your userid:");
    printf("  pw_name  : %s\n",       p->pw_name);
    printf("  pw_uid   : %d\n", (int) p->pw_uid);
    printf("  pw_gid   : %d\n", (int) p->pw_gid);
    printf("  pw_dir   : %s\n",       p->pw_dir);
    printf("  pw_shell : %s\n",       p->pw_shell);
  }
}
```

Output

getpwuid() returns the following information for your user ID:

```
pw_name  : MVSUSR1
pw_uid   : 25
pw_gid   : 500
pw_dir   : /u/mvsusr1
pw_shell : /bin/sh
```

getgid() — Get the real group ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

gid_t getgid(void);
```

General description

Finds the real group ID (GID) of the calling process.

Returned value

Returns the real group ID of the calling process. It is always successful.

There are no documented errno values.

Example

CELEBG07

```
/* CELEBG07

   This example gets the real group ID.

 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>

main() {
  printf("my group id is %d\n", (int) getgid());
}
```

Output

```
my group id is 500
```

getgrent() — Get group database entry

The information for this function is included in “endgrent() — Group database entry functions” on page 420.

getgrgid() — Access the group database by ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <grp.h>

struct group *getgrgid(gid_t gid);
```

General description

Provides information about the group specified by *gid* and its members.

Returned value

If successful, getgrgid() returns a pointer to a group structure containing an entry from the group database with the specified *gid*. The return value may point to static data that is overwritten by each call. This group structure, defined in the grp.h header file, contains the following members:

gr_name
The name of the group

gr_gid The numerical group ID (GID)

gr_mem A NULL-terminated vector of pointers to the individual member names

If unsuccessful, getgrgid() returns a NULL pointer.

There are no documented errno values.

Example

CELEBG08

```
/* CELEBG08

   This example provides the root GID and group name.
```

```
 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <sys/stat.h>   /*FIX: used to be <stat.h>*/

main() {
  struct stat info;
  struct group *grp;

  if (stat("/", &info) < 0)
    perror("stat() error");
  else {
    printf("The root is owned by gid %d\n", info.st_gid);
    if ((grp = getgrgid(info.st_gid)) == NULL)
      perror("getgrgid() error");
    else
      printf("This group name is %s\n", grp->gr_name);
  }
}
```

Output

```
The root is owned by gid 500
This group name is SYS1
```

Related information

getgrgid_r() — Get group database entry for a group ID

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 z/OS UNIX	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <grp.h>

int getgrgid_r(gid_t gid, struct group *grp, char *buffer,
size_t bufsize, struct group **result);

#define _POSIX_SOURCE
#include <grp.h>

int __getgrgid1(gid_t gid, struct group *grp, char *buffer,
size_t bufsize, struct group **result);
```

General description

The getgrgid_r() function updates the group structure pointed to by *grp* and stores a pointer to that structure at the location pointed to by *result*. The structure contains an entry from the group database with a matching *gid*. Storage referenced by the group structure is allocated from the memory provided with the *buffer* parameter, which is *bufsize* bytes in size. A NULL pointer is returned at the location pointed to by *result* on error or if the requested entry is not found.

The __getgrgid1() function is identical to getgrgid_r() except that it does not return the individual group member names. Element gr_mem of the group structure pointed to by *grp* will be set to NULL.

Returned value

If successful, getgrgid_r() or __getgrgid1() returns 0.

If unsuccessful, getgrgid_r() or __getgrgid1() returns an error number and sets errno to one of the following values:

Error Code
Description

EINVAL
One of the input arguments was not valid. Arguments *grp*, *buffer*, and *result* must not be NULL. Argument *bufsize* must not be 0.

ERANGE
Insufficient storage was supplied in *buffer* and *bufsize* to contain the data to be referenced by the resulting group structure.

EMVSSAFEXTRERR
The system authorization facility (SAF) RACROUTE EXTRACT service had an error.

EMVSSAF2ERR
The SAF Get GMAP service had an error.

getgrnam() — Access the group database by name

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <grp.h>

struct group *getgrnam(const char *name);
```

General description

Accesses the group structure containing an entry from the group database with the specified *name*.

Returned value

If successful, getgrnam() returns a pointer to a group structure. The return value may point to static data that is overwritten by each call.

The group structure, defined in the grp.h header file, contains the following members:

gr_name
The name of the group

gr_gid The numerical group ID (GID)

gr_mem A NULL-terminated vector of pointers to the individual member names.

If unsuccessful or if the requested entry is not found, getgrnam() returns a NULL pointer.

There are no documented errno values.

Example

CELEBG09

```
/* CELEBG09

   This example provides the members of a group.

 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>

main() {
  struct group *grp;
  char   grpname[]="USERS", **curr;

  if ((grp = getgrnam(grpname)) == NULL)
    perror("getgrnam() error");
  else {
    printf("The following are members of group %s:\n", grpname);
    for (curr=grp->gr_mem; (*curr) != NULL; curr++)
      printf("  %s\n", *curr);
  }
}
```

Output

```
The following are members of group USERS:
  MVSUSR1
  MVSUSR2
  MVSUSR3
  MVSUSR4
```

```
MVSUSR5
MVSUSR6
MVSUSR7
MVSUSR8
MVSUSR9
```

getgrnam_r() — Search group database for a name

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 z/OS UNIX	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <grp.h>

int getgrnam_r(const char *name, struct group *grp, char *buffer,
size_t bufsize, struct group **result);

#define _POSIX_SOURCE
#include <grp.h>

int __getgrnam1(const char *name, struct group *grp, char *buffer,
size_t bufsize, struct group **result);
```

General description

The getgrnam_r() function updates the group structure pointed to by *grp* and stores a pointer to that structure at the location pointed to by *result*. The structure contains an entry from the group database with a matching name. Storage referenced by the group structure is allocated from the memory provided with the *buffer* parameter, which is *bufsize* bytes in size. A NULL pointer is returned at the location pointed to by *result* on error or if the requested entry is not found.

The __getgrnam1() function is identical to getgrnam_r() except that it does not return the individual group member names. Element gr_mem within the group structure pointed to by *grp* will be set to NULL.

Returned value

If successful, getgrnam_r() or __getgrnam1() returns 0.

If unsuccessful, getgrnam_r() or _getgrnam1() returns an error number and sets errno to one of the following values:

Error Code
Description

EINVAL
One of the input arguments was not valid. Arguments *grp*, *buffer*, and *result* must not be NULL. Argument *bufsize* must not be 0.

ERANGE
Insufficient storage was supplied in *buffer* and *bufsize* to contain the data to be referenced by the resulting group structure.

EMVSSAFEXTRERR
The system authorization facility (SAF) RACROUTE EXTRACT service had an error.

EMVSSAF2ERR
The SAF Get GMAP service had an error.

getgroups() — Get a list of supplementary group IDs

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int getgroups(int size, gid_t list[]);
```

General description

Stores the supplementary group IDs of the calling process in the *list* array. *size* gives the number of `gid_t` elements that can be stored in the *list* array.

Returned value

If successful, getgroups() returns the number of supplementary group IDs that it puts into *list*. This value is always greater than or equal to 1 and less than or equal to the value of **NGROUPS_MAX** (which is defined in the limits.h header file).

If *size* is zero, getgroups() returns the total number of supplementary group IDs for the process. getgroups() does not try to store group IDs in *list*.

If unsuccessful, getgroups() returns -1 and sets errno to one of the following values.

Error Code
Description

EINVAL
size was not equal to 0 and is less than the total number of supplementary group IDs for the process. *list* may or may not contain a subset of the supplementary group IDs for the process.

Example

CELEBG10

```
/* CELEBG10

   This example provides a list of the supplementary group IDs.

 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <unistd.h>

#define dim(x) (sizeof(x)/sizeof(x[0]))

main() {
  gid_t gids[500];
  struct group *grp;
  int count, curr;

  if ((count = getgroups(dim(gids), gids)) == -1)
    perror("getgroups() error");
  else {
    puts("The following is the list of my supplementary groups:");
    for (curr=0; curr<count; curr++) {
      if ((grp = getgrgid(gids[curr])) == NULL)
        perror("getgrgid() error");
      else
        printf("  %8s (%d)\n", grp->gr_name, (int) gids[curr]);
    }
  }
}
```

Output

```
The following is the list of my supplementary groups:
      SYS1 (500)
     KINGS (512)
    NOBLES (513)
   KNIGHTS (514)
   WIZARDS (515)
   SCRIBES (516)
   JESTERS (517)
  PEASANTS (518)
```

getgroupsbyname() — Get supplementary group IDs by user name

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int getgroupsbyname(char username[], int size, gid_t list[]);
```

General description

Stores the supplementary group IDs of the specified *username* in the array, *list*. *size* gives the number of `gid_t` elements that can be stored in the array, *list*.

Returned value

If successful, getgroupsbyname() returns the number of supplementary group IDs that it puts into *list*. This value is always greater than or equal to one, and less than or equal to the value of **NGROUPS_MAX**.

If *size* is zero, getgroupsbyname() returns the total number of supplementary group IDs for the process. getgroupsbyname() does not try to store group IDs in *list*.

If unsuccessful, getgroupsbyname() returns -1 and sets errno to one of the following values.

Error Code
Description

EINVAL
size was less than or equal to the total number of supplementary group IDs for the process. *list* may or may not contain a subset of the supplementary group IDs for the process.

Example

CELEBG11

```
/* CELEBG11

   This example provides a list of the supplementary group IDs for
   MVSUSR1.

 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <unistd.h>

#define dim(x) (sizeof(x)/sizeof(x[0]))

main() {
  gid_t gids[500];
  struct group *grp;
  int count, curr;
  char user[]="MVSUSR1";

  if ((count = getgroupsbyname(user, dim(gids), gids)) == -1)
    perror("getgroups() error");
  else {
    printf("The following is the list of %s's supplementary groups:\n",
           user);
    for (curr=0; curr<count; curr++) {
      if ((grp = getgrgid(gids[curr])) == NULL)
        perror("getgrgid() error");
      else
        printf("  %8s (%d)\n", grp->gr_name, (int) gids[curr]);
    }
  }
}
```

Output

```
The following is the list of MVSUSR1's supplementary groups:
      SYS1 (500)
     USERS (523)
```

gethostbyaddr() — Get a host entry by address

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>
extern int h_errno;

struct hostent *gethostbyaddr(const void *address, size_t len, int type);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct hostent *gethostbyaddr(char *address, int address_len, int domain);
```

General description

The gethostbyaddr() call tries to resolve the host address through a name server, if one is present. gethostbyaddr() searches the local host tables until a matching host address is found or an EOF marker is reached.

Parameter
Description

address The pointer to a structure containing the address of the host. (An unsigned long for AF_INET.)

address_len
The size of *address* in bytes.

domain The address domain supported (AF_INET).

If you want gethostbyaddr() to bypass the name server and instead resolve the host address using the local host tables, you must define the RESOLVE_VIA_LOOKUP symbol before including any sockets-related include files in your source program.

You can use the **X_ADDR** environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization.

Note: For more information on these local host tables or the environment variables, see *z/OS Communications Server: IP Configuration Guide, SC27-3650*.

The gethostbyaddr() call returns a pointer to a `hostent` structure for the host address specified on the call.

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the `hostent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The **netdb.h** include file defines the `hostent` structure and contains the following elements:

Element
Description

h_addr_list
A pointer to a NULL-terminated list of host network addresses.

h_addrtype
The type of address returned; currently, it is always set to AF_INET.

h_aliases
A zero-terminated array of alternative names for the host.

h_length
The length of the address in bytes.

h_name
The official name of the host.

The following function (X/Open sockets only) is defined in **netdb.h** and should be used by multithreaded applications when attempting to reference *h_errno* return on error:

```
int *__h_errno(void);
```

Also use this function when you invoke gethostbyaddr() in a DLL.

This function returns a pointer to a thread-specific value for the *h_errno* variable.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The gethostbyaddr() and gethostbyname() functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The getaddrinfo() and getnameinfo() functions are preferred for portability.

Returned value

The return value points to static data that is overwritten by subsequent calls. A pointer to a `hostent` structure indicates success. A NULL pointer indicates an error or End Of File (EOF).

If unsuccessful in X/Open, gethostbyaddr() sets *h_errno* to indicate the error as follows:

Error Code
Description

HOST_NOT_FOUND
No such host is known.

NO_DATA
The server recognized the request and the name but no address is available. Another type of request to the name server might return an answer.

NO_RECOVERY
An unexpected server failure occurred from which there is no recovery.

TRY_AGAIN
A temporary error such as no response from a server, indicating the information is not available now but may be at a later time.

gethostbyname() — Get a host entry by name

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>
extern int h_errno;

struct hostent *gethostbyname(const char *name);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct hostent *gethostbyname(char *name);
```

General description

The gethostbyname() call tries to resolve the host name through a name server, if one is present. If a name server is not present, gethostbyname() searches the local host tables until a matching host name is found or an EOF marker is reached.

Parameter
Description

name The name of the host.

The gethostbyname() call returns a pointer to a `hostent` structure for the host name specified on the call.

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the `hostent` structure. This static area is only valid until the next one of these functions is called on the same thread.

If you want gethostbyname() to bypass the name server and instead resolve the host name using the local host tables, you must define the RESOLVE_VIA_LOOKUP symbol before including any sockets-related include files in your source program.

If the name server is not present or the RESOLVE_VIA_LOOKUP option is in effect, you can use the **X_SITE** environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization.

Note: For more information on these local host tables or the environment variables, see *z/OS Communications Server: IP Configuration Guide, SC27-3650*.

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the HOSTENT structure. This static area is only valid until the next one of these functions is called on the same thread.

The **netdb.h** include file defines the `hostent` structure and contains the following elements:

Element
Description

h_addr_list
A pointer to a NULL-terminated list of host network addresses.

h_addrtype
The type of address returned; currently, it is always set to AF_INET.

h_aliases
A zero-terminated array of alternative names for the host.

h_length
The length of the address in bytes.

h_name
The official name of the host.

The following function (X/Open sockets only) is defined in **netdb.h** and should be used by multithreaded applications when attempting to reference *h_errno* return on error:

```
int *__h_errno(void);
```

Also use this function when you invoke gethostbyname() in a DLL. This function returns a pointer to a thread-specific value for the *h_errno* variable.

Special Behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The gethostbyaddr() and gethostbyname() functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The getaddrinfo() and getnameinfo() functions are preferred for portability.

Returned value

The return value points to static data that is overwritten by subsequent calls. A pointer to a `hostent` structure indicates success. A NULL pointer indicates an error or End Of File (EOF).

If unsuccessful in X/Open, gethostbyname() sets *h_errno* to one of the following values:

Error Code
  Description

HOST_NOT_FOUND
  No such host is known.

NO_DATA
  The server recognized the request and the name but no address is available. Another type of request to the name server might return an answer.

NO_RECOVERY
  An unexpected server failure occurred from which there is no recovery.

TRY_AGAIN
  A temporary error such as no response from a server, indicating the information is not available now but may be at a later time.

gethostent() — Get the next host entry

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct hostent *gethostent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct hostent *gethostent(void);
```

General description

The gethostent() call reads the next line of the local host tables.

The gethostent() call returns a pointer to the next entry in the local host tables. gethostent() uses the local host tables to get aliases.

You can use the **X_SITE** environment to specify different local host tables and override those supplied by the z/OS resolver during initialization.

Note: For more information on these local host tables or the environment variables, see *z/OS Communications Server: IP Configuration Guide, SC27-3650* .

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the `hostent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The **netdb.h** include file defines the `hostent` structure and contains the following elements:

Element
Description

h_addrtype
The type of address returned; currently, it is always set to AF_INET.

h_addr A pointer to the network address of the host.

h_aliases
A zero-terminated array of alternative names for host.

h_length
The length of the address in bytes.

h_name
The official name of the host.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, gethostent() returns a pointer to a `hostent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, gethostent() returns a NULL pointer, indicating an error or End Of File (EOF).

gethostid() — Get the unique identifier of the current host

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

long gethostid(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <unistd.h>

int gethostid();
```

General description

The gethostid() call gets the unique 32-bit identifier for the current host. This value is the default home Internet address.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, gethostid() returns the 32-bit identifier of the current host, which should be unique across all hosts.

If unsuccessful, gethostid() returns -1 and stores the error value in errno. For return codes, see *z/OS UNIX System Services Messages and Codes*.

Related information

- "unistd.h" on page 82
- "gethostname() — Get the name of the host processor" on page 724

gethostname() — Get the name of the host processor

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int gethostname(char *name, size_t namelen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <unistd.h>

int gethostname(char *name, int namelen);
```

General description

The gethostname() call returns the name of the host processor that the program is running on. Up to *namelen* characters are copied into the name array. The returned name is NULL-terminated unless there is insufficient room in the name array.

Parameter
Description

name The character array to be filled with the host name.

namelen
The length of *name*.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, gethostname() returns 0.

If unsuccessful, gethostname() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
Using *name* and *namelen* would result in an attempt to copy the address into a portion of the caller's address space to which data cannot be written.

EMVSPARM
Incorrect parameters were passed to the service.

Related information

- “unistd.h” on page 82

getibmopt() — Get IBM TCP/IP image

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int getibmopt(int cmd, struct ibm_gettcpinfo *bfrp);
```

General description

The getibmopt() function call returns -1 with errno EOPNOTSUPP to indicate that this function is not currently supported.

Parameter
Description

cmd The value in domain must be AF_INET.

bfrp The pointer to an ibm_gettcpinfo structure.

Returned value

getibmopt() always returns -1, indicating that this function is not currently supported.

Error Code
Description

EOPNOTSUPP
This function is not supported.

Related information

- “sys/socket.h” on page 74

getibmsockopt() — Get IBM specific options associated with a socket

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int getibmsockopt(int s, int level, int optname, char *optval, int *optlen);
```

General description

Like getsockopt(), the getibmsockopt() gets the options associated with a socket in the AF_INET or AF_INET6 domain. Only SOL_SOCKET is supported. This call is for options specific to the IBM implementation of sockets. Currently, only the

SOL_SOCKET level and the socket options SO_NONBLOCKLOCAL and SO_IGNOREINCOMINGPUSH are supported.

Parameter
Description

s The socket descriptor.

level The level for which the option is set.

optname
The name of a specified socket option.

optval The pointer to option data.

optlen The pointer to the length of the option data.

The fields b_num_UNITs_sent and b_num_UNITs_received represent cumulative totals for this socket since the time the application was started.

For SO_NONBLOCKLOCAL, *optval* should point to an integer. getibmsockopt() returns 0 in *optval* if the socket is in blocking mode, and returns 1 in *optval* if the socket is in nonblocking mode.

For SO_IGNOREINCOMINGPUSH, *optval* should point to an integer. getibmsockopt() returns 0 in *optval* if the option is not set, and returns 1 in *optval* if the option is set.

Returned value

If successful, getibmsockopt() returns 0.

If unsuccessful, getibmsockopt() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
The s parameter is not a valid socket descriptor.

EFAULT
Using optval and optlen parameters would result in an attempt to access storage outside the caller's address space.

ENOPROTOOPT
The optname parameter is unrecognized, or the level parameter is not SOL_SOCKET.

Related information

- “sys/socket.h” on page 74
- “setibmsockopt() — Set IBM specific options associated with a socket” on page 1542

__getipc() — Query interprocess communications

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _XOPEN_SOURCE
#include <sys/__getipc.h>

int __getipc(int token_id, IPCQPROC *bufptr, size_t buflng, int cmd);
```

General description

The __getipc() function provides means for obtaining information about the status of interprocess communications (IPC) resources, message queues, semaphores, shared memory, and map service memory.

The argument *token_id* is a number that identifies the relative position of an IPC member in the system or specifies a message queue ID, semaphore ID, or shared memory ID. Zero represents the first IPC member ID in the system. On the first call to __getipc(), pass the a *token_id* of zero; the function will return the token that identifies the next IPC resource to which the caller has access. Use this token on the next call to __getipc().

The argument *bufptr* is the address where the data is to be stored.

The argument *buflen* is the length of the buffer.

The argument *cmd* specifies one of the following commands:

IPCQALL
Retrieve the next shared memory, semaphore, or message queue

IPCQMSG
Retrieve the next message member

IPCQSEM
Retrieve the next semaphore member

IPCQSHM
Retrieve the next shared memory member

IPCQMAP
Retrieve the next map service memory currently allocated

IPCQOVER
Overview of system variables. Ignores the value of the first argument *token_id*.

Returned value

If successful, __getipc() returns 0.

If unsuccessful, __getipc() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
Operation permission (read) is denied to the calling process for the member ID specified by *token_id*.

EFAULT
The argument *bufptr* contains an non-valid address.

EINVAL
The member ID specified in the argument *token_id* is not valid for the command specified, or the argument *cmd* is not a valid command.

getipv4sourcefilter() — Get source filter

Standards

Standards / Extensions	C or C++	Dependencies
RFC3678	both	z/OS V1.9

Format

```
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int getipv4sourcefilter(int s, struct in_addr interface,struct in_addr group,
                        uint32_t *fmode, uint32_t *numsrc, struct in_addr *slist);
```

General description

This function allows applications to get a previously set multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is IPv4-specific, must be used only on AF_INET sockets with an open socket of type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument
Description

s
Identifies the socket.

interface
Holds the local IP address of the interface.

group Holds the IP multicast address of the group.

fmode Points to an integer that will contain the filter mode on a successful return. The value of this field will be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.

numsrc
It is a pointer that on input, points to the number of source addresses that will fit in the slist array. On return, points to the total number of sources associated with the filter.

slist Points to buffer into which an array of IP addresses of included or excluded (depending on the filter mode) sources will be written. If numsrc was 0 on input, a NULL pointer may be supplied.

Returned value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

errno Description

EADDRNOTAVAIL
The tuple consisting of socket, interface, and multicast group values does not exist, or the specified interface address is incorrect for this host, or the specified interface address is not multicast capable.

EBADF
s is not a valid socket descriptor.

EINVAL
Interface or group is not a valid IPv4 address, or the socket s has already requested multicast setsockopt options.

EPROTOTYPE
The socket s is not of type SOCK_DGRAM or SOCK_RAW.

getitimer() — Get value of an interval timer

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/time.h>

int getitimer(int which, struct itimerval *value);
```

General description

getitimer() gets the current value of an (previously set) interval timer. An interval timer is a timer which sends a signal after each repetition (interval) of time.

The *which* argument indicates what kind of time is being controlled. Values for *which* are:

ITIMER_REAL
This timer is marking real (clock) time. A SIGALRM signal is generated after each interval of time.

Note: alarm() also sets the real interval timer.

ITIMER_VIRTUAL
This timer is marking process virtual time. Process virtual time is the amount of time spent while executing in the process, and can be thought of as a CPU timer. A SIGVTALRM signal is generated after each interval of time.

ITIMER_PROF
This timer is marking process virtual time plus time spent while the system is running on behalf of the process. A SIGPROF signal is generated after each interval of time.

Note: In a multithreaded environment, each of the above timers is specific to a thread of execution for both the generation of the time interval and the measurement of time. For example, an ITIMER_VIRTUAL timer will mark execution time for just the thread, not the entire process.

The *value* argument is a pointer to a structure containing:

`it_interval`
timer interval

`it_value`
current timer value (time remaining)

Each of these fields is a timeval structure, and contains:

`tv_sec` seconds since January 1, 1970 (UTC)

`tv_usec`
microseconds

Returned value

If successful, getitimer() returns 0, and *value* points to the itimerval structure.

If unsuccessful, getitimer() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
which is not a valid timer type.

getlogin() — Get the user login name

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

_POSIX_SOURCE:

```
#define _POSIX_SOURCE
#include <unistd.h>

char *getlogin(void);
```

_XOPEN_SOURCE:

```
#define _XOPEN_SOURCE
#include <unistd.h>

char *getlogin(void);
```

General description

Finds the name that the login process associated with the current terminal. This string is stored in a static data area and, therefore, may be overwritten with every call to getlogin().

Special behavior for _POSIX_SOURCE: If called from a batch program, a TSO command, or a shell command, getlogin() returns the MVS user name associated with the program. With z/OS UNIX services, this name is a TSO/E user ID. When _POSIX_SOURCE is defined and _XOPEN_SOURCE is not defined, then getlogin() is the same as __getlogin1().

Special behavior for XPG4.2: You must have a TTY at file descriptor 0, 1, or 2, and the TTY must be recorded in the /etc/utmpx database. Someone must have logged in using the TTY. Also, the program must be invoked from a shell session, and file descriptors 0, 1, and 2 are not all redirected.

If getlogin() cannot determine the login name, you can call getuid() to get the user ID of the process, and then call getpwuid() to get a login name associated with that user ID. getpwuid() always returns the `passwd struct` for the same user, even if multiple users have the same UID.

Returned value

If successful, getlogin() returns a pointer to a string that has the login name for the current terminal.

Special behavior for _POSIX_SOURCE: If unsuccessful, getlogin() returns the NULL pointer.

There are no documented errno values.

Special behavior for XPG4.2: If unsuccessful, getlogin() returns a NULL pointer and sets errno to one of the following values:

Error Code
  Description

EMFILE
  OPEN_MAX file descriptors are currently open in the calling process.

ENFILE
  The maximum allowable number of files is currently open in the system.

ENXIO
  The calling process has no controlling terminal.

Example

CELEBG12

```
/* CELEBG12

   This example gets the user login name.

 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <unistd.h>

main() {
  char *user;

  if ((user = __getlogin1()) == NULL)
    perror("__getlogin1() error");
  else printf("__getlogin1() returned %s\n", user);
}
```

Output

```
getlogin() returned MEGA
```

getlogin_r() — Get login name

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE 500
#include <unistd.h>

int getlogin_r(char *name, size_t namesize);
```

General description

The getlogin_r() function puts the name associated by the login activity with the control terminal of the current process in the character array pointed to by *name*. The array is *namesize* characters long and should have space for the name and the terminating NULL character. The maximum size of the login name is **LOGIN_NAME_MAX**.

If getlogin_r() is successful, *name* points to the name the user used at login, even if there are several login names with the same user ID.

Returned value

If successful, getlogin_r() returns 0.

If unsuccessful, getlogin_r() sets errno to one of the following values:

Error Code
Description

ERANGE
The value of *namesize* is smaller than the length of the string to be returned including the terminating NULL character.

Related information

__getlogin1() — Get the user login name

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2	both	

Format

_POSIX_SOURCE:

```
#define _POSIX_SOURCE
#include <unistd.h>

char *__getlogin1(void);
```

General description

Finds the name that the login process associated with the current terminal. If called from batch, __getlogin1() finds the name associated with the batch program. With z/OS UNIX services, this name is a TSO/E user ID unless the USERIDALISTABLE is in use. If the USERIDALISTABLE is setup and a z/OS UNIX alias name exists for a given MVS(TSO, batch user, etc.) userid, then that will be returned.

If __getlogin1() cannot determine the login name, you can call getuid() to get the user ID of the process, and then call getpwuid() to get a login name associated with that user ID. getpwuid() always returns the `passwd struct` for the same user, even if multiple users have the same UID.

Returned value

If successful, __getlogin1() returns a pointer to a string that has the login name for the current terminal.

If unsuccessful, __getlogin1() returns the NULL pointer.

There are no documented errno values.

Example

CELEBG12

```
/* CELEBG12

   This example gets the user login name.

 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <unistd.h>

main() {
  char *user;

  if ((user = __getlogin1()) == NULL)
    perror("__getlogin1() error");
  else printf("__getlogin1() returned %s\n", user);
}
```

Output

```
getlogin() returned MEGA
```

getmccoll() — Get next collating element from string

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <collate.h>

collel_t getmccoll(char **src);
```

General description

If the object pointed to by *src* is not a NULL pointer, the getmccoll() library function determines the longest sequence of bytes in the array pointed to by *src* that constitute a valid multicharacter collating element. It then produces the value of type `collel_t` corresponding to that collating element. The object pointed to by *src* is assigned the address just past the last byte of the multicharacter collating element processed.

Returned value

If successful, getmccoll() returns the value of type `collel_t` that represents the collating element found.

If the object pointed to by *src* is a NULL pointer, or if it points to NULL character, getmccoll() returns 0.

getmsg(), getpmsg() — Receive next message from a STREAMS file

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int getmsg(int fildes, struct strbuf *ctlptr,
           struct strbuf *dataptr, int *flagsp);
int getpmsg(int fildes, struct strbuf *ctlptr,
            struct strbuf *dataptr, int *bandp, int *flagsp);
```

General description

The getmsg() function retrieves the contents of a message located at the head of the STREAM head read queue associated with a STREAMS file and places the contents into one or more buffers. The message contains either a data part, a control part, or both. The data and control parts of the message are placed into separate buffers, as described below. The semantics of each part is defined by the originator of the message.

The getpmsg() function does the same thing as getmsg(), but provides finer control over the priority of the messages received. Except where noted, all requirements on getmsg() also pertain to getpmsg().

The *fildes* argument specifies a file descriptor referencing a STREAMS-based file.

The *ctlptr* and *dataptr* arguments each point to a `strbuf` structure, in which the **buf** member points to a buffer in which the data or control information is to be placed, and the **maxlen** member indicates the maximum number of bytes this buffer can hold. On return, the **len** member contains the number of bytes of data or control information actually received. The **len** member is set to 0 if there is a zero-length control or data part and **len** is set to -1 if no data or control information is present in the message.

When getmsg() is called, *flagsp* should point to an integer that indicates the type of message the process is able to receive. This is described further below.

The *ctlptr* argument is used to hold the control part of the message, and *dataptr* is used to hold the data part of the message. If *ctlptr* (or *dataptr*) is a NULL pointer or the **maxlen** member is -1, the control (or data) part of the message is not processed and is left on the STREAM head read queue. If the *ctlptr* (or *dataptr*) is not a NULL pointer, **len** is set to -1. If the **maxlen** member is set to 0 and there is a zero-length control (or data) part, that zero-length part is removed from the read queue and **len** is set to 0. If the **maxlen** member is set to 0 and there are more than 0 bytes of control (or data) information, that information is left on the read queue and **len** is set to 0. If the **maxlen** member in *ctlptr* (or *dataptr*) is less than the control (or data) part of the message, **maxlen** bytes are retrieved. In this case, the remainder of the message is left on the STREAM head read queue and a nonzero return value is provided.

By default, getmsg() processes the first available message on the STREAM head read queue. However, a process may choose to retrieve only high-priority messages by setting the integer pointed to by *flagsp* to `RS_HIPRI`. In this case, getmsg() and getpmsg() will only process the next message if it is a high-priority message. When the integer pointed to by *flagsp* is 0, any message will be retrieved. In this case, on return, the integer pointed to by *flagsp* will be set to `RS_HIPRI` if a high-priority message was retrieved, or 0 otherwise.

For getpmsg(), the flags are different. The *flagsp* argument points to a bitmask with the following mutually-exclusive flags defined: `MSG_HIPRI`, `MSG_BAND`, and `MSG_ANY`. Like getmsg(), getpmsg() processes the first available message on the STREAM head read queue. A process may choose to retrieve only high-priority messages by setting the integer pointed to by *flagsp* to `MSG_HIPRI` and the integer pointed to by *bandp* to 0. In this case, getpmsg() will only process the next message if it is a high-priority message. In a similar manner, a process may choose to retrieve a message from a particular priority band by setting the integer pointed to by *flagsp* to `MSG_BAND` and the integer pointed to by *bandp* to the priority band of interest. In this case, getpmsg() will only process the next message if it is in a priority band equal to, or greater than, the integer pointed to by *bandp*, or if it is a high-priority message. If a process just wants to get the first message off the queue, the integer pointed to by *flagsp* should be set to `MSG_ANY` and the integer pointed to by *bandp* should be set to 0. On return, if the message retrieved was a high-priority message, the integer pointed to by *flagsp* will be set to `MSG_HIPRI` and the integer pointed to by *bandp* will be set to 0. Otherwise, the integer pointed to by *flagsp* will be set to `MSG_BAND` and the integer pointed to by *bandp* will be set to the priority band of the message.

If O_NONBLOCK is not set, getmsg() and getpmsg() will block until a message of the type specified by *flagsp* is available at the front of the STREAM head read queue. If O_NONBLOCK is set and a message of the specified type is not present at the front of the read queue, getmsg() and getpmsg() fail and set errno to EAGAIN.

If a hang-up occurs on the STREAM from which messages are to be retrieved, getmsg() and getpmsg() continue to operate normally, as described above, until the STREAM head read queue is empty. Thereafter, they return 0 in the *len* members of *ctlptr* and *dataptr*.

The following symbolic constants are defined under _XOPEN_SOURCE_EXTENDED 1 in <stropts.h>.

MSG_ANY
Receive any message.

MSG_BAND
Receive message from specified band.

MSG_HIPRI
Send/Receive high priority message.

MORECTL
More control information is left in message.

MOREDATA
More data is left in message.

Returned value

If successful, getmsg() and getpmsg() return a nonnegative value. A value of 0 indicates that a full message was read successfully. A return value of MORECTL indicates that more control information is waiting for retrieval. A return value of MOREDATA indicates that more data is waiting for retrieval. A return value of the bitwise logical OR of MORECTL and MOREDATA indicates that both types of information remain. Subsequent getmsg() and getpmsg() calls retrieve the remainder of the message. However, if a message of higher priority has come in on the STREAM head read queue, the next call to getmsg() or getpmsg() retrieves that higher-priority message before retrieving the remainder of the previous message.

If unsuccessful, getmsg() and getpmsg() return -1 and set errno to one of the following values.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for getmsg() and getpmsg() to get a message from a STREAMS file. It will always return -1 with errno set to indicate the failure. See "open() — Open a file" on page 1152 for more information.

Error Code
Description

EAGAIN
The O_NONBLOCK flag is set and no messages are available.

EBADF
The *fildes* argument is not a valid file descriptor open for reading.

EBADMSG
The queued message to be read is not valid for getmsg() or getpmsg() or a pending file descriptor is at the STREAM head.

EINTR
A signal was caught during getmsg() or getpmsg()

EINVAL
An illegal value was specified by *flagsp*, or the STREAM or multiplexer referenced by *fildes* is linked (directly or indirectly) downstream from a multiplexer.

ENOSTR
A STREAM is not associated with *fildes*.

In addition, getmsg() and getpmsg() will fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of errno does not reflect the result of getmsg() or getpmsg() but reflects the prior error.

getnameinfo() — Get name information

Standards

Standards / Extensions	C or C++	Dependencies
RFC2553 Single UNIX Specification, Version 3	both	z/OS V1R4

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <sys/socket.h>
#include <netdb.h>

int getnameinfo(cons struct sockaddr *sa, socklen_t salen,
                char *host, socklen_t hostlen,
                char *serv, socklen_t servlen,
                int flags);
```

SUSV3

```
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>

int getnameinfo(cons struct sockaddr *__restrict__ sa, socklen_t salen,
        char *__restrict__ host, socklen_t hostlen, char *__restrict__ serv,
          socklen_t servlen, int flags);
```

General description

The getnameinfo() function translates a socket address to a node name and service location. The getnameinfo() function looks up an IP address and port number provided by the caller in the DNS and system-specific database, and returns text strings for both in buffers provided by the caller.

The *sa* argument points to either a sockaddr_in structure (for IPv4) or a sockaddr_in6 structure (for IPv6) that holds the IP address and port number. The sockaddr_in6 structure may also contain a zone index value, if the IPv6 address represented by this sockaddr_in6 structure is a link-local address. The *salen* argument gives the length of the sockaddr_in or sockaddr_in6 structure.

If the socket address structure contains an IPv4-mapped IPv6 address or an IPv4-compatible IPv6 address, the embedded IPv4 address is extracted and the the lookup is performed on the IPv4 address.

Note: The IPv6 unspecified address ("::") and the IPv6 loopback address ("::1") are not IPv4-compatible addresses. If the address is the IPv6 unspecified address, a lookup is not performed, and the EAI_NONAME error code is returned.

The node name associated with the IP address is returned in the buffer pointed to by the host argument. The caller provides the size of this buffer in the *hostlen* argument. The caller specifies not to return the node name by specifying a zero value for *hostlen* or a null host argument. If the node's name cannot be located, the numeric form of the node's address is returned instead of its name. If a zone index value was present in the sockaddr_in6 structure, the numeric form of the zone index, or the interface name associated with the zone index, is appended to the node name returned, using the format node name%scope information.

If the size of the buffer specified in the *hostlen* argument is insufficient to contain the entire node name, or node name and scope information combination, up to *hostlen* characters will be copied into the buffer as a null terminated string.

The service name associated with the port number is returned in the buffer pointed to by the *serv* argument, and the *servlen* argument gives the length of this buffer. The caller specifies not to the service name by specifying a zero value for *servlen* or a null *serv* argument. If the service's name cannot be located, the numeric of the service address (for example, its port number) will be returned instead of its name.

If the size of the buffer specified in the *servlen* argument is insufficient to contain the entire service name, up to *servlen* characters will be copied into the buffer as a null terminated string.

The final argument, *flags*, is a flag that changes the default actions of this function. By default the fully-qualified domain name (FQDN) for the host is returned.

If the flag bit NI_NOFQDN is set, only the node name portion of the FQDN is returned for local hosts.

If the flag bit NI_NUMERICHOST is set, the numeric form of the host's address is returned instead of its name.

If the flag bit NI_NAMEREQD is set, an error is returned if the host's name cannot be located.

If the flag bit NI_NUMERICSERV is set, the numeric form of the service address is returned (for example, its port number) instead of its name.

If the flag bit NI_NUMERICSCOPE is set, the numeric form of the scope identifier is returned (for example, zone index) instead of its name. This flag is ignored if the *sa* argument is not an IPv6 address.

If the flag bit NI_DGRAM is set, this specifies that the service is a datagram service, and causes getservbyport() to be called with a second argument of "udp" instead of its default of "tcp". This flag is required for the few ports (for example, [512,514]) that have different services for UDP and TCP.

Note: The three NI_NUMERICxxx flags are required to support the "-n" flag that many commands provide.

Special behavior for SUSv3: Starting with z/OS V1.9, environment variable _EDC_SUSV3 can be used to control the behavior of getnameinfo() with respect to detecting if the buffer pointed to by the host or serv argument is too small to contain the entire resolved name. The function will fail and return EAI_OVERFLOW. By default, getnameinfo() will truncate the values pointed to by host or serv and return successfully. When _EDC_SUSV3 is set to 1, getnameinfo() will check for insufficient size buffers to contain the resolved name.

Returned value

Upon successful completion, getnameinfo() returns the node and service names, if requested, in the buffers provided. The returned names are always null-terminated strings.

A zero return value for getnameinfo() indicates successful completion; a non-zero return value indicates failure. The possible values for the failures are listed as follows.

Error Code
    Description

EAI_AGAIN
    The specified host address could not be resolved within the configured time interval, or the resolver address space has not been started. The request can be retried later.

EAI_BADFLAGS
    The flags parameter had an incorrect value.

EAI_FAIL
    An unrecoverable error occurred.

EAI_FAMILY
    The address family was not recognized, or the address length was not valid for the specified family.

EAI_MEMORY
    A memory allocation failure occurred.

EAI_NONAME
    The name does not resolve for the supplied parameter. One of the following occurred:

1. NI_NAMEREQD is set, and the host name cannot be located.
2. Both host name and service name were null.
3. The requested address is valid, but it does not have a record at the name server.

EAI_OVERFLOW
    An argument buffer overflowed. The buffer specified for the host name or the service name was not sufficient to contain the entire resolved name, and the caller previously specified _EDC_SUSV3=1, indicating that truncation was not permitted.

EAI_SYSTEM
An unrecoverable error occurred.

For more information on the above error codes, refer to *z/OS Communications Server: IP and SNA Codes*.

getnetbyaddr() — Get a network entry by address

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

XPG4.2:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct netent *getnetbyaddr(ip_addr_t net, int type);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <netdb.h>
struct netent  *getnetbyaddr(uint32_t net, int type);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <netdb.h>

struct netent *getnetbyaddr(unsigned long net, int type);
```

General description

The getnetbyaddr() call searches the *tcpip*.HOSTS.ADDRINFO data set for the specified network address.

Parameter	**Description**
net	The network address.
type	The address domain supported (AF_INET).

If the name server is not present or the RESOLVE_VIA_LOOKUP option is in effect, you can use the **X_ADDR** environment variable to specify a data set other than *tcpip*.HOSTS.ADDRINFO.

Note: For more information on these data sets and environment variables, *tcpip*.HOSTS.LOCAL, *tcpip*.HOSTS.ADDRINFO, and *tcpip*.HOSTS.SITEINFO, see *z/OS Communications Server: IP Configuration Guide, SC27-3650*.

getnetbyaddr(), getnetbyname(), and getnetent() all use the same static area to return the `netent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `netent` structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

n_addrtype
The type of network address returned. The call always sets this value to AF_INET.

n_aliases
An array, terminated with a NULL pointer, of alternative names for the network.

n_name
The official name of the network.

n_net The network number, returned in host byte order.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, getnetbyaddr() returns a pointer to a `netent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, getnetbyaddr() returns a NULL pointer, indicating an error or End Of File (EOF).

Related information

getnetbyname() — Get a network entry by name

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct netent *getnetbyname(const char *name);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct netent *getnetbyname(name);
```

General description

The getnetbyname() call searches the *tcpip*.HOSTS.SITEINFO data set for the specified network name.

Parameter
Description

name The pointer to a network name.

You can use the **X_SITE** environment variable to specify a data set other than *tcpip*.HOSTS.SITEINFO.

Note: For more information on these data sets and environment variables, *tcpip*.HOSTS.LOCAL, *tcpip*.HOSTS.SITEINFO, and *tcpip*.HOSTS.SITEINFO, see *z/OS Communications Server: IP Configuration Guide, SC27-3650*.

The getnetbyname() call returns a pointer to a `netent` structure for the network name specified on the call. getnetbyaddr(), getnetbyname(), and getnetent() all use the same static area to return the `netent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `netent` structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

n_addrtype
The type of network address returned. The call always sets this value to AF_INET.

n_aliases
An array, terminated with a NULL pointer, of alternative names for the network.

n_name
The official name of the network.

n_net The network number, returned in host byte order.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, getnetbyname() returns a pointer to a `netent` structure. The return value points to static data that is overwritten by subsequent calls.

If unsuccessful, getnetbyname() returns a NULL pointer, indicating an error or End Of File (EOF).

getnetent() — Get the next network entry

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct netent *getnetent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct netent *getnetent(void);
```

General description

The getnetent() call reads the next entry of the *tcpip*.HOSTS.ADDRINFO data set.

You can use the **X_ADDR** environment variable to specify a data set other than *tcpip*.HOSTS.ADDRINFO.

Note: For more information on these data sets and environment variables, *tcpip*.HOSTS.LOCAL, *tcpip*.HOSTS.ADDRINFO, and *tcpip*.HOSTS.SITEINFO, see *z/OS Communications Server: IP Configuration Guide, SC27-3650*.

The getnetent() call returns a pointer to the next entry in the *tcpip*.HOSTS.SITEINFO data set.

getnetbyaddr(), getnetbyname(), and getnetent() all use the same static area to return the `netent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The netent structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

n_addrtype
The type of network address returned. The call always sets this value to AF_INET.

n_aliases
An array, terminated with a NULL pointer, of alternative names for the network.

n_name
The official name of the network.

n_net The network number, returned in host byte order.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, getnetent() returns a pointer to a netent structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, getnetent() returns a NULL pointer, indicating an error or End Of File (EOF).

getopt() — Command option parsing

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <stdio.h>
int getopt(int argc, char *const argv[], const char *optsting);

extern char *optarg;
extern int optind, opterr, optopt;
```

SUSV3:

```
#define _XOPEN_SOURCE 600
#include <unistd.h>

int getopt(int argc, char *const argv[], const char *optsting);

extern char *optarg;
extern int optind, opterr, optopt;
```

General description

The getopt() function is a command-line parser that can be used by applications that follow Utility Syntax Guidelines 3, 4, 5, 6, 7, 9 and 10 in *X/Open CAE Specification, System Interface Definitions, Issue 4, Version 2* Section 10.2 , Utility Syntax Guidelines. The getopt() function provides the identical functionality described in the X/Open CAE Specification System Interfaces and Headers, Issue 4, Version 2 for the getopt() function with the following extensions:

- If the external variable *optind* is set to zero, the getopt() function treats this as an indication to restart the scan at the first byte of argv[1].

If getopt() encounters an option character that is not contained in *optstring*, it returns the question-mark (?) character. If it detects a missing option-argument, it returns the colon character (:) if the first character of *optstring* was a colon, or a question-mark character (?) otherwise. In either case, getopt() sets the variable *optopt* to the option character that caused the error. If the application has not set the variable *opterr* to 0 and the first character of *optstring* is not a colon, getopt() also prints a diagnostic message to stderr in the format specified for the getopts utility.

Because the getopt() function returns thread-specific data the getopt() function can be used safely from a multithreaded application.

Returned value

If successful, getopt() returns the value of the next option character from *argv* that matches a character in optstring.

A colon (:) is returned if getopt() detects a missing argument and the first character of optstring was a colon (:).

A question-mark (?) is returned if getopt() encounters an option character not in optstring or detects a missing argument and the first character of optstring was not a colon (:).

Otherwise getopt() returns -1 when all command line arguments have been parsed or an unexpected error is encountered in the command line.

getopt() sets the external variables optind, optarg and optopt as described in the X/Open CAE Specification System Interfaces and Headers, Issue 4, Version 2 for the getopt() function.

The following functions defined in <stdio.h> should be used by multithreaded applications when attempting to reference or change the optind, optopt, optarg and opterr external variables:

```
int *__opindf(void);

int *__opoptf(void);
```

```
char **__opargf(void);

int *__operrf(void);
```

Also use these functions when you invoke getopt() in a DLL. These functions return a pointer to a thread-specific value for each variable.

getopt() does not return any errno values.

If getopt() detects a missing argument or an option character not in optstring it will write an error message to stderr describing the option character in error and the invoking program.

getpagesize() — Get the current page size

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int getpagesize(void);
```

General description

The getpagesize() function returns the current page size. The getpagesize() function is equivalent to sysconf(_SC_PAGE_SIZE) and sysconf(_SC_PAGESIZE).

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use sysconf(_SC_PAGESIZE) instead of getpagesize().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

getpagesize() returns the current page size.

Related information

- “unistd.h” on page 82
- “sysconf() — Determine system configuration options” on page 1798

getpass() — Read a string of characters without echo

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2	both	

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

char *getpass(const char *prompt);
```

General description

The getpass() function opens the process's controlling terminal, writes to that device the NULL-terminated string *prompt*, disables echoing, reads a string of characters up to the next newline character or EOF, restores the terminal state and closes the terminal.

getpass() only works in an environment where either a controlling terminal exists, or stdin and stderr refer to tty devices. Specifically, it does not work in a TSO environment.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, getpass() returns a pointer to a NULL-terminated string of at most **PASS_MAX** bytes that were read from the terminal device.

If unsuccessful, getpass() returns a NULL pointer and the terminal state is restored.

Related information

- "unistd.h" on page 82

getpeername() — Get the name of the peer connected to a socket

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getpeername(int socket, struct sockaddr *__restrict__ name,
                socklen_t *__restrict__ namelen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getpeername(int socket, struct sockaddr *name,
                int *namelen);
```

General description

The getpeername() call returns the name of the peer connected to socket descriptor *socket*. *namelen* must be initialized to indicate the size of the space pointed to by *name* and is set to the number of bytes copied into the space before the call returns. The size of the peer name is returned in bytes. If the actual length of the address is greater than the length of the supplied *sockaddr*, the stored address is truncated. The *sa_len* member of the store structure contains the length of the untruncated address.

Parameter
Description

socket The socket descriptor.

name The Internet address of the connected socket that is filled by getpeername() before it returns. The exact format of *name* is determined by the domain in which communication occurs.

namelen
Must initially point to an integer that contains the size in bytes of the storage pointed to by *name*. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in sockaddr is truncated to the length supplied on input. If *name* is NULL, *namelen* is ignored.

Sockets in the AF_INET6 domain: For an AF_INET6 socket, the address is returned in a sockaddr_in6 address structure. The sockaddr_in6 structure is defined in the header file **netinet/in.h**.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The getpeername() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, getpeername() returns 0.

If unsuccessful, getpeername() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
The *socket* parameter is not a valid socket descriptor.

EFAULT
Using the *name* and *namelen* parameters as specified would result in an attempt to access storage outside of the caller's address space.

EINVAL
The *namelen* parameter is not a valid length. The socket has been shut down.

ENOBUFS
getpeername() is unable to process the request due to insufficient storage.

ENOTCONN
The socket is not in the connected state.

ENOTSOCK
The descriptor is for a file, not for a socket.

EOPTNOTSUPP
The operation is not supported for the socket protocol.

getpgid() — Get process group ID

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

pid_t getpgid(pid_t pid);
```

General description

The getpgid() function returns the process group ID of the process whose process ID is equal to *pid*. If *pid* is 0, getpgid() returns the PID of the calling process.

Returned value

If successful, getpgid() returns a process group ID.

If unsuccessful, getpgid() returns (pid_t)-1 and sets errno to one of the following values:

Error Code
Description

EPERM
The process whose process ID is equal to *pid* is not the same session as the calling process, and the implementation does not allow to the process group ID of that process from the calling process.

ESRCH
There is no process with a process ID equal to *pid*.

getpgid() may fail if:

Error Code
Description

EINVAL
The value of the *pid* argument is not valid.

getpgrp() — Get the process group ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

pid_t getpgrp(void);
```

General description

Finds the process group ID of the calling process.

Returned value

Returns the found value. It is always successful.

There are no documented errno values.

Example

CELEBG13

```
/* CELEBG13

   This example gets all the process group IDs.

 */
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/wait.h>

main() {
  int status;

  if (fork() == 0) {
    if (fork() == 0) {
      printf("grandchild's pid is %d, process group id is %d\n",
             (int) getpid(), (int) getpgrp());
      exit(0);
    }
    printf("child's pid is %d, process group id is %d\n",
           (int) getpid(), (int) getpgrp());
    wait(&status);
    exit(0);
  }
  printf("parent's pid is %d, process group id is %d\n",
         (int) getpid(), (int) getpgrp());
  printf("the parent's parent's pid is %d\n", (int) getppid());
  wait(&status);
}
```

Output

```
parent's pid is 5373959, process group id is 5111816
the parent's parent's pid is 5111816
child's pid is 5832710, process group id is 5111816
grandchild's pid is 196617, process group id is 5111816
```

getpid() — Get the process ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

pid_t getpid(void);
```

General description

Finds the process ID (PID) of the calling process.

Returned value

getpid() returns the found value. It is always successful.

There are no documented errno values.

Example

CELEBG14

```
/* CELEBG14 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <signal.h>
#include <unistd.h>

void catcher(int signum) {
  puts("catcher has control!");
}

main() {
  struct sigaction sact;

  sigemptyset(&sact.sa_mask);
  sact.sa_flags = 0;
  sact.sa_handler = catcher;
  sigaction(SIGUSR1, &sact, NULL);

  printf("sending SIGUSR1 to pid %d\n", (int) getpid());
  kill(getpid(), SIGUSR1);
}
```

Output

```
sending SIGUSR1 to pid 5570567
catcher has control!
```

getpmsg() — Receive next message from a STREAMS file

The information for this function is included in “getmsg(), getpmsg() — Receive next message from a STREAMS file” on page 735.

getppid() — Get the parent process ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

pid_t getppid(void);
```

General description

Gets the parent process ID (PPID).

Returned value

getppid() returns the parent process ID. It is always successful.

There are no documented errno values.

Example

CELEBG15

```
/* CELEBG15 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <signal.h>
#include <unistd.h>
#include <sys/wait.h>                  /*FIX: used to be <wait.h>*/

volatile short footprint=0;

void catcher(int signum) {
  switch (signum) {
    case SIGALRM: puts("caught SIGALRM");
                  break;
    case SIGUSR2: puts("caught SIGUSR2");
                  break;
    default: printf("caught unexpected signal %d\n", signum);
  }
  footprint++;
}

main() {
  struct sigaction sact;
  int status;

  sigemptyset(&sact.sa_mask);
  sact.sa_flags = 0;
  sact.sa_handler = catcher;
  sigaction(SIGUSR2, &sact, NULL);

  sigemptyset(&sact.sa_mask);
  sact.sa_flags = 0;
  sact.sa_handler = catcher;
  sigaction(SIGALRM, &sact, NULL);

  printf("parent (pid %d) is about to fork child\n", (int) getpid());

  if (fork() == 0) {
    printf("child is sending SIGUSR2 to pid %d\n", (int) getppid());
    kill(getppid(), SIGUSR2);
    exit(0);
  }

  alarm(30);
  while (footprint == 0);
  wait(&status);
  puts("parent is exiting");
}
```

Output

```
parent (pid 6094854) is about to fork child
is sending SIGUSR2 to pid 6094854
caught SIGUSR2
parent is exiting
```

- "kill() — Send a signal to a process" on page 931

getpriority() — Get process scheduling priority

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getpriority(int which, id_t who);
```

General description

getpriority() obtains the current priority of a process, process group or user.

Processes are specified by the values of the *which* and *who* arguments. The *which* argument may be any one of the following set of symbols defined in the *sys/resource.h* include file:

PRIO_PROCESS
indicates that the *who* argument is to be interpreted as a process ID

PRIO_PGRP
indicates that the *who* argument is to be interpreted as a process group ID

PRIO_USER
indicates that the *who* argument is to be interpreted as a user ID

The *who* argument specifies the ID (process, process group, or user). A 0 (zero) value for the *who* argument specifies the current process, process group or user ID.

Returned value

If successful, getpriority() returns the priority of the process, process group, or used ID requested in *who*. The priority is returned as an integer in the range -20 to 19 (the lower the numerical value, the higher the priority).

If more than one process is specified, getpriority() returns the highest priority pertaining to any of the specified processes.

If unsuccessful, getpriority() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The symbol specified in the *which* argument was not recognized, or the value of the *who* argument is not a valid process ID, process group ID or user ID.

ESRCH
No process could be located using the *which* and *who* argument values specified.

Because getpriority() can return the value -1 on successful completion, it is necessary to set the external variable errno to 0 before a call to getpriority(). If getpriority() returns -1, then errno can be checked to see if an error occurred or if the value is a legitimate priority.

Related information

- "sys/resource.h" on page 74

- "setpriority() — Set process scheduling priority" on page 1567

getprotobyname() — Get a protocol entry by name

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct protoent *getprotobyname(const char *name);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct protoent *getprotobyname(char name);
```

General description

The getprotobyname() call searches the */etc/protocol* or *tcpip*.ETC.PROTO data set for the specified protocol name.

Parameter
Description

name The name of the protocol.

The getprotobyname() call returns a pointer to a protoent structure for the network protocol specified on the call. getprotobyname(), getprotobynumber(), and getprotoent() all use the same static area to return the protoent structure. This static area is only valid until the next one of these functions is called on the same thread.

The protoent structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

p_aliases
An array, terminated with a NULL pointer, of alternative names for the protocol.

p_name
The official name of the protocol.

p_proto
The protocol number.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, getprotobyname() returns a pointer to a protoent structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, getprotobyname() returns a NULL pointer, indicating an error or End Of File (EOF).

Related information

getprotobynumber() — Get a protocol entry by number

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct protoent *getprotobynumber(int proto);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct protoent *getprotobynumber(int proto);
```

General description

The getprotobynumber() call searches the */etc/protocol* or *tcpip*.ETC.PROTO data set for the specified protocol number.

Parameter
Description

proto The protocol number.

The getprotobynumber() call returns a pointer to a `protoent` structure for the network protocol specified on the call. getprotobyname(), getprotobynumber(), and getprotoent() all use the same static area to return the `protoent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `protoent` structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

p_aliases
An array, terminated with a NULL pointer, of alternative names for the protocol.

p_name
The official name of the protocol.

p_proto
The protocol number.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, getprotobynumber() returns a pointer to a `protoent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, getprotobynumber() returns a NULL pointer, indicating an error or End Of File (EOF).

getprotoent() — Get the next protocol entry

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct protoent *getprotoent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct protoent *getprotoent(void);
```

General description

The getprotoent() call reads */etc/protocol* or the *tcpip*.ETC.PROTO data set.

The getprotoent()> call returns a pointer to the next entry in the */etc/protocol* or the *tcpip*.ETC.PROTO data set.

getprotobyname(), getprotobynumber(), and getprotoent() all use the same static area to return the `protoent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `protoent` structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

p_aliases
An array, terminated with a NULL pointer, of alternative names for the protocol.

p_name
The official name of the protocol.

p_proto
The protocol number.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, getprotoent() returns a pointer to a `protoent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, getprotoent() returns a NULL pointer, indicating an error or End Of File (EOF).

getpwent() — Get user database entry

The information for this function is included in "endpwent() — User database functions" on page 423.

getpwnam() — Access the user database by user name

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <pwd.h>

struct passwd *getpwnam(const char *name);
```

General description

Accesses the `passwd` structure (defined in the pwd.h header file), which contains the following members:

pw_name
User name

pw_uid User ID (UID) number
pw_gid Group ID (GID) number
pw_dir Initial working directory
pw_shell
Initial user program

Returned value

If successful, getpwnam() returns a pointer to a passwd structure containing an entry from the user database with the specified *name*. Return values may point to the static data that is overwritten on each call.

If unsuccessful, getpwnam() returns a NULL pointer and sets errno to one of the following values:

Error Code
Description

EINVAL
A non-valid user *name* is detected.

Example

CELEBG16

```
/* CELEBG16

   This example provides information for the user data
   base, MEGA.

 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>

main() {
  struct passwd *p;
  char user[]="MEGA";

  if ((p = getpwnam(user)) == NULL)
    perror("getpwnam() error");
  else {
    printf("getpwnam() returned the following info for user %s:\n",
           user);
    printf("  pw_name  : %s\n",       p->pw_name);
    printf("  pw_uid   : %d\n", (int) p->pw_uid);
    printf("  pw_gid   : %d\n", (int) p->pw_gid);
    printf("  pw_dir   : %s\n",       p->pw_dir);
    printf("  pw_shell : %s\n",       p->pw_shell);
  }
}
```

Output

```
  pw_name  : MEGA
  pw_uid   : 0
  pw_gid   : 512
  pw_dir   : /u/mega
  pw_shell : /bin/sh
```

getpwnam_r() — Search user database for a name

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <pwd.h>

int getpwnam_r(const char *nam, struct passwd *pwd,
char *buffer, size_t bufsize, struct passwd **result);
```

General description

The getpwnam_r() function updates the passwd structure pointed to by *pwd* and stores a pointer to that structure at the location pointed to by *result*. The structure will contain an entry from the user database with a matching name. Storage referenced by the structure is allocated from the memory provided with the *buffer* parameter, which is *bufsize* characters in size. A NULL pointer is returned at the location pointed to by *result* on error or if the requested entry is not found.

Returned value

If successful, getpwnam_r() returns 0.

If unsuccessful, getpwnam_r() sets errno to one of the following values:

Error Code
Description

EINVAL
One of the input arguments was not valid. Arguments *pwd*, *buffer*, and *result* must not be NULL. Argument *bufsize* must not be 0.

ERANGE
Insufficient storage was supplied in *buffer* and *bufsize* to contain the data to be referenced by the resulting passwd structure.

getpwuid() — Access the user database by user ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <pwd.h>

struct passwd *getpwuid(uid_t uid);
```

General description

Gets information about a user with the specified *uid*. getpwuid() returns a pointer to a passwd structure containing an entry from the user database for the specified *uid*. This structure (defined in the pwd.h header file), contains the following members:

pw_name
User name

pw_uid User ID (UID) number

pw_gid Group ID (GID) number

pw_dir Initial working directory

pw_shell
Initial user program

Return values may point to the static data that is overwritten on each call.

Returned value

If successful, getpwuid() returns a pointer.

If unsuccessful, getpwuid() returns a NULL pointer and sets errno to one of the following values:

Error Code
Description

EMVSSAF2ERR
The system authorization facility (SAF) or RACF Get GMAP or Get UMAP service had an error.

EMVSSAFEXTRERR
The SAF or RACF RACROUTE EXTRACT service had an error.

Example

CELEBG17

```
/* CELEBG17

   This example provides information for user ID 0.
```

```
 */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>

main() {
  struct passwd *p;
  uid_t  uid=0;

  if ((p = getpwuid(uid)) == NULL)
    perror("getpwuid() error");
  else {
    printf("getpwuid() returned the following info for uid %d:\n",
           (int) uid);
    printf("  pw_name  : %s\n",       p->pw_name);
    printf("  pw_uid   : %d\n", (int) p->pw_uid);
    printf("  pw_gid   : %d\n", (int) p->pw_gid);
    printf("  pw_dir   : %s\n",       p->pw_dir);
    printf("  pw_shell : %s\n",       p->pw_shell);
  }
}
```

Output

```
getpwuid() returned the following info for uid 0:
  pw_name  : MEGA
  pw_uid   : 0
  pw_gid   : 512
  pw_dir   : /u/mega
  pw_shell : /bin/sh
```

getrlimit() — Get current or maximum resource consumption

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getrlimit(int resource, struct rlimit *rlp);
```

General description

The getrlimit() function gets resource limits for the calling process. A resource limit is a pair of values; one specifying the current (soft) limit, the other a maximum (hard) limit.

The value RLIM_INFINITY defined in sys/resource.h, is considered to be larger than any other limit value. If a call to getrlimit() returns RLIM_INFINITY for a resource, it means the implementation does not enforce limits on that resource.

The *resource* argument specifies which resource to get the hard and/or soft limits for, and may be one of the following values:

RLIMIT_CORE
The maximum size of a dump of memory (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. Dump file creation will stop at this limit.

RLIMIT_CPU
The maximum amount of CPU time (in seconds) allowed for the process. If the limit is exceeded, a SIGXCPU signal is sent to the process and the process is granted a small CPU time extension to allow for signal generation and delivery. If the extension is used up, the process is terminated with a SIGKILL signal.

RLIMIT_DATA
The maximum size of the break value for the process, in bytes. In this implementation, this resource always has a hard and soft limit value of RLIM_INFINITY.

RLIMIT_FSIZE
The maximum file size (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. If the size is exceeded, a SIGXFSZ signal is sent to the process. If the process is blocking, catching, or ignoring SIGXFSZ, continued attempts to increase the size of a file beyond the limit will fail with an errno of EFBIG.

RLIMIT_MEMLIMIT
The maximum amount of usable storage above the 2 gigabyte bar (in 1 megabyte segments) that can be allocated.

RLIMIT_NOFILE
The maximum number of open file descriptors allowed for the process. This number is one greater than the maximum value that may be assigned to a newly created descriptor. (That is, it is one-based.) Any function that attempts to create a new file descriptor beyond the limit will fail with an EMFILE errno.

RLIMIT_STACK
The maximum size of the stack for a process, in bytes. Note that in z/OS UNIX services, the stack is a per-thread resource. In this implementation, this resource always has a hard and soft limit value of RLIM_INFINITY. A call to setrlimit() to set this resource to any value other than RLIM_INFINITY will fail with an errno of EINVAL.

RLIMIT_AS
The maximum address space size for the process, in bytes. If the limit is exceeded, malloc() and mmap() functions will fail with an errno of ENOMEM. Automatic stack growth will also fail.

The *rlp* argument points to a `rlimit` structure. This structure contains the following members:

rlim_cur
The current (soft) limit

rlim_max
The maximum (hard) limit

See the <sys/resource.h> header for more detail.

The resource limit values are propagated across exec and fork.

Special behavior for z/OS UNIX System Services: An exception exists for exec processing in conjunction with daemon support. If a daemon process invokes exec and it had previously invoked setuid() before exec, the `RLIMIT_CPU`, `RLIMIT_AS`, `RLIMIT_CORE`, `RLIMIT_FSIZE`, and `RLIMIT_NOFILE` limit values are set based on the limit values specified in the kernel parmlib member BPXPRMxx.

For processes which are not the only process within an address space, the `RLIMIT_CPU` and `RLIMIT_AS` limits are shared with all the processes within the address space. For `RLIMIT_CPU`, when the soft limit is exceeded, action will be taken on the first process within the address space. If the action is termination, all processes within the address space will be terminated.

In addition to the `RLIMIT_CORE` limit values, the dump file defaults are set by SYSMDUMP defaults. Refer to *z/OS MVS Initialization and Tuning Reference* for information on setting up SYSMDUMP defaults using the IEADMR00 parmlib member.

Dumps of memory are taken in 4160 byte increments. Therefore, RLIMIT_CORE values affect the size of memory dumps in 4160 byte increments. For example, if the RLIMIT_CORE soft limit value is 4000, the dump will contain no data. If the RLIMIT_CORE soft limit value is 8000, the maximum size of a memory dump is 4160 bytes.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, getrlimit() returns 0.

If unsuccessful, getrlimit() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
A non-valid *resource* was specified.

getrusage() — Get information about resource utilization

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getrusage(int who, struct rusage *r_usage);
```

General description

The getrusage() function provides measures of the resources used by the current process or its terminated and waited-for-child processes. If the value of the *who* argument is RUSAGE_SELF, information is returned about resources used by the current process. If the value of the *who* argument is RUSAGE_CHILDREN, information is returned about resources used by the terminated and waited-for-children of the current process. If the child is never waited for (for instance, if the parent has SA_NOCLDWAIT set or sets SIGCHLD to SIG_IGN), the resource information for the child process is discarded and not included in the resource information provided by getrusage()

The *r_usage* argument is a pointer of an object of type struct rusage in which the returned information is stored.

Returned value

If successful, getrusage() returns 0.

If unsuccessful, getrusage() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The value of the *who* argument is not valid.

gets() — Read a string

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <stdio.h>

char *gets(char *buffer);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

char *gets_unlocked(char *buffer);
```

General description

Reads bytes from the standard input stream `stdin`, and stores them in the array pointed to by *buffer*. The line consists of all characters up to and including the first newline character (`\n`) or EOF. The gets() function discards any newline character, and the NULL character (\0) is placed immediately after the last byte read. If there is an error, the value stored in *buffer* is undefined.

gets() is not supported for files opened with `type=record` or `type=blocked`.

gets() has the same restriction as any read operation, such as a read immediately following a write, or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

gets_unlocked() is functionally equivalent to gets() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, gets() returns its argument.

If unsuccessful, gets() returns a NULL pointer to indicate an error or an EOF condition with no characters read.

Use ferror() or feof() to determine which of these conditions occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBG18

```
/* CELEBG18

   This example gets a line of input from stdin.

 */
#include <stdio.h>
#define MAX_LINE 100

int main(void)
{
   char line[MAX_LINE];
   char *result;

   printf("Enter string:\n");
   if ((result = gets(line)) != NULL)
      printf("string is %s\n",result);
   else
      if (ferror(stdin))
        printf("Error\n");
}
```

getservbyname() — Get a server entry by name

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct servent *getservbyname(const char *name, const char *proto);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct servent *getservbyname(char *name, char *proto);
```

General description

The getservbyname() call searches the */etc/services* or *tcpip*.ETC.SERVICES data set for the first entry that matches the specified service name and protocol name. If proto is NULL, only the service name must match.

Parameter
Description

name The service name.

proto The protocol name.

The getservbyname() call returns a pointer to a *servent* structure for the network service specified on the call. getservbyname(), getservbyport(), and getservent() all use the same static area to return the *servent* structure. This static area is only valid until the next one of these functions is called on the same thread.

The *servent* structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

s_aliases
An array, terminated with a NULL pointer, of alternative names for the service.

s_name
The official name of the service.

s_port The port number of the service.

s_proto The protocol required to contact the service.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

The return value points to data that is overwritten by subsequent calls returning the same data structure.

If successful, getservbyname() returns a pointer to a *servent* structure.

If unsuccessful or End Of File (EOF), getservbyname() returns a NULL pointer.

Related information

getservbyport() — Get a service entry by port

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct servent *getservbyport(int port, const char *proto);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct servent *getservbyport(int port, char *proto);
```

General description

The getservbyport() call searches the */etc/services* or the *tcpip*.ETC.SERVICES data set for the first entry that matches the specified port number and protocol name. If proto is NULL, only the port number must match.

Parameter
Description

port The port number.

proto The protocol name.

The getservbyport() call returns a pointer to a *servent* structure for the port number specified on the call. getservbyname(), getservbyport(), and getservent() all use the same static area to return the *servent* structure. This static area is only valid until the next one of these functions is called on the same thread.

The *servent* structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

s_aliases
An array, terminated with a NULL pointer, of alternative names for the service.

s_name
The official name of the service.

s_port The port number of the service.

s_proto The protocol required to contact the service.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

The return value points to data that is overwritten by subsequent calls returning the same data structure.

If successful, getservbyport() returns a pointer to a *servent* structure.

If unsuccessful or End Of File (EOF), getservbyport() returns a NULL pointer.

getservent() — Get the next service entry

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct servent *getservent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct servent *getservent(void);
```

General description

The getservent() call reads the next line of the */etc/services* or the *tcpip*.ETC.SERVICES data set.

The getservent() call returns a pointer to the next entry in the */etc/services* or the *tcpip*.ETC.SERVICES data set.

getservbyname(), getservbyport(), and getservent() all use the same static area to return the *servent* structure. This static area is only valid until the next one of these functions is called on the same thread.

The *servent* structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

s_aliases
An array, terminated with a NULL pointer, of alternative names for the service.

s_name
The official name of the service.

s_port The port number of the service.

s_proto The protocol required to contact the service.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

The return value points to data that is overwritten by subsequent calls returning the same data structure.

If successful, getservent() returns a pointer to a *servent* structure.

If unsuccessful or End Of File (EOF), getservent() returns a NULL pointer.

getsid() — Get process group ID of session leader

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

pid_t getsid(pid_t pid);
```

General description

The getsid() function obtains the process group ID of the process that is the session leader of the process specified by *pid*. If *pid* is 0, the system uses the PID of the process calling getsid().

Returned value

If successful, getsid() returns the process group ID of the session leader of the specified process.

If unsuccessful, getsid() returns (pid_t)-1 and sets errno to one of the following values:

Error Code
Description

EPERM
The process specified by *pid* is not in the same session as the calling process, and the implementation does not allow access to the process group ID of the session leader of that process from the calling process.

ESRCH
There is no process with a process ID equal to *pid*.

getsockname() — Get the name of a socket

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getsockname(int socket, struct sockaddr *__restrict__ name,
                socklen_t *__restrict__ namelen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getsockname(int socket, struct sockaddr *name,
                int *namelen);
```

General description

The getsockname() call stores the current name for the socket specified by the *socket* parameter into the structure pointed to by the *name* parameter. It returns the address to the socket that has been bound. If the socket is not bound to an address, the call returns with the family set, and the rest of the structure set to zero. For example, an unbound socket in the Internet domain would cause the name to point to a **sockaddr_in** structure with the *sin_family* field set to AF_INET and all other fields zeroed.

If the actual length of the address is greater than the length of the supplied *sockaddr*, the stored address is truncated. The *sa_len* member of the store structure contains the length of the untruncated address.

Parameter
Description

socket The socket descriptor.

name The address of the buffer into which getsockname() copies the name of *socket*.

namelen
Must initially point to an integer that contains the size in bytes of the storage pointed to by *name*. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in sockaddr is truncated to the length supplied on input. If *name* is NULL, *namelen* is ignored.

The getsockname() call is often used to discover the port assigned to a socket after the socket has been implicitly bound to a port. For example, an application can call connect() without previously calling bind(). In this case, the connect() call completes the binding necessary by assigning a port to the socket. This assignment can be discovered with a call to getsockname().

Sockets in the AF_INET6 domain: For an AF_INET6 socket, the address is returned in a sockaddr_6 address structure. The sockaddr_in6 structure is defined in the header file **netinet/in.h**.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The getsockname() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2113 for details.

Returned value

If successful, getsockname() returns 0.

If unsuccessful, getsockname() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
The *socket* parameter is not a valid socket descriptor.

EFAULT
Using the *name* and *namelen* parameters as specified would result in an attempt to access storage outside of the caller's address space.

ENOBUFS
getsockname() is unable to process the request due to insufficient storage.

ENOTCONN
The socket is not in the connected state.

ENOTSOCK
The descriptor is for a file, not for a socket.

EOPNOTSUPP
The operation is not supported for the socket protocol.

getsockopt() — Get the options associated with a socket

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getsockopt(int socket, int level, int option_name,
               void *__restrict__ option_value,
               socklen_t *__restrict__ option_len);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getsockopt(int socket, int level, int option_name,
               char *option_value,
               int *option_len);
```

IPv6: To include support for IPv6 socket options, add the following code:

```
#define _OPEN_SYS_SOCK_IPV6 1
#include <netinet/in.h>
```

icmp6_filter structure: To include the icmp6_filter structure in your program, add the following code:

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/icmp6.h>
```

General description

The getsockopt() call gets options associated with a socket. Not all options are supported by all address families. See each option for details. Options can exist at multiple protocol levels.

Parameter
Description

socket The socket descriptor.

level The level for which the option is set.

option_name
The name of a specified socket option.

option_value
The pointer to option data.

option_len
The pointer to the length of the option data.

When manipulating socket options, you must specify the level at which the option resides and the name of the option. To manipulate options at the socket level, the *level* parameter must be set to SOL_SOCKET as defined in sys/socket.h. To manipulate options at the IPv4 or IPv6 level, the *level* parameter must be set to IPPROTO_IP as defined in sys/socket.h or IPPROTO_IPV6 as defined in netinet/in.h. To manipulate options at any other level, such as the TCP level, supply the appropriate protocol number for the protocol controlling the option. The getprotobyname() call can be used to return the protocol number for a named protocol.

The *option_value* and *option_len* parameters are used to return data used by the particular get command. The *option_value* parameter points to a buffer that is to receive the data requested by the get command. The *option_len* parameter points to the size of the buffer pointed to by the *option_value* parameter. It must be initially set to the size of the buffer before calling getsockopt(). On return it is set to the actual size of the data returned.

All the socket level options except SO_LINGER, SO_RCVTIMEO and SO_SNDTIMEO, expect *option_value* to point to an integer and *option_len* to be set to the size of an integer. When the integer is nonzero, the option is enabled. When it is zero, the option is disabled. The SO_LINGER option expects *option_value* to point to a linger structure as defined in sys/socket.h. This structure is defined in the following example:

```
struct  linger
{
       int     l_onoff;               /* option on/off */
       int     l_linger;              /* linger time */
};
```

The *l_onoff* field is set to zero if the SO_LINGER option is being disabled. A nonzero value enables the option. The *l_linger* field specifies the amount of time to linger on close.

The following options are recognized at the IPv4 level:

Option Description

IP_MULTICAST_IF
(RAW and UDP) Used to get the interface IP address used for sending outbound multicast datagrams. The IP address is passed using the in_addr structure.

IP_MULTICAST_LOOP
(RAW and UDP) Used to determine whether loopback is enabled or disabled. The loopback indicator is passed as an u_char. The value 0 indicates loopback is disabled and the value 1 indicates it is enabled.

IP_MULTICAST_TTL
(RAW and UDP) Returns the IP time-to-live of outgoing multicast datagrams. The TTL value is passed as an u_char.

IP_RECVPKINFO
(RAW and UDP) Indicates whether returning the destination IP address of an incoming packet and the interface over which the packet was received is enabled or disabled. If the setsockopt() function is used to set this option, the set value is returned. The option value is passed as an int. The value 0 indicates the option is disabled and the value 1 indicates the option is enabled. When the option is enabled, the information is returned as IP_PKTINFO ancillary data on recvmsg() function calls.

This option is protected by the _OPEN_SYS_SOCK_EXT4 feature test macro.

The following options are recognized at IPv6 level:

Option Description

IPV6_ADDR_PREFERENCES
(TCP and UDP) Used to get the source address selection preference flags for a given socket. The flags are defined as bits within the 32 bit unsigned integer returned option value. The flags returned will be either the default preference flags or will be the flags previously set by setsockopt(). The constants for the flag bit values are defined in netinet/in.h.

IPV6_CHECKSUM
(RAW) Used to determine if checksum processing is enabled for a RAW (non-ICMPv6) socket. The option value returned is the offset into the user data where the checksum is located. It is passed as int. A value of -1 means the function is disabled.

IPV6_DONTFRAG
(RAW and UDP) This option turns off the automatic inserting of a fragment header in the packet for UDP and raw sockets.

IPV6_DSTOPTS
(RAW and UDP) The application can remove any sticky destination options header by calling setsockopt() for this option with a zero option length.

IPV6_HOPOPTS
(RAW and UDP) The application can remove any sticky hop-by-hop options header by calling setsockopt() for this option with a zero option length.

IPV6_MULTICAST_HOPS
(RAW and UDP) Returns the hop limit value for outbound multicast datagrams. The hop limit value is passed as an int.

IPV6_MULTICAST_IF
(RAW and UDP) Returns the interface index for the interface used for sending outbound multicast datagrams. The interface index is passed as an u_int.

IPV6_MULTICAST_LOOP
(RAW and UDP) Used to determine whether loopback of outgoing multicast packets is enabled or disabled. The loopback indicator is passed as u_int. The value 0 indicates the option is disabled and the value 1 indicates it is enabled.

IPV6_NEXTHOP
(RAW and UDP) Specifies the next hop for the datagram as a socket address structure.

IPV6_RECVDSTOPTS
(RAW and UDP) To receive destination options header this option must be enabled.

IPV6_RECVHOPLIMIT
(RAW, TCP, and UDP) Returns the received hop limit as IPV6_HOPLIMIT ancillary data on recvmsg() function calls. The option value is passed as an int. The value 0 indicates the option is disabled and the value 1 indicates the option is enabled.

IPV6_RECVHOPOPTS
(RAW and UDP) To receive a hop-by-hop options header this option must be enabled.

IPV6_RECVPATHMTU
(RAW and UDP) Returns the path MTU as IPV6_PATHMTU ancillary data on recvmsg() function calls.

IPV6_RECVPKTINFO
(RAW and UDP) Indicates whether returning the destination IP address of an incoming packet and the interface over which the packet was received is enabled or disabled. The option value is passed as an int. The value 0 indicates the option is disabled and the value 1 indicates the option is enabled. When the option is enabled, the information is returned as IPV6_PKTINFO ancillary data on recvmsg() function calls.

IPV6_RECVRTHDR
(RAW and UDP) To receive a routing header this option must be enabled.

IPV6_RECVTCLASS
(RAW, TCP, and UDP) To receive the traffic class this option must be enabled.

IPV6_RTHDR
(RAW and UDP) The application can remove any sticky routing header by calling setsockopt() for this option with a zero option length.

IPV6_RTHDRDSTOPTS
(RAW and UDP) The application can remove any sticky destination options header by calling setsockopt() for this option with a zero option length.

IPV6_TCLASS
(RAW, TCP, and UDP) To specify the traffic class value this option must be enabled.

IPV6_UNICAST_HOPS
(RAW and UDP) Returns the hop limit value for outbound unicast datagrams. The hop limit value is passed as an int.

IPV6_USE_MIN_MTU
(RAW, TCP, and UDP) Indicates whether the IP layer will use the minimum MTU size (1280) for sending packets, bypassing path MTU discovery. The option value is passed as an int. A value of -1 causes the default values for unicast (disabled) and multicast (enabled) destinations to be used. A value of 0 disables this option for unicast and multicast destinations. A value of 1 enables this option for unicast and multicast

destinations and the minimum MTU size will be used. If a setsockopt() call has not been made prior to a getsockopt() call, the default value of -1 is returned.

IPV6_V6ONLY
(RAW, TCP, and UDP) Used to determine whether a socket is restricted to IPv6 communications only. The option value is passed as an int. A non-zero value means the option is enabled (socket can only be used for IPv6 communications). 0 means the option is disabled.

The following option is recognized at ICMPv6 level:

Option Description

ICMP6_FILTER
(RAW) Used to filter ICMPv6 messages. It returns the filter value being used for this socket. It is back in an icmp6_filter structure as defined in netinet/icmp6.h.

The following options are recognized at the socket level:

Option Description

SO_ACCEPTCONN
The socket had a listen() call.

SO_BROADCAST
Toggles the ability to broadcast messages. If this option is enabled, it allows the application to send broadcast messages over *socket*, if the interface specified in the destination supports the broadcasting of packets. This option has no meaning for stream sockets. This option is valid only for the AF_INET domain.

SO_DEBUG
Reports whether debugging information is being recorded. This option stores an int value.

SO_ERROR
Returns any pending error on the socket and clears the error status. You can use SO_ERROR to check for asynchronous errors on connected datagram sockets or for other asynchronous errors (errors that are not returned explicitly by one of the socket calls).

SO_KEEPALIVE
Toggles the TCP keep-alive mechanism for a stream socket. When activated, the keep-alive mechanism periodically sends a packet on an otherwise idle connection. If the remote TCP does not respond to the packet or to retransmissions of the packet, the connection is ended with the error ETIMEDOUT. Processes writing to that socket are notified with a SIGPIPE signal. This option stores an int value. This option is valid only for the AF_INET and AF_INET6 domains.

SO_LINGER
Lingers on close if data is present. When this option is enabled and there is unsent data present when close() is called, the calling application is blocked during the close() call until the data is transmitted or the connection has timed out. If this option is disabled, the TCP/IP address space waits to try to send the data. Although the data transfer is usually successful, it cannot be guaranteed, because the TCP/IP address space

waits only a finite amount of time trying to send the data. The close() call returns without blocking the caller. This option has meaning only for stream sockets.

SO_OOBINLINE
Toggles reception of out-of-band data. When this option is enabled, out-of-band data is placed in the normal data input queue as it is received; it is then available to recv(), recvfrom(), and recvmsg() without the need to specify the MSG_OOB flag in those calls. When this option is disabled, out-of-band data is placed in the priority data input queue as it is received; it is then available to recv(), recvfrom(), and recvmsg() only if the MSG_OOB flag is specified in those calls. This option has meaning only for stream sockets.

_SO_PROPAGATEUSERID
Toggles propagating a user ID (UID) over an AF_UNIX stream socket. When enabled, user (UID) information is extracted from the system when the connect() function is invoked. Then, when the accept() function is invoked, the accepter assumes the identity of the connecter until the accepted socket is closed.

SO_RCVBUF
Reports receive buffer size information. This option stores an int value.

SO_RCVTIMEO

Reports the timeout value with the amount of time an input function waits until it completes.

If a receive operation has blocked for this much time without receiving additional data, it returns with a partial count or errno set to EWOULDBLOCK if no data is received. The default for this option is zero, which indicates that a receive operation does not time out.

SO_REUSEADDR

Toggles local address reuse. When enabled, this option allows local addresses that are already in use to be bound. SO_REUSEADDR alters the normal algorithm used in the bind() call.

The system checks at connect time to ensure that the local address and port do not have the same foreign address and port. The error EADDRINUSE is returned if the association already exists.

After the 'SO_REUSEADDR' option is active, the following situation is supported:

A server can bind() the same port multiple times as long as every invocation uses a different local IP address and the wildcard address INADDR_ANY is used only one time per port.

This option is valid only for the AF_INET and AF_INET6 domains.

SO_SECINFO
Toggles receiving security information. When enabled on an AF_UNIX UDP socket, the recvmsg() function will return security information about the sender of each datagram as ancillary data. This information contains the sender's user ID, uid, gid, and jobname and it is mapped by the secsinfo structure in sys/socket.h.

SO_SNDBUF
Reports send buffer size information. This option stores an int value.

SO_SNDTIMEO

Reports the timeout value specifying the amount of time that an output function blocks due to flow control preventing data from being sent.

If a send operation has blocked for this time, it returns with a partial count or with errno set to EWOULDBLOCK if no data is sent. The default for this option is zero, which indicates that a send operation does not time out.

SO_TYPE

This option returns the type of the socket. On return, the integer pointed to by *option_value* is set to SOCK_STREAM or SOCK_DGRAM. This option is valid for the AF_UNIX, AF_INET and AF_INET6 domains.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, getsockopt() returns 0.

If unsuccessful, getsockopt() returns -1 and sets errno to one of the following values:

Error Code

Description

EBADF

The *socket* parameter is not a valid socket descriptor.

EFAULT

Using *option_value* and *option_len* parameters would result in an attempt to access storage outside the caller's address space.

EINVAL

The specified option is not valid at the specified socket level.

ENOBUFS

Buffer space is not available to send the message.

ENOPROTOOPT

The *option_name* parameter is unrecognized, or the *level* parameter is not SOL_SOCKET.

ENOSYS

The function is not implemented. You attempted to use a function that is not yet available.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The operation is not supported by the socket protocol. At least the following options are not supported:

- IPV6_JOIN_GROUP
- IPV6_LEAVE_GROUP
- IP_ADD_SOURCE_MEMBERSHIP
- IP_DROP_SOURCE_MEMBERSHIP
- IP_DROP_MEMBERSHIP
- IP_ADD_MEMBERSHIP
- IP_BLOCK_SOURCE
- IP_UNBLOCK_SOURCE

- MCAST_JOIN_GROUP
- MCAST_LEAVE_GROUP
- MCAST_BLOCK_SOURCE
- MCAST_UNBLOCK_SOURCE
- MCAST_JOIN_SOURCE_GROUP
- MCAST_LEAVE_SOURCE_GROUP

Example

The following are examples of the getsockopt() call. See “setsockopt() — Set options associated with a socket” on page 1578 for examples of how the setsockopt() call options are set.

```
int rc;
int s;
int option_value;
int option_len;
struct linger l;
int getsockopt(int s, int level, int option_name,
char *option_value,
     int *option_len);

⋮
/* Is out-of-band data in the normal input queue? */
option_len = sizeof(int);
rc = getsockopt(
        s, SOL_SOCKET, SO_OOBINLINE, (
char *) &option_value, &option_len);
if (rc == 0)
{
    if (option_len == sizeof(int))
    {
         if (option_value)
            /* yes it is in the normal queue */
         else
            /* no it is not
                  */
    }
}

⋮
/* Do I linger on close? */
option_len = sizeof(l);
rc = getsockopt(
        s, SOL_SOCKET, SO_LINGER, (char *) &l, &option_len);
if (rc == 0)
{
    if (option_len == sizeof(l))
    {
         if (l.l_onoff)
            /* yes I linger */
         else
            /* no I do not  */
    }
}
```

getsourcefilter() — Get source filter

Standards

Standards / Extensions	C or C++	Dependencies
RFC3678	both	z/OS V1.9

Format

```
#define _XOPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int getsourcefilter(int s, uint32_t interface, struct sockaddr *group,
  socklen_t grouplen, uint32_t *fmode, uint32_t *numsrc,
  struct sockaddr_storage *slist);
```

General description

This function allow applications to get a previously set multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is protocol-independent. It can be on either AF_INET or AF_INET6 sockets of the type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument
Description

s Identifies the socket.

interface
Holds the index of the interface.

group Points to either a sockaddr_in structure for IPv4 or a sockaddr_in6 structure for IPv6 that holds the IP multicast address of the group.

grouplen
Gives the length of the sockaddr_in or sockaddr_in6 structure.

fmode Points to an integer that will contain the filter mode on a successful return. The value of this field will be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.

numsrc
It is a pointer that on input, points to the number of source adresses that will fit in the slist array. On return, points to the total number of sources associated with the filter.

slist Points to buffer into which an array of IP addresses of included or excluded (depending on the filter mode) sources will be written. If numsrc was 0 on input, a NULL pointer may be supplied.

Returned value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

errno Description

EADDRNOTAVAIL
The tuple consisting of socket, interface, and multicast group values does not exist; or the specified interface address is not multicast capable.

EAFNOSUPPORT
The address family of the input sockaddr is not AF_INET or AF_INET6.

EBADF
s is not a valid socket descriptor.

EINVAL
Interface or group is not a valid address, or the socket s has already requested multicast setsockopt options (refer to z/OS Communications Server: IP Sockets Application Programming Interface Guide and Reference for details.) Or if the group address family is AF_INET and grouplen is not at least size of sockaddr_in or if the group address family is AF_INET6 and grouplen is not at least size of sockaddr_in6 or if grouplen is not at least size of sockaddr_in.

ENXIO
The specified interface index provided in the interface parameter does not exist.

EPROTOTYPE
The socket s is not of type SOCK_DGRAM or SOCK_RAW.

getstablesize() — Get the socket table size

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int getstablesize(void);
```

General description

Bulk mode sockets are not supported. Do not use this function.

Returned value

If successful, getstablesize() returns the current limit for this process.

If it has not been changed by the maxdesc() function, then the default is returned. The default is the hard limit returned by getrlimit() for RLIMIT_NOFILE. This is the value set by a BPXPRMnn parmlib member on its MAXFILEPROC statement.

There are no errno values defined.

Related information

- "sys/socket.h" on page 74
- "getrlimit() — Get current or maximum resource consumption" on page 765
- "maxdesc() — Get socket numbers to extend beyond the default range" on page 1039

getsubopt() — Parse suboption arguments

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int getsubopt(char **optionp, char *const *tokens, char **valuep);
```

General description

The getsubopt() function parses suboption arguments in a flag argument that was initially parsed by getopt(). These suboption arguments must be separated by commas and may consist of either a single token, or a token-value pair separated by an equal sign. Because commas delimit suboption arguments in the option string, they are not allowed to be part of the suboption arguments or the value of a suboption argument. Similarly, because the equal sign separates a token from its value, a token must not contain an equal sign.

The getsubopt() function takes the address of a pointer to the option argument string, a vector of possible tokens, and the address of a value string pointer. If the option argument string at *optionp* contains only one suboption argument, getsubopt() updates *optionp* to point to the NULL at the end of the string. Otherwise, it isolates the suboption argument by replacing the comma separator with a NULL, and updates *optionp* to point to the start of the next suboption argument. If the suboption argument has an associated value, getsubopt() updates *valuep* to point to the value's first character. Otherwise it sets *valuep* to a NULL pointer.

The token vector is organized as a series of pointers to strings. The end of the token vector is identified by a NULL pointer.

When getsubopt() returns, if *valuep* is not a NULL pointer, then the suboption argument processed included a value. The calling program may use this information to determine if the presence or lack of a value for the suboption is an error.

Additionally, when getsubopt() fails to match the suboption argument with the tokens in the *tokens* array, the calling program should decide if this is an error, or if the unrecognized option should be passed on to another program.

Because the getsubopt() function returns thread-specific data the getsubopt() function can be used safely from a multithreaded application.

Returned value

If successful, getsubopt() returns the index of the matched token string.

If no token strings were matched, getsubopt() returns -1.

getsubopt() does not return any errno values.

getsyntx() — Return LC_SYNTAX characters

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <variant.h>

struct variant *getsyntx(void);
```

General description

Determines the encoding of the special characters defined in the LC_SYNTAX category of the current locale, and stores the encoding values in the structure of type *variant*. For details of the variant structure, see “variant.h” on page 84.

Returned value

Returns the pointer to the structure containing the values of the special characters.

If the information about the special characters is not available in the current locale, getsyntx() returns a NULL pointer.

The structure returned is not modified by the program that this function is used in. The structure may be invalidated by calls to the setlocale() function with LC_ALL, LC_CTYPE, LC_COLLATE, or LC_SYNTAX.

Example

CELEBG19

```
/* CELEBG19 */
#include <stdio.h>
#include <stdlib.h>
#include <variant.h>
#include <wchar.h>

int main(void)
{
   struct variant *var;

   var = getsyntx();
   printf("codeset        : %s\n",  var->codeset        );
   printf("backslash      : %3d\n", var->backslash      );
   printf("right_bracket  : %3d\n", var->right_bracket  );
   printf("left_bracket   : %3d\n", var->left_bracket   );
   printf("right_brace    : %3d\n", var->right_brace    );
   printf("left_brace     : %3d\n", var->left_brace     );
   printf("circumflex     : %3d\n", var->circumflex     );
   printf("tilde          : %3d\n", var->tilde          );
   printf("exclamation_mark: %3d\n", var->exclamation_mark);
   printf("number_sign    : %3d\n", var->number_sign    );
   printf("vertical_line  : %3d\n", var->vertical_line  );
   printf("dollar_sign    : %3d\n", var->dollar_sign    );
   printf("commercial_at  : %3d\n", var->commercial_at  );
   printf("grave_accent   : %3d\n", var->grave_accent   );
}
```

__get_system_settings() — Retrieves system parameters

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R10

Format

```
#define _OPEN_SYS_EXT 1
#include <sys/ps.h>

struct _Optn *__get_system_settings(void);
```

General description

The __get_system_settings() function retrieves system parameter information from the BPXPRM member used during IPL, or updated by the OMVS operator command.

Returned value

If successful, __get_system_settings() returns a pointer to an _Optn structure containing the values set for the BPXPRMxx member process during IPL, or updated by the OMVS operator command.

If unsuccessful, __get_system_settings() returns NULL and may set errno to one of the following values:

Error Code
Description

ENOMEM
Insufficient memory available to allocate _Optn structure.

Related information

- "sys/ps.h" on page 74

gettimeofday(), gettimeofday64() — Get date and time

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1

#undef _ALL_SOURCE
#include <sys/time.h>

int gettimeofday(struct timeval *__restrict__ tp,
                 void *__restrict__ tzp);

#define _ALL_SOURCE
#include <sys/time.h>

int gettimeofday(struct timeval *__restrict__ tp,
                 struct timezone *__restrict__ tzp);
#define _LARGE_TIME_API
#include <time.h>

int gettimeofday64(struct timeval64 *__restrict__ tp,
                   void *__restrict__ tzp);
```

General description

The gettimeofday() function obtains the current time, expressed as seconds and microseconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970, and stores it in the timeval structure pointed to by *tp*.

Special behavior for _ALL_SOURCE: The gettimeofday() function has two prototypes. Which one is used depends on whether or not you define the _ALL_SOURCE feature test macro when you compile your program. If _ALL_SOURCE is NOT defined when the C/370 preprocessor processes the <sys/time.h> header, it includes a prototype for gettimeofday() which defines the second argument, *tzp*, as a void pointer and includes a C/370 pragma map statement for a C/370 version of gettimeofday() which ignores *tzp*.

If _ALL_SOURCE is defined, the C/370 preprocessor includes a prototype for gettimeofday() which defines *tzp* as a pointer to a timezone structure and includes a pragma map statement for a C/370 version of gettimeofday() which stores time zone information in the timezone structure to which the second argument points. The timezone structure contains the following members:

```
int tz_minuteswest;   /* Time west of Greenwich in minutes */
int tz_dsttime;       /* Type of DST correction to apply   */
```

When _ALL_SOURCE is defined, the gettimeofday() function:

1. invokes tzset() to set the values of the timezone and daylight external variables.
2. converts the value of the timezone external variable to minutes and stores the converted value, rounded up to the nearest minute, in *tzp*->tz_minuteswest.
3. stores the value of the daylight external variable in *tzp*->tz_dsttime.

The function gettimeofday64() will behave exactly like gettimeofday() except it will support calendar times beyond 03:14:07 UTC on January 19, 2038.

There is no support for an _ALL_SOURCE version of gettimeofday64().

Returned value

If successful, gettimeofday() returns 0.

If overflow occurs, gettimeofday() returns nonzero. Overflow occurs when the current time in seconds since 00:00:00 UTC, January 1, 1970 exceeds the capacity of the *tv_sec* member of the timeval structure pointed to by *tp*. The *tv_sec* member is type time_t.

getuid() — Get the real user ID

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

uid_t getuid(void);
```

General description

Finds the real user ID (UID) of the calling process.

Returned value

getuid() returns the found value. It is always successful.

There are no documented errno values.

Example

CELEBG20

```
/* CELEBG20

   This example provides information for your user ID.

 */
#define _POSIX_SOURCE
#include <pwd.h>
#include <sys/types.h>
#include <unistd.h>

main() {
  struct passwd *p;
  uid_t  uid;

  if ((p = getpwuid(uid = getuid())) == NULL)
    perror("getpwuid() error");
  else {
    puts("getpwuid() returned the following info for your userid:");
    printf("  pw_name  : %s\n",       p->pw_name);
    printf("  pw_uid   : %d\n", (int) p->pw_uid);
    printf("  pw_gid   : %d\n", (int) p->pw_gid);
    printf("  pw_dir   : %s\n",       p->pw_dir);
    printf("  pw_shell : %s\n",       p->pw_shell);
  }
}
```

Output

```
  pw_name  : MVSUSR1
  pw_uid   : 25
  pw_gid   : 500
  pw_dir   : /u/mvsusr1
  pw_shell : /bin/sh
```

__getuserid() — Retrieve the active MVS user ID

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R9

Format

```
#define _OPEN_SYS_EXT
#include <sys/ps.h>

int __getuserid(char *userid, int userlen);
```

General description

Retrieves the current active user ID for the requester. When successful, the output in user ID will be the active MVS *userid*.

Returned value

If successful, __getuserid() returns 0.

If unsuccessful, __getuserid() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
One of the following error conditions exists:
- The length supplied by *userlen* does not allow enough storage in the string to retrieve the MVS user ID.
- The z/OS UNIX system service returned a failure.

getutxent() — Read next entry in utmpx database

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxent(void);
```

General description

The getutxent() function reads in the next entry from the utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.

The pututxline() function obtains an exclusive lock in the utmpx database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions getutxent(), getutxid(), and getutxline() might continue to read and are not affected by pututxline().

Because the getutxent() function returns thread-specific data the getutxent() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

The name of the database file defaults to /etc/utmpx. To process a different database file name use the __utmpxname() function.

For all entries that match a request, the `ut_type` member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the `ut_type` member as follows:

EMPTY
No other members have meaningful data.

BOOT_TIME
ut_tv is meaningful.

__RUN_LVL
ut_tv and ut_line are meaningful

OLD_TIME
ut_tv is meaningful.

NEW_TIME
ut_tv is meaningful.

USER_PROCESS
ut_id, ut_user (login name of the user), ut_line, ut_pid, and ut_tv are meaningful.

INIT_PROCESS
ut_id, ut_pid, and ut_tv are meaningful.

LOGIN_PROCESS
ut_id, ut_user (implementation-specific name of the login process), ut_pid, and ut_tv are meaningful.

DEAD_PROCESS
ut_id, ut_pid, and ut_tv are meaningful.

Returned value

If successful, getutxent() returns a pointer to a utmpx structure containing a copy of the requested entry in the user accounting database.

If unsuccessful, getutxent() returns a NULL pointer.

No errors are defined for this function.

getutxid() — Search by ID utmpx database

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxid(const struct utmpx *id);
```

General description

The getutxid() function searches forward from the current point in the utmpx database. If the database is not already open, it opens it. If the `ut_type` value of the `utmpx` structure pointed to by *id* is **BOOT_TIME**, **__RUN_LVL**, **OLD_TIME**, or **NEW_TIME**, then it stops when it finds an entry with a matching `ut_type` value. If the `ut_type` value is **INIT_PROCESS**, **LOGIN_PROCESS**, **USER_PROCESS**, or **DEAD_PROCESS**, then it stops when it finds an entry whose type is one of these four and whose `ut_id` member matches the `ut_id` member of the utmpx structure pointed to by *id*. If the UT_type value is EMPTY, getutxid() fails (returns NULL) without repositioning the utmpx database to the end. If the end of the of the database is reached without a match, getutxid() fails.

The pututxline() function obtains an exclusive lock in the utmpx database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions getutxent(), getutxid(), and getutxline() might continue to read and are not affected by pututxline().

Because the getutxid() function returns thread-specific data the getutxid() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

The name of the database file defaults to /etc/utmpx. To process a different database file name use the __utmpxname() function.

For all entries that match a request, the `ut_type` member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the `ut_type` member as follows:

EMPTY
No other members have meaningful data.

BOOT_TIME
ut_tv is meaningful.

__RUN_LVL
ut_tv and ut_line are meaningful

OLD_TIME
ut_tv is meaningful.

NEW_TIME
ut_tv is meaningful.

USER_PROCESS
ut_id, ut_user (login name of the user), ut_line, ut_pid, and ut_tv are meaningful.

INIT_PROCESS
ut_id, ut_pid, and ut_tv are meaningful.

LOGIN_PROCESS
ut_id, ut_user (implementation-specific name of the login process), ut_pid, and ut_tv are meaningful.

DEAD_PROCESS
ut_id, ut_pid, and ut_tv are meaningful.

Returned value

If successful, getutxid() returns a pointer to a utmpx structure containing a copy of the requested entry in the user accounting database.

If unsuccessful, getutxid() returns a NULL pointer.

No errors are defined for this function.

getutxline() — Search by line utmpx database

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxline(const struct utmpx *line);
```

General description

The getutxline() function searches forward from the current point in the utmpx database until it finds an entry of the type **LOGIN_PROCESS** or **USER_PROCESS** which also has a *ut_line* value matching that in the utmpx structure pointed to by argument *line*. If the database is not already open, it opens it. If it reaches the end of the database, it fails.

The pututxline() function obtains an exclusive lock in the utmpx database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions getutxent(), getutxid(), and getutxline() might continue to read and are not affected by pututxline().

Because the getutxline() function returns thread-specific data the getutxline() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

The name of the database file defaults to /etc/utmpx. To process a different database file name use the __utmpxname() function.

The functions getutxent(), getutxid(), and getutxline() cache the last entry read from the database. For this reason, to use getutxline() function to search for multiple occurrences, it is necessary to zero out the utmpx structure pointed to by the return value from these functions.

For all entries that match a request, the `ut_type` member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the `ut_type` member as follows:

EMPTY
No other members have meaningful data.

BOOT_TIME
ut_tv is meaningful.

__RUN_LVL
ut_tv and ut_line are meaningful

OLD_TIME
ut_tv is meaningful.

NEW_TIME
ut_tv is meaningful.

USER_PROCESS
ut_id, ut_user (login name of the user), ut_line, ut_pid, and ut_tv are meaningful.

INIT_PROCESS
ut_id, ut_pid, and ut_tv are meaningful.

LOGIN_PROCESS
ut_id, ut_user (implementation-specific name of the login process), ut_pid, and ut_tv are meaningful.

DEAD_PROCESS
ut_id, ut_pid, and ut_tv are meaningful.

Returned value

If successful, getutxline() returns a pointer to a utmpx structure containing a copy of the requested entry in the user accounting database.

If unsuccessful, getutxline() returns a NULL pointer.

No errors are defined for this function.

getw() — Get a machine word from a stream

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2	both	

Format

```
#define _XOPEN_SOURCE
#include <stdio.h>

int getw(FILE *stream);
```

General description

The getw() function reads the next word from the *stream*. The size of the word is the size of an int, and varies from machine to machine. The getw() function presumes no special alignment in the file.

The getw() function may mark the *st_atime* field of the file associated with *stream* for update. The *st_atime* field will be marked for update by the first successful execution of fgetc(), fgets(), fread(), getc(), getchar(), gets(), fscanf() or scanf() using *stream* that returns data not supplied by a prior call to ungetc().

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use character-based input functions to replace getw() for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, getw() returns the next word from the input stream pointed to by *stream*. If the stream is at End Of File (EOF), the End Of File indicator for the stream is set and getw() returns EOF. If a read error occurs, the error indicator for the stream is set, getw() returns EOF and sets errno to indicate the error.

Refer to "fgetc() — Read a character" on page 526 for errno values.

Because the representation of EOF is a valid integer, applications wishing to check for errors should use ferror() and feof().

Related information

- "stdio.h" on page 68

getwc() — Get a wide character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <wchar.h>

wint_t getwc(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t getwc_unlocked(FILE *stream);
```

General description

Obtains the next multibyte character from `stdin`, converts it to a wide character, and advances the associated file position indicator for `stdin`.

The getwc() function is equivalent to the fgetwc() function. Therefore, the argument should never be an expression with side effects.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with getwc() results in undefined behavior. This happens because getwc() processes a whole multibyte character and does not expect to be "within" such a character. In addition, getwc() expects state information to be set already. Because functions like fgetc() and fputc() do not obey such rules, their results fail to meet the assumptions made by getwc().

getwc() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

getwc_unlocked() is functionally equivalent to getwc() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

Returns the next wide character from the input stream pointed to by *stream* or else the function returns WEOF.

If there is an error, getwc() sets the error indicator. If the EOF is encountered, it sets the EOF indicator. If an encoding error is encountered, it sets EILSEQ in errno.

Use ferror() or feof() to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBG21

```
/* CELEBG21 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
   FILE    *stream;
   wint_t   wc;

   if ((stream = fopen("myfile.dat", "r")) == NULL) {
      printf("Unable to open file.");
      exit(1);
   }

   errno = 0;
   while ((wc = getwc(stream)) != WEOF)
      printf("wc=0x%lx\n", wc);

   if (errno == EILSEQ) {
      printf("An invalid wide character was encountered.\n");
      exit(1);
   }

   fclose(stream);
}
```

Related information

getwchar() — Get a wide character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <wchar.h>

wint_t getwchar(void)

#define _OPEN_SYS_UNLOCKED_EXT 1;
#include <wchar.h>

wint_t getwchar_unlocked(void)
```

General description

The getwchar() function is equivalent to getwc() with the argument `stdin`.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

getwchar_unlocked() is functionally equivalent to getwchar() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

Returns the next wide character from the input stream pointed to by stdin or else the function returns WEOF. If the stream is at EOF, the EOF indicator for the stream is set and fgetwc() returns WEOF. If a read error occurs, the error indicator for the stream is set and fgetwc() returns WEOF. If an encoding error occurs, the value of the macro EILSEQ is stored in errno and WEOF is returned.

Use ferror() or feof() to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBG22

```
/* CELEBG22 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
```

```
int main(void)
{
   wint_t   wc;

   errno = 0;
   while ((wc = getwchar()) != WEOF)
      printf("wc=0x%X\n", wc);

   if (errno == EILSEQ) {
      printf("An invalid wide character was encountered.\n");
      exit(1);
   }
}
```

getwd() — Get the current working directory

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

char *getwd(char *path_name);
```

General description

The getwd() function determines an absolute path name of the current working directory of the calling process, and copies that path name into the array pointed to by *path_name* argument.

If the length of the path name of the current working directory is greater than (**PATH_MAX**+1) including the NULL byte, getwd() fails and returns a NULL pointer.

For portability to implementations conforming to earlier versions of the standards, getcwd() is preferred over this function.

Note: The getwd() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The getcwd() function is preferred for portability.

Returned value

If successful, getwd() returns a pointer to the string containing the absolute path name of the current working directory.

If unsuccessful, getwd() returns a NULL pointer and the contents of the array pointed to by *path_name* are undefined.

There are no errno values defined.

Related information

- “unistd.h” on page 82
- “getcwd() — Get path name of the working directory” on page 697

getwmccoll() — Get next collating element from wide string

Standards

Standards / Extensions	C or C++	Dependencies
C Library	both	

Format

```
#include <collate.h>

collel_t getwmccoll(wchar_t **src);
```

General description

If the object pointed to by *src* is not a NULL pointer, the getwmccoll() library function determines the longest sequence of wide characters in the array pointed to by *str* that constitute a valid multi-wide-character collating element. It then produces the value of type `collel_t` corresponding to that collating element. The object pointed to by *src* is assigned the address just past the last wide character of the multi-wide-character collating element processed.

Returned value

If successful, getwmccoll() returns the value of type `collel_t` that represents the collating element found.

If the object pointed to by *src* is a NULL pointer or if it points to a NULL wide character, getwmccoll() returns 0.

If the object pointed to by *src* points to a non-valid wide character, getwmccoll() returns -1 and sets errno to EILSEQ.

givesocket() — Make the specified socket available

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int givesocket(int d, struct clientid *clientid);
```

General description

The givesocket() call makes the specified socket available to a takesocket() call issued by another program. Any socket can be given. Typically, givesocket() is used by a master program that obtains sockets by means of accept() and gives them to application programs that handle one socket at a time.

Parameter
Description

d The descriptor of a socket to be given to another application.

clientid A pointer to a client ID structure specifying the program to which the socket is to be given.

To pass a socket, the giving program first calls givesocket() with the client ID structure filled in as follows:

The clientid structure:

```
struct clientid {
   int domain;
   union  {
     char name[8];
     struct {
       int NameUpper;
       pid_t pid;
     } c_pid;
   } c_name;
   char subtaskname[8];

   struct  {
     char type;
     union  {
        char specific[19];
        struct  {
          char unused[3];
          int SockToken;
        } c_close;
     } c_func;
   } c_reserved;
};
```

Element
Description

domain The domain of the input socket descriptor.

c_name.name
If the *clientid* was set by a getclientid() call, *c_name.name* can be

- set to the application program's address space name, left-justified and padded with blanks. The application program can run in the same address space as the master program, in which case this field is set to the master program's address space.
- set to blanks, so any z/OS address space can take the socket.

subtaskname

If the *clientid* was set by a getclientid() call, *subtaskname* can be

- set to the task identifier of the taker. This, combined with a *c_name.name* value, allows only a process with this *c_name.name* and *subtaskname* to take the socket.
- set to blanks. If *c_name.name* has a value and *subtaskname* is blank, any task with that *c_name.name* can take the socket.

c_pid.pid

If the *clientid* was set by a __getclientid() call, *c_pid.pid* should be set to the process id (PID) of the taker, so only a process with that PID can take the socket. The *subtaskname* field is ignored when the *c_pid* has a value.

c_reserved.type

When set to SO_CLOSE, this indicates the socket should be automatically closed by givesocket(), and a unique socket identifying token is to be returned in *c_close.SockToken*. The *c_close.SockToken* should be passed to the taking program to be used as input to takesocket() instead of the socket descriptor. The now closed socket descriptor could be re-used by the time the takesocket() is called, so the *c_close.SockToken* should be used for takesocket().

When set to _SO_SELECT, this indicates that the application intends to block on the select() for exception, waiting for the takesocket() to occur before closing the socket. If *c_reserved.type* is set to _SO_SELECT and the caller of givesocket() closes the socket before it has been taken, the connection will be severed. _SO_SELECT also allows select() to return exception status if select() is done after the socket was taken with takesocket().

When set to zero, this indicates that the application will not be calling select() to coordinate with the taker of the socket. Either the socket is not going to be closed or the giver and taker have some other method of coordination for the giver to know when the taker has called takesocket(). Note that if select() for exception is called before takesocket(), the select will return when takesocket() is called but if select() is called after takesocket(), it will hang. _SO_SELECT should be used if select() is going to be called by the giver.

Also, if the given socket is closed before the takesocket() is issued, it is possible for that socket descriptor number to be reused in the giver's process. A sequence of accept(), givesocket(), and close() calls issued several times before any takesocket() calls can result in several sockets with the same descriptor number waiting to be taken. In this case, the oldest given socket will be taken; that is, in FIFO order. Note that if select() is called when there are several given sockets with the same descriptor number waiting to be taken, select() will operate on the current active socket for that descriptor. It effectively waits for the last (newest) given socket to be taken; that is, in LIFO order.

c_close.SockToken
The unique socket identifying token returned by givesocket() to be used as input to takesocket(), instead of the socket descriptor when *c_reserved.type* has been set to SO_CLOSE.

c_reserved
Specifies binary zeros if an automatic close of a socket is not to be done by givesocket().

Using name and subtaskname for givesocket/takesocket:

1. The giving program calls getclientid() to obtain its client ID. The giving program calls givesocket() to make the socket available for a takesocket() call. The giving program passes its client ID along with the descriptor of the socket to be given to the taking program by the taking program's startup parameter list.
2. The taking program calls takesocket(), specifying the giving program's client ID and socket descriptor.
3. Waiting for the taking program to take the socket, the giving program uses select() to test the given socket for an exception condition. When select() reports that an exception condition is pending, the giving program calls close() to free the given socket.
4. If the giving program closes the socket before a pending exception condition is indicated, the connection is immediately reset, and the taking program's call to takesocket() is unsuccessful. Calls other than the close() call issued on a given socket return -1, with errno set to EBADF.

Note: For backward compatibility, a client ID can point to the struct client ID structure obtained when the target program calls getclientid(). In this case, only the target program, and no other programs in the target program's address space, can take the socket.

Using process id (PID) for givesocket/takesocket:

1. The giving program calls __getclientid() to obtain its client ID. The giving program sets the *c_pid.pid* in the clientid structure to the PID of the taking program that will take the socket (that is, issue the takesocket() call). This ensures only a process that has obtained the giver's PID can take the specified socket. If the giving program wants the socket to be automatically closed by givesocket(), *c_reserved.type* should be set to SO_CLOSE. The giving program calls givesocket() to make the socket available for a takesocket() call. The giving program passes its client ID, the descriptor of the socket to be given, and the giving program's PID to the taking program by the taking program's startup parameter list.
2. The taking program sets the *c_pid.pid* in the clientid structure to the PID of the giving program to identify the process from which the socket is to be taken. If the *c_reserved.type* field was set to SO_CLOSE on givesocket(), the *c_close.SockToken* should be used as input to the takesocket() instead of the normal socket descriptor. The taking program calls takesocket(), specifying the giving program's client ID and either the socket descriptor or *c_close.SockToken*.
3. If the *c_reserved.type* field in the clientid structure was set to SO_CLOSE on the givesocket() call, the socket is closed and the giving program does not have to wait for the taking program to issue the takesocket(). Otherwise, steps 3 and 4 of "Using name and subtaskname for givesocket/takesocket" should be followed.

Returned value

If successful, givesocket() returns 0.

If unsuccessful, givesocket() returns -1 and sets errno to one of the following values:

Error Code
  Description

EBADF
  The *d* parameter is not a valid socket descriptor. The socket has already been given.

EFAULT
  Using the *clientid* parameter as specified would result in an attempt to access storage outside the caller's address space.

EINVAL
  The *clientid* parameter does not specify a valid client identifier or the clientid domain does not match the domain of the input socket descriptor.

glob() — Generate path names matching a pattern

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <glob.h>

int glob(const char *__restrict__ pattern, int flags,
        int (*errfunc)(const char *epath, int eerrno),
        glob_t *__restrict__ pglob);
```

General description

The glob() function is a path name generator that implements the rules defined in topic about pattern matching notation in *X/Open CAE Specification, Commands and Utilities, Issue 4, Version 2*, with optional support for rule 3 in the topic about patterns used for file name expansion.

The structure *glob_t* is defined in the header <glob.h> and includes at least the following members:

gl_pathc
Count of paths matched by *pattern*.

gl_pathv
Pointer to a list of matched file names.

gl_offs
Slots to reserve at the beginning of *gl_pathv*.

The argument *pattern* is a pointer to a path name pattern to be expanded. The glob() function matches all accessible path names against this pattern and develops a list of all path names that match. In order to have access to a path name, glob() requires search permission on every component of a path except the last, and read permission on each directory of any file name component of *pattern* that contains any of the following special characters:

```
*       ?       [
```

The glob() function stores the number of matched path names into *pglob->gl_pathc* and a pointer to a list of pointers to path names into *pglob->gl_pathv*. The path names are in sort order as defined by the current setting of the LC_COLLATE category, see *X/Open CAE Specification, System Interface Definitions, Issue 4, Version 2* Section 5.3.2 , LC_COLLATE. The first pointer after the last path name is a NULL pointer. If the pattern does not match any path names, the returned number of matched paths is set to 0, and the contents of *pglob->gl_pathv* are implementation-dependent.

It is the caller's responsibility to create the structure pointed to by *pglob*. The glob() function allocates other space as needed, including the memory pointed to by *gl_pathv*.

The *flags* argument is used to control the behavior of glob() The value of *flags* is a bitwise inclusive-OR of zero or more of the following constants, which are defined in the header <glob.h>:

GLOB_APPEND
Append path names generated to the ones from a previous call to glob().

GLOB_DOOFFS
Make use of *pglob->gl_offs*. If this flag is set, *pglob->gl_offs* is used to specify how many NULL pointers to add to the beginning of *pglob->gl_pathv*. In other words, *pglob->gl_pathv* will point to *pglob->gl_offs* NULL pointers, followed by *pglob->gl_pathc* path name pointers, followed by a NULL pointer.

GLOB_ERR
Causes glob() to return when it encounters a directory that it cannot open or read. Ordinarily, glob() continues to find matches.

GLOB_MARK
Each path name that is a directory that matches *pattern* has a slash appended.

GLOB_NOCHECK
Support rule 3 in the XCU specification, Section 2.13.3 , Patterns Used for Filename Expansion. If *pattern* does not match any path name, then glob() returns a list consisting of only *pattern*, and the number of matched path names is 1.

GLOB_NOESCAPE
Disable backslash escaping.

GLOB_NOSORT
Ordinarily, glob() sorts the matching path names according to the current setting of the LC_COLLATE category, see the XBD specification, Section 5.3.2 , LC_COLLATE. When this flag is used the order of path names returned is unspecified.

The GLOB_APPEND flag can be used to append a new set of path names to those found in a previous call to glob(). The following rules apply when two or more calls to glob() are made with the same value of *pglob* and without intervening calls to globfree():

1. The first such call must not set GLOB_APPEND. All subsequent calls must set it.
2. All calls must set GLOB_DOOFFS, or all must not set it.
3. After the second call, *pglob->gl_pathv* points to a list containing the following:
   a. Zero or more NULL pointers, as specified by GLOB_DOOFFS and *pglob->gl_offs*.
   b. Pointers to the path names that were in the *pglob->gl_pathv* list before the call, in the same order as before.
   c. Pointers to the new path names generated by the second call, in the specified order.
4. The count returned in *pglob->gl_pathc* will be the total number of path names from the two calls.
5. The application can change any of the fields after a call to glob(). If it does, it must reset them to the original value before a subsequent call, using the same *pglob* value, to globfree() or glob() with the GLOB_APPEND flag.

If, during the search, a directory is encountered that cannot be opened or read and *errfunc* is not a NULL pointer, glob() calls (**errfunc*()) with two arguments:

1. The *epath* argument is a pointer to the path that failed.
2. The *eerrno* argument is the value of errno from the failure, as set by opendir(), readdir() or stat(). (Other values may be used to report other errors not explicitly documented for those functions.)

Returned value

If successful, glob() returns 0. The argument *pglob->gl_pathc* returns the number of matched path names and the argument *pglob->gl_pathv* contains a pointer to a NULL-terminated list of matched and sorted path names. However, if *pglob->gl_pathc* is 0, the content of *pglob->gl_pathv* is undefined.

If glob() terminates due to an error, it returns one of the following nonzero constants defined in <glob.h> as error return values for glob():

GLOB_ABORTED
The scan was stopped because GLOB_ERR was set or (**errfunc*()) returned nonzero.

GLOB_NOMATCH
The pattern does not match any existing path name, and GLOB_NOCHECK was notset in *flags*.

GLOB_NOSPACE
An attempt to allocate memory failed.

If (**errfunc*()) is called and returns nonzero, or if the GLOB_ERR flag is set in *flags*, glob() stops the scan and returns GLOB_ABORTED after setting *gl_pathc* and *gl_pathv* in *pglob* to reflect the paths already scanned. If GLOB_ERR is not set and either *errfunc* is a NULL pointer or (**errfunc*()) returns 0, the error is ignored.

globfree() — Free storage allocated by glob()

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <glob.h>

void globfree(glob_t *pglob);
```

General description

The globfree() function frees storage associated with *pglob* by a previous call to glob().

Returned value

globfree() returns no values.

Related information

- “glob.h” on page 32
- “glob() — Generate path names matching a pattern” on page 807

gmtime(), gmtime64() — Convert time to broken-down UTC time

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <time.h>

struct tm *gmtime(const time_t *timer);
```

```
#define _LARGE_TIME_API
#include <time.h>

struct tm *gmtime64(const time64_t *timer);
```

General description

Converts the calendar time pointed to by *timer* into a broken-down time, expressed as Coordinated Universal Time (UTC).

[2]

The value pointed to by *timer* is usually obtained by a call to the time() function.

The relationship between a time in seconds since the Epoch used as an argument to gmtime() and the tm structure (defined in the <time.h> header) is that the result is as specified in the expression given in the definition of seconds since the Epoch, where the names in the structure and in the expression correspond.

The function gmtime64() will behave exactly like gmtime() except it will break down a time64_t value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

Returns a pointer to a *tm* structure containing the broken-down time, expressed in Coordinated Universal Time (UTC) corresponding to calendar time pointed to by *timer*. The fields in *tm* are shown in Table 16 on page 80. If the calendar time pointed to by *timer* cannot be converted to broken-down time (in UTC), gmtime() returns a NULL pointer.

Error code
Description

EOVERFLOW
The result cannot be represented.

Notes:

1. The range (0-60) for *tm_sec* allows for as many as one leap second.
2. The gmtime() and localtime() functions may use a common, statically allocated buffer for the conversion. Each call to one of these functions may alter the result of the previous call.
3. The calendar time returned by the time() function begins at the epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

Example

CELEBG23

[2] Coordinated Universal Time (UTC) was formerly known as Greenwich Mean Time (GMT).

```
/* CELEBG23

   This example uses the &gmtime. function to convert a
   time_t representation to a Coordinated Universal Time
   character string and then converts it to a printable string
   using &asct..

 */
#include <stdio.h>
#include <time.h>

int main(void)
{
   time_t ltime;
   time(&ltime);
   printf ("Coordinated Universal Time is %s\n",
            asctime(gmtime(&ltime)));
}
```

Output

```
Coordinated Universal Time (UTC) is Fri Jun 16 21:01:44 2006
```

gmtime_r(), gmtime64_r() — Convert a time value to broken-down UTC time

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>

struct tm *gmtime_r(const time_t *__restrict__ clock,
                     struct tm *__restrict__ result);
```

```
#define _LARGE_TIME_API
#include <time.h>

struct tm *gmtime64 _r(const time64_t *__restrict__ clock,
                      struct tm *__restrict__ result);
```

General description

The gmtime_r() function converts the calendar time pointed to by *clock* into a broken-down time expressed as Coordinated Universal Time (UTC). The broken-down time is stored in the structure referred to by *result*. The gmtime_r() function also returns the address of the same structure.

The relationship between a time in seconds since the Epoch used as an argument to gmtime() and the tm structure (defined in the <time.h> header) is that the result is as specified in the expression given in the definition of seconds since the Epoch, where the names in the structure and in the expression correspond.

The function gmtime64_r() will behave exactly like gmtime_r() except it will break down a time64_t value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, gmtime_r() returns the address of the structure pointed to by the argument *result*.

If an error is detected or UTC is not available, gmtime_r() returns a NULL pointer.

There are no documented errno values.

Error Code
Description

EOVERFLOW
The result cannot be represented.

grantpt() — Grant access to the slave pseudoterminal device

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int grantpt(int fildes);
```

General description

The grantpt() function changes the mode and ownership of the slave pseudoterminal device. *fildes* should be the file descriptor of the corresponding master pseudoterminal. The user ID of the slave is set to the real UID of the calling process and the group ID is set to the group ID associated with the group name specified by the installation in the TTYGROUP() initialization parameter. The permission mode of the slave pseudoterminal is set to readable and writable by the owner, and writable by the group.

You can provide secure connections by either using grantpt() and unlockpt(), or by simply issuing the first open against the slave pseudoterminal from the first userid or process that opened the master terminal.

Returned value

If successful, grantpt() returns 0.

If unsuccessful, grantpt() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The slave pseudoterminal was opened before grantpt(), or a grantpt() was already issued. In either case, slave pseudoterminal permissions and ownership have already been updated. If you use grantpt() to change slave pseudoterminal permissions, you must issue grantpt() between the master open and the first pseudoterminal open, and grantpt() can only be issued once.

EBADF
The *fildes* argument is not a valid open file descriptor.

EINVAL
The *fildes* argument is not associated with a master pseudoterminal device.

ENOENT
The slave pseudoterminal device was not found during lookup.

Related information

hcreate() — Create hash search tables

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <search.h>

int hcreate(size_t nel);
```

General description

The hcreate() function allocates sufficient space for a hash table containing *nel* elements, and must be called before hsearch() is used.

The *nel* argument is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by hcreate() for the actual table allocation in order to obtain certain mathematically favorable circumstances.

Threading Behavior: see “hsearch() — Search hash tables” on page 817.

Returned value

If successful, hcreate() returns nonzero.

If hcreate() cannot allocate sufficient space for the table, it returns 0 and sets errno to one of the following values:

Error Code
 Description

ENOMEM
 Insufficient storage space is available.

- “tsearch() — Binary tree search” on page 1920

hdestroy() — Destroy hash search tables

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <search.h>

void hdestroy(void);
```

General description

The hdestroy() function disposes of the search table, and may be followed by another call to hcreate(). After the call to hdestroy(), the data can no longer be considered accessible.

Threading Behavior: see "hsearch() — Search hash tables" on page 817.

Returned value

hdestroy() returns no values.

Related information

- "search.h" on page 62
- "bsearch() — Search arrays" on page 220
- "hcreate() — Create hash search tables" on page 815
- "hsearch() — Search hash tables" on page 817
- "lsearch() — Linear search and update" on page 1019

- "strcmp() — Compare strings" on page 1731
- "tsearch() — Binary tree search" on page 1920

__heaprpt() — Obtain dynamic heap storage report

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdlib.h>

typedef struct{long __uheap_size;
               long __uheap_bytes_alloc;
               long __uheap_bytes_free;
              } hreport_t;

int __heaprpt(hreport_t *heap_report_structure);
```

General description

__heaprpt() gets statistics about the application's storage utilization and places them in the area pointed to by the *heap_report_structure* argument. The storage report is similar in content to the user heap storage report that is generated with the RPTSTG(ON) runtime option.

To use this function, the calling program must obtain storage where the user's heap storage report will be stored. The address of this storage is passed as an argument to __heaprpt().

Returned value

If successful, __heaprpt() fills the struct hreport_t with the user's heap storage report information.

If the address is not valid, __heaprpt() returns -1 and sets errno to EFAULT.

Example

```
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
  hreport_t * strptr;

  strptr = (hreport_t *) malloc(sizeof(hreport_t));

  if (__heaprpt(strptr) != 0)
     perror("__heaprpt() error");

  else
  {
     printf("Total amount of user heap storage    : %ld\n",
            strptr->__uheap_size);
     printf("Amount of user heap storage in use   : %ld\n",
            strptr->__uheap_bytes_alloc);
     printf("Amount of available user heap storage: %ld\n",
            strptr->__uheap_bytes_free);
  }

}
```

Related information

- "stdlib.h" on page 70

hsearch() — Search hash tables

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <search.h>

ENTRY *hsearch(ENTRY item, ACTION action);
```

General description

The hsearch() function is a hash-table search routine. It returns a pointer into a hash table indicating the location at which an entry can be found. The *item* argument is a structure of type `ENTRY` (defined in the `<search.h>` header) containing two pointers: *item.key* points to the comparison key (a `char *`), and *item.data* (a `void *`) points to any other data to be associated with that key. The comparison function used by hsearch() is `strcmp().` The *action* argument is a member of an enumeration type `ACTION` indicating the disposition of the entry if it cannot be found in the table. *ENTER* indicates that the item should be inserted in the table at an appropriate point. *FIND* indicates that no entry should be made.

Threading Behavior: The hcreate() function allocates a piece of storage for use as the hash table. This storage is not exposed to the user, and is referred to by all threads. In other words, these functions operate on one hash table global to the process. The library serializes access to the table and attendant data across threads using an internal mutex.

Returned value

hsearch() returns a NULL pointer if either the action is *FIND* and the item could not be found or the action is *ENTER* and the table is full.

If an error occurs, hsearch() sets errno to one of the following values:

Error Code
Description

ENOMEM
Insufficient storage space is available.

```

SUSV3

```
#define _POSIX_C_SOURCE 200112L
#include <apar/inet.h>

uint32_t htonl(uint32_t hostlong);
```

Berkeley Sockets

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <arpa/inet.h>
#include <netinet/in.h>

unsigned long htonl(unsigned long a);
```

General description

The htonl() function translates a long integer from host byte order to network byte order.

Parameter
Description

a The unsigned long integer to be put into network byte order.

in_addr_t *hostlong*
Is typed to the unsigned long integer to be put into network byte order.

Notes:

1. For MVS, host byte order and network byte order are the same.
2. Since this function is implemented as a macro, you need one of the feature test macros and the inet header file.

Returned value

htonl() returns the translated long integer.

hypot(), hypotf(), hypotl() — Calculate the square root of the squares of two arguments

Standards

Standards / Extensions	C or C++	Dependencies
SAA XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

SAA:

```
#include <math.h>

double hypot(double side1, double side2);
```

SAA compiler option: LANGLVL(EXTENDED), LANGLVL(SAA), or LANGLVL(SAAL2)

XPG4:

```
#define _XOPEN_SOURCE
#include <math.h>

double hypot(double side1, double side2);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float hypotf(float side1, float side2);
long double hypotl(long double side1, long double side2);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float hypot(float side1, float side2);
long double hypot(long double side1, long double side2);
```

General description

The hypot() family of functions calculates the length of the hypotenuse of a right-angled triangle based on the lengths of two sides *side1* and *side2*. A call to hypot() is equal to:

```
 sqrt(side1* side1 + side2 * side2);
```

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	SPC	Hex	IEEE
hypot	X	X	X
hypotf		X	X
hypotl		X	X

Restriction: The hypotf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

The hypot() family of functions returns the calculated length of the hypotenuse.

If the correct value is outside the range of representable values, ±HUGE_VAL is returned, according to the sign of the value. The value of the macro ERANGE is stored in errno, to show the calculated value is out of range. If the correct value would cause an underflow, zero is returned and the value of the macro ERANGE is stored in errno.

Special behavior for IEEE: If successful, The hypot() family of functions returns the calculated length of the hypotenuse. If the correct value overflows, hypot() sets errno to ERANGE and returns HUGE_VAL.

Example

CELEBH01

```
/* CELEBH01

   This example calculates the hypotenuse of a right-angled
   triangle with sides of 3.0 and 4.0.

 */
#include <math.h>
#include <stdio.h>

int main(void)
{
   double x, y, z;

   x = 3.0;
   y = 4.0;
   z = hypot(x,y);

   printf("The hypotenuse of the triangle with sides %lf and %lf"
          " is %lf\n", x, y, z);
}
```

Output

```
The hypotenuse of the triangle with sides 3.000000 and 4.000000 is 5.000000
```

hypotd32(), hypotd64(), hypotd128() — Calculate the square root of the squares of two arguments

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.11

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  hypotd32(_Decimal32 x, _Decimal32 y);
_Decimal64  hypotd64(_Decimal64 x, _Decimal64 y);
_Decimal128 hypotd128(_Decimal128 x, _Decimal128 y);

_Decimal32  hypot(_Decimal32 x, _Decimal32 y);     /* C++ only */
_Decimal64  hypot(_Decimal64 x, _Decimal64 y);     /* C++ only */
_Decimal128 hypot(_Decimal128 x, _Decimal128 y);    /* C++ only */
```

General description

The hypot() family of functions calculates the length of the hypotenuse of a right-angled triangle based on the lengths of two sides x and y. A call to hypot() is equal to:

```
sqrt(x* x + y * y);
```

Notes:

1. These functions work in IEEE decimal floating-point format. See "IEEE decimal floating-point" on page 95IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, The hypot() family of functions returns the calculated length of the hypotenuse.

If the correct value overflows, hypot() sets errno to ERANGE and returns HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 accordingly.

Example

```
/* CELEBH03

   This example illustrates the hypotd64() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
   _Decimal64 x, y, z;

   x = 3.0DD;
   y = 4.0DD;
   z = hypotd64(x,y);

   printf("The hypotenuse of a triangle with sides %Df and %Df"
          " is %Df\n", x, y, z);
}
```

iconv() — Code conversion

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#include <iconv.h>

size_t iconv(iconv_t cd, char **__restrict__ inbuf,
     size_t *__restrict__ inbytesleft, char **__restrict__ outbuf,
             size_t *__restrict__ outbytesleft);
```

General description

Converts a sequence of characters, indirectly pointed to by *inbuf*, from one encoded character set into a sequence of corresponding characters in another encoded character set. The resulting character sequence is then stored into the array indirectly pointed to by *outbuf*. The encoded character sets are those specified in the iconv_open() call that returned the conversion descriptor, *cd*. If the descriptor refers to the state-dependent encoding, then before it is first used, the *cd* descriptor is in its initial shift state.

The *inbuf* argument points to a variable that points to the first character in the input buffer. *inbytesleft* indicates the number of bytes to the end of the buffer to be converted. The *outbuf* argument points to a variable that points to the first character in the output buffer. *outbytesleft* indicates the number of available bytes to the end of the buffer.

If the output character set refers to the state-dependent encoding—if it contains the multibyte characters with shift-states—the conversion descriptor *cd* is placed in its initial state by a call for which *inbuf* is a NULL pointer, or for which *inbuf* points to a NULL pointer. When iconv() is called in this way, and if *outbuf* is not a NULL pointer or a pointer to a NULL pointer, and *outbytesleft* points to a positive value, iconv() places in the output buffer the byte sequence to change the output buffer to the initial shift state. If the output buffer is not large enough to hold the entire reset sequence, iconv() fails, and sets errno to E2BIG. Subsequent calls with *inbuf* as other than a NULL pointer or a pointer to a NULL pointer cause conversion from the current state of the conversion descriptor.

If a sequence of input bytes does not form a valid character in the specified encoded character set, conversion stops after the previous successfully converted character, and iconv() sets errno to EILSEQ. If the input buffer ends with an incomplete character or shift sequence, conversion stops after the previous successfully converted bytes, and iconv() sets errno to EINVAL. If the output buffer is not large enough to hold the entire converted input, conversion stops just before the input bytes that would cause the output buffer to overflow.

The variable pointed to by *inbuf* is updated to point to the byte following the last byte of a successfully converted character. The value pointed to by *inbytesleft* is decremented to reflect the number of bytes still not converted in the input buffer. The variable pointed to by *outbuf* is updated to point to the byte following the last byte of converted output data. The value pointed to by *outbytesleft* is decremented to reflect the number of bytes still available in the output buffer. For state-dependent encoding, the conversion descriptor is updated to reflect the shift state in effect at the end of the last successfully converted byte sequence.

If iconv() encounters a character in the input buffer that is valid, but for which a conversion is not defined in the conversion descriptor, *cd*, then iconv() performs a nonidentical conversion on this character. The conversion is implementation-defined.

The <iconv.h>header file declares the `iconv_t` type that is a pointer to the object capable of storing the information about the converters used to convert characters in one coded character set to another. For state-dependent encoding, the object must be capable of storing the encoded information about the current shift state.

Special considerations for bidirectional language support: If the _BIDION environment variable is set to TRUE, iconv() performs bidirectional layout transformation to the converted characters. The required attributes for bidirectional layout transformation can be specified using the environment variable _BIDIATTR (eg. export _BIDIATTR="@ls typeoftext=visual:implicit, orientation=ltr:ltr,numerals=nominal:national"). For a detailed description of the bidirectional layout transformation, see “Bidirectional Language Support” in *z/OS XL C/C++ Programming Guide*. If the environment variable _BIDIATTR is not set, the default values will be used.

iconv() can perform bidirectional layout transformation while converting the data from the fromCodePage to the toCodePage. Bidirectional layout transformation will take place only if bidirectional language support is activated, see “iconv_open() — Allocate code conversion descriptor” on page 829 for more information about activating bidirectional layout transformation. In case iconv encounters any error in input or output buffers in the bidirectional part it will bypass the bidirectional layout transformation and continue its normal function as usual.

Special behavior for POSIX C: In the POSIX environment, a conversion descriptor returned from a successful iconv_open() may be used safely within a single thread. In addition, it may be opened on one thread, used on a second thread (iconv()), and closed (iconv_open()) on a third thread. However, you must ensure correct cross-thread sequencing and synchronization (that is: iconv_open(), followed by optional iconv() calls, followed by iconv_close()). The use of a shared conversion descriptor by iconv() across multiple threads may result in undefined behavior.

Returned value

If successful, iconv() updates the variables pointed to by the arguments to reflect the extent of the conversion and returns the number of nonidentical conversions performed.

If the entire string in the input buffer is converted, the value pointed to by *inbytesleft* will be 0. If the input conversion is stopped because of any conditions mentioned above, the value pointed to by *inbytesleft* will be nonzero and errno is set to indicate the condition.

If an error occurs, iconv() returns (size_t)-1 and sets errno to one of the following values:

Error Code
: **Description**

EBADF
: *cd* is not a valid descriptor.

ECUNNOENV
: A CUN_RS_NO_UNI_ENV error was issued by Unicode Conversion Services.

  See *z/OS Unicode Services User's Guide and Reference* documentation for user action.

ECUNNOCONV
: A CUN_RS_NO_CONVERSION error was issued by Unicode Conversion Services.

  See *z/OS Unicode Services User's Guide and Reference* documentation for user action.

ECUNNOTALIGNED
: A CUN_RS_TABLE_NOT_ALIGNED error was issued by Unicode Conversion Services.

See *z/OS Unicode Services User's Guide and Reference* documentation for user action.

ECUNERR

Function iconv() encountered an unexpected error while using Unicode Conversion Services.

See message EDC6258 for additional information.

EILSEQ
Input conversion stopped due to an input byte that does not belong to the input codeset.

EINVAL
Input conversion stopped due to an incomplete character or shift sequence at the end of the input buffer.

E2BIG Input conversion stopped due to lack of space in the output buffer.

Example

CELEBI01

```
/* CELEBI01

   This example converts an array of characters coded in encoded character
   set IBM-1047 to an array of characters coded in encoded character set
   IBM-037.
   Input is in inbuf, output will be in outbuf.

 */
#include <iconv.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

main ()
{
            char   *inptr;  /* Pointer used for input buffer  */
            char   *outptr; /* Pointer used for output buffer */
            char    inbuf[20] =
                  "ABCDEFGH!@#$1234";
                                            /* input buffer */
   unsigned char    outbuf[20];   /* output buffer  */
   iconv_t          cd;     /* conversion descriptor          */
   size_t           inleft; /* number of bytes left in inbuf  */
   size_t           outleft;/* number of bytes left in outbuf */
   int              rc;     /* return code of iconv()         */

   if ((cd = iconv_open("IBM-037", "IBM-1047")) == (iconv_t)(-1)) {
      fprintf(stderr, "Cannot open converter from %s to %s\n",
                                        "IBM-1047", "IBM-037");
      exit(8);
   }

   inleft = 16;
   outleft = 20;
   inptr = inbuf;
   outptr = (char*)outbuf;

   rc = iconv(cd, &inptr, &inleft, &outptr, &outleft);
   if (rc == -1) {
      fprintf(stderr, "Error in converting characters\n");
      exit(8);
   }
   iconv_close(cd);
}

iconv_close() — Deallocate code conversion descriptor

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#include <iconv.h>

int iconv_close(iconv_t cd);
```

General description

Deallocates the conversion descriptor *cd* and all other associated resources allocated by the iconv_open() function. For an illustration of using iconv_open(), see "Example" on page 827.

Returned value

If successful, iconv_close() returns 0.

If unsuccessful, iconv_close() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
cd is not a valid descriptor.

Related information

- "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*
- "iconv.h" on page 32
- "locale.h" on page 40

iconv_open() — Allocate code conversion descriptor

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#include <iconv.h>

iconv_t iconv_open(const char *tocode, const char *fromcode);
```

General description

Performs all the initialization needed to convert characters from the encoded character set specified in the array pointed to by the *fromcode* argument to the encoded character set specified in the array pointed to by the *tocode* argument.

The conversion descriptor relates the two encoded character sets.

For state-dependent encodings, the conversion descriptor will be in an encoded-character-set-dependent initial shift state, ready for immediate use with iconv(). The conversion descriptor remains valid until it is closed with iconv_close().

Settings of *fromcode*, *tocode*, and their permitted combinations are implementation-dependent.

Note: The iconv() family of functions has been modified to utilize character conversion services provided by Unicode Services. The iconv_open(), iconv() and iconv_close()'s function interfaces will remain unchanged except for the addition of four new errno values and two new environment variables described in the following paragraphs.

There are differences in externals between the iconv() family of functions and Unicode Services. However, these differences will be managed by the iconv() family of functions except where noted in the *z/OS XL C/C++ Compiler and Runtime Migration Guide for the Application Programmer*. All conversions listed in the section of the *z/OS XL C/C++ Programming Guide* entitled "Code Set Converters Supplied" will continue to work as they did prior to the integration of Unicode Services, as long as _ICONV_TECHNIQUE is left undefined. If the application does not define the _ICONV_TECHNIQUE environment variable, iconv_open() uses a default value of LMREC.

Unicode Services supports conversions between thousands of additional character sets not listed in the *z/OS XL C/C++ Programming Guide*. A complete list of conversions supported by Unicode Services can be found in tables 25 an tables 26 in the *z/OS Unicode Services User's Guide and Reference*. To set up a conversion using iconv_open() for any of the character sets listed in these tables, the user needs to use a character string representing the CCSID's for *fromcode* and *tocode*. For example, to set up a conversion from CCSID 00256 to CCSID 00870 using conversion technique R, the user would set the _ICONV_TECHNIQUE environment variable to R and call iconv_open() as follows:

```
cd = iconv_open("00870", "00256");
```

and continue to use iconv() and iconv_close() as in previous releases.

iconv() uses the following environment variables.

_ICONV_UCS2
Tells iconv_open(Y, X) what type of conversion method to setup when there is a choice between "direct" conversion from X to Y and "indirect" X to UCS-2 to Y.

_ICONV_UCS2_PREFIX
Tells iconv_open() what z/OS dataset name prefix to use to find UCS-2 tables if they cannot be found in the HFS.

_ICONV_MODE
Selects the behavior mode for iconv_open(), iconv() and iconv_close()..

_ICONV_TECHNIQUE
This is the technique value used while using Unicode Conversion Services. For more information regarding the Unicode Conversion Services technique value, refer to Chapter 3 - Creating a Unicode Environment section of the *z/OS Unicode Services User's Guide and Reference*.

For illustration of using iconv_close(), see “Example” on page 827.

Special considerations for bidirectional language support: Performs all the initialization needed to activate the bidirectional layout transformation to be used by iconv. The following three conditions must be satisfied to enable the bidirectional layout transformation:

1. The _BIDION environment variable must be set to TRUE.
2. The current locale environment at iconv_open() time must be an Arabic or Hebrew locale (eg. Ar_AA or Iw_IL).
3. The conversion code set must be an Arabic or Hebrew code set.

Conversion code sets differ in the following three cases:

1. Case fromCodeSet is UCS-2 and toCodeSet is single byte code set. In this case toCodeSet must be an Arabic or Hebrew code set.
2. Case fromCodeSet is single byte code set and toCodeSet is UCS-2. In this case fromCodeSet must be an Arabic or Hebrew code set.
3. Case both fromCodeSet and toCodeSet are single byte code sets. In this case toCodeSet must be an Arabic or Hebrew code set.

iconv_open( ) checks for the existence of the environment variable _BIDIATTR to get the bidirectional layout transformation attributes. It will use default values in case _BIDIATTR is not defined, is unset, or in case of the existence of some erroneous values in the _BIDIATTR environment variable. The default values are code set dependent according to the Arabic or Hebrew code set used. For the Arabic 420 code set the default values will be: orientation RTL, type of text visual, shaping shaped, numerals national and swapping on. For the Hebrew 424 code set the default values will be: orientation RTL, type of text visual and swapping on. For the rest of the Arabic code sets the default values will be: orientation RTL, type of text implicit, shaping nominal, numerals national and swapping on.

iconv_open() uses the following environment variables.

_BIDION

Tells iconv_open() whether to activate bidirectional handling of the converted data or not. _BIDION can be assigned either the value TRUE, if you want to turn on bidirectional layout transformation, or the value FALSE, if you want to turn off the BiDi layout transformation. Bidirectional layout transformation can also be turned off if the variable_BIDION is not defined in the environment.

_BIDIATTR

Holds the bidirectional layout transformation attributes which will be used later by iconv, _BIDIATTR will be read only in iconv_open() time. The _BIDIATTR environment variable is in the form of input/output pairs separated by colon, at the beginning of the string there is an @ that identifies the beginning of the attributes list, then followed by the attributes in the form of `<attribute_name1>=<input1>:<output1>, <attribute_name2>=<input2>:<output2> ..... (eg. export _BIDIATTR="@ls typeoftext=visual:implicit,orientation=ltr:ltr, numerals=nominal:national").`

Returned value

If successful, iconv_open() returns a conversion descriptor.

If unsuccessful, iconv_open() returns (iconv_t)-1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The conversion between encoded character sets specified is not supported.

ECUNNOENV

A CUN_RS_NO_UNI_ENV error was issued by Unicode Conversion Services.

See *z/OS Unicode Services User's Guide and Reference* for user action.

ECUNNOCONV

A CUN_RS_NO_CONVERSION error was issued by Unicode Conversion Services.

See *z/OS Unicode Services User's Guide and Reference* for user action.

ECUNNOTALIGNED

A CUN_RS_TABLE_NOT_ALIGNED error was issued by Unicode Conversion Services.

See *z/OS Unicode Services User's Guide and Reference* for user action.

ECUNERR

Function iconv() encountered an unexpected error while using Unicode Conversion Services.

Refer to message EDC6258 for additional information.

```

General description

The if_nameindex() function returns an array of if_nameindex structures, one structure per interface. The end of the array is indicated by a structure with an if_index of zero and an if_name of NULL.

The if_nameindex structure holds the information about a single interface and is defined as a result of including the <net/if.h> header.

```
struct if_nameindex {
   unsigned int if_index;  /* 1, 2, ... */
   char       *if_name;   /* null terminated name:  "le0", ... */
};
```

The memory used for this array of structures along with the interface names pointed to by the if_name members is obtained dynamically. This memory is freed by calling the if_freenameindex() function.

Returned value

When successful, if_nameindex() returns a pointer to an array of if_nameindex structures. Upon failure, if_nameindex() returns NULL and sets errno to one of the following:

Error Code
Description

ENOMEM
Insufficient storage is available to supply the array.

Related information

if_nametoindex() — Map a network interface name to its corresponding index

Standards

Standards / Extensions	C or C++	Dependencies
RFC2553 Single UNIX Specification, Version 3	both	z/OS V1R4

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <net/if.h>

unsigned int if_nametoindex(const char *ifname);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <net/if.h>

unsigned int if_nametoindex(const char *ifname);
```

General description

The if_nametoindex() function returns the interface index corresponding to the interface name *ifname*.

Returned value

When successful, if_nametoindex() returns the interface index corresponding to the interface name *ifname*. Upon failure, if_nametoindex() returns zero and sets errno to one of the following:

Error Code
Description

EINVAL
Non-valid parameter was specified. The *ifname* parameter was NULL.

ENOMEM
Insufficient storage is available to obtain the information for the interface name.

ENXIO
The specified interface name provided in the *ifname* parameter does not exist.

Related information

- "if_freenameindex() — Free the memory allocated by if_nameindex()" on page 832

ilogb(), ilogbf(), ilogbl() — Integer unbiased exponent

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

int ilogb(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

int ilogbf(float x);
int ilogbl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

int ilogb(float x);
int ilogb(long double x);
```

General description

The ilogb() functions returns the unbiased exponent of its argument *x* as an integer.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
ilogb	X	X
ilogbf	X	X
ilogbl	X	X

Returned value

If successful, the ilogb() functions return the unbiased exponent of *x* as an integer.

If *x* is 0, the value `FP_ILOGB0` is returned.

if *x* is a NaN, ilogb() will return `FP_ILOGBNAN`

if *x* is infinity, ilogb() will return `INT_MAX`

If the correct value is greater than {INT_MAX}, {INT_MAX} is returned and a domain error occurs.

If the correct value is less than {INT_MIN}, {INT_MIN} is returned and a domain error occurs.

Special behavior for hex: This function will return the unbiased exponent minus 1 (Because hex representation has no hidden bit, this treatment is needed to satisfy the logb() inequality).

Error Code
 Description

EDOM
 The x argument is zero, NaN, or ±inf, or the correct value is not representable as an integer.

Related information

- “math.h” on page 44
- “logb(), logbf(), logbl() — Unbiased exponent” on page 991

ilogbd32(), ilogbd64(), ilogbd128() — Integer unbiased exponent

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

int  ilogbd32(_Decimal32 x);
int  ilogbd64(_Decimal64 x);
int  ilogbd128(_Decimal128 x);
int  ilogb(_Decimal32 x);   /* C++ only */
int  ilogb(_Decimal64 x);   /* C++ only */
int  ilogb(_Decimal128 x);  /* C++ only */
```

General description

Returns the unbiased exponent of its argument *x* as an integer. For typical numbers, the value returned is the logarithm of |*x*| rounded down (toward -INF) to the nearest integer value.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, these functions return the unbiased exponent of *x* as an integer.

If *x* is equal to 0.0, ilogb() will return _FP_DEC_ILOGB0 (= -INT_MAX).

If *x* is a NaN or infinity, ilogb() will return INT_MAX.

Example

```
/* CELEBI11

   This example illustrates the ilogbd128() function.

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
   _Decimal128 x = -12345.678901DL;
   int y;

   y = ilogbd128(x);

   printf("The result of ilogbd128(%DDf) is %d\n", x, y);
}
```

imaxabs() — Absolute value for intmax_t

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <inttypes.h>

intmax_t imaxabs(intmax_t j);
```

Compile requirement: Function imaxabs() requires long long to be available.

General description

The imaxabs() function computes the absolute value of *j*. When the input value is INTMAX_MIN, the value is undefined. The imaxabs() function is similar to llabs() and labs(). The only difference being that the return value and the argument passed in are of type intmax_t.

Returned value

The imaxabs function returns the absolute value of *j*.

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>
int main(void)
{
  intmax_t a = -1234;

  intmax_t b = imaxabs(a);

  printf("%jd \n", b );
}

Output:

1234
```

Related information

- llabs()

imaxdiv() — Quotient and remainder for intmax_t

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <inttypes.h>

imaxdiv_t imaxdiv(intmax_t numer, intmax_t denom);
```

Compile requirement: Function imaxdiv() requires long long to be available.

General description

The imaxdiv() function computes numer / denom and numer % denom in a single operation. The imaxdiv function is similar to lldiv() and ldiv(). The only difference being that the return value is of type imaxdiv_t and those being passed in are of type intmax_t.

Returned value

imaxdiv() returns a structure of type imaxdiv_t comprising both the quotient and the remainder. If either part of the result cannot be represented, the behavior is undefined. if the denominator is zero, a divide by zero exception is raised.

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
 intmax_t num = 45;
 intmax_t den = 7;
 imaxdiv_t res;
       printf("Original numerator: %jd and denominator: %jd "
             ,num,den);
       res = imaxdiv(num,den);
       printf("Quotient: %jd  Remainder: %jd\n"
             , res.quot,res.rem);
}

Output

Original numerator: 45 and denominator: -7 Quotient: -6  Remainder: 3
```

- inttypes.h
- ldiv()
- lldiv()

ImportWorkUnit() — WLM import service

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R9

Format

```
#include <sys/__wlm.h>

int ImportWorkUnit(wlmxtok_t *exporttoken,
                   wlmetok_t *enclavetoken,
                   unsigned int *conntoken);
```

General description

Imports an enclave that has been previously exported using the ExportWorkUnit() function. The caller must invoke UnDoImportWorkUnit() when it no longer needs access to the enclave.

The ImportWorkUnit() function uses the following parameters:

**enclavetoken*
: Points to a work unit export token that was returned from a call to ExportWorkUnit().

**exporttoken*
: Points to a data field of type wlmetok_t where the ImportWorkUnit() function is to return the WLM work unit enclave token.

**conntoken*
: Specifies the connect token that represents the WLM connection.

Returned value

If successful, ImportWorkUnit() returns 0.

If unsuccessful, ImportWorkUnit() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
An argument of this function contained an address that was not accessible to the caller.

EINVAL
An argument of this function contained a value that is not correct.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be

permitted to the BPX.WLMSERVER Facility class, if the BPX.WLMSERVER class is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

index() — Search for character

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

char *index(const char *string, int c);
```

General description

The index() function locates the first occurrence of *c* (converted to an unsigned char) in the string pointed to by *string*. The character *c* can be the NULL character (\0); the ending NULL is included in the search.

The string argument to the function must contain a NULL character (\0) marking the end of the string.

The index() function is identical to "strchr() — Search for character" on page 1729.

Note: The index() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The strchr() function is preferred for portability.

Returned value

If successful, index() returns a pointer to the first occurrence of *c* (converted to an unsigned character) in the string pointed to by *string*.

If unsuccessful because *c* was not found, index() returns a NULL pointer.

There are no errno values defined.

inet6_is_srcaddr() - Socket address verification

Standards

Standards / Extensions	C or C++	Dependencies
RFC 5014	both	

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

short inet6_is_srcaddr(struct sockaddr_in6 *srcaddr, uint32_t flags);
```

General description

The inet6_is_srcaddr() function validates source address selection preference flags against the given socket address.

Argument
Description

srcaddr
A non-NULL pointer to a sockaddr_in6 structure initialized as follows:

- Clear the entire structure for sizeof(struct sockaddr_in6).
- *sin6_family* must be set to AF_INET6.
- Set *sin6_len* to the correct length for AF_INET6.
- Set *sin6_addr* to a 128-bit IPv6 source address to validate against the flags.
- The *sin6_scope_id* must be set if the address is link-local.

flags The source preference flags which can be set to any of the following:

- IPV6_PREFER_SRC_HOME - prefer home address as source
- IPV6_PREFER_SRC_COA - prefer care-of address as source
- IPV6_PREFER_SRC_TMP - prefer temporary address as source
- IPV6_PREFER_SRC_PUBLIC - prefer public address as source
- IPV6_PREFER_SRC_CGA - prefer CGA address as source
- IPV6_PREFER_SRC_NONCGA - prefer a non-CGA address as source

These flags can be combined into a flag set to express complex address preferences, but some can result in a contradictory flag set.

For example, the following flags are mutually exclusive:

- IPV6_PREFER_SRC_HOME and IPV6_PREFER_SRC_COA
- IPV6_PREFER_SRC_TMP and IPV6_PREFER_SRC_PUBLIC
- IPV6_PREFER_SRC_CGA and IPV6_PREFER_SRC_NONCGA

Returned value

When the IPv6 address corresponds to a valid address in the node and satisfies the given preference flags, inet6_is_srcaddr() returns 1.

If the input address matches an address in the node, but does not satisfy the preference flags indicated, the function returns 0.

If unsuccessful, inet6_is_srcaddr() returns -1 and sets errno to the following:

Error Code
Description

EADDRNOTAVAIL
The address provided does not match a home address in the node.

EAFNOSUPPORT
The address provided does not have a family of AF_INET6.

EAGAIN
A TCP/IP stack is not active to process the request.

EINVAL
Undefined flags were used, or a link-local IPv6 address was used with a zero scopeid, or a global address was used with a non-zero scopeid.

inet6_opt_append() — Add an option with length "len" and alignment "align"

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_append(void *extbuf, socklen_t extlen, int offset,
                     uint8_t type, socklen_t len, uint8_t align,
                     void **databufp);
```

General description

inet6_opt_append() returns the updated total length after adding an option with length *len* and alignment *align*. If *extbuf* is not NULL, it inserts any necessary padding and sets the type and length fields. A pointer to the location for the option content in *databufp* is then returned.

offset should be the length returned by inet6_opt_init() or the previous inet6_opt_append(). *type* is the 8-bit option type and *len* is the length of the option data (excluding the option type and option length fields).

Returned value

If successful, inet6_opt_append() returns the updated total length of the extension header.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- *extbuf* is NULL and *extlen* is non-zero;
- *extbuf* is non-NULL and *extlen* is not a positive multiple of 8;
- *offset* is less than the size of the empty extension header;
- *type* is not valid (specifies one of the PAD options);
- *len* is less than 0 or greater than 255;
- *align* is not 1, 2, 4, or 8;
- *align* is greater than *len*;
- new updated total length would exceed *extlen* (extbuf is non-NULL);
- *databufp* is NULL (extbuf is non-NULL).

Usage notes

1. The option, *type*, must have a value from 2 to 255 (0 and 1 are reserved for the Pad1 and PadN options).
2. The option data length must have a value between 0 and 255, including the values 0 and 255. It is the length of the option data that follows.
3. The *align* parameter must have a value of 1, 2, 4, or 8 and can not exceed the value of *len*.
4. Once inet6_opt_append() has been called, the application can use *databufp* directly or use inet6_opt_set_val() to specify the content of the option.

Related information

- “netinet/in.h” on page 53
- “inet6_opt_find() — Search for an option specified by the caller”

- “inet6_opt_set_val() — Insert data items into the data portion of the option” on page 850

inet6_opt_find() — Search for an option specified by the caller

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_find(void *extbuf, socklen_t extlen, int offset,
                   uint8_t type, socklen_t *lenp, void **databufp);
```

General description

inet6_opt_find() is similar to inet6_opt_next(), except it lets the caller specify the option type to be searched for.

Returned value

If successful, inet6_opt_find() returns the updated "previous" total length computed by advancing past the option that was returned and past any options that did not match the type.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- *extbuf* is NULL;
- *extlen* is not a positive multiple of 8;
- *offset* is less than 0 or greater than or equal to *extlen*;
- *lenp* or *databufp* is NULL;
- the option was not located;
- the extension header is malformed.

Usage notes

The returned "previous" length can be passed to subsequent calls of inet6_opt_find() for finding the next occurrence of the same option type.

Related information

- “netinet/in.h” on page 53
- “inet6_opt_append() — Add an option with length "len" and alignment "align"” on page 843

inet6_opt_finish() — Return the updated total length of extension header

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_finish(void *extbuf, socklen_t extlen, int offset);
```

General description

inet6_opt_finish() returns the updated total length taking into account the final padding of the extension header to make it a multiple of 8 bytes. If *extbuf* is not NULL the function also initializes the option by inserting a Pad1 or PadN option of the proper length.

Returned value

If successful, inet6_opt_finish() returns the total length of the extension header including the final padding.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- *extbuf* is NULL and *extlen* is non-zero;
- *extbuf* is non-NULL and *extlen* is not a positive multiple of 8;
- *extbuf* is non-NULL and offset is greater than *extlen;*
- *offset* is less than the size of the empty extension header.

Usage notes

offset should be the length returned by inet6_opt_init() or inet6_opt_append().

Related information

- “netinet/in.h” on page 53
- “inet6_opt_append() — Add an option with length "len" and alignment "align"” on page 843
- “inet6_opt_find() — Search for an option specified by the caller” on page 844

- “inet6_opt_set_val() — Insert data items into the data portion of the option” on page 850

inet6_opt_get_val() — Extract data items in the data portion of the option

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_get_val(void *databuf, int offset,
                      void *val, socklen_t vallen);
```

General description

inet6_opt_get_val() extracts data items of various sizes in the data portion of the option.

Returned value

If successful, inet6_opt_get_val() returns the offset for the next field (*offset* + *vallen*) that can be used when extracting option content with multiple fields.

Upon failure, returns -1 and sets errno to one of the following:

EINVAL If one of the following is true:
- *databuf* is NULL;
- *val* is null;
- *offset* is less than 0;
- *offset* + *vallen* is greater than the option length.

Usage notes

1. *databuf* should be a pointer returned by inet6_opt_next() or inet6_opt_find().
2. *val* should point to the destination for the extracted data.
3. *offset* specifies from where in the data portion of the option the value should be extracted; the first byte after the option type and length is accessed by specifying an *offset* of zero.

Related information

inet6_opt_init() — Return the number of bytes for empty extension header

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_init(void *extbuf, socklen_t extlen);
```

General description

inet6_opt_init() returns the number of bytes needed for the empty extension header. If *extbuf* is not NULL, the extension header is initialized to have the correct length field and the *extlen* value must be a positive, non-zero, multiple of 8, or the function will fail.

Returned value

If successful, inet6_opt_init() returns the number of bytes needed for the empty extension header.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- *extbuf* is NULL and *extlen* is non-zero;
- *extbuf* is non-NULL and *extlen* is not a positive multiple of 8.

Related information

- “netinet/in.h” on page 53
- “inet6_opt_append() — Add an option with length "len" and alignment "align"” on page 843
- “inet6_opt_find() — Search for an option specified by the caller” on page 844
- “inet6_opt_finish() — Return the updated total length of extension header” on page 846
- “inet6_opt_get_val() — Extract data items in the data portion of the option” on page 847

- “inet6_opt_set_val() — Insert data items into the data portion of the option” on page 850

inet6_opt_next() — Parse received option headers returning the next option

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_next(void *extbuf, socklen_t extlen, int offset,
                   uint8_t *typep, socklen_t *lenp, void **databufp);
```

General description

inet6_opt_next() parses received option extension headers and returns the next option.

Returned value

If successful, inet6_opt_next() returns the updated "previous" length computed by advancing past the option that was returned. This returned "previous" length can then be passed to subsequent calls to inet6_opt_next(). This function does not return any PAD1 or PADN options.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:

- *extbuf* is NULL;
- *extlen* is not a positive multiple of 8;
- *offset* is less than 0 or greater than or equal to *extlen*;
- *typep*, *lenp*, or *databufp* is NULL;
- there are no more options;
- the extension header is malformed.

Usage notes

1. *extbuf* and *extlen* specifies the extension header.
2. *offset* should either be zero (for the first option) or the length returned by a previous call to inet6_opt_next() or inet6_opt_find(). It specifies the position to continue scanning the extension buffer. The next option is returned by updating *typep*, *lenp*, and *databufp*.
3. *typep* points to the option type field.
4. *lenp* stores the length of the option data (excluding the option type and option length fields).
5. *databufp* points to the data field of the of the option.

inet6_opt_set_val() — Insert data items into the data portion of the option

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_set_val(void *databuf, int offset,
                      void *val, socklen_t vallen);
```

General description

inet6_opt_set_val() inserts items of various sizes in the data portion of the option.

Returned value

If successful, inet6_opt_set_val() returns the *offset* for the next field (*offset* + *vallen*) that can be used when composing option content with multiple fields.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- *databuf* is NULL;
- *val* is NULL;
- *offset* is less than 0;
- *offset* + *vallen* is greater than the option length.

Usage notes

1. *databuf* should be a pointer returned by inet6_opt_append().
2. *val* should point to the data to be inserted.
3. *offset* specifies where in the data portion of the option the value should be inserted; the first byte after the option type and length is accessed by specifying an *offset* of 0.

inet6_rth_add() — Add an IPv6 address to end of the routing header

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_rth_add(void *bp, const struct in6_addr *addr);
```

General description

inet6_rth_add() adds the IPv6 address pointed to by *addr* to the end of the routing header that is being constructed.

Returned value

If successful, inet6_rth_add() returns 0 and the segleft member of the routing header is updated to account for the new address.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- *bp* is NULL;
- the routing header indicates an unsupported header type;
- the routing header contains a non-valid number of segments for the type;
- there is not enough room to add the address.

Related information

- “netinet/in.h” on page 53

inet6_rth_getaddr() — Return pointer to the IPv6 address specified

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

struct in6_addr *inet6_rth_getaddr(const void *bp, int index);
```

General description

inet6_rth_getaddr() returns a pointer to the IPv6 address specified by *index* in the routing header described by *bp*.

Returned value

If successful, inet6_rth_getaddr() returns a pointer to the IPv6 address.

Upon failure, returns NULL and errno is set to one of the following:

EINVAL If one of the following is true:
- *bp* is NULL;
- the routing header indicates an unsupported header type;
- the routing header contains a non-valid number of segments;
- *index* is less than 0 or greater than or equal to the number of segments.

Usage notes

1. To obtain the number of segments in the routing header, a call to inet6_rth_segments() should be made first.
2. *index* must have a value between 0 and one less than the value returned by inet6_rth_segments().

Related information

- “netinet/in.h” on page 53

inet6_rth_init() — Initialize an IPv6 routing header buffer

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

void *inet6_rth_init(void *bp, socklen_t bp_len,
                     int type, int segments);
```

General description

inet6_rth_init() initializes the buffer pointed to by *bp* to contain a routing header of the specified *type* and sets ip6r_len based on the *segments* parameter.

Returned value

When successful, inet6_rth_init() returns the pointer to the buffer, bp. This is then used as the first argument to the inet6_rth_add() function.

Upon failure, returns NULL and errno is set to one of the following:

EINVAL If one of the following is true::
- *bp* is NULL;
- *type* indicates an unsupported header type;
- *segments* is not valid for the *type*;
- the buffer is not large enough, *bp_len* is too small.

Usage notes

1. The caller must allocate the buffer; its size can be determined by calling inet6_rth_space().
2. Any cmsghdr fields must be initialized when the application uses ancillary data.

Related information

- “netinet/in.h” on page 53

- “inet6_rth_segments() — Return number of segments contained in header” on page 854
- “inet6_rth_space() — Return number of bytes for a routing header” on page 855

inet6_rth_reverse() — Reverse the order of the addresses

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_rth_reverse(const void *in, void *out);
```

General description

inet6_rth_reverse() takes a routing header, pointed to by *in*, and writes a new routing header that sends datagrams along the reverse of that route. It reverses the order of the addresses and sets the segleft member in the new routing header to the number of segments required to send the datagram back to where it originated. Both arguments are allowed to point to the same buffer (the reversal can occur in place).

Returned value

If successful, inet6_rth_reverse() returns 0.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- *in* is NULL or *out* is NULL;
- the input routing header indicates an unsupported header type;
- the input routing header contains a non-valid number of segments;
- *in* and *out* overlap, but *in* and *out* are not the same buffer.

Related information

- “netinet/in.h” on page 53
- “inet6_rth_add() — Add an IPv6 address to end of the routing header” on page 851
- “inet6_rth_getaddr() — Return pointer to the IPv6 address specified” on page 852

- “inet6_rth_segments() — Return number of segments contained in header”
- “inet6_rth_space() — Return number of bytes for a routing header” on page 855

inet6_rth_segments() — Return number of segments contained in header

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_rth_segments(const void *bp);
```

General description

inet6_rth_segments() returns the number of segments (addresses) contained in the routing header described by *bp*.

Returned value

If successful, inet6_rth_segments() returns the number of segments or 0, if there are none in the header.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- *bp* is NULL;
- the routing header indicates an unsupported header type;
- the routing header contains a non-valid number of segments.

Related information

- "netinet/in.h" on page 53

- "inet6_rth_reverse() — Reverse the order of the addresses" on page 853
- "inet6_rth_space() — Return number of bytes for a routing header"

inet6_rth_space() — Return number of bytes for a routing header

Standards

Standards / Extensions	C or C++	Dependencies
RFC3542	both	z/OS V1R7

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

socklen_t inet6_rth_space(int type, int segments);
```

General description

inet6_rth_space() calculates the number of bytes required to hold a routing header for the specified *type* containing the specified number of *segments* (addresses).

Returned value

If successful, inet6_rth_space() returns the number of bytes, space required, for the routing header.

Upon failure, returns 0 and errno is set to one of the following:

EINVAL If one of the following is true:

- *type* indicates an unsupported header type;
- *segments* is not valid for the *type*.

Usage notes

1. This function returns the size but does not allocate the space required for the ancillary data. This allows an application to allocate a larger buffer, if other ancillary data objects are desired, because all the ancillary data objects must be specified to sendmsg() as a single msg_control buffer.
2. For an IPv6 Type 0 routing header, the number of *segments* must be between 0 and 127, inclusive. When the application uses ancillary data it must pass the returned length to CMSG_SPACE() to determine how much memory is needed for the ancillary data object (including the cmsghdr structure).

inet_addr() — Translate an Internet address into network byte order

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t inet_addr(const char *cp);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_addr(char *cp);
```

General description

The inet_addr() function interprets character strings representing host addresses expressed in standard dotted-decimal notation and returns host addresses suitable for use as an Internet address.

Parameter
Description

cp A character string in standard dotted-decimal (**.**) notation.

Values specified in standard dotted-decimal notation take one of the following forms:

```
a.b.c.d
a.b.c
a.b
a
```

When a 4-part address is specified, each part is interpreted as a byte of data and assigned, from left to right, to one of the 4 bytes of an Internet address.

When a three-part address is specified, the last part is interpreted as a 16-bit quantity and placed in the two rightmost bytes of the network address. This makes the three-part address format convenient for specifying class-B network addresses as **128.net.host**.

When a two-part address is specified, the last part is interpreted as a 24-bit quantity and placed in the three rightmost bytes of the network address. This makes the two-part address format convenient for specifying class-A network addresses as **net.host**.

When a one-part address is specified, the value is stored directly in the network address space without any rearrangement of its bytes.

Numbers supplied as address parts in standard dotted-decimal notation can be decimal, hexadecimal, or octal. Numbers are interpreted in C language syntax. A leading 0x implies hexadecimal; a leading 0 implies octal. A number without a leading 0 implies decimal.

The address must be terminated with a null or other white space character to be valid. Any or all of the parts of the address may be empty strings. Each empty part resolves to the value 0. Input character strings that begin with a null or other white space character is treated as an empty address and will result in the value INADDR_ANY being returned.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Notes:
1. To provide an ASCII input/output format for applications using this function, define the feature test macro __LIBASCII as described in topic "__LIBASCII" on page 7.
2. The inet_addr() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, inet_addr() returns the Internet address in network byte order.

If the input character string is not in the correct format, the value INADDR_NONE is returned and errno is set to EINVAL.

inet_lnaof() — Translate a local network address into host byte order

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t inet_lnaof(struct in_addr in);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_lnaof(struct in_addr in);
```

General description

The inet_lnaof() function breaks apart the Internet host address and returns the local network address portion.

Parameter
Description

in The host Internet address.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

The local network address is returned in host byte order.

Related information

inet_makeaddr() — Create an Internet host address

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

struct in_addr inet_makeaddr(in_addr_t net, in_addr_t lna);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

struct in_addr inet_makeaddr(unsigned long net, unsigned long lna);
```

General description

The inet_makeaddr() function takes a network number and a local network address and constructs an Internet address.

Parameter
Description

net The network number.

lna The local network address.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

The Internet address is returned in network byte order.

inet_netof() — Get the network number from the Internet host sddress

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t inet_netof(struct in_addr in);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_netof(struct addr_in in);
```

General description

The inet_netof() function breaks apart the Internet host address and returns the network number portion.

Parameter
Description

in The Internet address in network byte order.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

The network number is returned in host byte order.

Related information

- “arpa/inet.h” on page 17
- “netinet/in.h” on page 53
- “sys/socket.h” on page 74

- “sys/types.h” on page 75

inet_network() — Get the network number from the decimal host address

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t inet_network(const char *cp);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_network(char cp);
```

General description

The inet_network() function interprets character strings representing addresses expressed in standard dotted-decimal notation and returns numbers suitable for use as a network number.

Parameter
Description

cp A character string in standard, dotted-decimal (.) notation.

Note: The input value is handled as an octal number when there are 3 integers within the dotted-decimal notation. For example, the input value of inet_network(“40.001.016.000”) validly returns X'28010e00' (40.1.14.0) since the 016 is treated as an octal number.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The inet_network() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2113 for details.

Returned value

The network number is returned in host byte order.

Related information

- “arpa/inet.h” on page 17
- “netinet/in.h” on page 53
- “sys/socket.h” on page 74
- “sys/types.h” on page 75

inet_ntoa() — Get the decimal Internet host address

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

char *inet_ntoa(struct in_addr in);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

char *inet_ntoa(struct in_addr in);
```

General description

The inet_ntoa() function returns a pointer to a string expressed in the dotted-decimal notation. inet_ntoa() accepts an Internet address expressed as a 32-bit quantity in network byte order and returns a string expressed in dotted-decimal notation.

Parameter
    Description

in The host Internet address.

To provide an ASCII input/output format for applications using this function, define feature test macro __LIBASCII as described “__LIBASCII” on page 7.

Note: The inet_ntoa() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2113 for details.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

Returns a pointer to the Internet address expressed in dotted-decimal notation. The storage pointed to exists on a per-thread basis and is overwritten by subsequent calls.

Related information

inet_ntop() — Convert Internet address format from binary to text

Standards

Standards / Extensions	C or C++	Dependencies
RFC2553 Single UNIX Specification, Version 3	both	z/OS V1R2

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <arpa/inet.h>

const char *inet_ntop(int af, const void *src, char *dst, socklen_t size);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

const char *inet_ntop(int af, const void *__restrict__ src,
                      char * __restrict__ dst, socklen_t size);
```

General description

The inet_ntop() function converts from an Internet address in binary format, specified by *src*, to standard text format, and places the result in *dst*, when *size*, the space available in *dst*, is sufficient. The argument *af* specifies the family of the Internet address. This can be AF_INET or AF_INET6.

The argument *src* points to a buffer holding an IPv4 Internet address if the *af* argument is AF_INET, or an IPv6 Internet address if the *af* argument is AF_INET6. The address must be in network byte order.

The argument *dst* points to a buffer where the function will store the resulting text string. The *size* argument specifies the size of this buffer. The application must specify a non-NULL *dst* argument. For IPv6 addresses, the buffer must be at least 46 bytes. For IPv4 addresses, the buffer must be at least 16 bytes.

In order to allow applications to easily declare buffers of the proper size to store IPv4 and IPv6 addresses in string form, the following two constants are defined in <netinet/in.h>:

```
#define INET_ADDRSTRLEN 16
#define INET6_ADDRSTRLEN 46
```

Note: The inet_ntop() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2113 for details.

Returned value

If successful, inet_ntop() returns a pointer to the buffer containing the converted address.

If unsuccessful, inet_ntop() returns NULL and sets errno to one of the following values:

Error Code
Description

EAFNOSUPPORT
The address family specified in *af* is unsupported.

ENOSPC
The destination buffer *size* is too small.

Note: For Enhanced ASCII usage, the inet_ntop() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2113 for details.

inet_pton() — Convert Internet address format from text to binary

Standards

Standards / Extensions	C or C++	Dependencies
RFC2553 Single UNIX Specification, Version 3	both	z/OS V1R2

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <arpa/inet.h>

int inet_pton(int af, const char *src, void *dst);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

int inet_pton(int af, const char *__restrict__ src, void *__restrict__ dst);
```

General description

The inet_pton() function converts an Internet address in its standard text format into its numeric binary form. The argument *af* specifies the family of the address.

Note: AF_INET and AF_INET6 address families are currently supported.

The input argument *src* is a null terminated string. It points to the string being passed in. The argument *dst* points to a buffer into which inet_pton() stores the numeric address. The address is returned in network byte order. The caller must ensure that the buffer pointed to by *dst* is large enough to hold the numeric address.

If the *af* argument is AF_INET, inet_pton() accepts a string in the standard IPv4 dotted-decimal form:

```
ddd.ddd.ddd.ddd
```

where *ddd* is a 1 to 3 digit decimal number between 0 and 255.

If the *af* argument is AF_INET6, the *src* string must be in one of the following standard IPv6 text forms:

1. The preferred form is *x:x:x:x:x: x:x: x:x:*, where the *x*'s are the hexadecimal values of the eight 16-bit pieces of the address. Leading zeros in individual fields can be omitted, but there should be at least one numeral in every field.
2. A string of contiguous zero fields in the preferred form can be shown as *::* The *::* can only appear once in an address. Unspecified addresses *(0:0:0:0:0:0:0:0:)* may be represented simply as *::*.
3. A third form that is sometimes more convenient when dealing with a mixed environment of IPv4 and IPv6 is *x:x:x:x:x:x:d.d.d.d.*, where *x*'s are the hexadecimal values of the six high-order 16-bit pieces of the address, and the *d*'s are the decimal values of the four low-order 8-bit pieces of the address (standard IPv4 representation).

Notes:

1. A more extensive description of the IPv6 standard representations can be found in RFC2373.
2. The inet_pton() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If successful, inet_pton() returns 1 and stores the binary form of the Internet address in the buffer pointed to by *dst*.

If unsuccessful because the input buffer pointed to by *src* is not a valid string, inet_pton() returns 0.

If unsuccessful because the *af* argument is unknown, inet_pton() returns -1 and sets errno to one of the following values:

Error Code
Description

EAFNOSUPPORT
The address family specified in *af* is unsupported.

initgroups() — Initialize the supplementary group ID list for the process

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS
#include <sys/types.h>
#include <grp.h>

int initgroups(const char *user, const gid_t basegid);
```

General description

The initgroups() function obtains the supplementary group membership of *user*, and sets the current process supplementary group IDs to that list. The *basegid* is also included in the supplementary group IDs list.

The caller of this function must be a superuser or must specify the password of the target user name specified on the initgroups() call - issue the passwd() function before initgroups().

Returned value

If successful, initgroups() returns 0.

If unsuccessful, initgroups() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The number of supplementary groups for the specified user plus the basegid group exceeds the maximum number of groups allowed, or a non-valid *user* is specified.

EMVSERR
An MVS environmental or internal error occurred.

EMVSSAF2ERR
The Security Authorization Facility (SAF) had an error.

EPERM
The caller is not authorized, only authorized users are allowed to alter the supplementary group IDs list.

initstate() — Initialize generator for random()

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *initstate(unsigned seed, char *state, size_t size);
```

General description

The initstate() function allows a state array, pointed to by the *state* argument, to be initialized for future use in calls to the random() functions by the calling thread. The *size* argument, which specifies the size in bytes of the state array, is used by the initstate() function to decide how sophisticated a random-number generator to use; the larger the state array, the more random the numbers. Values for the amount of state information are 8, 32, 64, 128, and 256 bytes. While other amounts are rounded down to the nearest known value. The *seed* argument specifies a starting point for the random-number sequence and provides for restarting at the same point. The initstate() function returns a pointer to the previous state information array.

Returned value

If successful, initstate() returns a pointer to the previous state array.

If unsuccessful, initstate() returns a NULL pointer.If initstate() is called with *size* less than 8, it will return NULL.

insque() — Insert an element into a doubly-linked list

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <search.h>

void insque(void *element, void *pred);
```

General description

The insque() function inserts the element pointed to by *element* into a doubly-linked list immediately after the element pointed to by *pred*. The function operates on pointers to structures which have a pointer to their successor in the list as their first element, and a pointer to their predecessor as the second. The application is free to define the remaining contents of the structure, and manages all storage itself. To insert the first element into a linear (non-circular) list, an application would call *insque(element, NULL);*. To insert the first element into a circular list, the application would set the element's forward and back pointers to point to the element.

Returned value

insque() returns no values.

ioctl() — Control device

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

Terminals:

```
#include <sys/ioctl.h>

int ioctl(int fildes int cmd, ... /* arg */);
```

Sockets:

```
#define _XOPEN_SOURCE_EXTENDED 1

/**     OR      **/

#define _OE_SOCKETS

#include <sys/ioctl.h>
#include <net/rtrouteh.h>
#include <net/if.h>
int ioctl(int fildes, int cmd, ... /* arg */);
```

STREAMS:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>
int ioctl(int fildes int cmd, ... /* arg */);
```

General description

ioctl() performs a variety of control functions on devices. The *cmd* argument and an optional third argument (with varying type) are passed to and interpreted by the device associated with *fildes*.

The *cmd* argument selects the control function to be performed and will depend on the device being addressed.

The *arg* argument represents additional information that is needed by this specific device to perform the requested function. The type of *arg* depends upon the particular control request, but it is either an integer or a pointer to a device-specific data structure.

ioctl() information is divided into the following section s:

- Terminals
- Sockets
- STREAMS
- ACLs

Terminals

The following ioctl() commands are used with terminals:

Command
: **Description**

TIOCSWINSZ
: Set window size. Used as the second operand in an ioctl() against a terminal. The window size information pointed to by the third operand is copied into an area in the kernel associated with the terminal, and a SIGWINCH signal is generated against the foreground process group.

TIOCGWINSZ
: Get window size. Used as the second operand in an ioctl() against a terminal. The current window size is returned in the area pointed to by the third operand - a winsize structure.

The winsize structure is the third operand in an ioctl() call when you use TIOCSWINSZ or TIOCGWINSZ. The structure contains four unsigned short integers:

Field **Description**

ws_row
: Number of rows in the window, in characters.

ws_col
: Number of columns in the window, in characters. This assumes single-byte characters. Multibyte characters may take more room.

ws_xpixel
: Horizontal size of the window, in pixels.

ws_ypixel
: Vertical size of the window, in pixels.

Sockets

The following ioctl() commands are used with sockets:

Command
: **Description**

FIONBIO
: Sets or clears nonblocking I/O for a socket. *arg* is a pointer to an integer. If the integer is 0, nonblocking I/O on the socket is cleared. Otherwise, the socket is set for nonblocking I/O.

FIONREAD
: Gets the number of immediately readable bytes for the socket. *arg* is a pointer to an integer. Sets the value of the integer to the number of immediately readable characters for the socket.

FIONWRITE
: Returns the number of bytes that can be written to the connected peer AF_UNIX stream socket before the socket blocks or returns EWOULDBLOCK. The number of bytes returned is not guaranteed unless there is serialization by the using applications.

FIOGETOWN
: Returns the PID that has been set that designates the recipient of signals.

FIOSETOWN
: Sets the PID to be used when sending signals

FIOGETOWN and FIOSETOWN are equivalent to the F_GETOWN and F_SETOWN commands of fctl(). For information on the values for pid, refer to that function. This function is only valid for AF_INET stream sockets.

SECIGET
Gets the peer socket's security identity values for an AF_UNIX connected stream socket. The MVS user ID, effective UID, and effective GID of the peer process are returned in the **seci** structure, which is mapped by BPXYSECI. This option is valid only for the AF_UNIX domain.

SECIGET_T
Returns both the process and, if available, the task level security information of the peer for an AF_UNIX stream connected to the socket. The task level security information is from the task that issued the connect() or accept(). The security information is returned in a struct __sect_s as defined in <sys/ioctl.h>. The security information is not available until accept() completes. The availability of the peer's task level security data is determined by the task level userid length field. If zero, the peer does not have task level security data.

SIOCADDRT
Adds a routing table entry. *arg* is a pointer to a **rtentry** structure, as defined in <net/rtrouteh.h>. The routing table entry, passed as an argument, is added to the routing tables. This option is valid only for the AF_INET domain.

SIOCATMARK
Queries whether the current location in the data input is pointing to out-of-band data. *arg* is a pointer to an integer. SIOCATMARK sets the argument to 1 if the socket points to a mark in the data stream for out-of-band data; otherwise, it sets the argument to 0. Refer to recv(), recvfrom() and recvmsg() for more information on receiving out-of-band data.

SIOCDELRT
Deletes a routing table entry. *arg* is a pointer to a **rtentry** structure, as defined in <net/rtrouteh.h>. If it exists, the routing table entry passed as an argument is deleted from the routing tables. This option is valid only for the AF_INET domain.

SIOCGIFADDR

Gets the network interface address. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface address is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFBRDADDR

Gets the network interface broadcast address. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface broadcast address is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFCONF

Gets the network interface configuration. *arg* is a pointer to an **ifconf** structure, as defined in <net/if.h>. The interface configuration is returned in the buffer pointed to by the **ifconf** structure. The returned data's length is returned in the field that had originally contained the length of the buffer. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFCONF6

Gets the name, address, and other information about the IPv6 network interfaces that are configured. This is similar to the SIOCGIFCONF command for IPv4.

To request OSM interfaces, the application must have READ authorization to the EZB.OSM.sysname.tcpname resource.

A struct __net_ifconf6header_s is passed as the argument of the ioctl. This structure specifies the buffer where the configuration information is to be written and is returned with the number of entries and entry length of each struct, and __net_ifconf6entry_s that was written to the output buffer. These structures are defined in <sys/ioctl.h>.

If __nif6h_buflen and __nif6h_buffer are both zero, a query function is performed and the header is returned with:

__nif6h_version

The maximum supported version.

Note: If the version number is supplied (not zero), the entry length returned will be for the specified version. (If it is supported)

__nif6h_entries

The total number of entries that will be output.

__nif6h_entrylen

The length of each individual entry.

If a call to get information fails with either

```
errno = ERANGE, or
errno = EINVAL and __nif6h_version has changed
```

The call was converted into a query function and the header has been filled in as described above. In these cases, the content of the output buffer is undefined.

If Common INET is configured and multiple TCP/IP stacks are attached to the socket, the output from each stack that is enabled for IPv6 will be concatenated in the output buffer and the header will contain the total number of entries returned from all the stacks. The version returned with the query function will be the highest version supported by all the stacks.

This ioctl can be issued on an AF_INET or AF_INET6 socket.

Error Code

Description

EAFNOSUPPORT

No IPv6 enabled TCP/IP stacks are active.

EINVAL

The input version number is not supported.

ERANGE

The buffer is too small to contain all of the IPv6 network interface entries.

SIOCGIFDSTADDR

Gets the network interface destination address. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface destination (point-to-point) address is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFFLAGS

Gets the network interface flags. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface flags are returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFMETRIC

Gets the network interface routing metric. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface routing metric is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFMTU

Gets the network interface MTU (maximum transmission unit). arg is a pointer to an ifreq structure, as defined in <net/if.h>. The interface MTU is returned in the argument, arg->ifr_mtu. This option is only valid for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFNETMASK

Gets the network interface network mask. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface network mask is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGSPLXFQDN

Gets the fully qualified domain name for a given server and domain name in a sysplex. This is an special purpose command to support applications that have registered with WorkLoad Manager (WLM) for connection optimization services using the Domain Name System (DNS). 'arg' is a pointer to sysplexFqDn structure, as defined in <ezbzsdnc.h>. sysplexFqDn contains pointer to sysplexFqDnData structure, as defined in <ezbzsdnc.h>.

sysplexFqDnData structure contains server name(input), group name(input) and fully qualified domain name(output).

ioctl() with the SIOCGSPLXFQDN command will fail if:

Error Code

Description

EFAULT

Write user storage failed

EINVAL

One of the following:
- Group name required
- Buffer length not valid
- Socket call parameter error

ENXIO
One of the following:
- Sysplex address not found
- Res not found In DNS
- Time out
- Time Unexpected Error

Example: The following is an example of the ioctl() call used with SIOCGSPLXFQDN.

```
#include <ezbzsdnc.h>
    sysplexFqDn       splxFqDn;
    sysplexFqDnData   splxData;
    int               rc;

    splxFqDn.splxVersion = splxDataVersion;
    splxFqDn.splxBufLen  = sizeof(sysplexFqDnData);
    splxFqDn.splxBufAddr = &splxData;

    /*  Assign values to splxData.groupName, */
    /*  splxData.serverName if required      */
        .
        .

    /* Get the fully qualified domain name   */
    rc = ioctl(s,SIOCGSPLXFQDN, (char *) &splxFqDn);

    /* splxData.domainName contains the fully*/
    /* qualified domain name.                */
```

SIOCSECENVR

Used to SET or GET the security environment for a server socket. arg points to a struct __seco_s where element __seco_argument is set to 1 for a SET and 2 for a GET request.

When used with the SET argument, the AF_UNIX stream socket server will designate the server socket as one that requires the full security environment of the connecting client to be available before the connect will complete successfully. During connect processing, connect obtains the security environment of the connector and anchors it off the connector's socket for use by the server. If the security environment cannot be obtained during connect processing, the connect will fail. This command has no effect on sockets that do not become server sockets.

When used with the GET argument, the AF_UNIX stream socket server will copy the previously SET security environment from the connector's address space to the server's address space so it can be used as input on calls to the security product. This command has meaning only for server sockets that previously issued SIOCSECENVR with the SET argument.

SIOCSIFMETRIC

Sets the network interface routing metric. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. SIOCSIFMETRIC sets the interface routing metric to the value passed in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCSPARTNERINFO
Sets an indicator to retrieve the partner security credentials during connection setup and saves the information, enabling an application to issue a SIOCGPARTNERINFO ioctl without suspending the application, or

at least minimizing the time to retrieve the information. The SIOCSPARTNERINFO ioctl must be issued prior to the SIOCGPARTNERINFO ioctl. For more information, see *z/OS Communications Server: IP Programmer's Guide and Reference*.

SIOCSVIPA
Defines or deletes an IPv4 dynamic VIPA. *arg* is a pointer to a **dvreq** structure as defined in <ezbzdvpc.h>. This option is valid only for the AF_INET domain.

SIOCSVIPA6
Defines or deletes an IPv6 dynamic VIPA. *arg* is a pointer to a **dvreq6** structure as defined in <ezbzdvpc.h>. This option is valid only for the AF_INET6 domain.

SIOCTIEDESTHRD
Associates (ties) or disassociates (unties) a descriptor with a thread. `arg` is a pointer to an int. When `*arg` is 1, the descriptor is tied to the calling thread. When `*arg` is 0, the descriptor is untied from the calling thread. If the task should terminate before the descriptor is closed or untied from the task, z/OS UNIX file system thread termination processing will close the descriptor. This command can be used on both heavy weight and medium weight threads.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Terminal and sockets returned value

If successful, ioctl() returns 0.

If unsuccessful, ioctl() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
The *fildes* parameter is not a valid socket descriptor.

EINVAL
The request is not valid or not supported.

EIO The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

EMVSPARM
Incorrect parameters were passed to the service.

ENODEV
The device is incorrect. The function is not supported by the device driver.

ENOTTY
An incorrect file descriptor was specified. The file type was not character special.

Example

The following is an example of the ioctl() call.

```
int s;
int dontblock;
int rc;
⋮
/* Place the socket into nonblocking mode */
dontblock = 1;
rc = ioctl(s, FIONBIO, (
char *) &dontblock);
⋮
```

STREAMS

The following ioctl() commands are used with STREAMS:

L_PUSH

Pushes the module whose name is pointed to by *arg* onto the top of the current STREAM, just below the STREAM head. It then calls the open() function of the newly-pushed module.

ioctl() with the I_PUSH command will fail if:

Error Code
Description

EINVAL
Non-valid module name.

ENXIO
Open function of new module failed.

ENXIO
Hang-up received on *fildes*

L_POP

Removes the module just below the STREAM pointed to by *fildes*. The *arg* argument should be 0 in an I_POP request.

ioctl() with the I_POP command will fail if:

Error Code
Description

EINVAL
No module present in the STREAM.

ENXIO
Hang-up received on *fildes*.

L_LOOK

Retrieves the name of the module just below the STREAM head of the STREAM pointed to by *fildes* and places it in a character string pointed to by *arg*. The buffer pointed to by *arg* should be at least FMNAMESZ+1 bytes long, where FMNAMESZ is defined in <stropts.h>.

ioctl() with the I_LOOK command will fail if:

Error Code
Description

EINVAL
No module present in the STREAM.

L_FLUSH

This request flushes read and/or write queues, depending on the value of *arg*. Valid *arg* values are:

FLUSHR
Flush all read queues.

FLUSHW
Flush all write queues.

FLUSHRW
Flush all read and all write queues.

ioctl() with the I_FLUSH command will fail if:

Error Code
Description

EAGAIN or ENOSR
Unable to allocate buffers for flush message.

EINVAL
Non-valid *arg* value.

ENXIO
Hang-up received on *fildes*.

I_FLUSHBAND
Flushes a particular band of messages. The *arg* argument points to a bandinfo structure. The bi_flag member may be one of FLUSHER, FLUSHW, or FLUSHRW as described above. The bi_pri member determines the priority band to be flushed.

I_SETSIG
Requests that the STREAMS implementation send the SIGPOLL signal to the calling process when a particular event has occurred on the STREAM associated with *fildes*. I_SETIG supports an asynchronous processing capability in STREAMS. The value of *arg* is a bitmask that specifies the events for which the process should be signaled. It is the bitwise OR of any combination of the following constants:

S_RDNORM
A normal (priority band set to 0) message has arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

S_RDBAND
A message with a nonzero priority band has arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

S_INPUT
A message, other than a high-priority message, has arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

S_HIPRI
A high-priority message is present on a STREAM head read queue. A signal will be generated even if the message is of zero length.

S_OUTPUT
The write queue for normal data (priority band 0) just below the STREAM head is no longer full. This notifies the process that there is room on the queue for sending (or writing) normal data downstream.

S_WRNORM
Same as S_OUTPUT.

S_WRBAND
The write queue for a nonzero priority band just below the STREAM head is no longer full. This notifies the process that there is no room on the queue for sending (or writing) priority data downstream.

S_MSG
A STREAMS signal message that contains the SIGPOLL signal has reached the front of the STREAM head read queue.

S_ERROR
Notification of an error condition has reached the STREAM head.

S_HANGUP
When used in conjunction with S_RDBAND, SIGURG is generated instead of SIGPOLL when a priority message reaches the front of the STREAM head read queue.

If *arg* is 0, the calling process will be unregistered and will not receive further SIGPOLL signals for the STREAM associated with *fildes*.

Processes that wish to receive SIGPOLL signals must explicitly register to receive them using I_SETSIG. If several processes register to receive this signal for the same event on the same STREAM, each process will be signaled when the event occurs.

ioctl() with the I_SETSIG command will fail if:

Error Code
Description

EAGAIN
There were insufficient resources to store the signal request.

EINVAL
The value of *arg* is not valid.

EINVAL
The value of *arg* is 0 and the calling process is not registered to receive the SIGPOLL signal.

I_GETSIG
Returns the events for which the calling process is currently registered to be sent a SIGPOLL signal. The events are returned as a bitmask in an int pointed to by *arg*, where the events are those specified in the description of I_SETSIG above.

ioctl() with the I_GETSIG command will fail if:

Error Code
Description

EINVAL
Process is not registered to receive the SIGPOLL signal.

I_FIND
This request compares the names of all modules currently present in the STREAM to the name pointed to by *arg*, and returns 1 if the name module is present in the STREAM, or returns 0 if the named module is not present.

ioctl() with the I_FIND command will fail if:

Error Code
Description

EINVAL
arg does not contain a valid module name.

I_PEEK
This request allows a process to retrieve the information in the first message on the STREAM head read queue without taking the message off the queue. It is analogous to getmsg() except that this command does not remove the message from the queue. The *arg* argument points to a strpeek structure.

The maxlen member in the ctlbuf and databuf strbuf structure must be set to the number of bytes of control information and/or data information, respectively, to retrieve. The flags member may be marked RS_HIPRI or 0, as described by getmsg() - getpmsg(). If the process sets flags to RS_HIPRI, for example, I_PEEK will only look for a high-priority message on the STREAM head read queue.

I_PEEK returns 1 if a message was retrieved, and returns 0 if no message was found on the STREAM head read queue, or if the RS_HIPFI flag was set in flags and a high-priority message was not present on the STREAM head read queue. It does not wait for a message to arrive. On return, ctlbuf specifies information in the control buffer, databuf specifies information in the data buffer, and flags contains the value RS_HIPRI or 0.

I_SRDOPT
Sets the read mode using the value of the argument *arg*. Read modes are described in read(). Valid *arg* flags are:

RNORM
Byte-stream mode, the default.

RMSGD
Message-discard mode.

RMSGN
Message-nondiscarded mode.

The bitwise inclusive-OR of RMSGD and RMSGN will return EINVAL. The bitwise inclusive-OR of RNORM and either RMSGD or RMSGN will result in the other flag overriding RNORM which is the default.

In addition, treatment of control messages by the STREAM head may be changed by setting any of the following flag in *arg*:

RPROTNORM
Fail read() with EBADMSG if a message containing a control part is at the front of the STREAM head read queue.

RPROTDAT
Deliver the control part of a message as data when a process issues a read().

RPROTDIS
Discard the control part of a message, delivery any data portion, when a process issues a read().

ioctl() with the I_SRDOPT command will fail if:

Error Code
Description

EINVAL
The *arg* argument is not valid.

I_GRDOPT
Returns the current read mode setting, as described above, in an int pointed to by the argument *arg*. Read modes are described in read().

I_NREAD
Counts the number of data bytes in the data part of the first message on the STREAM head read queue and places this value in the init pointed to by *arg*. The return value for the command is the number of messages on the STREAM head read queue. For example, if 0 is returned in *arg*, but the ioctl() return value is greater than 0, this indicates that a zero-length message is next on the queue.

I_FDINSERT
Creates a message from specified buffer(s), adds information about another STREAM, and sends the message downstream. The message contains a control part and an optional data part. The data and control parts to be sent are distinguished by placement in separate buffers, as described below. The *arg* argument points to a **strfdinsert** structure.

The **len** member in the ctlbuf strbuf structure must be set to the size of a pointer plus the number of bytes of control information to be sent with the message. The *fildes* member specifies the file descriptor of the other STREAM, and the offset member, which must be suitably aligned for use as a pointer, specifies the offset from the start of the control buffer where I_FDINSERT will store a pointer whose interpretation is specific to the STREAM end. The **len** member in the databuf strbuf structure must be set to the number of bytes of data information to be sent with the message, or 0 if no data part is to be sent.

The **flags** member specifies the type of message to be created. A normal message is created if flags is set to 0, and a high-priority message is created if **flags** is set to RS_HIPRI. For non-priority messages, I_FDINSERT will block if the STREAM write queue is full due to internal flow control conditions. For priority messages, I_FDINSERT does not block on this condition. For non-priority messages, I_FDINSERT does not block when the write queue is full and O_NONBLOCK is set. Instead, it fails and sets errno to EAGAIN.

I_FDINSERT also blocks, unless prevented by lack of internal resources, waiting for the availability of message blocks in the STREAM, regardless of priority or whether O_NONBLOCK has been specified. No partial message is sent.

ioctl() with the I_FDINSERT command will fail if:

Error Code
Description

EAGAIN
A non-priority message is specified, the O_NONBLOCK flag is set, and the STREAM write queue is full due to internal flow control conditions.

EAGAIN or ENOSR
Buffers can not be allocated for the message that is to be created.

EINVAL
One of the following:

- The *fd* member of the **strfdinsert** structure is not a valid, open STREAM file descriptor.
- The size of a pointer plus *offset* is greater than the *len* member for the buffer specified through *ctlptr*
- the *offset* member does not specify a properly-aligned location in the data buffer.
- An undefined value is stored in **flags**

ENXIO
Hang-up received for *fd* or *fildes*.

ERANGE
The *len* member for the buffer specified through *databuf* does not fall within the range specified by the maximum and minimum packet sizes of the topmost STREAM module or the *len* member for the buffer specified through *databuf* is larger than the maximum configured size of the data part of a message; or the *len* member for the buffer specified through *ctlbuf* is larger than the maximum configured size of the control part of a message.

I_STR Constructs an internal STREAMS ioctl() message from the data pointed to by *arg*, and sends that message downstream.

This mechanism is provided to send ioctl() requests to downstream modules and drivers. It allows information to be sent with ioctl(), and returns to the process any information sent upstream by the downstream recipient. I_STR blocks until the system responds with either a positive or negative acknowledgement message, or until the request "times out" after some period of time. If the request times out, it fails with errno set to ETIME.

At most, one I_STR can be active on a STREAM. Further I_STR calls will block until the active I_STR completes at the STREAM head. The default timeout interval for these requests is 15 seconds. The O_NONBLOCK flag has no effect on this call.

To send requests downstream, *arg* must point to a **strioctl** structure.

The **ic_cmd** member is the internal ioctl() command intended for a downstream module or driver and **ic_timeout** is the number of seconds (-1 = infinite, 0 = use implementation-dependent timeout interval, >0 = as specified) an I_STR request will wait for acknowledgement before timing out. **ic_len** member has two uses: on input, it contains the length of the data argument passed in, and on return from the command, it contains the number of bytes being returned to the process (the *buffer* pointed to by **ic_dp** should be large enough to contain the maximum amount of data that any module or the driver in the STREAM can return.)

The STREAM head will convert the information pointed to by the **strioctl** structure to an internal ioctl() command message and send it downstream.

ioctl() with the I_STR command will fail if:

Error Code
Description

EAGAIN or ENOSR
Unable to allocate buffers for the ioctl() message.

EINVAL
This *ic_len* member is less than 0 or larger than the maximum configured size of the data part of a message, or *ic_timeout* is less than -1.

ENXIO
Hang-up received on *fildes*.

ETIME
A downstream ioctl() timed out before acknowledgement was received.

An I_STR can also fail while waiting for an acknowledgement if a message indicating an error or a hang-up is received at the STREAM head. In addition, an error code can be returned in the positive or negative acknowledgement message, in the event the ioctl() command sent downstream fails. For these cases, I_STR fails with errno set to the value in the message.

I_SWROPT
Sets the write mode using the value of the argument *arg*. Valid bit settings for *arg* are:

SNDZERO
Send a zero-length message downstream when a write() if 0 bytes occurs. To not send a zero-length message when a write() of 0 bytes occurs, this bit must not be set in *arg* (for example, *arg* would be set to 0).

ioctl() with the I_SWROPT command will fail if:

Error Code
Description

EINVAL
arg is not the above value.

I_GWROPT
Returns the current write mode setting as described above, in the int that is pointed to by the argument *arg*.

I_SENDFD
I_SENDFD creates a new reference to the open file description associated with the file descriptor *arg* and writes a message on the STREAMS-based pipes *fildes* containing the reference, together with the user ID and group ID of the calling process.

ioctl() with the I_SENDFD command will fail if:

Error Code
Description

EAGAIN
The sending STREAM is unable to allocate a message block to contain the file pointer; or the read queues of the receiving STREAM head is full and cannot accept the message sent by I_SENDFD.

EBADF
The *arg* argument is not a valid, open file descriptor.

EINVAL
The *fildes* argument is not connected to a STREAM pipe.

ENXIO
Hang-up received on *fildes*.

I_RECVFD

Retrieves the reference to an open file description from a message within a STREAMS-based pipe using the I_SENDFD command, and allocates a new file descriptor in the calling process that refers to this open file description. The *arg* argument is a pointer to an **strrecvfd** data structure as defined in <stropts.h>.

The **fd** member is a file descriptor. The **uid** and **gid** members are the effective user ID and effective group ID, respectively, of the sending process.

If O_NONBLOCK is not set I_RECVFD blocks until a message is present at the STREAM head. If O_NONBLOCK is set, I_RECVFD fails with errno set to EAGAIN if no message is present at the STREAM head.

If the message at the STREAM head is a message sent by an I_SENDFD, a new file descriptor is allocated for the open file descriptor referenced in the message. The new file descriptor is placed in the **fd** member of the **strrecvfd** structure pointed to by *arg*.

ioctl() with the I_RECVFD command will fail if:

Error Code
Description

EAGAIN
A message is not present at the STREAM head read queue and the O_NONBLOCK flag is set.

EBADMSG
The message at the STREAM head read queue is not a message containing a passed file descriptor.

EMFILE
The process has the maximum number of file descriptors currently open that is allowed.

ENXIO
Hang-up received on *fildes*.

I_LIST

This request allows the process to list all the module names on the STREAM, up to and including the topmost driver names. If *arg* is a NULL pointer, the return value is the number of modules, including the driver, that are on the STREAM pointed to by *fildes*. This lets the process allocate enough space for the module names. Otherwise, it should point to an **str_list** structure.

The **sl_nmods** member indicates the number of entries the process has allocated in the array. Upon return, the **sl_modlist** member of the **str_list** structure contains the list of module names. The number of entries that have been filled into the **sl_modlist** array is found in the **sl_nmode** member (the number includes the number of module including the driver). The return value from ioctl() is 0. The entries are filled in starting at the top of the STREAM and continuing downstream until either the end of the STREAM is reached, or the number of requested modules (**sl_nmods**) is satisfied.

ioctl() with the I_LIST command will fail if:

Error Code
Description

EAGAIN or ENOSR
Unable to allocate buffers.

EINVAL
The **sl_nmods** member is less than 1.

I_ATMARK
This request allows the process to see if the message at the head of the STREAM head read queue is marked by some module downstream. The *arg* argument determines how the checking is done when there may be multiple marked messages on the STREAM head read queue. It may take on the following values:

ANYMARK Check if the message is marked.

LASTMARK Check if the message is the last one marked on the queue.

The bitwise inclusive-OR of the flags ANYMARK and LASTMARK is permitted.

The return value is 1 if the mark condition is satisfied and 0 otherwise.

ioctl() with the I_ATMARK command will fail if:

EINVAL Non-valid *arg* value.

I_CKBAND
Check if he message of a given priority band exists on the STREAM head read queue. This returns 1 if a message of the given priority exists, 0 if no message exists, or -1 on error. *arg* should be of type int.

ioctl() with the I_CKBAND command will fail if :

EINVAL Non-valid *arg* value.

I_GETBAND
Return the priority band of the first message on the STREAM head read queue in the integer referenced by *arg*.

ioctl() with the I_GETBAND command will fail if:

ENODATA No message on the STREAM head read queue.

I_CANPUT
Check if a certain band is writable. *arg* is set to the priority band in question. The return value is 0 if the band is flow-controlled, 1 if the band is writable, or -1 on error.

ioctl() with the I_CANPUT command will fail if:

EINVAL Non-valid *arg* value.

I_SETCLTIME
This request allows the process to set the time the STREAM head will delay when a STREAM is closing and there is data on the write queues. Before closing each module or driver, if there is a data on its write queue, the STREAM head will delay for the specified amount of time to allow the data to drain. If, after the delay, data is still present, it will be flushed. The *arg* argument is a pointer to an integer specifying the number of milliseconds to delay, rounded up to the nearest valid value. If I_SETCLTIME is not performed on a STREAM, an implementation-dependent default timeout interval is used.

ioctl() with the I_SETCLTIME command will fail if:

EINVAL Non-valid *arg* value.

I_GETCLTIME
This request returns the close time delay in the integer pointed to by *arg*

Multiplexed STREAMS configurations: The following four commands are used for connecting and disconnecting multiplexed STREAMS configurations. These commands use an implementation-dependent default timeout interval.

I_LINK
Connects two STREAMS, where *fildes* is the file descriptor of the STREAM connected to the multiplexing driver, and *arg* is the file descriptor of the STREAM connected to another driver. The STREAM designated by *arg* gets connected below the multiplexing driver. I_LINK requires the multiplexing driver to the send an acknowledgement message to the STREAM head regarding the connection. This call returns a multiplexer ID number (an identifier used to disconnect the multiplexer; see (I_UNLINK) on success, and -1 on failure.

ioctl() with the I_LINK command will fail if:

Error Code
Description

EAGAIN or ENOSR
Unable to allocate STREAMS storage to perform the I_LINK.

EBADF
The *arg* argument is not a valid, open file descriptor.

EINVAL
The *fildes* does not support multiplexing; or *arg* is not a STREAM or is already connected downstream from a multiplexer, or the specified I_LINK operation would connect the STREAM head in more than one place in the multiplexed STREAM.

ENXIO
Hang-up received on *fildes*.

ETIME
Time out before acknowledgement message was received at STREAM head.

An I_LINK can also fail while waiting for the multiplexing driver to acknowledge the request, if a message indicating an error or a hang-up is received at the STREAM head of *fildes*. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, I_LINK fails with errno set to the value in the message.

I_UNLINK
Disconnects the two STREAMs specified by *fildes* and *arg*. *fildes* is the file descriptor of the STREAM connected to the multiplexing driver. The *arg* argument is the multiplexer ID number that was returned by the I_LINK ioctl() command when a STREAM was connected downstream from the multiplexing driver. If *arg* is MUXID_ALL, then all STREAMs that were connected to *fildes* are disconnected. As in I_LINK, this command requires acknowledgement.

ioctl() with the I_UNLINK command will fail if:

Error Code
Description

EAGAIN or ENOSR
Unable to allocate buffers for the acknowledgement message.

EINVAL
Non-valid multiplexer ID number.

ENXIO
Hang-up received on *fildes*.

ETIME
Time out before acknowledgement message was received at STREAM head.

An I_UNLINK can also fail while waiting for the multiplexing driver to acknowledge the request if a message indicating an error or a hang-up is received at the STREAM head of *fildes* In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, I_UNLINK fails with errno set to the value in the message.

I_PLINK
Creates a *persistent connection* between two STREAMs, where *fildes* is the file descriptor of the STREAM connected to another driver. This call creates a persistent connection which can exist even if the file descriptor *fildes* associated with the upper STREAM to the multiplexing driver is closed. The STREAM designated by *arg* gets connected using a persistent connection below the multiplexing driver. I_PLINK requires the multiplexing driver to send an acknowledgement message to the STREAM head. This call returns a multiplexer ID number (an identifier that may be used to disconnect the multiplexer, see I_PUNLINK) on success, and -1 on failure.

ioctl() with the I_PLINK command will fail if:

Error Code
Description

EAGAIN or ENOSR
Unable to allocate STREAMS storage to perform the I_PLINK.

EBADF
The *arg* argument is not valid, open file descriptor.

EINVAL
The *fildes* argument does not support multiplexing; or *arg* is not a STREAM or is already connected downstream from a multiplexer; or the specified I_PLINK operation would connect the STREAM head in more than one place in the multiplexed STREAM.

ENXIO
Hang-up received on *fildes*.

ETIME
Time out before acknowledgement message was received at STREAM head.

An I_PLINK can also fail while waiting for the multiplexing driver to acknowledge the request, if a message indicating an error or a hang-up is received at the STREAM head of *fildes* In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, I_PLINK fails with errno set to the value in the message.

I_PUNLINK

Disconnects the two STREAMs specified by *fildes* and *arg* from a persistent connection. The *fildes* argument is the file descriptor of the STREAM connected to the multiplexing driver. The *arg* argument is the multiplexer ID number that was returned by the I_PLINK ioctl() command when a STREAM was connected downstream from the multiplexing driver. If *arg* is MUXID_ALL then all STREAMs which are persistent connections to *fildes* are disconnected. As in I_PLINK, this command requires the multiplexing driver to the acknowledge the request.

ioctl() with the I_PUNLINK command will fail if:

Error Code
Description

EAGAIN or ENOSR
Unable to allocate buffers for the acknowledgement message.

EINVAL
Non-valid multiplexer ID number.

ENXIO
Hang-up received on *fildes*.

ETIME
Time out before acknowledgement message was received at STREAM head.

An I_PUNLINK can also fail while waiting for the multiplexing driver to acknowledge the request if a message indicating an error or a hang-up is received at the STREAM head of *fildes*. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, I_PUNLINK fails with errno set to the value in the message.

STREAMS returned value

If successful, ioctl() returns a value other than -1 that depends upon the STREAMS device control function.

If unsuccessful, ioctl() returns -1 and sets errno to one of the following values.

Note: It is impossible for ioctl() to perform any STREAMS type commands successfully, since z/OS UNIX services do not provide any STREAMS-based files. The function will always return -1 with errno set to indicate the failure. See "open() — Open a file" on page 1152 for more information.

Under the following general conditions, ioctl() will fail if:

Error Code
Description

EBADF
The *fildes* argument is not a valid open file descriptor.

EINTR
A signal was caught during the ioctl() operation.

EINVAL
The STREAM or multiplexer referenced by *fildes* is linked (directly or indirectly) downstream from a multiplexer.

If an underlying device driver detects an error, ioctl() will fail if:

Error Code
Description

EINVAL
The *cmd* or *arg* argument is not valid for this device.

EIO Some physical I/O error has occurred.

ENODEV
The *fildes* argument refers to a valid STREAMS device, but the corresponding device driver does not support ioctl().

ENOTTY
The *fildes* argument is not associated with a STREAMS device that accepts control functions.

ENXIO
The *cmd* or *arg* argument is not valid for this device driver, but the service requested can not be performed on this particular sub-device.

If a STREAM is connected downstream from a multiplexer, any ioctl() command except I_UNLINK and I_PUNLINK will set errno to EINVAL.

ACLs

The following ioctl() commands are used with ACLs:

Command
Description

SETFACL
Set ACL. Used to set information into an Access Control List. *arg* specifies the user buffer containing the input ACL which is mapped by struct ACL_buf followed immediately by an array of struct ACL_entrys. *arglen* specifies the combined length of the struct ACL_buf and the array of struct ACL_entrys. See *z/OS UNIX System Services Programming: Assembler Callable Services Reference* for more information about ACL_buf and the ACL_entrys.

GETFACL
Get ACL. Used to retrieve information from an Access Control List. *arg* specifies the user buffer into which the requested ACL will be returned. The data is mapped by struct ACL_BUF followed immediately by an array of struct ACL_entrys. See *z/OS UNIX System Services Programming: Assembler Callable Services Reference* for more information about ACL_buf and the ACL_entrys. *Arglen* specifies the combined length of the struct ACL and the array of struct ACL_entrys in the user buffer.

ACLs returned value

If successful, ioctl() returns 0.

If unsuccessful, ioctl() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
The *fildes* parameter is not a valid file descriptor.

EINVAL
The request is not valid or not supported.

EMVSPARM
Incorrect parameters were passed to the service.

ENODEV
The device is incorrect. The function is not supported by the device driver.

Example

The following is an example of the ioctl() call.

```
int s;
int rc;
int acllen;
ext_acl_t aclbufp;
s = open("datafile", O_RDWR);
acllen = sizeof struct ACL_buf + (1024 * sizeof ACL_entry);
aclbufp = (ext_acl_t) malloc(acllen);
rc  =  ioctl(s, GETFACL, acllen, aclbufp)
```

__ipdbcs() — Retrieve the list of requested DBCS tables to load

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <__ftp.h>

struct __ipdbcss *__ipdbcs(void);
```

General description

The __ipdbcs() function determines the values that IP address resolution initialization found in the resolver configuration data set for the keywords LoadDBCSTables. If the LoadDBCSTables keywords are not found in the resolver configuration data set, the structure returned has a count of zero and each element in the structure list points to a NULL string.

Returned value

If successful, __ipdbcs() returns a NULL-terminated character string containing the complete structure *__ipdbcss* with each entry in *__ip_dbcs_list*[] initialized either to a valid name or to a NULL string. The number of valid names, up to the maximum of 8, is placed in *__ipdbcsnum*. If no table names are specified then *__ipdbcsnum* is set to zero.

If unsuccessful, __ipdbcs() returns NULL and stores one of the following error values in h_errno. __ipdbcs() is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code
Description

NO_RECOVERY
An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.

TRY_AGAIN
An error occurred while initializing the __res_state structure name selected, which can be retried.

Related information

__ipDomainName() — Retrieve the resolver supplied domain name

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	OS/390 V2R9

Format

```
#include <__ftp.h>

char *__ipDomainName(void);
```

General description

Lets an application get the values which IP address resolution initialization established for the domain name (supplied by keywords Domain or DomainOrigin).

Returned value

If successful, __ipDomainName() returns the NULL-terminated character string which is the name found for the domain name or a NULL string if no domain name was found in the IP address resolution initialization.

If unsuccessful, __ipDomainName() returns NULL and stores one of the following error values in h_errno. The __ipDomainName() function is only unsuccessful if IP address resolution initialization fails to complete.

Error Code
Description

NO_RECOVERY
An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.

TRY_AGAIN
An error occurred while initializing the __res_state structure name selected, which can be retried.

Related information

__ipdspx() — Retrieve the data set prefix specified

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <__ftp.h>

char *__ipdspx(void);
```

General description

The __ipdspx() function determines the value that IP address resolution initialization found in the resolver configuration data set for the keyword DataSetPrefix. If no DataSetPrefix keyword is found in the resolver configuration data set, then the default value is returned.

Returned value

If successful, __ipdspx() returns the NULL-terminated character string that was supplied in the configuration data set. If the configuration data set did not supply a value for the keyword DataSetPrefix, then __ipdspx() returns the string TCPIP.

If unsuccessful, __ipdspx() returns NULL and stores one of the following error values in h_errno. __ipdspx() is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code
Description

NO_RECOVERY
An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.

TRY_AGAIN
An error occurred while initializing the __res_state structure name selected, which can be retried.

Related information

__iphost() — Retrieve the resolver supplied hostname

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <__ftp.h>

char *__iphost(void);
```

General description

The __iphost() function lets an application determine the values that IP address resolution initialization found in the resolver configuration data set for the keyword HOSTname. If the keyword is not found in the resolver configuration data set, the char string returned will be a NULL string.

Returned value

If successful, __iphost() returns the NULL-terminated character string, which is the name supplied on the HOSTname keyword found in the resolver configuration file.

If unsuccessful, __iphost() returns NULL and stores one of the following error values in h_errno. __iphost() is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code
Description

NO_RECOVERY
An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.

TRY_AGAIN
An error occurred while initializing the __res_state structure name selected, which can be retried.

Related information

__ipmsgc() — Determine the case to use for FTP messages

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <__ftp.h>

int __ipmsgc(void);
```

General description

The __ipmsgc() function determines the value that IP address resolution initialization found in the resolver configuration data set for the keyword MessageCase. If no MessageCase keyword is found in the resolver configuration data set, then the default value is returned.

The *init* argument returned is one of the following set of symbols defined in the __ftp.h header file, each one stands for a message case selection.

__MIXED
Represents mixed case value selected for the messages FTP will send.

__UPPER
Represents uppercase value selected for the messages FTP will send.

Returned value

__ipmsgc() is always successful and returns either the value of the __MIXED or the value of __UPPER for all requests. __MIXED is the default value.

Related information

- “__ftp.h” on page 32
- “__ipdbcs() — Retrieve the list of requested DBCS tables to load” on page 889 “__ipdspx() — Retrieve the data set prefix specified” on page 891

__ipnode() — Retrieve the resolver supplied node name

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <__ftp.h>

char *__ipnode(void);
```

General description

The __ipnode() function lets an application determine the values that IP address resolution initialization found as the NodeID name used by the VMCF platform. If the VMCF nodeID name is not found, the char string returned will be a NULL string.

Returned value

If successful, __ipnode() returns the NULL-terminated character string, which is the name found for the VMCF platform.

If unsuccessful, __ipnode() returns NULL and stores one of the following error values in h_errno. __ipnode() is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code
Description

NO_RECOVERY
An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.

TRY_AGAIN
An error occurred while initializing the __res_state structure name selected, which can be retried.

Related information

- “__ipmsgc() — Determine the case to use for FTP messages” on page 893
- “__iptcpn() — Retrieve the resolver supplied jobname or user ID”

__iptcpn() — Retrieve the resolver supplied jobname or user ID

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <__ftp.h>

char *__iptcpn(void);
```

General description

The __iptcpn() function lets an application determine the values that IP address resolution initialization found in the resolver configuration data set for either of the keywords TCPIPuserid or TCPIPjobname, whichever is the last one read. If neither keyword is found in the resolver configuration data set, the char string returned will be a NULL string.

Returned value

If successful, __iptcpn() returns the NULL-terminated character string which is the name supplied on the TCPIPuserid or TCPIPjobname keyword found in the resolver configuration file.

If unsuccessful, __iptcpn() returns NULL and stores one of the following error values in h_errno. __iptcpn() is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code
Description

NO_RECOVERY
An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.

TRY_AGAIN
An error occurred while initializing the __res_state structure name selected, which can be retried.

isalnum() to isxdigit() — Test integer value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <ctype.h>

int isalnum(int c);
int isalpha(int c);
int iscntrl(int c);
int isdigit(int c);
int isgraph(int c);
int islower(int c);
int isprint(int c);
int ispunct(int c);
int isspace(int c);
int isupper(int c);
int isxdigit(int c);
```

General description

The functions listed above, which are all declared in ctype.h, test a given integer value. The valid integer values for *c* are those representable as an *unsigned char* or EOF.

By default, the functions are defined as macros when ctype.h is included. For better performance, the macro forms are recommended over the functional forms.

However, to get the functional forms, do one or more of the following:

- For C only: do *not* include ctype.h.
- Specify `#undef`, for example, `#undef islower`
- Surround the call statement by parentheses, for example, `(islower)('a')`

Here are descriptions of each function in this group.

isalnum()
Test for an upper- or lowercase letter, or a decimal digit, as defined in the `alnum` locale source file and in the `alnum` class of the LC_CTYPE category of the current locale.

isalpha()
Test for an alphabetic character, as defined in the `alpha` locale source file and in the `alpha` class of the LC_CTYPE category of the current locale.

iscntrl()
Test for any control character, as defined in the `cntrl` locale source file and in the `cntrl` class of the LC_CTYPE category of the current locale.

isdigit()
Test for a decimal digit, as defined in the `digit` locale source file and in the `digit` class of the LC_CTYPE category of the current locale.

isgraph()
Test for a printable character excluding space, as defined in the `graph` locale source file and in the `graph` class of the LC_CTYPE category of the current locale.

islower()
Test for a lowercase character, as defined in the `lower` locale source file and in the `lower` class of the LC_CTYPE category of the current locale.

isprint()
Test for a printable character including space, as defined in the `print` locale source file and in the `print` class of the LC_CTYPE category of the current locale.

ispunct()
Test for any nonalphanumeric printable character, excluding space, as defined in the `punct` locale source file and in the `punct` class of the LC_CTYPE category of the current locale.

isspace()
Test for a white space character, as defined in the `space` locale source file and in the `space` class of the LC_CTYPE category of the current locale.

isupper()
Test for an uppercase character, as defined in the `upper` locale source file and in the `upper` class of the LC_CTYPE category of the current locale.

isxdigit()
Test for a hexadecimal digit, as defined in the `xdigit` locale source file and in the `xdigit` class of the LC_CTYPE category of the current locale.

The space, uppercase, and lowercase characters can be redefined by their respective class of the LC_CTYPE in the current locale. The LC_CTYPE category is discussed in the “Internationalization: Locales and Character Sets” in *z/OS XL C/C++ Programming Guide*.

Returned value

If the integer satisfies the test condition, these functions return nonzero.

If the integer does not satisfy the test condition, these functions return 0.

Example

CELEBI02

```
/* CELEBI02

   This example analyzes all characters between code 0x0 and
   code UPPER_LIMIT.
   The output of this example is a 256-line table showing the
   characters from 0 to 255, and a notification of whether they
   have the attributes tested.

 */
#include <stdio.h>
#include <ctype.h>

#define UPPER_LIMIT   0xFF

int main(void)
{
   int ch;

   for ( ch = 0; ch <= UPPER_LIMIT; ++ch )
   {
      printf("%3d ", ch);
      printf("%#04x ", ch);
      printf(" %c",  isprint(ch)  ? ch   : ' ');
      printf("%3s ", isalnum(ch)  ? "Alphanumeric" : " ");
      printf("%2s ", isalpha(ch)  ? "Alphabetic"  : " ");
      printf("%2s",  iscntrl(ch)  ? "Control"  : " ");
      printf("%2s",  isdigit(ch)  ? "Digit"  : " ");
      printf("%2s",  isgraph(ch)  ? "Graphic"  : " ");
      printf("%2s ",  islower(ch)  ? "Lower"  : " ");
      printf("%3s",  ispunct(ch)  ? "Punctuation" : " ");
      printf("%2s",  isspace(ch)  ? "Space"  : " ");
      printf("%3s",  isprint(ch)  ? "Printable" : " ");
      printf("%2s ",  isupper(ch)  ? "Upper"  : " ");
      printf("%2s ",  isxdigit(ch) ? "Hex"  : " ");

      putchar('\n');
   }
}
```

isalpha() — Test for an alphabetic character

The information for this function is included in “isalnum() to isxdigit() — Test integer value” on page 895.

isascii() — Test for 7-bit US-ASCII character

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

_XOPEN_SOURCE:

```
#define _XOPEN_SOURCE
#include <ctype.h>

int isascii(int c);
```

_ALL_SOURCE:

```
#define _ALL_SOURCE
#include <ctype.h>

int isascii(int c);
```

General description

Special behavior for _XOPEN_SOURCE: The isascii() function tests whether c is a 7-bit US-ASCII character code. The isascii() function is defined on all integer values.

Special behavior for _ALL_SOURCE: The isascii() function tests whether the character with EBCDIC encoding *c* in the current locale is a member of the set of POSIX Portable Characters and POSIX Control Characters shown below.

Returned value

Special behavior for _XOPEN_SOURCE: isascii() returns nonzero if *c* is a 7-bit US-ASCII character code between 0 and hexadecimal 007F inclusive; otherwise it returns 0.

Special behavior for _ALL_SOURCE: isascii() returns nonzero if *c* is the EBCDIC encoding in the current locale for a character in the set of POSIX Portable Characters and Control Characters; otherwise it returns 0.

Following is a list of the symbolic names, IBM-1047 EBCDIC code page encoding, and ISO8859-1 ASCII encoding for the set of POSIX Portable Characters and POSIX Control Characters. Cases where EBCDIC character encoding varies across EBCDIC Country Extended Code Pages (CECPs) are noted.

isastream() — Test a file descriptor

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int isastream(int fildes);
```

General description

The isastream() function tests whether *filedes*, an open file descriptor, is associated with a STREAMS-based file.

Returned value

If successful, isastream() returns 1 if *fildes* refers to a STREAMS-based file and 0 if not.

If unsuccessful, isastream() returns -1 and sets errno to one of the following values.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for isastream() to return 1 since there are no STREAMS-based file descriptors. It will return 0 unless *fildes* is not a valid open file descriptor, in which case it will return -1 with errno set to indicate the failure. See “open() — Open a file” on page 1152

Error Code
Description

EBADF
The *fildes* argument is not a valid open file descriptor.

Related information

- “stropts.h” on page 72

isatty() — Test if descriptor represents a terminal

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int isatty(int fildes);
```

General description

Determines if a file descriptor, *fildes*, is associated with a terminal.

isatty() only works in an environment where either a controlling terminal exists, or stdin and stderr refer to tty devices. Specifically, it does not work in a TSO environment.

Returned value

isatty() returns 1 if the given file descriptor is a terminal, or 0 otherwise.

Special behavior for XPG4

isatty() returns 1 if the given file descriptor is a terminal, or 0 otherwise and sets errno to one of the following values:

Error Code
Description

EBADF
The *fildes* argument is not a valid open file descriptor.

ENOTTY
The *fildes* argument is not associated with a terminal.

Example

CELEBI03

```
/* CELEBI03

   This example determines if a file descriptor is
   associated with a terminal.

 */
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>

void check_fd(int fd) {
  printf("fd %d is ", fd);
  if (!isatty(fd))
    printf("NOT ");
  puts("a tty");
}

main() {
  int p[2], fd;
  char fn[]="temp.file";

  if (pipe(p) != 0)
    perror("pipe() error");
  else {
    if ((fd = creat(fn, S_IWUSR)) < 0)
      perror("creat() error");
    else {
      check_fd(0);
      check_fd(fileno(stderr));
      check_fd(p[1]);
      check_fd(fd);
      close(fd);
      unlink(fn);
    }
    close(p[0]);
    close(p[1]);
  }
}
```

Output

```
fd 0 is a tty
fd 2 is a tty
fd 4 is NOT a tty
fd 5 is NOT a tty
```

__isBFP() — Determine application floating-point format

Standards

Standards / Extensions	C or C++	Dependencies
	both	OS/390 V2R6

Format

```
#include <_Ieee754.h>

int __isBFP(void);
```

General description

The __isBFP() function determines the application floating-point mode.

Returned value

__isBFP() returns 1 if the floating-point mode of the caller is IEEE, and returns 0 if the floating-point mode of the caller is hexadecimal.

Related information

- "_Ieee754.h" on page 32
- "fp_read_rnd() — Determine rounding mode" on page 579

isblank() — Test for blank character classification

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <ctype.h>

int isblank(int c);
```

General description

Tests whether the current LC_CTYPE locale category assigns *c* the blank character attribute. The *tab* and *space* characters have the blank attribute in the POSIX locale (with name "POSIX" or "C").

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (for example, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Note: The isblank() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

isblank() returns nonzero if the current LC_CTYPE locale category assigns *c* the blank character attribute.

Otherwise, isblank() returns 0.

Example

```
/* This example tests if c is a blank type.  */
#include <stdio.h>
#include <ctype.h>
#include <locale.h>

void check(char c) {
  if ((c != ' ') && (isprint(c)))
    printf(" %c  is ", c);
  else
    printf("x%02x is ", c);
  if (!isblank(c))
```

```
    printf("not ");
  puts("a blank type character");
}

main() {
  printf("\nIn LC_CTYPE category of locale \ with name \"%s\":\n",
     setlocale(LC_CTYPE, NULL));
  check('a');
  check(' ');
  check(0x00);
  check('\n');
  check('\t');
}
```

Output:

```
In LC_CTYPE category of locale with name "......";
 a  is not a blank type character
x40 is a blank type character
x00 is not a blank type character
x15 is not a blank type character
x05 is a blank type character
```

iscics() — Verify whether CICS is running

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <cics.h>

int iscics(void);
```

General description

Determines whether the program is running under CICS.

Returned value

If your program is currently running under CICS, iscics() returns nonzero.

If not running under CICS, iscics() returns 0.

Example

CELEBI04

```
/* CELEBI04

   This example tests to see if the program is running under CICS.
   If not, it calls a subroutine ABCPGM; otherwise, it uses a CICS EXEC
   statement to invoke ABCPGM.
```

```
 */
#define _POSIX_SOURCE
#ifdef __cplusplus
  extern "OS" void ABCPGM(char *);
#else
  #pragma linkage(ABCPGM, OS)
  void ABCPGM(char *);
#endif

#include <stdio.h>
#include <cics.h>
#include <string.h>
#include <sys/wait.h>
#include <sys/types.h>
#include <unistd.h>

int main(void)
{
 char mydata[123];

 if (iscics() == 0)
    {
     /* not a CICS environment */
     ABCPGM(mydata);
    }

 else {
       /* this is a CICS environment */
       EXEC CICS, LINK PROGRAM,("ABCPGM  "), COMMAREA(mydata);
      }
}
```

The information for this function is included in "isalnum() to isxdigit() — Test integer value" on page 895.

isfinite() — Determines if its argument has a finite value

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int isfinite(real-floating x);
```

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

int isfinite(real-floating x);  /* C only */
int isfinite(decimal-floating x);  /*C only */
bool isfinite(real-floating x);  /* C++ only */

#define _TR1_C99
#include <math.h>

bool isfinite(real-floating x);  /* C++ only */
```

General description

The isfinite() macro or function template determines if its argument has a finite value.

Function	Hex	IEEE
isfinite	X	X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The isfinite() macro returns 1 if and only if its argument value is finite, else returns 0. The C++ function template returns true if and only if its argument value is finite, else returns false.

Special behavior in hex: The isfinite() macro always returns 1. The C++ function template always returns true.

bool isinf(real-floating x);  /* C++ only */

#define _TR1_C99
#include <math.h>

bool isinf(real-floating x);  /* C++ only */
```

General description

The isinf() macro or function template determines if its argument is plus or minus infinity.

Function	Hex	IEEE
isinf	X	X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The isinf() macro returns 1 if the argument is plus or minus infinity, else returns 0. The C++ function template returns true if the argument is plus or minus infinity, else returns false.

Special behavior in hex: The isinf() macro returns zero. The C++ function template returns false.

isless() — Determines if X is less than Y

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int isless(real-floating x, real-floating y);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isless(real-floating x, real-floating y);  /* C only */
int isless(decimal-floating x, decimal-floating y);  /* C only */
bool isless(real-floating x, real-floating y);  /* C++ only */
bool isless(decimal-floating x, decimal-floating y);  /* C++ only */

#define _TR1_C99
#include <math.h>

bool isless(real-floating x, real-floating y);  /* C++ only */
```

General description

The isless() macro or function template determines whether the argument *x* is less than *y*. It is equivalent to (*x*) < (*y*), but no exception is raised if *x* or *y* are NaN.

Function	Hex	IEEE
isless	X	X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The isless() macro returns 1 if the value of *x* is less than *y*, else returns 0. The C++ function template returns true if the value of x is less than y, else returns false.

islower() — Test for lowercase

The information for this function is included in "isalnum() to isxdigit() — Test integer value" on page 895.

ismccollel() — Identify a multicharacter collating element

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <collate.h>

int ismccollel(collel_t c);
```

General description

Determines whether a character is a multicharacter collating element. A collating element is a glyph, usually a character, that has a value used to define its order in a collating sequence. A multicharacter collating element is a sequence of two or more characters that are to be collated as one entity.

Returned value

ismccollel() returns:

1 if collel_t represents a multicharacter collating element

0 if collel_t represents a single-character collating element

-1 if collel_t is out of range, or otherwise not valid

Example

CELEBI05

```
/* CELEBI05

   This example prints all of the collating elements in the
   collating sequence, by using the &ismc. function to determine
   if the collating element is a multi-character collating
   element.

 */
#include <collate.h>
#include <locale.h>
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
   collel_t e, *rp;
   int i;

   setlocale(LC_ALL, "");
   i = collorder(&rp);
   for (; i-- > 0; rp++) {
      if (ismccollel(*rp))
         printf("'%s' ", colltostr(*rp));
      else if (iswprint(*rp))
         printf("'%lc' ", *rp);
      else
         printf("'%x' ", *rp);
   }
}
```

isnan() — Test for NaN

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8

Format

```
#define  _XOPEN_SOURCE
#include <math.h>

int isnan(double x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isnan(real-floating x);  /* C only */
int isnan(decimal-floating x);  /* C only */
bool isnan(real-floating x);  /* C++ only */
bool isnan(decimal-floating x);  /* C++ only */

#define _TR1_C99
#include <math.h>

bool isnan(double x);  /* C++ only */
```

General description

The isnan() function tests whether *x* is NaN (not a number).

isnan() is available as a macro. For better performance, the macro form is recommended over the functional form. For C compiles only, to use the functional form, do one of the following:

- Do not include math.h.
- Specify `#undef isnan` after the inclusion of math.h.
- Enclose the call statement in parentheses.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

For IEEE Decimal Floating Point numbers and Binary Floating Point numbers, a non-zero value is returned if x is a NAN. The C++ function template returns true if x is a NAN.

Special behavior in Hex

The isnan() macro returns zero. The C++ function template returns false.

Related information

- "math.h" on page 44

isnormal() — Determines if X is normal

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99	both	z/OS V1R8

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int isnormal(real-floating x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isnormal(real-floating x);  /* C only */
int isnormal(decimal-floating x);  /* C only */
bool isnormal(real-floating x);  /* C++ only */
bool isnormal(decimal-floating x);  /* C++ only */

#define _TR1_C99
#include <math.h>

bool isnormal(real-floating x);  /* C++ only */
```

General description

The isnormal() macro or function template determines if its argument value is normal, that is, not zero, infinity, subnormal or a NaN.

Function	Hex	IEEE
isnormal	X	X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The isnormal() macro returns 1 if the argument value is normal, else returns 0. The C++ template returns true if the argument value is normal, else returns false.

Special behavior in Hex: For normalized numbers, isnormal() returns one. For zero or an unnormalized number, isnormal() returns zero. The C++ function template for normalized numbers, isnormal() returns true. For zero or a number that is not normalized, isnormal() returns false.

Related information

__isPosixOn() — Test for POSIX runtime option

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <unistd.h>

int __isPosixOn(void);
```

General description

The __isPosixOn() function returns 1 if the kernel is active and the POSIX runtime option is in effect for the calling process.

Returned value

The __isPosixOn() function returns 1 if the POSIX runtime option is in effect for the calling process and returns 0 otherwise.

If POSIX is in effect, then the kernel is active, although the kernel may be active without POSIX being in effect.

There are no errno values defined.

#define _TR1_C99
#include <math.h>

bool isunordered(real-floating x, real-floating y);  /* C++ only */
```

General description

The isunordered() macro or function template determines if either *x* or *y* is unordered, that is if *x* or *y* is a NaN.

Function	Hex	IEEE
isunordered	X	X

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The isunordered() macro returns 1 if either *x* or *y* is unordered, else returns 0. The C++ function template returns true if either x or y is unordered, else returns false.

Special behavior in hex: The isunordered() macro always returns 0. The C++ function template always returns false.

isupper() — Test for uppercase letter classification

The information for this function is included in “isalnum() to isxdigit() — Test integer value” on page 895.

iswalnum() to iswxdigit() — Test wide integer value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <wctype.h>

int iswalnum(wint_t wc);
int iswalpha(wint_t wc);
int iswcntrl(wint_t wc);
int iswdigit(wint_t wc);
int iswgraph(wint_t wc);
int iswlower(wint_t wc);
int iswprint(wint_t wc);
int iswpunct(wint_t wc);
int iswspace(wint_t wc);
int iswupper(wint_t wc);
int iswxdigit(wint_t wc);
```

General description

The functions listed above, which are all declared in wctype.h, test a given wide integer value. These functions are sensitive to locale. For locale descriptions, see “Internationalization: Locales and Character Sets” in *z/OS XL C/C++ Programming Guide*. Here are descriptions of each function in this group.

iswalnum()
Test for a wide alphanumeric character, as defined in the `alnum` locale source file and in the `alnum` class of the LC_CTYPE category of the current locale.

iswalpha()
Test for a wide alphabetic character, as defined in the `alpha` locale source file and in the `alpha` class of the LC_CTYPE category of the current locale.

iswcntrl()
Test for a wide control character, as defined in the `cntrl` locale source file and in the `cntrl` class of the LC_CTYPE category of the current locale.

iswdigit()
Test for a wide decimal-digit character: 0 through 9, as defined in the `digit` locale source file and in the `digit` class of the LC_CTYPE category of the current locale.

iswgraph()
Test for a wide printing character, not a space. as defined in the `graph` locale source file and in the `graph` class of the LC_CTYPE category of the current locale.

iswlower()
Test for a wide lowercase letter, as defined in the `lower` locale source file and in the `lower` class of the LC_CTYPE category of the current locale.

iswprint()
Test for any wide printing character, as defined in the `print` locale source file and in the `print` class of the LC_CTYPE category of the current locale.

iswpunct()
Test for a wide nonalphanumeric, nonspace character, as defined in the `punct` locale source file and in the `punct` class of the LC_CTYPE category of the current locale.

iswspace()
Test for a wide white space character, as defined in the `space` locale source file and in the `space` class of the LC_CTYPE category of the current locale.

iswupper()
Test for a wide uppercase letter, as defined in the `upper` locale source file and in the `upper` class of the LC_CTYPE category of the current locale.

iswxdigit()
Test for a wide hexadecimal digit 0 through 9, a through f, or A through F, as defined in the `xdigit` locale source file and in the `xdigit` class of the LC_CTYPE category of the current locale.

The behavior of these wide-character function are affected by the LC_CTYPE category of the current locale. The space, uppercase, and lowercase characters can be redefined by their respective class of the LC_CTYPE in the current locale. If you change the category, undefined results can occur.

Returned value

If the wide integer satisfies the test value, these functions return nonzero.

If the wide integer does not satisfy the test value, these functions return 0.

The value for *wc* must be representable as a wide unsigned character. WEOF is a valid input value.

Example

CELEBI06

```
/* CELEBI06

 This example tests for various wide integer values and prints a result.

 */
#include <stdio.h>
#include <wctype.h>

int main(void)
{
   wint_t wc;

   for (wc=0; wc <= 0xFF; wc++) {
      printf("%3d", wc);
      printf(" %#4x ", wc);
      printf("%3s", iswalnum(wc)  ? "AN" : " ");
      printf("%2s", iswalpha(wc)  ? "A"  : " ");
      printf("%2s", iswcntrl(wc)  ? "C"  : " ");
      printf("%2s", iswdigit(wc)  ? "D"  : " ");
      printf("%2s", iswgraph(wc)  ? "G"  : " ");
      printf("%2s", iswlower(wc)  ? "L"  : " ");
      printf(" %c", iswprint(wc)  ? wc   : ' ');
      printf("%3s", iswpunct(wc)  ? "PU" : " ");
      printf("%2s", iswspace(wc)  ? "S"  : " ");
      printf("%3s", iswprint(wc)  ? "PR" : " ");
      printf("%2s", iswupper(wc)  ? "U"  : " ");
      printf("%2s", iswxdigit(wc) ? "X"  : " ");

      putchar('\n');
   }
}
```

Related information

iswblank() — Test for blank character classification

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <wctype.h>

int iswblank(wint_t wc);
```

C99:

```
#define _ISOC99_SOURCE
#include <wctype.h>

int iswblank(wint_t wc);
```

General description

Tests for a wide blank character.

The space, uppercase, and lowercase characters can be redefined by their respective classes of the LC_CTYPE in the current locale.

For use as a C library function: To avoid infringing on the user's name space, this nonstandard function has two names. One name, __iswblk(), and the other as shown above. The name shown above is exposed only when you use the compiler option LANGLVL(EXTENDED) or define the _EXT feature test macro.

For use as a z/OS UNIX function: Define the _OPEN_SYS feature test macro.

Note: The iswblank() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2113 for details.

Returned value

If the wide integer satisfies the test value, iswblank() returns nonzero.

If the wide integer does not satisfy the test value, iswblank() returns 0.

The value for *wc* must be representable as a wide unsigned char. WEOF is a valid input value.

The behavior of iswblank() is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Related information

- "wctype.h" on page 86
- "isblank() — Test for blank character classification" on page 905
- "iswalnum() to iswxdigit() — Test wide integer value" on page 920

iswcntrl() — Test for control classification

The information for this function is included in "iswalnum() to iswxdigit() — Test wide integer value" on page 920.

iswctype() — Test for character property

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <wctype.h>

int iswctype(wint_t wc, wctype_t wc_prop);
```

General description

Determines whether the wide character *wc* has the property *wc_prop*. If the value of *wc* is neither WEOF nor any value of the wide character that corresponds to a multibyte character, the behavior is undefined. If the value of *wc_prop* is not valid (that is, not obtained by a previous call to wctype(), or *wc_prop* has been invalidated by a subsequent call to setlocale() that has affected category LC_CTYPE), the behavior is undefined.

These twelve strings are reserved for the standard (basic) character classes: alnum, alpha, blank, cntrl, digit, graph, lower, print, punct, space, upper, and xdigit.

The functions are shown below with their equivalent isw*() function:

```
iswctype(wc, wctype("alnum"));  - iswalnum(wc);
iswctype(wc, wctype("alpha"));  - iswalpha(wc);
iswctype(wc, wctype("blank"));  - iswblank(wc);
iswctype(wc, wctype("cntrl"));  - iswcntrl(wc);
iswctype(wc, wctype("digit"));  - iswdigit(wc);
iswctype(wc, wctype("graph"));  - iswgraph(wc);
iswctype(wc, wctype("lower"));  - iswlower(wc);
iswctype(wc, wctype("print"));  - iswprint(wc);
iswctype(wc, wctype("punct"));  - iswpunct(wc);
iswctype(wc, wctype("space"));  - iswspace(wc);
iswctype(wc, wctype("upper"));  - iswupper(wc);
iswctype(wc, wctype("xdigit")); - iswxdigit(wc);
```

Returned value

iswctype() returns nonzero (true) if the wide character *wc* has the property *wc_prop*.

Example

CELEBI07

```
/* CELEBI07

   This example test various wide characters for certain properties and
   prints the result.

 */
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>

int main(void)
{
   int wc;

   for (wc=0; wc <= 0xFF; wc++) {
      printf("%3d", wc);
      printf(" %#4x ", wc);
      printf("%3s", iswctype(wc, wctype("alnum"))  ? "AN" : " ");
      printf("%2s", iswctype(wc, wctype("alpha"))  ? "A"  : " ");
      printf("%2s", iswctype(wc, wctype("cntrl"))  ? "C"  : " ");
      printf("%2s", iswctype(wc, wctype("digit"))  ? "D"  : " ");
      printf("%2s", iswctype(wc, wctype("graph"))  ? "G"  : " ");
      printf("%2s", iswctype(wc, wctype("lower"))  ? "L"  : " ");
      printf(" %c", iswctype(wc, wctype("print"))  ? wc   : ' ');
      printf("%3s", iswctype(wc, wctype("punct"))  ? "PU" : " ");
      printf("%2s", iswctype(wc, wctype("space"))  ? "S"  : " ");
      printf("%3s", iswctype(wc, wctype("print"))  ? "PR" : " ");
      printf("%2s", iswctype(wc, wctype("upper"))  ? "U"  : " ");
      printf("%2s", iswctype(wc, wctype("xdigit")) ? "X"  : " ");

      putchar('\n');
   }
}
```

isxdigit() — Test for hexadecimal-digit classification

The information for this function is included in “isalnum() to isxdigit() — Test integer value” on page 895.

itoa() — Convert int into a string

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R5

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * itoa(int n, char * buffer, int radix);
```

General description

The itoa() function coverts the integer n into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, itoa() produces the same result as the following statement:

```
(void) sprintf(buffer, "%d", n);
```

with buffer the returned character string. When the radix is OCTAL, itoa() formats integer n into an unsigned octal constant. When the radix is HEX, itoa() formats integer n into an unsigned hexadecimal constant. The hexadecimal value will include lower case abcdef, as necessary.

Returned value

String pointer (same as buffer) will be returned. When passed a non-valid radix argument, function will return NULL and set errno to EINVAL.

Portability considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Example

CELEBI12

```
/* CELEBI12

   This example reads an int and formats it to decimal, unsigned
   octal, and unsigned hexadecimal constants converted to a
   character string.

*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
   int i;
   char buffer [sizeof(int)*8+1];
   printf ("Enter a number: ");
   if (scanf ("%d",&i) == 1) {
      itoa (i,buffer,DECIMAL);
      printf ("decimal: %s\n",buffer);
      itoa (i,buffer,HEX);
      printf ("hexadecimal: %s\n",buffer);
      itoa (i,buffer,OCTAL);
      printf ("octal: %s\n",buffer);
   }
   return 0;
}
```

Output

If the input is 1234, then the output should be:

```
decimal: 1234
hexadecimal: 4d2

JoinWorkUnit() — Join a WLM work unit

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

int JoinWorkUnit(wlmetok_t *enclavetoken);
```

General description

The JoinWorkUnit function provides the ability for an application to join a WLM work unit.

******enclavetoken*
: Points to a work unit enclave token that was returned from a call to either CreateWorkUnit() or ContinueWorkUnit().

Returned value

If successful, JoinWorkUnit() returns 0.

If unsuccessful, JoinWorkUnit() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
An argument of this function contained an address that was not accessible to the caller.

EINVAL
An argument of this function contained an incorrect value.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM join enclave failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

jrand48() — Pseudo-random number generator

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

long int jrand48(unsigned short int x16v[3]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The jrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

```
X(n+1) = (aX(n) + c)mod(2**48)     n>=0
```

The jrand48() function uses storage provided by the argument array, *x16v*[3], to save the most recent 48-bit integer value in the sequence, X(i). The jrand48() function uses *x16v*[0] for the low-order (rightmost) 16 bits, *x16v*[1] for the middle-order 16 bits, and *x16v*[2] for the high-order 16 bits of this value.

The initial values of a, and c are:

```
a   = 5deece66d (base 16)
c   = b         (base 16)
```

The values a and c, may be changed by calling the lcong48() function. The initial values of a and c are restored if either the seed48() or srand48() function is called.

Special behavior for z/OS UNIX Services: You can make the jrand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested and the jrand48() function is called from thread t, the jrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread according to the linear congruential formula:

```
X(t,n+1) = (a(t)X(t,n) + c(t))mod(2**48)     n>=0
```

The jrand48() function uses storage provided by the argument array, *x16v*[3], to save the most recent 48-bit integer value in the sequence, X(t,i). The jrand48() function uses *x16v*[0] for the low-order (rightmost) 16 bits, *x16v*[1] for the middle-order 16 bits, and *x16v*[2] for the high-order 16 bits of this value.

The initial values of a(t) and c(t) on the thread t are:

```
a(t)   = 5deece66d (base 16)
c(t)   = b         (base 16)
```

The values a(t) and c(t) may be changed by calling the lcong48() function from the thread t. The initial values of a(t) and c(t) are restored if either the seed48() or srand48() function is called from the thread.

Returned value

jrand48() saves the generated 48-bit value, X(n+1), in storage provided by the argument array, *x16v*[3]. jrand48() transforms the generated 48-bit value to a signed long integer value on the interval [-2**31,2**31) and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the drand48 family and the jrand48() function is called on thread t, the jrand48() function saves the generated 48-bit value, X(t,n+1), in storage provided by the argument array, *x16v*[3]. The jrand48() function transforms the generated 48-bit value to a signed long integer value on the interval [-2**31,2**31) and returns this transformed value.

j0(), j1(), jn() — Bessel functions of the first kind

Standards

Standards / Extensions	C or C++	Dependencies
SAA XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#include <math.h>

double j0(double x);

double j1(double x);

double jn(int n, double x);
```

Compiler option: LANGLVL(SAA), LANGLVL(SAAL2), or LANGLVL(EXTENDED)

General description

The j0(), j1(), and jn() functions are Bessel functions of the *first kind*, for orders 0, 1, and *n*, respectively. Bessel functions are solutions to certain types of differential equations. The argument *x* must be positive. The argument *n* should be greater than or equal to 0. If *n* is less than 0, there will be a negative exponent in the result.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

If successful, the calculated value is returned.

For j0(), j1(), y0(), or y1(), if the absolute value of *x* is too large, the function sets errno to ERANGE to indicate a value that is out of range, and returns 0.

Special behavior for IEEE: If *x* is negative, y0(), y1(), and yn() return the value NaNQ. If *x* is 0, y0(), y1(), and yn() return the value -HUGE_VAL. In all cases, errno remains unchanged.

Example

CELEBJ01

```
/* CELEBJ01

   This example computes y to be the order 0 Bessel function of
   the first kind for x, and z to be the order 3 Bessel function
   of the second kind for x.

 */
#include <math.h>
#include <stdio.h>
```

```
int main(void)
{
   double x, y, z;
   x = 4.27;

   y = j0(x);      /* y = -0.3660 is the order 0 bessel */
                    /* function of the first kind for x  */
   z = yn(3,x);    /* z = -0.0875 is the order 3 bessel */
                    /* function of the second kind for x */
   printf("x = %f\n  y = %f\n  z = %f\n", x, y, z);
}
```

kill() — Send a signal to a process

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int kill(pid_t pid, int sig);
```

General description

Sends a signal to a process or process group. A process has permission to send a signal if the real or effective user ID of the sender is the same as the real or effective user ID of the intended recipient. A process can also send signals if it has appropriate privileges. If _POSIX_SAVED_IDS is defined in the unistd.h header file, the saved set user ID of the intended recipient is checked instead of its effective user ID.

Regardless of user ID, a process can always send a SIGCONT signal to a process that is a member of the same session (same session ID) as the sender.

You can use either signal() or sigaction() to specify how a signal will be handled when kill() is invoked.

A process can use kill() to send a signal to itself. If the signal is not blocked or ignored, at least one pending unblocked signal is delivered to the sender before kill() returns. If there are no other pending unblocked signals, the delivered signal is *sig*.

pid can be used to specify these processes:

pid_t *pid*;
Specifies the processes that the caller wants to send a signal to:

- If *pid* is greater than 0, kill() sends its signal to the process whose ID is equal to *pid*.
- If *pid* is equal to 0, kill() sends its signal to all processes whose process group ID is equal to that of the sender, except for those that the sender does not have appropriate privileges to send a signal to.
- If *pid* is -1, kill() returns -1.
- **Special behavior for XPG4.2:** If *pid* is -1, kill() sends the signal, *sig*, to all processes, except for those to which the sender does not have appropriate privileges to send a signal.
- If *pid* is less than -1, kill() sends its signal to all processes whose process group ID is equal to the absolute value of *pid*, except for those that the sender does not have appropriate privileges to send a signal to.

int *sig*;
The signal that should be sent to the processes specified by *pid*. (For a list of signals, see Table 48 on page 1612.) This must be 0 or one of the signals defined in the signal.h header file. If *sig* is 0, kill() performs error checking but does not send a signal. You can code *sig* as 0 to check whether the *pid* argument is valid.

This function is supported only in a POSIX program. You can use it to pass SIGIOERR.

Usage notes

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Returned value

kill() returns 0 if it has permission to send *sig* to any of the processes specified by *pid*.

If kill() fails to send a signal, it returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The value of *sig* is incorrect or is not the number of a supported signal.

EPERM
The caller does not have permission to send the signal to any process specified by *pid*.

ESRCH
There are no processes or process groups corresponding to *pid*.

Example

CELEBK01

```
/* CELEBK01 */
#define _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>
#include <sys/types.h>
```

```
#include <unistd.h>
#include <sys/wait.h> /*FIX: used to be <wait.h>*/

main() {
  sigset_t sigset;
  int    p[2], status;
  char   c='z';
  pid_t  pid;

  if (pipe(p) != 0)
    perror("pipe() error");
  else {
    if ((pid = fork()) == 0) {
      sigemptyset(&sigset);
      puts("child is letting parent know he's ready for signal");
      write(p[1], &c, 1);
      puts("child is waiting for signal");
      sigsuspend(&sigset);
      exit(0);
    }

    puts("parent is waiting for child to say he's ready for signal");
    read(p[0], &c, 1);
    puts("child has told parent he's ready for signal");

    kill(pid, SIGTERM);

    wait(&status);
    if (WIFSIGNALED(status))
      if (WTERMSIG(status) == SIGTERM)
        puts("child was ended with a SIGTERM");
      else
        printf("child was ended with a %d signal\n", WTERMSIG(status));
    else puts("child was not ended with a signal");

    close(p[0]);
    close(p[1]);
  }
}
```

Output

```
parent is waiting for child to say he's ready for signal
child is letting parent know he's ready for signal
child is waiting for signal
child has told parent he's ready for signal
child was ended with a SIGTERM
```

killpg() — Send a signal to a process group

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int killpg(pid_t pgrp, int sig);
```

General description

The killpg() function sends a signal to a process group.

A process has permission to send a signal if the real or effective user ID of the sender is the same as the real or effective user ID of the intended recipient. A process can also send signals if it has appropriate privileges. If _POSIX_SAVED_IDS is defined in the <unistd.h> include file, the saved set user ID of the intended recipient is checked instead of its effective user ID.

Regardless of user ID, a process can always send a SIGCONT signal to a process group that is a member of the same session (same session ID) as the sender.

pid_t *pgrp*;
Specifies the process group that the caller wants to send a signal to:

- If *pgrp* is greater than one, killpg() sends the signal, *sig*, to the process whose process group ID is equal to *pgrp* and which the sender has appropriate privileges to send a signal.
- If *pgrp* is equal to or less than one, killpg() returns a -1 and sets errno to EINVAL.

int *sig*;
The signal that should be sent to the processes specified by *pid*. (For a list of signals, see Table 48 on page 1612.) This must be zero, or one of the signals defined in the <signal.h> include file. If *sig* is zero, killpg() performs error checking but doesn't really send a signal. You can code *sig* as zero to check whether the *pid* argument is valid.

This function is supported only in a POSIX program.

Usage notes

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, killpg() returns 0 if it has permission to send *sig* to any of the processes in the process group ID specified by *pgrp*.

If unsuccessful, killpg() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The value of *sig* is incorrect or is not the number of a supported signal, or the value of *pgrp* is less than or equal to one.

EPERM
The caller does not have permission to send the signal to any process in the process group ID specified by *pgrp*.

ESRCH
There are no process groups corresponding to *pgrp*.

labs() — Calculate long absolute value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

long int labs(long int n);
```

General description

Calculates the absolute value of its long integer argument *n*. The result is undefined when the argument is equal to LONG_MIN, the smallest available long integer (-2 147 483 648). The value LONG_MIN is defined in the limits.h header file.

Returned value

Returns the absolute value of the long integer argument *n*.

Example

CELEBL01

```
/* CELEBL01

   This example computes y as the absolute value of
   the long integer -41567.

 */
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
   long x, y;

   x = -41567L;
   y = labs(x);

   printf("The absolute value of %ld is %ld\n", x, y);
}
```

Output

```
The absolute value of -41567 is 41567
```

Related information

- "stdlib.h" on page 70

__lchattr() — Change the attributes of a file or directory when they point to a symbolic or external link

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R5

Format

```
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __lchattr (char *pathname, attrib_t *attributes, int attributes_len);
```

General description

The __lchattr() function modifies the attributes that are associated with a file. The pathname specifies a symbolic or external link (a pointer to another file, directory, or data set).

The __lchattr() service changes the attributes of the symbolic link itself, provided the attributes requested can apply to a symbolic link. Only the owner and security label can be changed for a symbolic link, all other attributes do not apply and will be ignored.

The attributes argument is the address of an attrib_t structure which is used to identify the attributes to be modified and the new values desired. The attrib_t type is an f_attributes structure as defined in <sys/stat.h> for use with the __lchattr() function. For proper behavior, the user should ensure that this structure has been initialized to zeros before it is populated. The f_attributes structure is defined as indicated in Table 20 on page 261.

Returned value

If successful, __lchattr() returns 0.

If unsuccessful, __lchattr() returns -1 and sets errno to one of the following values:

EACCES
The calling process did not have appropriate permissions. Possible reasons include:

- The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.
- The calling process was attempting to truncate the file, and it does not have write permission for the file.

EFBIG
The calling process was attempting to change the size of a file, but the specified length is greater than the maximum file size limit for the process.

EINVAL
The attributes structure containing the requested changes is not valid.

ELOOP
A loop exists in symbolic links that were encountered during resolution of the pathname argument. This error is issued if more than 24 symbolic links are detected in the resolution of pathname.

ENAMETOOLONG
pathname is longer than 1023 characters, or a component of the pathname is longer than 255 characters (Filename truncation is not supported).

ENOENT
No file named pathname was found.

ENOTDIR
Some component of pathname is not a directory.

EPERM
The operation is not permitted for one of the following reasons:

- The calling process was attempting to change the mode or the file format, but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the owner, but it does not have appropriate privileges.
- The calling process was attempting to change the general attribute bits, but it does not have write permission for the file.
- The calling process was attempting to set a time value (not current time), but the effective user ID does not match the owner of the file, and it does not have appropriate privileges.

- The calling process was attempting to set the change time or reference time to current time, but it does not have write permission for the file.
- The calling process was attempting to change auditing flags, but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the Security Auditor's auditing flags, but the user does not have auditor authority.
- Attributes indicate that the security label is to be set, and one or more of the following conditions applies:
  - The calling process does not have RACF SPECIAL authorization and appropriate privileges.
  - The security label currently associated with the file is already set.

EROFS
pathname specifies a file that is on a read-only file system.

Related information

- "sys/stat.h" on page 75
- "__fchattr() — Change the attributes of a file or directory by file descriptor" on page 465
- "__chattr() — Change the attributes of a file or directory" on page 261

lchown() — Change owner and group of a file

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int lchown(const char *path, uid_t owner, gid_t group);
```

General description

The lchown() function has the same effect as chown() except in the case where the named file is a symbolic link. In this case lchown() changes the ownership of the symbolic link file itself, while chown() changes the ownership of the file or directory to which the symbolic link refers.

Returned value

If successful, lchown() returns 0.

If unsuccessful, lchown() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
Search permission is denied on a component of the path prefix of path.

EINVAL
The owner or group id is not a value supported by the implementation.

ELOOP
Too many symbolic links were encountered in resolving *path*

ENAMETOOLONG
The length of a pathname exceeds **PATH_MAX** or a pathname component is longer than **NAME_MAX**.

ENOENT
A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR
A component of the path prefix of *path* is not a directory.

EOPNOTSUPP
The *path* argument names a symbolic link and the implementation does not support setting the owner or group of a symbolic link.

EPERM
The effective user ID does not match the owner of the file and the process does not have appropriate privileges.

EROFS
The file resides on a read-only file system.

The lchown() function may fail if:

Error Code
Description

EINTR
A signal was caught during execution of the function.

EIO An I/O error occurred while reading or writing to the file system.

ENAMETOOLONG
Pathname resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.

lcong48() — Pseudo-random number initializer

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

void lcong48(unsigned short int param[7]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The lcong48(), seed48(), and srand48() functions are initialization functions, one of which should be invoked before either the drand48(), lrand48() or mrand48() function is called.

The drand48(), lrand48() and mrand48() functions generate a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

```
X(n+1) = (aX(n) + c)mod(2**48)     n>=0
```

The initial values of X, a, and c are:

```
X(0)= 1
a   = 5deece66d (base 16)
c   = b         (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The lcong48() function is used to reinitialize the most recent 48-bit value in this storage. The lcong48() function replaces the low-order (rightmost) 16 bits of this storage with *param*[0], the middle-order 16 bits with *param*[1], and the high-order 16 bits with *param*[2].

The values a and c, may also be changed by calling the lcong48() function. The lcong48() function replaces the low-order (rightmost) 16 bits of a with *param*[3], the middle-order 16 bits with *param*[4], and the high-order 16 bits with *param*[5]. The lcong48() function replaces c with *param*[6].

Special behavior for z/OS UNIX Services: You can make the lcong48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, calls to the drand48(), lrand48() and mrand48() functions from thread t generate a sequence of 48-bit integer values, X(t,i), according to the linear congruential formula:

```
X(t,n+1) = (a(t)X(t,n) + c(t))mod(2**48)     n>=0
```

C/370 provides thread-specific storage to save the most recent 48-bit integer value of the sequence, X(t,i). When the lcong48() function is called from thread t, it reinitializes the most recent 48-bit value in this storage. The lcong48() function replaces the low-order (rightmost) 16 bits of this storage with *param*[0], the middle-order 16 bits with *param*[1], and the high-order 16 bits with *param*[2].

The lcong48() function may also be used to change values of a(t) and c(t) for the thread t. The lcong48() function replaces the low-order (rightmost) 16 bits of a(t) with *param*[3], the middle-order 16 bits with *param*[4], and the high-order 16 bits with *param*[5]. The lcong48() function replaces c(t) with *param*[6].

Returned value

After lcong48() has used values from the argument array, *param*[7], to change the values of a and c and to reinitialized storage for the most recent 48-bit integer value in the sequence, X(i), it returns.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the drand48 family and lcong48() is called on thread t, it uses the argument array, *param*[7], to change the values of a(t) and c(t) and to reinitialize storage for the most recent 48-bit integer value in the sequence, X(t,i), for the thread. Then it returns.

ldexp(), ldexpf(), ldexpl() — Multiply by a power of two

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double ldexp(double x, int exp);
float ldexp(float x, int exp);               /* C++ only */
long double ldexp(long double x, int exp);   /* C++ only */
float ldexpf(float x, int exp);
long double ldexpl(long double x, int exp);
```

General description

Calculates the value of $x*(2^{exp})$.

Restriction: The ldexpf() and ldexpl() functions do not support the _FP_MODE_VARIABLE feature test macro.

Returned value

Returns the calculated value.

Otherwise, if the correct calculated value is outside the range of representable values, ±HUGE_VAL is returned, according to the sign of the value. The value ERANGE is stored in errno to indicate that the result was out of range.

Special behavior for XPG4.2:

Error Code
Description

ERANGE
The result underflowed. ldexp() returns 0.0.

Example

CELEBL02

```
/* CELEBL02

   This example computes  y = 1.5*&lpar.2**5&rpar.

 */
#include <math.h>
#include <stdio.h>

int main(void)
{
   double x, y;
   int p;

   x = 1.5;
   p = 5;
   y = ldexp(x,p);

   printf("%lf times 2 to the power of %d is %Lf\n", x, p, y);
}
```

Output

```
1.500000 times 2 to the power of 5 is 48.000000
```

Related information

- “modf(), modff(), modfl() — Extract fractional and integral parts of floating-point value” on page 1086

ldexpd32(), ldexpd64(), ldexpd128() — Multiply by a power of ten

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  ldexpd32(_Decimal32 x, int exp);
_Decimal64  ldexpd64(_Decimal64 x, int exp);
_Decimal128 ldexpd128(_Decimal128 x, int exp);
```

```
_Decimal32  ldexp(_Decimal32 x, int exp);   /* C++ only */
_Decimal64  ldexp(_Decimal64 x, int exp);   /* C++ only */
_Decimal128 ldexp(_Decimal128 x, int exp);  /* C++ only */
```

General description

Calculates the value of $x*10^{exp}$.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the calculated value.

Otherwise, if the correct calculated value is outside the range of representable values, ±HUGE_VAL_D32, ±HUGE_VAL_D64, or ±HUGE_VAL_D128 is returned, according to the sign of the value. The value ERANGE is stored in errno to indicate that the result was out of range.

Example

```
/* CELEBL19

   This example illustrates the ldexpd32() function.

   This example computes  y = 1.5*10**5

*/

#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
  _Decimal32 x, y;
  int p;

  x = 1.5DF;
  p = 5;
  y = ldexpd32(x, p);

  printf("%Hf times 10 to the power of %d is %Hf\n", x, p, y);
}
```

ldiv() — Compute quotient and remainder of integral division

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

ldiv_t ldiv(long int numerator, long int denominator);
```

General description

Calculates the quotient and remainder of the division of *numerator* by *denominator*.

Returned value

Returns a structure of type `ldiv_t`, containing both the quotient `long int quot` and the remainder `long int rem`.

If the value cannot be represented, the returned value is undefined. If *denominator* is 0, a divide by 0 exception is raised.

Example

CELEBL03

```
/* CELEBL03

   This example uses the &ldiv. function to calculate the
   quotients and remainders for a set of two dividends and two
   divisors.

 */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
   long int num[2] = {45,-45};
   long int den[2] = {7,-7};
   ldiv_t ans;   /* ldiv_t is a struct type containing two long ints:
                    'quot' stores quotient; 'rem' stores remainder */
   short i,j;

   printf("Results of long division:\n");
   for (i = 0; i < 2; i++)
      for (j = 0; j < 2; j++)
      {
         ans = ldiv(num[i], den[j]);
         printf("Dividend: %6ld  Divisor: %6ld", num[i], den[j]);
         printf("  Quotient: %6ld  Remainder: %6ld\n", ans.quot, ans.rem);
      }
}
```

Output

```
Results of long division:
Dividend:  45  Divisor:   7  Quotient:   6  Remainder:   3
Dividend:  45  Divisor:  -7  Quotient:  -6  Remainder:   3
Dividend: -45  Divisor:   7  Quotient:  -6  Remainder:  -3
Dividend: -45  Divisor:  -7  Quotient:   6  Remainder:  -3
```

LeaveWorkUnit() — Leave a WLM work unit

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#include <sys/__wlm.h>

int LeaveWorkUnit(wlmetok_t *enclavetoken);
```

General description

The LeaveWorkUnit() function provides the ability for an application to leave a WLM work unit.

**enclavetoken*
Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().

Returned value

If successful, LeaveWorkUnit() returns 0.

If unsuccessful, LeaveWorkUnit() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
An argument of this function contained an address that was not accessible to the caller.

EINVAL
An argument of this function contained an incorrect value.

EMVSSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM leave enclave failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be

permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

__le_ceegtjs() — Retrieve the value of an exported JCL symbol

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

void __le_ceegtjs(_INT4 * function_code,
                  _VSTRING * symbol_name,
                  _CHAR255 * symbol_value,
                  _INT4 * value_length,
                  _FEEDBACK * fc);
```

General description

The __le_ceegtjs() function retrieves and returns to the caller the symbol value and length of the requested exported JCL symbol.

Parameter
Description

function_code
A fullword integer containing the function code of the following value:

1 Retrieve the value and its associate length of an exported JCL symbol.

symbol_name
A halfword length-prefixed character string(VSTRING), representing the name of an exported JCL symbol to be retrieved.

symbol_value
A 255-byte fixed-length string. On return from this service, the *symbol_value* contains the value of the exported JCL symbol. If the length of the exported JCL symbol is shorter than 255 characters, the returned string is padded with blanks.

value_length
A fullword integer containing the length of the value of the specified JCL symbol.

fc A 16-byte Feedback Code indicating the results of this function.

Table 34. Feedback Codes for __le_ceegtjs()

Code	Severity	Message Number	Message Text
CEE000	0	- -	The function completed successfully.
CEE3L9	0	3753	The input symbol cannot be found in the current job step.
CEE3LA	3	3754	Incorrect parameters detected.
CEE3QS	1	3932	The system service failed with return code *return_code* and reason code *reason_code*.

Usage notes

1. Lower case characters in the *symbol_name* will be converted to upper case by the __le_ceegtjs function.
2. For more information about JCL symbols and their usage, see "Using System Symbols and JCL symbols" in *z/OS MVS JCL Reference*.

Example

CELEBL31

```
/* CELEBL31

   This example retrieves the value of an exported JCL symbol.

*/
#include <stdio.h>
#include <string.h>
#include <__le_api.h>

int main()
{
   _FEEDBACK fc;
   _INT4 funcode;
   _CHAR255 symvalue;
   _VSTRING symname;
   _INT4 valuelen;
   char *symbol="SYM1";

   /* Setting the function code */
   funcode=1;

   /* Preparing the JCL symbol name */
   symname.length=strlen(symbol);
   memcpy(symname.string, symbol,strlen(symbol));

   /* Retrieving the value of the JCL symbol */
   __le_ceegtjs(&funcode,&symname,symvalue,&valuelen,&fc);
   if( fc.tok_sev > 0) {
      printf("__le_ceegtjs failed with message number %d\n",
             fc.tok_msgno);
      exit(1);
   }
   symvalue[valuelen]='\0';
   printf("The value of JCL symbol %s is %s. The length
          of the value is %d\n",symbol,symvalue,valuelen);
}
```

Output

Use the following JCL to run CELEBL31:

```
//JOB1     JOB    FELE,MSGLEVEL=(2,0)
//STEP1    EXEC   PGM=CELEBL31
//E1       EXPORT SYMLIST=(SYM1,SYM2,SYM3)
//S1       SET    SYM1=XXXX
//S2       SET    SYM2=YYYY
//STEPLIB  DD     DSN=USER.LOADLIB,DISP=SHR
//SYSPRINT DD     SYSOUT=*
//SYSOUT   DD     SYSOUT=*
```

Running this example would produce the following output:

```
The value of JCL symbol SYM1 is XXXX. The length of the value is 4.
```

__le_cib_get() — Get condition information block

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

struct cib  *__le_cib_get(void);
```

General description

Returns the Condition Information Block (CIB) structure associated with the current signal.

Notes:

1. This function is valid when called while a Language Environment exception handler is running.
2. This function is valid when called while a POSIX(OFF) signal catcher is running.
3. This function is valid when called while a POSIX(ON) signal catcher is running, if the signal is generated and caught immediately to the same thread. __le_cib_get() will fail if called from POSIX(ON) signal catchers that are driven as a result of signals generated by another thread or process. It may also fail when called from a catcher, if the caught signal is from the same thread but was delayed by blocking or by other signals being delivered at the same time.

Returned value

If there is an active condition the returned value is a pointer to the currently active CIB. If there is more than one active condition, the returned CIB will be for the most recent (most deeply nested) condition.

NULL is returned there is no active CIB, and the errno will be set to EMVSERR.

Error Code
Description

EMVSERR
No active CIB is available.

__le_condition_token_build() — Build a Language Environment condition token

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

void  *__le_condition_token_build(_INT2 * c_1, _INT2 * c_2,
                                  _INT2 * format, _INT2 * severity,
                                  _INT2 * control, _CHAR3 facility_ID,
                                  _INT4 * i_s_info,
                                  _FEEDBACK * cond_token,
                                  _FEEDBACK * fc);
```

General description

Dynamically constructs a 16–byte Language Environment condition token. The condition token is only to be used to retrieve messages from a Language Environment message file.

Parameter
Description

c_1 *c_1* is a 2–byte binary integer representing the value of the first 2 bytes of the 4–byte condition_ID. *c_1* and *c_2* make up the condition_ID portion of the condition token.

c_2 *c_2* is a 2–byte binary integer representing the value of the second 2 bytes of the 4–byte condition_ID.

For format 1, this is the Msg_No; for format 2, the cause_code.

format A 2–byte binary integer defining the format of the condition_ID portion of the token.

severity
A 2–byte binary integer indicating the condition's severity. In both format 1 and 2 conditions, this field is used to test the condition's severity. For format 1 conditions, the value of this field is the same as the severity value specified in the condition_ID.

Possible *severity* Values:

0 = Information only, if entire token is 0 there is no information.
1 = Warning
2 = Error
3 = Severe Error
4 = Critical Error

control A 2–byte binary integer containing flags describing or controlling various aspects of condition handling. Valid values for the control field are 1 and 0. 1 indicates the *facility_ID* assigned by IBM, 0 indicates the *facility_ID* assigned by the user.

facility_ID
A 3 character field containing three alphanumeric characters (A-Z, a-z, and 0-9) identifying the product or component of a product generating this condition or feedback information, for example, CEE.

The *facility_ID* is associated with the repository of the runtime messages. If a unique ID is required (for IBM and non-IBM products), an ID can be obtained by contacting an IBM project office.

If you creat a new *facility_ID* to use with a message table, created using the CEEBLDTX utility, be aware that the *facility_ID* must be part of the Language Environment message table name. For more information about the CEEBLDTX utility, see *z/OS Language Environment Programming Guide*. It is important to follow the naming guidelines below in order to have a module name that does not cause your application to abend.

First, begin a non-IBM assigned product *facility_ID* with letters J through Z. (See the *control* parameter above to indicate whether the *facility_ID* has been assigned by IBM.) Secondly, special characters, including blank spaces, cannot be used in a *facility_ID*. Lastly, there are no other constraints (besides the alphanumeric requirement) on a non-IBM assigned *facility_ID*.

i_s_info
A fullword binary integer identifying the ISI, that contains insert data.

cond_token
A 16–byte representation of the constructed condition token.

fc A 16–byte Feedback Code indicating the results of this function.

Table 35. Feedback Codes for __le_condition_token_build()

Code	Severity	Message Number	Message Text
CEE000	0	- -	The function completed successfully.
CEE0CH	3	401	A non-valid case code *case-code* was passed to routine *routine-name*.
CEE0CI	3	402	A non-valid control code *control-code* was passed to routine *routine-name*.
CEE0CJ	3	403	A non-valid severity code *severity-code* was passed to routine *routine-name*.
CEE0CK	3	404	Facility ID, *facility-id*, with non-alphanumeric characters was passed to routine *routine-name*.
CEE0E4	1	452	An invalid facility ID *facility-id* was passed to routine *routine-name*.

Usage notes

1. The structure of the condition token (type _FEEDBACK) is described in the "__le_api.h" header file shipped with Language Environment. You can assign values directly to the fields of the token in the header file without using the __le_condition_token_build() function.
2. This condition token is **only** to be used to retrieve messages from a Language Environment message table.

__le_debug_set_resume_mch() — Move the resume cursor to a predefined location represented by a machine state

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

void  __le_debug_set_resume_mch(__mch_t * position, _FEEDBACK * fc);
```

General description

Moves the resume cursor to a predefined location represented by the machine state.

Parameter
Description

position
A pointer to a valid machine state block to which the resume cursor is moved.

fc A 16–byte Feedback Code indicating the results of this function.

Table 36. Feedback Codes for __le_debug_set_resume_mch()

Code	Severity	Message Number	Message Text
CEE000	0	- -	The function completed successfully.
CEE07V	3	255	*Position* parameter not a machine state

Related information

- “__le_api.h” on page 38

__le_msg_add_insert() — Add insert to a Language Environment message

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

void  *__le_msg_add_insert(_FEEDBACK * cond_token,
                           _INT4 * insert_seq_num,
                           _VSTRING * insert_data,
                           _FEEDBACK * fc);
```

General description

Copies message insert data and loads the address of that data into the Instance Specific Information (ISI) associated with the condition being processed. The number of ISIs per thread is limited to 15.

Parameter
Description

cond_token
A 16–byte condition token that defines the condition for which the q_data_token is retrieved.

insert_seq_num
A 4–byte integer that contains the insert sequence number (such as insert 1 insert 2). It corresponds to an insert number specified with an :ins. tag in the message source file created by the CEEBLDTX utility. For more information about the CEEBLDTX utility see *z/OS Language Environment Programming Guide*.

insert_data
A halfword-prefixed length string, used without truncation, that represents the insert data. DBCS strings must be enclosed within shift-out (0x0E) and shift-in (0x0F) characters.

Note: The maximum size for an individual insert item is 254 bytes.

fc A 16–byte Feedback Code indicating the results of this function.

Table 37. Feedback Codes for __le_msg_add_insert()

Code	Severity	Message Number	Message Text
CEE000	0	- -	The function completed successfully.
CEE0EB	3	459	Not enough storage was available to create a new Instance Specific Information block.
CEE0EC	1	460	Multiple instances of the condition token with message number *message-number* and facility ID *facility-id* were detected.

Table 37. Feedback Codes for __le_msg_add_insert() (continued)

Code	Severity	Message Number	Message Text
CEE0ED	3	461	The maximum number of unique message insert blocks was reached. This condition token had it's I_S_info field set to 1.
CEE0EE	3	462	Instance Specific Information for the condition token with message number *message-number* and facility ID *facility-id* could not be found.
CEE0EF	3	463	The maximum size for an insert data item was exceeded be located.
CEE0H9	3	553	An internal error was detected in creating the inserts for a condition.

Usage notes

1. z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_add_insert() applies to message insert data for only the invoking thread.

Related information

- "__le_api.h" on page 38
- "__le_msg_get() — Get a Language Environment message"
- "__le_msg_get_and_write() — Get and output a Language Environment message" on page 955
- "__le_msg_write() — Output a Language Environment message to stderr" on page 956

__le_msg_get() — Get a Language Environment message

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

void  *__le_msg_get(_FEEDBACK * cond_token,
                    _CHAR80 message_area,
                    _INT4 * msg_index,
                    _FEEDBACK * fc);
```

General description

Retrieves, formats, and stores, in a passed message area, a Language Environment message corresponding to a user supplied condition token. The caller can later retrieve the message to modify or to write as output.

Parameter
Description

cond_token
A 16–byte condition token supplied by the invoker.

message_area
A fixed-length 80 character string, where the message is placed.

Note: The message is left-justified and padded on the right with blanks.

msg_index
A 4–byte binary integer returned to the invoker.

The *msg_index* should be set to zero on the first invocation of __le_msg_get(). If a message is too large to be contained in the *message_area*, *msg_index* is returned as an index into the message. This index is used on subsequent invocations to retrieve the remaining portion of the message. Feedback Code is also returned, indicating the message has been truncated. When the entire message is returned, *msg_index* is zero.

msg_idex contains different results based on the length of the message.

- If a message contains fewer than 80 characters, the entire message is returned on the first invocation. *msg_index* contains 0.
- If a message contains exactly 80 characters, the entire message is returned on the first invocation. *msg_index* contains 0.
- If the message is more than 80 characters it is split into segments. The *msg_index* does not contain the cumulative index for the entire message returned, but contains only the index of the segment that was just returned. It is up to the user to maintain the cumulative count if needed. When a message is too long, the following can occur:
  - If a message contains more than 80 characters and at least one blank is contained in the first 80 characters, the string up to and including the last blank is returned on the first invocation.
  - If the 80th character is non-blank (even if the 81st character is a blank), *msg_index* contains the index of the last blank (something less than 80), and the next invocation starts with the next character.
  - If the 80th character is a blank, *msg_index* contains 80 and the next invocation starts with the 81st character, blank or non-blank.
  - If a message contains more than 80 characters and at least the first 80 are all non-blank, the first 80 are returned. The next invocation does not add any blanks and starts with the 81st character. *msg_index* contains 80.

fc
A 16–byte Feedback Code indicating the results of this function.

Table 38. Feedback Codes for __le_msg_get()

Code	Severity	Message Number	Message Text
CEE000	0	- -	The function complete successfully.
CEE036	3	102	An unrecognized condition token was passed to the function and could not be used.
CEE0E2	3	450	The message inserts for the condition token with message number *message-number* and facility ID *facility-id* could not be located.
CEE0E6	3	454	The message number *message-number* could not be found for facility ID *facility-id*.

Table 38. Feedback Codes for __le_msg_get() (continued)

Code	Severity	Message Number	Message Text
CEE0E7	1	455	The message with message number *message-number* and facility ID *facility-id* was truncated.
CEE0EA	1	458	The message repository *repository-name* could not be located.

Usage notes

1. z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_get() affects only the invoking thread. However, __le_msg_get() uses the NATLANG value of the enclave. Any subsequent calls to __le_msg_get(), for a given condition, use the NATLANG value in effect at the time of the first invocation.

__le_msg_get_and_write() — Get and output a Language Environment message

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

void  *__le_msg_get_and_write(_FEEDBACK * cond_token,
                              _INT4 * destination_code,
                              _FEEDBACK * fc);
```

General description

Retrieves, formats, and stores, in a passed message area, a Language Environment message corresponding to a user supplied condition token. The caller can later retrieve the message to modify or to write as output.

Parameter
  Description

cond_token
  A 16–byte condition token supplied by the invoker.

destination_code
A 4–byte binary integer written to 'stderr'. The only acceptable value for is 2.

fc A 16–byte Feedback Code indicating the results of this function.

Table 39. Feedback Codes for __le_msg_get_and_write()

Code	Severity	Message Number	Message Text
CEE000	0	- -	The function completed successfully.
CEE0E2	3	450	The message inserts for the condition token with message number *message-number* and facility ID *facility-id* could not be located.
CEE0E3	3	451	An invalid destination code *destination-code* was passed to routine *routine*.
CEE0E6	3	454	The message number *message-number* could not be found for facility ID *facility-id*.
CEE0E9	1	457	The message file destination *ddname* could not be located.
CEE0EA	1	458	The message repository *repository-name* could not be located.
CEE3CT	3	3,485	An internal message service error occurred while locating the message number within a message file.
CEE3CU	3	3,486	An internal message service error occurred while formatting a message.
CEE3CV	3	3,487	An internal message service error occurred while locating a message number within the ranges specified in the repository.

Usage notes

1. z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_get_and_write() affects only the invoking thread. When multiple threads write to 'stderr' the output is interwoven by line. To group lines of output, serialize 'stderr' access (for example, by using a mutex).

Related information

- "__le_msg_write() — Output a Language Environment message to stderr"

__le_msg_write() — Output a Language Environment message to stderr

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

void  *__le_msg_write(_VSTRING * message_string,
                      _INT4 * destination_code,
                      _FEEDBACK * fc);
```

General description

Writes a user-defined Language Environment message string to 'stderr'.

Parameter
  Description

message_string
A halfword-prefixed printable character string containing a message. DBCS characters must be enclosed within shift-out (0x0F) and shift-in (0x0E) characters.

Insert data cannot be placed in the message with __le_msg_write(). The halfword-prefixed message string must contain only printable characters and be a length greater than zero. Unpredictable results will occur if the byte following the halfword prefix is 0x00.

destination_code
A 4–byte binary integer written to 'stderr'. The only acceptable value is 2.

fc A 16–byte Feedback Code indicating the results of this function.

Table 40. Feedback Codes for __le_msg_write()

Code	Severity	Message Number	Message Text
CEE000	0	- -	The function completed successfully.
CEE0E3	3	451	An invalid destination code *destination-code* was passed to routine *routine*.
CEE0E9	3	457	The message file destination *ddname* could not be located.

Usage notes

1. z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_write() affects only the invoking thread. When multiple threads write to 'stderr' the output is interwoven by line. To group lines of output, serialize 'stderr' access (for example, by using a mutex).

Related information

__le_record _dump() — Record information for the active condition

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	AMODE 64

Format

```
#include <__le_api.h>

int __le_record _dump(int function_code,
                      void *information);
```

General description

The __le_record _dump() function records information of the active condition, so that the information can be retrieved from the CIB later. Use this function only during condition handling.

Parameter
Description

function_code
A fullword integer that contains the function code of the following value:

1 Record the dataset name of a dump for the active condition.

information
The information to be recorded. When the value of *function_code* is 1, the information is a halfword length-prefixed EBCDIC character string, which is expected to be the dataset name of a dump for the active condition. Language Environment will validate that the length is positive and it does not exceed 44.

Returned value

If successful, __le_record_dump() returns 0.

If unsuccessful, __le_record_dump() returns nonzero and sets errno to one of the following values:

Error Code
Description

EMVSERR
No active CIB is available.

EINVAL
Incorrect parameters detected.

Usage notes

1. After the condition handling functions return control to your application, CIB that represents the condition is no longer valid, therefore the recorded information is no longer accessible.
2. If __le_record_dump() is called more than once for the same condition, the information of the last call is recorded.

__le_traceback() — Call chain traceback service

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	z/OS V1.9 AMODE 64

Format

```
#include <__le_api.h>

void  __le_traceback(int cmd, void* cmd_parms, _FEEDBACK *fc);
```

General description

The __le_traceback() function assists in tracing the call chain. It identifies the language, program unit, entry point, current location, caller's DSA, and other information from the address of a DSA for a program unit. This is essential for creating meaningful traceback messages.

Parameter
Description

cmd The __le_traceback() command to be used. The following commands can be used:

__TRACEBACK_FIELDS
Information that can be used to create a traceback message is returned in individual fields.

cmd_parms
A pointer to a structure that contains additional command specific parameters. For the command __TRACEBACK_FIELDS, this parameter must point to a __tf_parms_t.

fc A 16-byte feedback code indicating the results of this function.

Table 41. Feedback Codes for __le_traceback()

Code	Severity	Message number	Message text
CEE000	0	- -	The service completed successfully.
CEE310	3	3104S	Information could not be successfully extracted for this DSA. It is likely that the dsaptr parameter does not point to an actual DSA or save area.
CEE316	2	3110E	The *cmd* parameter is not a valid command for __le_traceback().
CEE3NS	1	3836W	A statement number is not available for this DSA. DWARF data in the load module is corrupted.
CEE3NT	1	3837W	Statement numbers are not available. The explicit DLL load of DLL CDAEQED failed with feedback code *fc*.

Table 41. Feedback Codes for __le_traceback() (continued)

Code	Severity	Message number	Message text
CEE3NU	1	3838W	Statement numbers are not available. The explicit DLL load of DLL CDAEQDPI failed with feedback code *fc*.
CEE3NV	1	3839W	Statement numbers are not available. The explicit DLL load of DLL CELQDSNF failed with feedback code *fc*.
CEE3O0	1	3840	Statement numbers are not available. dllqueryfn() failed for a function in the DLL CELQDSNF.
CEE3O1	1	3841	A statement number is not available for this DSA. An internal routine failed with return code *return-code* and reason code *reason-code*.

The __tf_parms_s structure is defined as follows:

```
typedef struct __tf_string_s {
     size_t     __tf_bufflen;

     char*   __tf_buff;
} __tf_string_t;

typedef struct __tf_parms_s {
     /*****************************************************************/
     /* Input                                                         */
     /*****************************************************************/
     void*   __tf_dsa_addr;
     void*   __tf_caa_addr;
     void*   __tf_call_instruction;
     /*****************************************************************/
     /* Output related to input DSA                                   */
     /*****************************************************************/
     void*   __tf_ pu_addr;
     void*   __tf_ entry_addr;
     struct __cib*   __tf_cib_addr;
     uint8_t     __tf_member_id;
     int     __tf_is_main:1;
     int     :23;
     int     :32;
     __tf_string_t __tf_pu_name;
     __tf_string_t __tf_entry_name;
     __tf_string_t __tf_statement_id;
     /*****************************************************************/
     /* Output related to caller's DSA                                */
     /*****************************************************************/
     void*   __tf_caller_dsa_addr;
     void*   __tf_caller_call_instruction;
} __tf_parms_t;
```

The following are members of the structure:

Member
Description

void* __tf_dsa_addr
The address of the DSA for the current routine in the traceback. When this field is zero on input, the address of the DSA for the caller of

__le_traceback() will be used and the address will be returned. No attempt is made to verify that the input is a DSA. Incorrect input can lead to unpredictable results.

void* __tf_caa_addr
The address of the CAA associated with the DSA. When this field is zero on input, the address of the CAA for the current thread will be used and the address will be returned. No attempt is made to verify that the input is a CAA. Incorrect input can lead to unpredictable results.

void* __tf_call_instruction
The address of the instruction that caused transfer out of the routine. This is either the address of a BASR, BRAS or BRASL instruction if transfer was made by subroutine call, or the address of the interrupted statement if transfer was caused by an exception. When multiple calls are made to __le_traceback() to scan the call chain, the callers_call_instruction (described below) returned from the previous call can be used here. If the address is not known, this field should be set to zero. When this field is zero on input and the address can be determined, it will be returned.

void* __tf_pu_addr
The address of the start of the program unit for the routine associated with the DSA is returned in this field. If the program unit address cannot be determined, this field is set to zero.

void* __tf_entry_addr
The address of the entry point into the routine associated with the DSA is returned in this field. If the entry point address cannot be determined, this parameter is set to zero.

struct __cib* __tf_cib_addr
The address of the CIB (struct __cib) associated with the DSA, if an exception occurred, is returned in this field. If no exception occurred, this field is set to zero. Note that if an exception caused transfer out of the routine, the state of the registers after the last instruction ran in the routine is saved in the CIB, rather than in the DSA.

uint8_t __tf_member_id
The member identifier for the routine associated with the DSA will be returned in this field. If the member ID cannot be determined, this field is set to negative one.

int __tf_is_main:1
One of two values is returned in this field: 0 (the routine associated with the DSA is not the main program) or 1 (the routine associated with the DSA is the main program).

__tf_string_t __tf_pu_name
A structure that will be used to return the name of the program unit containing the routine associated with the DSA. The structure has the following fields:

char* __tf_buff
The address of a buffer in which the program unit name will be returned. The name will be returned in the buffer as a null terminated string.

size_t __tf_bufflen
The size of the buffer

If the program unit name cannot be determined, the buffer is set to a null string. If the program unit name cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the program unit name is not returned.

__tf_string_t __tf_entry_name
A structure that will be used to return the name of the entry point into the routine associated with the DSA. The structure has the following fields:

char* __tf_buff
The address of a buffer in which the entry point name will be returned. The name will be returned in the buffer as a null terminated string.

size_t __tf_bufflen
The size of the buffer

If the entry point name cannot be determined, the buffer is set to a null string. If the entry point name cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the entry point name is not returned

__tf_string_t __tf_statement_id
A structure that will be used to return the identifier of the statement containing the instruction which caused transfer out of the routine associated with the DSA. The structure has the following fields:

char* __tf_buff
The address of a buffer in which the statement id will be returned. The statement id will be returned in the buffer as a null terminated string.

size_t __tf_bufflen
The size of the buffer

If the statement id cannot be determined, the buffer is set to a null string. If the statement id cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the statement id is not returned

void* __tf_callers_dsa_addr
The address of the DSA for the caller is returned in this field. If the address of the caller's DSA cannot be determined or is not valid (points to inaccessible storage), then this field is set to zero.

void* __tf_callers_call_instruction
The address of the instruction that caused transfer out of the caller is returned in this field. This is either the address of a BASR, BRAS or BRASL instruction if transfer was made by subroutine call, or the address of the interrupted statement if transfer was caused by an exception. If the address cannot be determined, this parameter is set to zero.

Example

```
#include <__le_api.h>
#include <stdlib.h>

int main() {
  __tf_parms_t   tbck_parms;
  char                           pu_name[256];
  char                           entry_name[256];
  char                              statement_id[256];
  _FEEDBACK                         fc;
  int                               rc;

  tbck_parms.__tf_pu_name. __tf_bufflen = sizeof(pu_name);
  tbck_parms.__tf_entry_name. __tf_bufflen = sizeof(entry_name);
  tbck_parms.__tf_statement_id. __tf_bufflen = sizeof(statement_id);

  tbck_parms.__tf_pu_name. __tf_buff = pu_name;
  tbck_parms.__tf_entry_name. __tf_buff = entry_name;
  tbck_parms.__tf_statement_id. __tf_buff = statement_id;

  tbck_parms.__tf_dsa_addr = 0;
  tbck_parms.__tf_caa_addr = 0;
  tbck_parms.__tf_call_instruction = 0;

  do {

    _le_traceback(__TRACEBACK_FIELDS, &tbck_parms, &fc);

    if ( fc.tok_sev >= 2 ) {
      printf("Error: __le_traceback() failed.\n");
      break;
    }

    printf("Entry=%s Offset=%c%x Line=%s\n",
           tbck_parms.__tf_entry_name.__tf_buff,
           tbck_parms.__tf_call_instruction
           < tbck_parms.__tf_entry_addr ? '-' : '+',
           abs((int)((long)tbck_parms.__tf_call_instruction
           - (long)tbck_parms.__tf_entry_addr)),
           tbck_parms.__tf_statement_id.__tf_buff
          );

    tbck_parms.__tf_dsa_addr = tbck_parms.__tf_caller_dsa_addr;
    tbck_parms.__tf_call_instruction =
       tbck_parms.__tf_caller_call_instruction;

  } while (!tbck_parms.__tf_is_main);

  return 0;
}
```

Output

```
Entry=main Offset=+da Line=28
Entry=CELQINIT Offset=+134c Line=
```

lfind() — Linear search routine

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <search.h>

void *lfind(const void *key, const void *base, size_t *nelp,
           size_t width, int (*compar)(const void *, const void *));
```

General description

The lfind() function is the same as a lsearch() except that if the entry is not found, it is not added to the table. Instead, a NULL pointer is returned.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, lfind() cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to lfind(), the compiler will flag it as an error. You can pass a C or C++ function to lfind() by declaring it as extern "C".

Returned value

If the searched-for entry is found, lfind() returns a pointer to it.

If not found, lfind() returns a NULL pointer.

No errors are defined.

Related information

- "search.h" on page 62
- "bsearch() — Search arrays" on page 220
- "hsearch() — Search hash tables" on page 817

lgamma(), lgammaf(), lgammal() — Log gamma function

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#define _XOPEN_SOURCE
#include <math.h>

double lgamma(double x);
extern int signgam;
int *__signgam(void);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

double lgamma(double x);
float lgammaf(float x);
long double lgammal(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float lgamma(float x);
long double lgamma(long double x);
```

General description

The lgamma() function computes the

$$\log_e | \Gamma(x) |$$

where

$$\Gamma(x)$$

is defined as

$$\int_0^{\infty} e^{-t} \; t^{(x - 1)} \, dt$$

The sign of

$$\Gamma(x)$$

is returned in the external integer *signgam*. The argument *x* may not be a non-positive integer.

In a multithreaded process, each thread has its own instance of the *signgam* variable. Threads access their instances of the variable by calling the __signgam() function. See "__signgam() — Return signgam reference" on page 1648. The math.h header (see "math.h" on page 44) redefines the string "*signgam*" to an invocation of the __signham function. The actual *signgam* external variable is used to store the *signgam* value for the IPT.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
lgamma	X	X
lgammaf	X	X
lgammal	X	X

Returned value

If successful, lgamma() returns the above function of its argument.

lgamma() will fail under the following conditions:

- If the result overflows, the function will return HUGE_VAL and set errno to ERANGE.
- If *x* is a non-positive integer and _XOPEN_SOURCE is defined, lgamma() returns HUGE_VAL and sets errno to EDOM.
- If *x* is a non-positive integer and _ISOC99_SOURCE is defined, lgamma() returns HUGE_VAL and sets errno to ERANGE.

Note: If both _XOPEN_SOURCE and _ISOC99_SOURCE are defined, the _ISOC99_SOURCE behavior will take precedence.

Special behavior for IEEE: Even when _XOPEN_SOURCE is defined and _ISOC99_SOURCE not, lgamma() returns HUGE_VAL and sets errno to ERANGE.

Example

```
/*
   This example uses lgamma() to calculate ln(|G(x)|), where x = 42.
 */
#include <math.h>
#include <stdio.h>

int main(void)
{
   double x=42, g_at_x;

   g_at_x = exp(lgamma(x));       /* g_at_x = 3.345253e+49 */
   printf ("The value of G(%4.2f) is %7.2e\n", x, g_at_x);
}
```

Output

```
The value of G(42.00) is 3.35e+49
```

lgammad32(), lgammad64(), lgammad128() - Log gamma function

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.10

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  lgammad32(_Decimal32 x);
_Decimal64  lgammad64(_Decimal64 x);
_Decimal128 lgammad128(_Decimal128 x);
```

```
_Decimal32  lgamma(_Decimal32 x);     /* C++ only */
_Decimal64  lgamma(_Decimal64 x);     /* C++ only */
_Decimal128 lgamma(_Decimal128 x);    /* C++ only */
```

General description

The lgamma() function computes the

$$\log_e | \Gamma (x) |$$

is defined as

$$\int_{o}^{\infty} e^{-t} \; t^{(x-1)} \, dt$$

The sign of

$$\Gamma (x)$$

is returned in the external integer signgam. The argument *x* may not be a non-positive integer.

In a multithreaded process, each thread has its own instance of the *signgam* variable. Threads access their instances of the variable by calling the __signgam() function. The math.h header redefines the string *signgam* to an invocation of the __siggam function. The actual signgam external variable is used to store the signgam value for the IPT.

These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, lgamma() returns the above function of its argument.

lgamma() will fail under the following conditions:
- If the result overflows, the function will return +HUGE_VAL_D32, +HUGE_VAL_D64 or +HUGE_VAL_D128 and set errno to ERANGE.
- If *x* is a non-positive integer, lgamma() returns +HUGE_VAL_D32, +HUGE_VAL_D64 or +HUGE_VAL_D128 and sets errno to ERANGE.

Example

CELEBL26

```
/* CELEBL26

   This exaxmple illustrates the lgammad64() function.

*/
```

```
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
int main(void)
{
   _Decimal64 x, y;

   x = 42.0DD;
   y = lgammad64(x);

   printf ("lgammad64(%Df) = %Df\n", x, y);
}
```

__librel() — Query release level

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <stdlib.h>

int __librel(void);
```

General description

The __librel() function provides the release level of the z/OS XL C/C++ library. To use this function, you must compile your application with LANGLVL(EXTENDED).

Returned value

The __librel() function returns the z/OS XL C/C++ library release level that your application is using. The value is printed in hexadecimal format. The first byte of the value returned contains the product and version, second byte the release, and the third and fourth bytes contain the modification level.

Figure 4 shows the format of the hexadecimal value returned by the __librel() function.

```
0xPVRRMMMM
  ||||||||
  ||||++++ Modification Level (M)
  ||++---- Release (R)
  |+------ Version (V)
  +------- Product Number (P)
```

Figure 4. Format of the __librel() function return value

Table 42 on page 969 correlates library release level with the corresponding __librel() return value.

Table 42. Library release level and value returned by the __librel() function

Library release level	Return value	Notes
z/OS V2.2	0x42020000	
z/OS V2.1	0x42010000	
z/OS V1.13	0x410D0000	
z/OS V1.12	0x410C0000	
z/OS V1.11	0x410B0000	
z/OS V1.10	0x410A0000	
z/OS V1.9	0x41090000	
z/OS V1.8	0x41080000	
z/OS V1.7	0x41070000	
z/OS V1.6	0x41060000	
z/OS V1.5	0x41050000	
z/OS V1.4	0x41040000	
z/OS V1.3	0x41030000	
z/OS V1.2	0x41020000	
z/OS V1.1	0x220A0000	When running under z/OS V1.1, the __librel() function returns the same value as returned for OS/390 V2.10.
OS/390 V2.10	0x220A0000	
OS/390 V2.9	0x22090000	
OS/390 V2.8	0x22080000	
C/370 V2.2	0x02020000	For application running under the C/370 specific library (the common library version), the product designation is 0.

Example

CELEBL04

```
/* CELEBL04

   This example calls the __librel() function that returns
   the library release level your program is currently
   using in the following hexadecimal format 0xPVRRMMMM.

 */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
   printf("The current release of the library is: %X\n",__librel());
}
```

Output

```
The current release of the library is: 42020000
```

link() — Create a link to a file

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int link(const char *oldfile, const char *newname);
```

General description

Provides an alternative pathname for the existing file, so that the file can be accessed by either the old or the new name. link() creates a link from the pathname *newname* to an existing file, with the pathname *oldfile*. The link can be stored in the same directory as the original file or in a completely different one.

Links are allowed to files only, not to directories.

This is a hard link, which ensures the existence of a file even after its original name has been removed.

If link() successfully creates the link, it increments the *link count* of the file. The link count tells how many links there are to the file. At the same time, link() updates the change time of the file, and the change time and modification time of the directory that contains *newname* (that is, the directory that holds the link). If link() fails, the link count is not incremented.

If *oldfile* names a symbolic link, link() creates a link that refers to the file that results from resolving the pathname contained in the symbolic link. If *newname* names a symbolic link, link() fails and sets errno to EEXIST.

Returned value

If successful, link() returns 0.

If unsuccessful, link() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The process did not have appropriate permissions to create the link. Possible reasons include no search permission on a pathname component of *oldfile* or *newname*, no write permission on the directory intended to contain the link, or no permission to access *oldfile*.

EEXIST
Either *newname* refers to a symbolic link, or a file or directory with the name *newname* already exists.

EINVAL
Either *oldfile* or *newname* is incorrect, because it contains a NULL.

ELOOP
A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of *oldfile* or *newname* is greater than POSIX_SYMLOOP.

EMLINK
oldfile already has its maximum number of links. The maximum number of links to a file is given by **LINK_MAX**, which you can determine by using pathconf() or fpathconf().

ENAMETOOLONG
oldfile or *newname* is longer than **PATH_MAX**, or a component of one of the pathnames is longer than **NAME_MAX** while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link in *oldfile* or *newname* exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT
A pathname component of *oldfile* or *newname* does not exist, or *oldfile* itself does not exist, or one of the two arguments is an empty string.

ENOSPC
The directory intended to contain the link cannot be extended to contain another entry.

ENOTDIR
A pathname component of one of the arguments is not a directory.

EPERM
oldfile is the name of a directory, and links to directories are not supported.

EROFS
Creating the link would require writing on a read-only file system.

EXDEV
oldfile and *newname* are on different file systems.

Example

```
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#include <stdlib.h>
#include <stdio.h>

main() {
  char fn[]="link.example.file";
  char ln[]="link.example.link";
  int fd;

  if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    close(fd);
    if (link(fn, ln) != 0) {
      perror("link() error");
      unlink(fn);
    }
    else {
      unlink(fn);
      unlink(ln);
    }
  }
}
```

listen() — Prepare the server for incoming client requests

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int listen(int socket, int backlog);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

int listen(int socket, int backlog);
```

General description

The listen() function applies only to stream sockets. It indicates a readiness to accept client connection requests, and creates a connection request queue of length *backlog* to queue incoming connection requests. Once full, additional connection requests are rejected.

Parameter
Description

socket The socket descriptor.

backlog Defines the maximum length for the queue of pending connections.

The listen() call indicates a readiness to accept client connection requests. It transforms an active socket into a passive socket. Once called, *socket* can never be used as an active socket to initiate connection requests. Calling listen() is the third of four steps that a server performs to accept a connection. It is called after allocating a stream socket with socket(), and after binding a name to *socket* with bind(). It must be called before calling accept().

If the backlog is less than 0, *backlog* is set to 0. If the backlog is greater than SOMAXCONN, as defined in **sys/socket.h**, *backlog* is set to SOMAXCONN.

For AF_UNIX sockets, this value is variable and can be set in the application. For AF_INET and AF_INET6 sockets, the value cannot exceed the maximum number of connections allowed by the installed TCP/IP.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, listen() returns 0.

If unsuccessful, listen() returns -1 and sets errno to one of the following values:

Error Code
  Description

EBADF
  The *socket* parameter is not a valid socket descriptor.

EDESTADDRREQ
  The socket is not bound to a local address, and the protocol does not support listening on an unbound socket.

EINVAL
  An invalid argument was supplied. The socket is not named (a bind() has not been done), or the socket is ready to accept connections (a listen() has already been done). The socket is already connected.

ENOBUFS
  Insufficient system resources are available to complete the call.

ENOTSOCK
  The descriptor is for a file, not for a socket.

EOPNOTSUPP
  The *socket* parameter is not a socket descriptor that supports the listen() call.

llabs() — Calculate absolute value of long long integer

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	OS/390 V2R10

Format

```
#include <stdio.h>

long long llabs(long long int n);
```

Compile requirement: Use of this function requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

Calculates the absolute value of its long long integer argument *n*. The result is undefined when the argument is equal to `LONGLONG_MIN`, the smallest available long long integer (-9 223 372 036 854 775 808). The value `LONGLONG_MIN` is defined in the limits.h header file.

Returned value

Returns the absolute value of the long long integer argument *n*.

Related information

- "stdio.h" on page 68
- "stdlib.h" on page 70
- "limits.h" on page 39
- "labs() — Calculate long absolute value" on page 935

lldiv() — Compute quotient and remainder of integral division for long long type

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	OS/390 V2R10

Format

```
#include <stdio.h>

long long lldiv(long long numer, long long denom);
```

Compile requirement: Use of this function requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

Calculates the quotient and remainder of the division of numerator by denominator.

Returned value

Returns a structure of type `lldiv_t`, containing both the quotient `long long quot` and the remainder `long long rem`.

If the value cannot be represented, the returned value is undefined. If *denominator* is 0, a divide by 0 exception is raised.

Example

```
/*
   This example uses the
   lldiv() function to calculate the quotients and
   remainders for a set of two dividends and two divisors.
 */
#define _LONG_LONG 1
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
   long long  num[2] = {45,-45};
   long long  den[2] = {7,-7};
   lldiv_t ans;   /* lldiv_t is a struct type containing
                     two long long int fields:
                    'quot' stores quotient; 'rem' stores remainder */
   short i,j;

   printf("Results of long division:\n");
   for (i = 0; i < 2; i++)
      for (j = 0; j < 2; j++)
      {
         ans = lldiv(num[i], den[j]);
         printf("Dividend: %6lld  Divisor: %6lld", num[i], den[j]);
         printf("  Quotient: %6lld  Remainder: %6lld\n", ans.quot,
                                                          ans.rem);
      }
}
```

Output

```
Results of long division:
Dividend:  45  Divisor:   7  Quotient:   6  Remainder:   3
Dividend:  45  Divisor:  -7  Quotient:  -6  Remainder:   3
Dividend: -45  Divisor:   7  Quotient:  -6  Remainder:  -3
Dividend: -45  Divisor:  -7  Quotient:   6  Remainder:  -3
```

llround(), llroundf(), llroundl() — Round to the nearest integer

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <math.h>

long long int llround(double x);
long long int llroundf(float x);
long long int llroundl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

long long int llround(float x);
long long int llround(long double x);
```

Compile requirement: Use of this function requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

The llround() family of functions round *x* to the nearest integer, rounding halfway cases away from zero, regardless of the current rounding mode.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
llround	X	X
llroundf	X	X
llroundl	X	X

Returned value

If successful, they return the rounded integer. If the correct value is positive or negative and too large to represent as a **long long**, a domain error will occur and an unspecified value is returned.

Example

```
/*
 * This program illustrates the use of llround() function
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <_Ieee754.h>  /* fpc functions */
#include <stdio.h>

void main() {

  _FP_fpcreg_t   save_rmode;
  long long int  rnd2nearest;
  double         number;

  printf("Illustrates the llround() function\n\n");
  save_rmode.rmode = _RMODE_RZ;
  __fpc_sm(save_rmode.rmode);  /* set rounding mode to round to zero */

  number=501.1;
  rnd2nearest = llround(number);
  printf ("llround(%.1f) = %lli\n",number, rnd2nearest);

  number=1.5;
  rnd2nearest = llround(number);
  printf ("llround(%.1f) = %lli\n",number, rnd2nearest);

  number=-2.5;
  rnd2nearest = llround(number);
  printf ("llround(%.1f) = %lli\n",number, rnd2nearest);
}
```

```
Output

Illustrates the llround() function

llround(501.1) = 501
llround(1.5) = 2
llround(-2.5) = -3
```

llroundd32(), llroundd64(), llroundd128() — Round to the nearest integer

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

long long int llroundd32(_Decimal32 x);
long long int llroundd64(_Decimal64 x);
long long int llroundd128(_Decimal128 x);

long long int llround(_Decimal32 x);   /* C++ only */
long long int llround(_Decimal64 x);   /* C++ only */
long long int llround(_Decimal128 x);  /* C++ only */
```

Compile requirement: Use of this function requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

The llround() family of functions round *x* to the nearest integer, rounding halfway cases away from zero, regardless of the current rounding mode.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, they return the rounded integer. If the correct value is positive or negative and too large to represent as a long long, a domain error will occur and an unspecified value is returned.

Example

```
/* CELEBL21

   This example illustrates the llroundd32() function.

*/

#pragma strings(readonly)

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <math.h>
#include <stdio.h>

static void try_rm(int, _Decimal32);

/* pass back printable rounding mode */

lltoa() — Convert long long into a string

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R5

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * lltoa(int64_t ll, char * buffer, int radix);
```

Compile requirement: Use of this function requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

The lltoa() function coverts the int64_t *ll* into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, lltoa() produces the same result as the following statement:

```
(void) sprintf(buffer, "%lld", ll);
```

with buffer the returned character string. When the radix is OCTAL, lltoa() formats int64_t *ll* into an unsigned octal constant. When the radix is HEX, lltoa() formats int64_t *ll* into an unsigned hexadecimal constant. The hexadecimal value will include lower case abcdef, as necessary.

Returned value

String pointer (same as buffer) will be returned. When passed an invalid radix argument, function will return NULL and set errno to EINVAL.

Usage notes

1. This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Example

CELEBL30

```
/* CELEBL30

   This example reads an int64_t and formats it to decimal, unsigned
   octal, unsigned hexadecimal constants converted to a character
   string.

*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
   int64_t i;
   char buffer [sizeof(int64_t)*8+1];
   printf ("Enter a number: ");
   if (scanf ("%lld",&i) == 1) {
      lltoa (i,buffer,DECIMAL);
      printf ("decimal: %s\n",buffer);
      lltoa (i,buffer,HEX);
      printf ("hexadecimal: %s\n",buffer);
      lltoa (i,buffer,OCTAL);
      printf ("octal: %s\n",buffer);
   }
   return 0;
}
```

Output

If the input is 1234, then the output should be:

```
decimal: 1234
hexadecimal: 4d2
octal: 2322
```

localdtconv() — Date and time formatting convention inquiry

Standards

Standards / Extensions	C or C++	Dependencies
Language Environment	both	

Format

```
#include <locale.h>

struct dtconv *localdtconv(void);
```

General description

Determines the date/time format information of the current locale.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Returned value

Returns the address of the *dtconv* structure:

```
struct dtconv {
        char *abbrev_month_names[12];   /* Abbreviated month names      */
        char *month_names[12];          /* full month names             */
        char *abbrev_day_names[7];      /* Abbreviated day names        */
        char *day_names[7];             /* full day names               */
        char *date_time_format;         /* date and time format         */
        char *date_format;              /* date format                 */
        char *time_format;              /* time format                 */
        char *am_string;                /* AM string                   */
        char *pm_string;                /* PM string                   */
        char *time_format_ampm;         /* long date format            */
        char *iso_std8601_2000;         /* ISO 8601:2000 std date format*/
};
```

The dtconv structure is an IBM extension that stores values from the LC_TIME category of the current locale. It is initialized by the setlocale() function and copied to the user-supplied dtconv when localdtconv() is called.

The dtconv structure can be overwritten by subsequent calls to localdtconv() and setlocale() with LC_ALL or LC_TIME.

localeconv() — Query numeric conventions

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <locale.h>

struct lconv *localeconv(void);
```

General description

Sets the components of a structure having type `struct lconv` to values appropriate for the current locale. The structure may be overwritten by another call to localeconv() or by calling setlocale() and passing LC_ALL, LC_MONETARY, or LC_NUMERIC.

For a list of the elements in the `lconv` structure, see Table 6 on page 40.

Pointers to strings with a value of "" indicate that the value is not available in the C locale or is of 0 length. char types with a value of UCHAR_MAX indicate that the value is not available in the current locale.

Returned value

Returns a pointer to the structure.

Example

CELEBL06

```
/* CELEBL06

   This example prints out the default decimal point for your locale and
   then the decimal point for the Fr_CA locale.

 */
#include <stdio.h>
#include <locale.h>

int main(void)
{
  char * string;
  struct lconv * mylocale;
  mylocale = localeconv();
  /* Display default decimal point */
  printf( "Default decimal point is a %s\n",
          mylocale->decimal_point );

  if (NULL != (string = setlocale(LC_ALL, "Fr_CA.IBM-1047" )))
  {
     mylocale = localeconv();
     /* A comma is set to be the decimal point
        when the locale is Fr_CA.IBM-1047 */
  printf( "French-speaking Canadian decimal point is a %s\n",
          mylocale->decimal_point );
   }
   else {
      printf("setlocale(LC_ALL, Fr_CA.IBM-1047) returned <NULL>\n");
   }
   return 0;
}
```

Output

```
Default decimal-point is a .
French-speaking Canadian decimal-point is a ,
```

localtime(), localtime64() — Convert time and correct for local time

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <time.h>

struct tm *localtime(const time_t *timeval);
```

```
#define _LARGE_TIME_API
#include <time.h>

struct tm *localtime64(const time64_t *timeval);
```

Compile requirement: Use of localtime64() function requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

The localtime() funtion converts the calendar time pointed to by *timeval* to a broken-down time expressed in local time. Calendar time is usually obtained by a call to the time() function.

The localtime64() function behaves exactly like localtime() except it will break down a time64_t value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Usage notes

1. This function is sensitive to time zone information which is provided by:
   - The TZ environmental variable when POSIX(ON) and TZ is correctly defined, or by the _TZ environmental variable when POSIX(OFF) and _TZ is correctly defined.
   - The LC_TOD category of the current locale if POSIX(OFF) or TZ is not defined.

   The time zone external variables `tzname`, `timezone`, and `daylight` declarations remain feature test protected in time.h.
2. The ctime(), localtime(), and mktime() functions now return Coordinated Universal Time (UTC) unless customized locale information is made available, which includes setting the `timezone_name` variable.

3. In POSIX you can supply the necessary information by using environment variables.
4. In non-POSIX applications, you can supply customized locale information by setting time zone and daylight information in LC_TOD.
5. By customizing the locale, you allow the time functions to preserve both time and date, correctly adjusting for daylight time on a given date.
6. The gmtime() and localtime() functions may use a common, statically allocated structure for the conversion. Each call to one of these functions will alter the result of the previous call.
7. Calendar time returned by the time() function begins at the epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.
8. The localtime() function converts calendar time (that is, seconds elapsed since the epoch) to broken-down time, expressed as local time, using time zone information provided by the TZ or _TZ environment variable or the LC_TOD category of the current locale:
   - When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see “Customizing a time zone” in *z/OS XL C/C++ Programming Guide*.

Returned value

Returns a pointer to a *tm* structure containing the broken-down time, expressed as a local time, and corresponding to the calendar time pointed to by *timeval*. If the calendar time cannot be converted, localtime() returns a NULL pointer. See “time.h” on page 79 for a description of the fields of the *tm* structure.

Error Code
Description

EOVERFLOW
The result cannot be represented.

Example

CELEBL07

```
/* CELEBL07

   This example queries the system clock and displays the local time.

 */
#include <time.h>
#include <stdio.h>

int main(void)
{
   struct tm *newtime;
   time_t ltime;

   time(&ltime);
   newtime = localtime(&ltime);
   printf("The date and time is %s", asctime(newtime));
}
```

Output

This output would occur if the local time is 3:00 p.m. June 16, 2006):

```
The date and time is Fri Jun 16 15:00:00 2006
```

localtime_r(), localtime64_r() — Convert time value to broken-down local time

Standards

Standards / Extensions	C or C++	Dependencies
Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment	both	OS/390 V2R8

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>

struct tm *localtime_r(const time_t *__restrict__ clock,
                       struct tm *__restrict__ result);
```

```
#define _LARGE_TIME_API
#include <time.h>

struct tm *localtime64_r(const time64_t *__restrict__ clock,
                       struct tm *__restrict__ result);
```

Compile requirement: Use of localtime64_r() function requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

The localtime_r() function converts the calendar time pointed to by *clock* into a broken-down time stored in the structure to which *result* points. The localtime_r() function also returns a pointer to that same structure.

Unlike localtime(), the reentrant version is not required to set tzname.

The localtime64_r() function behaves exactly like localtime_r() except it will break down a time64_t value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, localtime_r() returns a pointer to the structure pointed to by the argument *result*.

If an error is detected, localtime() returns a null pointer and set errno to indicate the error.

Error Code
Description

EOVERFLOW
The result cannot be represented.

lockf() — Record locking on files

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int lockf(int filedes, int function, off_t size);
```

General description

The lockf() function allows sections of a file to be locked with advisory-mode locks. Calls to lockf() from other processes which attempt to lock the locked file section will either return an error value or block until the section becomes unlocked. All the locks for a process are removed when the process terminates. Record locking with lockf() is supported for regular files.

The *filedes* argument is an open file descriptor. The file descriptor must have been opened with a write-only permission (O_WRONLY) or with read/write permission (O_RDWR) to establish a lock with this function.

The *function* argument is a control value which specifies the action to be taken. The permissible values for *function* are defined in <unistd.h> as follows:

Function	Description
F_ULOCK	unlock locked sections
F_LOCK	lock a section for exclusive use
F_TLOCK	test and lock a section for exclusive use
F_TEST	test a section for locks by other processes

F_TEST detects if a lock by another process is present on the specified section; F_LOCK and F_TLOCK both lock a section of a file if the section is available; F_ULOCK removes locks from a section of the file.

The *size* argument is the number of contiguous bytes to be locked or unlocked. The section to be locked or unlocked starts at the current offset in the file and extends forward for a positive size or backward for a negative size (the preceding bytes up to but not including the current offset). If *size* is 0, the section from the current offset through the largest possible file offset is locked (that is, from the current offset through the present or any future End Of File (EOF)). An area need not be allocated to the file to be locked because locks may exist past the End Of File.

The sections locked with F_LOCK or F_TLOCK may, in whole or in part, contain or be contained by a previously locked section for the same process. When this occurs, or if adjacent locked sections would occur, the sections are combined into a single locked section. If the request would cause the number of locks to exceed a system-imposed limit, the request will fail.

F_LOCK and F_TLOCK requests differ only by the action taken if the section is not available. F_LOCK blocks the calling process until the section is available. F_TLOCK makes the function fail if the section is already locked by another process.

File locks are released on first close by the locking process of any file descriptor for the file.

F_ULOCK requests may release (wholly or in part) one or more locked sections controlled by the process. Locked sections will be unlocked starting at the current file offset through *size* bytes or to the End Of File (EOF) if *size* is (off_t)0. When all of a locked section is not released (that is, when the beginning or end of the area to be unlocked falls within a locked section), the remaining portions of that section are still locked by the process. Releasing the center portion of a locked section will cause the remaining locked beginning and end portions to become two separate locked sections. If the request would cause the number of locks in the system to exceed a system-imposed limit, the request will fail.

A potential for deadlock occurs if a process controlling a locked section is blocked by accessing another process's locked section. If the system detects that a deadlock would occur, lockf() will fail with an EDEADLK error.

Locks obtained by lockf() are controlled by the same facility controlling locks obtained by fcntl().

The interaction between fcntl() and lockf() locks is unspecified.

Blocking on a section is interrupted by any signal.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, lockf() returns 0.

If unsuccessful, existing locks are not changed, lockf() returns -1, and sets errno to one of the following values:

Error Code
: **Description**

EACCES or EAGAIN
: The *function* argument is F_TLOCK or F_TEST and the section is already locked by another process

EBADF
: The *filedes* argument is not a valid open file descriptor; or *function* is F_LOCK or F_TLOCK and *filedes* is not a valid file descriptor open for writing.

EDEADLK
: The *function* argument is F_LOCK and a deadlock is detected.

EINTR
: A signal was caught during execution of the function.

EOVERFLOW
: The offset of the first, or if size is not 0 then the last, byte in the requested section cannot be represented correctly in an object of type off_t.

log(), logf(), logl() — Calculate natural logarithm

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double log(double x);
float log(float x);                     /* C++ only */
long double log(long double x);         /* C++ only */
float logf(float x);
long double logl(long double x);
```

General description

Calculates the natural logarithm (base e) of *x*, for *x* greater than 0.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Returns the computed value.

If *x* is negative, the function sets errno to EDOM and returns -HUGE_VAL. If *x* is 0.0, the function returns -HUGE_VAL and sets errno to ERANGE. If the correct value would cause an underflow, 0 is returned and the value ERANGE is stored in errno.

Special behavior for IEEE: If *x* greater than 0, the function returns the natural logarithm (base e) of *x*.

If *x* is negative, the function sets errno to EDOM and returns NaNQ. If *x* is 0.0, the function returns -HUGE_VAL and errno remains unchanged.

Note: When environment variable _EDC_SUSV3 is set to 2, and if *x* is 0.0, the function returns -HUGE_VAL and sets errno to ERANGE.

Example

CELEBL08

```
/* CELEBL08

  This example calculates the natural logarithm of 1000.0.

 */
```

```
#include <math.h>
#include <stdio.h>

int main(void)
{
   double x = 1000.0, y;

   y = log(x);

   printf("The natural logarithm of %lf is %lf\n", x, y);
}
```

Output

```
The natural logarithm of 1000.000000 is 6.907755
```

logb(), logbf(), logbl() — Unbiased exponent

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7 for logbf(), logbl()

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double logb(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float logbf(float x);
long double logbl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float logb(float x);
long double logb(long double x);
```

General description

Returns the exponent of its argument *x*, as a signed integer value in floating-point mode. If x is subnormal, it is treated as a normalized number.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
logb	X	X
logbf	X	X
logbl	X	X

Returned value

If successful, logb() returns the exponent of *x*.

logb() will fail under the following condition: If *x* is equal to 0.0, logb() will return -HUGE_VAL and set errno to EDOM.

Example

```
/*
 * This program illustrates the use of logb() function
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <float.h>  /* Needed for FLT_RADIX */
#include <stdio.h>

void main() {

  int i;
  union {
    double number;
    unsigned char  uchars [sizeof(double)];
  } dblval;
  double logbx;

  printf("Illustrates the logb() function");

  #ifdef __BFP__
    printf(" (IEEE version)\n\n");
  #else
    printf(" (HFP version)\n\n");
  #endif

  /* generate the smallest possible double number */
  for (i=0; i<sizeof(double); i++)
    dblval.uchars[i] = 0;
  dblval.uchars[1] = 0x10;

  logbx = logb(dblval.number);

  printf("x = %g\n",dblval.number);
  printf("logb(x) = %f\n\n", logbx);

  printf("pow(FLT_RADIX, logb(x) ) should equal x\n");
  printf("pow(%d,%f) = %g\n",FLT_RADIX, logbx, pow(FLT_RADIX, logbx));
}
```

```
Output

Illustrates the logb() function (IEEE version)
```

```
x = 2.22507e-308
logb(x) = -1022.000000

pow(FLT_RADIX, logb(x) ) should equal x
pow(2,-1022.000000) = 2.22507e-308
```

Related information

- “math.h” on page 44
- “ilogb(), ilogbf(), ilogbl() — Integer unbiased exponent” on page 835

logbd32(), logbd64(), logbd128() — Unbiased exponent

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.8

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  logbd32(_Decimal32 x);
_Decimal64  logbd64(_Decimal64 x);
_Decimal128 logbd128(_Decimal128 x);

_Decimal32  logb(_Decimal32 x);     /* C++ only */
_Decimal64  logb(_Decimal64 x);     /* C++ only */
_Decimal128 logb(_Decimal128 x);    /* C++ only */
```

General description

Returns the unbiased exponent of its argument *x* as a signed integer value in decimal floating-point mode. For typical numbers, the value returned is the logarithm of |*x*| rounded down (toward -INF) to the nearest integer value.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, these functions return the unbiased exponent of *x* as a signed integer value in decimal floating-point mode.

These functions will fail under the following condition: If *x* is equal to 0.0, -HUGE_VAL_D32, -HUGE_VAL_D64, or -HUGE_VAL_D128 is returned and errno is set to EDOM.

Example

```
/* CELEBL24

   This program illustrates the use of logbd32() function

*/
```

```
#define  __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

void main()
{
  _Decimal32 x, logbx;

  printf("Illustrates the logbd32() function\n");

  /* Generate the smallest possible positive _Decimal32 number       */

  x = strtod32("0000001.E-101", NULL);

  logbx = logbd32(x);

  printf("x       = %Hg\n"  , x    );
  printf("logb(x) = %Hf\n\n", logbx);

  printf("powd32(10.0, logb32(x)) should equal x\n");
  printf("powd32(%Hf, %Hf) = %Hg\n",
         10.0DF, logbx, powd32(10.0DF, logbx));
}
```

__login(), __login_applid() — Create a new security environment for process

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	OS/390 V2R6

Format

```
#define  _OPEN_SYS
#include <unistd.h>

int __login(int   function_code,
            int   identity_type,
            int   identity_length,
            void  *identity,
            int   pass_length,
            char  *pass,
            int   certificate_length,
            char  *certificate,
            int   option_flags);
int __login_applid(int function_code,
    int identity_type,
    int identity_length,
    void *identity,
    int pass_length,
    char *pass,
    int certificate_length,
    char *certificate,
    int option_flags,
    const char *applid);
```

General description

The __login() function provides a way for a process to change its identity so as to be different than the address space identity and create a new security environment for the process. Once changed the process should not revert back to a previous identity and security environment. The following rules apply:

- Any single-threaded process can issue a __login to change its security environment.
- If the process is in a multiprocessing or multiple user environment and there is no task level security associated with the process, then the new security environment will be associated with the process.
- If the process is in a multiprocessing or multiple user environment and there is task level security associated with the process, then the old security environment will be replaced by the new security environment.

The __login_applid() function is equivalent to __login() with the added feature that it also allows the application identifier (APPLID) to be supplied that will be passed on to the security product to assist with authentication. This is useful, for example, in situations where a pass ticket is provided and the pass ticket was created with a USERID/APPLID combination. When applid is NULL or a pointer to NULL, no application identifier will be passed on to the security product.

The function has the following parameters:

Parameter
Description

function_code
Specifies the function. Specify __LOGIN_CREATE, as defined in the unistd.h header file, to create a process level security environment for the caller's process.

identity_type
Specifies the format of the the user identity being provided in **identity*. Specify __LOGIN_USERID, as defined in the unistd.h header file. The user ID identity is in the format of a 1-to-8-character userid and is passed as input.

identity_length
Specifies the length of the *identity* as defined by *identity_type*.

**identity*
Specifies the user identity as defined by *identity_type*.

pass_length
Specifies the length of the password or PassTicket, or the password phrase defined by *pass*.

**pass* Specifies a user password or PassTicket, or a password phrase.

certificate_length
Is not used presently and must be set to zero.

certificate
Is not used presently and must point to void.

option_flags
Specifies options used to tailor request. Must be set to 0.

applid Specifies the application identifier that will be used for authentication with the security product.

Usage notes

1. The intent of the __login() service is to provide a way for a process to change its identity so as to be different than the address space identity. The process should either terminate or select a new user ID, but should not try to revert back to the original identity. The user could issue the __login() again with the original user identity, but the task would retain its own security environment and not share the the security environment at the address space level.
2. A security product supporting multiprocessing or multiple user environment must be installed and operational.

Returned value

If successful, __login() returns 0.

If unsuccessful, __login() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
Permission is denied.

EINVAL
A parameter is not valid. For example, length of applid exceeds 8 bytes.

EMVSERR
An MVS environmental error or internal occurred.

EMVSEXPIRE
The password or PassTicket, or a password phrase for the specified resource has expired.

EMVSSAF2ERR
An error occurred in the security product. The userid has been revoked or is unable to use the application.

ENOSYS
The function is not implemented.

EPERM
The operation is not permitted. Calling process may not be authorized in BPX.DAEMON facility class. The function is not supported in an address space where a load was done from an uncontrolled library. A required password or PassTicket, or a password phrase was not specified.

ESRCH
The USERID cannot become an OMVS process. The userid provided is not defined to the security product or doesn't have an OMVS segment defined.

log1p(), log1pf(), log1pl() — Natural log of x+1

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double log1p(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float log1pf(float x);
long double log1pl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float log1p(float x);
long double log1p(long double x);
```

General description

Computes

$$\text{Log}_e (1.0 + x)$$

The value of x must be greater than -1.0.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
log1p	X	X
log1pf	X	X
log1pl	X	X

Returned value

If successful, log1p() returns the value of the above function of *x*.

log1p() will fail under the following conditions:
- If *x* is less than -1.0, log1p() will return -HUGE_VAL and set errno to EDOM.
- If *x* is equal to -1.0, log1p() will return -HUGE_VAL and set errno to ERANGE.

Special behavior for IEEE: If successful, log1p() returns the

$$\mathrm{Log}_e\,(1.0 + x)$$

The value of *x* must be greater than -1.0.

log1p() will fail under the following conditions:
- If *x* is less than -1.0, log1p() will return NaNQ and set errno to EDOM.
- If *x* is equal to -1.0, log1p() will return -HUGE_VAL and errno remains unchanged.

Note: When environment variable _EDC_SUSV3 is set to 2, and if *x* is equal to -1.0, the function returns -HUGE_VAL and sets errno to ERANGE.

log1pd32(), log1pd64(), log1pd128() — Natural log of x+1

Standards

Standards / Extensions	C or C++	Dependencies
C/C++ DFP	both	z/OS V1.11

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  log1pd32(_Decimal32 x);
_Decimal64  log1pd64(_Decimal64 x);
_Decimal128 log1pd128(_Decimal128 x);

_Decimal32  log1p(_Decimal32 x);     /* C++ only */
_Decimal64  log1p(_Decimal64 x);     /* C++ only */
_Decimal128 log1p(_Decimal128 x);    /* C++ only */
```

General description

Computes

$$\mathrm{Log}_e\,(1.0 + x)$$

The value of x must be greater than -1.0.

Notes:

1. These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 95IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, log1p() returns the Log (1.0 + *x*) The value of *x* must be greater than -1.0.

log1p() will fail under the following conditions:

- If *x* is less than -1.0, log1p() will return NaNQ and set errno to EDOM.
- If *x* is equal to -1.0, log1p() will return -HUGE_VAL_D32, -HUGE_VAL_D64 or -HUGE_VAL_D128 and errno remains unchanged.

Example

```
/* CELEBL27

   This exaxmple illustrates the log1pd128() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
void main(void)
{
   _Decimal128 x, y;

   x = 23.2DL;
   y = log1pd128(x);

   printf("log1pd128( %DDf ) = %DDf\n", x , y);
}
```

log10(), log10f(), log10l() — Calculate base 10 logarithm

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	

Format

```
#include <math.h>

double log10(double x);
```

```
float log10(float x);                   /* C++ only */
long double log10(long double x);       /* C++ only */
float log10f(float x);
long double log10l(long double x);
```

General description

Calculates the base 10 logarithm of the positive value of *x*.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Returns the computed value.

If *x* is negative, the function sets errno to EDOM and returns -HUGE_VAL. If *x* is 0, the function returns -HUGE_VAL, and sets errno to ERANGE. If the correct value would cause an underflow, 0 is returned and the value ERANGE is stored in errno.

Special behavior for IEEE: If successful, the function returns the base 10 logarithm of the positive value of *x*.

If *x* is negative, the function sets errno to EDOM and returns NaNQ. If *x* is 0, the function returns -HUGE_VAL and errno remains unchanged.

Note: When environment variable _EDC_SUSV3 is set to 2, and if *x* is 0, the function returns -HUGE_VAL and sets errno to ERANGE.

Example

CELEBL09

```
/* CELEBL09

   This example calculates the base 10 logarithm of 1000.0.

 */
#include <math.h>
#include <stdio.h>

int main(void)
{
   double x = 1000.0, y;

   y = log10(x);

   printf("The base 10 logarithm of %lf is %lf\n", x, y);
}
```

Output

```
The base 10 logarithm of 1000.000000 is 3.000000
```

longjmp() — Restore stack environment

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 C11 Single UNIX Specification, Version 3	both	

Format

```
#include <setjmp.h>

__noreturn__ void longjmp(jmp_buf env, int value);
```

General description

Restores a stack environment previously saved in *env* by setjmp(). The setjmp() and longjmp() functions provide a way to perform a nonlocal goto. They are often used in signal handlers.

A call to setjmp() causes the current stack environment to be saved in *env*. A subsequent call to longjmp() restores the saved environment, and returns control to a point in the program corresponding to the setjmp() call. Execution resumes as if the setjmp() call had just returned the given *value* of the value argument. All variables that are accessible to the function that receives control contain the values they had when longjmp() was called. The values of register variables are unpredictable. Nonvolatile *auto* variables that are changed between calls to setjmp() and longjmp() are also unpredictable.

Note: Ensure that the function that calls setjmp() does not return before you call the corresponding longjmp() function. Calling longjmp() after the function calling setjmp() returns causes unpredictable program behavior.

The *value* argument passed to longjmp() must be nonzero. If you give a 0 argument for *value*, longjmp() substitutes a 1 in its place.

Notes:

1. If longjmp() is used to jump back into an XPLink routine, any alloca() requests issued by the XPLink routine after the earlier setjmp() (or _setjmp(), sigsetjmp(), getcontext(), and so on) was called and before longjmp() is called are backed out. All storage obtained by these alloca() requests is freed before the XPLink routine is resumed.
2. If longjmp() is used to jump back into a non-XPLink routine, alloca() requests made after setjmp() (and so on) and before longjmp() are not backed out.

Special behavior for POSIX: In a POSIX program, the signal mask is *not* saved. Thus, to save and restore a stack environment that includes the current signal mask, use sigsetjmp() and siglongjmp() instead of setjmp() and longjmp(). The sigsetjmp()—siglongjmp() pair, the setjmp()—longjmp() pair, the _setjmp()—_longjmp() pair, and the getcontext()—setcontext() pair cannot be intermixed. A stack environment saved by setjmp() can be restored only by longjmp().

Special behavior for C++: If setjmp() and longjmp() are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. Additionally, if any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to longjmp() at the throw point that transfers control to the same (destination) point has undefined behavior. This applies to both z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of setjmp() and longjmp() in conjunction with try(), catch(), and throw() is also undefined.

Special behavior for XPG4.2: In a program that was compiled with the feature test macro, _XOPEN_SOURCE_EXTENDED, defined, another pair of functions, _setjmp()—_longjmp() are available. These functions are, on this implementation, functionally identical to setjmp()—longjmp(). Therefore it is possible, but not recommended, to intermix the setjmp()—longjmp() pair with the _setjmp()—_longjmp() pair.

Special behavior for XPLINK-compiled C++: Restrictions concerning setjmp.h and ucontext.h:

1. All XPLINK programs compiled with the Release 10 or later C compilers that are to run with Language Environment Release 10 or later libraries and use the **jmp_buf**, **sigjmp_buf** or **ucontext_t** types must not be compiled with C headers from Language Environment 2.9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define**jmp_buf**, **sigjmp_buf** or **ucontext_t** data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.
3. When __XPLINK__ is defined, the Release 10 and later headers define a larger **jmp_buf**, **sigjmp_buf** or **ucontext_t**area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Release 10 and later headers define a shorter **jmp_buf**, **sigjmp_buf** or **ucontext_t** area. The Language Environment headers before Release 10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short **jmp_buf**, **sigjmp_buf** or **ucontext_t** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

longjmp() does not use the normal function call and return mechanisms; it returns no values.

Example

This example provides for saving the stack environment at this statement:

```
if(setjmp(mark) != 0) ...
```

When the system first performs the `if` statement, it saves the environment in *mark* and sets the condition to `FALSE` because setjmp() returns a 0 when it saves the environment. The program prints the message: `setjmp has been called`

The subsequent call to function *p* tests for a local error condition, which can cause it to perform the longjmp() function. Then, control returns to the original setjmp() function using the environment saved in *mark*. This time the condition is `TRUE` because -1 is the returned value from the longjmp() function. The example then performs the statements in the block and prints: `longjmp has been called`

It then performs the *recover* function and leaves the program.

```
/*    Illustration of longjmp().     */
#include <stdio.h>
#include <setjmp.h>

jmp_buf mark;

void p(void);
void recover(void);

int main(void)
{
   if (setjmp(mark) != 0)
   {
      printf("longjmp has been called\n");
      recover();
      exit(1);
      }
   printf("setjmp has been called\n");
⋮
   p();
⋮
}

void p(void)
{
   int error = 0;
⋮
   error = 9;
⋮
   if (error != 0)
      longjmp(mark, -1);
⋮
}

void recover(void)
{
⋮
}
```

_longjmp() — Nonlocal goto

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <setjmp.h>

void _longjmp(jmp_buf env, int value);
```

General description

The _longjmp() function restores a stack environment previously saved in *env* by _setjmp(). The _setjmp() and _longjmp() functions provide a way to perform a nonlocal *goto*. They are often used in signal handlers.

A call to _setjmp() causes the current stack environment to be saved in *env*.

A subsequent call to _longjmp() restores the saved environment and returns control to a point in the program corresponding to the _setjmp() call. Execution resumes as if the _setjmp() call had just returned the given *value* of the value argument. All variables that are accessible to the function that receives control contain the values they had when _longjmp() was called. The values of register variables are unpredictable. Nonvolatile *auto* variables that are changed between calls to _setjmp() and _longjmp() are also unpredictable.

The X/Open standard states that _longjmp() and _setjmp() are functionally identical to longjmp() and setjmp(), respectively, with the addition restriction that _longjmp() and _setjmp() do not manipulate the signal mask. However, on this implementation longjmp() and setjmp() do not manipulate the signal mask. So on this implementation _longjmp() and _setjmp() are literally identical to longjmp() and setjmp(), respectively.

To save and restore a stack environment, including the current signal mask, use sigsetjmp() and siglongjmp() instead of _setjmp() and _longjmp(), or setjmp() and longjmp().

The _setjmp()—_longjmp() pair, the setjmp()—longjmp() pair, the sigsetjmp()—siglongjmp() pair, and the getcontext()—setcontext() pair cannot be intermixed. A stack environment saved by _setjmp() can be restored only by _longjmp().

Notes:

1. However, on this implementation, since the _setjmp()—_longjmp() pair are functionally identical to the setjmp()—longjmp() pair it is possible to intermix them, but it is not recommended.
2. Ensure that the function that calls _setjmp() does not return before you call the corresponding _longjmp() function. Calling _longjmp() after the function calling _setjmp() returns causes unpredictable program behavior.
3. If _longjmp() is used to jump back into an XPLink routine, any alloca() requests issued by the XPLink routine after the earlier _setjmp() (or setjmp(), sigsetjmp(),

getcontext() and so on) was called and before _longjmp() is called are backed out. All storage obtained by these alloca() requests is freed before the XPLink routine is resumed.

4. If _longjmp() is used to jump back into a non-XPLink routine, alloca() requests made after _setjmp() (and so on) and before _longjmp() are not backed out.

The *value* argument passed to _longjmp() must be nonzero. If you give a zero argument for *value*, _longjmp() substitutes a 1 in its place.

env An address for a `jmp_buf` structure

value The return value from _setjmp()

Special behavior for C++: If _setjmp() and _longjmp() are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. Additionally, if any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to _longjmp() at the throw point that transfers control to the same (destination) point has undefined behavior. This applies both to z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of _setjmp() and _longjmp() in conjunction with try(), catch(), and throw() is also undefined.

Special behavior for XPLINK-compiled C++: Restrictions concerning setjmp.h and ucontext.h:

1. All XPLINK programs compiled with the Release 10 or later C compilers that are to run with Language Environment Release 10 or later libraries and use the **jmp_buf**, **sigjmp_buf** or **ucontext_t** types must not be compiled with C headers from Language Environment 2.9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define**jmp_buf**, **sigjmp_buf** or **ucontext_t** data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.
3. When __XPLINK__ is defined, the Release 10 and later headers define a larger **jmp_buf**, **sigjmp_buf** or **ucontext_t**area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Release 10 and later headers define a shorter **jmp_buf**, **sigjmp_buf** or **ucontext_t** area. The Language Environment headers before Release 10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short **jmp_buf**, **sigjmp_buf** or **ucontext_t** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

_longjmp() does not use the normal function call and return mechanisms; it returns no values. When _longjmp() completes, program execution continues as if the corresponding invocation of _setjmp() had just returned the value specified by *value*.

lrand48() — Pseudo-random number generator

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

long int lrand48(void);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The lrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

```
X(n+1) = (aX(n) + c)mod(2**48)     n>=0
```

The initial values of X, a, and c are:

```
X(0) = 1
a   = 5deece66d (base 16)
c   = b         (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The value, X(n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function. Likewise, the values of a and c, may be changed by calling the lcong48() function. Thereafter, whenever the seed48() or srand48() function is called to change X(n), the initial values of a and c are also reestablished.

Special behavior for z/OS UNIX Services: You can make the lrand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, and the lrand48() function is called from thread t, the lrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread t. The sequence of values for a thread is generated according to the linear congruential formula:

```
X(t,n+1) = (a(t)X(t,n) + c(t))mod(2**48)     n>=0
```

The initial values of X(t), a(t) and c(t) for the thread t are:

```
X(t,0) = 1
a(t)   = 5deece66d (base 16)
c(t)   = b         (base 16)
```

C/370 provides storage which is specific to the thread t to save the most recent 48-bit integer value of the sequence, X(t,i), generated by the drand48(), lrand48() or mrand48() function. The value, X(t,n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function from the thread t. Likewise, the values of a(t) and c(t) for thread t may be changed by calling the lcong48() function from the thread. Thereafter, whenever the seed48() or srand48() function is called from the thread t to change X(t,n), the initial values of a(t) and c(t) are also reestablished.

Returned value

lrand48() transforms the generated 48-bit value, X(n+1), to a nonnegative, long integer value on the interval [0,2**31) and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the drand48 family and lrand48() is called on thread t, lrand48() transforms the generated 48-bit value, X(t,n+1), to a nonnegative, long integer value on the interval [0,2**31) and returns this transformed value.

lrint(), lrintf(), lrintl() and llrint(), llrintf(), llrintl() — Round the argument to the nearest integer

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R7

Format

```
#define _ISOC99_SOURCE
#include <math.h>

long int lrint(double x);
long int lrintf(float x);
long int lrintl(long double x);

long long int llrint(double x);
long long int llrintf(float x);
long long int llrintl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

long int lrint(float x);
long int lrint(long double x);
long long int llrint(float x);
long long int llrint(long double x);
```

Compile requirement: The llrint() family of functions requires the long long data type. See *z/OS XL C/C++ Language Reference* for information on how to make long long available.

General description

The lrint() and llrint() families of functions round their argument to the nearest integer value according to the current rounding mode. If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of *x* is too large.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
lrint	X	X
lrintf	X	X
lrintl	X	X
llrint	X	X
llrintf	X	X
llrintl	X	X

Returned value

If successful, they return the rounded integer value. If the correct value is positive or negative and too large to represent as a **long** (lrint() family) or **long long** (llrint() family), a domain error will occur and an unspecified value is returned.

Example

```
/*
 * This program illustrates the use of lrint() function
 *
 * Note: To get the output shown in this book , this program
 *       should be compiled using FLOAT(IEEE)
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>
#include <_Ieee754.h>   /* save/get fpc functions   */

char *RoundStr (_FP_rmode_t rm_type) {
  char *RndStr="undetermined";
   switch (rm_type) {
     case (_RMODE_RN):
        RndStr="round to nearest";
        break;
     case (_RMODE_RZ):
        RndStr="round toward zero";
        break;
     case (_RMODE_RP):
        RndStr="round toward +infinity ";
        break;
     case (_RMODE_RM):
        RndStr="round toward -infinity ";
        break;
   }
   return (RndStr);
}

void main() {

  _FP_fpcreg_t save_rmode, current_rmode;
  long int     rnd2nearest;
  double       number=500.99;

  printf("Illustrates the lrint() function\n");
  __fpc_rd(&current_rmode);     /* get current rounding mode */

  rnd2nearest = lrint(number);
  printf ("When rounding direction is %s:\n lrint(%.2f) = %li\n",
          RoundStr(current_rmode.rmode), number, rnd2nearest);
  save_rmode.rmode = _RMODE_RZ;
  __fpc_sm(save_rmode.rmode);   /* set rounding mode to round to zero */

  rnd2nearest = lrint(number);
  printf ("When rounding direction is %s:\n lrint(%.2f) = %li\n",
          RoundStr(save_rmode.rmode), number, rnd2nearest);
}

Output

Illustrates the lrint() function
When rounding direction is round to nearest:
 lrint(500.99) = 501
When rounding direction is round toward zero:
 lrint(500.99) = 500
```

lround(), lroundf(), lroundl() — Round a decimal floating-point number to its nearest integer

Standards

Standards / Extensions	C or C++	Dependencies
C99 Single UNIX Specification, Version 3 C++ TR1 C99	both	z/OS V1R5

Format

```
#define _ISOC99_SOURCE
#include <math.h>

long int lround(double x);
long int lroundf(float x);
long int lroundl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

long lround(float x);
long lround(long double x);
```

General description

The lround functions round x to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding mode.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Function	Hex	IEEE
lround	X	X
lroundf	X	X
lroundl	X	X

Returned value

The lround functions return the rounded integer value of *x*.

If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of *x* is too large.

lsearch() — Linear search and update

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <search.h>

void *lsearch(const void *key, void *base, size_t *nelp,
              size_t width,
              int (*compar)(const void *, const void *));
```

General description

The lsearch() function is a linear search routine. It returns a pointer into a table indicating where an entry may be found. If the entry does not occur, it is added at the end of the table. The *key* argument points to the entry to be sought in the table. The base argument points to the first element in the table. The *width* argument is the size of an element in bytes. The *nelp* argument points to an integer containing the current number of elements in the table. The integer to which *nelp* points is incremented if the entry is added to the table. The *compar* argument points to a comparison function which the user must supply (strcmp(), for example). It is called with two arguments that point to the elements being compared. The function must return 0 if the elements are equal and nonzero otherwise.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, lsearch() cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to lsearch(), the compiler will flag it as an error. You can pass a C or C++ function to lsearch() by declaring it as extern "C".

Returned value

If the searched for entry is found, lsearch() returns a pointer to it.

If not found, lsearch() returns a pointer to the newly added element. A NULL pointer is returned in case of error.

No errors are defined.

lseek() — Change the offset of a file

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

off_t lseek(int fildes, off_t offset, int pos);
```

General description

Changes the current file offset to a new position in a z/OS UNIX file. The new position is the given byte *offset* from the position specified by *pos*. After you have used lseek() to seek to a new location, the next I/O operation on the file begins at that location.

lseek() lets you specify new file offsets past the current end of the file. If data is written at such a point, read operations in the gap between this data and the old end of the file will return bytes containing zeros. (In other words, the gap is assumed to be filled with zeros.)

Seeking past the end of a file, however, does not automatically extend the length of the file. There must be a write operation before the file is actually extended.

Special behavior for POSIX C: For character special files, lseek() sets the file offset to the specified value. z/OS UNIX services ignore the file offset value during the read/write processing to character special files.

int *fildes***;**
The file whose current file offset you want to change.

off_t *offset***;**
The amount (positive or negative) the byte offset is to be changed. The sign indicates whether the offset is to be moved forward (positive) or backward (negative).

int *pos***;**
One of the following symbols (defined in the unistd.h header file):

SEEK_SET
The start of the file

SEEK_CUR
The current file offset in the file

SEEK_END
The end of the file

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, lseek() returns the new file offset, measured in bytes from the beginning of the file.

If unsuccessful, lseek() returns -1 and sets errno to one of the following values:

Error Code
Description

EBADF
fildes is not a valid open file descriptor.

EINVAL
pos contained something other than one of the three options, or the combination of the *pos* values would have placed the file offset before the beginning of the file.

EOVERFLOW
The resulting file offset would be a value which cannot be represented correctly in an object of type off_t.

ESPIPE
fildes is associated with a pipe or FIFO special file.

Example

This fragment positions a file (that has at least 10 bytes) to an offset of 10 bytes before the end of the file.

```
lseek(fildes,-10,SEEK_END);
```

lstat() — Get status of file or symbolic link

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX1_SOURCE 2
#include <sys/stat.h>

int lstat(const char *__restrict__ pathname, struct stat *__restrict__ buf);
```

General description

Gets status information about a specified file and places it in the area of memory pointed to by the *buf* argument. You do not need permissions on the file itself, but you must have search permission on all directory components of the *pathname*.

If the named file is a symbolic link, lstat() returns information about the symbolic link itself.

The information is returned in the following stat structure, defined in the sys/stat.h header file.

Table 43. Elements of stat Structure

Structure	Description
mode_t st_mode	A bit string indicating the permissions and privileges of the file. Symbols are defined in the sys/stat.h header file to refer to bits in a mode_t value; these symbols are listed in "chmod() — Change the mode of a file or directory" on page 272.
ino_t st_ino	The serial number of the file.
dev_t st_dev	The numeric ID of the device containing the file.
nlink_t st_nlink	The number of links to the file.

Table 43. Elements of stat Structure (continued)

Structure	Description
uid_t st_uid	The numeric user ID of the file's owner.
gid_t st_gid	The numeric group ID of the file's group.
off_t st_size	For regular files, the file's size in bytes. For symbolic links, the length of the pathname contained therein not counting the trailing NULL. For other kinds of files, the value of this field is unspecified.
time_t st_atime	The most recent time the file was accessed.
time_t st_ctime	The most recent time the status of the file was changed.
time_t st_mtime	The most recent time the contents of the file were changed.

Values for `time_t` are given in terms of seconds that have elapsed since epoch.

If the named file is a symbolic link, lstat() updates the time-related fields before putting information in the `stat` structure.

You can examine properties of a `mode_t` value from the `st_mode` field by using a collection of macros defined in the sys/modes.h header file. If *mode* is a `mode_t` value, and *genvalue* is an `unsigned int` value from the stat structure, then:

S_ISBLK(*mode***)**
Is nonzero for block special files.

S_ISCHR(*mode***)**
Is nonzero for character special files.

S_ISDIR(*mode***)**
Is nonzero for directories.

S_ISEXTL(*mode,genvalue***)**
Is nonzero for external links.

S_ISFIFO(*mode***)**
Is nonzero for pipes and FIFO special files.

S_ISLNK(*mode***)**
Is nonzero for symbolic links.

S_ISREG(*mode***)**
Is nonzero for regular files.

S_ISSOCK(*mode***)**
Is nonzero for sockets.

If lstat() successfully determines all this information, it stores it in the area indicated by the *buf* argument.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, lstat() returns 0.

If unsuccessful, lstat() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The process does not have search permission on some component of the *pathname* prefix.

EINVAL
buf contains a NULL.

EIO
Added for XPG4.2: An I/O error occurred while reading from the file system.

ELOOP
A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of the *pathname* argument is greater than POSIX_SYMLOOP.

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined through pathconf().

ENOENT
There is no file named *pathname*, or *pathname* is an empty string.

ENOTDIR
A component of the *pathname* prefix is not a directory.

EOVERFLOW
The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by buf.

Note: Starting with z/OS V1.9, environment variable _EDC_EOVERFLOW can be used to control behavior of lstat() with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, lstat() will not set EOVERFLOW when the file size can not be represented correctly in structure pointed to by buf. When _EDC_EOVERFLOW is set to YES, lstat() will check for an overflow condition.

Example

CELEBL12

```
/* CELEBL12

   This example provides status information for a file.

 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
```

```
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <time.h>

main() {
  char fn[]="temp.file", ln[]="temp.link";
  struct stat info;
  int fd;

  if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    close(fd);
    if (link(fn, ln) != 0)
      perror("link() error");
    else {
      if (lstat(ln, &info) != 0)
        perror("lstat() error");
      else {
        puts("lstat() returned:");
        printf("  inode:   %d\n",   (int) info.st_ino);
        printf(" dev id:   %d\n",   (int) info.st_dev);
        printf("   mode:   %08x\n",       info.st_mode);
        printf("  links:   %d\n",         info.st_nlink);
        printf("    uid:   %d\n",   (int) info.st_uid);
        printf("    gid:   %d\n",   (int) info.st_gid);
        printf("created:   %s",           ctime(&info.st_createtime));
      }
      unlink(ln);
    }
    unlink(fn);
  }
}
```

Output

```
lstat() returned:
  inode:   3022
 dev id:   1
   mode:   03000080
  links:   2
    uid:   25
    gid:   500
created:   Fri Jun 16 15:00:00 2006
```

l64a() — Convert long to base 64 string representation

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define  _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *l64a(long value);
```

General description

The l64a() function converts a long integer into its corresponding base 64 character representation. In this notation, long integers are represented by up to 6 characters, each character representing a digit in base 64 notation. The following characters are used to represent digits:

Character	Digit represented
.	0
/	1
0-9	2-11
A-Z	12-37
a-z	38-63

Returned value

l64a() returns a pointer to the base 64 representation of *value*. If *value* is zero, l64a() returns a pointer to a NULL string.

l64a() returns a pointer to a static buffer, which will be overwritten by subsequent calls. Buffers are allocated on a per-thread basis.

There are no errno values defined.

Related information

- "stdlib.h" on page 70
- "a64l() — Convert base 64 string representation to long integer" on page 207

ltoa() — Convert long into a string

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	z/OS V1R5

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * ltoa(long l, char * buffer, int radix);
```

General description

The ltoa() function coverts the long *l* into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, ltoa() produces the same result as the following statement:

```
(void) sprintf(buffer, "%ld", l);
```

with buffer the returned character string. When the radix is OCTAL, ltoa() formats long *l* into an unsigned octal constant. When the radix is HEX, ltoa() formats long *l* into an unsigned hexadecimal constant. The hexadecimal value will include lower case abcdef, as necessary

Usage note

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Returned value

String pointer (same as buffer) will be returned. When passed an invalid radix argument, function will return NULL and set errno to EINVAL.

Example

CELEBL29

```
/* CELEBL29

   This example reads a long int and formats it to decimal, unsigned
   octal, unsigned hexadecimal constants converted to a character
   string.

*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
   long i;
   char buffer [sizeof(long)*8+1];
   printf ("Enter a number: ");
   if (scanf ("%ld",&i) == 1) {
      ltoa (i,buffer,DECIMAL);
      printf ("decimal: %s\n",buffer);
      ltoa (i,buffer,HEX);
      printf ("hexadecimal: %s\n",buffer);
      ltoa (i,buffer,OCTAL);
      printf ("octal: %s\n",buffer);
   }
   return 0;
}
```

Output

If the input is 1234, then the output should be:

```
decimal: 1234
hexadecimal: 4d2
octal: 2322
```

makecontext() — Modify user context

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

void makecontext(ucontext_t *ucp, void (*func)(), int argc, ...);
```

General description

The makecontext() function modifies the context specified by *ucp*, which has been initialized using getcontext(). When this context is resumed using setcontext() or swapcontext(), program execution continues by calling *func()*, passing it the arguments that follow *argc* in the makecontext() call.

The value of *argc* must match the number of integer arguments passed to *func()*, otherwise the behavior is undefined.

The **uc_link** member of **ucontext_t** is used to determine the context that will be resumed when the context being modified by makecontext() returns. If the **uc_link** member is not equal to 0, the process continues as if after a call to setcontext() with the context pointed to by the **uc_link** member. If the **uc_link** member is equal to 0, the process exits as if exit() were called. The **uc_link** member should be initialized before the call to makecontext().

This function is supported only in a POSIX program.

This function is not supported in an AMODE 31 XPLINK environment (for example, one which is in AMODE 31 and in which either the main() function was compiled with the XPLINK option, or the XPLINK(ON) runtime option was specified).

The **<ucontext.h>** header file defines the **ucontext_t** type as a structure that includes the following members:

```
mcontext_t       uc_mcontext     A machine-specific representation
                                 of the saved context.
ucontext_t      *uc_link         Pointer to the context that will
                                 be resumed when this context returns.
sigset_t         uc_sigmask      The set of signals that are blocked
                                 when this context is active.
stack_t          uc_stack        The stack used by this context.
```

Special behavior for C++

Because C and C++ linkage conventions are incompatible, makecontext() cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to makecontext(), the compiler will flag it as an error. To use the C++ makecontext() function, you must ensure that all functions registered for makecontext() have C linkage by declaring them as `extern "C"`. For example:

```
C:   void func(int, int);
     :
     makecontext(&context, func, 2, arg1, arg2);

C++: extern "C" void func();
     :
     makecontext(&context, func, 2, arg1, arg2);
```

AMODE 64 considerations

Storage for the stack must be above the 2GB bar. It may not be storage acquired with the __malloc24() or __malloc31() functions. The stack must be big enough to allow for the creation of a 1M guard page (aligned on a 1M boundary).

The environment variable _EDC_CONTEXT_GUARD can be used to control when the stack is guarded and unguarded. For details on the _EDC_CONTEXT_GUARD environment variable, see the "Using Environment Variables" chapter in *z/OS XL C/C++ Programming Guide*.

Returned value

makecontext() returns no values.

If unsuccessful, makecontext() sets errno to one of the following values:

Error Code
    Description

EINVAL
    The context being modified is using an alternate stack, and the target function entry point is not a valid Language Environment or C entry point.

The *argc* argument specifies a value less than 0.

ENOMEM
The *ucp* argument does not have enough stack left to complete the operation. Or more than 15 arguments are passed to the target function, and there is not enough storage to hold all of the arguments.

Note: If the target function is in a DLL that has not yet been loaded, then makecontext() cannot determine the size requirement and assumes that the size required is MINSIGSTKSZ. Therefore, in this case, the stack must be at least the size indicated by MINSIGSTKSZ. If the size required by the target function is more than MINSIGSTKSZ, then you must load the DLL before invoking makecontext().

Example

This example creates a context in main with the getcontext() statement, then modifies the context to have its own stack and to invoke the function *func*. It invokes the function with the setcontext() statement. Since the **uc_link** member is set to 0, the process exits when the function returns.

```
/* This example shows the usage of makecontext().                   */

#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>
#include <stdio.h>
#include <ucontext.h>
#include <errno.h>

 #ifdef _LP64
  #define STACK_SIZE 2097152+16384 /* large enough value for AMODE 64 */
 #else
  #define STACK_SIZE 16384         /* AMODE 31 addressing */
 #endif

void func(int);

ucontext_t context, *cp = &context;

int main(void) {

  int  value = 1;

  getcontext(cp);
  context.uc_link = 0;
  if ((context.uc_stack.ss_sp = (char *) malloc(STACK_SIZE)) != NULL) {
    context.uc_stack.ss_size = STACK_SIZE;
    context.uc_stack.ss_flags = 0;
             errno = 0;
    makecontext(cp,func,1,value);
              if(errno != 0){
                perror("Error reported by makecontext()");
                return -1;        /* Error occurred exit */ }
  }
  else {
    perror("not enough storage for stack");
    abort();
  }
  printf("context has been built\n");
  setcontext(cp);
  perror("returned from setcontext");
  abort();

}
```

```
void func(int arg) {

  printf("function called with value %d\n",arg);
  printf("process will exit when function returns\n");
  return;

}
```

Output

```
context has been built
function called with value 1
process will exit when function returns
```

malloc() — Reserve storage block

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

void *malloc(size_t size);
```

General description

Reserves a block of storage of *size* bytes. Unlike the calloc() function, the content of the storage allocated is indeterminate. The storage to which the returned value points is always aligned for storage of any type of object. Under z/OS XL C only, if 4K alignment is required, use the __4kmalc() function. (This function is available to C applications in stand-alone System Productivity Facility (SPF) applications.) The library functions specific to the System Programming C (SPC) environment are described in *z/OS XL C/C++ Programming Guide*.

Special behavior for C++

The C++ keywords new and delete are not interoperable with calloc(), free(), malloc(), or realloc().

Returned value

If successful, malloc() returns a pointer to the reserved space. The storage space to which the returned value points is always suitably aligned for storage of any type of object.

If not enough storage is available, or if *size* was specified as 0, malloc() returns NULL. If malloc() returns NULL because there is not enough storage, it sets errno to one of the following values:

Error Code
Description

ENOMEM
Insufficient memory is available

Example

CELEBM01

```
/* CELEBM01

   This example prompts you for the number of array entries you
   want and then reserves enough space in storage for the entries.
   If &malloc. was successful, the example assigns values
   to the entries and prints out each entry; otherwise, it prints
   out an error.

 */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
  long * array;    /* start of the array */
  long * index;    /* index variable     */
  int    i;        /* index variable     */
  int  num;        /* number of entries of the array */

  printf( "Enter the size of the array\n" );
  scanf( "%i", &num );

  /* allocate num entries */
  if ( (index = array = (long * )malloc( num * sizeof( long ))) != NULL )
  {

    for ( i = 0; i < num; ++i )           /* put values in array    */
       *index++ = i;                      /* using pointer notation */

    for ( i = 0; i < num; ++i )           /* print the array out    */
      printf( "array[ %i ] = %i\n", i, array[i] );
  }
  else { /* malloc error */
    printf( "Out of storage\n" );
    abort();
  }
}
```

Output

```
Enter the size of the array
array[ 0 ] = 0
array[ 1 ] = 1
array[ 2 ] = 2
array[ 3 ] = 3
array[ 4 ] = 4
```

__malloc24() — Allocate 24-bit storage

Standards

Standards / Extensions	C or C++	Dependencies
	both	AMODE 64

Format

```
#include <stdlib.h>

void  *__malloc24(size_t size);
```

General description

Reserves a block of storage of *size* bytes from “below-the-line” storage (that is, below 16 MB).

Returned value

If successful, __malloc24() returns a pointer to the reserved space. The storage space to which the returned value points is always suitably aligned for storage of any type of object.

If not enough storage is available, or if *size* was specified as 0, __malloc24() returns NULL. If __malloc24() returns NULL because there is not enough storage, it sets errno to one of the following values:

Error Code
Description

ENOMEM
Insufficient memory is available

__malloc31() — Allocate 31–bit storage

Standards

Standards / Extensions	C or C++	Dependencies
	both	AMODE 64

Format

```
#include <stdlib.h>

void  *__malloc31(size_t size);
```

General description

Reserves a block of storage of *size* bytes from "below-the-bar" storage (that is, below 2 GB).

Returned value

If successful, __malloc31() returns a pointer to the reserved space. The storage space to which the returned value points is always suitably aligned for storage of any type of object.

If not enough storage is available, or if *size* was specified as 0, __malloc31() returns NULL. If __malloc31() returns NULL because there is not enough storage, it sets errno to one of the following values:

Error Code
    Description

ENOMEM
    Insufficient memory is available

__map_init() — Designate a storage area for mapping blocks

Standards

Standards / Extensions	C or C++	Dependencies
	both	POSIX(ON) OS/390 V2R9

Format

```
#define _OPEN_SYS_MAP_EXTENTION
#include <sys/mman.h>

int __map_init(struct _Mmg_init *parmlist);
```

General description

The __map_init() function allocates a map area in the private area of the calling address space. This map area is propagated to child address spaces on fork, which is the only way that multiple processes can share a map area. The application can connect and disconnect blocks of storage in the map area, providing a very fast way to connect up to persistent memory. The __map_init() function is meant to be used by applications which need more shared memory or mmap storage than will fit in the address space.

The application should set the following values in the _Mmg_init structure:

Element
: **Description**

_Mmg_numblks
: Set to the number of blocks to be contained in the map area.

_Mmg_megsperblk
: Set to the size in megabytes of each block in the map area.

_Mmg_token
: Set to an 8 character map token when successful. This map token should be saved and must be used as a parameter on calls to the __map_service() function calls.

_Mmg_res01a
: Reserved, set to 0.

_Mmg_res01b
: Reserved, set to 0.

_Mmg_areaaddr
: As input, set to 0 if you want the address assigned or set to the address of storage where you want the map to begin. As output, this field contains the actual address of the map area.

Usage notes

- It is intended that the application call the __map_init() service once to create the map area.
- The application then issues fork to create child processes which will inherit a map area initialized to the hidden state.
- The initial process or the child (and grandchildren) process can then use the __map_service to connect and disconnect blocks of storage which are persistent until explicitly deleted.
- When the process which created the initial map area terminates, all further activity against the map blocks is terminated. The map blocks are then deleted when the last child process with an active map area terminates.
- There is no explicit call to delete the map area. This is unlike shared memory or other IPC constructs.

Returned value

If successful, __map_init() returns NULL.

If unsuccessful, __map_init() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EEXIST
: An attempt was made to create more than one map for the process.

EFAULT
: The *parmlist* (_Mmg_init structure) has an argument that is not accessible to the caller.

EINVAL
: One of the following occurred:

The number of blocks (_Mmg_numblks) was zero or negative.

The number of megabytes per block (_Mmg_Megsperblk) was zero or negative.

A reserved field contained nonzero data.

The specified address (_Mmg_areaaddr) is not on a megabyte multiple.

EMVSSAF2ERR
An error occurred in the security product. Use the __errno2() function to retrieve the reason code to determine the exact reason the error occurred.

ENOMEM
The requested storage at location _Mmg_areaaddr or the size requested could not be obtained. The storage is either not available or your Region size is too small to contain the map area. Or, there is insufficient free virtual storage in the address space to satisfy the request.

EPERM
The user is not authorized to use the __map_init() function. Callers must be permitted to the BPX.MAP FACILITY class profile to use this service.

Related information

- "sys/mman.h" on page 73
- "__map_service() — Set memory mapping service"

__map_service() — Set memory mapping service

Standards

Standards / Extensions	C or C++	Dependencies
	both	POSIX(ON) OS/390 V2R9

Format

```
#define _OPEN_SYS_MAP_EXTENTION
#include <sys/mman.h>

int __map_service(struct _Mmg_service *parmlist, int count, *_Map_token_t);
```

General description

The __map_service() function is used to manipulate the map area created by the __map_init() function. The supported functions are defined under _Mmg_servicetype below.

Before calling the __map_service() service, the application should set values in the _Mmg_service structure as follows:

Element
Description

_Mmg_servicetype
Set the type of service being requested for each memory block defined in the array.

Request
Description

_Mmg_newblock
Set for an allocation of a new data block in the mapped area.

_Mmg_conn
Set to request that a data block be connected at the requested location in the map area.

_Mmg_disconn
Set to disconnect a data block from the map area.

_Mmg_free
Set to free the storage backing a data block.

_Mmg_cntl
Set to change the read or write permission settings for a data block.

_Mmg_serviceIflag
Used for _Mmg_cntl to indicate read or write and all other bits set to zero. For _Mmg_disconn to indicate if the backing storage is to be freed after disconnect. For _Mmg_newblock the option of _Mmg_NoConn can be set on to bypass the connect to the map area block. The token returned will have to be saved and used for connect services on a later call to make the block accessible. For all other _Mmg_serviceItype requests, set all the bits to zero.

_Mmg_serviceOflag
Used for status of the request. When the request has been successfully processed all the bits are set to zero. When processing an list of requests and a failure occurs in _Mmg_Reqfail is set on and further processing on the list is aborted. _Mmg_servicetype requests, set all the bits to zero.

_Mmg_token
This is returned as output for a _Mmg_newblock request and is used as input for _Mmg_conn, and _Mmg_free. It is ignored for _Mmg_disconn and _Mng_cntl.

_Mmg_res0b
Reserved, set to 0.

_Mmg_blkaddr
For _Mmg_newblock and _Mmg_conn this is input. It should be set to an address within the map area (on a block multiple) where you want to allocate a block or 0. If 0 is specified, the first available block in the map area is used. On output, this field contains the address within the map area that was assigned to the data block. For _Mmg_disconn it is input only and contains the address of the map block to be disconnected. For _Mng_cntl this field is required and specifies the block to be use for the _Mmg_cntl option. For _Mmg_free, _Mmg_cntl and _Mmg_newblock, when the option of _Mmg_NoConn is set on, this field is ignored.

With *count* reflecting the number of _Mmg_service structures included in the array structure supplied on *parmlist* parameter. With *count* a positive integer in the range of 1-1000.

With *_Map_token_t* the 8 character token retrieved from the _Mmg_token field in a _Mmg_service structure that returned successful from a __map_init() function call.

Usage notes

- The __map_init and the __map_service functions are intended to be used in the following manner:
  - The initial process calls __map_init to create a map area large enough for the biggest expected usage.
  - The initial process forks worker processes which inherit the map area at the same virtual address. By having the map area at the same virtual address, storage blocks can be connected to the same block in map areas of different

worker processes and pointers can be used to point to data in this or other blocks. This assumes they are always connected at the same location in the map area.

- As worker processes perform their tasks, they can request new blocks of storage to be created in the map area. Each block has a token associated with it. This token allows other worker processes to connect to the same block. In this respect, the map area acts like shared memory.
- The worker processes can connect as many blocks to their map area as will fit.
- When the worker process has no further need for a data block, it can disconnect it from the map area. After a delete request for a block, this block is actually freed when the last worker process disconnects for this block.
- When a worker process is completely done with a data block, the storage can be freed. This data is actually freed when the last worker process disconnects from that block.
- Using these services, the application could create multiple gigabytes of storage, of which only certain blocks are mapped into the worker processes at a given time.
- This service is designed to perform the storage connects and disconnects very fast. No data movement occurs.
- Storage blocks are initially connected in write mode. When a block is in write mode, all worker processes which have the block connected, have the block in write mode. If the block access is changed to read-only, then all worker processes which have the block connected, have the block in read-only mode.
- If the initial process or a worker process forks, then the child process inherits a map area initialized to the hidden state.
- Any areas within the map area which do not have a block connected are in the hidden state. Any reference to storage in the hidden state will trigger a SIGSEGV signal.

Returned value

If successful, __map_service() returns 0.

If unsuccessful, __map_service() returns -1 and sets errno to one of the following values:

Error Code
: **Description**

EEXIST
: A request was made to perform a service on a block but a map is not currently active in the process.

EFAULT
: The *parmlist* (_Mmg_service structure) argument addresses either could not be accessed or was in read-only storage and could not be updated.

EINVAL
: For one of the following reasons:

  The block address provided is either not in the map area or it is not on a map block boundary.

  A request was made to connect to a block or free the backing storage for a block but the token provided does not match that of any allocated block in the backing store.

  A request was made to disconnect from a block but the block is not currently in the map area for this process.

A newblock or connect request was specified for a map area block that is already in use.

A request was made to connect to a block in the backing store that is currently marked to be freed. The connect is not permitted.

The *count* value was not a positive integer in the range of 1-1000.

ENOMEM
A request to create a new block or connect to an existing block was made but there are no unused blocks in the map area to satisfy the request.

maxdesc() — Get socket numbers to extend beyond the default range

Standards

Standards / Extensions	C or C++	Dependencies
z/OS UNIX	both	

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/types.h>
#include <sys/socket.h>

int maxdesc(int *totdesc, int *inetdesc);
```

General description

Bulk mode sockets are not supported. Do not use this function.

Returned value

If successful, maxdesc() returns 0.

If unsuccessful, maxdesc() returns -1 and sets errno to one of the following values:

Error Code
  Description

EALREADY
  Your program called maxdesc() after creating a socket, after a call to setibmsockopt(), or after a previous call to maxdesc().

EFAULT
  Using the totdesc parameter as specified results in an attempt to access storage outside of the caller's address space, or storage not modifiable by the caller.

ENOMEM
  Your address space has insufficient storage.

mblen() — Calculate length of multibyte character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

int mblen(const char *string, size_t n);
```

General description

Determines the length in bytes of the multibyte character pointed to by *string*. A maximum of *n* bytes is examined.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. Changing the LC_CTYPE category invalidates the internal shift state: undefined results can occur.

If the current locale supports EBCDIC DBCS characters, then the shift state is updated where applicable. (See "Conforming to ANSI Standards" in *z/OS XL C/C++ Language Reference*.) The length returned may be up to 4 (for the shift-out character, 2-byte code, and the shift-in character). If *string* is a NULL pointer, this function resets itself to the initial state.

The function maintains the internal shift state that is altered by subsequent calls.

Returned value

If *string* is NULL, mblen() returns:
- Nonzero when DBCS-host code (EBCDIC systems) is used
- Nonzero if multibyte encodings are state-dependent
- Zero otherwise

If *string* is not NULL, mblen() returns:
- Zero if *string* points to the NULL character
- The number of bytes comprising the multibyte character
- The value -1 if *string* does not point to a valid multibyte character

Example

```
#include <locale.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *mbs = "a"
                "\x0E"      /* shift out */
                "\x44\x66"  /* <j0158> */
                "\x44\x76"  /* <j0159> */
                "\x42\x4e"  /* <j0160> */
                "\x0F"      /* shift in */
                "b";
    char *loc = setlocale(LC_ALL, "JA_JP.IBM-939");
    int n;

    if (!loc)   /* setlocale() failure */
    {
        exit(8);
    }

    printf("We're in the %s locale.\n", loc);

    n = mblen(NULL, MB_CUR_MAX);
    /*****************************************************************/
    /* n is nonzero, indicating state-dependent encoding; mblen() has */
    /* forced the internal shift state to "initial".                 */
    /*****************************************************************/
    printf("n = mblen(NULL, MB_CUR_MAX);     ===> n = %s\n",
        n ? "NONZERO" : "ZERO");

    n = mblen(mbs, MB_CUR_MAX);
    /*****************************************************************/
    /* n is 1, 'a' is a multibyte character of length 1, internal    */
    /* shift state remains at "initial".                             */
    /*****************************************************************/
    printf("n = mblen(mbs, MB_CUR_MAX);      ===> n = %d\n", n);
    n = mblen(mbs + 1, MB_CUR_MAX);
    /******************************************************************/
    /* n is 3, 'shift out' plus two byte character '<j0158>'.  The    */
    /* internal state changes to "shift out".                         */
    /******************************************************************/
    printf("n = mblen(mbs + 1, MB_CUR_MAX);  ===> n = %d\n", n);

    n = mblen(mbs + 4, MB_CUR_MAX);
    /******************************************************************/
    /* n is 2, two byte character '<j0159>'.  The internal shift      */
    /* state remains "shift out"                                      */
    /******************************************************************/
    printf("n = mblen(mbs + 4, MB_CUR_MAX);  ===> n = %d\n", n);

    n = mblen(mbs + 6, MB_CUR_MAX);
    /******************************************************************/
    /* n is 3, two byte character '<j0160>' plus 'shift in'.  The     */
    /* internal shift state returns to "initial".                     */
    /******************************************************************/
    printf("n = mblen(mbs + 6, MB_CUR_MAX);  ===> n = %d\n", n);

    n = mblen(mbs + 9, MB_CUR_MAX);
    /******************************************************************/
    /* n is 1, 'b' is a multibyte character of length 1, internal     */
    /* shift state remains at "initial".                              */
    /******************************************************************/
    printf("n = mblen(mbs + 9, MB_CUR_MAX);  ===> n = %d\n", n);

    n = mblen(mbs + 10, MB_CUR_MAX);
    /******************************************************************/
    /* n is 0 (end of multibyte character string).                    */
    /******************************************************************/
    printf("n = mblen(mbs + 10, MB_CUR_MAX); ===> n = %d\n", n);

    return 0;
}
```

Output

```
We're in the JA_JP.IBM-939 locale.
n = mblen(NULL, MB_CUR_MAX);     ===> n = NONZERO
n = mblen(mbs, MB_CUR_MAX);      ===> n = 1
n = mblen(mbs + 1, MB_CUR_MAX);  ===> n = 3
n = mblen(mbs + 4, MB_CUR_MAX);  ===> n = 2
n = mblen(mbs + 6, MB_CUR_MAX);  ===> n = 3
n = mblen(mbs + 9, MB_CUR_MAX);  ===> n = 1
n = mblen(mbs + 10, MB_CUR_MAX); ===> n = 0
```

mbrlen() — Calculate length of multibyte character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C99 Single UNIX Specification, Version 3	both	

Format

Non-XPG4

```
#include <wchar.h>

size_t mbrlen(const char * __restrict__s, size_t n, mbstate_t * __restrict__ps);
```

XPG4

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbrlen(const char *s, size_t n, mbstate_t *ps);
```

General description

Calculates the number of bytes required to return to the initial shift state. This is equivalent to

```
   mbrtowc((wchar_t *)0, s, n, ps != NULL ? ps : &internal);
```

where `&internal` is the address of the internal `mbstate_t` object for the mbrlen() function.

mbrlen() is a restartable version of mblen(). That is, shift state information is passed as one of the arguments, and is updated on exit. With mbrlen(), you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbrlen() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If *s* is a NULL pointer, mbrlen() resets the shift state to the initial shift state and returns 0.

If *s* is not a NULL pointer, mbrlen() returns the first of the following that applies.

0 If the next *n* or fewer bytes complete the valid multibyte character that corresponds to the NULL wide character.

positive
If the next *n* or fewer bytes complete the valid multibyte character; the value returned is the number of bytes that complete the multibyte character.

-2 If the next *n* bytes form an incomplete (but potentially valid) multibyte character, and all *n* bytes have been processed; it is unspecified whether this can occur when the value of *n* is less than that of the MB_CUR_MAX macro.

Note: When a -2 value is returned, and *n* is at least MB_CUR_MAX, the string would contain redundant shift-out and shift-in characters. To continue processing the multibyte string, increment the pointer by the value *n*, and call the mbrtowc() function.

-1 If an encoding error occurs (when the next *n* or fewer bytes do not contribute to the complete and valid multibyte character), the value of the macro EILSEQ is stored in errno, but the conversion state remains unchanged.

Example

CELEBM03

```
/* CELEBM03 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
   char      mbs[5] = "a";    /* string containing the multibyte char */
   mbstate_t ss     = 0;      /* set shift state to the initial state */
   int       length;

   /* Determine the length in bytes of a multibyte character pointed  */
   /* to by mbs.                                                      */

   length = mbrlen(mbs, MB_CUR_MAX, &ss);

   printf("    length: %d \n", length);
   printf("       mbs:\"%s\"\n", mbs);
   printf("MB_CUR_MAX: %d \n", MB_CUR_MAX);
   printf("        ss: %d \n", ss);
}
```

Output

```
    length: 1
       mbs:"a"
MB_CUR_MAX: 4
        ss: 0
```

mbrtoc16() — Convert a multibyte character to a char16_t character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C11	both	z/OS V2R1

Format

```
#include <uchar.h>

size_t mbrtoc16(char16_t * restrict pc16,
                const char * restrict s,
                size_t n,
                mbstate_t * restrict ps);
```

General description

The mbrtoc16() function converts a multibyte character to a wide character of type char16_t, and returns the number of bytes of the multibyte character.

If *s* is not a null pointer, the mbrtoc16() function inspects at most *n* bytes beginning with the byte pointed to by *s* to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding wide characters and then, if *pc16* is not a null pointer, stores the value of the first (or only) such character in the object pointed to by *pc16*. Subsequent calls will store successive wide characters without consuming any additional input until all the characters have been stored. If the corresponding wide character is the null wide character, the resulting state described is the initial conversion state.

If *s* is a null pointer, the mbrtoc16() function is equivalent to the call `mbrtoc16(NULL,"",1,ps)`. In this case, the values of the parameters *pc16* and *n* are ignored.

If *ps* is a null pointer, mbrtoc16() uses its own internal object to track the shift state. Otherwise **ps* must be a valid mbstate_t object. An mbstate_t object **ps* can be initialized to the initial state by assigning 0 to it, or by calling `mbrtoc16(NULL,NULL,0,ps)`.

Usage notes

1. To use the mbrtoc16() function, compile the source code with the LANGLVL(EXTC1X) option.
2. The mbrtoc16() function only supports the CCSIDs that are provided by Unicode Services.

3. The result of converting multiple string alternately in one thread by using multiple mbstate_t objects (including the internal one) is undefined.

Returned value

The mbrtoc16() function returns the first of the following that applies (given the current conversion state):

0
: If the next *n* or fewer bytes complete the multibyte character that corresponds to the null wide character (which is the value stored).

between 1 and *n* inclusive
: If the next *n* or fewer bytes complete a valid multibyte character (which is the value stored); the value returned is the number of bytes that complete the multibyte character.

-3
: If the next character resulting from a previous call has been stored (no byte from the input has been consumed by this call).

-2
: If the next *n* bytes contribute to an incomplete (but potentially valid) multibyte character, and all *n* bytes have been processed (no value is stored). When *n* has at least the value of the MB_CUR_MAX macro, this case can only occur if *s* points to a sequence of redundant shift sequence (for implementations with state-dependent encodings).

-1
: If an encoding error occurs (when the next *n* or fewer bytes do not contribute to a complete and valid multibyte character). The value of the macro EILSEQ is stored in errno, and the conversion state is unspecified.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <uchar.h>

int main(void)
{
   char16_t c16;
   char mbs[] = "a" ; /* string containing the multibyte character */
   mbstate_t ss = 0 ;    /* set shift state to the initial state */
   int length = 0 ;

   /* Determine the length of the multibyte character pointed to by */
   /* mbs. Store the multibyte character in the char16_t object */
   /* called c16. */

   length = mbrtoc16(&c16, mbs, MB_CUR_MAX, &ss);
   if (length < 0) {
      /* -2 and -3 return value could not happen during converting the 'a' */
      perror("mbrtoc16() fails to convert");
      exit(-1);
   }

   printf(" mbs:\"%s\"\n", mbs);
   printf(" length: %d \n", length);
   printf(" c16: 0x%04hx \n", c16);
}
```

Output:

```
mbs:"a"
length: 1
c16: 0x0061
```

mbrtoc32() — Convert a multibyte character to a char32_t character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C11	both	z/OS V2R1

Format

```
#include <uchar.h>

size_t mbrtoc32(char32_t * restrict pc32,
               const char * restrict s,
               size_t n,
               mbstate_t * restrict ps);
```

General description

The mbrtoc32() function converts a multibyte character to a wide character of type char32_t, and returns the number of bytes of the multibyte character.

If *s* is not a null pointer, the mbrtoc32() function inspects at most *n* bytes beginning with the byte pointed to by *s* to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding wide characters and then, if *pc32* is not a null pointer, stores the value of the first (or only) such character in the object pointed to by *pc32*. Subsequent calls will store successive wide characters without consuming any additional input until all the characters have been stored. If the corresponding wide character is the null wide character, the resulting state described is the initial conversion state.

If *s* is a null pointer, the mbrtoc32() function is equivalent to the call `mbrtoc32(NULL,"",1,ps)`. In this case, the values of the parameters *pc32* and *n* are ignored.

If *ps* is a null pointer, mbrtoc32() uses its own internal object to track the shift state. Otherwise **ps* must be a valid mbstate_t object. An mbstate_t object **ps* can be initialized to the initial state by assigning 0 to it, or by calling `mbrtoc32(NULL,NULL,0,ps)`.

Usage notes

1. To use the mbrtoc32() function, compile the source code with the LANGLVL(EXTC1X) option.

2. The mbrtoc32() function only supports the CCSIDs that are provided by Unicode Services.
3. The result of converting multiple string alternately in one thread by using multiple mbstate_t objects (including the internal one) is undefined.

Returned value

The mbrtoc32() function returns the first of the following that applies (given the current conversion state):

0
If the next *n* or fewer bytes complete the multibyte character that corresponds to the null wide character (which is the value stored).

between 1 and *n* inclusive
If the next *n* or fewer bytes complete a valid multibyte character (which is the value stored); the value returned is the number of bytes that complete the multibyte character.

-3
If the next character resulting from a previous call has been stored (no byte from the input has been consumed by this call).

-2
If the next *n* bytes contribute to an incomplete (but potentially valid) multibyte character, and all *n* bytes have been processed (no value is stored). When *n* has at least the value of the MB_CUR_MAX macro, this case can only occur if *s* points to a sequence of redundant shift sequence (for implementations with state-dependent encodings).

-1
If an encoding error occurs (when the next *n* or fewer bytes do not contribute to a complete and valid multibyte character). The value of the macro EILSEQ is stored in errno, and the conversion state is unspecified.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <uchar.h>

int main(void)
{
   char32_t c32;
   char mbs[] = "a" ; /* string containing the multibyte character */
   mbstate_t ss = 0 ;    /* set shift state to the initial state */
   int length = 0 ;

   /* Determine the length of the multibyte character pointed to by */
   /* mbs. Store the multibyte character in the char32_t object */
   /* called c32. */

   length = mbrtoc32(&c32, mbs, MB_CUR_MAX, &ss);
   if (length < 0) {
      /* -2 and -3 return value could not happen during converting the 'a' */
      perror("mbrtoc32() fails to convert");
      exit(-1);
   }

   printf(" mbs:\"%s\"\n", mbs);
   printf(" length: %d \n", length);
   printf(" c32: 0x%08x \n", c32);
}
```

Output:

```
mbs:"a"
length: 1
c32: 0x00000061
```

mbrtowc() — Convert a multibyte character to a wide character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C99 Single UNIX Specification, Version 3	both	

Format

Non-XPG4

```
#include <wchar.h>

size_t mbrtowc(wchar_t * __restrict__pwc, const char * __restrict__s,
               size_t n, mbstate_t * __restrict__ps);
```

XPG4

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbrtowc(wchar_t *pwc, const char *s, size_t n, mbstate_t *ps);
```

General description

The mbrtowc() function is equivalent to `mbrtowc(NULL,"",1,ps)`.

If *s* is a NULL pointer, the mbrtowc() function ignores the *n* and the *pwc*, and resets the shift state, pointed to by *ps*, to the initial shift state.

If *s* is not a NULL pointer, mbrtowc() inspects at most *n* bytes, beginning with the byte pointed to by *s*, and the shift state pointed to by *ps*, and determines the number of bytes that is needed to complete the valid multibyte character.

When the multibyte character is completed, mbrtowc() determines the value of the corresponding wide character and stores it in the object pointed to by *pwc*, so long as *pwc* is not a NULL pointer. Finally, mbrtowc() stores the actual shift state in the object pointed to by *ps*. If *ps* is a NULL pointer, mbrtowc() uses its own internal object to track the shift state.

mbrtowc() is a restartable version of mbtowc(). That is, shift-state information is passed as one of the arguments and is updated on exit. With mbrtowc(), you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results may occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbrtowc() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If *s* is a NULL pointer, mbrtowc() resets the shift state to the initial shift state and returns 0.

If *s* is not a NULL pointer, mbrtowc() returns one of the following, in the order shown:

0
If the next *n* or fewer bytes complete the valid multibyte character that corresponds to the NULL wide character.

positive integer
If the next *n* or fewer bytes complete the valid multibyte character; the value returned is the number of bytes that complete the multibyte character.

-2
If the next *n* bytes form an incomplete (but potentially valid) multibyte character, and all *n* bytes have been processed. It is unspecified whether this can occur when the value of *n* is less than that of the MB_CUR_MAX macro.

Note: When a -2 value is returned, and *n* is at least MB_CUR_MAX, the string would contain redundant shift-out and shift-in characters. To continue processing the multibyte string, increment the pointer by the value *n*, and call the mbrtowc() function.

-1
If an encoding error occurs (when the next *n* or fewer bytes do not contribute to the complete and valid multibyte character). The value of the macro EILSEQ is stored in errno, but the conversion state is unchanged.

Example

CELEBM04

```
/* CELEBM04 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
   wchar_t   wc;
   char      mbs[5] = "a";    /* string containing the multibyte char */
   mbstate_t ss     = 0;      /* set shift state to the initial state */
   int      length;

   /* Determine the length of the multibyte character pointed to by   */
   /* mbs.  Store the multibyte character in the wchar_t object       */
   /* called wc.                                                      */

   length = mbrtowc(&wc, mbs, MB_CUR_MAX, &ss);

   printf("    length: %d \n", length);
   printf("        wc:'%lc'\n", wc);
   printf("       mbs:\"%s\"\n", mbs);
   printf("MB_CUR_MAX: %d \n", MB_CUR_MAX);
   printf("        ss: %d \n", ss);
}
```

mbsinit() — Test state object for initial state

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C99 Single UNIX Specification, Version 3	both	

Format

Non-XPG4

```
#include <wchar.h>

int mbsinit(const mbstate_t *ps);
```

XPG4

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int mbsinit(const mbstate_t *ps);
```

General description

If *ps* is not a NULL pointer the mbsinit() function determines whether the pointer to mbstate_t object describes an initial conversion state.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbsinit() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If *ps* is a NULL pointer or if the pointed-to object describes an initial conversion state, mbsinit() returns nonzero.

Otherwise, mbsinit() returns 0.

Example

CELEBM05

```
/* CELEBM05

   This example checks the conversion state to see if it is in the
   initial state.

 */
#include "stdio.h"
#include "wchar.h"
#include "stdlib.h"

main() {
   char     *string = "ABC";
   mbstate_t state = 0;
   wchar_t   wc;
   int   rc;

   rc = mbrtowc(&wc, string, MB_CUR_MAX, &state);
   if (mbsinit(&state))
     printf("In initial conversion state\n");
}
```

mbsrtowcs() — Convert a multibyte string to a wide-character string

Standards

Standards / Extensions	C or C++	Dependencies
ISO C Amendment C99 Single UNIX Specification, Version 3	both	

Format

Non-XPG4

```
#include <wchar.h>

size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len, mbstate_t *ps);
```

XPG4

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len, mbstate_t *ps);
```

General description

Converts a sequence of multibyte characters that begins in the conversion state described by *ps* from the array indirectly pointed to by *src*. It converts this sequence into a sequence of corresponding wide characters, that, if *dst* is not a NULL pointer, are then stored into the array pointed to by *dst*. Conversion continues up to and including a terminating NULL character, and the terminating NULL wide character is also stored. Conversion stops earlier in two cases: (1) when a sequence of bytes is reached that does not form a valid multibyte character, or (2) if *dst* is not a NULL pointer, when *len* codes have been stored into the array pointed to by *dst*. Each conversion takes place as if by a call to the mbrtowc() function.

If *dst* is not a NULL pointer, the pointer object pointed to by *src* is assigned either a NULL pointer (if conversion stopped because a terminating NULL character was reached) or the address just past the last multibyte character converted. If conversion stopped because a terminating NULL character was reached, the resulting state is the initial state.

mbsrtowcs() is a restartable version of mbstowcs(). That is, shift-state information is passed as on of the arguments and is updated on exit. With mbsrtowcs(), you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbsrtowcs() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If successful, mbsrtowcs() returns the number of multibyte characters converted, not including the terminating NULL character, if any.

If the *dst* argument is a null pointer, the *len* argument is ignored and mbsrtowcs() returns the required size in wide characters for the destination string.

If the input string contains an invalid multibyte character, mbsrtowcs() returns (size_t)-1 and sets errno to one of the following values:

Error Code
Description

EILSEQ
Encoding error (the conversion state is undefined).

Example

CELEBM06

```
/* CELEBM06 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

#define SIZE 10

int main(void)
{
   wchar_t wcs[SIZE];
   char    mbs[SIZE]="abcd";  /* string containing the multibyte char */
   char   *ptr      = mbs;    /* pointer to the mbs string             */
   int     length;

   /* Determine the length of the multibyte string pointed to by       */
   /* mbs.  Store the multibyte characters in the wchar_t array        */
   /* pointed to by wcs.                                               */

   length = mbsrtowcs(wcs, (const char**)&ptr, SIZE, NULL);
   wcs[length] = L'\0';

   printf("    length: %d \n", length);
   printf("       wcs:\"%ls\"\n",wcs);
   printf("       mbs:\"%s\"\n",mbs);
   printf("      &mbs: %p \n", mbs);
   printf("      &ptr: %p \n", ptr);
}
```

mbstowcs() — Convert multibyte characters to wide characters

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

size_t mbstowcs(wchar_t * __restrict__pwc, const char* __restrict__string, size_t n);
```

General description

Determines the length of the sequence of the multibyte characters that start in the initial shift state and that are pointed to by *string*. It then converts each of the multibyte characters to a `wchar_t`, and stores no more than *n* codes in the array pointed to by *pwc*. The conversion stops if either an invalid multibyte sequence is encountered or if *n* codes have been converted.

Processing continues up to and including the terminating NULL character, and characters that follow it are not processed. The terminating NULL character is converted into a code with the value 0.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

If pwc is a NULL pointer, mbstowcs() will return the length required to convert the entire array regardless of the value of n, but no values are stored.

Returned value

If successful, mbstowcs() returns the number of *pwc* array elements modified (or required if *pwc* is NULL) , not counting the terminating 0 code (the `wchar_t` 0 code). Note that, if the return value is *n*, the resulting *wchar_t* array will *not* be NULL-terminated.

If an invalid multibyte character is encountered, mbstowcs() returns (size_t)-1.

Example

CELEBM07

```
/* CELEBM07

   This example uses &mbstowcs. to convert a multibyte character
   string to a wide character string.

 */
#include <stdio.h>
#include <stdlib.h>

int main()
{
    char      mbsin[8] = "\x50\x0e\x42\xf1\x0f\x50\x00";
    wchar_t   wcsout[5];
    size_t    wcssize;

    printf("mbsin is 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x\n",
            mbsin[0], mbsin[1], mbsin[2],
            mbsin[3], mbsin[4], mbsin[5],
            mbsin[6]);

    wcssize = mbstowcs(wcsout, mbsin, 5);

    printf("mbstowcs(wcsout, mbsin, 5); returned %d\n", wcssize);

    printf("wcsout is 0x%.4x 0x%.4x 0x%.4x 0x%.4x\n",
            wcsout[0], wcsout[1],
            wcsout[2], wcsout[3]);
}
```

Output

```
mbsin is 0x50 0x0e 0x42 0xf1 0x0f 0x50 0x00
mbstowcs(wcsout, mbsin, 5); returned 3
wcsout is 0x0050 0x42f1 0x0050 0x0000
```

mbtowc() — Convert multibyte character to wide character

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <stdlib.h>

int mbtowc(wchar_t * __restrict__pwc, const char* __restrict__string, size_t n);
```

General description

Converts a multibyte character to a wide character and returns the number of bytes of the multibyte character. It first determines the length of the multibyte character pointed to by *string*. It then converts the multibyte character to the corresponding wide character and places the wide character in the location pointed to by *pwc*, if *pwc* is not a NULL pointer. A maximum of *n* bytes is examined.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If *string* is NULL, mbtowc() returns:

- Nonzero if the multibyte encoding in the current locale (LC_CTYPE) is shift-dependent.
- 0 otherwise.
- The current shift state is set to the initial state.

Otherwise if *string* is not NULL, mbtowc() returns:

- The number of bytes comprising the converted multibyte character, if *n* or fewer bytes form a valid multibyte character.
- 0 if *string* points to the NULL character.
- -1 if *string* does not point to a valid multibyte character, and the next *n* bytes do not form a valid multibyte character.

If the current locale supports EBCDIC DBCS characters, the shift state is updated where applicable. The length returned may be up to 4 characters long (for the shift-out character, 2-byte code, and the shift-in character).

After the function is placed into its initial state, it interprets multibyte characters—pointed to by *string*—accordingly. During the processing of shift-dependent encoded characters, you cannot stop processing one string, then move temporarily to processing another string, and return to the first, because the state would be valid for the second string, not the place where you stopped in the first string.

Example

```
/* This example uses mbtowc() to convert a multibyte character into a wide
   character.
 */
#include <stdio.h>
#include <stdlib.h>

int temp;
char string [6];
wchar_t arr[6];

int main(void)
{ /* Set string to point to a multibyte character. */
⋮
   temp = mbtowc(arr, string, MB_CUR_MAX);
   printf("wide-character string: %ls",arr);
}
```

m_create_layout() — Create and initialize a layout object (bidi data)

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 C99	both	z/OS V1R2

Format

```
#include <sys/layout.h>

LayoutObject m_create_layout(const AttrObject attrobj, const char *modifier);
```

General description

The m_create_layout() function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The m_create_layout() function creates a LayoutObject associated with the locale identified by *attrobj*. The LayoutObject is an opaque object containing all the data and methods necessary to perform the layout operations on context-dependent or directional characters of the locale identified by the *attrobj*.

The memory for the LayoutObject is allocated by m_create_layout(). The LayoutObject created has default layout values. If the *modifier* argument is not NULL, the layout values specified by the *modifier* will overwrite the default layout values associated with the locale. Also, internal states maintained by the layout transformation function across transformations are set to their initial values.

The *attrobj* argument is or may be an amalgam of many opaque objects. A locale object is just one example of the type of object that can be attached to an attribute object. The *attrobj* argument specifies a name that is usually associated with a locale category. If *attrobj* is NULL, the LayoutObject created is associated with the current locale as set by the setlocale() function.

The *modifier* argument can be used to announce a set of layout values when the LayoutObject is created.

A LayoutObject created by m_create_layout() is deleted by calling the m_destroy_layout() function.

For a detailed description of bidirectional layout transformation, see Bidirectional Language Support in *z/OS XL C/C++ Programming Guide*.

Returned value

If successful, m_create_layout() returns a LayoutObject for use in subsequent calls to m_*_layout() functions.

If unsuccessful, m_create_layout() returns (LayoutObject)0 and sets errno to one of the following values:

Error Code
Description

EBADF
The attribute object is invalid or the locale associated with the attribute object is not available.

EINVAL
The modifier string has a syntax error or it contains unknown layout values.

ENOMEM
Insufficient storage space is available.

m_destroy_layout() — Destroy a layout object (bidi data)

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 C99	both	z/OS V1R2

Format

```
#include <sys/layout.h>

int m_destroy_layout(const LayoutObject layoutobject);
```

General description

The m_destroy_layout() function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The m_destroy_layout() function destroys a LayoutObject by deallocating the layout object and all the associated resources previously allocated by the m_create_layout( ) function.

Returned value

If successful, m_destroy_layout() returns 0.

If unsuccessful, m_destroy_layout() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT
Errors occurred while processing the request.

memccpy() — Copy bytes in memory

Standards

Standards / Extensions	C or C++	Dependencies
XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _XOPEN_SOURCE
#include <string.h>

void *memccpy(void *__restrict__ s1, const void *__restrict__ s2, int c, size_t n);
```

General description

The memccpy() function copies bytes from memory area s2 into memory area s1, stopping after the first occurrence of byte c (converted to an unsigned char) is copied, or after n bytes are copied, whichever comes first.

Returned value

If successful, memccpy() returns a pointer to the byte after the copy of *c* in *s1*.

If *c* was not found in the first *n* bytes of *s2*, memccpy() returns a NULL pointer.

Related information

- “string.h” on page 72

memchr() — Search buffer

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <string.h>

void *memchr(const void *buf, int c, size_t count);
```

General description

The memchr() built-in function searches the first *count* bytes pointed to by *buf* for the first occurrence of *c* converted to an unsigned character. The search continues until it finds *c* or examines *count* bytes.

Returned value

If successful, memchr() returns a pointer to the location of *c* in *buf*.

If *c* is not within the first *count* bytes of *buf*, memchr() returns NULL.

Example

CELEBM11

```
/* CELEBM11

   This example finds the first occurrence of "x" in
   the string that you provide.
   If it is found, the string that starts with that character is
   printed.
   If you compile this code as MYPROG, then it could be invoked
   like this, with exactly one parameter:
        MYPROG skixing

 */
#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
  char * result;

  if ( argc != 2 )
    printf( "Usage: %s string\n", argv[0] );
  else
  {
    if ((result = (char *)memchr( argv[1], 'x', strlen(argv[1])) ) != NULL)
      printf( "The string starting with x is %s\n", result );
    else
      printf( "The letter x cannot be found in the string\n" );
  }
}
```

Output

```
The string starting with x is xing
```

memcmp() — Compare bytes

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <string.h>

int memcmp(const void *buf1, const void *buf2, size_t count);
```

General description

The memcmp() built-in function compares the first *count* bytes of *buf1* and *buf2*.

The relation is determined by the sign of the difference between the values of the leftmost first pair of bytes that differ. The values depend on EBCDIC encoding. This function is *not* locale sensitive.

Returned value

Indicates the relationship between *buf1* and *buf2* as follows:

Value	Meaning
< 0	The contents of the buffer pointed to by *buf1* less than the contents of the buffer pointed to by *buf2*
= 0	The contents of the buffer pointed to by *buf1* identical to the contents of the buffer pointed to by *buf2*
> 0	The contents of the buffer pointed to by *buf1* greater than the contents of the buffer pointed to by *buf2*

Example

CELEBM12

```
/* CELEBM12

   This example compares first and second arguments passed to
   main to determine which, if either, is greater.
```

```
 */
#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
  int  len;
  int  result;

  if ( argc != 3 )
  {
     printf( "Usage: %s string1 string2\n", argv[0] );
  }
  else
  {
     /* Determine the length to be used for comparison */
     if (strlen( argv[1] ) < strlen( argv[2] ))
       len = strlen( argv[1] );
     else
       len = strlen( argv[2] );

     result = memcmp( argv[1], argv[2], len );

     printf( "When the first %i characters are compared,\n", len );
     if ( result == 0 )
       printf( "\"%s\" is identical to \"%s\"\n", argv[1], argv[2] );
     else if ( result < 0 )
       printf( "\"%s\" is less than \"%s\"\n", argv[1], argv[2] );
     else
       printf( "\"%s\" is greater than \"%s\"\n", argv[1], argv[2] );
  }
}
```

Output

If the program is passed the arguments *firststring* and *secondstring*, you would obtain following:

```
When the first 11 characters are compared,
"firststring" is less than "secondstring"
```

memcpy() — Copy buffer

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <string.h>

void *memcpy(void * __restrict__dest, const void * __restrict__src, size_t count);
```

General description

The memcpy() built-in function copies *count* bytes from the object pointed to by *src* to the object pointed to by *dest*. See "Built-in functions" on page 93 for information about the use of built-in functions. For memcpy(), the source characters may be overlaid if copying takes place between objects that overlap. Use the memmove() function to allow copying between objects that overlap.

Returned value

memcpy() returns the value of *dest*.

Example

CELEBM13

```
/* CELEBM13

   This example copies the contents of source to target.

 */
#include <string.h>
#include <stdio.h>

#define MAX_LEN 80

char source[ MAX_LEN ] = "This is the source string";
char target[ MAX_LEN ] = "This is the target string";

int main(void)
{
  printf( "Before memcpy, target is \"%s\"\n", target );
  memcpy( target, source, sizeof(source));
  printf( "After memcpy, target becomes \"%s\"\n", target );
}
```

Output

```
Before memcpy, target is "This is the target string"
After memcpy, target becomes "This is the source string"
```

- "memmove() — Move buffer" on page 1065
- "memset() — Set buffer to value" on page 1066
- "strcpy() — Copy string" on page 1734

memmove() — Move buffer

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <string.h>

void *memmove(void *dest, const void *src, size_t count);
```

General description

Copies *count* bytes from the object pointed to by *src* to the object pointed to by *dest*. The memmove() function allows copying between possibly overlapping objects as if the *count* bytes of the object pointed to by *src* must first copied into a temporary array before being copied to the object pointed to by *dest*.

Returned value

memmove() returns the value of *dest*.

Example

CELEBM14

```
/* CELEBM14

   This example copies the word shiny from position target + 2
   to position target + 8.

 */
#include <string.h>
#include <stdio.h>
#define SIZE    21

char target[SIZE] = "a shiny white sphere";

int main( void )
{
  char * p = target + 8;  /* p points at the starting character
                          of the word we want to replace */
  char * source = target + 2; /* start of "shiny" */

  printf( "Before memmove, target is \"%s\"\n", target );
  memmove( p, source, 5 );
  printf( "After memmove, target becomes \"%s\"\n", target );
}
```

Output

```
Before memmove, target is "a shiny white sphere"
After memmove, target becomes "a shiny shiny sphere"
```

memset() — Set buffer to value

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3	both	

Format

```
#include <string.h>

void *memset(void *dest, int c, size_t count);
```

General description

The memset() built-in function sets the first *count* bytes of *dest* to the value *c* converted to an unsigned int.

Returned value

memset() returns the value of *dest*.

Example

CELEBM15

```
/* CELEBM15

   This example sets 10 bytes of the buffer to "A" and
   the next 10 bytes to "B".

 */
#include <string.h>
#include <stdio.h>
#define  BUF_SIZE     20
#define  HALF_BUF_SIZE   BUF_SIZE/2

int main(void)
{
   char buffer[BUF_SIZE + 1];
   char *string;

   memset(buffer, 0, sizeof(buffer));
   string = (char *)memset(buffer,'A', HALF_BUF_SIZE);
   printf("\nBuffer contents: %s\n", string);
   memset(buffer+HALF_BUF_SIZE, 'B', HALF_BUF_SIZE);
   printf("\nBuffer contents: %s\n", buffer);
}
```

Output

```
Buffer contents: AAAAAAAAAA

Buffer contents: AAAAAAAAAABBBBBBBBBB
```

m_getvalues_layout() — Query layout values of a layout object (bidi data)

Standards

Standards / Extensions	C or C++	Dependencies
ISO C XPG4 C99	both	z/OS V1R2

Format

```
#include <sys/layout.h>

int m_getvalues_layout(const LayoutObject layout_object, LayoutValues values,
                       int *index_returned);
```

General description

The m_getvalues_layout() function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The m_getvalues_layout() function is used to query the current setting of layout values within a LayoutObject. The *layout_object* argument specifies a LayoutObject returned by the m_create_layout() function. The *values* argument specifies the list of layout values which are to be queried.

Each value element of a LayoutValueRec must point to a location where the layout value is stored. For example, if a layout value is of type T, the argument must be of type T*. The values are queried from the LayoutObject and represent its current state.

If the layout value name has **QueryValueSize** OR-ed to it, instead of the value of the layout value, only its size is returned. This option can be used by the caller to determine the amount of memory needed to be allocated for the layout values queried.

It is the user's responsibility to manage the space allocation for the layout values queried.

For a detailed description of bidirectional layout transformation, see Bidirectional Language Support in *z/OS XL C/C++ Programming Guide*.

Returned value

If successful, m_getvalues_layout() returns 0.

If any value cannot be queried, m_getvalues_layout() stores into *index_returned* the (zero-based) index of the value causing the error. It returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The layout value specified by index_returned is unknown or its value is invalid or the argument layout_object is invalid.

Related information

- "sys/layout.h" on page 73
- "m_create_layout() — Create and initialize a layout object (bidi data)" on page 1058

mkdir() — Make a directory

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int mkdir(const char *pathname, mode_t mode);
```

General description

Creates a new, empty directory, *pathname*. The file permission bits in *mode* are modified by the file creation mask of the process, and then used to set the file permission bits of the directory being created. For more information on the file creation mask, see "umask() — Set and retrieve file creation mask" on page 1947.

The *mode* argument is created with one of the flags defined in the sys/stat.h header file. Any mode flags that are not defined will be turned off, and the function will be allowed to proceed.

Flag **Description**

S_IRGRP
Read permission for the file's group.

S_IROTH
Read permission for users other than the file owner.

S_IRUSR
Read permission for the file owner.

S_IRWXG
Read, write, and search or execute permission for the file's group. S_IRWXG is the bitwise inclusive OR of S_IRGRP, S_IWGRP, and S_IXGRP.

S_IRWXO
Read, write, and search or execute permission for users other than the file owner. S_IRWXO is the bitwise inclusive OR of S_IROTH, S_IWOTH, and S_IXOTH.

S_IRWXU
Read, write, and search, or execute, for the file owner; S_IRWXU is the bitwise inclusive OR of S_IRUSR, S_IWUSR, and S_IXUSR.

S_ISGID
Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is set to the group ID of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.

S_ISUID
Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.

S_ISVTX
Indicates shared text. Keep loaded as an executable file in storage.

S_IWGRP
Write permission for the file's group.

S_IWOTH
Write permission for users other than the file owner.

S_IWUSR
Write permission for the file owner.

S_IXGRP
Search permission (for a directory) or execute permission (for a file) for the file's group.

S_IXOTH
Search permission for a directory, or execute permission for a file, for users other than the file owner.

S_IXUSR
Search permission (for a directory) or execute permission (for a file) for the file owner.

The owner ID of the new directory is set to the effective user ID of the process. The group ID of the new directory is set to the group ID of the owning directory.

mkdir() sets the access, change, and modification times for the new directory. It also sets the change and modification times for the directory that contains the new directory.

If *pathname* names a symbolic link, mkdir() fails.

Returned value

If successful, mkdir() returns 0.

If unsuccessful, mkdir() does not create a directory, returns -1, and sets errno to one of the following values:

Error Code
: **Description**

EACCES
: The process did not have search permission on some component of *pathname*, or did not have write permission on the parent directory of the directory to be created.

EEXIST
: Either the named file refers to a symbolic link, or there is already a file or directory with the given *pathname*.

ELOOP
: A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP (defined in the limits.h header file) symbolic links are detected in the resolution of *pathname*.

EMLINK
: The link count of the parent directory has already reached LINK_MAX (defined in the limits.h header file).

ENAMETOOLONG
: *pathname* is longer than **PATH_MAX** characters or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT
: Some component of *pathname* does not exist, or *pathname* is an empty string.

ENOSPC
: The file system does not have enough space to contain a new directory, or the parent directory cannot be extended.

ENOTDIR
: A component of the *pathname* prefix is not a directory.

EROFS
: The parent directory of the directory to be created is on a read-only file system.

Example

CELEBM16

```
/* CELEBM16

   The following example creates a new directory.

 */
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  char new_dir[]="new_dir";

  if (mkdir(new_dir, S_IRWXU|S_IRGRP|S_IXGRP) != 0)
    perror("mkdir() error");
  else if (chdir(new_dir) != 0)
    perror("first chdir() error");
  else if (chdir("..") != 0)
    perror("second chdir() error");
  else if (rmdir(new_dir) != 0)
    perror("rmdir() error");
  else
    puts("success!");
}
```

mkfifo() — Make a FIFO special file

Standards

Standards / Extensions	C or C++	Dependencies
POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3	both	

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int mkfifo(const char *pathname, mode_t mode);
```

General description

Sets the access, change, and modification times for the new file. It also sets the change and modification times for the directory that contains the new file.

mkfifo() creates a new FIFO special file, *pathname*. The file permission bits in *mode* are changed by the file creation mask of the process, and then used to set the file permission bits of the FIFO file being created. If *pathname* contains a symbolic link, mkfifo() fails. For more information on the file creation mask, see “umask() — Set and retrieve file creation mask" on page 1947; for information about the file permission bits, see "chmod() — Change the mode of a file or directory" on page 272.

The owner ID of the FIFO file is set to the effective user ID of the process. The group ID of the FIFO file is set to the group ID of the owning directory. *pathname* cannot end in a symbolic link.

Returned value

If successful, mkfifo() returns 0.

If unsuccessful, mkfifo() does not create a FIFO file, returns -1, and sets errno to one of the following values:

Error Code
Description

EACCES
The process does not have search permission on some component of *pathname*, or does not have write permission on the parent directory of the file to be created.

EEXIST
Either the named file refers to a symbolic link, or there is already a file or directory with the given *pathname*.

EINTR
A signal is received while this open is blocked waiting for an open() for read (if O_WRONLY was specified) or for an open() for write (if O_RDONLY was specified).

ELOOP
A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP (defined in the limits.h header file) symbolic links are detected in the resolution of *pathname*.

EMLINK
The link count of the parent directory has already reached the maximum defined for the system.

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT
Some component of *pathname* does not exist, or *pathname* is an empty string.

ENOSPC
The file system does not have enough space to contain a new file, or the parent directory cannot be extended.

ENOTDIR
A component of the *pathname* prefix is not a directory.

EROFS
The parent directory of the FIFO file is on a read-only file system.

Example

CELEBM17

```
/* CELEBM17

   This example uses mkfifo() to create a FIFO specail file named
   temp.fifo and then writes and reads from the file before closing it.

 */
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <unistd.h>
#include <fcntl.h>
#include <stdio.h>

main() {
  char fn[]="temp.fifo";
  char out[20]="FIFO's are fun!", in[20];
  int rfd, wfd;

  if (mkfifo(fn, S_IRWXU) != 0)
    perror("mkfifo() error");
  else {
    if ((rfd = open(fn, O_RDONLY|O_NONBLOCK)) < 0)
      perror("open() error for read end");
    else {
      if ((wfd = open(fn, O_WRONLY)) < 0)
        perror("open() error for write end");
      else {
        if (write(wfd, out, strlen(out)+1) == -1)
          perror("write() error");
        else if (read(rfd, in, sizeof(in)) == -1)
          perror("read() error");
        else printf("read '%s' from the FIFO\n", in);
        close(wfd);
      }
      close(rfd);
    }
    unlink(fn);
  }
}
```

Output

```
read 'FIFO's are fun!' from the FIFO
```

mknod() — Make a directory or file

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3 z/OS UNIX	both	

Format

_OPEN_SYS

```
#define _OPEN_SYS
#include <sys/stat.h>

int mknod(const char *path, mode_t mode, rdev_t dev_identifier);
```

_XOPEN_SOURCE_EXTENDED 1

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/stat.h>

int mknod(const char *path, mode_t mode, dev_t dev_identifier);
```

General description

Creates a new directory, regular file, character special file, or FIFO special file (named pipe), with the pathname specified in the *path* argument.

The first byte of the *mode* argument determines the file type of the file:

S_IFCHR
Character special file

S_IFFIFO
FIFO special file

S_IFREG
Regular file

S_IFDIR
Directory file

The file permission bits of the new file are initialized with the remaining bits in *mode* and changed by the file creation mask of the process. For more information on these symbols, refer to "chmod() — Change the mode of a file or directory" on page 272.

dev_identifier applies only to a character special file. It is ignored for the other file types. *dev_identifier* contains a value representing the device major and device minor numbers. The major number is contained in the high-order 16 bits; it identifies a device driver supporting a class of devices, such as interactive terminals. The minor number is contained in the low-order 16 bits of *dev_identifier*; it identifies a specific device within the class referred to by the device major number. With z/OS UNIX services, the device major numbers are:

1 Master pseudoterminal

2 Slave pseudoterminal

3 /dev/tty

4 /dev/null

5 /dev/fdn

6 Sockets

7 OCSRTY

8 OCSADMIN

9 "/dev/console"

Device major numbers 1,2 and 7: The device minor numbers range between 0 and one less than the maximum number of pseudoterminal pairs defined by the installation.

Device major numbers 3,4,6,8 and 9: The device minor number is ignored.

Device major number 5: The device minor number value represents the file descriptor to be referred to. For example, device minor 0 refers to file descriptor 0.

When it completes successfully, mknod() marks for update the following fields of the file: `st_atime`, `st_ctime`, and `st_mtime`. It also marks for update the `st_ctime` and `st_mtime` fields of the directory that contains the new file.

Returned value

If successful, mknod() returns 0.

If unsuccessful, mknod() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
Search permission is denied on a component of *path*, or write permission is denied on the parent directory of the file to be created.

EEXIST
A file by that name already exists.

ELOOP
A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP (defined in the limits.h header file) symbolic links are detected in the resolution of *path*.

EMLINK
The link count of the parent directory has already reached the maximum defined for the system.

ENAMETOOLONG
pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined through pathconf().

ENOENT
A component of *path* was not found, or no *path* was specified.

ENOSPC
The file system does not have enough space to contain a new directory, or the parent directory cannot be extended.

ENOTDIR
A component of *path* is not a directory

EPERM
Added for XPG4.2: The invoking process does not have appropriate privileges and the file type is not FIFO-special.

EROFS
The file named in *path* cannot be created, because it would reside on a read-only file system.

Example

CELEBM18

```
/* CELEBM18 */
#include <sys/stat.h>
#include <unistd.h>
#include <stdio.h>

#define master 0x00010000

main() {
  char fn[]="char   ec";

  if (mknod(fn, S_IFCHR|S_IRUSR|S_IWUSR, master|0x0001) != 0)
    perror("mknod() error");
  else if (unlink(fn) != 0)
    perror("unlink() error");
}
```

mkstemp() — Make a unique filename

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int mkstemp(char *template);
```

General description

The mkstemp() function replaces the contents of the string pointed to by *template* with a unique file name, and returns a file descriptor for the file open for reading and writing. The function thus prevents any possible race condition between testing whether the file exists and opening it for use. The string in *template* should look like a file name with six trailing 'X's; mkstemp() replaces each 'X' with a character from the portable file name character set. The characters are chosen such that the resulting name does not duplicate the name of an existing file. This function is supported only in a POSIX program.

Returned value

If successful, mkstemp() returns an open file descriptor.

If no suitable file could be created, mkstemp() returns -1.

There are no errno values defined.

mktemp() — Make a unique file name

Standards

Standards / Extensions	C or C++	Dependencies
XPG4.2 Single UNIX Specification, Version 3	both	POSIX(ON)

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *mktemp(char *template);
```

General description

The mktemp() function replaces the contents of the string pointed by *template* by a unique file name and returns *template*. The application must initialize *template* to be a file name with six trailing 'X's; mktemp() replaces each 'X' with a single-byte character from the portable file name character set.

This function is supported only in a POSIX program.

Note: The mktemp() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The mkstemp() function is preferred for portability and greater reliability.

Returned value

If successful, mktemp() returns a pointer to *template*.

If a unique name cannot be created, mktemp() sets *template* to a NULL string.

There are no errno values defined.

mktime(), mktime64() — Convert local time

Standards

Standards / Extensions	C or C++	Dependencies
ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment	both	

Format

```
#include <time.h>

time_t mktime(struct tm *tmptr);
```

```
#define _LARGE_TIME_API
#include <time.h>

time64_t mktime64 (struct tm *tmptr);
```

Compile requirement: Use of mktime64() function requires the long long data type. For more information on how to make long long data type available, see *z/OS XL C/C++ Language Reference*.

General description

The mktime() function converts broken-down time, expressed as a local time, in the tm structure (described in Table 16 on page 80) pointed to by *tmptr*, to calendar time. Calendar time is the number of seconds since epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

The values of the structure members passed to the mktime() function are not restricted to the ranges described in "time.h" on page 79. For values that are outside the specified range, the mktime() function will use date arithmetic to adjust the values to produce a valid date and time (see "Example" on page 1080). The values of *tm_wday* and *tm_yday* are ignored and are assigned their correct values on return.

On the successful completion of the function, all the members of the structure pointed to by *time* are set to represent the specified time since the Epoch with their values forced into the ranges described in "time.h" on page 79. The value of *tm_wday* is set after the values of *tm_mon* and *tm_year* are determined. The output value of *tm_isdst* is determined by the mktime() function, independent of the value presented as input to the mktime() function.
