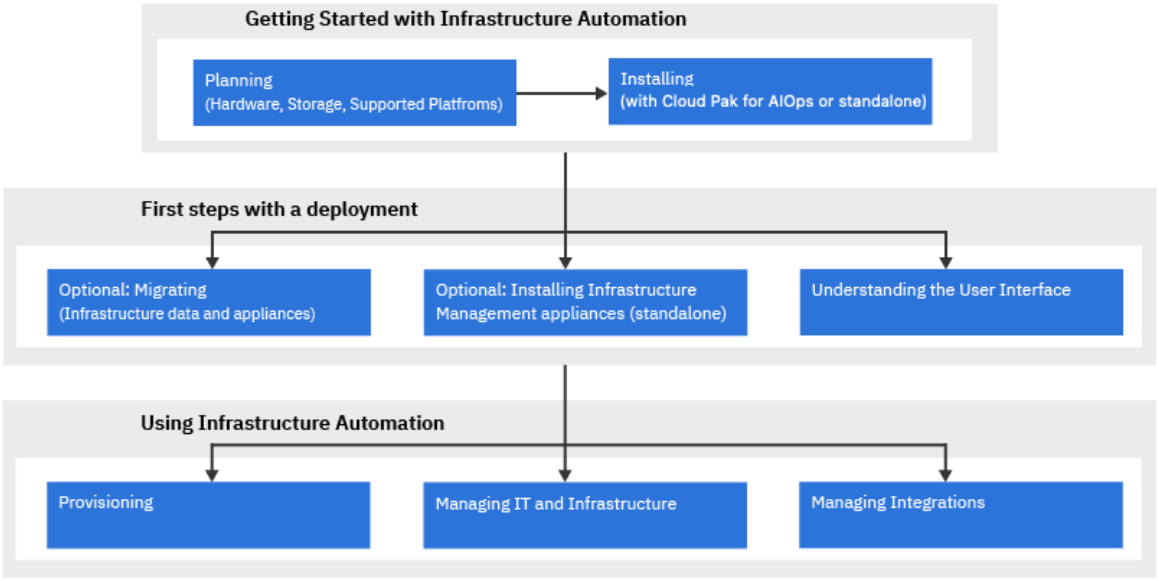
Glossary 1400

Infrastructure Automation

Infrastructure Automation is a stand-alone capability/module included within IBM Cloud Pak for AIOps. When you have a license for IBM Cloud Pak for AIOps, you are entitled to install and use Infrastructure Automation.



Infrastructure Automation brings together Terraform and ManageIQ for an integrated, Infrastructure Automation capability for IT Operators.

Infrastructure Automation delivers two distinct features:

- Managed services, previously called Terraform and Service Automation. This feature uses self-service capabilities to orchestrate resources.
- Infrastructure Management, previously called IBM Red Hat CloudForms. This feature provides capabilities for discovering, managing, and automating the deployment of VMs, cloud services and Kubernetes clusters.

To learn more about Infrastructure Automation, click a subject within the following image to view the related available documentation (or review the subjects that are listed following the image):

Infrastructure Automation documentation flow

Getting started

Planning

Before you install IIBM Cloud Pak for AIOps - Infrastructure Automation, plan your installation, configuration, and overall cluster requirements. For more information, see Planning.

Installing

Infrastructure Automation is included with IBM Cloud Pak for AIOps and can be installed for use with IBM Cloud Pak for AIOps or as a stand-alone component. For information about, see Installing Infrastructure automation.

First steps with a deployment

Migrating data from another deployment

You can migrate infrastructure data, such as services data and appliances, to Infrastructure Automation from other products and services, such as IBM Cloud Pak for Multicloud Management, IBM Cloud Private, and IBM Red Hat CloudForms. For more information, see Migrating to IBM Cloud Pak for AIOps.

Installing Infrastructure Management appliances

With Infrastructure Automation installed, you can install Infrastructure management appliances for your environment. These appliances can be installed on different supported platforms, such as Red Hat OpenStack Platform and Red Hat Virtualization, VMware vSphere, and Amazon Elastic Compute Cloud (Amazon EC2). For more information, see Installing and upgrading appliances.

Understanding the user interface

Learn how to use the IBM Cloud Pak for AIOps console to access and use Infrastructure Automation tools and features. For more information, see User interface.

Infrastructure Automation use cases

Once set up, you and your DevOps teams can use Infrastructure Automation to provision, integrate, and manage IT and infrastructure.

Provisioning

Infrastructure Automation provide the capability to automate provisioning of infrastructure and virtual machine applications using Terraform and Ansible. Provisioning IT brings infrastructure-as-code support and helps with sharing templates across multiple instances and with provisioning repeatable infrastructure with confidence. This infrastructure-as-code support helps to provide you with a standardized environment for your developers. For more information, see Provisioning.

Managing It and infrastructure

Infrastructure Automation includes supported versions of Terraform that works across multiple cloud environments like RHEV, VMWare, OpenStack and multiple cloud providers, like AWS, Microsoft Azure, Google, and IBM Cloud. For more information, see Managing IT and infrastructure.

Managing integrations

With Infrastructure Automation, you can enable default integrations with ServiceNow, Ansible Tower, Turbonomic, and Business Process Manager. Once integrations are setup, the cloud infrastructures can be provisioned through the Infrastructure Automation catalog or through APIs. Changes and operations to the provisioned infrastructures go through Infrastructure Automation, which can synchronize the changes with other systems. For more information, see Managing integrations.

Infrastructure Automation UI console views

Use the Infrastructure Automation UI console to view, create, and automate the management of your infrastructure.

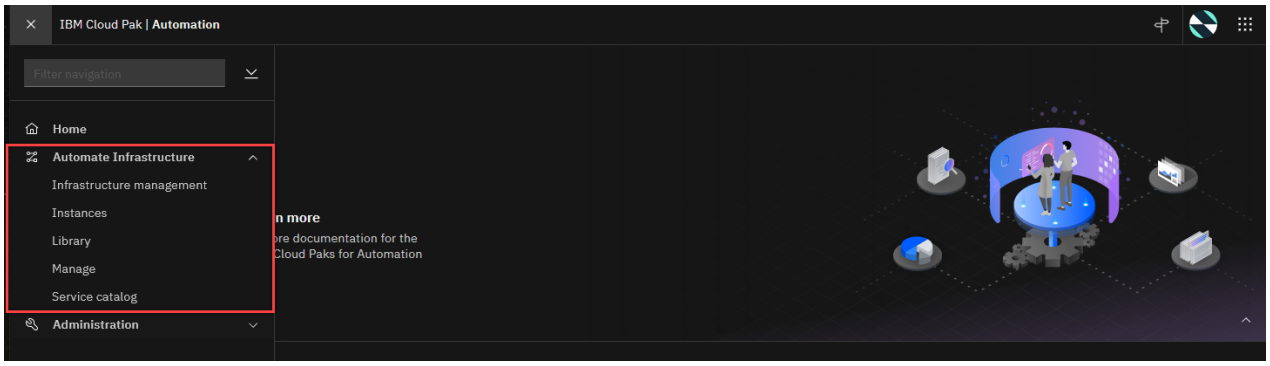


Figure. Main page

Instances

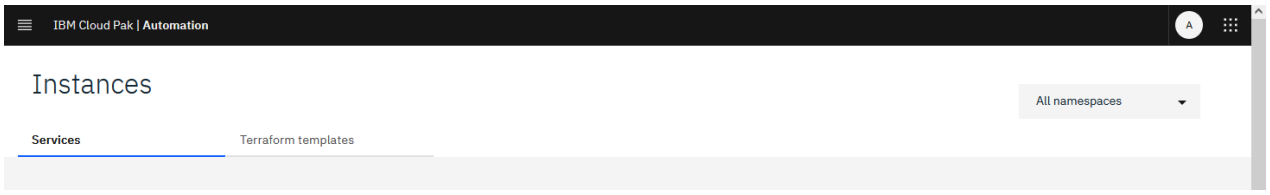

Figure. Instances

Services

On the *Services* tab, you can view service instances. If you need to create a service instance, you are redirected to the **Library** > **Services** page, where you can create the service instance.

For more information, see Services.

Terraform templates

On the *Services* tab, you can view Terraform instances. If you need to create a Terraform instance, you are redirected to the **Library** > **Terraform templates** page, where you can create the Terraform instance.

For more information, see Templates.

Library

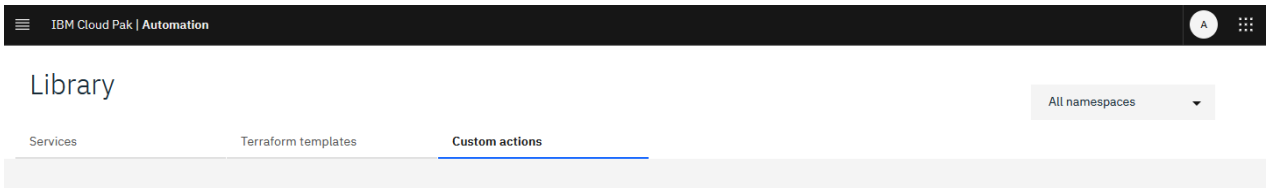

Figure. Library page

Services

On the *Services* tab, you can view all services, which can be sorted by category. You can also choose to create or import services.

For more information, see Services.

Terraform templates

On the *Terraform templates* tab, you can view all templates. You can also choose to import a template.

For more information, see Templates.

Custom actions

On the *Custom actions* tab, you can view all custom actions, which can be sorted by category. You can also choose to create different custom actions.

For more information, see Creating and managing custom actions.

Manage

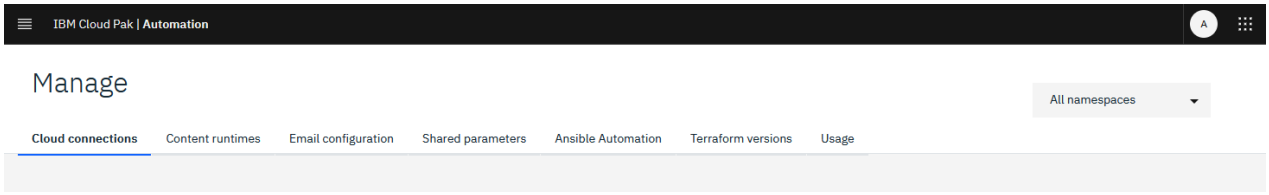

Figure. Manage page

Cloud connections

On the *Cloud connections* tab, you can view and create cloud connections. Cloud connections allow you to create connections to each of your target cloud providers that are used when you deploy instances.

For more information, see Managing connections

Content runtimes

On the *Content runtimes* tab, you can view and create advanced content runtimes.

For more information about creating advanced content runtimes, see Managing content runtime

Email configuration

On the *Email configuration* tab, you can view and create email server configurations. To use email-related features within Manage services, you need to configure an email server to send these emails.

For more information about configuring and managing SMTP server connection for email notifications, see Managing Email Configuration

Shared parameters

On the *Shared parameters* tab, you can view and create data types and data objects that can be used as shared parameters. Shared parameters define shared configuration to store data and are used by templates. You can create reusable data objects using shared parameters. This helps save time when you are deploying new instances and creating services.

For more information, see Shared parameters.

Ansible Automation

On the *Ansible Automation* tab, you can create and view Ansible connections. By creating a globally accessible connection to Ansible Tower, you can include Ansible Automation within your services.

For more information about configuring an Ansible Tower connection, see Configuring the Ansible Tower connection.

Terraform versions

On the *Terraform versions* tab, you can view versions of Terraform that can be offered when you deploy templates and services. You can also create versions, if needed. A default version can be set, which is used when the template metadata does not specify a version.

For more information, see Managing Terraform Versions.

Usage

On the *Usage* tab, you can view the highest number of virtual machines (VMs) managed by Manage services each month. You can view the current and monthly usage, and download the usage data.

For more information, see Managing the usage of virtual machines.

Access Control

In the *Access Control* tab, you can provide access for users to certain namespaces. An administrator user can assign namespaces to the user or user groups by using this feature.

For more information, see Managing Access Control.

Service catalog

The Service catalog view displays the deployable services and applications and related details. It also displays the deployed instances and related details. With the service catalog you can complete the following tasks:

- As an IT administrator, you can define a new service by using the service composer, test it and when it is ready, publish it to the Service catalog. You can decide which parameters to expose to users, such as to hide the complexity around provisioning from users.
- As a user, such as a developer, you can access the Service catalog to provision infrastructure and applications.

The Service catalog view can be refreshed at a particular interval by using the **`Autorefresh`** menu. The default is 10 seconds. You can also disable the autorefresh.

To access the Service catalog, go to IBM Cloud Pak for AIOps console and click **Automate infrastructure** > **Service library**.

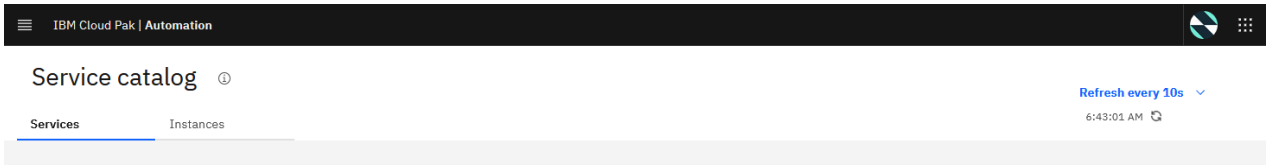

Figure. Service catalog page

- Services
- Instances

Services

On the *Services* tab, a tiled list of published services and applications is displayed. The list of services and applications is sorted according to categories. Clicking the service deploys that service to your environment. You can search a service by using **Search services** option or search by category.

For more information about services, see the following topics:

- Creating a service
- Publishing a service
- Deploying a service

Instances

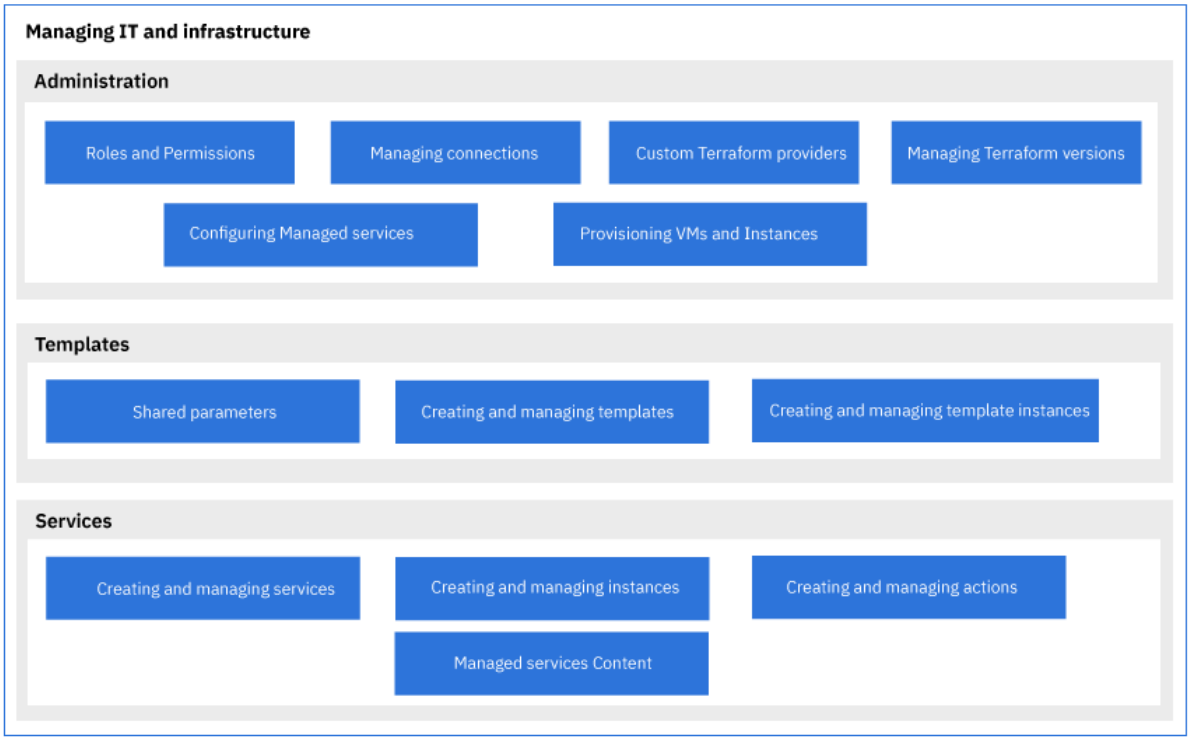
On the *Instances* tab, a list of all deployed service and application instances is displayed. If needed, you can use the search box to filter the listed instances.

For each instance, the following information is displayed:

- The name of the instance
- The name of the service
- The status of the instance, Executed or Terminated
- The date and time when the service was deployed

A typical operation user can access all the following instance actions from the overflow menu:

- **View**: For more information, see Viewing service instance details.
- **Edit**: For more information, see Editing a service instance.
- **Custom actions**: For more information, see Custom actions.
- **Retry/resume** : For more information, see Resuming or retrying a service instance.
  - Applicable only for **`Error`** state instances.
  - **`Retry`** tries to deploy the instance from the beginning of the execution.
  - **`Resume`** tries to resume deploying the instance from the point of failure.
- **Upgrade/downgrade**: For more information, see Upgrading or downgrading a service instance
- **Terminate**/**Delete**: For more information, see Terminating and deleting a service instance.
  - Only **`Active`** instances can be terminated.
  - Only **`Terminated`** instances can be deleted.



Provisioning

Provisioning IT brings infrastructure-as-code support and helps with sharing templates across multiple instances and with provisioning repeatable infrastructure with confidence.

The Manage Services compose complex full stack services with ease using Terraform and Ansible.

The provisioning IT also provides RBAC controlled self service access for developers to provision the infrastructure they need.

To learn more about provisioning IT for Infrastructure Automation, click a subject within the following image to view the related available documentation (or click the subject from list that follows the image):

- Adminstration
  - Roles and permissions
  - Managing connections
  - Custom Terraform providers
  - Managing Terraform Versions
  - Configuring Managed services
  - Provisioning Virtual Machines and Instances
- Templates
  - Shared parameters
  - Creating and managing templates
  - Creating and managing template instances
- Services
  - Creating and managing services
  - Creating and managing service instances
  - Creating and managing custom actions
  - Managed services Content

Provisioning administration

- Roles and permissions for Infrastructure Automation
- Managing connections

- Managing Terraform versions
- Configuring Managed services
- Provisioning Virtual Machines and Instances
- Creating a Service in Infrastructure Management for Virtual Machine Provisioning
- Service Provisioning in Infrastructure Management using an orchestration template
- Assigning a Custom Analysis Profile to a Virtual Machine
- Creating a tag mapping for Infrastructure Management integration

Roles and permissions for Infrastructure Automation

For accessing and completing actions with IBM Cloud Pak® for AIOps Infrastructure Automation, users require specific roles and permissions. Review the different available roles, permissions, and the associated actions that users can complete with the roles and permissions. These roles and permissions help you get your users set up to begin day to day operations.

- Predefined roles
- Creating a role
- Permissions

Predefined roles

A role defines the permissions that a user or group has. You can edit the default roles or create new roles if the default set of permissions in a role does not align with your business needs. For more information, see Managing roles.

The following roles are available by default:

- Administrator
- Automation Administrator
- Automation Analyst
- Automation Developer (AIOps Developer role)
- Automation Operator
- User

Notes:

- The User predefined role is listed as available by default but this role does not include any permissions for completing actions within IBM Cloud Pak for AIOps. This default role is used within the IBM® Automation family of offerings, which includes IBM Cloud Pak for AIOps, however, this roles is not used within IBM Cloud Pak for AIOps.

  As this role does not include or provide any permissions within IBM Cloud Pak for AIOps, do not assign the role to users within IBM Cloud Pak for AIOps. If more IBM Cloud Paks are installed, this roles can have permissions for completing actions within tools for those other IBM Cloud Paks.

- Not all permissions are associated with a predefined role. A user with with a permission to manage roles, such as the Administer platform permission, can assign permissions to a role when needed.

Default user

The default user (`admin`) is automatically assigned the following roles when the roles are added to the platform:

- Administrator

Creating a role

When adding a user, you can choose to create a role instead of assigning an existing role. You can also choose to directly create a role. The options for creating a role are the same regardless of the path you select to create the role.

To directly create a role, complete the following steps:

1. Log in to the console as an administrator with permissions to manage users.
2. From the main navigation, click **Administration** > **Access control**.
3. Select the **Roles** tab and click **New role**.
4. Enter the details for the new role:
   - Name - Enter a distinctive and descriptive name for the role.
   - Description - Enter an optional description for the role to define the role, such as to identify the objective or responsibilities for users with the role.
5. Click **Next**.
6. Select the permissions for the role. You can use the *Find permissions* search field to find and filter the list of permissions.
7. Click **Next**.
8. Review the details for the role and click **Create**.

Permissions

The following table describes the actions that are associated with each permission.

Infrastructure Automation

Table: User administration permissions

Permissions	Actions	Automation Developer	Automation Operator	Automation Analyst	Automation Administrator	Administrator
View Kubernetes resources	(1)			X		
Edit Kubernetes resources	(2)	X				
Manage Kubernetes resources	(3)		X			
Administer Kubernetes resources	(4)				X	
Administer Kubernetes namespace	(5)					X

1. View Kubernetes resources in the Cloud Pak namespaces.
    - View resources
2. Edit Kubernetes resources in the Cloud Pak namespaces.
    - View resources
    - Edit resources
3. Manage Kubernetes resources in the Cloud Pak namespaces.
    - View resources
    - Edit resources
    - Create resources
4. Administer Kubernetes resources in the Cloud Pak namespaces.
    - View resources
    - Edit resources
    - Create resources
    - Delete resources
5. Administer Kubernetes namespace
    - Administer Kubernetes namespace (administrator ClusterRole)
    - Access Administration Hub
    - Manage identity providers
    - Manage teams
    - Manage service IDs

Platform administration

Permissions in this category enable an administrator to configure, customize, monitor, and manage the platform.

Only the Administer platform permission is associated with a predefined role (Adminstrator). This permission includes all other platform administration permissions.

Table: Platform administration permissions

Permissions	Actions	Automation Developer	Automation Operator	Automation Administrator	Administrator
Administer platform	(1)				X
Manage configurations	(2)				
Manage platform health	(3)				
View platform health	(4)				

1. Administer platform

    This permission offers the most comprehensive set of actions for managing and monitoring the platform. Users with this permission have elevated privileges and can grant or revoke all permissions, including other administrative permissions. Users with this permission can complete the same actions as users that have the following permissions:

    - Manage configurations (Administer platform)
    - Manage platform health (Administer platform)
    - Manage platform roles (User administration)
    - Manage users (User administration)
    - Manage user groups (User administration)
    - Manage service instances (Service instances)
2. Manage configurations

    Users with this permission can customize the platform, integrate the platform with other applications, and enable connections to unsupported data sources. Users with this permission can access the Customizations page, the Configurations page, and the JDBC drivers tab on the Platform connections page. Some actions require specific services to be installed. Users with this permission can complete the following actions:

    - Configure connection to SMTP server

      Note: Requires Watson Studio or Watson Knowledge Catalog. An SMTP connection enables the platform to send emails.

    - Configure integration with IBM Guardium appliances

      Note: Requires Watson Knowledge Catalog. Use IBM Guardium to audit access to sensitive data on remote databases.

    - Configure connections to Hadoop clusters

      Note: Requires Execution Engine for Apache Hadoop.

- Customize branding
- Enable and disable home page cards
- Enable and disable default support links
- Add and delete custom support links
- Enable and disable guided tours
- Import JDBC drivers

  Note: Requires the common core services. JDBC drivers enable users to connect to unsupported data sources.

3. Manage platform health

   Users with this permission can monitor resource use, set quotas and alerts, manage workloads to maintain the health of the platform, and gather diagnostic data when problems occur. Users with this permission can access the Monitoring page and the Diagnostics page. Users with this permission can complete the following actions:

   - Monitor workloads and resource use

     Note: Workloads include active runtimes and jobs. Resources include memory and vCPU use across services, instances, and environments.

   - Stop any runtime environment

     Note: Environments are hardware and software configurations defined for running analytical assets or jobs.

   - View pod status, details, and logs

     Note: Services are composed of Kubernetes pods. A pod is an instance of a process that runs on the cluster.

   - Restart pods
   - View platform quotas and service quotas

     Note: A quota specifies the maximum amount of memory or vCPU that the platform or a service should use.

   - View event history and alerts
   - Set and edit platform resource quotas
   - Set and edit individual service resource quotas
   - Create and run diagnostics jobs

     Note: A diagnostic job gathers information that can be used for troubleshooting problems.

   - Delete diagnostics jobs

4. View platform health

   Users with this permission can monitor resource use and workloads across the platform to gauge the health of the platform. Users with this permission have read-only access to the Monitoring page. Users with this permission can complete the following actions:

   - Monitor workloads and resource use

     Note: Workloads include active runtimes and jobs. Resources include memory and vCPU use across services, instances, and environments.

   - View pod status, details, and logs

     Note: Services are composed of Kubernetes pods. A pod is an instance of a process that runs on the cluster.

   - View platform quotas and service quotas

     Note: A quota specifies the maximum amount of memory or vCPU that the platform or a service should use.

   - View event history and alerts

Service instances

A service instance is a specific deployment of a service. Some services can be deployed more than once. Some service instances have their own access controls.

Table: Service instances permissions

Permissions	Actions	Automation Developer	Automation Operator	Automation Administrator	Administrator
Create service instances	(1)				X
Manage service instances	(2)				

1. Create service instances

   Users with this permission can create service instances and storage volumes. The types of service instances depend on the services that are installed. Users with this permission can complete the following actions:

   - Create service instances

Note: If an instance has access controls, the user who creates the instance is an instance administrator.

2. Manage service instances

   Users with this permission can manage access to any service instance or delete any service instance from the Instances page. Users with this permission can complete the following actions:

   - Create service instances
   - View all service instances
   - Add users to any service instance
   - Assign an instance role to instance users
   - Remove users from a service instance
   - Delete any service instance

What permissions do I have?

You can see what permissions you have from your profile. Your permissions are determined by the roles that are assigned to you.

To see what roles are assigned to you:

1. Log in to the IBM Cloud Pak for AIOps console and click your avatar in the upper right of the toolbar.
2. Click **Profile and settings**.
3. Click the **Roles** tab.

The permissions that are associated with your role (or roles) are listed in the **Enabled permissions** column.

Adding users

To add users, you need to have an external LDAP server set up for creating user profiles and authentication. When a user record is included within the LDAP server, you can add the user account within the IBM Cloud Pak for AIOps console. You can add a user directly or as part of an LDAP group. For more information, see Adding users.

Assigning roles and permissions

When you add a user or group, you must specify the role and permissions that they have. These roles and permissions can be granted to users through a combination of the IBM Cloud Pak for AIOps console and an external LDAP server for managing user authentication.

Red Hat OpenShift Container Platform roles

To add and manage users and roles for accessing and using the Red Hat OpenShift Container Platform web console, you need to use the Red Hat role-based access control (RBAC). For more information, see the Red Hat OpenShift topic Using RBAC to define and apply permissions.

Managing connections

In the Connections view, manage your connections to define the Connections you want to set up.

Managing connections:

- Add a connection
- Search for a connection
- Edit a connection
- Testing a connection
- Delete a connection

Add a connection

To add a connection, complete the following steps:

1. In the navigation bar, click **Manage** > **Cloud connections**.
2. Click **Create connection**.
3. Select the cloud provider to which you want to connect. The following cloud providers are supported:

   - Alibaba Cloud
   - Amazon EC2
   - IBM
   - IBM Cloud Kubernetes Service
   - Google Cloud
   - Huawei Cloud
   - Microsoft Azure
   - Microsoft HyperV
   - Nutanix

- OpenStack
- Tencent Cloud
- VMware NSX-T
- VMware NSXv
- VMware vRealize Automation
- VMware vSphere
- Other

Note: Apart from the values available in the provider type drop-down list, a generic provider type that is named `Other` can be used. You do not have to explicitly define a cloud connection of type `Other` because it is provided implicitly by the system. It does not define any connectivity attributes and must be used for cases where the cloud connection details are captured inside the provider section of the template itself.

4. In **Select a namespace** > **Assign access** section, select either of the following values based on your requirement:

   - **Make connection globally accessible** - Connections created globally are accessible by all users.
   - **Make connection part of a namespace** - Associate the connection with a specific namespace. For this option, you must select a **Namespace** from the drop-down list to which the connection must be assigned. The namespace that is present on the **Cloud connections** main page is preselected and you can modify if needed.

   Note: If you create a cloud connection in a specific namespace, then only deployments to that namespace can use the cloud connection.

5. Enter the connection name and description, and specify the required connection parameters depending on the cloud provider you selected.

   Note: The connection name must begin with a letter and must have a combination of only these characters: [a-zA-Z][a-zA-Z0-9_-]

   Managed services must have access to the provider cloud region where you want to deploy your templates. The access is granted by supplying Managed services with access credentials. The method for obtaining access credentials depends on the cloud provider.

For information about specifying an Alibaba Cloud Configuring an Alibaba Cloud connection

For information about specifying Amazon EC2 access credentials, see Configuring an Amazon EC2 connection.

For information about specifying IBM Cloud access credentials, see Configuring an IBM Cloud connection.

For information about specifying IBM Cloud Kubernetes Service credentials, see Configuring IBM Cloud Kubernetes Service.

For information about specifying Huawei Cloud credentials, see Configuring a Huawei Cloud connection.

For information about specifying Azure access credentials, see Configuring an Azure connection.

For information about specifying Nutanix credentials, see Configuring a Nutanix connection.

For information about specifying OpenStack access credentials, see Configuring an OpenStack connection

For information about specifying Tencent Cloud Configuring Tencent Cloud connection

For information about specifying VMware vRealize Automation credentials, see Configuring VMware vRealize Automation.

For information about specifying vSphere access credentials, see Configuring a vSphere connection.

For information about specifying VMware NSX-T access credentials, see Configuring a VMware NSX-T connection.

For information about specifying NSXv access credentials, see Configuring an NSXv connection.

For information about specifying Microsoft HyperV credentials, see Configuring Microsoft HyperV connection

Note: If you require a more secure environment for connections then follow the steps for Create an EgressNetworkPolicy

6. Click **Create**. The connection is added to the connection list.

Search for a connection

In **Cloud connections** page, you can use the following methods to search for connections:

- You can select a namespace from the **All namespaces** drop-down list. The list of cloud connections in the page changes based on the selected namespace. You can also select "All namespaces" to see all cloud connection records for which you have access.
- You can enter text in the search text to filter the connection list.
- You can use the show filter icon next to search text to filter records based on type or namespace. The namespace option has **Show globally accessible** option, which refers to those connections that are globally accessible across all namespaces and are not assigned to any specific namespace.
- You can click the **Name** header to sort the connection records.
- You can even combine these search mechanisms for better results.
- The pagination option allows you to limit the number of records displayed at a time.

Edit a connection

To edit an existing connection, follow these steps:

1. In the navigation bar, click **Manage** > **Cloud connections**.
2. In the connection list, click the connection that you want to edit.
3. Modify the existing connection details and parameters.

Important: You can change a namespace to globally accessible but cannot assign a different namespace for a connection. You can also change a globally accessible namespace to a different namespace but be informed that with this namespace change you might not be able to perform any operations on existing deployments.

4. Click **Update**.

Testing a connection

To test a connection, follow these steps:

1. In the navigation bar, click **Manage** > **Cloud connections**.
2. In the connection list, click the menu in the **ACTIONS** column for the connection that you want to test.
3. In the action list, click **Test connection**. If the connection is successful, a green check mark is displayed in the **ACTIONS** column for the connection.

Delete a connection

To delete a connection, follow these steps:

1. In the navigation bar, click **Manage** > **Cloud connections**.
2. In the connection list, click the menu in the **ACTIONS** column for the connection that you want to delete.
3. In the action list, click **Delete connection**. A confirmation window is opened.
4. Click **Delete** to confirm that you want to delete the connection.

Note: Remember to remove any EgressFirewall rules you may have added for this connection. See Create an EgressFirewall.

Configuring an Alibaba cloud connection

In order for Managed services to access your Alibaba Cloud environment, you must provide the value of the following parameters:

- Access Key ID - This is the Alicloud access key. This is a required field.
- Access Key Secret - This is the Alicloud secret key. This is a required field.
- STS Session Token - This is the Alicloud Security Token Service. This is an optional field.
- Region - This is the Alicloud region. This is a required field.

Configuring an Amazon EC2 connection

In order for Managed services to access your Amazon Web Services (AWS) account, an access key and the secret access key to your account are required.

The access key and the secret access key are not your AWS user name and password, but they are special tokens that allow Managed services to communicate with your AWS account through secure API calls. You can also have temporary access keys, access secrets, and session tokens that expires in a specified amount of time. Refresh the credentials in this cloud connections page after the temporary credentials expire. Alternatively, you can define the access key, access secret, and session token in the `Provider` section:

```
provider "aws" {
 region = "${var.aws_region}"
 token  = "${var.aws_token}"
 access_key = "${var.aws_access_key}"
 secret_key = "${var.aws_secret_key}"
}
```

For more information about creating AWS access keys, see Creating, Modifying, and Viewing Access Keys (AWS Management Console).

For information about the available resources, see AWS Provider.

Configuring an IBM Cloud connection

For Managed services to access your IBM Cloud environment, specify the IBM Cloud API key to deploy IBM Cloud services, and also the IBM Cloud User and IBM Cloud Classic Infrastructure API Key to deploy IBM Cloud classic infrastructure like compute instances.

- **IBM Cloud API Key** - Enter the IBM Cloud API key that is associated with your user identity.
- **IBM Cloud Classic Infrastructure User Name** and **IBM Cloud Classic Infrastructure API Key** fields - Enter the IBM Cloud user name and the IBM Cloud classic infrastructure API key values respectively.

To retrieve the **IBM Cloud Classic Infrastructure User Name**:

1. Log in to the IBM Cloud Portal.
2. Click **Manage** > **Access (IAM)** > **Users**.

3. Select the user from the list. The **User details** tab of the **Manage user** page displays.
4. The **User name** value, a combination of a `number_emailID` is listed under the **VPN Password** section.

To retrieve the **IBM Cloud Classic Infrastructure API Key** values:

1. Log in to the IBM Cloud Portal.
2. Click **Manage** > **Access (IAM)** > **API keys** > **In View** dropdown, select **Classic infrastructure API keys** >.
3. In the returned list, select the additional action icon (vertical ellipses) > **Details** > **Copy the API key**.

To create the **IBM Cloud API Key** values:

1. Log in to the IBM Cloud Portal.
2. Click **Manage** > **Access (IAM)** > **API keys** > **In View** dropdown, select **My IBM Cloud API Keys** >.
3. Click **Create an IBM Cloud API key** to create a new one.

For more details, see IBM Cloud IAM.

For information about the available Terraform resources, see IBM Cloud Provider.

Note: If you created templates with an old version that uses `terraform-provider-ibm` older than v0.4, be aware that the resource names for the IBM Cloud provider were changed. For more information, see Migrating to v0.4.

Configuring an IBM Cloud Kubernetes Service

For Managed services to access Kubernetes clusters, you must provide the value of the following parameters:

Note: You must have administrator privileges for the deployment of IBM Cloud Kubernetes Service cluster and charts into that cluster. If you do not have these privileges, contact your administrator.

- **IBM Cloud API Key** - Enter the IBM Cloud API Key. It is the key to access your Kubernetes cluster.
- **IBM Cloud region name** - Enter the IBM Cloud region name where your cluster is running.
- **IBM Cloud Kubernetes Service cluster name** - Enter the Kubernetes cluster name.
- **Kubernetes Helm version** - Select the Kubernetes Helm version on which the cluster is running.

The cluster credentials are validated before creating a cloud connection. However, the health of the cluster is not validated.

If you want to know the details of your cluster, carry out the following steps:

1. Go to bluemix console at https://console.bluemix.net/dashboard/apps/.
2. Click **Containers**.
3. From the **Containers** page menu, click **Clusters**.
4. On the Clusters page, select the **Location** from the drop-down menu or enter your region name in the **Filter** to search. You can find a list of all clusters including the clusters that were deployed with Managed services.
5. Click your cluster to view its details.

For information about IBM Cloud Kubernetes Services, see IBM Cloud Kubernetes Service.

Configuring a Huawei Cloud connection

For Managed services to access your Huawei Cloud server, specify the authentication URL, user name, and password of the Huawei Cloud server.

- **Authentication URL** - The authentication url of Huawei Cloud server.
- **User Name** - The user name to connect to Huawei Cloud server.
- **Password** - The password of the Huawei Cloud user.
- **Domain Name** - The project domain name.
- **Region** - The region where the resources are created.
- **Project Name** - The tenant or project name.

For more information about Huawei Cloud, see Huawei documentation.

Note: The Huawei cloud connection may fail even with correct credentials. However, this error does not prevent you from using the connection for template deployment.

Configuring Google Cloud connection

For Managed services to access your Google Cloud account, upload account credentials, enter the ID of the Google Cloud project and the region to deploy the service.

For **Service Account Credentials**, upload a JSON file that is used to describe account credentials. It is downloaded from Google Cloud console.

For more information about Google Cloud, see Google Cloud documentation.

Configuring a vSphere connection

In order for Managed services to access your vSphere environment, you must provide the IP address or host name of the vCenter server and the user credentials to access it. Managed services supports vCenter version 6.0 or later.

For more information about vSphere, see the VMware vSphere 6.0 Documentation Center.

What to do next

Deploy a vSphere template. For more information, see Importing a template and Deploying a template.

For information about the available resources, see VMware vSphere Provider and Resource Documentation.

Configuring a Nutanix connection

For Managed services to access your Nutanix server, specify the user name and password of the Nutanix server.

- **Nutanix User** - The user to connect to Nutanix.
- **Nutanix Password** - The password of the Nutanix user.
- **Nutanix Server** - The Nutanix server IP or host name.
- **Nutanix Port** - The Nutanix port. The default value is 9440.
- **Allow insecure connections** - Select true or false value. This indicates whether insecure connections are allowed in the Nutanix server.

For more information about Nutanix AHV (on-prem) offering, see Nutanix AHV Admin Guide.

Configuring an OpenStack connection

Managed services supports OpenStack cloud connection, PowerVC on Openstack connection, and z/VM Cloud Manager Appliance on OpenStack connection.

- OpenStack connection
- PowerVC cloud on OpenStack
- z/VM Cloud Manager Appliance on OpenStack

OpenStack connection

Managed services supports OpenStack cloud connection. For Managed services to access your OpenStack environment, you must provide the value of the following OpenStack cloud connection parameters:

- **Authentication URL** - Enter the authentication URL. It is used for the purpose of identification. The syntax is `http://IP_ADDRESS/identity/v3`. Here, v3 refers to version 3 of the keystone identity API.
- **User Name** - Enter the user name that is used to log into OpenStack server.
- **Password** - Enter the password of the OpenStack user.
- **Domain Name** - Enter the keystone domain name.
- **Region** - Enter the region of the cloud OpenStack.
- **Project Name** - Enter the name of the project that is supported by OpenStack and is within the specified domain.

Note: The values for the URL, domain, and region can be discovered on any OpenStack implementation by examining the output of 'OpenStack catalog list'.

For more information about these values, see OpenStack Provider.

PowerVC cloud on OpenStack

Managed services can manage PowerVC cloud V1.3.3 or higher on OpenStack. For more information about PowerVC, see PowerVC documentation.

For Managed services to access your PowerVC OpenStack environment, you must provide the value of the following connection configuration parameters:

- **Authentication URL** - Enter the authentication URL. It is used for the purpose of identification. The syntax is `https://<hostname_or_ip-address>:5000/v3`. Here, v3 refers to version 3 of the keystone identity API.
- **User Name** - Enter the user name that is used to log into the OpenStack server.
- **Password** - Enter the password of the OpenStack user.
- **Domain Name** - Enter the keystone domain name. The default is the PowerVC cloud default value.
- **Region** - Enter the region of the cloud OpenStack.
- **Project Name** - Enter the name of the project that is supported by OpenStack and is within the specified domain.

For more information about these values, see OpenStack Provider.

z/VM Cloud Manager Appliance on OpenStack

Managed services can now manage IBM z/VM 7.1 virtual machines using the IBM Cloud Infrastructure Center.

About the task

For more information about IBM Cloud Infrastructure Center, see Documentation. You must configure OpenStack cloud connection.

For Managed services to access your IBM Cloud Infrastructure Center OpenStack environment, you must provide the value of the following parameters:

- **Authentication URL** - Enter the authentication URL. It is used for the purpose of identification. The syntax is http://IP_ADDRESS:5000/v3. Here, v3 refers to version 3 of the keystone identity API.
- **User Name** - Enter the user name that is used to log into OpenStack server.
- **Password** - Enter the password of the OpenStack user.
- **Domain Name** - Enter the keystone domain name. Default is the IBM Cloud Infrastructure Center default.
- **Region** - Enter the region of the cloud OpenStack. RegionOne is the IBM Cloud Infrastructure Center default.
- **Project Name** - Enter the name of the project that is supported by OpenStack and is within the specified domain.

For more information about these values, see OpenStack Provider.

Configuring Tencent cloud connection

In order for Managed services to access your Tencent Cloud environment, you must provide the value of the following parameters:

- Secret ID - This is the TencentCloud secret id.
- Secret Key - This is the TencentCloud secret key.
- Region - This is the TencentCloud region.

Configuring a VMware NSX-T connection

For Managed services to access your VMware NSX-T server, specify the user name, password, and manager host details.

- **NSX_T User** - The user name to connect to VMware NSX-T server.
- **NSX_T Password** - The password of the VMware NSX-T user.
- **NSX_T Manager Host** - The VMware NSX_T manager host name or IP address.
- **Allow insecure connections** - Indicates whether insecure connections are allowed in VMware NSX-T server. You must set this value to True.

For more information about VMware NSX-T, see VMware NSX-T documentation.

Configuring VMware vRealize Automation

For Managed services to access your VMware vRealize Automation environment, you must provide the details of the server.

- **vRA User** - The user name to log in to the vRA server.
- **vRA Password** - The password for the user name to log in to the vRA server.
- **vRA tenant** - The vRA portal tenant.
- **vRA Host** - The path (IP or fully qualified host name) to the end point of vRA REST APIs (usually the vRA server). For example, https://myvra.example.com/.
- **Insecure** - Enter "true" to make an insecure connection to the vRA server. The default value is "False".

For more information about VMware vRealize Automation, see VMware Terraform provider for vRealize Automation.

Configuring an NSXv connection

For Managed services to access your NSX environment, you must provide the IP address of the NSX manager and the user credentials to access it.

What to do next

Deploy an NSXv template. For more information, see Importing a template and Deploying a template.

For information about the available resources, see NSXv Terraform Provider and Resource Documentation.

Configuring an Azure connection

In order for Managed services to access your Azure environment, you must provide the value of the following parameters:

- `subscription_id`
- `client_id`
- `client_secret`
- `tenant_id`

For information about getting these values, see Creating Credentials in the Azure Portal.

What to do next

Deploy an Azure template. For more information, see Importing a template and Deploying a template.

For information about the available resources, see Microsoft Azure Provider.

Configuring the Ansible connection

Before you begin

- Make sure the Ansible Integration is activated from the Managed services. See Enabling or disabling Ansible Integration.
- Make sure the variable **Prompt On Launch** is checked for the Credential and Inventory on the Ansible for the job templates that are created in the Ansible and used in the Managed services integration.

Procedure

From the Managed services to access your Ansible set up, specify username, password, and URL of the Ansible.

1. In the navigation bar, click **Manage** > **Ansible automation**.
2. Click **Create connection**.
3. Enter the following values:
    - **Ansible connection name** - Enter a unique name for the Ansible connection.
    - **Ansible user** - Enter the username of the Ansible.

      Note: The Ansible user needs to have access to the Ansible artifacts that are consumed in the designed Managed services service.
    - **Ansible password** - Enter the password for the Ansible username.
    - **Ansible URL** - Enter the URL of the Ansible.
4. Click **Create** to create and test the connection.
5. Click **Test** from the overflow menu to test the Ansible connection.

Note: The user can create one Ansible connection per namespace and only one global connection that is available to all namespaces.

Configuring Microsoft HyperV cloud connection

In order for Managed services to access the Microsoft HyperV Cloud environment, you must provide value for the following parameters:

- Microsoft HyperV username - The user to connect to Microsoft HyperV, which is a mandatory field.
- Microsoft HyperV password - The password to connect to Microsoft HyperV, which is a mandatory field.
- Microsoft HyperV Host - Microsoft HyperV hostname or IP address, which is a mandatory field.
- Port - The port on which winrm runs on Microsoft HyperV system (port that is used by the Microsoft HyperV APIs to communicate with the system). The default value is 5985, and it is a mandatory field.
- Https enabled - Boolean value field that indicates whether communication to winrm on the Microsoft HyperV system (used by the Microsoft HyperV API) is over http or https, the latter being the default value.
- TLS disabled - Boolean value field that indicates whether TLS Verification is used for the Microsoft HyperV API calls. The default value is TLS verification disabled.
- NTLM enabled - Boolean value field that indicates whether winrm on Microsoft HyperV system (used by the Microsoft HyperV API) uses NTLM authentication. The default value is NTLM authentication enabled.
- Connection timeout - The timeout to wait for the connection to become available for Microsoft HyperV API calls. The default value is 30s. It's a mandatory field.
- CA certificate path - The path to the CA certificate to use for Microsoft HyperV API calls, which is an optional field.
- Certificate path - The path to the certificate to use for authentication for Microsoft HyperV API calls, which is an optional field.
- Certificate private key path - The path to the certificate private key to use for authentication for Microsoft HyperV API calls, which is an optional field.
- TLS server name - The TLS server name for the host used for Microsoft HyperV API calls.

Uploading certificates

You must upload the certificates to the provider terraform pod using the Create a Terraform file API with `type=file`. The API uploads the certificates to /home/terraform/.terraform.d/cam. The value for certificate path variables must be /home/terraform/.terraform.d/cam/your_certificate_name.

Microsoft HyperV provider plugin binary

Microsoft HyperV provider is classified by Hashicorp as a community provider. The provider binary is not included with Managed services since it is neither official nor a verified provider.

If your Managed services installation has access to the internet, then the provider will be downloaded when you run the Microsoft HyperV Terrafrom template.

If your Managed services installation is in an air tight environment, then you need to download the provider binary from Microsoft HyperV Terrafrom Github repository.

If you installed Managed services on IBM Power, then you need to download the source from Microsoft HyperV Terrafrom GitHub repository and build the binary for IBM Power.

Custom Terraform providers

The Shipped Terraform providers page lists the Terraform provider plug-ins that is shipped with the product. If the provider that you need is missing, then you can directly Bring Your Own (BYO) providers into the Terraform pod volume. The file naming convention for the binaries is as follows:

- For provider plug-in: `terraform-provider-<NAME>_vX.Y.Z`
- For provisioner plug-in: `terraform-provisioner-<NAME>_vX.Y.Z`

Terraform relies on file names to determine plug-in types, names, and versions.

Follow the below steps to copy the third-party Terraform provider to the cam-provider-terraform pods:

- Create an archive with plug-in or plug-ins. The archive is expanded in the `/home/terraform/.terraform.d/plugins/` folder on provider terraform pods when the pods are restarted.

Example of a plug-in archive that contains the ibm-cloud terraform plug-in:

```
unzip -l ibm_cloud_plugin.zip
Archive: ibm_cloud_plugin.zip
  Length      Date    Time    Name
---------  ---------- -----   ----
        0  2021-10-12 13:34   registry.terraform.io/
        0  2021-10-12 13:34   registry.terraform.io/ibm-cloud/
        0  2021-10-12 13:34   registry.terraform.io/ibm-cloud/ibm/
        0  2021-10-12 13:34   registry.terraform.io/ibm-cloud/ibm/1.33.1/
        0  2021-10-12 13:36   registry.terraform.io/ibm-cloud/ibm/1.33.1/linux_amd64/
 60833792  2021-10-01 09:08   registry.terraform.io/ibm-cloud/ibm/1.33.1/linux_amd64/terraform-provider-ibm_v1.33.1
     5816  2021-10-01 09:13   registry.terraform.io/ibm-cloud/ibm/1.33.1/linux_amd64/README.md
    88983  2021-10-01 09:13   registry.terraform.io/ibm-cloud/ibm/1.33.1/linux_amd64/CHANGELOG.md
    15977  2021-10-01 09:13   registry.terraform.io/ibm-cloud/ibm/1.33.1/linux_amd64/LICENSE
---------                     -------
 60944568                     9 files
```

When you upload this archive file by using the API and restart the pod, the `terraform-provider-ibm_v1.33.1` binary is laid out under `/home/terraform/.terraform.d/plugins/registry.terraform.io/ibm-cloud/ibm/1.33.1/linux_amd64`.

- Use the Terraform file API to upload the plug-in archive.
- Restart `cam-provider-terraform-api` pods. If you have enabled the isolation mode for Provider Terraform runtime during the installation, then you must restart the `cam-provider-terraform-runtime` pods.

The location of the plug-in provider binary varies based on the Terraform version a provider plug-in supports:

Terraform version	Location of plugin provider binary
Terraform engine 0.12.x or lower	`/home/terraform/.terraform.d/plugins/`
Terraform engine 0.13.0 or higher and is listed in the Terraform official registry	`/home/terraform/.terraform.d/plugins/registry.terraform.io/<namespace>/<type>/<version>/linux_<arch>`
Terraform engine 0.13.0 or higher and is provided by IBM Cloud Pak for AIOps	`/home/terraform/.terraform.d/plugins/registry.ibm.com/<namespace>/<type>/<version>/linux_<arch>`
Terraform engine 0.13.0 or higher and is built inhouse	`/home/terraform/.terraform.d/plugins/<your.registry.com>/<namespace>/<type>/<version>/linux_<arch>`

Managing Terraform Versions

The Managed services component supports multiple Terraform engine versions that are offered when deploying the templates. The following Terraform engine version is shipped with the platform:

- 1.1.3

Terraform engine versions are shipped with the platform, but you can add your own versions. Terraform default version can be changed using these instructions.

The list displays the Version, the type of version and the status. The versions that are shipped with the Managed services are listed as **`System`** and the user created versions are listed as **`User`**.

Only an Administrator or Cluster Administrator can create/delete/edit Terraform versions.

The Terraform versions are not namespace specific.

Managing Terraform Versions:

- Create a version
- Search for a version
- Rename a version
- Disable a version
- Enable a version
- Set a default version
- Delete a version

Create a version

Before creating a Terraform version in Managed services, follow these steps to get the Terraform version:

1. Download and extract the Terraform binary of the version you want.
2. Rename the Terraform binary to include the version. For example, for Terraform version 0.12.16 rename **`terraform`** to **`terraform_0.12.16`**.
3. Archive the file.

To create a new version, follow these steps:

1. In the navigation bar, click **Manage** > **Terraform versions**.
2. Click **Create version**.
3. Enter the version name in the **Terraform version name** text box.
4. Click **Upload** and select your terraform archive.
5. Check **Set as default** if this version should be considered in case template metadata does not specify a version.
6. Click **Create**. The new version is added to the version list.

You must restart your **`cam-provider-terraform-api`** and **`cam-provider-terraform-runtime`** pods after you finish the above steps.

Search for a version

In **Terraform versions** page, you can use the following methods to search for versions:

- You can enter text in the search text to filter the version list.
- You can click the **Version** header to sort the versions.
- The pagination options allows you to limit the number of records displayed at a time.

Rename a version

To rename an existing version, follow these steps:

1. In the navigation bar, click **Manage** > **Terraform versions**.
2. From the overflow menu of a version, click **Rename**.
3. Modify the existing version name.
4. Click **Rename**.

Disable a version

To disable a version, follow these steps:

1. In the navigation bar, click **Manage** > **Terraform versions**.
2. From the overflow menu of a version, click **Disable**. The default version can not be disabled.
3. Click **Disable**.

   Note: This disabled version cannot be used in the future template deployments.

Enable a version

To enable a version, follow these steps:

1. In the navigation bar, click **Manage** > **Terraform versions**.
2. From the overflow menu of a version, click **Enable**.
3. Click **Enable**.

Set a default version

To set a default version, follow these steps:

1. In the navigation bar, click **Manage** > **Terraform versions**.
2. From the overflow menu of a version, click **Set as default**.
3. Click **Set as default** to confirm that you want to set this version as default.

   Note: This default version is used as a primary selection while deploying the template.

Delete a version

Only the user defined Terraform versions can be deleted. Also if the version is set as default, the delete option is disabled. If you still want to delete this version, select other version as a default version.

To delete a version, follow these steps:

1. In the navigation bar, click **Manage** > **Terraform versions**.
2. From the overflow menu of a version, click **Delete**. A confirmation window is opened.
3. Type **Delete** to confirm that you want to delete the version.
4. Click **Delete**.

   Note: The deleted version cannot be used in the future template deployments.

Modifying a provisioned environment from your local Template Designer

From the locally installed Template Designer user interface, you can modify a template and apply those changes to an existing environment.

Procedure

1. In a locally installed Template Designer, go to **Repositories** and select your repository and branch.
2. Go to **Blueprints** and open your project to provision.
3. Click **Provision**. The **Provision Environment** page is displayed. To modify an existing environment, select **Modify**. To deploy a new environment, select **Deploy**.

   Note: When **modify** is selected, the location is set to the location given when the environment was originally provisioned. You cannot change it during a **Modify** task.
4. Select the **Orchestration Service** from the drop-down list.
5. Select the environment to modify from the **Existing Environment Name** drop-down list.
6. Click **Next Edit Variables**.
7. In the **Edit Variables** tab, click **Variables** to expand the section.
8. Update any variable values that you want to change.
9. Here, you can click **Next Plan Changes** to see the plan results or you can skip the step and directly **Apply Changes**.
10. If you click **Next Plan Changes**, you can see the **Plan Output** with the status as success or failed. You can use the **Copy Log** to copy the plan summary to the clipboard.
11. If you are satisfied with the plan summary, click **Next Apply Changes** to apply the changes. A message appears after a successful plan and apply of the template.
12. Click the message to go to the **Environment** list page.
13. If you do not see your environments in the list, select the appropriate orchestration service from the **Environment** drop-down list.
14. Click the environment name to view the environment details. You can also click the **Log File** tab to view the log file for the most recent activity. Initially, the environment status is in progress and then, after successful deployment, it changes to running.

Post-installation configuration of the Managed services

Optional configuration steps after Managed services installation.

- Using an external database for the module
- Configuring a custom HTTPS certificate for the console
- Enabling or disabling IBM Business Process Manager
- Enabling or disabling Ansible integration

- Accessing Managed services by using a custom URL
- Using pre-created secrets in Managed services
- Configuring Managed services to use a proxy
- Configuring Managed services to import out of box templates and services using your github.com token
- Configuring SSH keys and known hosts in provider terraform pod

Using an external database for Managed services

You can configure Managed services to use an external MongoDB. This configuration is optional.

External MongoDB connection

The supported version for external MongoDB is 5.0.24.

Steps to connect an external MongoDB connection:

1. Edit **IAConfig**.

   ```
   oc edit IAConfig -A
   ```

2. Update **IAConfig** using the following spec for Managed services.

   ```
   spec:
     imagePullSecret: ibm-entitlement-key
     infraAutoComposableComponents:
     - enabled: true
       name: ibm-management-im-install
     - enabled: true
       name: ibm-management-cam-install
       spec:
         manageservice:
           global:
             externalDb: <true | false >
             externalDbConfig: < external DB config in base 64 >
             externalMongoDBCertificate: <CA certificate  in  base 64 >
             mongoDbUrl: <mongodburl in  base 64  >
     license:
       accept: true
     storageClass: rook-cephfs
     storageClassLargeBlock: rook-ceph-block
   ```

   - externalDb: Set this value to true.
   - externalDbConfig: Add base64 encode for extra configuration. This is added as an object and contain all the options that require to connect the mongo connection.

   Sample configuration:

   ```
   {
     "ssl":true,
     "sslValidate":false,
   }
   ```

   Note: Add **certType: 'crt'** for crt type certification or **certType: 'pem'** for pem type certification in the external database configuration.

   - externalMongoDBCertificate: base64 encode of the certificate.
   - mongoDbUrl: External database url.

   Note: Some of the mongo instance may use only url and need not require any certificate. In such case, update externalDb and mongoDbUrl.

3. Save your **IAConfig** changes.
4. All the pods are deleted and newly created pods points to the external MongoDB connection.

Disconnection of external MongoDB and reconnect to the cam-mongo pods

Steps to disconnect from an external MongoDB connection and reconnect to the cam-mongo pods:

1. Edit the **IAConfig**.

   ```
   oc edit IAConfig -A
   ```

2. Set the externalDb to false in **IAConfig**.

   ```
   global:
        externalDb:  false
   ```

3. Save your **IAConfig** changes.
4. All the pods are deleted and newly created pods points to the cam-mongo pods.

When you are unable to access Managed services routes with correct externalDB configuration, then increase the **icpdata_addon_version** to a higher value in the configmap **cam-proxy-zen-extension**.

```
oc -n cp4aiops edit configmap cam-proxy-zen-extension
```

Configuring a custom HTTPS certificate for Managed services Management Console

Procedure to install a custom certificate for use by the Managed services management console. You must first install Managed services and then customize your secrets using instructions in Procedure to configure your custom HTTPS certificate postinstallation.

You can configure your custom HTTPS certificate either during installation of Managed services or update the certificate postinstallation. Before you follow the below procedure, you need to create a secret to store your custom certificates required by the nginx server. The secret must contain the following key values.

- A key named **tls.crt** whose value must be the tls certificate.
- A key named **tls.key** whose value must be the tls key.

After creating the secret, follow one of the following procedures:

- Procedure to configure your custom HTTPS certificate during installation
- Procedure to configure your custom HTTPS certificate postinstallation

Procedure to follow to configure your custom HTTPS certificate during installation

To set the custom HTTPS certificate during installation, use the name of a new secret which contains the custom certificates as the value for **camProxy.customNginxSSLCertificate.customNginxSSLCertName** in the **IAConfig** resource specification. For more details on how to create **IAConfig** resource, see Online install of Infrastructure Automation for IBM Cloud Pak for AIOps or Online installation of Infrastructure Automation.

The following sample yaml shows **IAConfig** resource specification with customized certificate name as value for **camProxy.customNginxSSLCertificate.customNginxSSLCertName**.

```
cat << EOF | oc apply -f -
kind: IAConfig
apiVersion: aiops.ibm.com/v1alpha1
metadata:
  name: ibm-ia-installer
  namespace: cp4aiops
spec:
  imagePullSecret: ibm-entitlement-key
  infraAutoComposableComponents:
    - enabled: <Set true to install Infrastructure Management component of {{site.data.keyword.infra_automation}} false
otherwise>
      name: ibm-management-im-install
      spec: {}
    - enabled: <Set true to install Managed services component of {{site.data.keyword.infra_automation}} false otherwise>
      name: ibm-management-cam-install
      spec:
        manageservice:
          camProxy:
            customNginxSSLCertificate:
              customNginxSSLCertName: mycert
  license:
    accept: <Set true to accept the license>
  storageClass: <Storage Class name that supports RWO>
  storageClassLargeBlock: <Select a storage class with a large block size (for example, 64k)>
EOF
```

Note: If Infrastructure Automation is installed with IBM Cloud Pak for AIOps, then set **storageClass** and **storageClassLargeBlock** to the same classes that IBM Cloud Pak for AIOps uses.

To verify whether cam-proxy uses your custom secret, the **type** value for volume **cam-nginx-cert** must be set to your secret name once the cam-proxy pod comes up. If your secret name is **mycert**, then the type column must display **mycert**.

Procedure to configure your custom HTTPS certificate postinstallation

To set the custom HTTPS certificate after installation, do the following:

1. In Red Hat OpenShift Container Platform console, navigate to your installed ManagedService custom resource YAML.
2. Find string **customNginxSSLCertName** in the YAML.
3. Set the secret name of your custom certificate (tls.crt and tls.key) as the value for **customNginxSSLCertName**. If your secret name is **mycert** then your modified YAML looks as below:

```
camProxy:
  replicaCount: 1
  resources:
    limits:
      cpu: 500m
      memory: 1500Mi
```

```
    requests:
      cpu: 100m
      memory: 256Mi
  customNginxSSLCertificate:
    customNginxSSLCertName: mycert
```

4. Save your changes.
5. Your cam-proxy pod will be restarted. To verify whether cam-proxy uses your custom secret, once the cam-proxy pod comes up, the **type** value for volume **cam-nginx-cert** must be set to your secret name. If your secret name is **mycert**, then the type column must display **mycert**.

Enabling or disabling IBM Business Process Manager

Post the installation of Managed services, you can enable or disable Business Process Manager from the IBM Cloud Pak for AIOps.

Procedure

Complete these steps from your OpenShift console.

1. Click **Operators** > **Installed Operators**.
2. Select **cp4aiops** namespace from the **Project** drop-down list.
3. Select the operator **IBM Management Infrastructure managed services**.
4. Select the tab Managed services.
5. Edit the Managed services instance by selecting **Edit ManageService** from the overflow menu.
6. Search **camBpmProvider** in YAML and change the following values:
   - Change **replicaCount** to 1.
   - Edit **bpmEndpoint** with the BPM endpoint value.
   - Edit **bpmUserName** with the user name value.
   - Edit **bpmUserPwd** with the password.

     These are the sample values for BPM provider:

     ```
     camBpmProvider:
       bpmEndpoint: 'https://9.9.9.9:9443/'
       bpmUserName: 'admin'
       bpmUserPwd: 'passw0rd'
       replicaCount: 1
     ```
7. Save the YAML file.

Note: The supported version of IBM Business Process Manager is 8.5.7.

Enabling or disabling Ansible Integration

Post the installation of Managed services, you can enable or disable Ansible integration from the IBM Cloud Pak for AIOps.

Procedure

Complete these steps from your OpenShift console.

1. Click **Operators** > **Installed Operators**.
2. Select **cp4aiops** namespace from the **Project** drop-down list.
3. Select the operator **IBM Management Infrastructure managed services**.
4. Select the tab Managed services`.
5. Edit the Managed services instance by selecting **Edit ManageService** from the overflow menu.
6. Search **camAnsibleProvider** in YAML and change the **replicaCount** to 1.
7. Save the YAML file.

Accessing Managed services by using a custom URL

You can access Managed services by using a custom URL.

Before you begin

An ingress must be defined in your cluster.

About the task

You need to perform the procedure from a node that can run OpenShift Client (oc) commands.

Procedure

1. Set up variables with necessary information.

   ```
   FIP=<Hostname>
   ```

   Where **<Hostname>** is the IBM Cloud Pak for AIOps hostname or IP.

   ```
   OAUTH2_CLIENT_REGISTRATION_SECRET=$(oc -n <IA_installation_namespace> get secret platform-oidc-credentials -o yaml | grep OAUTH2_CLIENT_REGISTRATION_SECRET | awk '{ print $2}' | base64 --decode)
   ```

   Where **<IA_installation_namespace>** is the namespace that Infrastructure Automation is installed in.

   ```
   TSA_WLP_CLIENT_ID=$(oc -n cp4aiops get secrets cam-oauth-client-secret -o yaml -o yaml | grep CLIENT_ID | awk '{ print $2}' | base64 --decode)
   ```

2. Verify whether the variables have values.

   ```
   echo $FIP
   ```

   ```
   echo $OAUTH2_CLIENT_REGISTRATION_SECRET
   ```

   ```
   echo $TSA_WLP_CLIENT_ID
   ```

3. Download Managed services OIDC registration using the following command:

   ```
   curl -kvv -X GET -u oauthadmin:$OAUTH2_CLIENT_REGISTRATION_SECRET https://$FIP/idauth/oidc/endpoint/OP/registration/$TSA_WLP_CLIENT_ID | python -m json.tool > tsa-oidc-registration.json
   ```

4. Modify the resulting **tsa-oidc-registration.json** file.

   1. Remove **client_id_issued_at** and **registration_client_uri** attributes.
   2. Under the **redirect_uris** section, add the following entries:

      ```
      "https://<custom_ingresss_or_hostname_and_port>/auth/liberty/callback"
      ```

      ```
      "https://<custom_ingresss_or_hostname_and_port>/cam/auth/liberty/callback"
      ```

      Note: To access the Managed services by using a domain name and Managed services port, replace **<custom_ingresss_or_hostname_and_port>** with **<domain_name>:<port>**. If you created an ingress to access Managed services, replace **<custom_ingresss_or_hostname_and_port>** with the ingress hostname and port.

5. Update Managed services OIDC registration.

   ```
   curl -kvv -X PUT -u oauthadmin:$OAUTH2_CLIENT_REGISTRATION_SECRET -H "Content-Type: application/json" -d @tsa-oidc-registration.json https://$FIP/idauth/oidc/endpoint/OP/registration/$TSA_WLP_CLIENT_ID
   ```

Using pre-created secrets in Managed services

During the installation of Managed services, a secret named **cam-secure-values-secret** is automatically created. This secret contains the default database credentials, encryption credentials, and GitHub credentials to import default templates (IBM Cloud Pak for AIOps 2.3.x fix pack 2 onwards) and proxy information. You can override the default secret values at the time of IBM Cloud Pak for AIOps installation or post-installation by using the following procedure.

Managed services installation specification has an option **secureValues.secretName**. By default, the secret name is empty as IBM Cloud Pak for AIOps automatically creates a secret named **cam-secure-values-secret** at the time of installation. The values in this secret are used by the Managed services deployments. To override the default secret values, you must first create a new secret and then provide the name of your secret in the **secureValues.secretName** section during installation.

If you want to change the values in default secret **cam-secure-values-secret** post-installation, then create a new secret, edit the ManagedService custom resource that was created during installation and provide the name of the new secret as value for **secureValues.secretName** parameter.

You must first install Managed services and then customize your secrets using instructions in Change the secret post installation.

Procedure to change the secret value during installation and post-installation

To change the secret value either during installation or post-installtion, you first need to create a new Kubernetes secret resource with the set of secret values required by the Managed services.

Create a new Kubernetes secret resource

Complete the following steps to create a secret by using a YAML file. Your secret must contain all the data that is shown in the sample yaml file.

1. Log in to your Red Hat® OpenShift® Container Platform cluster by using the **oc login** command:

   ```
   oc login -u kubeadmin -p <YOUR_PASSWORD> --server=<YOUR_SERVER_API_URL>
   ```

2. Encode the secret values in base64. Depending on the data that you are providing, you might need to encode the HTTP and HTTPS proxy URLs, the MongoDB URL and password, and the encryption password.

   IBM Cloud Pak for AIOps 2.3.x fix pack 2 onwards, a new secret data **contentGitHubTokens** is provided to import the default templates and services by using your organizations github.com token. For more information, see Configuring Managed services to import out of box templates and services by using your github.com token

   Use the following command to encode the values to base64.

   ```
   echo "<value-to-be-encoded>" | tr -d '\n' | base64
   ```

   Here is an example command to encode the HTTP proxy URL:

   ```
   echo "http://user1:pass1@some.proxy.com:1234" | tr -d '\n' | base64
   ```

   Note: The `tr -d '\n'` removes newline character before base64 encoding. Example output:

   ```
   aHR0cDovL3VzZXIxOnBhc3MxQHNvbWUucHJveHkuY29tOjEyMzQ=
   ```

3. Define the **my-cam-secure-values-secret.yaml** YAML file by using any editor.

   ```
   vi my-cam-secure-values-secret.yaml
   ```

   Following is a sample content of the YAML file. Replace the values with your base64 encoded values:

   ```
   ###############################################################################

   ###############################################################################
     apiVersion: v1
     kind: Secret
     metadata:
       name: my-cam-secure-values-secret
       namespace: cp4aiops
       labels:
         app: cam
     data:
       httpProxy: aHR0cDovL3VzZXJuYW1lOnBhc3N3b3JkQHByb3h5X2hvc3Q6cHJveHlfcG9ydA==
       httpsProxy: aHR0cDovL3VzZXJuYW1lOnBhc3N3b3JkQHByb3h5X2hvc3Q6cHJveHlfcG9ydA==
       noProxy:
       mongoDbPassword: ZkZDWGI1WjlSNlg3TGhr
       mongoDbUrl: bW9uZ29kYjovL2NhbXVzZXI6ZkZDWGI1WjlSNlg3TGhrQGNhbS1tb25nbzoyNzAxNy9jYW0/c3NsPXRydWU=
       encryptionPassword: ZkZDWGI1WjlSNlg3TGhr
       contentGitHubTokens:
   ```

   Note: If there are some environments, such as Git, vCenter, or OpenStack, that you need to access by bypassing the proxy, then add their IP address or domain names as the **noProxy** parameter value. Separate the values by using commas. **Note**: You must not leave any parameter value as blank. Overwrite the values that you want to change, and leave the other values as they are.

4. Save the YAML file.

5. Create the secret.

   ```
   oc create -f my-cam-secure-values-secret.yaml
   ```

   You can also create the secret by passing the parameter values at command line. You do not need to encode the values. The base64 conversion is automatically done when you run the command. See the following example:

   ```
   oc -n cp4aiops create secret generic my-cam-secure-values-secret --from-
   literal=httpProxy=http://username:password@proxy_host:proxy_port --from-
   literal=httpsProxy=http://username:password@proxy_host:proxy_port --from-literal=noProxy= --from-
   literal=mongoDbPassword=fFCXb5Z9R6X7Lhk  --from-literal=mongoDbUrl=mongodb://camuser:fFCXb5Z9R6X7Lhk@cam-
   mongo:27017/cam?ssl=true --from-literal=encryptionPassword=fFCXb5Z9R6X7Lhk --from-literal=contentGitHubTokens=
   ```

Change the secret during installation

Once you create the new secret with your secret values, use this new secret as a value for **secureValues.secretName** in the **IAConfig** resource specification. For more information on how to create **IAConfig** resource, see Online install of Infrastructure Automation for IBM Cloud Pak for AIOps or Online installation of Infrastructure Automation.

The following sample yaml shows **IAConfig** resource specification with customized **secureValues.secretName**.

```
cat << EOF | oc apply -f -
kind: IAConfig
apiVersion: aiops.ibm.com/v1alpha1
metadata:
  name: ibm-ia-installer
  namespace: cp4aiops
spec:
  imagePullSecret: ibm-entitlement-key
```

```
  infraAutoComposableComponents:
    - enabled: <Set true to install Infrastructure Management component of {{site.data.keyword.infra_automation}} false
otherwise>
      name: ibm-management-im-install
      spec: {}
    - enabled: <Set true to install Managed services component of {{site.data.keyword.infra_automation}} false otherwise>
      name: ibm-management-cam-install
      spec:
        manageservice:
          secureValues:
            secretName: my-cam-secure-values-secret
  license:
    accept: <Set true to accept the license>
  storageClass: <Storage Class name that supports RWO>
  storageClassLargeBlock: <Select a storage class with a large block size (for example, 64k)>
EOF
```

Note: If Infrastructure Automation is installed with IBM Cloud Pak for AIOps, then set **storageClass** and **storageClassLargeBlock** to the same classes that IBM Cloud Pak for AIOps uses.

Change the secret post installation

If you installed Managed services by using the default secret, then you need to replace the default secret with a new secret. First, create a new secret with your new secret values. Then set the name of the new secret as the value of **secureValues.secretName** in the **ManageService** custom resource either by using the Red Hat OpenShift Container Platform console or by the following OC command line

```
oc edit manageservice cam -n cp4aiops
```

Once you change the secret name in **secureValues.secretName**, save the configuration. The deployments that use the secret will be restarted automatically.

Change the value of secret data in your secret

If you want to change secret data value in the secret you created, then edit the secret you created and change the value. You must restart all the cam running pods that use the secret for the changes to take effect.

Configuring Managed services to use a proxy

If your corporate policies dictate that you use a proxy server for all HTTP(s) communication to the internet, then you must configure the Managed services to use that proxy server.

There are two steps required in order to enable Managed services to use the proxy server:

1. Create the secret and specify the http(s) proxy using the procedure explained in this topic, Using pre-created secrets in Managed services.

   Note: If there are some environments, such as Git, vCenter, or OpenStack, that you need to access by bypassing the proxy, then add their IP addresses or domain names as the **noProxy** parameter value while creating a secret. Separate the values by using commas.

2. Set **useProxy=true** in the installation parameters. For more information, see Installation parameters.

Configuring Managed services to import templates and services by using your github.com token

You can use your organization's github.com token to import the default provided terraform templates and services into Managed services library. These templates and services are imported into Managed services library during installation of the product.

In the previous releases, the default provided terraform templates and services were imported into Managed services library by using IBM provided token. The downside of this approach is if the IBM provided token is expired or deleted, then you must use the UI to change the token one at a time or contact IBM Support to change the token.

To avoid this downside, it is recommended that you use your organization's github.com token to import the out of box terraform templates and services into Managed services library instead of IBM provided token. Since the templates are stored in github.com, you can genereate new tokens by logging into github.com and then navigate to **Setting** > **Developer settings** > **Personal access tokens**.

contentGitHubTokens secret data

A secret data **contentGitHubTokens** is introduced to the list of pre-created secret data. For more information, see Using pre-created secrets in Managed services. The value for this new secret data **contentGitHubTokens** is a base64 encoded comma-separated list of github.com tokens. The following example shows you how to convert a list of GitHub tokens into base64 encoded string.

Example:

If you want to use the following token list as value for **contentGitHubTokens** secret data:

```
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, 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
```

then encode the above token list by using the following command"

```
echo "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, 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" | tr -d '\n' | base64 -w0
```

Execution of the above command results in the following base64 encoded string:

```
Z2hwX0V4SEptazhlU3k0R0VSWEc1U044T3JtTVBPTmdTUTNUU3gxWiwgZ2hwXzNUZ2FuUGFWcnVseW9ENEZvRU9JVjh5Ylp0dmU5eDBGSW5QUQ==
```

Use this base64 encoded string as the value of secret data **contentGitHubTokens**.

Procedure to use your base64 encoded token list

Once you get the base64 encoded token list, follow the procedure in Using pre-created secrets in Managed services to change the default IBM provided token.

Note

Do the following if your organizations token used in contentGitHubTokens is expired or revoked:

1. You must first regenerate a new base64 encoded token list.
2. Change the value for contentGitHubTokens in the secret you created by using the procedure in Using pre-created secrets in Managed services.
3. Since contentGitHubTokens secret data value is set as the value of the environment variable CONTENT_GITHUB_TOKENS in cam-iaas deployment, you must restart the cam-iaas pod for the changes to reflect.

Configuring Managed services to set the SSH keys and known hosts in provider terraform pod

To download and execute any terraform module that is stored in a repository and protected by a private key, you need to set private SSH keys and known hosts under **/home/terraform/.ssh** folder in the **cam-provider-terraform** pod. The **/home/terraform** folder in provider terraform is a read only directory hence you cannot create any files or folder under the directory. The following process helps you to create the private keys and known host files that are required to download and execute the external terraform modules.

Create secret that contains private keys and known hosts

You must first create a secret that contains the content of your private key and known host file. You can use the following command to create it.

```
oc -n <namespace> create secret generic <secret_name> --from-file=id_rsa=<path-to-private-ssh-key-file> --from-file=known_hosts=<<path-to-knownhosts-file>
```

Alternately, you can define the secret in a yaml file **mysshkey.yaml** as follows:

```
#############################################################################
# Licensed Materials - Property of IBM.
# Copyright IBM Corporation 2022. All Rights Reserved.
# U.S. Government Users Restricted Rights - Use, duplication or disclosure
# restricted by GSA ADP Schedule Contract with IBM Corp.
#
# Contributors:
#  IBM Corporation - initial API and implementation
#############################################################################
apiVersion: v1
kind: Secret
metadata:
  name: <secret_name>
  namespace: <namespace>
data:
  id_rsa: <base64 encoded private key content>
  known_hosts: <base64 encoded known hosts content>
type: Opaque
```

Execute the following command to create the secret:

```
oc create -f mysshkey.yaml
```

Procedure to add the key files to provider terraform pod

Once the secret is created, you can add the key and known host files to the **cam-provider-terraform** pod either during installation of Infrastructure Automation or after installation.

- To add the key files during installation, you must set the customization parameters under **spec.manageservice** section in the install yaml as follows:

```
cat << EOF | oc apply -f -
  kind: IAConfig
  apiVersion: aiops.ibm.com/v1alpha1
  metadata:
    name: ibm-ia-installer
    namespace: cp4aiops
  spec:
    imagePullSecret: ibm-entitlement-key
    infraAutoComposableComponents:
    - enabled: <Set true to install Infrastructure Management component of {{site.data.keyword.infra_automation}}
```

```
false otherwise>
      name: ibm-management-im-install
      spec: {}
    - enabled: <Set true to install Managed services component of {{site.data.keyword.infra_automation}} false
otherwise>
      name: ibm-management-cam-install
      spec:
        manageservice:
          camProviderTerraform:
            terraformSSHDir:
              terraformSSHDirSecret: <ssh_secret_name>
  license:
    accept: <Set true to accept the license>
  storageClass: <Storage Class name that supports RWO>
  storageClassLargeBlock: <Select a storage class with a large block size (for example, 64k)>
EOF
```

Note: If Infrastructure Automation is installed with IBM Cloud Pak for AIOps, then set **storageClass** and **storageClassLargeBlock** to the same classes that IBM Cloud Pak for AIOps uses.

- To set the key files after installation, do the following:

  1. In Red Hat OpenShift Container Platform console, navigate to your installed **ManagedService** custom resource YAML.
  2. Find the string **terraformSSHDirSecret** in the YAML.
  3. Set the secret name of your ssh key and known host file as the value for **terraformSSHDirSecret**. If your secret name is **terraform-ssh-secret**, then your modified YAML looks as follows:

     ```
     camProviderTerraform:
       isolateRuntime: true
       replicaCount: 1
       runtime:
         replicaCount: 1
       terraformSSHDir:
         terraformSSHDirSecret: terraform-ssh-secret
     ```

  4. Save the changes.
  5. Your **cam-provider-terraform** pod is restarted. To verify the **cam-provider-terraform** pod changes, you can list the key files using **ls /home/terraform/.ssh**. This should display the ssh key and known host files.

Note: After you change the contents of the secret, ensure to restart the **cam-provider-terraform** pod to reflect the changes.

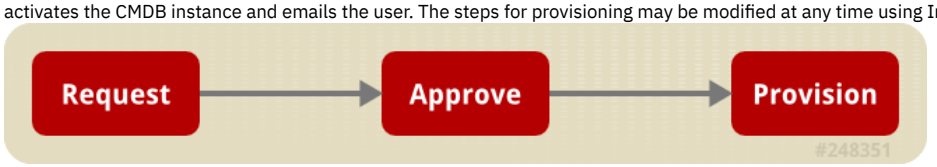
Provisioning Virtual Machines and Instances

Infrastructure Automation Lifecycle



This guide discusses lifecycle activities such as provisioning and retirement that are part of the Infrastructure Automation Automate component. Infrastructure Automation Automate enables real-time, bidirectional process integration and adaptive automation for management events and administrative or operational activities.

- Operations Management with service level resource enforcement.
- Resource Management including datastore cleanup, snapshot aging and enforcement, and virtual machine or instance aging and retirement.
- Configuration and Change Management including enforced closed loop change management.
- Lifecycle Management such as provisioning, customization, reconfiguration, approval, CMDB updates, and retirement.

Provisioning requires the **Automation Engine** server role enabled. Check your server role settings in the settings menu, **Configuration > Server > Server Control**.

Provisioning

When a virtual machine or cloud instance is provisioned, it goes through multiple phases. First, the request must be made. The request includes ownership information, tags, virtual hardware requirements, the operating system, and any customization of the request. Second, the request must go through an approval phase, either automatic or manual. Finally, the request is executed. This part of provisioning consists of pre-processing and post-processing. Pre-processing acquires IP addresses for the user, creates CMDB instances, and creates the virtual machine or instance based on information in the request. Post-processing activates the CMDB instance and emails the user. The steps for provisioning may be modified at any time using Infrastructure Automation.

Provisioning Requests

The following options are available when making provisioning requests:

- Set an owner (User can do this using LDAP lookup)
- Assign a purpose (tag)
- Select a template or image from which to create a new virtual machine or instance respectively
- Choose placement
- Set hardware requirements
- Specify the vLan
- Customize the guest operating system
- Schedule the provisioning

Requirements for Provisioning Virtual Machines and Instances

Infrastructure Automation supports the provisioning of VMware ESX hypervisors. To provision a virtual machine from VMware providers, you must have an appliance with the Automation Engine role enabled.

If you are using a Windows template, the following configuration is required:

- To customize settings that are inside the operating system, Sysprep must be copied to the appropriate directory on your vCenter computer. Usually this location is: **`C:\Documents and Settings\All Users\Application Data\VMware\VMware VirtualCenter\sysprep`**. Copy the Sysprep tools to the relevant operating system subdirectory. If you are running a standard Win2008 operating system, this step is unnecessary as Sysprep is included as standard.
- The Windows template must have the latest version of VMware tools for its ESX Server. Check the VMware Site for more information. If you are creating a new password for the Administrator account, the Administrators password must be blank on the template. This is a limitation of Microsoft Sysprep.

See the VMware documentation for a complete list of customization requirements.

Requirements for Provisioning Virtual Machines from Red Hat Virtualization Manager

Item	Requirements
Red Hat Virtualization Manager version 4.0 or higher	Red Hat Virtualization Manager properly installed with API in default location https://server:8443/api
Red Hat Virtualization Manager History Database	Red Hat Virtualization Manager Data Warehouse (DWH) properly installed with access to the PostgreSQL database on the Red Hat Virtualization Manager server. Port 5432 open in iptables. md5 authentication allowed to Infrastructure Automation appliances in **`pg_hba.conf`**. PostgreSQL set to listen for connections on **`*:5432`** in **`postgresql.conf`**. Credentials provided during database setup to be used in Infrastructure Automation UI.
Storage Supported for Infrastructure Automation Virtual Machine Analysis	NFS - Infrastructure Automation server must be able to mount NFS storage domain. iSCSI / FCP - Cluster must use full Red Hat Enterprise Linux (not Red Hat Virtualization Hypervisor) Hosts. DirectLUN Hook installed on each host and registered to Red Hat Virtualization Managers. Must have Infrastructure Automation appliance in each Cluster with this storage type. Infrastructure Automation appliance virtual machine container must have DirectLUN attribute set. Local storage - Not yet supported (Red Hat does not recommend due to single point of failure).

PXE Provisioning

PXE is a boot method that allows you to load files from across a network link. Infrastructure Automation uses it for files required for provisioning virtual machines. PXE can be used for provisioning for either Red Hat Virtualization Manager or VMware.

Procedure Overview

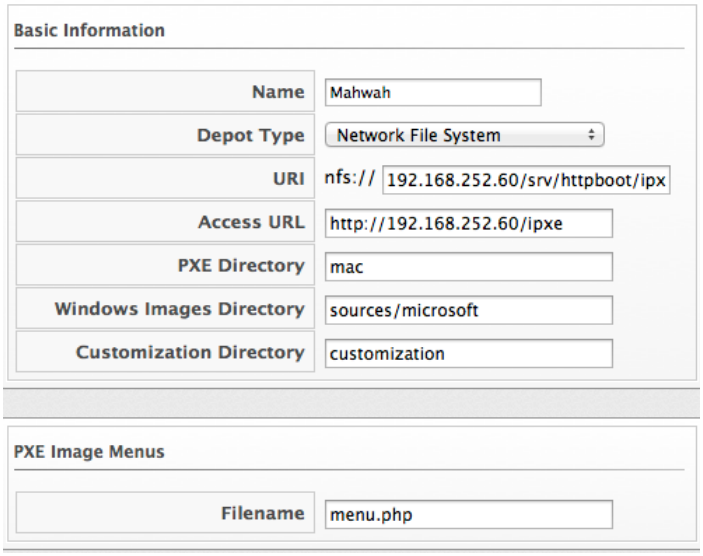
1. Connect to the **PXE Server**.
2. Create a **System Image Type**.
3. Associate each **PXE** image with an image type.
4. Create a customization template.

Requirements for PXE Provisioning

- DHCP server configured with required PXE implementation
- PXE implementation for Linux virtual machine provisioning
- NFS or SAMBA read and write access to create and modify files on the PXE server
- Infrastructure Automation Server uses NFS mount to read and write the response files
- HTTP read access to the NFS share location as virtual machines use this URL to access PXE images and Kickstart or Cloud-Init configuration files
- Operating system installation media available to be streamed from PXE server
- Images configured for desired operating systems
- Kickstart or Cloud-Init templates to configure operating systems with desired packages

Additional Requirements for Provisioning Linux Virtual Machines

- Linux distribution kernel and ramdisk available over HTTP
- Linux sources available over HTTP
- Sample PXE menu item that boots this kernel



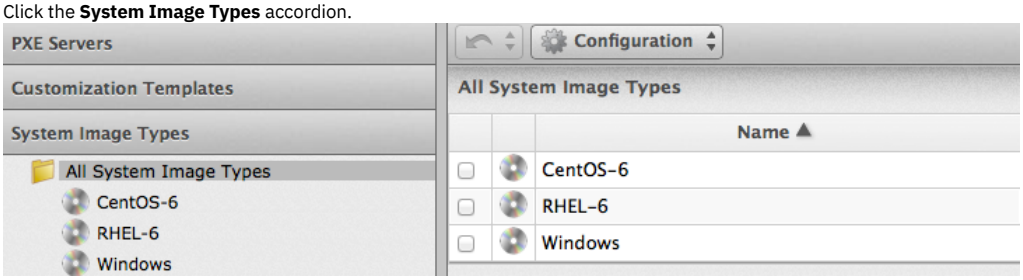
Additional Requirements for Provisioning Windows Virtual Machines

- WinPE ISO built with rhev-agent-tools (for RHEV-M environments) and configured to mount shares for Windows source files and Sysprep files and configured to run customization script
- Windows based WIM file with operating system installed and configured with Sysprep
- Sample Sysprep unattend file to be used with the operating system
- Sample PXE menu item that downloads WinPE ISO, mount in memdisk and boot into WinPE environment

Connecting to a PXE Server

The following procedure connects to a PXE server and adds its details to Infrastructure Automation.

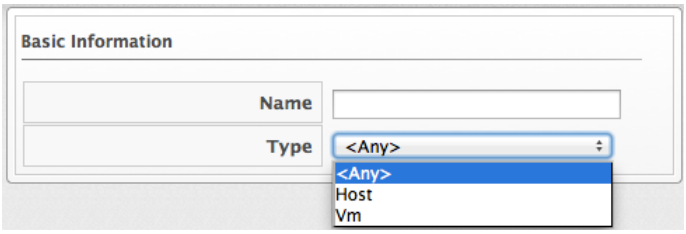
1. Navigate to **Compute > Infrastructure > PXE**.
2. Click (**Configuration**), then (**Add a New PXE Server**).
3. In **Basic Information**, type a **Name** that will be meaningful in your environment.



4. For **Depot Type**, select either **Network File System** (NFS) or **Samba**. The fields to enter in the dialog depend on the **Depot Type**.
   - For NFS, type in the **URI**, **Access URL**, **PXE Directory**, **Windows Images Directory**, and **Customization Directory**. When you provision, Infrastructure Automation writes a text file to the **PXE Directory**. The file is named after the MAC address of the NIC that is assigned to the virtual machine. It contains where to get the kernel and initrd image. This file is removed after a successful provision. The **Windows Images Directory** is where the files are located on your NFS for the provisioning of Windows operating systems. The **Customization Directory** is where your Kickstart and Sysprep files are located.
   - If using a **Depot Type** of **Samba**, you will not need **Access URL**, but you will need a **User ID**, and **Password**, in addition to the items required for NFS.
5. For **PXE Image Menus**, type the **Filename** for the PXE Boot menu.
6. Click **Add**.
7. Select the new PXE server from the tree on the left, and click (**Configuration**), then (**Refresh**) to see your existing images.

Next, create PXE Image types to associate with the customization templates and to specify if the image type is for a virtual machine, a host, or both.

Creating System Image Types for PXE



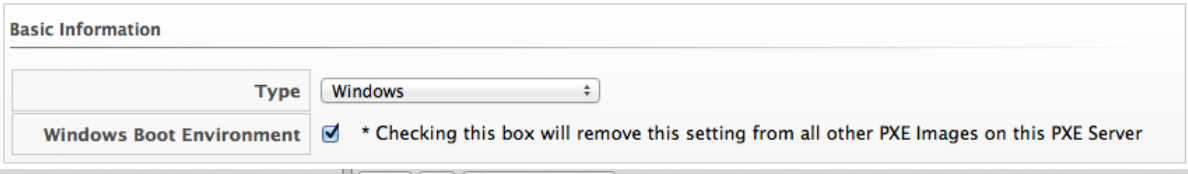
The following procedure creates a system image type for PXE servers.

1. Navigate to **Compute > Infrastructure > PXE**.
2. Click the **System Image Types** accordion.

3. Click (**Configuration**), then (**Add a new System Image Type**).

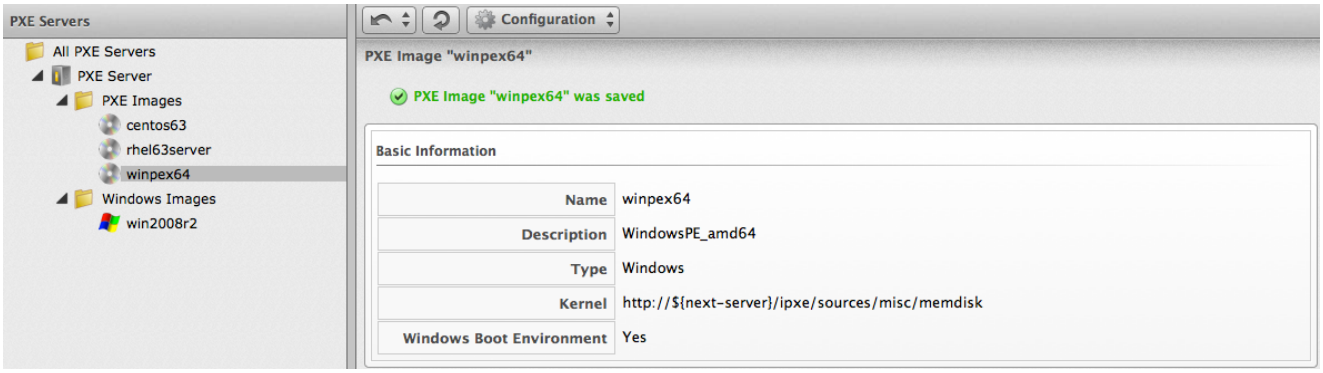
4. In **Basic Information**, type in a **Name** and select a **Type**.

   - Use **Vm** if you want this image type to only apply to virtual machines.
5. Click **Add**.



Example:

After creating the System Image Types, assign the types to each image on your PXE servers. To do this, you will select each image on the PXE server and identify its type.



Setting the PXE Image Type for a PXE Image

The following procedure sets the image type for a chosen PXE image.

1. Navigate to **Compute > Infrastructure > PXE**.
2. Click the **PXE Servers** accordion and select the image that you want to set a type for.
3. Click (**Configuration**), then (**Edit this PXE Image**).
4. From the **Basic Information** area, select the correct type. If this PXE image will be used as the **Windows Boot Environment**, check **Windows Boot Environment**. At the time of this writing, only one PXE Image can be identified as the **Windows Boot Environment**. Therefore, checking one as the **Windows Boot Environment**, will remove that from any other PXE image with that check.

Click **Save**.

ISO Provisioning

Infrastructure Automation also allows ISO provisioning from Red Hat Virtualization Manager datastores. To use this feature, you will need to do the following before creating a provision request.

1. Add the **ISO Datastore**. The Red Hat Virtualization Manager system must have already been discovered or added into the VMDB. For more information, see Adding a Red Hat Enterprise Virtualization Manager Provider in *Managing Providers*.
2. Refresh the **ISO Datastore**.
3. Create a **System Image Type**.
4. Set the **ISO Image Type**.
5. **Create** a customization template.

Adding an ISO Datastore

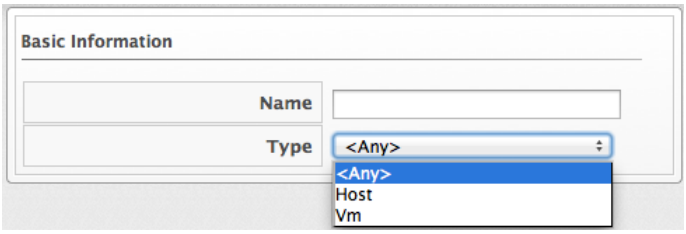
The following procedure adds an ISO Datastore from your Red Hat Virtualization environment.

1. Navigate to **Compute > Infrastructure > PXE**.
2. Click the **ISO Datastores** accordion.
3. Click (**Configuration**), (**Add a new ISO Datastore**).
4. Select the Cloud or Infrastructure provider hosting the ISO Datastore.

5. Click **Add**.

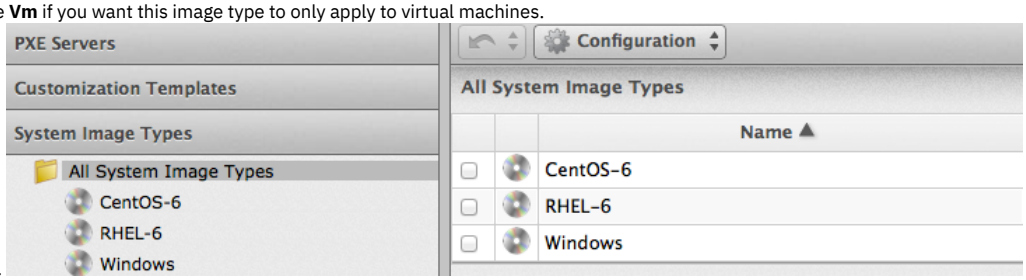
The ISO datastore is added to Infrastructure Automation.

Refreshing an ISO Datastore



The following procedure refreshes the chosen ISO datastore and updates Infrastructure Automation with available ISOs.

1. Navigate to **Compute > Infrastructure > PXE**.
2. Click the **ISO Datastores** accordion, and select an ISO datastore.
3. Click (**Configuration**), then click (**Refresh Relationships**).

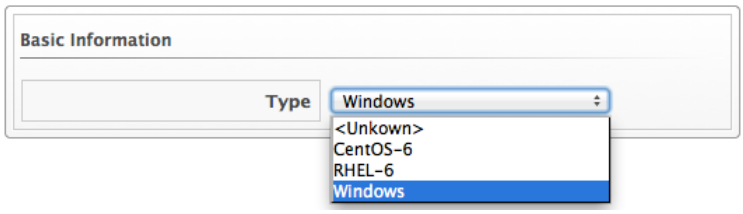


Creating System Image Types for ISO

The following procedure creates a system image type for ISO Servers.

1. Navigate to **Compute > Infrastructure > PXE**.
2. Click the **System Image Types** accordion.
3. Click (**Configuration**), then (**Add a new System Image Type**).
4. In **Basic Information**, type in a **Name** and select a **Type**.

   - Use **Vm** if you want this image type to only apply to virtual machines.
5. Click **Add**.



Example:

After creating the system image types, assign the types to each image on your ISO servers. To do this, you will select each image on the ISO server and identify its type.

Setting the Image Type for an ISO Image

The following procedure sets the image type for an ISO image.

1. Navigate to **Compute > Infrastructure > PXE**.
2. Click the **ISO Datastores** accordion, and select the image that you want to set a type for.
3. Click (**Configuration**), then (**Edit this ISO Image**).
4. From the **Basic Information** area, select the correct **Type**.

5. Click **Save**.

Customization Templates for Virtual Machine and Instance Provisioning

Add a customization template to provide **Kickstart**, **Cloud-Init**, or **Sysprep** files for the initial loading of the operating system.

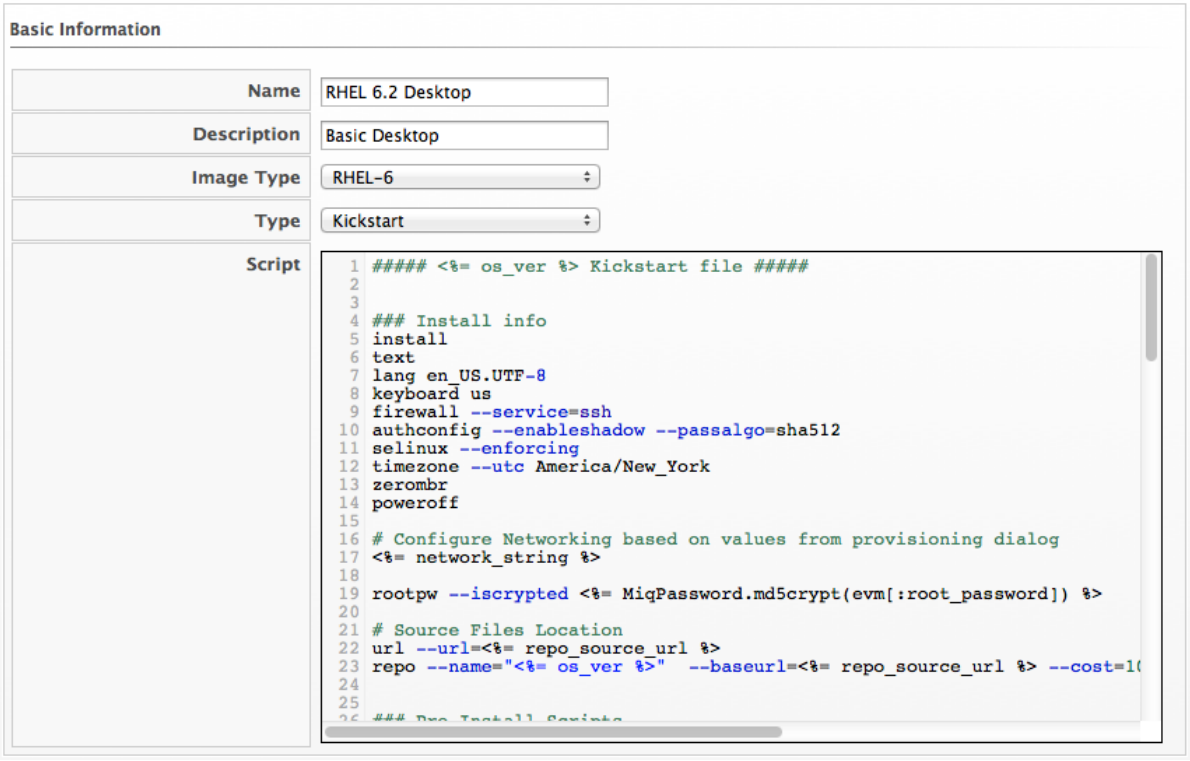
- When creating a template using Red Hat Virtualization, install the **cloud-init** package on the source virtual machine. This enables Cloud-Init to source configuration scripts when a virtual machine built on that template boots.

- See Using Cloud-Init to Automate the Configuration of Virtual Machines in the Red Hat Virtualization *Administration Guide* for more information on using Cloud-Init in a Red Hat Virtualization environment.
- See the Cloud-Init Documentation web site for example scripts.
- The **Kickstart** file must be named **ks.cfg**.
- Set the new virtual machine to power down after provisioning is complete.
- Infrastructure Automation must use the virtual machine payload feature of Red Hat Virtualization to create a floppy disk containing the data from the selected customization template.
- Customize the installer to include the data written to the floppy disk payload.
- RHEL 7.5 and above
- **`isolinux.cfg`** NDASH add **ks=cdrom** to the **append** line
- **`ks.cfg`** NDASH which must minimally include:

```
### Pre Install Scripts
%pre

# Mount the floppy drive
modprobe floppy
mkdir /tmp/floppy
mount /dev/fd0 /tmp/floppy
%end

# Include ks.cfg file from the floppy (written by CFME based on selected customization template)
%include /tmp/floppy/ks.cfg
```



Customization Script Additions for Virtual Machine and Instance Provisioning

Customization Type	Reason to Include	Script entries		
Kickstart	Takes the values from the **Customize** tab in **Provisioning Dialog** and substitutes them into the script.	*Configure Networking based on values from provisioning dialog <% if evm[:addr_mode].first == 'static' %> <% network_string = "network –onboot yes –device=eth0 –bootproto=static –noipv6" %> <% ["ip", :ip_addr, "netmask", :subnet_mask, "gateway", :gateway, "hostname", :hostname, "nameserver", :dns_servers].each_slice(2) do	ks_key, evm_key	%> <% network_string << " –*{ks_key} # {evm[evm_key]}" unless evm[evm_key].blank ? %> <% end %> <%= network_string %> <% else %> network –device=eth0 –bootproto=dhcp <% end %>
Kickstart	Encrypts the root password from the **Customize** tab in the **Provisioning Dialog**.	rootpw –iscrypted <%= ManageIQ::Password.md5crypt(evm[:root_password]) %>		
Kickstart	Sends status of the provision back to Infrastructure Automation Server for display in the Infrastructure Automation Console.			
Sysprep	Encrypts the root password from the **Customize** tab in the **Provisioning Dialog**. The value for the **AdministratorPassword** line must be inserted to use the password from the **Provision Dialog** and encrypt it.	<UserAccounts> <AdministratorPassword> <Value><%= ManageIQ::Password.sysprep_crypt(evm[:root_password]) %> </Value> <PlainText>false</PlainText> </AdministratorPassword> </UserAccounts>		

Adding a Customization Template

1. Navigate to **Compute > Infrastructure > PXE**.
2. Click the **Customization Templates** accordion.
3. Click (**Configuration**), (**Add a new Customization Template**).

4. In **Basic Information**, type in a **Name** and **Description**.

5. Select the **Image Type**. This list should include the PXE image types you created.
6. In **Type**, select **Kickstart** or **CloudInit** for Linux based systems, and **Sysprep** for Windows based system.
7. In the **Script** area, either paste the script from another source or type the script directly into the Infrastructure Automation interface.
8. Click **Add**.

Example:

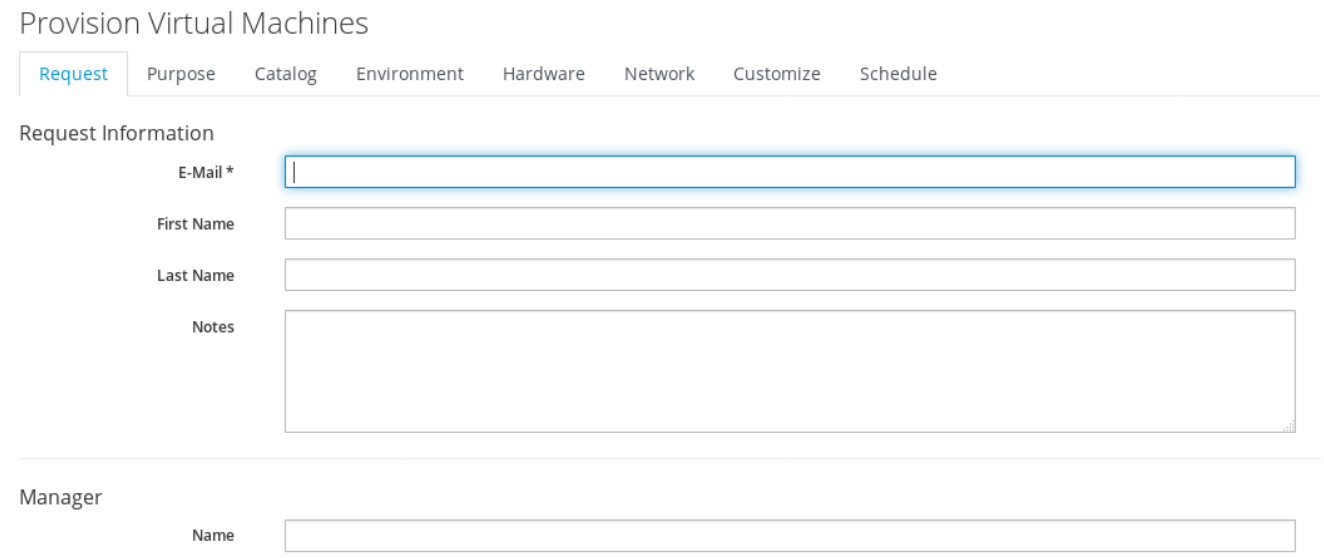
The default dialogs show all possible parameters for provisioning. To limit the options shown, see Customizing Provisioning Dialogs.

Provisioning Virtual Machines

There are four types of provisioning requests available in Infrastructure Automation:

1. Provision a new virtual machine from a template
2. Clone a virtual machine
3. Publish a virtual machine to a template
4. Provision a virtual machine using cloud-init via REST API.

Provisioning a Virtual Machine from a Template



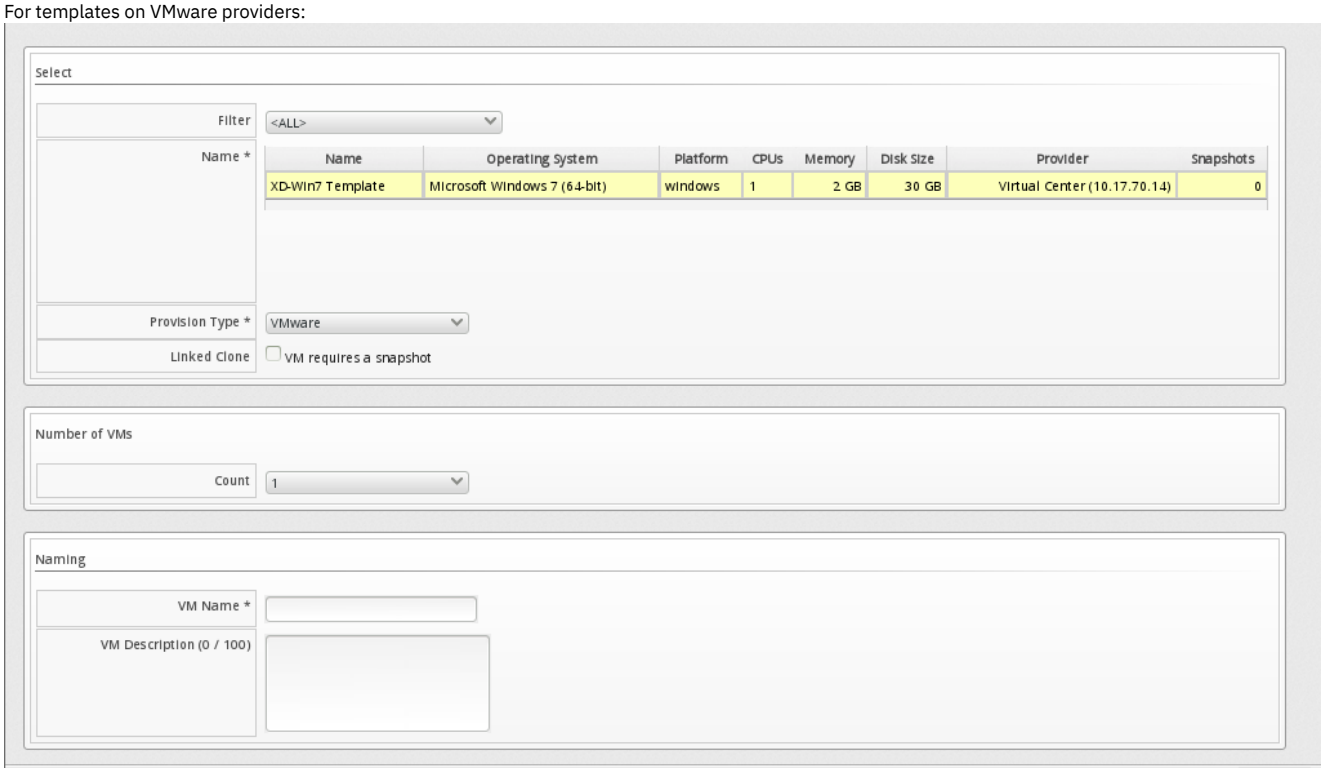
You can provision virtual machines through various methods. One method is to provision a virtual machine directly from a template stored on a provider.

Important:

- To provision a virtual machine, you must have the “Automation Engine” role enabled.
- During virtual machine provisioning, the **Customize** tab is hidden if the template has an unknown operating system (OS) type. To make the **Customize** tab visible in the user interface, you will need to set the OS type from the provider or perform SmartState analysis on the template to detect the OS type.

To provision a virtual machine from a template:

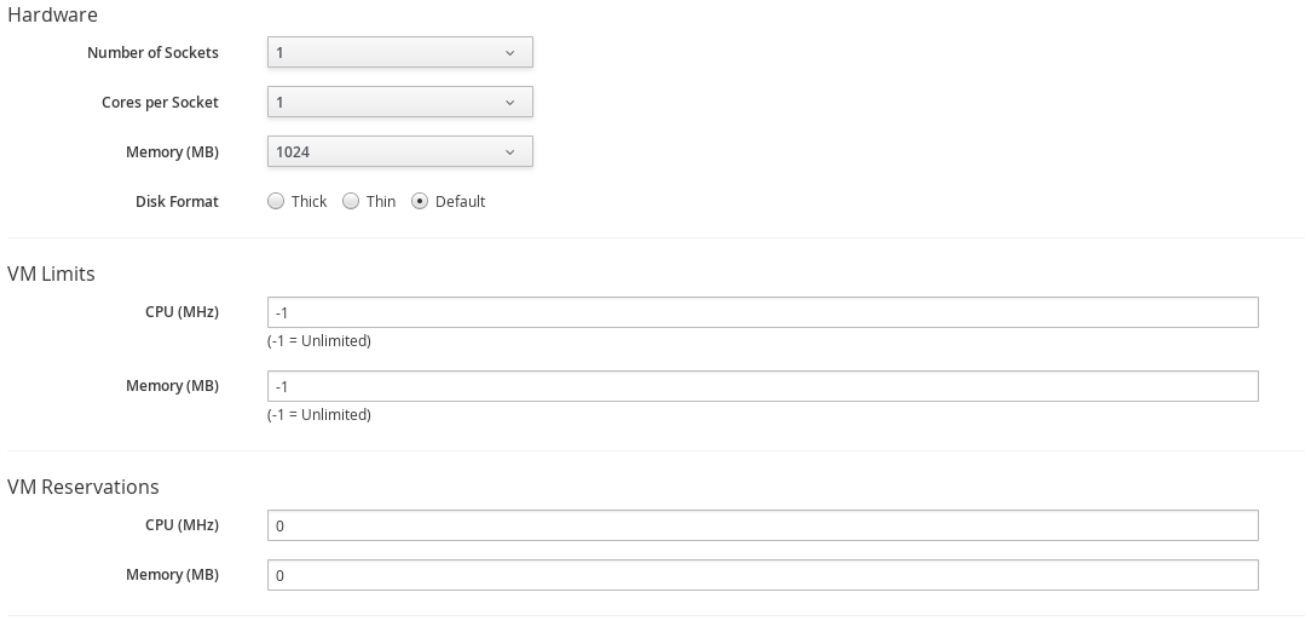
1. Navigate to **Compute > Infrastructure > Virtual Machines**.
2. Click (**Lifecycle**), and then (**Provision VMs**).
3. Select a template from the list.
4. Click **Continue**.
5. On the **Request** tab, enter the request information.



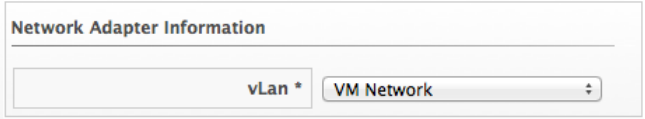
In **Request Information**, enter your name and email address. The requester will receive status emails about the provisioning request such as auto-approval, quota, provision complete, retirement, request pending approval, and request denied.

Note:

Parameters with a * next to the label are required to submit the provisioning request. To change the required parameters, see Customizing Provisioning Dialogs.



6. Click the **Purpose** tab to select the appropriate tags for the provisioned virtual machines.
7. Click the **Catalog** tab to select the template to provision from. This tab is context sensitive based on provider.
8. For templates on VMware providers:



1. For **Provision Type**, select **VMware** or **PXE**.
    1. If **VMware** is selected, select **Linked Clone** to create a linked clone to the virtual machine instead of a full clone. Since a snapshot is required to create a linked clone, this box is only enabled if a snapshot is present. Select the snapshot you want to use for the linked clone.
    2. If **PXE** is selected, select a PXE **Server** and **Image** to use for provisioning.
2. Under **Count**, select the number of virtual machines to create in this request.
3. Use **Naming** to specify a virtual machine name and virtual machine description. When provisioning multiple virtual machines, a number will be appended to the virtual machine name.

9. For templates on Red Hat providers:
    1. Select the **Name** of a template to use.
    2. For **Provision Type**, select either **ISO**, **PXE**, or **Native Clone**. You must select **Native Clone** in order to use a Cloud-Init template.
        1. If **Native Clone** is selected, select **Linked Clone** to create a linked clone to the virtual machine instead of a full clone. This is equivalent to *Thin Template Provisioning* in Red Hat Virtualization. Since a snapshot is required to create a linked clone, this box is only enabled if a snapshot is present. Select the snapshot to use for the linked clone.
        2. If **ISO** is selected, select an ISO **Image** to use for provisioning.
        3. If **PXE** is selected, select a PXE **Server** and **Image** to use for provisioning.
    3. Under **Count**, select the number of virtual machines you want to create in this request.
    4. Use **Naming** to specify a **VM Name** and **VM Description**. When provisioning multiple virtual machines, a number will be appended to the **VM Name**.
10. Click the **Environment** tab to decide where you want the new virtual machines to reside.
    1. If provisioning from a template on VMware, you can either let Infrastructure Automation decide for you by checking **Choose Automatically**, or select a specific cluster, resource pool, folder, host, and datastore. VMware virtual machines can also be provisioned to a clustered datastore by selecting it under **Datastore**. Additionally, you can assign a storage profile to a VMware virtual machine under **Datastore** to configure the virtual machine to operate using a storage profile from that datastore.

        Note, read-only datastores are excluded when provisioning a virtual machine.
    2. If provisioning from a template on Red Hat, you can either let Infrastructure Automation decide for you by checking **Choose Automatically**, or select a datacenter, cluster, host and datastore.
11. Click the **Hardware** tab to set hardware options.

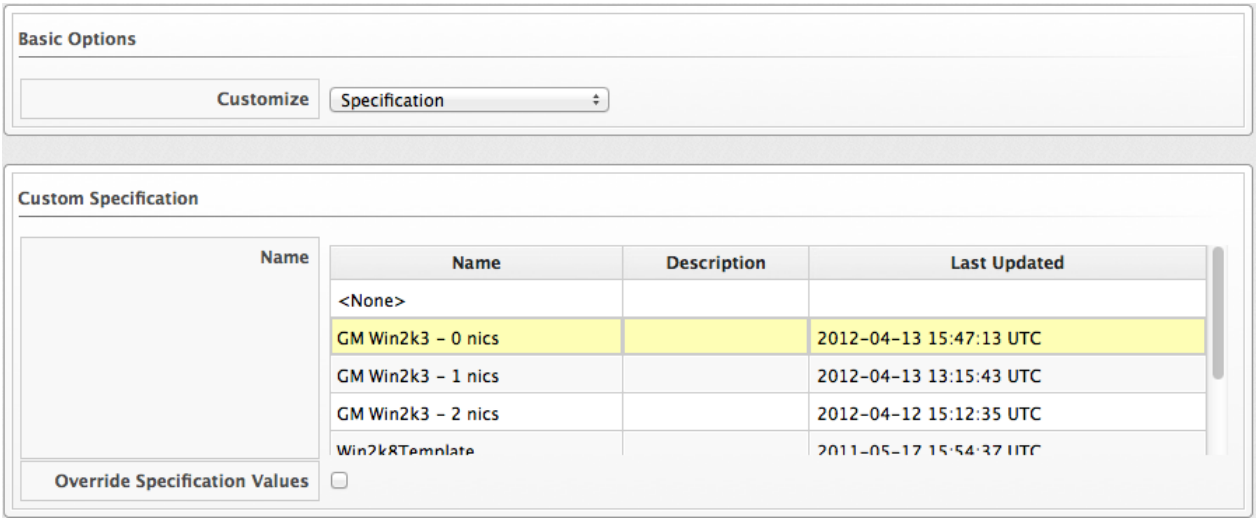
    1. In **Hardware**, set the number of sockets, cores per socket, memory in MB, and disk format: thin, pre-allocated/thick or same as the provisioning template (default).
    2. For VMware provisioning, set the **VM Limits** of CPU and memory the virtual machine can use.
    3. For VMware provisioning, set the **VM Reservation** amount of CPU and memory.
12. Click **Network** to set the vLan adapter. Additional networking settings that are internal to the operating system appear on the **Customize** tab.

    1. In **Network Adapter Information**, select the **vLan**.

        Note:

        A VMware virtual machine can be provisioned to a DVPortgroup by selecting it from the **vLan** list. Prior to provisioning a virtual machine, the DVPortgroup must be created on a vSphere Distributed Switch (VDS) in VMware vCenter in order for Infrastructure Automation to list the DVPortgroup under **vLan**.

13. Click **Customize** to customize the operating system of the new virtual machine. These options vary based on the operating system of the template.



14. For Windows provisioning:

    1. To use a custom specification from the provider, click **Specification**. To select an appropriate template, choose from the list in the custom specification area. The values that are honored by Infrastructure Automation display.

       Note:

       Any values in the specification that do not show in the Infrastructure Automation console's request dialogs are not used by Infrastructure Automation. For example, for Windows operating systems, if you have any run once values in the specification, they are not used in creating the new virtual machines. Currently, for a Windows operating system, Infrastructure Automation honors the unattended GUI, identification, workgroup information, user data, windows options, and server license. If more than one network card is specified, only the first is used.

       To modify the specification, select **Override Specification Values**.

    2. Select **Sysprep Answer File**, to upload a Sysprep file or use one that exists for a custom specification on the Provider where the template resides. To upload a file, click **Browse** to find the file, and then upload. To use an answer file in **Customization Specification**, click on the item. The answer file will automatically upload for viewing. You cannot make modifications to it.

15. For Linux provisioning:

    1. Under **Credentials**, enter a **Root Password** for the **root** user to access the instance.
    2. Enter a **IP Address Information** for the instance. Leave as **DHCP** for automatic IP assignment from the provider.
    3. Enter any **DNS** information for the instance if necessary.
    4. Select **Customize Template** for additional instance configuration. Select from the Kickstart or Cloud-Init customization templates stored on your appliance.

16. Click the **Schedule** tab to select when provisioning begins.

    1. In **Schedule Info**, select when to start provisioning. If you select **Schedule**, you will be prompted to enter a date and time. Select **Stateless** if you do not want the files deleted after the provision completes. A stateless provision does not write to the disk so it requires the PXE files on the next boot.
    2. In **Lifespan**, select to power on the virtual machines after they are created, and to set a retirement date. If you select a retirement period, you will be prompted for when you want a retirement warning.

17. Click **Submit**.

The provisioning request is sent for approval. For the provisioning to begin, a user with the administrator, approver, or super administrator account role must approve the request. The administrator and super administrator roles can also edit, delete, and deny the requests. You will be able to see all provisioning requests where you are either the requester or the approver.

After submission, the appliance assigns each provision request a **Request ID**. If an error occurs during the approval or provisioning process, use this ID to locate the request in the appliance logs. The Request ID consists of the region associated with the request followed by the request number. As regions define a range of one trillion database IDs, this number can be several digits long.

Request ID Format

Request 99 in region 123 results in Request ID 123000000000099.

Provisioning a Virtual Machine using Cloud-Init via REST API

Cloud-init is a tool for automating the initial setup of virtual machines. In Infrastructure Automation, you can use cloud-init via REST API to provision a virtual machine that was created based on a template.

Note:

To use cloud-init, the template from which the virtual machine is provisioned must have cloud-init package installed, and have the **Use Cloud-Init/Sysprep** option selected.

For a virtual machine provision request via REST API, ensure the following two fields in the request's body are set correctly, otherwise cloud-init may not work.

- VLAN
- sysprep_enabled

VLAN.

The value of **VLAN** in the API request can be one of the following options:

VLAN value	Note	vNIC profile
<empty>	Must be written within the <..>	No vNIC profile
<Template>	Must be written within the <..>	Use the template's default vNIC profile
profile_name (network_name)	Must include a space between profile_name (network_name), otherwise it will fail. For example, **ovirtmgmt (ovirtmgmt)**	Set the specified vNIC profile.
vNIC profile ID		Set the specified vNIC profile, such as `3a8dce01-dd59-4a46-8a6f-823acccda79f`.

sysprep_enabled.

The value of sysprep_enabled in the API request must be in the following format.

Note:

Sysprep_enabled is written in the order: [value] - [it's meaning] - [how it appears in the Infrastructure Automation user interface virtual machine provision dialog's **Customize** tab]

For Windows template:

- **"fields"** - Sysprep Specification In the Infrastructure Automation user interface, when you navigate to the virtual machine provision dialog (**Compute > Infrastructure

Virtual Machine**), this option located under the **Customize** tab's **Customize** drop-down list is called **Sysprep Specification**.

- **"file"** - Sysprep answer file in the Infrastructure Automation user interface, when you navigate to the virtual machine provision dialog (**Compute > Infrastructure > Virtual Machine**), this option located under the **Customize** tab's **Customize** drop-down list is called **Sysprep answer file**.

For Linux template:

- **"fields"** - Customized template and any Customized parameters will be used In the Infrastructure Automation user interface, when you navigate to the virtual machine provision dialog (**Compute > Infrastructure

  Virtual Machine**), this option located under the **Customize** tab's **Customize** drop-down list is called **Specification**.

Note:

For cloud-init to work *(that is, to have the provisioned virtual machine marked with **Use cloud-init** and the customized template as well as customized parameters, if any, will be used)* "sysprep_enabled" must be set to "fields". If you do not set it correctly, the customized template will be ignored and the provisioned virtual machine will not be marked with **Use cloud-init**; although, the template from which the virtual machine is provisioned has it marked.

For both Windows and Linux template:

- **"disabled"** - Do not customize In the Infrastructure Automation user interface, when you navigate to the virtual machine provision dialog (**Compute > Infrastructure > Virtual Machine**), this option located under the **Customize** tab's **Customize** drop-down list is called **<None>**. The customized template will be ignored, and the provisioned virtual machine will not be marked with **Use cloud-init**, even though the template from which the virtual machine was provisioned, has it marked. The default value is 'disabled'.

Note:

For an example of virtual machine provisioning request using cloud-init via REST API, see *Provision Requests* in the Infrastructure Automation API Guide.

Cloning a Virtual Machine

Virtual machines can be cloned in other providers as well.

1. Navigate to **Compute > Infrastructure > Virtual Machines**, and select the virtual machine you want to clone.
2. Click (**Lifecycle**), and then (**Clone selected item**).
3. Enter the requested information in the dialogs. Be sure to check the **Catalog** tab.
4. Schedule the request on the **Schedule** tab.
5. Click **Submit**.

Publishing a Virtual Machine to a Template (VMware Virtual Machines Only)

1. Navigate to **Compute > Infrastructure > Virtual Machines**, and select the virtual machine you want to publish as a template.
2. Click (**Lifecycle**), and then (**Publish selected VM to a Template**).
3. Enter the requested information in the dialogs. Be sure to check the **Catalog** tab.
4. Schedule the request on the **Schedule** tab.
5. Click **Submit**.

Renaming a Provisioned Virtual Machine (VMware Virtual Machines Only)

Infrastructure Automation allows you to rename a VMware virtual machine without having to reprovision it.

To rename a VMware virtual machine:

1. Navigate to **Compute > Infrastructure > Virtual Machines**, and select the VMware virtual machine you want to rename.
2. Click (**Configuration**), (**Rename selected item**).
3. In the **Basic Information** screen, provide a new **name**.
4. Click **Save**.

The renamed virtual machine will appear in the inventory view.

Provisioning Instances

Cloud instances follow the same process (Request, Approval, Deployment) as a standard virtual machine from virtualization infrastructure. First, a user makes a request for instances and specifies the image, volume or volume snapshot, tags, availability zone and hardware profile flavor. Second, the request goes through the approval phase. Finally, Infrastructure Automation executes the request.

Provisioning an EC2 Instance from an Image

1. Navigate to **Compute > Clouds > Instances**.

2. Click (**Lifecycle**), then click (**Provision Instances**).
3. Select an image from the list presented.
4. Click **Continue**.
5. On the **Request** tab, enter information about this provisioning request. In **Request Information**, type in at least a first and last name and an email address. This email is used to send the requester status emails during the provisioning process for items such as auto-approval, quota, provision complete, retirement, request pending approval, and request denied. The other information is optional. If the Infrastructure Automation Server is configured to use LDAP, you can use the **Look Up** button to populate the other fields based on the email address.

   Note:

   Parameters with a * next to the label are required to submit the provisioning request. To change the required parameters, see Customizing Provisioning Dialogs.
6. Click the **Purpose** tab to select the appropriate tags for the provisioned instance.
7. Click the **Catalog** tab for basic instance options.
   1. To change the image to use as a basis for the instance, select it from the list of images.
   2. Select the **Number of VMs** to provision.
   3. Type a **VM Name** and **VM Description**.
8. Click the **Environment** tab to select the instance's **Availability Zone**, **Virtual Private Cloud**, **Cloud Subnet**, **Security Groups**, and **Elastic IP Address**. If no specific availability zone is required, select the **Choose Automatically** checkbox.
9. Click the **Properties** tab to set provider options such as hardware flavor and security settings.
   1. Select a flavor from the **Instance Type** list.
   2. Select a **Guest Access Key Pair** for access to the instance.
   3. Select the **CloudWatch** monitoring level. Leave as **Basic** for the default EC2 monitoring.
10. Click the **Customize** tab to set additional instance options.
    1. Under **Credentials**, enter a **Root Password** for the **root** user access to the instance.
    2. Enter a **IP Address Information** for the instance. Leave as **DHCP** for automatic IP assignment from the provider.
    3. Enter any **DNS** information for the instance if necessary.
    4. Select a **Customize Template** for additional instance configuration. Select from the Cloud-Init scripts stored on your appliance.
11. Click the **Schedule** tab to set the provisioning and retirement date and time.
    1. In **Schedule Info**, choose whether the provisioning begins upon approval, or at a specific time. If you select **Schedule**, you will be prompted to enter a date and time.
    2. In **Lifespan**, select whether to power on the instances after they are created, and whether to set a retirement date. If you select a retirement period, you will be prompted for when to receive a retirement warning.
12. Click **Submit**.

The provisioning request is sent for approval. For the provisioning to begin, a user with the admin, approver, or super admin account role must approve the request. The admin and super admin roles can also edit, delete, and deny the requests. You will be able to see all provisioning requests where you are either the requester or the approver.

After submission, the appliance assigns each provision request a **Request ID**. If an error occurs during the approval or provisioning process, use this ID to locate the request in the appliance logs. The Request ID consists of the region associated with the request followed by the request number. As regions define a range of one trillion database IDs, this number can be several digits long.

Request ID Format

Request 99 in region 123 results in Request ID 123000000000099.

Provisioning an OpenStack Instance from an Image, Volume or Volume Snapshot

Create a request to provision Red Hat OpenStack Platform cloud instances from images, volumes, and volume snapshots using Infrastructure Automation. Only bootable volumes not in use will be available.

1. Browse to menu: **Compute > Clouds > Instances**
2. Click (**Lifecycle**), then click (**Provision Instances**).
3. Select an OpenStack image, volume or volume snapshot from the list presented. These files must be available on your OpenStack provider.
4. Click **Continue**.
5. On the **Request** tab, enter information about this provisioning request. In **Request Information**, type in at least an email address. This email is used to send the requester status emails during the provisioning process for items such as auto-approval, quota, provision complete, retirement, request pending approval,

and request denied. The other information is optional. If the Infrastructure Automation Server is configured to use LDAP, you can use the **Look Up** button to populate the other fields based on the email address.

Note:

Parameters with a * next to the label are required to submit the provisioning request. To change the required parameters, see Customizing Provisioning Dialogs.

6. Click the **Purpose** tab to select the appropriate tags for the provisioned instance.
7. Click the **Catalog** tab for basic instance options.
    1. To change the source file to use as a basis for the instance, select it from the list of images, volumes, or volume snapshots.
    2. Select the **Number of Instances** to provision.
    3. Type a **Instance Name** and **Instance Description**.
8. Click the **Environment** tab to select the instance's **Cloud Tenant**, **Availabilty Zones**, **Cloud Network**, **Security Groups**, and **Public IP Address**. If no specific Cloud Tenant is required, select the **Choose Automatically** checkbox.
9. Click the **Properties** tab to set provider options such as flavors and security settings.
    1. Select a flavor from the **Instance Type** list.
    2. Select a **Guest Access Key Pair** for access to the instance. For more information about key pairs, see Managing Key Pairs.
10. Click the **Volumes** tab to provision any volumes with the instance. Volumes are useful for augmenting ephemeral storage of instances with persistent, general-purpose block storage:
    1. Fill in the **Volume Name** and **Size (gigabytes)** fields.
    2. If you want the volume to be deleted once the instance terminates (thereby making it non-persistent), check **Delete on Instance Terminate**.
    3. To provision and add multiple volumes to the instance, click **Add Volume**. Doing so will add new fields you can fill in.

       For more information about persistent storage in OpenStack, see the Red Hat OpenStack Platform *Storage Guide*.
11. Click the **Customize** tab to set additional instance options.
    1. Under **Credentials**, enter a **Root Password** for the **root** user access to the instance.
    2. Enter a **IP Address Information** for the instance. Leave as **DHCP** for automatic IP assignment from the provider.
    3. Enter any **DNS** information for the instance if necessary.
    4. Select a **Customize Template** for additional instance configuration. Select from the Cloud-Init scripts stored on your appliance.
12. Click the **Schedule** tab to set the provisioning and retirement date and time.
    1. In **Schedule Info**, choose whether the provisioning begins upon approval, or at a specific time. If you select **Schedule**, you will be prompted to enter a date and time.
    2. In **Lifespan**, select whether to power on the instances after they are created, and whether to set a retirement date. If you select a retirement period, you will be prompted for when to receive a retirement warning.
13. Click **Submit**.

The provisioning request is sent for approval. For the provisioning to begin, a user with the admin, approver, or super admin account role must approve the request. The admin and super admin roles can also edit, delete, and deny the requests. You will be able to see all provisioning requests where you are either the requester or the approver.

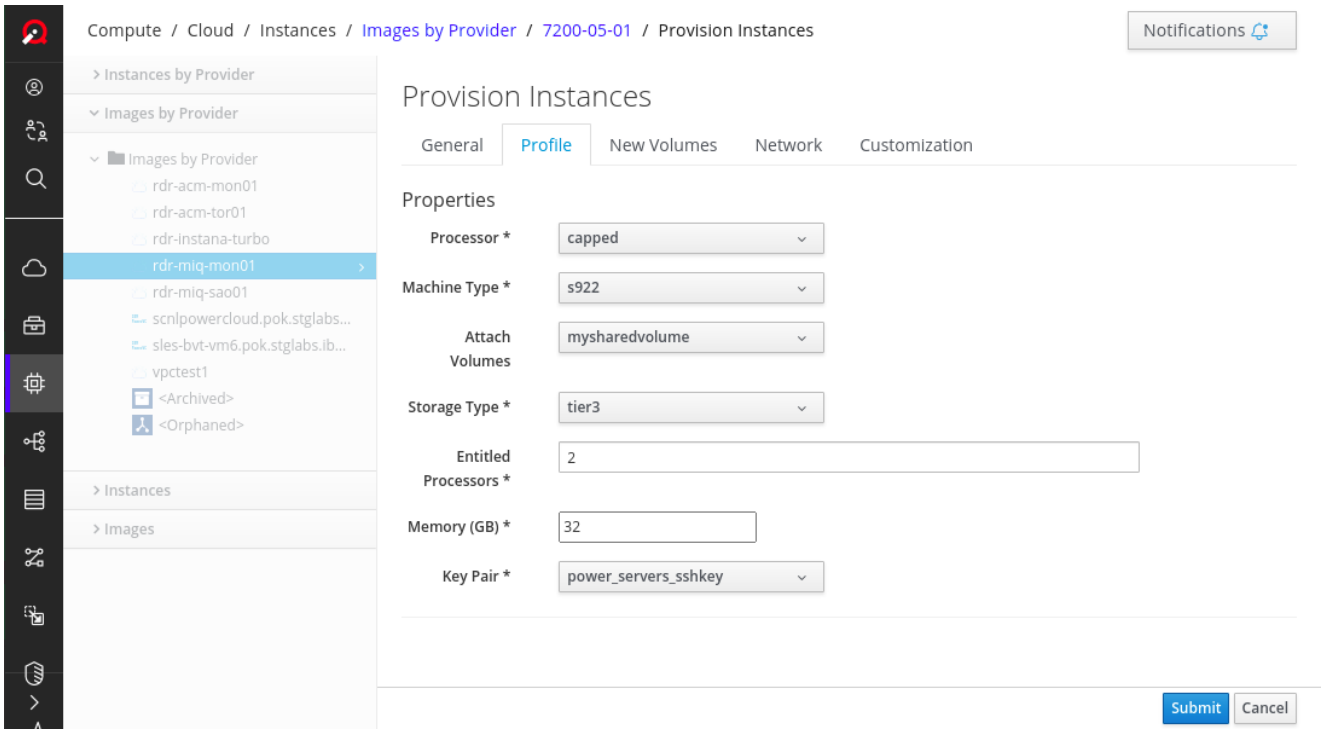
After submission, the appliance assigns each provision request a **Request ID**. If an error occurs during the approval or provisioning process, use this ID to locate the request in the appliance logs. The Request ID consists of the region associated with the request followed by the request number. As regions define a range of one trillion database IDs, this number can be several digits long.

Request ID Format

Request 99 in region 123 results in Request ID 123000000000099.

Provisioning an IBM Power Systems Virtual Servers Instance from an Image

For an overview of IBM Power Systems Virtual Servers, including terminology used in Infrastructure Automation, see Getting started with IBM Power Systems Virtual Servers



Create a request to provision IBM Power Systems Virtual Servers instances from images.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click **Lifecycle**, then click (**Provision Instances**).
3. Select an image from the list presented. Each image is associated with a single Power Systems Virtual Servers provider instance. If there are multiple provider instances registered be sure to select an image associated with the desired instance.

Notes:

- Images must already be imported into a Power Systems Virtual Servers provider instance before becoming available in the Infrastructure Automation inventory. This can be done using the IBM Cloud web interface, CLI, or API. For detailed instructions see IBM Cloud PowerVS docs: Importing a boot image and IBM Cloud CLI: ibmcloud pi image-create.
- SAP HANA on IBM Power Systems Virtual Servers requires special SLES for SAP HANA images. These boot images are added to a Power Systems Virtual Servers provider instance automatically when provisioning an SAP HANA instance through the IBM Cloud web interface. Once the SLES for SAP HANA image has been added, subsequent instances can be provisioned using Infrastructure Automation.

4. Click **Continue**.
5. Click the **General** tab for general instance options.
    1. Select the **Number of Instances** to provision.
    2. Type an **Instance Name**.
6. Click the **Profile** tab for hardware profile options.

    1. Select the **Processor** type.

        Note: See Power Systems Virtual Servers documentation for more information.

    2. Select a **Machine Type**.

        Note: When provisioning with an SAP HANA image, the **Machine Type** field is used to select the SAP profile. The SAP profile includes the number of entitled processors and memory (these fields will be automatically set and can only be changed by selected a different SAP profile).

    3. Optionally, select **Attach Volumes** items.

        Note: A VM cannot have disks from different storage types. Only existing volumes matching the **Storage Type** will be available for selection.

    4. Select a **Storage Type**.

        Note: See Power Systems Virtual Servers documentation for more information on volume types.

    5. Enter number of **Entitled Processors**.

        Notes:

        - If 'dedicated' **Processor** is selected, **Entitled Processors** must be allocated in whole numbers.
        - If 'shared' or 'uncapped' **Processor** is selected, **Entitled Processors** must be allocated in a multiple of '0.25'.
        - When provisioning with an SAP HANA image this field is set by the profile (**Machine Type**) selection.

    6. Enter **Memory (GB)**.

        Note: When provisioning with an SAP HANA image this field is set by the profile (**Machine Type**) selection.

    7. Optionally, select a **Key Pair**.

7. Click the **New Volumes** tab to optionally create new volumes to be attached to the VM.

   All new volumes will be the **Storage Type** selected in the **Profile** tab. For each new volume:

   1. Type a volume **Name**.
   2. Enter **Size (GB)**.
   3. Select a **Sharable**.

8. Click the **Network** tab to select networks.

   1. Select an existing network from **Network Interface**. If 'None' is selected then **Attach to New Public Network** must be selected.
   2. Select **Attach to New Public Network** to create a new public network to attach to the VM.

9. Click the **Customization** tab for additional options.

   1. Use the **Upload File** section to upload a Cloud-init file.
   2. In the **Other** section, select **Migratable** and **VM pinning**

      Note: Learn more about VM pinning.

   3. In the **IP Address Information** section, optionally enter an IP address to request for the selected **Network Interface** in the **Network** tab.

10. Click **Submit**.

The provisioning request is sent for approval. For the provisioning to begin, a user with the admin, approver, or super admin account role must approve the request. The admin and super admin roles can also edit, delete, and deny the requests. You will be able to see all provisioning requests where you are either the requester or the approver.

After submission, the appliance assigns each provision request a **Request ID**. If an error occurs during the approval or provisioning process, use this ID to locate the request in the appliance logs. The Request ID consists of the region associated with the request followed by the request number. As regions define a range of one trillion database IDs, this number can be several digits long.

Request ID Format

Request 99 in region 123 results in Request ID 123000000000099.

Customizing Provisioning Dialogs

The default set of provisioning dialogs shows all possible options. However, Infrastructure Automation also provides the ability to customize which tabs and fields are shown. You can decide what fields are required to submit the provisioning request or set default values.

For each type of provisioning, there is a dialog that can be created to adjust what options are presented. While samples are provided containing all possible fields for provisioning, you can remove what fields are shown but cannot add new fields or tabs.

Edit the dialogs to:

1. Hide or show provisioning tabs.
2. Hide or show fields. If you hide an attribute, the default will be used, unless you specify otherwise.
3. Set default values for a field.
4. Specify if a field is required to submit the request.
5. Create custom dialogs for specific users.

Adding a Provision Dialog for All Users

1. Login to the Infrastructure Automation console for the Infrastructure Automation server where you want to change the dialog.
2. Navigate to **Automation > Embedded Automate > Customization**.
3. Click the **Provisioning Dialogs** accordion.
4. Click the type of dialog you want to create: **Host Provision**, **VM Provision** or **VM Migrate**.
5. Select one of the default dialogs.
6. Click **Configuration**, and then click **(Copy this Dialog)**.
7. Type a new **Name** and **Description** for the dialog.
8. In the **Content** field,

   - To remove a tab from display, change its display value to ignore. By choosing ignore, you not only hide the tab, but also skip any fields on that tab that were required. To show the tab, change the display value to show.
   - To hide a field, change its `:display:` value from `:edit` to `:hide`. To display fields of most data types, use `:edit`. To display a button, use `:show`. To set a default value for a field, add `:default: defaultvalue` to the list of parameters for the field. Set the `:required:` parameter to either `true` or `false` based on your needs.

Note:

If you set `:required:` to `true`, the field must have a value for the provision request to be submitted.

9. Click **Add**.

If you are using **Provisioning Profiles**, you can specify a specific file that holds the customizations. To do this, you must create an instance mapping to this file in the Infrastructure Automation **Applications/provisioning/profile/VM provisioning by group** class. By default, if you are using provisioning profiles and the group does not have a defined instance, the appropriate default dialog file will be used based on the type of provisioning selected.

Creating a Custom Provision Dialog

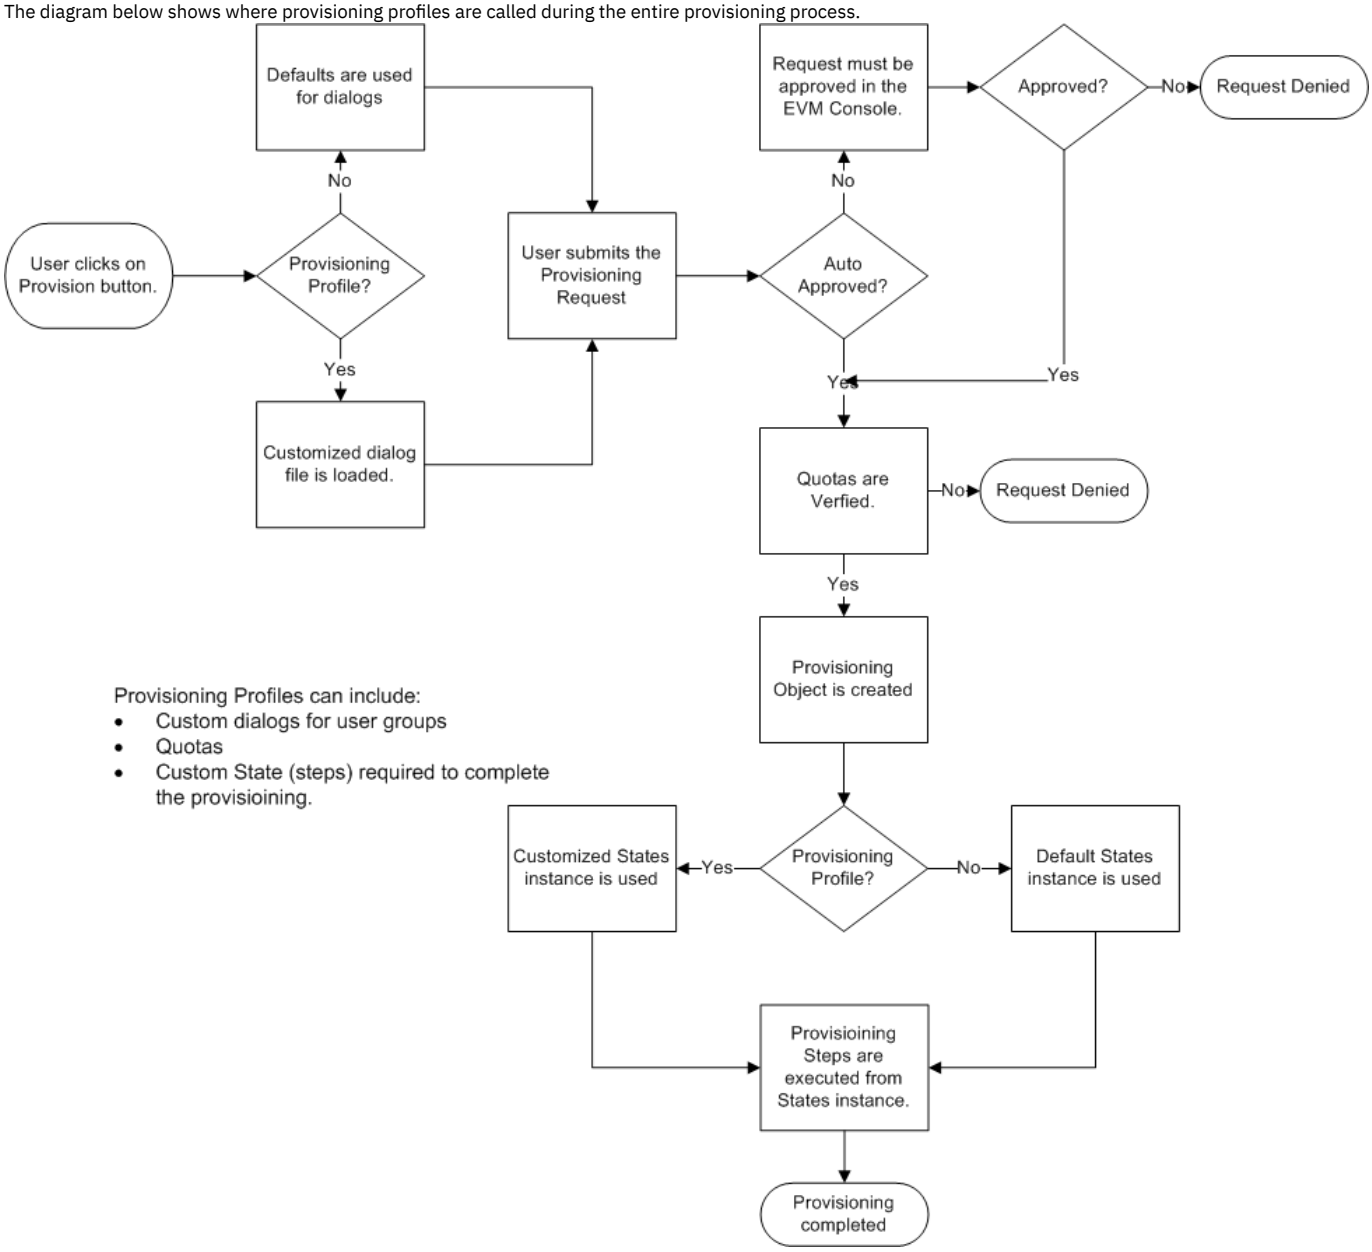
1. Navigate to **Automation > Embedded Automate > Customization**.
2. Click on the **Provisioning Dialogs** accordion.
3. Click on the type of dialog you want to create, **Host Provision**, **VM Provision** or **VM Migrate**.
4. Select one of the default dialogs.
5. Click (**Configuration**), and then (**Copy this Dialog**).
6. Rename the dialog as shown in the examples below.

Type of Provision	Dialog Name
Provision Virtual Machine from a template	miq_provision_dialogs_groupname_template Example: miq_provision_dialogs_ EvmGroup-user_self_service _template
Clone a Virtual Machine	miq_provision_dialogs_groupname_clone_to_vm Example: miq_provision_dialogs_ EvmGroup-user_self_service _clone_to_vm
Publish a Virtual Machine to a template	miq_provision_dialogs_groupname_clone_to_template Example: miq_provision_dialogs_ EvmGroup-user_self_service _clone_to_template

7. Make any changes you need.
8. In the **Content** field,
   - To remove a tab from display, change its display value to ignore. By choosing ignore, you not only hide the tab, but also skip any fields on that tab that were required. To show the tab, change the display value to show.
   - To hide a field, change its `:display:` value from `:edit` to `:hide`. To ensure the field does not get turned back on by a workflow model, use `:display_override: :hide`. To display fields of most data types, use `:edit`. To display a button, use `:show`. To set a default value for a field, add `:default:`
     `defaultvalue` to the list of parameters for the field. Set the `:required:` parameter to either `true` or `false` based on your needs.

     Note:

     If you set `:required:` to `true`, the field must have a value for the provision request to be submitted.
9. Click **Add**.



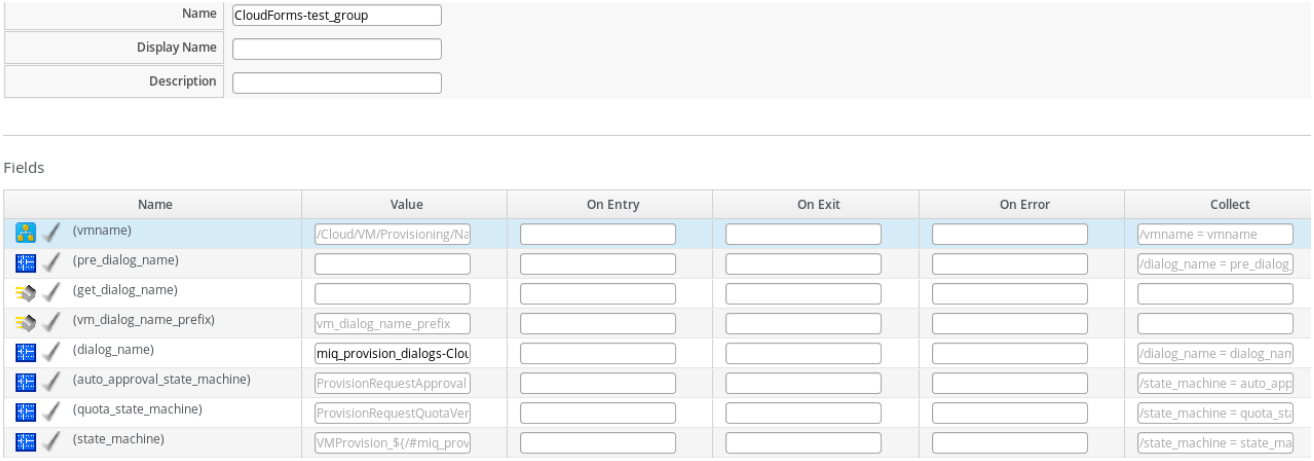
Enter the name of the new dialog into the dialog name field in the appropriate Infrastructure Automation **Applications/provisioning/profile instance**. This dialog can now be referred to in an instance in the Provisioning Profiles class so that it can be used for groups of users.

Provisioning Profiles

Provisioning profiles can be used to customize the dialogs and the state machine (steps used to provision the machine). Profiles can be created for LDAP or Infrastructure Automation groups. To use provisioning profiles:

- Create a **Provisioning Profile** instance for the LDAP or Infrastructure Automation group. If no instance exists, then default settings will be used.
- If customizing dialogs, create a custom dialog file, and specify the name of that file in the provisioning profile instance. If customizing the states for provisioning, create a state instance and set the name of the state instance in the provisioning profile instance.

The diagram below shows where provisioning profiles are called during the entire provisioning process.



Creating a Provisioning Profile Instance

1. Navigate to **Automation > Embedded Automate > Explorer**.
2. Using the tree located in the accordion, click **DOMAIN > Cloud > VM > Provisioning > Profile**.

   Note:

   DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.

   This example uses the **Cloud** Namespace, but can also use the **Infrastructure** namespace.
3. Click (**Configuration**), (**Add a New Instance**).
4. Make the name of the tag identical to the name of the LDAP or Infrastructure Automation group you are creating the instance for, replacing spaces in the group name with underscores. For example, change **Infrastructure Automation-test group** to **Infrastructure Automation-test_group**.

5. In the dialog name field, enter the name of the customized dialog file. This file must reside on the Infrastructure Automation appliance in the **`/var/www/miq/vmdb/db/fixtures`** directory. Red Hat recommends naming the file in the format **`miq_provision_dialogs-groupname.rb`** and copying this file to all Infrastructure Automation appliances. For instructions on creating a custom dialog file, see Customizing Provisioning Dialogs.

   Note:

   Be sure that the custom dialog file exists. If it does not, an error will appear when the user clicks on the **Provisioning** button in the Infrastructure Automation console.

6. Click **Add**.

Setting Provisioning Scope Tags

Some non-default placement methods, for example the **redhat_best_placement_with_scope** or **vmware_best_fit_with_scope** methods, may require you to set **Provisioning Scope** tags for a host and a datastore.

To enable these resources for all groups, set the scope to **All**. To limit access to a select group, create a tag in the **Provisioning Scope** category with the exact name of the user group and set this tag on the desired resources. See Tags in *General Configuration* for information on creating tags.

To set the scope for a datastore:

1. Navigate to **Compute > Infrastructure > Datastores**.
2. Select the datastore to set the provisioning scope for.
3. Click (**Policy**), and then (**Edit Tags**).
4. From the **Select a customer tag to assign** drop down, select **Provisioning Scope** and then a value for the tag from the next drop down menu.
5. Click **Save**.

Managing Key Pairs

Key pairs allow you to manage SSH access between a user and provisioned instance. For more information about key pairs in OpenStack, see Manage Key Pairs in the *Instances and Images Guide*.

To manage key pairs, browse to menu: **Compute > Clouds > Key Pairs**. From there, you can view a list of available key pairs. Click on a key pair to view its details.

To create a new key pair:

1. Browse to menu: **Compute > Clouds > Key Pairs**.
2. Click **Configuration**, (**Add a new Key Pair**).
3. Enter a **Name** for the key pair.
4. If you want to use a public key, copy its contents into the **Public Key (optional)** field.

   Note: You must have a public key value for the IBM POWER VS provider to create the key pair. An error message is returned if you fail to add a public key value and can be viewed in **Settings > Tasks**.

5. Select which cloud provider on which to create the key pair. The key pair will then be available for use by instances in that provider.
6. Click **Add**.

Working with Requests

Provisioning Request Approval Methods

In this chapter, you will learn about the different approval methods. The request can be approved manually in the Infrastructure Automation console, set for automatic approval by setting options in the **Automate Explorer**, or by using an external method.

When using an external method, the approval actually takes place on the external system and is sent directly for execution. This chapter discusses how to view and edit requests in the Infrastructure Automation Console, how to approve a request, and how to set automatic approval parameters.

Working with Provisioning Requests

After a provisioning request is sent, if you have proper authority, you can copy, edit, delete, approve, or deny a request.

After submission, the appliance assigns each provision request a **Request ID**. If an error occurs during the approval or provisioning process, use this ID to locate the request in the appliance logs. The **Request ID** consists of the region associated with the request followed by the request number. As regions define a range of one trillion database IDs, this number can be several digits long.

Request ID Format

Request 99 in region 123 results in **Request ID 123000000000099**.

Reloading the Status of Provisioning Requests

1. Navigate to **Services > Requests**.
2. Click (**Refreshes the current display**).

Approving a Provisioning Request

After a user creates provisioning request, administrators have the ability to approve the request and allow Infrastructure Automation to complete virtual machine or instance creation.

1. Navigate to **Services > Requests**.
2. Click on the request you want to approve.
3. Click (**Approve this request**).
4. Type in a **Reason** for the approval.

Denying a Provisioning Request

1. Navigate to **Services > Requests**.
2. Click on the request you want to deny.
3. Click (**Deny this request**).
4. Type in a **Reason** for the denial.

Copying a Provisioning Request

1. Navigate to **Services > Requests**.
2. Click on the request you want to copy.
3. Click (**Copy original provision request**).
4. Make changes to the request.
5. Click **Submit**.

If the logged in user is not same as the requester or the request has been already approved or denied, you cannot edit or delete the request.

Editing a Provisioning Request

1. Navigate to **Services > Requests**.
2. Click on the request you want to edit.
3. Click (**Edit the original provision request**).
4. Make changes to the request.
5. Click **Submit**.

Deleting a Provisioning Request

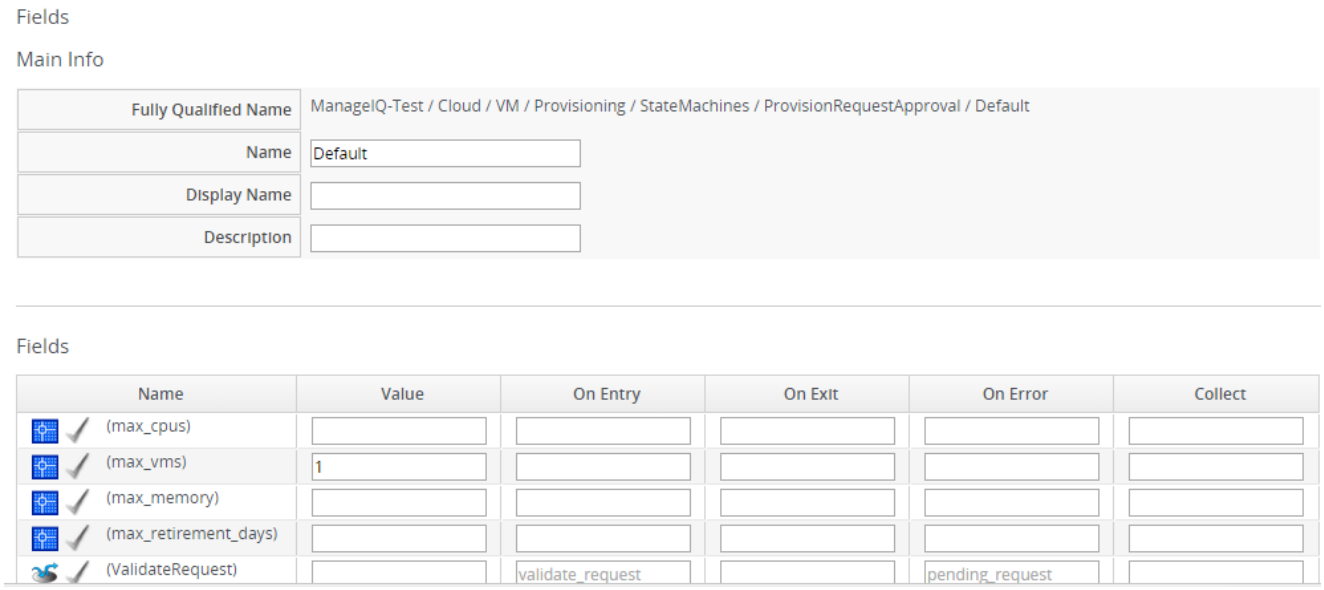
1. Navigate to **Services > Requests**.
2. Click on the request you want to delete.
3. Click (**Delete this request**).
4. Click **OK** to confirm.

Automatically Approving Requests

You can set thresholds for automatic approval of provisioning requests and, therefore, remove the requirement to manually approve the request. You can do this either as a global default or on a per template basis.

Enabling Global Defaults for Automatic Approval

To enable a global set of default approval values, edit the defaults instance by navigating to **Automation > Embedded Automate > Explorer**, then **DOMAIN > Cloud|Infrastructure > VM > Provisioning > StateMachines > ProvisionRequestApproval** in the accordion menu. The parameters in this instance are used by the methods in that same class. By default, the maximum number of virtual machines or instances that can be automatically approved for provisioning is 1. To skip the check for the maximum number of virtual machines, set this field to 0. Set this field to -1 to force manual approval. At a minimum, you must change this parameter for all others to be validated.



1. Navigate to **Automation > Embedded Automate > Explorer**.
2. From the tree in the accordion menu, select **DOMAIN > Cloud > VM

   Provisioning > StateMachines > ProvisionRequestApproval Class**.

   Note:

   DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.

   This example uses the **Cloud** Namespace but can also use the **Infrastructure** namespace.
3. Click (**Configuration**), then (**Edit this instance**).

   Note:

   Do not change any values other than those listed below. Doing so may prevent the automatic approval process from running.

   - Use **max_cpus** to set the number of CPUs allowed to approve automatically the provisioning request.
   - Use **max_vms** to set the maximum number of virtual machines or instances that are allowed to be provisioned automatically approve the request. If this is set to blank, no requests will be automatically approved.
   - Use **max_memory** to set the maximum memory allowed to approve automatically the provisioning request.
   - Use **max_retirement_days** to set the maximum number of days until the virtual machine or instance is retired to automatically approve this request.
   - If a value is blank or **0**, the parameter is ignored.
4. Click **Save**.

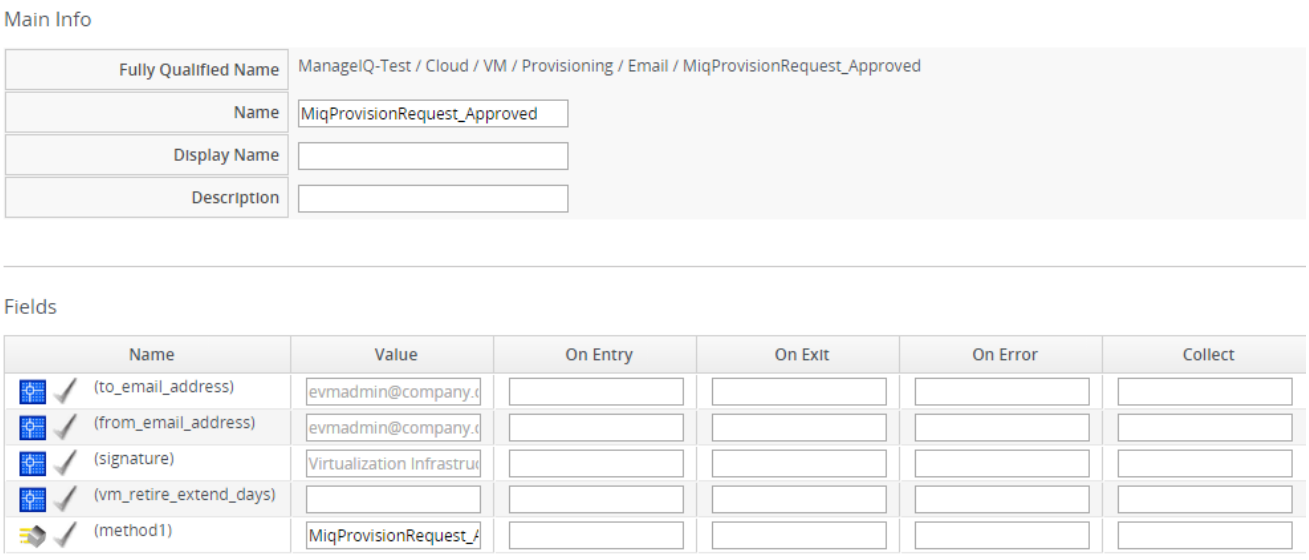
The thresholds for automatic approval are set. The next time a provision request is created these thresholds will be checked. If the requirements are met, the provisioning request will be approved with no user intervention.

Template Specific Approval Defaults

Infrastructure Automation provides tags that can be used to set default automatic approval values on a per template or image basis. These values **supersede** those in the **Automate** model. Use these tags to eliminate the need for manual approval for all provisioning requests. To enable automatic approval, assign the tags directly to templates or images.

Category Display Name (Name)	Use (Sample values)
Auto Approve Max CPU (prov_max_cpus)	Sets the maximum number of CPUs that can be automatically approved in a single provisioning request. Sample Values: 1, 2, 3, 4, 5
Auto Approve Max Memory (prov_max_memory)	Sets the maximum number of memory that can be automatically approved in a single provisioning request. Sample Values: 1, 2, 4, 8 (in GB)
Auto Approve Max Retirement Days (prov_max_retirement_days)	Sets the maximum number of days until retirement that can be automatically approved in a single provisioning request. Sample Values: 30, 60, 90, 180 (in days)
Auto Approve Max VM (prov_max_vms)	Sets the maximum number of virtual machines or instances that can be automatically approved in a single provisioning request. Sample Values: 1, 2, 3, 4, 5

Assigning Tags to a Template for Auto Approval



1. Navigate to **Compute > Infrastructure > Virtual Machines**.
2. Click the **Templates** accordion, and select the templates that you want to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. Select a customer tag from the first dropdown, and then a value for the tag.

The thresholds for automatic approval for a specific template are set. The next time a provision request is created for this template these thresholds will be checked. If the requirements are met, the provisioning request will be approved with no user intervention.

Setting Provisioning Notification Email Addresses

Infrastructure Automation contains a set of Automate instances for provisioning. These Automate instances also include email fields to set the sender and recipient of provisioning notifications, such as requests. These fields are set to **evmadmin@company.com** as a default.

1. Navigate to **Automation > Embedded Automate > Explorer**.
2. Select an instance within the chosen class.
3. Click (**Configuration**), then (**Edit this instance**).
4. Type the desired email addresses in the **to_email_address** and **from_email_address** fields.
5. Click **Save**.

Fulfilling Requests

Fulfilling a Request

After a request has been approved, Infrastructure Automation then goes through the steps required to complete the request. The steps followed for a regular provision from a virtual machine to a virtual machine (not to a template) are found by navigating to **Automation > Embedded Automate > Explorer**, then listed under **DOMAIN > Cloud|Infrastructure > VM > Provisioning > StateMachines > VMProvision_VM > Provision VM from Template (template)**. The value for each state shows where the instance resides in the **Datastore** accordion. The default set of execution steps is shown below. For more information on state machines, see State Machines.

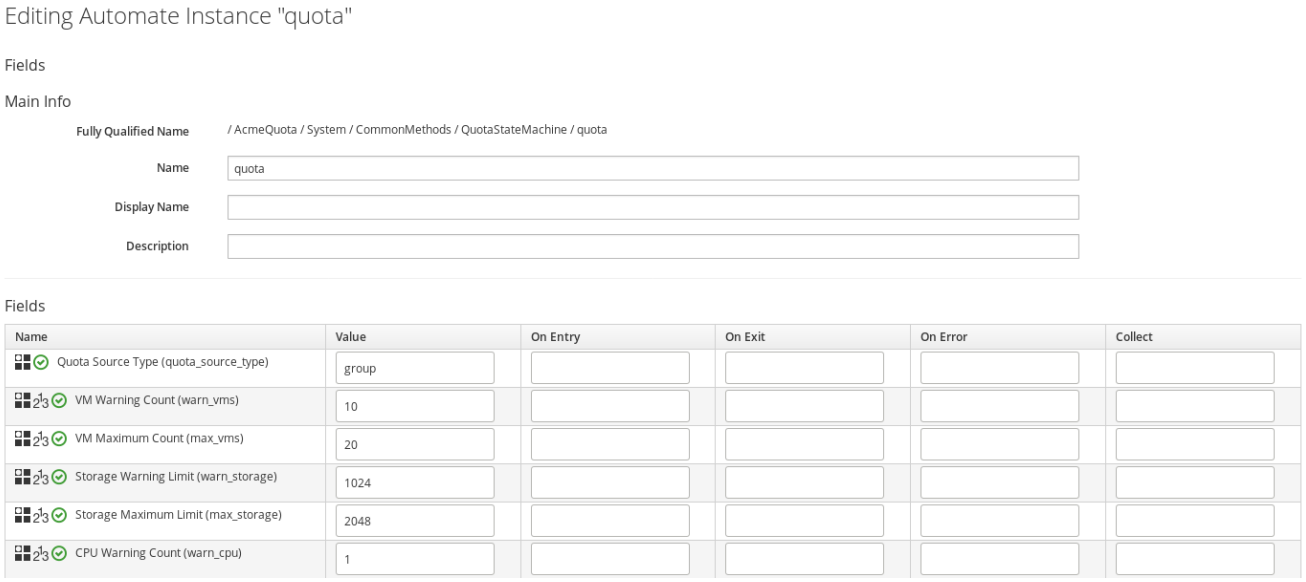
Default Execution Steps in States Instance

Step	Description
Customize Request	Apply customizations.
Acquire IP Address	Integrates with IPAM (IP Address Management) to get an IP Address.
Acquire MAC Address	Integrates with IPAM to get a MAC Address.
Register DNS	Integrates with IPAM to register with DNS.
Register CMDB	Integrates with CMDB (Configuration Management Database) to register with the CMDB.
Register AD	Integrates with IPAM to register with active directory.
Placement	Determine placement of virtual machine or instance.
PreProvision	Pre-provisioning steps.
Provision	Create the virtual machine or instance.
CheckProvisioned	Check that the new virtual machine or instance is in the VMDB.
PostProvision	Post-provisioning steps.
Register DHCP	Integrate with IPAM to register the IP address with DHCP Server.
Activate CMDB	Integrate with IPAM to activate the virtual machine or instance in the CMDB.
Email owner	Send email to owner that the virtual machine or instance has been provisioned.

Quotas

Quotas allow you to establish maximum usage thresholds for an user, group, or tenant for provisioned virtual machines or instances and are integrated into provisioning profiles. These maximums are checked after the approval but before the actual provision request is started. The quota is set for the tenant or group as a whole.

Applying User or Group Quotas



1. Log in as a user with administrator or super administrator rights to the Infrastructure Automation console.
2. Navigate to **Automation > Embedded Automate > Explorer**.
3. Copy the **ManageIQ > System > CommonMethods > QuotaStateMachine

   quota** instance to a custom DOMAIN.
4. From the accordion menu, click **DOMAIN > System > CommonMethods

   QuotaStateMachine > quota**.

   Note:

   By default, quotas are applied to tenants and do not require any change in **Automation > Embedded Automate > Explorer**.
5. Click (**Configuration**), (**Edit this instance**).

   1. Set the value for **Quota Source Type** to *user* or *group*.

      Important:

      A user creating a provisioning request must have an email address saved in their profile, or provisioning may fail. See Creating a User in *General Configuration* for details on configuring users.
   2. Set the values for **VM Warning Count**, **VM Maximum Count**, **Storage Warning Limit**, **Storage Maximum Limit**, **CPU Warning Count**, **CPU Maximum Count**, **Memory Warning Limit**, or **Memory Maximum Limit** to be the maximums for a specific user or group.
6. Click **Save**.

Using Tags for Owner and Group Quotas

Infrastructure Automation provides tags for enforcing quotas for the owners of virtual machines or instances. Ownership of a virtual machine or instance can be set either during the provisioning process or by using the **Configuration Set Ownership** button. If a virtual machine or instance has an owner, the value is displayed in the **Lifecycle** section of the virtual machine or instance summary page.

Quota tags can be assigned directly to **either** a group or owner **not** to a configuration item. The table below shows the tags for use in quotas.

Category Display Name (Name)	Use
Quota Max CPU (quota_max_cpu)	Sets the maximum number of CPUs summed over all virtual machines and instances owned by the group or user. Sample Values: 1, 2, 3, 4, 5, 10, 20, 30, 40, 50
Quota Max Memory (quota_max_memory)	Sets the maximum memory summed over all virtual machines and instances owned by the group or user. Sample Values: 1024, 2048, 4096, 8192, 10240, 20480, 40960, 81920 (in MB)
Quota Max Storage (quota_max_storage)	Sets the maximum storage summed over virtual machines and instances owned by the group or user. Sample Values: 10, 100, 1000, 20, 200, 40, 400 (in GB)

Applying a Tag to a User or User Group

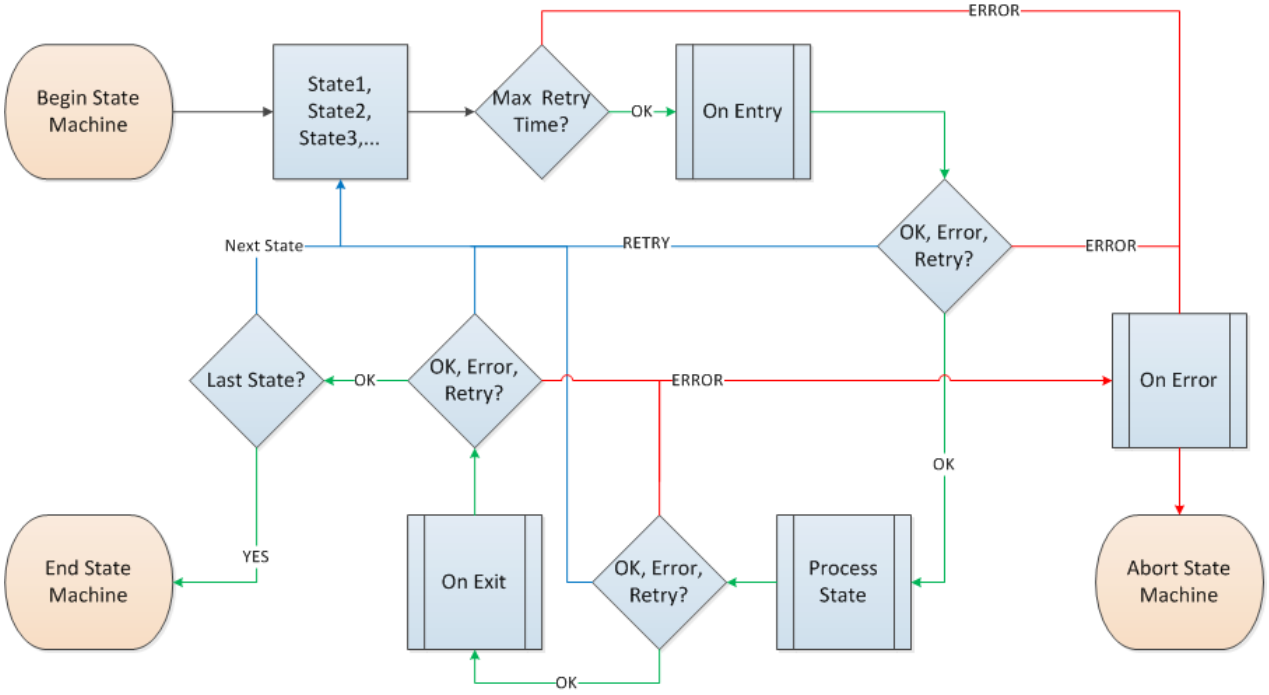
1. Click (**Settings**) > **Application Settings**.
2. Click the **Access Control** accordion, and select the user or group that you want to tag.
3. Click (**Policy**), then click (**Edit Tags**).
4. Select the appropriate customer tag to assign, then the value.
5. Click **Save**.

Note:

When quotas are applied by both automate instance and tagging, the tagged values will have higher precedence.

State Machines

The automate state machine processes an ordered list of states. It can ensure the successful completion of a step before the next step is run, permit steps to be retried, allow setting a maximum time to retry the state before exiting, and number of retries before exiting the state. Before each state is executed, the `On_Entry` method is executed and after the state ends the `On_Exit` or `On_Error` method is executed based on how the state ends.



The following components make up a Infrastructure Automation automate state machine:

Component	Description
On_Entry	Method to run when entering the state. It enables you to execute an automate method to do some pre-processing before the state of the state machine is processed.
On_Exit	Method to run when exiting the state.
On_Error	Method to run if an error is encountered when running the state. It enables you to execute an automate method to do some final processing before the state machine finally exits (MIQ_ABORT) due to the error.
Default Value	Runs after the On_Entry method completes (The actual state being processed).
Max Retries	Maximum number of times to retry the state before exiting.
Max Time	Maximum time in seconds to retry the state before exiting.

In the diagram below, you can see how these components combine to create a state machine workflow.

Note:

The retry logic, `On_Entry` and `On_Error` are distinct cases in the program flow.

Code snippet demonstrating the state machine retry logic:

```
# Get current provisioning status
task = $evm.root['service_template_provision_task']
task_status = task['status']
result = task.status

Then check the result to see how it should proceed:

case result
when 'error'
  $evm.root['ae_result'] = 'error'
.....
when 'retry'
  $evm.root['ae_result'] = 'retry'
  $evm.root['ae_retry_interval'] = '1.minute'
when 'ok'
  $evm.root['ae_result'] = 'ok'
end

When the result is "retry", it sets:
  $evm.root['ae_result'] = 'retry'
  $evm.root['ae_retry_interval'] = '1.minute'
```

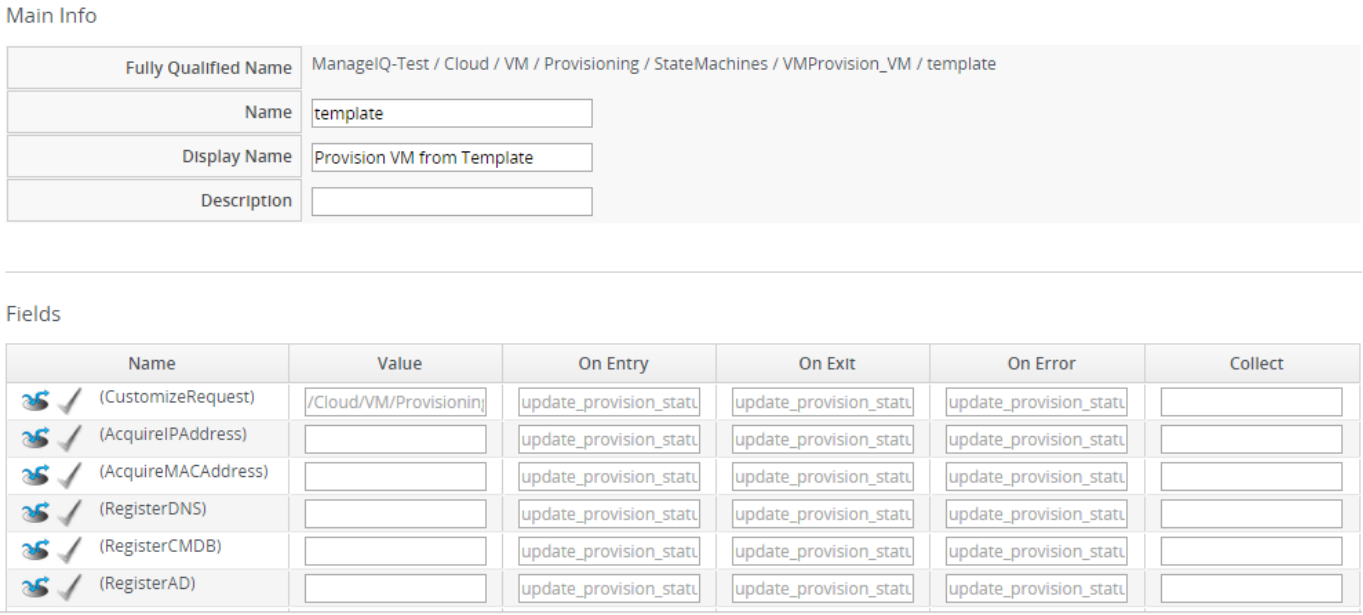
The following image shows a simple state machine pertaining to approving a provision request. This instance can be found in **Datastore > ManageIQ > Infrastructure > VM > Provisioning > StateMachines > ProvisioningRequestApproval > Default**.

Name	Value	On Entry	On Exit	On Error	Collect	Max Retries	Max Time	Message
max_vms	1							create
ValidateRequest		validate_request		pending_request		100		create
ApproveRequest		approve_request				100		create

1. The attribute **max_vms** has a value of 1. State machine processing can use the attributes of the state machine instance to make logic decisions. In this case, the **validate_request** method, which is processed during the **On_Entry** portion of the **ValidateRequest** state, evaluates the **max_vms** attribute. If the number of virtual machines requested is less than the **max_vms** value, the request can be auto-approved.
2. **ValidateRequest** is the first state to be executed.
3. **ApproveRequest** is the next state to be executed.

Note:

Grayed out items reflect values that are set in the class schema. These values can be overwritten on a per instance basis.



Customizing Provisioning States

The steps followed when provisioning a virtual machine or cloud instance are completed based on instances from the **DOMAIN > Cloud|Infrastructure > VM > Provisioning > StateMachines > VMProvision_VM** class.

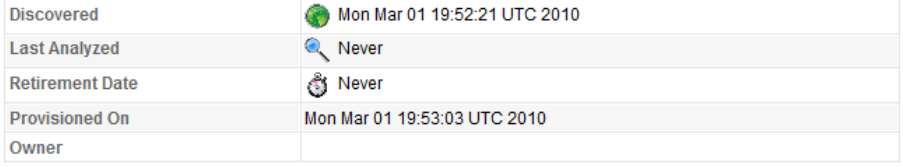
Editing the Default State Instance

1. Navigate to **Automation > Embedded Automate > Explorer**.
2. Click **Datastore** accordion. Select **Configuration** > Add a New Domain**. You must fill the Name and Description values and click **Add** to create a custom domain.
3. From the accordion menu, navigate to **Cloud > VM > Provisioning > StateMachines > VMProvision_VM**.
4. Click on the drop-down menu, **Configuration > Copy this class**.
5. To add the class to the custom domain, specify the custom domain in the **To Domain** list and click Copy.
6. From the Datastore accordion, navigate to **custom domain > Cloud > VM > Provisioning > StateMachines > VMProvision_VM**.
    1. Click **Schema** tab.
    2. Select **Configuration > Edit selected Schema**.
7. You can remove, update, or insert a line in the Editing Class Schema panel.

Note: Depending on your environment, you can leave the values blank in a provisioning process. For example, if you are not integrating with IPAM or a CMDB, then you can leave the values blank.

1. On the Datastore tree, navigate to **custom domain > Cloud > VM > Provisioning > StateMachines > VMProvision_VM**. Click **Schema** tab and select Configuration > Edit sequence.
2. Resequence the schema in the Edit of Class Schema Sequence panel.

Viewing the Status of a Provisioning Request



After a request has been approved, the various stages of fulfillment are executed. You can see the progress of the provisioning process by viewing its status.

1. Navigate to **Services > Requests**. The list of requests is shown.
2. Click on a specific request for more information. Once the provisioning begins, if the request was supposed to create more than one virtual machine or instance, a field will appear called **Provisioned VMs**. Click on the number that appears next to it for information on each of the individual provisions.

Viewing a Provisioned Virtual Machine or Instance

When a virtual machine or instance is created as a result of a provisioning request, its summary screen will show when it was provisioned in the **Lifecycle** area of the respective summary.

1. From **Services > Workloads**, click the virtual machine or instance that you want to view.

Viewing a Virtual Machine or Instance Summary

From **Services > Workloads**, click the virtual machine or instance that you want to view.

You can now request the log table from **Services > Request** to display logs related to a particular request.

Note: The table appears only if there are any logs to display. This table is sorted by the time, severity, and message.

Catalogs and Services

Through the use of catalogs, Infrastructure Automation provides support for multi-tier service provisioning to deploy layered workloads across hybrid environments. You can create customized dialogs that will give consumers of the services the ability to input just a few parameters and provision the entire service. The following table lists the terminology associated with catalogs that you will use within the Infrastructure Automation user interface for service provisioning.

Type	Information
Catalog Bundle	A group of templates.
Catalog Item	A single template.
Template	A template is a copy of a preconfigured virtual machine, designed to capture the installed software and software configurations, as well as the hardware configuration of the original virtual machine.
Dialog Tabs	Part of a service dialog.
Element	An item on a tab in a dialog. It can be a button, check box, drop down list, radio button, tag control, text area box, or a text box.
Provisioning Dialogs	Dialogs created for host provisioning, virtual machine migration, or virtual machine provisioning. The dialog name must be added to the appropriate provision instance to be processed.
Service Catalog	A catalog item or catalog bundle that is available for provisioning.
Service Dialogs	Made up of fully customizable tabs, items, and values for use with service provisioning.

Terminology

Generic Objects

Generic Objects are object-like entities, defined at runtime, that have unique names and user-defined attributes and relationships. Residing in the Automate Engine datastore, generic objects are designed to manage objects other than those related to private infrastructure, and public or private cloud providers.

Using automate requests, services and catalog items, generic objects can be directly accessed or passed, during any step, as a parameter to a service state machine. As a result, generic objects can be used to quickly add the capability to provision and collect data on resources not supported by Infrastructure Automation.

Viewing Generic Objects Classes

View a list of generic objects and click through to see detailed summary information for each object.

1. Navigate to **Automate > Generic Objects**.
2. Click on a generic object class in the table to view its summary information.

Creating Generic Objects Classes

Model a new resource by creating a generic object class and adding it to your Infrastructure Automation inventory. Each generic object class can have attributes, associations, and methods. Once created, generic object classes are visible to users of the Self Service user interface at the resource level.

Create a generic object class using the following steps:

1. Browse to menu: **Automation > Automate > Generic Objects**.
2. Click **Configuration**, then click (**Add a New Generic Object Class**).
3. Provide a **Name** and **Description** for the new object class.
4. In the **Attributes** field, enter a **Name** and choose a **Type** from the drop-down list. Click the button to add attributes.
5. Enter a **Name** and select a **Class** for the object class's **Associations**. Click the button to create additional associations.
6. Provide a **Name** for the **Methods**. Click the button to add methods.
7. Click **Add**.

Editing Generic Object Classes

Edit existing generic object classes using the following steps:

1. Browse to menu: **Automation > Automate > Generic Objects**.
2. Click on a generic object class in the list view.
3. Click **Configuration**, then click (**Edit this Generic Object Class**).
4. Make required changes to the generic object class fields.
5. Click **Save**.

Removing Generic Objects Classes

Remove generic object classes from your inventory using the following steps:

1. Browse to menu: **Automation > Automate > Generic Objects**.

2. Check the generic objects classes from the table to remove.
3. Click **Configuration**, then click (**Remove selected Generic Object Classes from Inventory**).
4. Click **OK** to confirm.

Exporting Generic Objects

Export generic objects from Infrastructure Automation to create a shared library.

Exporting a generic object requires the object has been created in Infrastructure Automation.

Procedure

1. ssh to the Infrastructure Automation appliance as **root**.
2. Browse to **/var/www/miq/vmdb**:

   ```
   # cd /var/www/miq/vmdb
   ```

3. Create a temporary directory to store the generic object definitions:

   ```
   # mkdir tmp/generic_object_definitions
   ```

4. Export the generic object definitions using the following **bin/rake** command:

   ```
   # bin/rake evm:export:generic_object_definitions -- --directory tmp/generic_object_definitions
   ```

Locate the exported yaml file containing the generic object properties in the temporary folder.

Importing Generic Objects

Import generic objects to Infrastructure Automation from a shared library.

Procedure

1. ssh to the Infrastructure Automation appliance as **root**.
2. Browse to **/var/www/miq/vmdb**:

   ```
   # cd /var/www/miq/vmdb
   ```

3. Create a temporary directory to store the generic object definitions:

   ```
   # mkdir tmp/generic_object_definitions
   ```

4. Copy the yaml file containing the generic object definitions to the temporary folder:

   ```
   # cp generic_objects.yaml tmp/generic_object_definitions
   ```

5. Import the generic object definitions to the Infrastructure Automation appliance using the following **bin/rake** command:

   ```
   # bin/rake evm:import:generic_object_definitions -- --source tmp/generic_object_definitions
   ```

Confirm the generic objects have imported successfully by Viewing Generic Objects Classes in the Infrastructure Automation user interface.

Service Dialogs

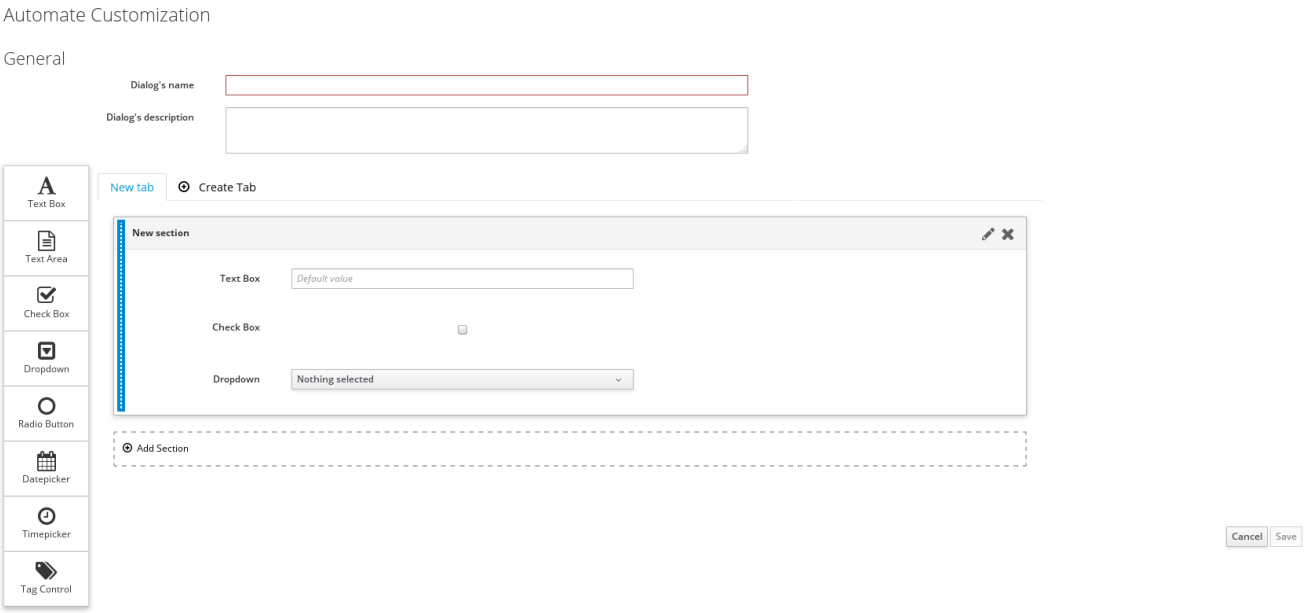
When provisioning a service, input will be needed from the requester. Service dialogs are used to take input from the user. This input is connected to a method in the Automate model that defines how the user's input is translated into the provision request. Before creating a service dialog, be sure to plan what items you need the user to input.

Adding a Service Dialog

- When creating a service dialog for use with Ansible playbook catalog items, variable elements must use the prefix **param_** when assigning the value. For example, a new variable labeled **key1** should have its value set as **param_key1**. - Using Ansible playbooks to populate dynamic dialog fields is not recommended due to delay times caused by the overhead of interaction between systems. - If you add the playbook automate method to a service dialog, only users with admin privileges can run the dialog.
Infrastructure Automation includes a drag-and-drop service dialog editor to create service dialogs. The editor, with its drag-and-drop feature, provides a visual representation of the components that comprise a service dialog. You can easily design your service dialog utilizing dialog tabs, sections (previously referred to as boxes), and elements.

When users access a service, the majority of options available to them are preset and cannot be altered. The requirements for the service determine the options and fields that need to be present in the dialog for user input. A service dialog exposes some of those options to the user so that even if they are ordering a basic Red Hat Enterprise Linux 7 machine, for example, they can at least choose the amount of memory, virtual CPUs, or other options available to the instance they order. In cases where certain fields must be unique, such as the name of virtual machines in Red Hat Virtualization, users must enter their own unique name for the virtual machine they choose or the operation will fail, so this field must be exposed.

A service dialog contains three components:



- One or more **Tabs**.
- Inside the tabs, one or more **Sections**. Note that in the previous method of creating service dialogs using the Infrastructure Automation user interface, **Sections** were referred to as **Boxes**.

- Inside the sections, one or more **Elements**. Elements are controls that accept input. Elements contain methods, like check boxes, drop-down lists or text fields, to fill in the options on the provisioning dialog.

Important:

The names of the elements must correspond to the options used in the provisioning dialog.

1. Browse to menu: **Automation > Automate > Customization**.
2. Click the **Service Dialogs** accordion.
3. Click **Configuration**, and then **Add a new Dialog**.

4. Enter basic details under **General**:
    1. Enter the **Dialog's name** and **Dialog's description**.
5. Add a new tab to the dialog:
    1. Click **Create Tab**. Then, click the icon on the new tab to edit tab information.
    2. Enter a **Label**.
    3. Optional: Enter a description for the tab in **Description**.
    4. Click **Save**.
6. Add a new section to the tab:
    1. Click **Add Section**. Then, click the icon on the upper-right to edit section details.
    2. Enter a **Label**.
    3. Optional: Enter a description for the section in **Description**.
    4. Click **Save**.
7. Add elements to the section:
    1. From the list of elements on the left, click an element you want to add, then drag-and-drop it inside the section. Then, click the icon next to the element to edit its field details.

Element Types	Additional Info
Text Area	Provides text area for users to enter text. You can enter the default text in **Default Value**, or leave it as blank.
Text Box	Text box is similar to a text area with the added option to enable **Protected** so the text is shown as asterisks(*), instead of plain text.
Check Box	Enable **Default Value** if you want the box checked by default.
Drop Down	Use drop down to create list entries either manually or using automate methods. Enable **Dynamic** to create lists using automate methods; use **Entry Point** to select an automate instance. Enable **Show Refresh Button** to allow users to refresh list options manually.
Radio Button	Similar to a drop down but displays options using radio buttons.
Datepicker	Use this to enable users to pick a date by clicking the calendar icon.
Timepicker	use this to enable users to pick a date and time.

Element Types	Additional Info
Tag Control	Select a **Category** of tags you want assigned to virtual machines associated with the service dialog. Enable **Single Select** if only one tag can be selected.

2. Enter a **Label**, **Name**, and **Description** for the element.

   Element names must correspond to the options used in the provisioning dialog. **Name** must use only alphanumeric characters and underscores without spaces. It is also used to retrieve the value of this element in the method used with the dialog and must start with **dialog_service_type**.
3. Optional: Add additional information in **Help** to assist the user to complete the fields in the service dialog. This field is useful for explaining unfamiliar terminology or providing configuration tips. This information is presented when you hover over the [!] exclamation mark in the Service Dialog while ordering a Service Catalog later.
4. Set other options as required.
5. Click **Save**.

8. Optional: Repeat the above step to add more elements to the existing section, or create and add elements to a new section as required.
9. Optional: Repeat the step to add a new tab to the dialog, and subsequent steps to add sections and elements to it as required.
10. Click **Save** to create the dialog.

The service dialog is now created, and added to the **Service Dialogs** accordion.

Creating a Service Dialog from a Container Template

Complete the following procedure to create a Service Dialog from a Container Template.

1. Navigate to **Compute > Containers > Container Templates** and select the template for provisioning.
2. Click (**Configuration**), then (**Create Service Dialog from Container Template**).
3. Enter a name for the dialog in **Service Dialog Name**.
4. Click **Save**.

You can use this service dialog when creating a catalog item for container template provisioning; see Creating an OpenShift Template Catalog Item.

Importing Service Dialogs

You can share service dialogs between appliances using the export and import features.

1. Navigate to **Automation > Embedded Automate > Customization**.
2. In the **Import/Export** accordion, click **Service Dialog Import/Export**.
3. In the **Import** area, click **Browse** to select an import file.
4. Click **Upload**.

Exporting Service Dialogs

You can share service dialogs between appliances using the export and import features.

1. Navigate to **Automation > Embedded Automate > Customization**.
2. In the **Import/Export** accordion, click **Service Dialog Import/Export**.
3. In the **Export** area, select the service dialogs that you want to export.
4. Click **Export**.

Methods

Creating a Method to Associate with the Dialog

You will need to create a method that connects the values in the dialog with the provisioning request. The method should be created in the `DOMAIN/Service/Provisioning/StateMachines/ServiceProvision_Template` class of the **Automate** model.

Note:

DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.

A method is provided below that was created for the following scenario:

- You want to provision a three-tiered service that contains catalog items of web, app and DB. Each of these virtual machines (or cloud instances) has been tagged under the **Service** category with the appropriate value. Then, added as a catalog item and combined into a catalog bundle.
- The **Service Dialog** captures the selection of small, medium or large application in a dropdown called **service_type**. When referring to a value captured in an element in a dialog, the name of the element should be prefixed with **dialog_**. For example, **service_type** becomes **dialog_service_type** when used in the method.

- The method will set the memory sizes for each of the catalog items based on the **service_type** selection.

```
#            Automate Method
#
$evm.log("info", "Automate Method ConfigureChildDialog Started")
#
#            Method Code Goes here
#
$evm.log("info", "==========================================")
$evm.log("info", "Listing ROOT Attributes:")
$evm.root.attributes.sort.each { |k, v| $evm.log("info", "\t#{k}: #{v}")}
$evm.log("info", "==========================================")

stp_task = $evm.root["service_template_provision_task"]
$evm.log("info", "==========================================")
$evm.log("info", "Listing task Attributes:")
stp_task.attributes.sort.each { |k, v| $evm.log("info", "\t#{k}: #{v}")}
$evm.log("info", "==========================================")

#############################################################
#### This is how the method would look for dialog variables
#############################################################
dialog_service_type = $evm.root['dialog_service_type']
$evm.log("info","User selected Dialog option = [#{dialog_service_type}]")

stp_miq_request_task = stp_task.miq_request_task
#$evm.log("info","(parent) miq_request_task:  = [#{stp_miq_request_task}]")

#############################################################
#### This is how you get the catalog items for the catalog bundle
#############################################################

stp_miq_request_tasks = stp_task.miq_request_tasks
#$evm.log("info","(children) miq_request_tasks count:  = [#{stp_miq_request_tasks.count}]")

#############################################################
#### By going through the children, you can set the dialog variable for each of the children (we based our values on the
childrens service tags)
#############################################################

stp_miq_request_tasks.each do |t|

  $evm.log("info"," Setting dialog for: #{t.description}")
  service = t.source
  service_resource = t.service_resource
  #$evm.log("info"," Child service resource name: #{service_resource.resource_name}")
  #$evm.log("info"," Child service resource description: #{service_resource.resource_description}")

  service_tag_array = service.tags(:app_tier)
  service_tag = service_tag_array.first.to_s

  memory_size = nil

#############################################################
#### The dialog_service_type is the attribute set on the service dialog
#### We use the service_tag to decide what child gets what dialog
#############################################################

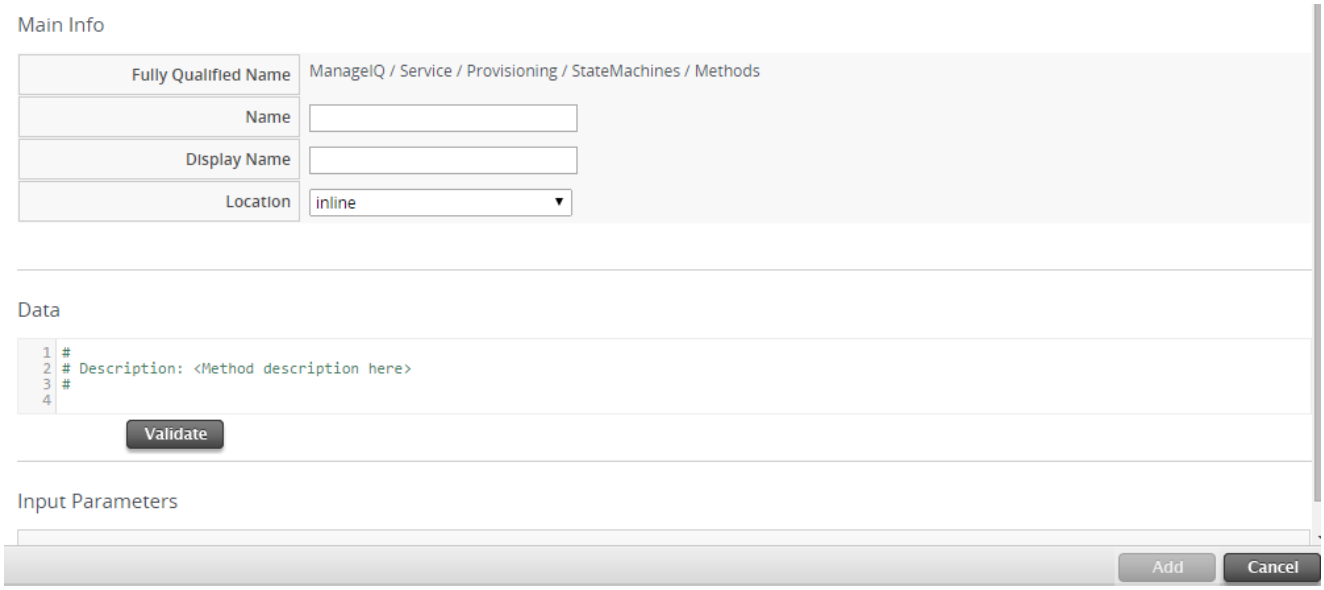
  case dialog_service_type
  when "Small"
    case service_tag
    when "app"
      memory_size = 1024
    when "web"
      memory_size = 1024
    when "db"
      memory_size = 4096
    else
      $evm.log("info","Unknown Dialog type")
    end
  when "Large"
    case service_tag
    when "app"
      memory_size = 4096
    when "web"
      memory_size = 4096
    when "db"
      memory_size = 8192
    else
      $evm.log("info","Unknown Dialog type")
    end
  else
    $evm.log("info","Unknown Dialog type - setting Dialog options here")
  end

#############################################################
#### set_dialog_option sets the dialog for the child
#############################################################

  t.set_dialog_option('memory',memory_size) unless memory_size.nil?
  $evm.log("info","Set dialog for selection: [#{dialog_service_type}]  Service_Tier: [#{service_tag}] Memory size: [#
```

```
{memory_size}]")

end
#
#
#
$evm.log("info", "Automate Method ConfigureChildDialog Ended")
exit MIQ_OK
```



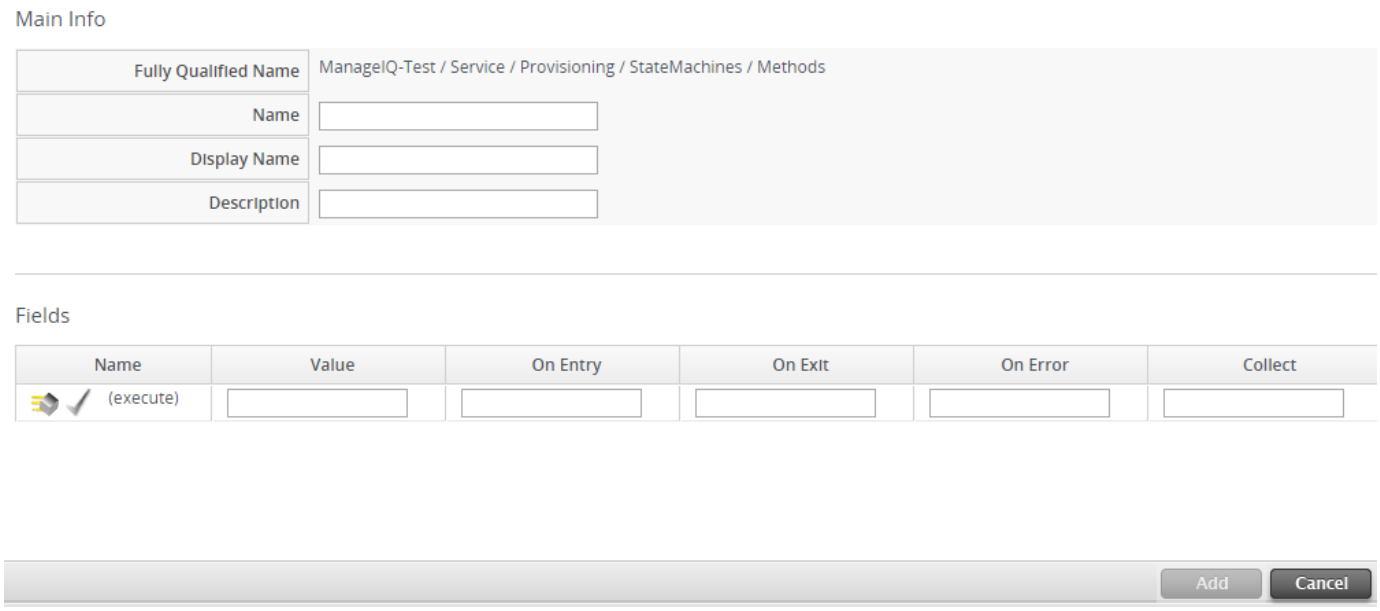
Creating a Method in the Service Class

Service methods have been split based on purpose.

1. Navigate to **Automation > Embedded Automate > Explorer**.
2. Service Class is located at **DOMAIN > Service > Provisioning > StateMachines > Methods** and **DOMAIN > Service > Retirement > StateMachines > Methods**.

   Note:

   DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.
3. Click the **Methods** tab.
4. Click (**Configuration**), then (**Add a New Method**).
5. Enter a **Name** and **Display Name**.
6. In the **Data** field, enter the method contents.
7. Click **Validate** and wait for your data entry to be successfully validated.
8. Click **Add**.



Creating an Instance in the Service Class

1. Navigate to **Automation > Embedded Automate > Explorer**.
2. Service Class is located at **DOMAIN > Service > Provisioning > StateMachines > Methods** and **DOMAIN > Service > Retirement > StateMachines > Methods**.

   Note:

   DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.
3. Click the **Instances** tab.
4. Click (**Configuration**), then (**Add a new Instance**).
5. Enter a **Name** and **Display Name**.
6. In the **Fields** area, enter the method's name in **Value**.
7. Click **Add**.

The instance is created so that it can be called from the **ServiceProvision** class.

Note:

After the method has been created, it must be mapped to an instance in the **`DOMAIN/Service/Service/Provisioning/StateMachines`** class. The name of the instance must be specified as the **Entry Point**. This method must be called before the provision job begins.

Associating a Method with an Automate Instance

Service methods have been split based on purpose.

1. Navigate to **Automation > Embedded Automate > Explorer**.
2. From the accordion menu, click the required service method.
3. Service Class is located at **DOMAIN > Service > Provisioning > StateMachines > Methods** and **DOMAIN > Service > Retirement > StateMachines > Methods**.

   Note:

   DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.
4. Either create a new instance or select the **clone_to_service** instance.
5. Click (**Configuration**), then (**Edit Selected Instance**).
6. In the **configurechilddialog** value, put the path to the method.
7. Click **Save** or **Add** if you are adding this to a new instance.

Provisioning Dialog

The following example shows how to create a Provisioning Dialog that modifies the parameters for provisioning a small, medium, or large service.

The **`provision-vm-small-med-large.asl`** workflow runs for every provisioned VM and is responsible for modifying the VM size. This workflow is the Provisioning service entry point.

You need to set the Provisioning service entry point to workflow script. For example, this workflow is run for every provisioned Virtual Machine (VM), and modifies the VM size.

Use the following sections and follow them in order to provision a VM service, create a Provisioning Dialog and modify the parameters.

Create a workflow (optional)

Note: If you want to use the existing **`provision-vm-small-med-large.asl`** workflow script without any changes, you can skip this section and proceed to **`Add a Workflow Repository`** section.

1. Fork **`https://github.com/ManageIQ/workflows-examples`** repository or create your own repository.
2. Clone the repo locally by using the clone command:

   ```
   git clone https://github.com/<owner>/workflows-examples
   ```

   Where **`<owner>`** is the owner of the repository.
3. Create a new branch:

   ```
   git checkout -b sm-md-lg
   ```

4. Create your own script or edit the existing script that is provided. The script used in this example is `provision-vm-small-med-large.asl`.
5. Push code changes to your branch.

Add a Workflow Repository

Use the following steps to add a Workflow Repository.

1. Click **Automation** > **Embedded Workflows** > **Repositories**.
2. Click **Configuration** > **Add new Repository**.
3. Provide the **Name** and **URL** for the repository:
   - **Name**: Local name to identify this repository. For example, `Example Workflows`.
   - **Url**: Git repository URL. For example, `https://github.com/ManageIQ/workflows-examples`.
   - **SCM Branch**: Git repository branch name. For example, leave this field blank if you want to use the existing `provision-vm-small-med-large.asl` script from the master branch, or use a branch name like `sm-md-lg` if you have edited or created your own workflow script.
4. Click **Save**.

Create a Provisioning Dialog

Use the following steps to create a Provisioning Dialog.

1. Click **Automation** > **Embedded Automate** > **Customization**.
2. Click **Service Dialogs** > **All Dialogs**.
3. Click **Configuration** > **Add a new Dialog**.
4. Provide a **Name** and **Description** for the dialog:
   - **Name**: Name used in the Service Catalog. For example, `sm-med-lg dialog`.
   - **Description**: Description for the dialog. For example, `Dialog choosing vm size`.
5. Add a text box named **vm_name**.
6. Add a dropdown named **size**.
7. Click the edit pencil icon for the **size** dropdown.
8. Under **Options** > **Entries** enter the following values:
   - Enter the following for the first row:
     - For **Name** field, type `Large`.
     - For **Value** field, type `large`.
   - Enter the following for the second row:
     - For **Name** field, type `Medium`.
     - For **Value** field, type `medium`.
   - Enter the following for the third row:
     - For **Name** field, type `Small`.
     - For **Value** field, type `small`.
9. Click **Save**.

Create a Service Catalog Item

Use the following steps to create a Service Catalog Item.

1. Click **Service** > **Catalogs**.
2. Click **Catalogs** > **All Catalogs**.
3. Click **Configuration** > **Add a New Catalog**.
4. Provide a **Name** and **Description**:
   - **Name**: Name displayed in the catalog. For example, `Provision VM`.
   - **Description**: Description of the catalog. For example, `Provisioning VM by size`.
5. Click **Save**.
6. Click **Catalog Items** > **All Catalog Items** > **Provisioning**.
7. Click **Configuration** > **Add a New Catalog Item**.
8. Provide a value for `Catalog Item Type`:
   - **Catalog Item Type**: The functionality of this catalog item. Choose **VMware**.
9. Under the **Basic Information** tab, provide the values for the following fields:
   - **Name**: Name displayed in the catalog. For example, `Provision VM with Size`.
   - **Description**: Description of the catalog. For example, `Provision a VM choosing size`.
   - **Display in Catalog**: Check to display this catalog item.
   - **Catalog**: Organization concept. For example, `My Company/Provisioning`.
   - **Dialog**: The dialog created previously. For example, `sm-med-lg dialog`.
   - **Provisioning Entry Point**:
     - For **endpoint type**, choose **Embedded Workflow**.
     - For the **endpoint value** choose the workflow script. For example, `provision-vm-small-med-large.asl`.
10. Under the **Request Info** > **Catalog** tab enter the following values:
    - **VM Name**: Name that is overwritten by the **VM name** in the dialog. Enter anything here.
11. Under the **Environment** tab, choose an appropriate **Host** and **Datastore**:
    - **Host**: Host that runs the VM.
    - **Datastore**: Disk that stores the VM.
12. Under the **Networking** tab, choose an appropriate **Network Adapter**.
13. Click **Add**.

Provisioning a Virtual Machine

1. Click **Services** > **Catalogs** > **Service Catalogs**.
2. Click **Order** under the newly created service, **Vm with Size**.

3. Provide the following fields:
    - **VM name**: Name for the newly created VM. For example `demo-1`.
    - **Size**: The desired VM size. You can choose `Small`, `Medium` or `Large`. For example, choose **Small**.
4. Click **Submit**

Iterate

If the provisioning did not go as planned use the following steps:

1. Edit the workflow script.
2. Push code changes to your branch.
3. Refresh the Workflow repository.
4. You can follow the workflows link to view the version of the script is stored on the server.
5. If you changed the script name, edit the Service Catalog Item that you previously created.
6. Provision the Virtual Machine.

Catalogs

Catalogs are used to create groups of virtual machines or instances for provisioning. For example, a complete package of a database server, desktop with specialized software already on it, and a firewall. You will need to complete the following steps to create and provision a service catalog.

1. Create **Catalog Items** for each virtual machine or instance that will be part of the service.
2. Create a **Service** dialog. For example, create a dropdown with three options small, medium, and large.
3. Create a method for the Service Dialog. This method defines what each of the options means to each of the individual virtual machines or cloud instances for the service. This method is called from a service provisioning instance in the Automate model.
4. Create an instance in the `DOMAIN/Service/Provisioning/StateMachines/ServiceProvision_Template` class that calls the method.

    Note:

    DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.
5. Associate method with Automate instance.
6. Create a **Catalog Bundle**, adding each of the catalog items to it. Select the **Service Dialog** you created. Use the instance created in the `DOMAIN/Service/Provisioning/StateMachines/ServiceProvision_Template` class as the **Entry Point**. Check **Display in Catalog** box.
7. Provision a service.

Creating a Catalog Bundle

1. Navigate to **Services > Catalogs**.
2. Click the **Catalog Items** accordion.
3. Click (**Configuration**), and then (**Add a New Catalog Bundle**).
4. Enter a name and description for the bundle. Select **Display in Catalog**.
5. Select the required **Catalog**.
6. Select the required **Dialog**.
7. Select chargeback currency.
8. Enter **Price / Month**.
9. Select the provisioning and retirement entry points.
10. Select **Additional Tenants**.
11. Click on the **Resources** tab, then select the catalog item you want to add to the bundle from the **Add a Resource** dropdown.
12. Click **Add**.

A catalog bundle is created and visible in the **Service Catalog** accordion.

Note:

You should also create and specify an Entry Point in the `DOMAIN/Service/Provisioning/StateMachines/Methods/CatalogBundle` class for each catalog item that is part of a bundle. If you do not, then the pre and post provision processing will occur for each item in the bundle in addition to processing for the **Catalog Bundle**. To set the entry point, go into each **Catalog Item** and check **Display in Catalog**. Then, you will see the **Entry Point** field.

Copying a Catalog Bundle

1. Navigate to **Services > Catalogs**.
2. Click the **Catalog Items** accordion.
3. Select the catalog bundle you want to copy from **All Catalog Items**.

4. Click (**Configuration**), and then (**Copy Selected Item**).
5. Enter a name for the copy of catalog bundle you are creating. Note that this name must not already be in use.
6. Click **Add**.

A copy of the catalog bundle is saved. You can now select this new copy of the catalog bundle and edit as required by navigating to (**Configuration**), then clicking (**Edit this Item**).

Creating a Catalog Item

Create a catalog item for each virtual machine or cloud instance that will be part of the service.

1. Browse to menu: **Services > Catalogs**.
2. Click the **Catalog Items** accordion.
3. Click **Configuration**, and then (**Add a New Catalog Item**).
4. Select the **Catalog Item Type** you are adding. This list only shows items related to providers available or options activated in the appliance (for example, **Ansible Playbook** is available as a **Catalog Item Type** option if the Embedded Ansible server role is enabled on the appliance).
5. Enter a name and description for the bundle. Select **Display in Catalog**.
6. Select a **Catalog**.
7. Select a **Dialog**.

   Note:

   You can only choose from the catalogs and dialogs you have already created. If you haven't done so, leave the values blank and edit later.
8. Select a **Zone**.
9. Select the chargeback currency.
10. Enter **Price / Month**.
11. Select the catalog item's **Subtype**.
12. Select the provisioning and retirement entry points, that is the Automate instance to run upon provisioning and retirement.

    Note:

    The entry point must be a State Machine since the **Provisioning Entry Point** list is filtered to only show State Machine class instances. No other entry points will be available from the **Provisioning Entry Point** field.
13. Select **Additional Tenants**.
14. Click **Add**.

Copying a Catalog Item

Note:

When copying a catalog item for reuse, you must click **Display in Catalog** in the copied catalog item for the item to appear in the catalog.

1. Navigate to **Services > Catalogs**.
2. Click the **Catalog Items** accordion.
3. Select the catalog item you want to copy from **All Catalog Items**.
4. Click (**Configuration**), and then (**Copy Selected Item**).
5. Enter a name for the copy of catalog item you are creating. Note that this name must not already be in use.
6. Click **Add**.

A copy of the catalog item is saved. You can now select this new copy of the catalog item and edit as required by navigating to (**Configuration**), then clicking (**Edit this Item**).

Creating a Generic Catalog Item

Create generic catalog items for services non-specific to virtualization or cloud environments. This catalog item type can serve a wide array of needs, from creating a vLAN across a network to accessing virtual machine IP addresses and adding them to a load balancer pool.

1. Browse to menu: **Service > Catalogs**.
2. Click the **Catalog Items** accordion.
3. Click **Configuration**, and then (**Add a New Catalog Item**).

4. Select **Generic** from the Catalog Item Type list.
5. In the **Basic Info** subtab:
    1. Type a **Name/Description**.
    2. Check **Display in Catalog** to display the item in the catalog. A **Dialog** will be required if you select **Display in Catalog**.
    3. Choose a **Catalog** to which to add the new item.
    4. Select a **Dialog** from the available options.
    5. Choose a **Subtype** from the list menu.
    6. Add **Entry Point(NS/Cls/Inst)** options.
        1. **Provisioning Entry Point (Domain/NS/Cls/Inst)** requires you to select an Automate instance to run upon provisioning.
        2. **Retirement Entry Point (Domain/NS/Cls/Inst)** requires you to select an Automate instance to run upon retirement.

            Note:

            The entry point must be a State Machine since the **Provisioning Entry Point** list is filtered to only show State Machine class instances. No other entry points will be available from the **Provisioning Entry Point** field.
6. In the **Details** subtab, write a **Long Description** for the catalog item.
7. Click **Add**.

Creating an Ansible Playbook Service Catalog Item

Create a catalog item that uses an Ansible Playbook to back it.

Note:

- Before creating an Ansible service, at least one repository, one playbook, and one credential must exist in the Infrastructure Automation inventory. Check your inventory and add the appropriate resources before creating an Ansible service. For more information, see Automation Management Providers in *Managing Providers*.
- Debugging verbosity is available for Ansible playbook catalog items. Selecting a higher verbosity value provides more detailed output as the playbook executes. **0 (Normal)** is the default value. **1 (Verbose)** will yield return data while a value of **3 (Debug)** provides connection attempt and task invocation details. Higher levels, such as **4 (Connection)** can be useful for debugging SSH connections. Use **5 (WinRM Debug)** when debugging WinRM connections.
- Using Ansible playbooks to populate dynamic dialog fields is not recommended due to delay times caused by the overhead of interaction between systems.
- Only users with administrator privileges can run a service dialog based on a playbook.

1. Browse to menu: **Services < Catalogs**.
2. In the **Catalog Items** accordion, click on the **All Catalog Items**.
3. Click **Configuration**, then (**Add a New Catalog Item**).
4. Select **Ansible Playbook** from the **Catalog Item Type** drop-down list.
5. Type a **Name** and **Description** for the new service catalog item.
6. Click **Display in Catalog**.
7. Select the appropriate **Catalog** from the drop-down list.
8. In the **Provisioning** tab, set parameters for your catalog item to use by configuring a Playbook to back your service item:
    1. Choose a **Repository** from the drop-down list.
    2. Select the **Ansible Playbook** to use.
    3. Assign the appropriate **Machine Credentials** from the drop-down list.
    4. Add **Cloud** or **Network Credentials** from the drop-down lists.
    5. Choose the **Host** against which to run the service item.
    6. Set the **Max TTL** in minutes. The Time To Live (TTL) field allows you to set the maximum execution time for the playbook to run.
    7. Use the **Escalate Privilege** toggle switch to enable user privilege escalation if called for in credentials during the playbook run.
    8. Choose a **Verbosity** value to set the debug level for playbook execution.
    9. Add key value pairs for **Variables** and their corresponding **Default Values**.
    10. In the **Dialog** options, choose an existing dialog from the **Use Existing** drop-down list or select **Create New** to add a new dialog.
9. In the **Retirement** tab, set parameters for your catalog item to use by selecting values for the following:

1. Choose a **Repository** from the drop-down list.
2. Select the **Ansible Playbook** to use.
3. Assign the appropriate **Machine Credentials** from the drop-down list.
4. Add **Cloud** or **Network Credentials** from the drop-down lists.
5. Choose the **Host** against which to run the service item.
6. Set the **Max TTL** in minutes. The Time To Live (TTL) field allows you to set the maximum execution time for the playbook to run.
7. Use the **Escalate Privilege** toggle switch to enable user privilege escalation if called for in credentials during the playbook run.
8. Choose a **Verbosity** value to set the debug level for playbook execution.
9. Add key value pairs for **Variables** and their corresponding **Default Values**.
10. In the **Dialog** options, choose an existing dialog from the **Use Existing** drop-down list or select **Create New** to add a new dialog.

10. Click **Add**.

Creating an Ansible Tower Service Catalog Item

Create a service catalog item from an Ansible Tower template you can use to execute an Ansible Tower playbook in Infrastructure Automation.

You must first create the job or workflow template in Ansible Tower. The job or workflow templates are automatically discovered by Infrastructure Automation when refreshing your Ansible Tower provider's inventory.
First, create a catalog:

1. Browse to menu: **Services > Catalogs**.
2. Click **Configuration**, then ⊕ (**Add a New Catalog**)
3. Enter a **Name** and **Description** for the catalog.
4. Click **Add**.

Then, create an Ansible Tower service catalog item:

1. Browse to menu: **Automation < Ansible Tower < Explorer**, then click on the **Templates** accordion menu.
2. Click **Ansible Tower Templates** and select an Ansible Tower job or workflow template.
3. Click **Configuration**, then ⊕ (**Create Service Dialog from this Template**).
4. Enter a **Service Dialog Name** (for example, *ansible_tower_job*)and click **Save**.
5. Browse to menu: **Services > Catalogs**. Click **Catalog Items**.
6. Click **Configuration**, then ⊕ (**Add a New Catalog Item**) to create a new catalog item with the following details, at minimum:
   - For **Catalog Item type**, select **Ansible Tower**.
   - Enter a **Name** for the service catalog item.
   - Select **Display in Catalog**.
   - In **Catalog**, select the catalog you created previously.
   - In **Dialog**, select the service dialog you created previously (in this example, *ansible_tower_job*). To ask the user to enter extra information when running the task, **Service Dialog** must be selected. A dialog is required if **Display in Catalog** is chosen.
   - In **Provider**, select your Ansible Tower provider. This brings up the **Ansible Tower Template** option and configures the **Provisioning Entry Point State Machine** automatically.
   - Add configuration information for **Reconfigure Entry Point** and **Retirement Entry Point** as applicable.
   - Select your desired **Ansible Tower Template** from the list. Generally, this is the Ansible Tower job or workflow template previously used to create the service dialog.
7. Click **Add**. The catalog item you created will appear in the **All Service Catalog Items** list.

Creating an Amazon Service Catalog Item

Use the following procedure to create an Amazon catalog item. Once created, the catalog item and service dialog combine with all of the options in the provisioning dialog. Users can then order Red Hat Enterprise Linux instances from the **Service Catalog** in the Infrastructure Automation Service user interface.

1. Browse to menu: **Services > Catalogs**, then click on the **Catalog Items** accordion.
2. Click **Configuration**, then ⊕**Add a New Catalog Item**.
3. Select **Amazon** from the **Catalog Item Type** list.

4. Enter the basic details in the **Basic Info** tab:
    1. Enter a **Name** and **Description** for the new service catalog item.
    2. Select **Display in Catalog**.
    3. Select the appropriate catalog from the **Catalog** list.
    4. Select the appropriate service dialog from the **Dialog** list.
5. Click the **Request Info** tab to enter request details:
    1. On the **Catalog** tab, select your Amazon AWS image name from the **Name** list, and the number of instances from the **Count** list. The **VM Name** will be overwritten during the provisioning process, but you can enter it as *changeme* for now.
    2. On the **Properties** tab, select *T2 Micro* from the **Instance Type** list, and *Basic* or *Advanced* for **CloudWatch**. If you plan to access the instance, select a **Guest Access Key Pair**, too.
    3. On the **Customize** tab, set the **Root Password** under **Credentials**, then select the *Basic root pass template* as a script for cloud-init under **Customize Template**.
6. Click **Add**.

Creating an Azure Service Catalog Item

Use the following procedure to create an Azure catalog item.

1. Browse to menu: **Services > Catalogs**, then click on the **Catalog Items** accordion.
2. Click **Configuration**, then (**Add a New Catalog Item**).
3. Select **Azure** from the **Catalog Item Type** list.
4. Enter the basic details in the **Basic Info** tab:
    1. Enter a **Name** and **Description** for the new service catalog item.
    2. Select **Display in Catalog**.
    3. Select the appropriate catalog from the **Catalog** list.
    4. Select the appropriate service dialog from the **Dialog** list.
5. Click the **Request Info** tab to enter request details:
    1. On the **Catalog** tab, select your Azure image name from the **Name** list, and the number of instances from the **Count** list. The **VM Name** will be overwritten during the provisioning process, but you can enter it as *changeme* for now.
    2. Select appropriate **Environment** settings that are known to work for your Azure environment.
    3. On the **Customize** tab, set the **Username** and **Password** under **Credentials**, then select the appropriate script under **Customize Template**.
6. Click **Add**.

Creating an OpenShift Template Catalog Item

Note:

Before adding a new catalog item for container template provisioning, create a service dialog from a container template. See Creating a Service Dialog from Container Template for details.

Complete the following procedure to create an OpenShift Template catalog item.

1. Browse to menu: **Service > Catalogs**, then click on the **Catalog Items** accordion.
2. Click **Configuration**, then (**Add a New Catalog Item**).
3. Select **OpenShift Template** from the **Catalog Item Type** list.
4. Enter a **Name** and **Description** for the new service catalog item. Select **Display in Catalog**.
5. Select the appropriate catalog from the **Catalog** list.
6. From the **Dialog list**, select the service dialog you have created from a container template.
7. Select your provider from the **Provider** list.
8. Set the **Provisioning Entry Point**.
9. Click **Add**.

Creating an Orchestration Catalog Item

Use the following procedure to create an Orchestration catalog item.

1. Browse to menu: **Services > Catalogs** and select **Catalog Items** in the accordion menu.
2. Click **Configuration**, then click ➕ **Add a New Catalog Item**. The **Adding a new Service Catalog Item** window is displayed.
3. Select **Orchestration** from the **Catalog Item Type** list.
4. Enter the basic details in the **Basic Info**:
    1. Enter a **Name** and **Description** for the new service catalog item.
    2. Select **Display in Catalog** box.
    3. Select the appropriate catalog from the **Catalog** list.
    4. Select the appropriate dialog from the **Dialog** list.
    5. Select the **Orchestration Template** from the list.
5. Click **Add**.

Creating a VMware Content Library OVF Template Catalog Item

Use the following procedure to create a VMware Content Library OVF Template catalog item.

Note:

Before you create the catalog item, make sure you have added a VMware vCenter Provider, and create a Service Dialog. See Adding a VMware vCenter Provider and Creating a Service Dialog for more information.

1. Browse to menu: **Services > Catalogs** and select **Catalog Items** in the accordion menu.
2. Click **Configuration**, then click ➕ **Add a New Catalog Item**. The **Adding a new Service Catalog Item** window is displayed.
3. Select **VMware Content Library OVF Template** from the **Catalog Item Type** list.
4. Enter the values in the **Basic Info**:
    1. Enter a **Name** and **Description** for the new service catalog item.
    2. Select **Display in Catalog** box.
    3. Select the appropriate catalog from the **Catalog** list.
    4. Select the appropriate dialog from the **Dialog** list.
    5. Select the **OVF Template** that you want to use for the deployment.
    6. Enter a **VM Name**.
    7. Select the **Accept EULA** box.
    8. Select the **Resource Pool**.
    9. Optional: Select the **Folder** and the **Host**.
5. Click **Add**.

Provisioning a Service

1. Browse to menu: **Services > Catalogs**.
2. Click the **Service Catalogs** accordion, and select the service to provision.
3. Click **Order**.
4. On the **Order Service** screen, select the box for **Do you want to continue?** and click **Submit**.

The parameters are passed to the children based on the method tied to the choices made in the dialog.

Orchestration Stacks

Cloud orchestration is a service that allows you to create, update, and manage cloud resources and their software components as a single unit and then deploy them in an automated, repeatable way through a template. Templates use a human-readable syntax and can be defined in text files, thereby allowing users to check them into version control. Templates allow you to easily deploy and reconfigure infrastructure for applications within your cloud. A user can author the stack templates, or can upload them from other sources.

Infrastructure Automation supports adding Amazon CloudFormation, OpenStack Heat, Microsoft Azure, VNF, and VMware vApp template type, and provides the ability to:

- Inventory stacks and elements of each type into the Infrastructure Automation VMDB.
- Model the relationships of instances to their stacks, inclusive of the user interface. For example, selecting an instance within a region that is within a stack, the user interface shows this on the standard instance view.

- Model the stack and its elements in the user interface.

Note:

When importing a template into Infrastructure Automation, the selected elements are converted according to their type. For example, lists convert to list boxes, and single items convert to text boxes.

Creating an Orchestration Template

Complete the following procedure to add an orchestration template.

1. Navigate to **Services > Catalogs** and select **Orchestration Templates** in the accordion menu.
2. Click **Configuration**, then click **Create a new Orchestration Template**.
3. Enter a **Name** and **Description** for your template.
4. Select the template type from the **Template Type** list. The default is Amazon CloudFormation.
5. Select **Draft** to create a draft template.
6. Add your template in the area below for the selected **Template Type**.
7. Click **Add**.

Editing Orchestration Templates

Complete the following procedure to edit orchestration templates.

1. Navigate to **Services > Catalogs** and select **Orchestration Templates** in the accordion menu.
2. Select the orchestration template you want to edit from the **All Orchestration Templates** list.
3. Click **Configuration**, then click **Edit this Orchestration Template**.
4. Edit the template as needed.

   Note:

   You can only edit the name and description of a read-only template as there can be stacks associated with the template.
5. Click **Save**.

Copying Orchestration Templates

Complete the following procedure to copy an orchestration template to create a new template.

1. Navigate to **Services > Catalogs** and select **Orchestration Templates** in the accordion menu.
2. Click **Configuration**, then click **Copy this Orchestration Template**.
3. Change the **Description** and the actual content of the template as required. Infrastructure Automation automatically prefixes *Copy of* to the old template **Name**.

   Note:

   To create a copy of an orchestration template into a new template, the old and new template content must differ.
4. Click **Add**.

Deleting Orchestration Templates

Complete the following procedure to delete orchestration templates.

1. Navigate to **Services > Catalogs** and select **Orchestration Templates** in the accordion menu.
2. Select the orchestration template you want to delete from the **All Orchestration Templates** list.
3. Click **Configuration**, then click **Remove this Orchestration Template from Inventory**.
4. Click **OK**.

Note:

Read-only templates cannot be deleted.

Retirement

Retiring Virtual Machines

Retiring Virtual Machines and Instances

When a virtual machine or instance is no longer required, it can be retired. Once a virtual machine or instance reaches its retirement date, it is immediately shut down and not allowed to restart. If an attempt to restart is made, Infrastructure Automation will shut down the virtual machine or instance.

There are three built-in policies involved with retirement:

- If the virtual machine or instance reaches its retirement date, it will be stopped even if it is running.
- If a retired virtual machine or instance is requested to start through Infrastructure Automation, the virtual machine or instance will not be allowed to start.
- If a provider starts a retired virtual machine or instance outside of Infrastructure Automation, the virtual machine or instance will be stopped.

Infrastructure Automation provides a number of ways to retire a virtual machine or instance:

- By using the allocated buttons in the Infrastructure Automation console.
- When creating a provision request, a retirement date can be set up.

Using the Console to Retire a Virtual Machine

Through the Infrastructure Automation console, you can retire a virtual machine on a specific date or immediately.

Retiring a Virtual Machine Immediately

1. Navigate to **Compute > Infrastructure > Virtual Machines**.
2. Select the virtual machine or instance that you want to retire.
3. Click (**Lifecycle**), then (**Retire this VM/Instance**).

The virtual machine or instance is immediately stopped, and will be shut down if an attempt is made to restart it.

Setting a Retirement Date and Time for a Virtual Machine or Instance

You can schedule virtual machine retirement by specifying a date and time, or by selecting a relative time a number of months, weeks, days or hours ahead of the present time.

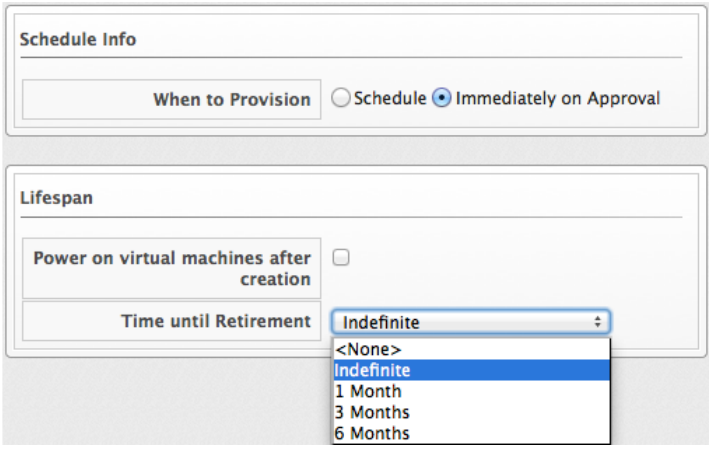
1. Navigate to **Compute > Infrastructure > Virtual Machines**.
2. Select the virtual machine or instance that you want to set a retirement date for.
3. Click (**Lifecycle**), then (**Set Retirement Dates**).
4. From **Enter Retirement Date as**, select **Specific Date and Time** or **Time Delay from Now** to schedule retirement.
    1. To choose a **Specific Date and Time**, click the **Retirement Date and Time** field to open the calendar.
        1. Select a retirement date using the calendar control.
        2. Click then select a retirement time (in UTC) using the arrows.
    2. To retire the virtual machine using a relative time, select **Time Delay from Now**.
        1. From **Time Delay**, specify a retirement time any number of months, weeks, days, or hours in the future using the arrows.
5. Select a **Retirement Warning** if desired.
6. Click **Save**.

The scheduled retirement date and time display in the virtual machine summary screen.

Removing a Retirement Date for a Virtual Machine or Instance

1. Navigate to **Compute > Infrastructure > Virtual Machines**.
2. Select the virtual machine or instance that you want to remove the retirement date from.
3. Click (**Lifecycle**), then click (**Set Retirement Date**).
4. Save a blank date to remove the retirement dates.

Setting Retirement in a Provision Request



If you are using Infrastructure Automation to provision, you can set when you want retirement in the provision request. To see how to create a request, see Provisioning Requests. A warning email will be sent to the owner before the retirement.

Scheduling Retirement in a Provision Request

When provisioning a cloud instance or virtual machine, a multi-tabbed screen appears where you can set up your provision requests.

1. Click the **Schedule** tab to set when to provision your request and the lifespan of the virtual machine or instance.
2. In **Lifespan**, you can choose to power on the virtual machines or instances after creation and set the **Time until Retirement**. If you select the time until retirement, you will select **Retirement Warning** accordingly.

3. Click **Submit**.

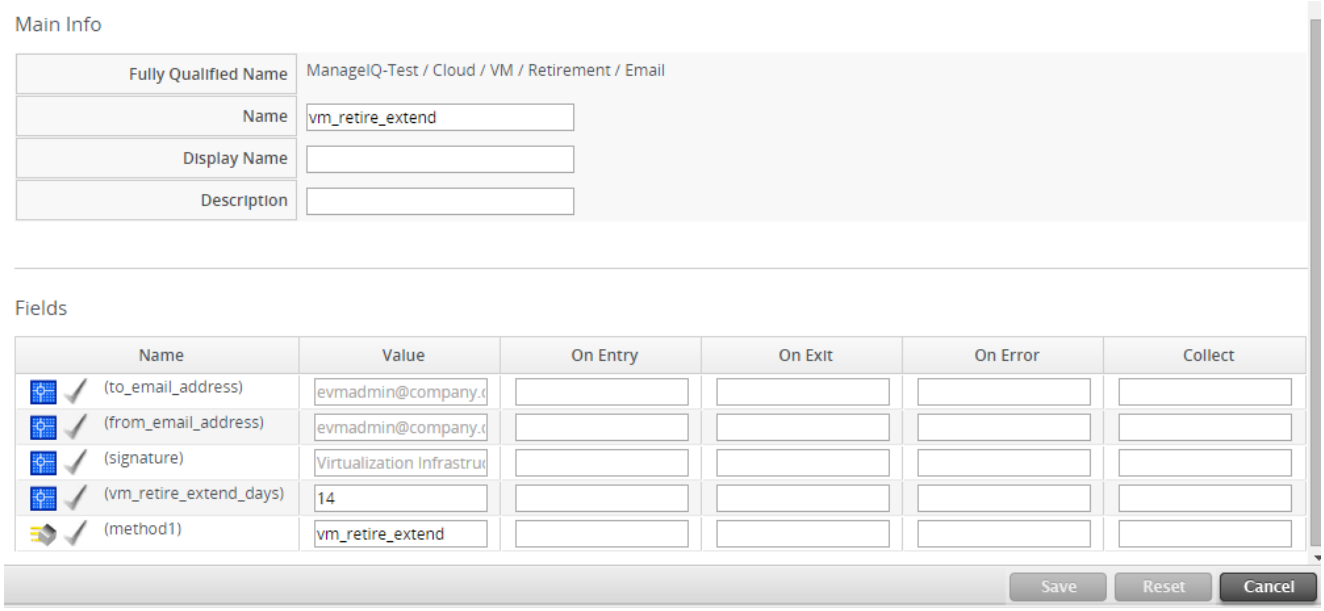
Extending Retirement Dates

Infrastructure Automation **Automate** includes a method to extend the retirement of a virtual machine or instance by 14 days. This section describes how to create a button that invokes this method and how to edit the method to change the number of days.

Creating a Custom Button to Extend Retirement

1. Navigate to **Automation > Embedded Automate > Customization**.
2. Click the **Buttons** accordion.
3. From the **Object Types** tree, select **VM and Instance**.
4. Navigate to the button group to which you want to add this button. (If you do not have a button group, add one and then create the button.)
5. Click (**Configuration**), then (**Add a new Button**).
6. Type in a button text and button hover text, and select the image you want to use.
7. In **Object Details**, select **Request** from the **/System/Process/** dropdown. By default, the message is `create`. Do not change it.
8. In **Request**, type `vm_retire_extend`.
9. Click **Add**.

Changing the Number of Days to Extend Retirement



1. Navigate to **Automation > Embedded Automate > Explorer**.
2. Click **DOMAIN > Cloud > VM > Retirement > Email > System > Request**.

   Note:

   DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.

   This example uses the **Cloud** Namespace, but you can also use the **Infrastructure** namespace.
3. Click (**Configuration**), then (**Edit this Instance**).
4. In the Value field, change the **vm_retire_extend_days** attribute to the new value.

5. Click **Save**.

- Creating a Service in for Virtual Machine Provisioning
  - Overview
  - Examining the Provisioning Dialog
  - Creating a Service Dialog
  - Creating a Catalog Item
  - Provisioning a Virtual Machine Using the Self Service User Interface

Creating a Service in for Virtual Machine Provisioning

Overview

Infrastructure Automation provides the ability to define services, which can include one or more virtual machines or instances, and can be deployed across hybrid environments. Services can be made available to users through the Self Service user interface, allowing users to order predefined IT services without IT operations getting involved.

The following three items are required to make a service available to users from the Infrastructure Automation Self Service user interface:

1. **Service Dialog**: A service dialog is where you allow users to configure virtual machine or instance options. A service dialog determines which options users get to change. You can choose the options presented to the user, from setting the service name to changing all provisioning dialog options.
2. **Service Catalog**: A service catalog is used to group service dialogs together.
3. **Service Catalog Item**: A service catalog item is the actual service which combines a service dialog with a provisioning dialog.

Examining the Provisioning Dialog

Understanding provisioning dialogs is important when working with services in Infrastructure Automation. Every provider in Infrastructure Automation comes with a sample provisioning dialog covering the options specific to that provider. The process begins with the provisioning dialog, which presents the basic configuration options for a virtual machine or instance. The options presented are dependent on the provider you are using. For instance, a cloud provider might have flavors of instances, whereas an infrastructure provider might allow you to set the memory size or number of CPUs on a virtual machine.

To see the sample provisioning dialog for Red Hat Virtualization:

1. Browse to menu: **Automation > Automate > Customization**.
2. Expand the **Provisioning Dialogs** accordion and select **Sample RedHat VM Provisioning Dialog** under **VM Provision**.

This is a textual representation of the dialog you will get when you provision a virtual machine.

Creating a Service Dialog

Using a service dialog you can determine which options users get to change. When users access a service, the majority of options available to them are preset and cannot be altered. A service dialog exposes some of those options to the user so that even if they are ordering a basic RHEL 7 machine, for example, they can at least choose the amount of memory, virtual CPUs, or other options available to the instance they order. In cases where certain fields must be unique, such as the name of virtual machines in Red Hat Virtualization, users must enter their own unique name for the virtual machine they choose or the operation will fail, so this field must be exposed.

Note:

A service requires an assigned service dialog, regardless of exposing details to user. A simple service dialog with a **Submit** and **Cancel** button is required at minimum.

A service dialog contains three components:

- One or more **Tabs**.
- Inside the tabs, one or more **Sections**. Note that in the previous method of creating a service dialog using the Infrastructure Automation user interface, **Sections** were referred to as **Boxes**.
- Inside the sections, one or more **Elements**. Elements are controls that accept input. Elements contain methods, like check boxes, drop-down lists or text fields, to fill in the options on the provisioning dialog.

The names of the elements must correspond to the options used in the provisioning dialog.
The following procedure outlines how to create a service dialog for your sample service:

1. Browse to menu: **Automation > Automate > Customization**.
2. Click the **Service Dialogs** accordion.
3. Click **Configuration**, and then (**Add a new Dialog**).
4. Enter basic information for your dialog under **General**:
    1. Enter `Provision RHV VM` in **Dialog's name**, and enter a description for the dialog in **Dialog's description**.
5. Add a new tab to the dialog:
    1. Click **Create Tab**. Then, click the icon on the new tab to edit tab information.
    2. Enter `General` in **Label**.
    3. Optional: Enter a description for the tab in **Description**.
    4. Click **Save**.
6. Add a new section to the tab:
    1. Click **Add Section**. Then, click the icon on the upper-right to edit section details.
    2. Enter `Service and VM Name` in **Label**.
    3. Optional: Enter a description for the section in **Description**.
    4. Click **Save**.
7. Add a **Text Box** element to the section for the service name:
    1. From the list of elements on the left, click the **Text Box** element, then drag-and-drop it inside the section. Then, click the icon next to the element to edit its field details.
    2. Enter `Service Name` in **Label**.
    3. Enter `service_name` in **Name**.
    4. Click **Options**, then select **String** from the **Value Type** list.
    5. Click **Save**.
8. Add a **Text Box** element to the section for the virtual machine name:
    1. From the list of elements on the left, click the **Text Box** element, then drag-and-drop it inside the section. Then, click the icon next to the element to edit its field details.
    2. Enter `VM Name` in **Label**.
    3. Enter `vm_name` in **Name**.
    4. Click **Options**, then select **String** from the **Value Type** list.
    5. Click **Save**.
9. Add a **Text Box** element to the section for the virtual machine description:
    1. From the list of elements on the left, click the **Text Box** element, then drag-and-drop it inside the section. Then, click the icon next to the element to edit its field details.
    2. Enter `VM Description` in **Label**.
    3. Enter `vm_description` in **Name**.
    4. Click **Options**, then select **String** from the **Value Type** list.

5. Click **Save**.

10. Add a new section to the tab:
    1. Click **Add Section**. Then, click the icon on the upper-right to edit section details.
    2. Enter `VM Characteristics` in **Label**.
    3. Optional: Enter a description for the section in **Description**.
    4. Click **Save**.
11. Add a **Dropdown** element to the section for the number of CPUs:
    1. From the list of elements on the left, click the **Dropdown** element, then drag-and-drop it inside the section. Then, click the icon next to the element to edit its field details.
    2. Enter `Number of CPUs` in **Label**.
    3. Enter `option_0_cores_per_socket` in **Name**.
    4. Click **Options**. Next to **Entries**, click + to add individual entries for the values `1`, `2`, and `4`, and their description.
    5. Click **Save**.
12. Add a **Dropdown** element to the section for the virtual machine memory:
    1. From the list of elements on the left, click the **Dropdown** element, then drag-and-drop it inside the section.
    2. Click the icon next to the element to edit its field details.
    3. Enter `VM Memory` in **Label**.
    4. Enter `option_0_vm_memory` in **Name**.
    5. Click **Options**. Next to **Entries**, click + to add individual entries for the values `1024`, `2048`, and `4096` and their description.
    6. Click **Save**.
13. Click **Save** to save the dialog.

Your service dialog is now added in the **Service Dialogs** accordion.

Creating a Catalog Item

Create a service catalog item to represent that service in a catalog.

1. Browse to menu: **Services > Catalog**.
2. Click the **Catalog Items** accordion.
3. Click **Configuration**, and then (**Add a new Catalog Item**).
4. Select **RHEV** from the **Catalog Item Type** list.
5. Enter the basic details in the Basic Info tab:
    1. Enter a name for the catalog item in **Name**.
    2. Enter a description for the catalog item in **Description**.
    3. Select **Display in Catalog**.
    4. Select the catalog you created from the **Catalog** list.
    5. Select the service dialog you created from the **Dialog** list.
6. Click the **Details** tab:
    1. Enter a description of the catalog item using HTML tags.
7. Click the **Request Info** tab to enter the request details. Enter the same data you did in the traditional provisioning dialog.
    1. In the **Catalog** tab, select the template on which to base the virtual machine from the **Selected VM** area.
    2. Enter `changeme` as the default name of the virtual machine in **VM Name**.
    3. In the Network tab, select **rhevm** from the **vLan** list.
8. Click **Add**.

Note:

In Infrastructure Automation, service catalog items can be more complex than a single virtual machine and are provisioned through a series of automation workflows. The service dialog you created will be used to gather information from the user requesting the virtual machine, hiding all the complexity of the details needed to actually deploy any of the components.

You can now provision a virtual machine through Red Hat Virtualization using the Self Service user interface.

Provisioning a Virtual Machine Using the Self Service User Interface

1. Log in to the Self Service User Interface at https://<hostname/ui/service>.
2. Click the **Service Catalog** tab.
3. Click the service you created.
4. In the **Service and VM Name**:
    1. Enter the service name in **Service Name**.
    2. Enter the virtual machine name in **VM Name**.
    3. Enter the virtual machine description in **VM Description**.
5. In **VM Characteristics**, enter **Number of CPUs** and **VM Memory**.
6. Click **Add to Shopping Cart** and access the shopping cart by clicking its icon on the upper-right corner of the screen.
7. Click **Order**.

You have ordered a new provisioning request. You can follow its progress and see additional details of the order request by selecting it from the **Orders** tab.

Also, see the Self Service User Interface Guide for more information about using the Self Service user interface.

Summary.

As part of the above sample service, you created a provisioning dialog that defines the options that can be set on a virtual machine. Then, you created a service dialog which allows us to expose certain options to be set by the user. For our example, the service name, virtual machine name, virtual machine description, and virtual machine characteristics are configurable. Additionally, you created a service catalog and finally a catalog item. The catalog item combines the service dialog with all of the options in the provisioning dialog. Lastly, you provisioned a Red Hat Virtualization virtual machine using the Self Service user interface.

- Service Provisioning Using an Orchestration Template
    - Overview
    - Creating an Orchestration Template
    - Creating a Service Dialog from an Orchestration Template
    - Creating an Orchestration Catalog Item
    - Creating a Catalog
    - Ordering a Service
    - Orchestration Stacks

Service Provisioning Using an Orchestration Template

Overview

Cloud orchestration is a service that allows you to create, update, and manage cloud resources and their software components as a single unit and then deploy them in an automated, repeatable way through a template. The deployed virtual machine instances and associated collection of resources are referred to as stack. Infrastructure Automation supports a number of orchestration template types, including Amazon CloudFormation and OpenStack Heat, that make deploying complex services easier in the cloud.

In the following example workflow, you will create an orchestration template, and add it as a catalog item to a service catalog. You can then create an orchestration stack from the template, and launch the stack from the catalog using a service dialog.

Creating an Orchestration Template

Complete the following procedure to create a new orchestration template.

1. Navigate to **Services > Catalogs** and select **Orchestration Templates** in the accordion menu.
2. Click **Configuration**, then click **Create a new Orchestration Template**.
3. Enter a **Name** and **Description** for your template.
4. Select **Amazon CloudFormation** from the **Template Type** list.
5. Select **Draft** to create a draft template.
6. Add your template in the area below for the selected **Template Type**. You can author your own stack template, or you can copy and paste from an existing text file.

7. Click **Add**.

Next, create a service dialog from the orchestration template.

Creating a Service Dialog from an Orchestration Template

Complete the following procedure to create a service dialog based on the input parameters defined in the orchestration template.

1. Navigate to **Services > Catalogs** and click **Orchestration Templates** in the accordion menu.
2. Expand **All Orchestration Templates**, then click the orchestration template you created in Creating an Orchestration Template to create a service dialog from it.
3. Click **Configuration**, then click **Create Service Dialog from Orchestration Template**.
4. Enter a name for the service dialog in **Service Dialog Name**.
5. Click **Save**.

Creating an Orchestration Catalog Item

Complete the following procedure to create a new catalog item from the orchestration template you created in Creating an Orchestration Template.

1. Navigate to **Services > Catalogs** and select **Catalog Items** in the accordion menu.
2. Click **Configuration**, then click **Add a New Catalog Item**.
3. Select **Orchestration** from the **Catalog Item Type** list.
4. Enter the basic details in the **Basic Info**:
    1. Enter a **Name** and **Description** for the new service catalog item.
    2. Select **Display in Catalog** box.
    3. Select the appropriate catalog from the **Catalog** list.
    4. Select the appropriate dialog from the **Dialog** list.
    5. Select the orchestration template you created in Creating an Orchestration Template from the **Orchestration Template** list.
    6. Select **Amazon** from the **Provider** list.
5. Click **Add**.

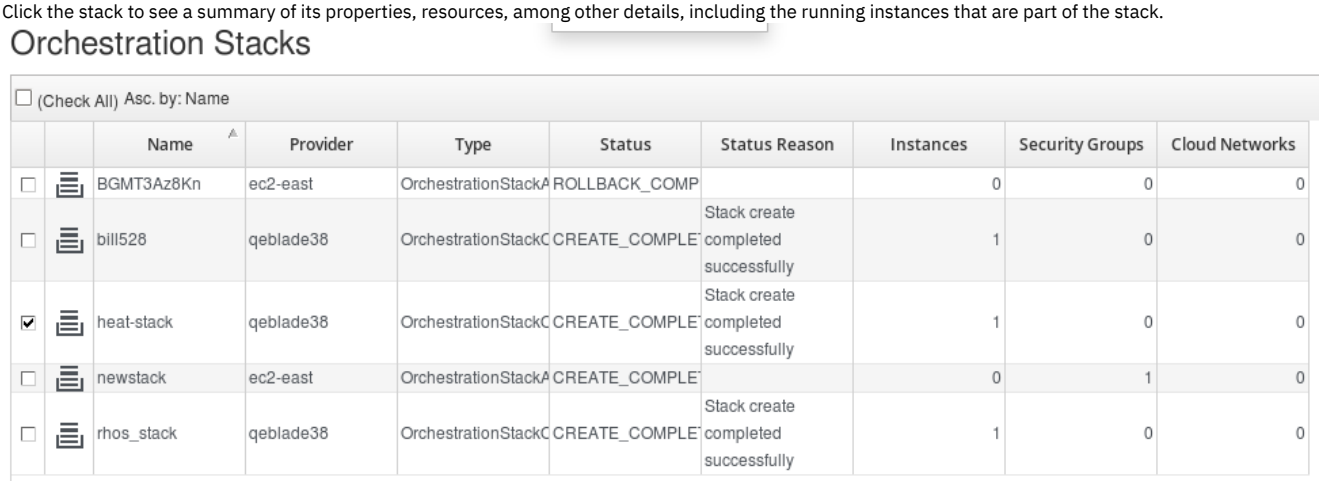
Next, assign the catalog item to a new service catalog.

Creating a Catalog

Complete the following procedure to create a new catalog, and assign the catalog item you created in Creating an Orchestration Template.

1. Navigate to **Services > Catalogs** and select **Catalogs** in the accordion menu.
2. Click **Configuration**, then click **Add a New Catalog**.
3. In **Basic Info**, add **Name** and **Description** for the new catalog.
4. Under **Assign Catalog Items**, select the catalog item you created in Creating an Orchestration Template from the **Unassigned** box, then move it to the **Selected** box.
5. Click **Add**.

Ordering a Service



Complete the following procedure to order catalog items from the service catalog.

1. Navigate to **Services > Catalogs** and select **Service Catalogs** in the accordion menu.
2. From **All Services**, select the catalog and the services (catalog items) that you want to order from your catalog, then click **Order**. You will see the **Order Service** window with **Options** and **Parameters**.
3. Enter a name for the stack in **Stack Name**.
4. From the **On Failure** list, select what to do if stack creation fails. The default is **Rollback**.
5. Optional: Enter **Timeout** in minutes.
6. Set the remaining options as needed that will vary depending on the dialog.
7. Click **Submit**.

You have now submitted your service provisioning request. Once a request has been approved, the various stages of fulfillment will be processed. You can monitor the request status and other details in **Services > Requests**.

Orchestration Stacks

1. Once the status of the provisioning request in **Services > Requests** is **Finished**, click **Compute > Clouds > Stacks** to see the deployed stack.
2. Click the stack to see a summary of its properties, resources, among other details, including the running instances that are part of the stack.

You have now deployed instances and associated collection of resources (referred to as a stack) using an orchestration template.

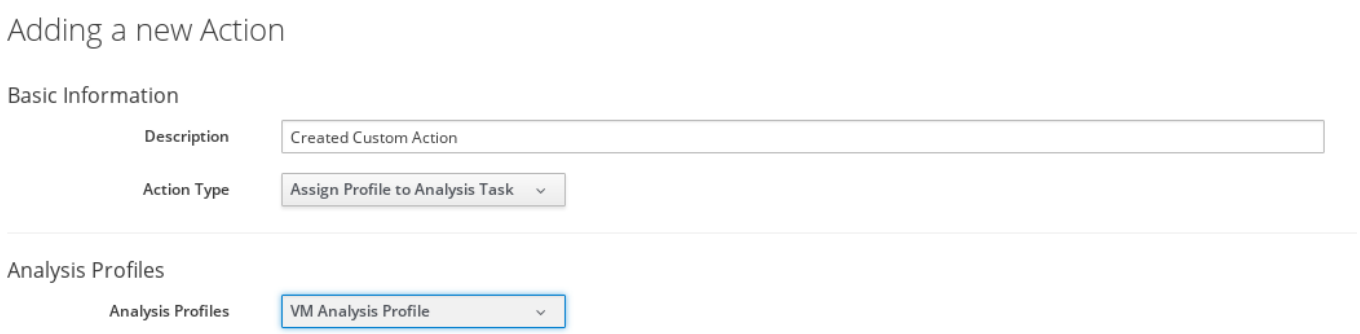
- Assigning a Custom Analysis Profile to a Virtual Machine
  - Creating a Virtual Machine Analysis Profile
  - Creating an Action to Assign the Virtual Machine Analysis Profile to the Analysis Task
  - Creating a Virtual Machine Control Policy
  - Creating a Policy Profile and Assigning the Virtual Machine Control Policy
  - Assigning the Policy Profile to a Virtual Machine

Assigning a Custom Analysis Profile to a Virtual Machine

You can create and assign different analysis profiles for specific virtual machine configurations using the Infrastructure Automation user interface. This document describes the steps required to create a custom virtual machine analysis profile, and assigning it to a virtual machine for use with SmartState analysis, via a control policy.

1. Creating a Virtual Machine Analysis Profile.
2. Creating an Action to Assign the Virtual Machine Analysis Profile to Analysis Task
3. Creating a Virtual Machine Control Policy.
4. Creating a Policy Profile and Assigning the Virtual Machine Control Policy.
5. Assigning the Policy Profile to a Virtual Machine.

Creating a Virtual Machine Analysis Profile



1. Log into the appliance as the **admin** user.
2. Click **Configuration**.
3. Expand the **Settings** accordion, then click **Analysis Profiles**.
4. Click (**Configuration**), then (**Add VM Analysis Profile**).
5. In **Basic Information**, enter **Name** and **Description** for the analysis profile.
6. In the **Category** tab, select the categories you want to collect information for under **Category Selection**. The **Category** tab is available for virtual machine profiles only.
7. In the **File** tab, click **<New Entry>** and specify the file to be scanned and if you want to collect contents for, then click **Save**. Repeat the step for adding multiple file name entries.
8. In the **Registry** tab, enter the **Registry Key** and **Registry Value**, then click **Save**. To determine whether a registry key exists without providing a value, enter ` ` in *Registry Value</emphasis>. The **Registry** tab is available for virtual machine profiles only.
9. In the **Event Log** tab, specify the event log entries to collect. Enter a **Filter Message** to look for specific text in a message. Enter a **Level** (*info*, *warn* or *error*, for example) to specify the event level. Enter the **Source** for the event log entry and **# (Number) of Days** to specify how far back to check.

10. Click **Add**.

Creating an Action to Assign the Virtual Machine Analysis Profile to the Analysis Task

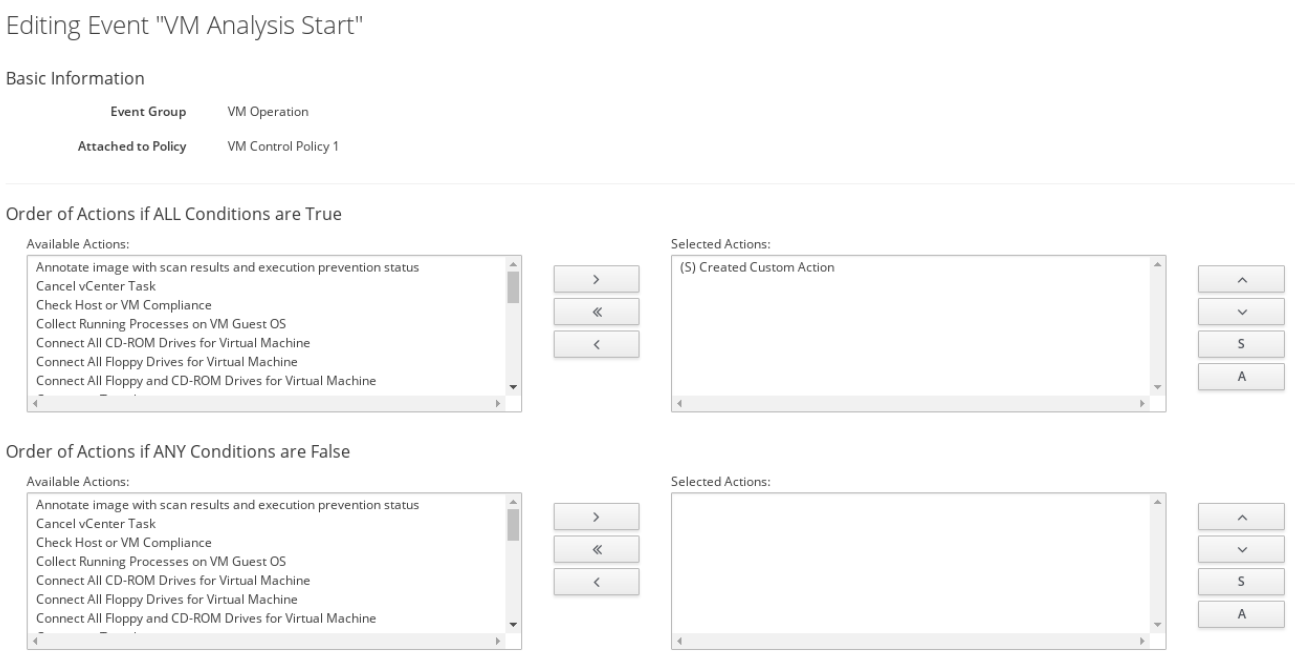
Actions are performed after the condition is evaluated. You can associate actions with specific events when you create a policy. Infrastructure Automation provides a set of default actions, but you can also create custom actions using the Infrastructure Automation user interface.

Use this procedure to create a custom action by adding the **Assign Profile to Analysis Task** action type to the virtual machine analysis profile (created in Creating a Virtual Machine Analysis Profile).

1. Browse to menu: **Control > Explorer**.
2. Expand the **Actions** accordion and click **Configuration**, then (**Add a new Action**).
3. Enter a **Description** for the new action. This will be the name given to your new action.
4. Select **Assign Profile to Analysis Task** from the **Action Type** list.
5. Select the newly-created virtual machine analysis profile from the **Analysis Profiles** list.
6. Click **Add**.

Note:

You can only associate this action with an analysis start event.



The action is created and added to the **Available Actions** list. Associate this action with the **VM Analysis Start** event when you create a virtual machine control policy in the next procedure.

Creating a Virtual Machine Control Policy

You can create a control policy by combining an event, a condition, and an action. The procedure below describes how to create a virtual machine control policy to assign the newly-created action to the **VM Analysis Start** event. Optionally, you can use a scope expression that is tested immediately when the policy is triggered by an event. If the item is out of scope, then the policy will not continue on to the conditions, and the assigned action will not run.

1. Browse to menu: **Control > Explorer**.
2. Expand the **Policies** accordion, and click **Control Policies**.
3. Select **Vm Control Policies**.
4. Click **Configuration**, then **Add a New VM and Instance Control Policy**.
5. Enter a **Description**. This will be the name given to your VM control policy.
6. Clear the **Active** box if you do not want this policy processed even when assigned to a resource.
7. Optional: Enter a **Scope** (you can also create a scope as part of a condition, or not use one at all). If the virtual machine is not included in the scope, the assigned action will not run.
   - You can use the drop-down list to create an expression for the **Scope**. Based on what you choose, different options appear. Click **Commit expression element changes** to add the scope.
8. Enter **Notes** if required.
9. Click **Add**. The policy is added and listed under **Vm Control Policies** in the **Policies** accordion.
10. Select the newly-added VM control policy. You can now associate events, conditions, and actions with the policy.
11. Click **Configuration**, then **Edit this Policy's Event assignments**.
12. Under **VM Operation**, set **VM Analysis Start** to **Yes**.
13. Click **Save**.

14. Click the **VM Analysis Start** event to configure actions.
15. Click **Configuration**, then **Edit Actions for this Policy Event**.
16. In **Order of Actions if ALL Conditions are True**, select the action created in Creating an Action to Assign the Virtual Machine Analysis Profile to the Analysis Task from the **Available Actions** list. This action will take place if the resources meet the conditions of the policy.

Note:

Each selected action can be executed synchronously or asynchronously; a synchronous action will not start until the previous synchronous action is completed, while an asynchronous action allows the next action to start whether or not the first action has completed. Also, at least one Infrastructure Automation server in the Infrastructure Automation zone must have the notifier server role enabled for the trap to be sent.

17. Click ( ) which will move the action to **Selected Actions**. The selected action is set to (S) Synchronous by default. From **Selected Actions**, select the action, then:
    - Click **A** (Set selected Actions to Asynchronous) to make it asynchronous.
    - Click **S** (Set selected Actions to Synchronous) to make it synchronous. If creating a synchronous action, use the up and down arrows to identify in what order you want the actions to run.
18. Click **Save**.

Creating a Policy Profile and Assigning the Virtual Machine Control Policy

Add a new policy profile and assign the virtual machine control policy (created in Creating a Virtual Machine Control Policy) to it.

1. Browse to menu: **Control > Explorer**.
2. Expand the **Policy Profiles** accordion, click **Configuration**, then **Add a New Policy Profile**.
3. In the **Basic Information** area, enter a **Description** for the policy profile.
4. Under **Policy Selection**, select the virtual machine control policy created in Creating a Virtual Machine Control Policy from the **Available Policies** list.
5. Click ( ) to move the selected virtual machine control policy into this profile.
6. Click **Add**.

Assigning the Policy Profile to a Virtual Machine

Assign the policy profile you created in Creating a Policy Profile and Assigning the Virtual Machine Control Policy to a virtual machine, and initiate SmartState analysis.

Note:

Policy profiles can be specified at multiple levels. If you assign a policy profile to a provider (Amazon EC2 or OpenStack for example), the profile will apply to all hosts or virtual machines for that provider.

1. Browse to menu: **Compute > Clouds > Instances** or menu: **Compute > Infrastructure > Virtual Machines**. Select the virtual machine or instance.
2. Click **Policy**, then **Manage Policies**.
3. Under **Select Policy Profiles**, select the policy profile created in Creating a Policy Profile and Assigning the Virtual Machine Control Policy. It will turn blue to show the selection. Click the triangle next to the policy profile to see its member policies.
4. Click **Save**.
5. Click **Configuration**, then **Perform SmartState Analysis**. A pop-up window appears to confirm the action.
6. Click **OK**. SmartState analysis is initiated for the selected virtual machine or instance from the Infrastructure Automation database.

SmartState analysis will now report back findings specified by the custom virtual machine analysis profile.

Creating a tag mapping for Infrastructure Management integration

It is possible to use the virtual machines created by the Service library in the Infrastructure Management. This is required for any additional tags defined by the user and used for pricing and policy integration. For example, if policy or pricing requires any additional tags, they need to be created in the Managed services in service definition and also mapped in Infrastructure Management.

The tag mapping requires the following steps on the Infrastructure Management side:

1. Create a tag mapping of the **`environment`** tag category. See Tag mapping.
2. Refresh the configuration. See Refreshing Cloud Providers.
3. Verify whether the virtual machine is tagged correctly by using the following steps:
    1. On the Infrastructure Management console, click **Compute**>**All VMs**.
    2. Select the virtual machine.
    3. Verify the tags in the **Smart Management** section.
    4. The virtual machines provisioned by the Managed services should have a list of all mapped labels.

Tag mapping is supported for the following cloud providers:

- Amazon
- Microsoft Azure
- Kubernetes
- OpenShift
- OpenStack

Managing Access Control

The *Access Control* tab is only visible to administrator users or the users with Cloud Pak administrator user roles. When you log in to the Infrastructure Automation UI console, any user with a role that is specific to Managed services is automatically added to the **`cam-default-team`** team.

To manage user access to certain namespaces, use the following actions:

- Create Team
- Edit Team
- Delete Team

Create Team

In order for users to have access to certain namespaces, you need to create a team. Only an administrator can create a team. Use the following steps to create a team:

1. Click **Manage** > **Access Control** in the Infrastructure Automation UI console.
2. Click **Create Team**.
3. Enter the name of the team that you want to create.
4. Select the users, groups, and namespaces from different tabs and click **Save**. The team is shown in the list after you create it.

Edit Team

When a team is created, you can later modify the users, groups, and namespaces that exist within a team. Use the following steps to edit a team:

1. Click **Manage** > **Access Control** in the Infrastructure Automation UI console.
2. Go to the table and select the team that you want to edit.
3. Click the **overflow** menu and select **Edit Team**. The dialog box appears with existing information.
4. Modify the users, groups, and namespaces as required.
5. Click **Save**. The team that you edited is shown in the list.

Delete Team

You can delete a team anytime after it is not in use by any user. Use the following steps to delete a team:

1. Click **Manage** > **Access Control** in the Infrastructure Automation UI console.
2. Go to the table and select the team that you want to delete.
3. Click the **overflow** menu and select **Delete**.
4. Type `delete` in the confirmation box. The team that you deleted is removed from the list.

Provisioning templates

Learn more about provisioning templates for Infrastructure Automation.

- Managing shared parameters
- Creating and managing templates
- Creating and managing template instances

Managing shared parameters

Shared parameters define shared configuration to store data and are used by templates.

The Data Types and Data Objects are constructs that are used to capture these shared configurations. These are essentially pointers to data structures that facilitate the dynamic binding at run time. You can create and manage Data Types and Data Objects in Managed services console. In addition, whenever you import a template from a Git repository, the Data Types of the template are also imported.

Data Types

The Data Types defines the data. Data Types contains the metadata of the attributes, such as name, attribute type, and default values. For example, you can have a data type **`IBM_Tivoli_Directory_Structure`**, which encapsulate the attributes of your LDAP server and then you can create a data object, which is an instance of this data type, and contains the values for these attributes which can be referenced in the template during deployment.

There are two Data Types:

- Explicit Data Types

  An administrator creates an explicit datatype either through a REST call or from the Admin Console UI. To create Data Type from the user interface, see Managing Datatypes from the user interface. To create Data Type by using REST APIs, see Shared parameters APIs. The name of the Data Types must be unique and for explicit data types the name must contain only alphanumeric and "_-" characters, and must start with an alphanumeric character.

- Implicit Data Types

  As Data Types and Data Objects are pointers to data structures, most of the existing constructs in Managed services can be referenced through an implicit Data Type. A use case for an implicit data type is the creation and use of a new cloud connection on the run without having to pre-define the cloud connection. This is very powerful when you have a service composed of multiple templates, and one of the templates depends on the cloud connection created by the template run prior to it. A cloud connection type can be referenced by **`com.ibm.cloud.cloudconnections`** followed by the provider name as follows **`com.ibm.cloud.cloudconnections.mycloud`**. Any data object instance of this datatype, for example, **`com.ibm.cam.provider.mycloud.dev_acccount`** points to this cloud connection.

  You can define these implicit data types and objects in the **`output_datatypes`** section of the camvariables.json file as follows in your template. On deployment of the template a new cloud connection **`com.ibm.cloud.cloudconnections.mycloud.dev_acccount`** with atttributes **`username`**, **`password`** and **`server`** with their correspoding values will be created and can be used by other templates.

```
"output_datatypes": [
  {
    "name": "com.ibm.cloud.cloudconnections.mycloud",
    "dataobject": {
      "name": "dev_acccount",
      "attributes": [
        {
          "name": "username",
          "value": "${template_input_params.admin_user}"
        },
        {
          "name": "password",
          "value": "${template_input_params.admin_password}"
        },
        {
          "name": "server",
          "value": "${template_output_params.private_master_ip}"
        }
      ]
    }
  }
],
```

Data Types lookup

Data Types lookup is the mechanism to reference a Data Type to retrieve the dataobjects associated with it. The API representation is `POST datatypes/lookup` wherein the Data Type is passed as a parameter in the body. For more information, see Shared parameters APIs.

Data Objects

The Data Objects represent an instantiation of a Data Type. For example, if you have a data type `IBM_Tivoli_Directory_Structure` that encapsulates your LDAP server, then you can create the following instances `IBM_Tivoli_Directory_Structure` of Data Type to represent the LDAP server for different environments.

- `Development_IBM_Tivoli_Directory_Structure`
- `Test_IBM_Tivoli_Directory_Structure`
- `Production_IBM_Tivoli_Directory_Structure`

The Data Objects inherit the attributes of the parent Data Type. If no value is provided for an attribute, the default value from the Data Type definition is used.

To create Data Object from the user interface, see Managing Dataobjects from the user interface. For more information about the REST APIs, see Shared parameter APIs.

Create Data Types and Data Objects from user interface

The following links provide the steps to create Data Types and Data Objects from the **Manage** > **Shared parameters** tab of the user interface:

- Data Types
- Data Objects
- Prebuilt Data Type list

Import Data Types from Git repository

To import Data Types, the template must have a datatypes folder with JSON and readme files. If the JSON is not properly defined, then the Data Types are not imported. To resolve this issue, fix the template and reimport the template. If the Data Types are already defined, then they are not overwritten during the template import.

Managing Data Types from the user interface

You can create, edit, and delete Data Types from the **Shared parameters** tab of the user interface.

- Create Data Type
- Upload Attributes
- Add Attributes
- Edit Attributes
- Delete Attributes
- Edit Data Type
- Delete Data Type

Create Data Type

1. Go to **Manage** > **Shared parameters** tab.
2. In the **Data types** section, click **Create data type**.
3. In the **Create data type**, enter the **Name**, **Data type**, and **Description**.

   Notes:

   - The Data Type name must begin with an alphabet letter and must have a combination of only these characters: [a-zA-Z][a-zA-Z0-9_-]
   - Do not use the following reserved names while naming a Data Type:
     - Anything that starts with `com.ibm.cloud.cloudconnections`
4. Click **Create**. The **Edit data type** page is displayed where you can edit name, Data type, and description or work on the attributes.

Upload Attributes

If the Data type has associated Data objects, then only the **View attributes** option is available.

1. In the **Data types** section, select **Edit** from the **Actions** overflow menu.
2. Click **Upload attributes**.
3. Click **Import from file** to import from a JSON file or copy and paste in the editor.
4. Click **Upload**.

Add Attribute

If the Data Type has associated Data Objects, then only the **View attributes** option is available.

1. In the **Data type** section, select **Edit** from the **Actions** overflow menu.
2. In the **Edit data type** page, click **Upload attributes**.
3. Click **Add attribute**.
4. Enter the **Parameter name**.
5. Select **End-user permission**. The available permissions are **Read-Only** and **Read & Write**.
6. Select a value from the **Parameter type** drop-down list. The available parameter types are string, password, list, boolean, counter, and map.
7. Enter the parameter values and click **Add**:
   - Enter the following common fields for all **Parameter type**:
     - **Display name** - Enter the label of the field.
     - **Description** - Enter a description of the field.
     - **Required** - Select if the field is mandatory. It is available only for **Read & Write** permission.
   - Enter the following values for string **Parameter type**:
     - **Specify options** - The **Specify options** is available for a **Read & Write** permission of type string. If you select **Specify options**, then **Default label** and **Value** pairs are displayed. To add more pairs of **Default label** and **Value**, click **Add**. Click the cross icon of a label to delete it.
     - **Validation rule** - Enter the **Validation rule**.
     - **Default string value** - Enter the default value of the string parameter. It is mandatory for **Read-Only** permission.
     - **Secured** - Select if the field is secured.
   - Enter the following values for map **Parameter type**:
     - **Key** and **Value** pair - Enter the key value pair. To add more key value pairs, click **Add**. Click the cross icon of a key to delete it.
   - Enter the following values for counter:
     - **Default counter value** - Enter the default value for the counter parameter. It is mandatory for **Read-only** permission.
     - **Maximum value** - Enter the maximum value of the counter parameter. It is available only for **Read & Write** permission.
     - **Minimum value** - Enter the minimum value of the counter parameter. It is available only for **Read & Write** permission.
   - Enter the following value for Boolean:
     - **Default boolean value** - Select **True** or **False** for the default Boolean parameter value.
   - Enter the following values for list:
     - **Default list value** - Click **Add** to add default value to the list. Click the cross icon for a default value to delete it.
   - Enter the following values for password:

     Note: Password type is applicable only for **Read & Write** permission.

Edit Attributes

You cannot edit the attributes if the data type is associated with data objects.

1. In the **Edit data type** page > **Attribute** section, select **Edit** from the **Actions** overflow menu for the attribute you want to modify.
2. Update the values and click **Edit** to save the changes.

Delete Attributes

You cannot delete the attributes if the data type is associated with data objects.

1. In the **Edit data type** page > **Attribute** section, select **Delete** from the **Actions** overflow menu for the attribute you want to delete.
2. Click **Delete** in the confirmation message box to delete.

Edit Data Type

You can edit description and upload or add attributes, but cannot edit the **Name** or **Type**. You cannot edit any of the Data Type values if it is associated with Data Objects.

1. In the **Data types** section, search for your Data Type.

   Note: To search for a Data Type, enter the keywords or name of the Data Type.
2. In the **Data type** section, select **Edit** from the **Actions** overflow menu of the Data Type you want to edit.
3. In the **Edit data type** page, click the edit icon to modify the **Description**.
4. In the **Attributes** section, you can add new attributes, edit, or delete an existing attribute.
5. Click **Save**.

Delete Data Type

You cannot delete a Data Type if it has associated data objects.

1. In the **Data types** section, search for your Data Type.

   Note: To search for a Data Type, enter the keywords or name of the Data Type.

2. In the **Data type** section, select **Delete** from the **Actions** overflow menu of the Data Type you want to delete.
3. If there are any associated data objects, a message box lists them. Delete those data objects first and then delete this Data Type.
4. If there are no associated data objects, click **Delete** in the confirmation message box to delete.

Managing Data Objects from the user interface

Shared parameters allow you to create reusable Data Objects. You can create, edit, and delete Data Objects from the **Shared Parameters** section of the user interface.

- Create Data Objects
- Edit Data Objects
- Delete Data Objects
- Duplicate Data Object

Create Data Objects

1. Go to **Settings** > **Shared parameters**.
2. In the **Data objects** section, click **Create data object**.
3. On the **Create data object** page, select or enter the following values:
   - Select the Data Type from the drop-down list.

     Note: When you use the selected Data Type, ensure that the value of Data Object is not empty.

   - In the **Select a namespace** > **Assign access** section, select either of the following values based on your requirements:
     - **Make data object globally accessible (available to all users)** - Data objects created globally are accessible by all users.
     - **Make data object part of a namespace** - Associate the data object with a specific namespace. For this option, you must select a **Namespace** from the drop-down list to which the data object is assigned. The namespace on the **Shared parameters** page is preselected. You can modify it, if needed.
   - Enter a unique name for the Data Object. It must be unique within the selected Data Type. If you do not enter a unique name or enter a character outside the permissible range, then an error message appears.

     Note: The Data object name must begin with an alphabet and must have a combination of only these characters: [a-zA-Z][a-zA-Z0-9_-]

   - In the **Attributes** section, enter a value for all the attributes. The attributes depend on the selected datatype.
4. Click **Create**.

Edit Data Objects

You can only edit the description and attribute values.

1. In the **Data objects** section, search for your Data Object.

   Note: You can search for a Data Object using the following methods:

   - To filter Data Objects based on the namespace, select a namespace from the **All namespaces** drop-down list. The list of Data Objects in the page changes based on the selected namespace. You can also select "All namespaces" to see all Data Objects for which you have access.
   - Enter the keywords or name of the Data Objects in **Search data objects**.
   - You can use the show filter icon next to search text to filter records. Namespace has a **Show globally accessible** option, which refers to those Data Objects that are globally accessible across all namespaces and are not assigned to any specific namespace.
2. Select **Edit** from the **Actions** overflow menu of the Data Object you want to update.
3. Update the details and click **Update**.

   Important: You can change a namespace to globally accessible but cannot assign a different namespace for a Data Object. You can also change a globally accessible namespace to a different namespace but keep in mind that with this namespace change you may not be able to perform any operations on existing deployments.

Delete Data Objects

1. In the **Data objects** section, search for your Data Object.

   Note: You can search for a Data Object by using the following methods:

- To filter Data Objects based on the namespace, select a namespace from the **All namespaces** drop-down list. The list of Data Objects in the page changes based on the selected namespace. You can also select "All namespaces" to see all Data Objects for which you have access.
- Enter the keywords or name of the Data Objects in **Search data objects**.
- You can use the show filter icon next to search text to filter records. Namespace has a **Show globally accessible** option, which refers to those Data Objects that are globally accessible across all namespaces and are not assigned to any specific namespace.

2. Select **Delete** from the **Actions** overflow menu of the Data Object you want to delete.
3. Click **Delete** in the confirmation message box to proceed with deletion.

Duplicate Data Object

1. In the **Data objects** section, search for your Data Object.
2. Select **Duplicate** from the **Actions** overflow menu of the Data Object.
3. Select either of the following options in **Assign access** section:
   - **Make data object globally accessible (available to all users)** - Data Objects created globally are accessible to all users.
   - **Make data object part of a namespace** - Associate the Data Object with a specific namespace. For this option, you must select a Namespace from the drop-down list to which the template must be assigned.
4. You can change the *Data Object Name*. The default name is `Copy_of_<name_of_original_Data_Object`.
5. Click **Duplicate**.

Prebuilt Data Type list

Managed services provides a list of preloaded data types that capture all attributes, for example, resource pool, datacenter, template name, virtual machine domain name of a vSphere cloud. Managed services Templates can make use of these data types and hardcode their values rather than redefining them everytime. This feature simplifies your data entry experience which is otherwise voluminous and repetitive in nature.

To know more about the preloaded data types, see Git repository.

To view the list of data types in Managed services user interface, go to **Manage** > **Shared parameters** tab > **Data types** section. For more details about working with Data Types and Data Object from Managed services user interface, see Managing shared parameters.

Creating and managing templates

Create your templates and deploy the template instances to your environment. Manage helm charts from IBM Cloud Pak for AIOps release management page.

- Defining the structure of Managed services template

- Deleting a template
- Viewing a template
- Changing preloaded content tokens

Defining the structure of Managed services template

The Managed services supported Terraform template is made up of datatypes, modules, metadata files and `.tf` files. This section provides you with the structure of the template so that you can build a new Terraform template from scratch.

The following block depicts the structure of a template:

```
- License
- README.md
- main.tf
- variables.tf
- output.tf
- camtemplate.json
- camvariables.json
- datatypes/
  - datatype.json
  - ...
- modules
  - moduleA/
    - LICENSE
    - main.tf
    - output.tf
    - scripts
      - script.sh
    - variables.tf
```

```
  - moduleB/
    - ...
- examples/
  - exampleA
    - main.tf
  - exampleB
    - main.tf
  - ...
- scripts
  - script.sh
  - ...
```

The following table describes the different components of a template structure:

Component	Description
cam_template_structure	This is the repository name or root folder of the template.
License	The license under which the template is made available.
README.md	This file contains a description of the template, expected usage, and variables required.
main.tf	The main entry point for the template.
variables.tf	Provides information and defaults of variables that are needed to execute the template.
output.tf	Provides information on important variables, which can be queried after deployment through Terraform and Managed services user interface.
camtemplate.json	A metadata file which provides information such as the short/long name, description, version and more for presentation in the Managed services Catalog.
camvariables.json	A metadata file describing how each variable is presented in the Managed services user interface. This creates an improved deployment experience with features such as: optional drop-downs, secure (masking), regex validation and descriptions.
datatypes directory	Directory contains json files to be loaded into Managed services Shared Parameters.
datatypes/datatype.json	Contains information about the Data Types which can be used by templates to facilitate dynamic binding at deployment time.
modules directory	This is optional and only used if nested Modules are included. Nested Modules allow you to break up complexity to provide more flexible configuration options.
modules/module	Directory for a specific nested Module. It must at least include a main.tf, output.tf and variables.tf.
modules/moduleA/main.tf / variables.tf / output.tf	Files are scoped to Module execution only but have the same definition as the preceding definition.
modules/moduleA/scripts directory	Directory contains scripts or files used by the Module.
scripts	Directory contains scripts or files used by the template.
examples	Directory containing an example(s) of additional configurations.

Modules

Modules are Terraform files in a folder. Even the working directory of a Terraform configuration where you run "Terraform apply" is considered as a root Module.

The Terraform Module is achieved by abstracting common configuration as building blocks, which can be reused by you and the rest of the organization. The Terraform configuration is by itself a Module sourcing other common building blocks (Modules) all with the right level of abstraction to enable reuse. The Terraform Modules provide developers with a structure to define reusable building blocks. You can define reusable configuration to meet industry guidelines and/or certify against your organization's unique standards. Large organizations can take advantage of structuring Terraform Modules by specialties like networking, security or by team ownership. When developing Terraform, use the Modules approach.

The following block depicts the structure of a module:

```
- modules
  - moduleA/
    - LICENSE
    - main.tf
    - output.tf
    - scripts
      - script.sh
    - variables.tf
  - moduleB/
    - ...
```

Tags module

For more information about system tags and user tags, see Tags module.

Managed services JSON files

You can create **camtemplate.json** and **camvariables.json** files for your template. It is not mandatory to have them in the template but its presence simplifies the deployment process.

- **camtemplate.json**

  The **camtemplate.json** file contains template metadata. It defines the function and features of the template.

  In the Managed services, the template **Overview** page includes the details defined in this JSON file.

  For example, you can go through this **camtemplate.json** file to understand its structure at - Sample camtemplate.json.

- **camvariables.json**

  The **camvariables.json** file contains metadata that is used in Managed services to augment the support for variables in Terraform. Metadata adds additional parameters for existing variables that are understood and handled by Managed services. Here, define **template_input_params** for all the variables in **main.tf** file.

  When you deploy the template in the Managed services user interface, all these defined variables are displayed. After you enter the values in the user interface, they are passed on to a JSON file which is in turn sent for execution to Terraform. Terraform matches these parameters with the variables in the **.tf** file.

  The structure of **camvariables.json** file is as follows:

```
{
"terraform_version": "~> 0.11.0",
"input_datatypes": [{"name": "namespacename", "label": "Formatted Name"},],
"output_datatypes": [{""},],
"input_groups":[{},],
"output_groups":[{},],
"template_input_params": [{},],
"template_output_params":[{},]
}
```

  Managed services variables structure to deploy content runtime:

```
 {
 "output_datatypes": "content_runtime_chef",
 "template_input_params": [{},],
 "template_output_params":[{},]
 }
```

  Managed services variable structure to consume content runtime in a new deployment:

```
{
 "input_namespaces": [{"name": "content_runtime_chef", "label": "Content Runtime: Chef"}],
 "template_input_params": [{},],
 "template_output_params": [{},]
 }
```

  The **template_input_params** is defined for every variable and the structure is as follows:

```
"template_input_params": [{
   "name": "The name of the service parameter",
   "label": "The label to be displayed in the user interface for this parameter",
   "description": "A description for this parameter",
   "type": "The type of parameter. For example, "list, string, map",
   "default": "The default value of the parameter",
   "hidden": "Specify if the parameter is not displayed in the user interface. The value must be true or false",
   "immutable": "Specify if the parameter is read only. The value must be true or false",
   "immutable_after_create": "Specify if the parameter is read only after create (cannot be changed during an update
or plan/apply). The value must be true or false (default)",
   "required": "Specify if the parameter is required. The value must be true or false",
   "secured": "Specify if the parameter value is shown as ********. The value must be true or false",
   "regex": "Define the regular expression - ^[A-Za-z0-9-]{1,52}$. The value you provide must match this regular
expression."
   "group_name": "The group to locate this parameter in when displaying on the UI". For example, "myGroup",
   "options": [  <--- in place of "default" for a list to select from
   {
     "value": "dc1",
     "label": "My Favorite DC",
     "default": "true"
    },
    {
     "value": "dc2",
     "label": "some other DC"
    }
   ]
      },]
```

  The **template_output_params** is defined for every variable and the structure is as follows:

```
"template_output_params":
[{
   "name": "name of the output variable in the template file", output section from Terraform
   "label": "The label to be displayed in the user interface for this parameter",
   "description": "A description for this parameter",
   "type": "The type of parameter. For example: "list, string, map, url",
   "shortname": The abbreviated name for a value (such as the URL shortname like "console link" which actually links
to https://asdf.com/asdf/asdf.html"
   "hidden": "Specify if the parameter is not displayed in the user interface. The value must be true or false",
   "secured": "Specify if the parameter value is shown as ********. The value must be true or false",
   "return_type": "The type of the parameter that is returned"
   "group_name": "The group to locate this parameter in when displaying on the UI" such as "myGroup",
   },]
```

Datatypes folder

Datatypes are yet another Managed services specific metadata.

Datatypes

Administrator defined connection is required as the templates that are defined in Managed services need access to external systems that are not necessarily backed up by a Managed services instance. The Data Types and Data Objects are two admin constructs that are used to capture these shared configurations.

You must define the datatypes for a template under the datatypes folder or else they get ignored by the import code:

```
{
   "name": "Name of the datatype",
   "label": "Lable of the datatype",
   "description": "Description of the datatype",
   "attributes": [
    {
      "name": "Name of the attribute",
      "type": "type of the attribute",
      "description": "Description of the attribute",
      "label": "Label of the attribute",
      "required": "Is it a mandatory attribute",
      "secured": "Is it a secured attribute",
      "immutable": "Is it immutable",
      "hidden": "Is it hidden",
      "default": "The default value of the attribute",
      "options": Options of the attribute.
     },
     {
       ...
       ...
     }
    ]
}
```

For a sample datatype, see GitHub repository.

For more information about shared parameters, see Shared parameters.

Terraform files

The template can have **main.tf** and **variables.tf** terraform files.

- **main.tf**

  The main template that gets deployed. It describes all the variables and resource structure that gets deployed on the cloud.

  Example:

  ```
  module "icam_agent_install_linux" {
  source = "./modules/icam_agent_install"
  ip_address = "${var.ip_address}"
  user = "${var.user}"
  password = "${var.password}"
  private_key = "${var.private_key}"
  icam_agent_location = "${var.icam_agent_location}"
  icam_agent_location_credentials = "${var.icam_agent_location_credentials}"
  icam_agent_source_subdir = "${var.icam_agent_source_subdir}"
  icam_agent_installation_dir = "${var.icam_agent_installation_dir}"
  icam_agent_name = "${var.icam_agent_name}"
  #######
  bastion_host        = "${var.bastion_host}"
  bastion_user        = "${var.bastion_user}"
  bastion_private_key = "${var.bastion_private_key}"
  bastion_port        = "${var.bastion_port}"
  bastion_password    = "${var.bastion_password}"
  #######
  }
  ```

- **variables.tf** - Terraform variables are defined in this file.

  For example:

  ```
  variable "ip_address" { type = "string" description = "IP Address of the host to install the IBM cloud App Management
  Agent"}
  variable "user" { type = "string" description ="Userid to install the IBM Cloud  App Management Agent"}
  variable "password" { type = "string" descritpion = "password of the installation user."}
  variable "private_key" { type = "string" description = "Private key of the installation user" }
  ```

  These variables are referenced in **camvariables.json** file.

Template lifecycle through branches

It is a best practice to use dedicated repository in Git for templates and auxiliary files. Whenever you make a change, create a branch at the repository level and not at the folder level. You can have multiple templates in the same repository and multiple versions of the same template. Whenever changes do not break compatibility with older versions, you can use the same branch and merge the changes. If you have changes that break compatibility, then use a new branch. In Managed services, import the new branch and make it the default. You can run a plan and apply that upgrade instances to the new configuration.

By using the Template Designer, you can manage branches effectively.

Tags module

Tags module is a helper to read the tags and get it in required formats.

System Tags

Managed services provisions these system tags automatically for a template and predefines their values. The tag keys are customizable so as to be compatible with other keys on the provider.

You can decide whether a system tag must be provisioned or not (enabled/disabled). The enable disable provision is available because the providers may or may not support a tag or they may limit the count of tags allowed. These system tags are available at CAM_terraform/cam-provider-terraform/stacks/stackjobs/Modules/camtags. If you want to include them in your template, set the source value relative to your path as follows:

```
module "camtags" {
  source = "../Modules/camtags"
}
```

To use the tag in a Terraform resource, write your template so you can read, pass, or format them.

For example, AWS needs its tag as a map:

```
output "tagsAsMap" {
   value = "${module.camtags.tagsmap}
}
```

This tags module has various outputs. It reads the tags that Managed services generates and converts it into a map format. For Deployments, set your tags in AWS and point your tags to this output value. Similarly, if you have a IBM Cloud, it takes tag in a list format with key value pairs. It formats the tags in a list and you can pass it to IBM Cloud.

User Tags

You can specify these tags at the time of provisioning. There are many ways a user tag can be designed, associated, and managed with a template.

Note: Consider the provider specific limitations when you name the tag or enter a key for it. For more information about IBM Cloud provider naming conventions, see Working with tags.

Tag Key Name can be set up / established at the following levels:

- Global - If you specify a user tag key here, it shows up whenever you request any template across all users / groups.
- Group - If you specify a user tag key here, it shows up whenever you request a template within a specific group.
- Template - If you specify user tag key here, it shows up whenever you request the specific template.
- Service - A tag key can be setup when you create a service in the Service Composer and it can be specific to service provisioning.

When a user specifies a tag key, they have an option of restricting the value types. The set of value types must be as follows:

- String - Any string possibly with a limit on the length and/or restricting certain characters.
- Integer - Only integers
- Number - Any number including long, decimal, float, and so on.
- Enumerated Value - A specific set of values with no ability to add new ones and the first one is set by default.
- Dynamic Value - Ability to specify a configuration or external API to retrieve the set of values allowed for this tag key dynamically.

For more information about using a template that has tags in a service, see Prerequisites for tags.

Importing a template

You can import a template from your Git repository.

About the task

By default, templates that are imported from Git repositories are not tagged to any namespace and are globally accessible. You can create a clone of the template and then associate a namespace to it.

Procedure

1. In the navigation bar, click **Library** > **Terraform templates**. The template library is displayed.
2. Click **Import template**.
3. For GitHub, GitLab, and Bitbucket Server, select either of the following options in **Assign access*** section:
    - **Make template globally accessible (available to all users)** - Templates created globally are accessible by all users.
    - **Make template part of a namespace** - Associate the template with a specific namespace. For this option, you must select a **Namespace** from the drop-down list to which the template must be assigned.

Note:

- If you create a template in a specific namespace, then only deployments to that namespace can use the template.
- Based on the value selected in the namespace drop-down list of the **Library** > **Terraform templates** main page, the **Assign access** and **Namespace** values are automatically selected. You can modify those values.

4. From **Import template source** drop-down list, select any of the following values:

   - **GitHub**
   - **GitLab**
   - **Bitbucket server**
   - **From scratch**
   - **From URL (.zip file)**
   - **From folder**
   - **From file(*.zip)**

5. Enter the following details of your selected repository:

   - For **GitLab** or **GitHub**, enter a repository URL, an access token, the relative directory of your service, and the related branch.

     - **GitHub repository URL** - `https://github.com/geekbass/terraform`

       Note: URL parsing is not possible if there exists "/" in branch name as it is not possible to differentiate between sub-directory and branch. You can still use the "/" but must manually update the fields after they are auto-parsed.

     - **GitHub access token**- It is the token required to access GitHub template files. You can find it in your GitHub user account, and is not required for public projects.

     - **GitHub repository download directory**- The path relative to GitHub project location where Terraform template files for this template can be referenced. `vsphere`.

     - **GitHub repository template run directory**- Optional field, the path relative to the GitHub download folder. The Terraform template runs from this folder.

     - **GitHub reference (branch or tag)**- The default value for branch or tag reference is `master`, however, you can change the value.

   - For **Bitbucket server**, enter the following details:

     - **Bitbucket repository URL** - The location where Bitbucket template files can be referenced from.

       Note: URL parsing is not possible if there exists "/" in branch name as it is not possible to differentiate between sub-directory and branch. You can still use the "/" but must manually update the fields after they are auto-parsed.

     - **Bitbucket access token** - The token used to access the Bitbucket template files

     - **Bitbucket repository download directory** - Optional field, the path relative to the Bitbucket server download folder. The Terraform template runs from this folder.

     - **Bitbucket repository template run directory**- Optional field, the path relative to the Bitbucket server download folder. The Terraform template runs from this folder.

     - **Bitbucket reference** - Select **Branch** or **Tag** option and enter the name of the tag or branch.

   - For **From scratch**, enter the following details:

     - **Name** - The name of the template.
     - **Description** - The description of the template.
     - **Cloud providers** - Select the cloud provider for the template.

     Note:

     - The template name must have a combination of only these characters: [a-zA-Z][a-zA-Z0-9_-]
     - For information about the available cloud providers, see Managing connections. If your cloud provider is not in the drop-down list, then select **Other** option. The created template is added to **My templates** in the library page.
     - The template can be associated with more than one provider.

   - For **From URL (.zip file)**, enter the following details:

     - **Name** - Optionally, enter the name of the template. This name overwrites the template name that is found in the repository.
     - **URL** - The location of the zip file (http/https) where the compressed template files can be referenced from. For example, "http://myserver.com/templates/template1.zip".
     - **Template run directory** - Optional field, the sub-folder of the zip file. The Terraform template runs from this folder.
     - **Artifactory API Key** - Optionally, if your .zip file URL is an artifactory location, then enter the artifactory API key.

   - For **From Folder**, enter the following details:

     - **Name** - The name of the template.
     - **Choose folder** - The directory containing the template source code.
     - **Template run directory** - Optional field, the sub-folder of the uploaded folder. The Terraform template runs from this folder.

   - For **From file(*.zip)**, enter the following details:

     - **Name** - The name of the template.
     - **Choose file(*.zip)** - The zip archive containing the template source code.
     - **Template run directory** - Optional field, the sub-folder of the uploaded folder. The Terraform template runs from this folder.

6. Click **Import**.

7. In the **Template metadata** tab, you can enter or change the template name, icon, short description, cloud provider, and details as a long description or the list of features.
8. In the **Manage template** tab, you can manage the template versions and the template parameters.

   If you are creating a template from scratch, in the **Edit version** tab, add your template source code by importing it from a file or from a URL. In the **Edit version** tab, click **Update parameters** to add parameters from the template source or from a file. For information about using Managed services Variables, see Template Middleware Parameters.

   For information about running a local executable after a resource is created during the deployment, see local-exec provisioner.
9. You can add new version of the template or delete an existing one by clicking the **Manage versions** tab. You can also edit an existing version, disable it, or set it as default by clicking the appropriate action in the overflow menu of the **ACTIONS** column.

   The template version follows `major.minor.patch` convention, where:

   - `major` refers to significant changes
   - `minor` refers to new features added but existing functionality remains broadly compatible
   - `patch` refers to bug fixes

   Note:

   - If you want to define the name of the stack instance in your Terraform template, you do not need to define a Managed services variables or a parameter but you can use the input variable named `ibm_stack_name` that is filled out automatically during the deployment with the name of the stack instance.
   - The character period (.) is not supported in the map name of the template parameters and shared parameters. Example of a map name with a period (.) that is not supported:

     ```
     {
      "my.key1": "myhostname"
     }
     ```

     It causes an internal server error. However, you can use the period (.) in the map value. Example of a map value with a period (.) that is supported:

     ```
     {
      "mykey": "myhostname.com"
     }
     ```
10. Click **Save** to save your template in the library.

    Note: If you created templates with a previous version of Managed services, be aware that the resource names for the IBM Cloud provider were changed. For more information, see Migrating to v0.4.

Reference links

From the overflow menu of a template, you can perform the following actions:

- Deploying a template
- Duplicating a template
- Deleting a template

Editing a template

You can search for a template from the library page.

1. In the navigation bar, click **Library** > **Terraform templates**. The template library is displayed.
2. In the template library page, you can use the following filters to search for a template:

   - Enter the name of the template in the **Search templates** filter.
   - Select the **Cloud provider** to view the list of all of the templates under a particular provider.

     The templates are categorized according to the provider type and template type. The templates you create are available in the **My templates** category. If you select **Other** option when you create the template or the template does not fall under any of the mentioned categories, then you can find your template under **Other** category. The templates that are provided by Managed services for import functionality are available in the **Import existing** category. The **All templates** includes all the templates irrespective of the categorization.
   - Click **Name** or **Created** timestamp header to sort the template records.
   - Use show filter icon next to the search text to filter records based on the cloud provider or namespace. The namespace option has **Show Globally accessible** option, which refers to those templates that are globally accessible across all namespaces and are not assigned to any specific namespace.
   - You can select a namespace from the **All namespaces** drop-down list. The list of templates in the page changes based on the selected namespace. You can also select "All namespaces" to see all records for which you have access.
   - Use pagination to decide the number of records that must fit in a page. Use the **>** or **<** to go through the next or previous set of records.

   For steps to import a template from Git repository, see Importing a template.

3. Select **Edit** in the template overflow menu. Alternatively, you can click **View** option in the overflow menu of a template or click the template record to open it. In the **Overview** page, click **Edit**.

   Note: From the template **Overview** page, you can **Duplicate** or **Delete** a template.

4. In the **Template metadata** tab, you do the following tasks:

   - Change the name, short and long description of the template.
   - Add, edit, or delete a feature.
   - Change the icon of the template.
   - Change the **Cloud provider**.
   - You cannot change the value of the namespace. However, you can create a duplicate of this template and associate it with a new namespace. To create a duplicate from this page, you can click the **duplicate** link in the **Assign access** section. Alternatively, you can also select **Duplicate** from the overflow menu. For more information about the procedure to duplicate a template, see Duplicating a template.

5. In the **Manage template** tab, you can edit the following details:

   - In the **Edit version** tab, you can edit the following details:

     - Select the version from the **Version** drop-down list or click **View source** of a version to view the source in read-only mode. If you had used the artifactory repository to import a compressed template file, then you can view the default version and the URL that was used to import the template and also the parameters if present.
     - Click **Update parameters** to update the parameters. In the **Update Parameters** page, you can import from a file or copy paste the details in the editor. Additionally, you can import the parameters from the original **Template source**. You also have an option to edit the parameters by clicking each parameter individually if the source file does not have the `camvariable.json` defined already.

   - In the **Manage versions** page, you can perform the following activities:

     - You can view a table with all version details in it.

     - Click **Add version** to add a new version of this template. In the **Add version** page, enter the following details:

       - Enter version number in the **Display name**.
       - Enter a branch or tag value in **Tag/Branch name**.
       - If you want to include a compressed file, enter the URL pointing to ".zip" file to add a new version

     - From the **Actions** over flow menu of an existing version, you can edit, disable, set as default, or delete a version.

       - If you select the edit option, you can modify the version display name but not the URL.

     Note: The template version follows `major.minor.patch` convention, where:

     - `patch` refers to bug fixes
     - `major` refers to significant changes
     - `minor` refers to new features added but existing functionality remains broadly compatible

     When you upgrade to a new instance through plan/apply for major changes, a compatibility warning is displayed in the plan user interface. For example, when you move from 1.1.0 to 2.1.0, the following warning is displayed:

     "Trying to upgrade to a version that will break compatibility may result in deployment errors. It is recommended to clean up the old instance first and then deploy the new version."

     In this example, version 2 breaks compatibility with version 1, which causes plan/apply to fail. When you upgrade to a new instance for minor or patch changes, then no warning message is displayed because backward compatibility is preserved. For example:

     ```
     - 1.0 to 1.1 or 3.0
     - 1.1.0 to 1.2.0 or 1.1.1
     ```

     You can ignore this warning and still proceed with the upgrade. The warning is displayed only if the version starts with a number followed by dot.

6. Click **Save** to save the changes you made to the template.

7. From the overflow menu of the template, you can duplicate, deploy, and delete a template.

Duplicating a template

Procedure to duplicate Managed services templates.

About the task

- If you duplicate a template in Git repository, then changes are not done to the Git repository. However, a duplicate of the record is created in Managed services, which points to the same Git repository as the source template. As a result, both the templates point to the same Git repository and a change to the Git repository impacts both the templates.
- The duplicate template includes copies of all the versions of the source template.

Procedure

1. In the navigation bar, click **Library** > **Terraform templates**. The template library is displayed.

2. In the overflow menu of the template you want to clone, click **Duplicate**. Alternatively, you can create a duplicate from the edit page and overview page.

3. In the **Duplicate template** page, select either of the following options in **Assign access** section:

- **Make template Globally Accessible** - Templates created globally are accessible by all users.
- **Make template part of a namespace** - Associate the template with a specific namespace. For this option, you must select a **Namespace** from the drop-down list to which the template must be assigned.

Note: If you create a template in a specific namespace, then only deployments to that namespace can use the template.

4. Enter the name of the new template.

   Note: Ensure that the name of the template is unique in that namespace for the template. The default name prepopulated is `Copy of <name of the original template>`.

5. Click **Duplicate**.
6. In the **Template metadata** and **Managed template** tabs of the newly created template, enter or modify the details. For more information to update the tabs, see Editing a template.
7. Click **Save**. The newly created template is listed in the **My templates** section of the Template Library.

Deleting a template

You can delete an existing template from the template library.

Procedure

1. Go to the Template Library page.
2. From the overflow menu of a template record, select **Delete**.
3. In **Delete template** page, enter "delete" and click **Delete**.

Viewing a template

You can view the details of a template from the library page.

Procedure

1. Open the **Library** > **Terraform templates** page.
2. Search for your template record to view.
3. Click the **View** option from the **Actions** menu of the template record. The details of the template are displayed in **Overview**, **Template source**, and **Parameters** tabs.
4. You can perform the following actions in view mode:
   - Click **Edit** to update the template.
   - Click **Deploy** to deploy the template.
   - From the overflow menu, you can create a **Duplicate** or **Delete** the template.

Changing preloaded content tokens

Starter pack templates are imported from Github and Gitlab. Managed services ships valid tokens to work with these templates. However, you can change to your own Github tokens from the **Template Source** tab of template details page.

Procedure

1. Go to **Library** > **Terraform templates**.
2. Click to open your starter pack template.
3. Open the **Template source** tab.
4. Click the edit icon in **GitHub access token**. Though you cannot see the token, you can delete and update a new token.
5. In the **Edit token** window, enter the new token value and click **Update**.

Creating and managing template instances

Creating and managing template instances and its resources.

- Deploying a template
- Managed services Kubernetes resource controller for Managed services templates
- Viewing template instance details

- Deleting a template instance
- Modifying a template instance
- Managing virtual machine resources
- Importing existing VMware vSphere virtual machine
- Importing an existing PowerVC or OpenStack virtual machine
- Migrating virtual machines using VMware VMotion
- Creating and managing snapshots

Deploying a template

Deploy a template in your Managed services environment.

Before you begin

- VMware templates need to have vmware-tools installed or else the operating system configuration post the deployment is not possible.

Procedure

To deploy a template, follow these steps:

1. In the navigation bar, click **Automate Infrastructure** > **Library**. The library is displayed. Click the **Terraform templates** tab.
2. Click the template that you want to deploy.
3. Read the information about the template and click **Deploy**.

   You can see the template source code in the **Template source** tab and the template parameters in the **Parameters** tab.
4. Specify the following details to deploy a template:
   - **Namespace** - Select the namespace from the drop-down list.

     Note: This step is applicable only for globally accessible templates. You cannot change the namespace during deployment for templates that are associated with a namespace.
   - **Instance name** - Enter a unique name for the instance. The instance name must begin with an alphabet and must have a combination of only these characters: [a-zA-Z][a-zA-Z0-9_-]
   - **Cloud Connection** - Select the cloud connection from the drop-down list. It is a connection to the cloud provider where you want to deploy the template. The cloud connection list only contains the connections defined for the type of cloud provider where you can deploy the template. For information about cloud connections, see Managing connections.
   - **Terraform version** - Select the Terraform version from the drop-down list. For information about creating a user defined Terraform version, see Managing Terraform Versions.
   - If you have used shared parameters while defining your template, then in the **Select data objects**, select the value of all Data Objects associated with the defined Data Types. For the following scenarios, a message is displayed with appropriate information:
     - Your template has an invalid Data Type. A link is provided in the message to edit the template.
     - You do not have any data objects associated with the specified data type. A link is provided in the message to create data objects.
   - If you are deploying enterprise middleware templates from the Enterprise Middleware Repository, select a value for **Advanced content runtime Chef**. This **Advanced content runtime Chef** value is a Data Object that is associated to "advanced_content_runtime_chef" Data Type. If you want your advanced content runtime to be available to middleware template deployments that are in a different namespaces, then modify the data object to be globally available by using the following steps:
     - In the navigation bar, click **Automate Infrastructure** > **Manage**. Click the **Shared parameters** tab.
     - Open the Data Object in edit mode.
     - Select the **Make data object globally accessible (available to all users)** radio button.

     Note: For middleware templates, you can select an Automated Content Runtime that is not deployed on the same cloud provided proper network connectivity exists.
   - Enter all the required deployment parameters. It varies from one template to another based on the definition.

     Note: If you must enter the user ID, then ensure that it corresponds to your operating system and cloud connection. Otherwise, the deployment fails with an error message. For more details, see the General issues section of Troubleshooting deployment issues.
5. Click **Deploy**. The template instance window is displayed. The `Ready` state indicates successful deployment.

   In the template instance window, you can see the instance status, the instance information, the related resource details, and the related input and output variables. You can view or copy the instance logs and you can also access the template from which the instance was deployed.

   Note: Managed services stores the Terraform state file in its database in an encrypted format.

Managed services Kubernetes resource controller for Managed services templates

The Managed services Kubernetes custom resource definition and controller provides you with the ability to deploy, update (Plan/Apply), and delete Managed services templates instances that use Kubernetes yaml resource files.

The templates in Managed services are declarative Terraform templates that allow you to deploy infrastructure as code. With this capability, a single Kubernetes yaml can be created to deploy a composite application that consists of both Kubernetes deployable resources and traditional infrastructure resources, which are deployed with Terraform in Managed services. A typical containerized application is an example of a Kubernetes deployable resource. Examples of traditional infrastructure resources are virtual machines, storage, and so on.

About the task

The Managed services Kubernetes resource controller deploys the Managed services template and waits for SUCCESS status. If the deployment FAILS, then the controller continues to issue PLAN/APPLY requests until the APPLY request returns with SUCCESS status.

If one or more of the template parameter values are changed, then the controller issues a PLAN/APPLY until the APPLY request returns with a status of SUCCESS.

Before you begin

A role binding must be defined for a user or group to have the authority to create/apply a **`templates.cloudautomationmgr.ibm.com`** resource or to deploy a template in Managed services.

The following is an example for the **`icp:camgroup:operator`** user group:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
   name: icp:camgroup:operator:template
roleRef:
   apiGroup: rbac.authorization.k8s.io
   kind: ClusterRole
   name: cam-controller-manager-role
subjects:
- apiGroup: rbac.authorization.k8s.io
   kind: Group
   name: icp:camgroup:operator
```

Procedure

- Deploying a Managed services template
- Displaying the status of a Managed services template
- Deleting a deployed Managed services template

Deploying a Managed services template

1. Go to your Kubernetes environment that is same as Managed services.
2. Create your YAML file. The file allows the definition of the template deployment to be placed under the source control that allows changes to be tracked. An example Managed services Kubernetes resource controller yaml file:

```
apiVersion: cloudautomationmgr.ibm.com/v1alpha1
kind: Template
metadata:
 name: template-ibmcloud-sample # The name of the resource. This name is used for the Managed services deployed
instance name. Therefore, the kubernetes resource name and the Managed services deployed instance name match with
each other.
 namespace: "default"  # Specifies the Kubernetes and Managed services namespace to use for the deployment.
spec:
 connection: "IBMCloud"  # It specifies the name of the Managed services cloud connection to use.
 template:
   name: "Virtual Server with SSH key"  # The name of the Managed services template to deploy.
   version: "2.3"  # The version of the Managed services template to deploy
   parameters:
     parameters:
       datacenter: "dal09"
       hostname: "lrhibmcloud1"
       domain: "raleigh.ibm.com"
```

   - **`parameters`** - It is the collection of name/value pairs that map to the Managed services Template Input Parameter Key and Value.

     ```
     parameters:
       datacenter: "dal09"
       hostname: "lrh1hostname"
     ```

     The following **`sharedParameters`** parameter is an optional parameter and is dependent on the Managed services template that is deployed:

   - **`sharedParameters`** - List of Managed services shared parameter data objects to use with the deployed template. For example:

     ```
     sharedParameters:
     - name: DefaultNoBastionHostRequired
       dataType: bastionhost
     ```

   - **`secretParameters`** - (Optional) List of Managed services secret parameter data objects to use with the deployed template. For example:

     ```
     secretParameters:
     name: vm_password_lrh
     ```

```
secretKeyRef:
       name: vm-password-lrh-secret
       key: password
```

Where:

- **name** is the name of the template parameter.
- **secretKeyRef.name** is the name of the Kubernetes secret.
- **secretKeyRef.key** is the name of the secret data defined in the secret.

3. Run the following kubectl command to deploy a Managed services template:

```
kubectl create -f <yaml file name>
```

Note: A template that is deployed by using the Kubernetes controller can be viewed in the deployed template instances page of Managed services user interface.

After deployment, if you want to modify and do a plan/apply, run the following kubectl command:

```
kubectl apply -f <yaml file name>
```

Displaying the status of a Managed services template

1. Verify the status of a deployed Managed services template by using either of the following commands:

```
kubectl describe -f <yaml file name>
```

or

```
kubectl describe templates.cloudautomationmgr.ibm.com nodejs-ibmcloud-test1 -n default
```

Example:

```
Name:          nodejs-ibmcloud-test1
Namespace:     default
Labels:        controller-tools.k8s.io=1.0
API Version:   cloudautomationmgr.ibm.com/v1alpha1
Kind:          Template
Metadata:
  Creation Timestamp:  2019-05-29T20:12:06Z
  Finalizers:
    template.cloudautomationmgr.ibm.com
  Generation:         2
  Resource Version:   7528303
  Self Link:          /apis/cloudautomationmgr.ibm.com/v1alpha1/namespaces/default/templates/nodejs-ibmcloud-test1
  UID:                08075b85-824e-11e9-b7be-00163e01cbab
Spec:
  Connection:  IBMCloud
  Template:
    Name:  Virtual Server with SSH key
    Parameters:
      Parameters:
        Datacenter:       dal09
        Domain:           raleigh.ibm.com
        Hostname:         lrh1hostname
        Public Ssh Key:   ssh-rsa
    Version:              2.3
Status:
  Action:  CREATE
  Conditions:
    Last Transition Time:  2019-05-29T20:15:41Z
    Reason:                SUCCESS
    Status:                True
    Type:                  CREATE
  Message:
  Outputs:
    Name:    vm_ip
    Type:    string
    Value:   "Public : 9.9.9.9"
  Stack ID:  5ceee797cdb119001c082077
  Status:    SUCCESS
Events:
  Type    Reason              Age    From                       Message
  ----    ------              ----   ----                       -------
  Normal  CREATE:IN_PROGRESS  5m34s  cam-template-controller  CREATE status changed for default/nodejs-ibmcloud-test1
  Normal  CREATE:SUCCESS      2m1s   cam-template-controller  CREATE status changed for default/nodejs-ibmcloud-test1
```

The Status fields returned from the **kubectl describe** command:

- Action - Last action performed, that is, CREATE, PLAN, APPLY.
- Message - Last error message, blank if no error message.
- Stack ID - Managed services stack ID of the deployment.
- Status - Status of the last action performed.
- Conditions
    - Last Transition Time - Last update time of the condition.

- Reason - The status of the Managed services action.
- Status - It is 'True' when the condition is valid.
- Type - The type of the condition - the Managed services action (such as CREATE, PLAN, APPLY).

- Outputs
  - Name - Name of the output parameter.
  - Type - The type of the parameter, that is, string, list, map.
  - Value - The value of the output parameter in json format.
- The Event fields returned from the **`kubectl describe`** command are Type, Reason, Age, and From. Example:

```
Type    Reason                Age   From                       Message
----    ------                ---   ----                       -------
Normal  CREATE:IN_PROGRESS    15m   cam-template-controller    CREATE status changed for default/nodejs-ibmcloud-
1
Normal  CREATE:SUCCESS        69s   cam-template-controller    CREATE status changed for default/nodejs-ibmcloud-
1
```

2. Optionally, you can also use Managed services Kubernetes controller startup parameters - controller parameter. They are defined in **`cam-controller-statefulset.yaml`** file. The args parameters are specified in the pod definition.

   The **`-syncPeriod`** is a controller parameter for the time duration between resource status checks. Value units are 's', 'm', 'h'." (Default is 2m).

   For example:

   - `-syncPeriod=2h30m`
   - `-syncPeriod=300s`
   - `-syncPeriod=30m`

Deleting a deployed Managed services template

If you no longer require the deployed instance of a template, run either of the following commands to delete it:

```
kubectl delete -f <yaml file name>
```

or

```
kubectl delete templates.cloudautomationmgr.ibm.com nodejs-ibmcloud-test1 -n default
```

Note: The command deletes the Managed services resources for the deployed instance and then the Managed services instance. After the Managed services instance is successfully deleted, the Kubernetes resource that represents the Managed services instance is also deleted.

Viewing template instance details

After you deploy a template, you can view the related instance details and perform actions on the related resources.

You can also use the Managed services API to import a virtual machine as a stack instance. The instance details for the imported virtual machine can be viewed and actions performed on the related resources. For more information, see Importing existing VMware vSphere virtual machine or Importing an existing PowerVC or OpenStack virtual machine.

Procedure

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Search for your instance.

   Note: You can also use the following search filters:

   - Enter the name of the instance in the search instance filter.
   - Click the show filter icon to list template instances based on the selected provider.
   - You can click the column headings to sort the list.
   - You can select a namespace from the **All namespaces** drop-down list. The list of template instances in the page changes based on the selected namespace. You can also select "All namespaces" to see all the template instances for which you have access.

   Use the **Instances per page** drop-down to select the number of instances to display per page. Use the **>** or **<** to go to the next or previous page.
3. Click the instance for which you want to see the details. The **Overview** tab of the instance is displayed.

   - From the **Overview** tab, you can see the instance status, template information, instance information, resource details, and the input and output variables. For each resource, you can access the console (if existing) and perform the actions that are listed by clicking the overflow menu.

     Note: To access the KVM console in the IBM Cloud Customer Portal, you must follow the procedure described in Access the KVM Console.
   - From the **Modify** tab, you can modify the instance. For more information about how to modify Resources and Parameters, see Modifying a deployed template instance.
   - From the **Log file** tab, you can view and copy the instance log.

     Note: If the Log exceeds the maximum size of 200 KB, then only the last 200 KB of the Log is displayed.

Deleting a template instance

You can delete a template instance and all its related resources when you do not need them any more.

About the task

In Managed services, you can create templates based on IBM PureApplication patterns. To delete a template instance is also supported for such templates.

Procedure

To delete a template instance, follow these steps:

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Search for your instance.

   You can use the following methods to search for template instances:

   - Enter the name of the instance in the search instance filter.
   - Click the show filter menu icon to list template instances based on the selected provider.
   - You can click the column headings to sort the list.
   - You can select a namespace from the **All namespaces** drop-down list. The list of template instances in the page changes based on the selected namespace. You can also select "All namespaces" to see all the template instances for which you have access.

   Use the **Instances per page** drop-down to select the number of instances to display per page. Use the **>** or **<** to go to the next or previous page.
3. In the instance list, click the overflow menu for the instance that you want to delete. The action list is displayed.
4. In the action list, click **Destroy resources** to delete all the resources related to the instance from the cloud provider. This option does not delete the instance from the Managed services environment.
5. Enter `destroy` to confirm and click **Destroy**. The instance status is changed to `Destroyed`.
6. In the action list, click **Delete instance** to delete the instance from the Managed services environment.
7. Enter `delete` to confirm and click **Delete**. The instance is deleted from the instances list.

   Note:

   - If you delete a template, then you cannot modify or deploy instances that are associated with this template.
   - If you are using AWS cloud connections with an expired temporary access key, then the destroy operation fails. Refresh the credentials in the cloud connections page, run a plan and then apply before you retry the destroy a template instance operation. For steps to refresh the credentials, see Configuring an Amazon EC2 connection.

Modifying a template instance

You can redeploy an existing instance after selecting the desired template version and modifying the input parameters.

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Search for your instance.

   Note: You can also use the following search filters:

   - Enter the name of the instance in the search instance filter.
   - Click the show filter icon to list template instances based on the selected provider.
   - You can click the column headings to sort the list.
   - You can select a namespace from the **All namespaces** drop-down list. The list of template instances in the page changes based on the selected namespace. You can select "All namespaces" to see all the template instances for which you have access.

   Use the **Instances per page** drop-down to select the number of instances to display per page. Use the **>** or **<** to go to the next or previous page.
3. Click to open a deployed instance.
4. Optionally, you can manage resources. For more information, see Modifying virtual machine resources.
5. Click **Modify** tab.
6. In the **Modify deployed instance** page, optionally, enter the following details:
   1. You can select a different template from the drop-down list. The list includes all templates that are available for all namespaces. Before you change the template itself, ensure that you are aware of its impact.

      Notes:

      - Even after changing the template, the original template and version details are available in read-only mode for reference.
      - The word `current` is added to the currently deployed template.

- For the modified instance to apply without any issues, ensure that the newly selected template is compatible with the original template. Otherwise, issues may occur during plan/apply.

2. Select a new template version from the drop-down list.

   Notes:

   - The word "current" next to a version indicates that it is the version with which the instance was deployed. You can verify the same in the **Instance details** section of the **Overview** tab.
   - A version change can add or remove parameters.
   - If you had selected a different template in the **Choose template** drop-down list, then the default version of that template is populated here.
   - The template version follows `major.minor.patch` convention where:
     - `major` refers to significant changes
     - `minor` refers to new features added but existing functionality remains broadly compatible
     - `patch` refers to bug fixes

7. Click **Next**.

8. In the **Edit parameters** tab, enter the following details:

   1. Select a cloud connection.

   2. **Terraform engine version** - Select the Terraform version from the drop-down list. For information about creating a user defined Terraform version, see Managing Terraform Versions.

   3. If the selected version has Data Types defined, then select values for the associated Data Objects from the drop down list. For the following scenarios, a message is displayed with appropriate information:

      - Your template has a invalid Data Type. A link is provided in the message to edit the template.
      - The specified data object is not associated with the data type or the data object is invalid. A link is provided in the message to create data objects.

      Notes:

      - In the **Overview** tab > **Input parameters** section, you can view the input parameter values used when the instance was deployed.
      - If there are no data objects associated with the datatype, then you will be prompted to either create a data object or manually enter values in this **Edit parameters** page.

   4. Enter values in **Additional options**.

      Notes

      - Whenever you change a parameter value, an undo icon is displayed. Click the icon to undo your changes and revert it to default values.
      - The default value for an the existing parameter is the value that was used during the previous deployment. The value used during the previous deployment takes precedence over the value defined in the template.
      - Consider the following points whenever you select a different version or a new template:
        - If there are new parameters in the selected version or template that do not match with the previously deployed template, then they are displayed with the word "new" in parenthesis.
        - The default value for the new parameters are the template values.
        - If a new parameter is not available in the selected version, then it is not displayed.
        - If a Data Object value is injected for a parameter in the template definition of the selected version, then the appropriate output parameter value is used as the default value.
        - If parameters are grouped in the selected template version, then they are displayed as separate collapsible sections. The headings of these sections are displayed in the **Edit parameters** tab for easy navigation.
        - If `immutable` is set to true for a parameter in the selected version, then you cannot edit the default value of the parameter.
        - If `immutable_after_create` is set to true for a parameter in the selected version, then you can enter a value and deploy it for the first time. You cannot edit it in subsequent plan changes.

9. Click **Plan changes**.

   Notes:

   - If you perform a resource taint activity at this stage, then the resource marked as tainted is not considered for the current completed plan.
   - When you taint a virtual machine resource, Managed services marks only that resource and recreates it during the next plan or apply. It does not recreate all resources on the selected virtual machine based on the template logic. If you want to recreate all associated resources of the virtual machine, then you must identify and individually taint all the required resources.

10. In the **Planned changes** page, wait for the status to change from **In progress** to **Success**. Alternatively, go to the **Activity** section of the **Overview** tab to see whether the status of the plan is complete. If the status displays **Failure**, then it indicates that the redeployment with the modified value can result in failure.

    Notes:

    - The resources are neither destroyed or created at this stage, but the **Log output** shows the outcome of your changes beforehand.
    - If the plan is in complete state, then you can revisit the modify page of the deployed instance at a later time and apply the changes.

11. Verify the **Log output** to reconfirm your changes. The log also provides information about what happens if the changes are applied. You can always see the log details for all completed activities in the **Activity** section of the **Overview** tab.

12. Click **Apply changes**. The instance gets redeployed with your latest modifications. At this stage, the resources are created and destroyed as per your plan.

13. In the **Apply changes** window, enter "apply" in **Confirm changes** and click **Apply**. The redeployment starts and you can see the status in the **Overview** tab next to the name of the deployed template instance. When the status changes to **Ready**, it indicates that the redeployment has completed successfully.

    Note:

    - You need to confirm here because the redeployment of your changes may result in adding, modifying, or destroying the associated resources.

- When you click **Apply**, the template instance moves to the new version irrespective of success or failure. It is because the apply might destroy some of the resources before the occurrence of failure.

14. You can also view the status of the deployment details in the **Activity** section of the **Overview** tab. The activity also shows the log of plan changes. If the template or version is changed in the plan/apply step and changes are applied, then you can see new changes in the **Overview** tab.

Managing virtual machine resources

You can manage resources from the **Overview** tab of the deployed template instances page.

You can also run the import a VMware virtual machine API and manage resources from the deployed template instance page of Managed services. For more information about the API, see Common Managed services APIs.

- Start and stop virtual machine resource
- Reset
- Shutdown OS
- Restart OS
- Snapshots
- Taint and untaint resource
- Details

The following table lists Managed services limitations for Cloud provider:

Cloud Provider	Limitations
IBM PureApplication	You can create templates based on IBM PureApplication patterns. You can start/stop virtual machines and destroy resources for such templates, but the taint/untaint feature is not supported.
IBM Cloud, Amazon AWS, and VMware vSphere	Start, stop, and shutdown are available for these providers. Reset, and View Snapshots are available for VMware vSphere only. Restart OS option is available for both Amazon AWS and VMware vSphere.
OpenStack, Google Cloud, Microsoft Azure, and IBM PureApplication	Start and Shutdown are available for these providers. **Note**: Stop (forced power off) is not supported for these providers. Instead the provider attempts a graceful operating system shutdown first. If shutdown does not complete in a given amount of time, then the provider forcefully powers off the virtual machine.
Nutanix	You cannot manage the resources for this provider in this release.
VMware NSXv, VMware NSX-T, IBM Cloud Pak for AIOps and IBM Cloud Kubernetes Service	Manage resources section is not applicable for these providers as they do not provision virtual machines.

Start and stop virtual machine resource

The start action powers on a stopped virtual machine and stop action does a force power off of the virtual machine without operating system shutdown.

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Click to open a deployed instance.
3. In the **Overview** tab, go to the **Resource details** section.
4. From the overflow menu of a resource, click **Start**. The **STATE** of the virtual machine resource changes from "Stopped" to "Running". Likewise, click **Stop** to change the **STATE** of the virtual machine resource from "Running" to "Stopped". The start/stop option is available only when the resource is of type `virtual_machine` and is in a powerstate.

Reset virtual machine resource

You can reset a VMware virtual machine resource. It resets and restarts the virtual machine.

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Click to open a deployed instance.
3. In the **Overview** tab, go to the **Resource details** section.
4. From the overflow menu of a resource, click **Reset**.
5. In the **Activity** section of the **Overview** page, you can view the status of the reset activity and also its logs.
6. Optionally, you can verify the status of the virtual machine in VMware.

Shutdown virtual machine resource

The shutdown action performs a graceful operating system shutdown and then powers off the virtual machine.

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Click to open a deployed instance.
3. In the **Overview** tab, go to the **Resource details** section.
4. From the overflow menu of a resource, click **Shutdown OS**. The **STATE** of the virtual machine resource changes from "Running" to "Stopped".

Restart OS

Restart OS action is available for VMware vSphere and Amazon AWS. This option is enabled only when the virtual machine power state is ON. On Amazon AWS, this option corresponds to a reboot action.

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.

2. Click to open a deployed instance.
3. In the **Overview** tab, go to the **Resource details** section.
4. From the overflow menu of a resource, click **Restart OS**. The operating system of the virtual machine is restarted.

Snapshots

Snapshots are available only for a VMware virtual machine.

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Click to open a deployed instance.
3. In the **Overview** tab, go to the **Resource details** section.
4. From the overflow menu of a resource, click **Snapshots** to view the details of a snapshot in read-only mode.

Taint and Untaint resource

Taint marks a Terraform managed resource as tainted and the tainted resource is deleted and recreated during the next apply.

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Click to open a deployed instance.
3. In the **Overview** tab, go to the **Resource details** section.
4. From the overflow menu of a resource, click **Taint**.
5. In the **Taint resource** confirmation window, click **Taint**. In the **Other** tab of the **Activity** section, a "Taint resource is in progress" entry is displayed. After the activity completes successfully, the activity changes to "Taint resource succeeded" with a green check mark.
6. You can click to view the log of the activity.
7. For a tainted resource, you can go to the overflow menu of the resource and click **Untaint** before you apply the changes. Untaint unmarks a tainted resource and restores it.
8. After you apply the changes, a resource that is marked as tainted gets destroyed and recreated. The **Taint** option is again available for a recreated resource.
9. You can see the status of the action in the **Activity** section.

Details

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Click to open a deployed instance.
3. In the **Overview** tab, go to the **Resource details** section.
4. From the overflow menu of a resource, click **Details**. All the details of the resource are displayed in the **Instance details** page. As an administrator or cluster administrator, you can hide some details of the resource. For more information about the APIs, see Retrieve all IaaS resource settings and Retrieve a specific IaaS resource settings.

Importing existing VMware vSphere virtual machine

You can import a VMware vSphere virtual machine as a Managed services stack instance, identify whether the instance is imported successfully, and manage the stack resources.

A default provided template, **`Import existing VM with a single disk - VMware vSphere for Terraform 1.x.x`**, is shipped as a sample to import a virtual machine. You can use this template during the import of VMware virtual machines. However, this template cannot be used to deploy new virtual machines.

Procedure

1. Use the **`Import VM by IDs`** or **`Import VM by Name`** to import a VMware vSphere virtual machine as a stack instance. For more information, see Import VM by IDs API and Import VM by Name API.
2. Log in to IBM Cloud Pak for AIOps console.
3. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
4. Click the deployed instance to open it and manage the imported virtual machine resources.
5. From the **Overview** tab > **Resources** section, use the overflow menu to start, stop, shutdown, taint, untaint, and view details. For more information, see Managing virtual machine resources.
6. You can also modify the virtual machine using the plan and apply process. For more information, see Modifying a deployed template instance.

Limitations

- The **`Import existing VM with a single disk - VMware vSphere for Terraform 1.x.x`** template works only for virtual machines with a single disk. Go to the template source to find the following single disk information:

  ```
  disk{
    unit_number = "${var.disk_0_unit_number}"
    path = "${var.disk_0_path}"
    label = "${var.disk_0_label}"
    size = "${var.disk_0_size}"
    datastore_id="${var.disk_0_datastore_id}"
  }
  ```

  If you are importing a virtual machine with more than one disk, clone this template to create a copy and duplicate the disk section for each additional disk. Make sure to increment the disk reference number in the variable names.

- The parameter values of **`Import existing VM with a single disk - VMware vSphere for Terraform 1.x.x`** template are automatically populated after a successful import. When the mapping occurs, if your variable values have dots (.), then Managed services automatically converts them to underscore (_) and sets the new values for the template variables. The conversion occurs because the dot (.) character is not supported for the template variable values.

Importing an existing PowerVC or OpenStack virtual machine

You can import PowerVC and OpenStack virtual machines as Managed services stack instances, identify whether the instances are imported successfully, and manage the stack resources.

A default provided template, **`Import existing VM - PowerVC and OpenStack for Terraform 1.x.x`**, is shipped as a sample to import a virtual machine. You can use this template to import virtual machines, but it cannot be used to deploy new virtual machines.

Procedure

1. Use the Managed services API to import virtual machine as a stack instance. For more information, see Import VM by IDs API and Import VM by Name API.

   Note:

   - The **`power_state`** property is discovered during import and is set to the power state of the virtual machine when it is imported.
   - The **`force_delete`** and **`stop_before_destroy`** properties are not discovered during import. These properties are given default values based on their default value in **`camvariables.json`**. These are non-destructive properties so they can easily be changed by modifying the instance.
2. Log in to IBM Cloud Pak for AIOps console.
3. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
4. Click the deployed instance to open it and manage the imported virtual machine resources.
5. From the **Overview** tab > **Resources** section, use the overflow menu to start, shutdown, taint, untaint, and view details. For more information, see Managing virtual machine resources.

   Note: If you make changes to the instance, be aware that the current virtual machine **`power_state`** may not match the discovered **`power_state`**. For example, if a virtual machine in "shutoff" state was active during import, then the value of the **`power_state`** property is still "active" when you modify the instance. Change the value to "shutoff", or else the virtual machine gets started after you apply your changes.
6. You can also modify the virtual machine using the plan and apply process. For more information, see Modifying a deployed template instance.

Resizing a PowerVC Virtual Machine

Shut down your PowerVC virtual machine before resizing it. To resize the virtual machine, do the following steps:

1. View the instance details for the imported virtual machine.
2. In the **Resource details** section, click **Shutdown OS** from the overflow menu of the virtual machine resource.
3. Modify the instance after the virtual machine is shutdown.
4. Change the flavor to a desired value.
5. Ensure the Power State is set to "shutoff".
6. Plan and apply your changes.
7. After the changes are applied, click **Restart OS** from the **Actions** overflow menu of the virtual machine resource.

For steps to shutdown and restart OS of the virtual machine, see Managing virtual machine resources.

Limitations

- Storage attached to the imported virtual machine is not discovered during import. This includes volume attachments as well as any block devices specified when the virtual machine got created.
- If the imported virtual machine was created using a bootable volume rather than an image, then the **Image Name** input variable value may be “Attempt to boot from volume – no image supplied”. If you make changes to the instance that results in the virtual machine being recreated, the virtual machine gets destroyed but does not get created. This issue occurs because block devices are not discovered during import.

Migrating virtual machines using VMware vMotion

Managed services supports VMware vMotion to migrate virtual machines between VMware ESX servers and datastores. In addition, it also supports the migration of virtual machines from one vCenter to another. You can perform the migration task from both VMware vSphere console and Managed services user interface.

- Steps to migrate virtual machine from Managed services
- Steps to migrate virtual machine from VMware vSphere client

Note: VMware vMotion is not supported in a cross-cluster scenario.

For more information about VMware vMotion, see VMware Docs.

Steps to migrate virtual machine from Managed services

1. Log in to Managed services.
2. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
3. Click to open a deployed instance.
4. Click **Modify** tab.
5. In the **Modify deployed instance** page, optionally, select a new template version from the drop down list.
6. If the selected version has Data Types defined, then you select values for the associated Data Objects.
7. In the **Edit parameters** tab, change the values for **Cluster** and **Storage**.
8. Plan and apply those changes to destroy the existing virtual machines and redeploy them to the new Host or Storage.
9. Go to Terraform logs to check the success of the migration.
10. To verify the migration in VMware vSphere client console, go to **Recent tasks** and see whether the datastore or the host has changed accordingly.

Steps to migrate virtual machine from VMware vSphere client

From the VMware vSphere client console, migrate a virtual machine through vMotion onto a different VMware ESX server / cluster and datastore.

For more information about VMware Vmotion, see VMware Docs.

Migrate to a different host

1. Log in to VMware vSphere client console.
2. Right-click the virtual machine and select **Migrate**.
3. Go to **Migrate Virtual Machine**.
4. Select the **Change host** as the Migration Type and click **Next**.
5. Select the destination host and click **Next**. A compatibility evaluation between the source and target is done and the status is displayed.
6. Select the vMotion priority and click **Next**. The recommended high priority option reserves CPU for optimal vMotion performance. You can also choose to migrate with available CPU resources.
7. Retain the default settings and click **Finish**.
8. Log in to Managed services and check whether you are able to work with the migrated virtual machine.

   Note: Example tasks to work with the migrated virtual machine are start, stop, plan, apply, and destroy the virtual machine.

Migrate to a different datastore

1. Log in to VMware vSphere client console.
2. Right-click the virtual machine and select **Migrate**.
3. Go to **Migrate Virtual Machine**.
4. Select the **Change datastore** as the Migration Type and click **Next**.
5. Select the destination datastore and click **Next**.
6. Retain the default settings and click **Finish**.
7. Log in to Managed services and check whether you are able work with the migrated virtual machine.

   Note: Example tasks to work with the migrated virtual machine are start, stop, plan, apply, and destroy the virtual machine.

Creating and managing snapshots

You can create and manage virtual machine snapshots for a VMware instance.

Create a snapshot

Steps to create a new snapshot of a virtual machine.

1. In the navigation bar, click **Automate Infrastructure** > **Instances**. Click the **Terraform templates** tab.
2. Open a VMWare deployed instance and click the **Snapshots** tab. Alternatively, in the **Resource Details** section, select **View Snapshot** from the overflow menu. The **Snapshots** tab opens, and a resource is selected by default. The snapshots of that selected resource are also displayed.
3. Click **Create Snapshot** to create a new snapshot.
4. Enter the **Name** and an optional **Description** of the snapshot.
5. If **Snapshot virtual machine's memory (needs more time)** and **Quiesce guest file system (Needs VMware tools installed)** options are enabled, select as per your requirement. These two options are enabled only if your virtual machine is in power on state. In case of power off state, the **No additional features** option is selected by default.
6. Click **Create**. A notification displays confirming the successful creation of the snapshot. The newly created snapshot is listed along with the other snapshots of the virtual machine. You can view the logs in the **Activity** > **Others** section of the instance **Overview** tab. Click **View Details** to view details of a snapshot log

record.

Manage snapshots

You can view details of a snapshot, delete a snapshot, revert to a snapshot, or revert to the latest snapshot.

- From the overflow menu of a snapshot, perform the following operations to manage a snapshot:
  - Click **View Details** to view the details of a snapshot in read-only mode. Click **Close** to go back to the **Snapshots** tab.
  - To revert to a particular snapshot, click **Revert to snapshot**.
  - To delete a snapshot, click **Delete** and enter "delete" in the confirmation window then click **Delete**.
- To restore to the parent snapshot of the current state of a virtual machine, click **Revert to Latest**. Enter "revert" in the confirmation window and click **Revert** to complete the operation.

Note: Managed services adds the size of the following associated files to determine the overall size of a snapshot:

- .mem - File created if the memory flag is set to "true". It stores the memory state of the virtual machine.
- .vmsn - Metadata file for a snapshot.
- .vmdk - Files created to store the difference of the current state of the disk with the state of the disk at the time of snapshot creation.

These files are associated with a specific snapshot. However, the .vmdk files of the parent snapshots are not included.

Managed services

By using the Managed services, you can automate provisioning of infrastructure and virtual machine applications across multiple cloud environments with optional workflow orchestration.

The Managed services was previously called as Terraform & Service Automation or IBM Cloud Automation Manager. For documentation for previous versions of IBM Cloud Automation Manager, see the IBM Cloud Automation Manager Documentation.

Managed services is a multi-cloud, self-service management platform running on IBM Cloud Pak® for AIOps that empowers developers and administrators to meet business demands.

Service Composer from the Managed services allows you to expose cloud services to any cloud through the Service library. It accelerates developer velocity and improves governance.

Managed services uses open source Terraform to manage and deliver cloud infrastructure as code. Cloud infrastructure delivered as code is reusable, able to be placed under version control, shared across distributed teams, and it can be used to easily replicate environments. Managed services brings a common approach to automate all workloads in all clouds to reduce configuration errors and improve operational efficiency. You can manage infrastructure as code using HashiCorp Terraform software.

The Managed services content library comes pre-populated with sample templates to help you get started quickly. It allows you to leverage IBM, community, and home-grown assets as building blocks and modernize legacy applications and build new cloud native applications. Use the sample templates as is or customize them as needed. A Chef runtime environment can also be deployed using Managed services for more advanced application configuration and deployment.

With Managed services, you can provision cloud infrastructure and accelerate application delivery into multiple cloud environments with a single user experience.

You can spend more time building applications and less time building environments when cloud infrastructure is delivered with automation. You are able to get started fast with pre-built infrastructure from the Managed services library.

To access the Managed services connection and configuration section, log in to IBM Cloud Pak® for AIOps console and click **Automate infrastructure** > **Manage**.

To access the Managed services template and Service library, log in to IBM Cloud Pak® for AIOps console and click **Automate infrastructure>Service library**.

To access the Managed services template and Service instances, log in to IBM Cloud Pak® for AIOps console and click **Automate infrastructure>Service instance**.

To access the Service catalog, log in to IBM Cloud Pak® for AIOps console and click **Automate infrastructure>Service catalog**.

To deploy infrastructure, you can orchestrate a flow with a wide variety of modules and integrations.

- Creating and managing services
- Creating and managing service instances
- Creating and managing custom actions
- Managed services Content

Creating and managing services

Managed services provide end to end IT management services whose deployment is similar to any other database server deployment on a cloud environment. You can create, edit, order, and maintain services from the Manage service Library page. Services include one or many components, such as user interaction, template, custom actions, and orchestration logic.

For troubleshooting and limitations in the service composer, see Troubleshooting Service Composer or Portal issues.

Tasks that you can perform to manage services and versions are as follows:

- Service level actions
- Service version level actions
- Sample services are provided by Managed services in the Manage service library of GIT repository. For the entire list of services, see Managing services in service library.
- Search for a service:
  - In the Manage service library page, the services are sorted according to their category. You can sort your view of the services based on service version statuses and you can toggle which status filter is available.
  - You can use the **Search services** filter. The service tile has the service icon, name, status, and overflow menu.
- Create a service instance - You can create service instances, customize them based on your requirement, and use it in the overall application development.
  - Create a service instance from Managed services
- View service instance details
- Terminate a service instance
- Create bind instances for service instances
- Resume or retry a service instance

Note: Each service can have multiple versions. If you want to use a single version service, you need to set the COMPATIBILITY_MODE to TRUE. To set this mode:

1. Make sure you have Kubernetes CLI installed.
2. Run the following command:

```
kubectl set env deployment/cam-service-composer-api COMPATIBILITY_MODE=true -n cp4aiops
```

You can now use a single version service.

Inbuilt services in Managed services

The GitHub repository includes services in JSON format. Many of these services are inbuilt in Managed services automatically. For services that are not automatically imported, you must manually download, import, and deploy them in Managed services.

You can customize or delete these inbuilt services from your Managed services user interface. To synchronize the Managed services Service Library page with GitHub repository, start or restart the **composer-api** pod. For reference, see GitHub repository link.

In Managed services user interface, go to **Library** > **Services** and view them in the following categories:

- Cluster Lifecycle Services
- Cloud Services
- Hybrid Cloud
- Approval
- Virtual machine

Note: All the services that are listed here are globally accessible from Managed services module. But to access these services in the Manage service Library of IBM Cloud Pak for AIOps, you need to duplicate these services in the user assigned namespace and then publish it from Managed services. For more information, see Duplicating a service and Publishing a service.

Cluster Lifecycle Services

These services create cloud provider-specific Kubernetes cluster and OpenShift clusters, and import them to Infrastructure management installed with Red Hat® Advanced Cluster Management for Kubernetes or without Red Hat Advanced Cluster Management.

Inbuilt services within the Cluster Lifecycle Services category to create a cluster and import them to Red Hat Advanced Cluster Management

Service name with GitHub link	Description
Google Kubernetes Engine Cluster with Red Hat Advanced Cluster Management import	Deploys a Google Kubernetes Engine cluster and imports the cluster into a Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.
Amazon Elastic Kubernetes Service Cluster with Red Hat Advanced Cluster Management import	Deploys an Amazon Elastic Cloud Kubernetes Service cluster and imports the cluster into a Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.
Azure Kubernetes Service Cluster with Red Hat Advanced Cluster Management import	Deploys a Microsoft Azure Kubernetes Service cluster and imports the cluster into a Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.
Red Hat OpenShift Kubernetes Service on IBM Cloud with Red Hat Advanced Cluster Management import	Deploys a Red Hat OpenShift Kubernetes Service cluster on IBM Cloud and imports the cluster into a Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.

Cloud Services

The following table lists all inbuilt services that can connect to Public Cloud Services

Service name with GitHub link	Description
Amazon Relational Database Service	This service configuration uses the AWS provider to provision a Relational Database Service (RDS) on AWS.
Amazon S3 Bucket	This service configuration uses the AWS provider to provision a S3 bucket on AWS.
IBM Database Service	This service configuration uses the IBM Terraform provider to provision a Database Service IBM Cloud.

Hybrid Cloud and ServiceNow CMDB Integration

The following table lists all inbuilt services within the Hybrid Cloud category:

Service name with GitHub link	Description
Multi Cloud - MEAN Stack deployment	Deploys a hybrid cloud MEAN stack (Mongo, Express, Angular, Node) on your choice of cloud. This deployment also deploys a simple sample application to validate the stack is operational. After the stack gets deployed and CMDB gets updated with server records.

Approval

The following table lists the inbuilt services that showcase integration with Infrastructure Management approval process.

Service name with GitHub link	Description
Infrastructure Management Approval	This service is used to get approval from Infrastructure Management before provisioning the resources.

Virtual machine

The following table lists all inbuilt services within the virtual machine. These services can be used to stand up a virtual machine in clouds such as IBM Cloud, Amazon Web Services, Google Cloud Platform, Azure, and VMware.

Service name with GitHub link	Description
Virtual machine on Amazon Web Services	Creates a virtual machine instance on Amazon Web Services
Virtual machine on Google Cloud Platform	Creates a virtual machine instance on Google Cloud Platform
Virtual machine on IBM Cloud	Creates a virtual machine instance on IBM Cloud
Virtual machine on Microsoft Azure	Creates a virtual machine instance on Microsoft Azure
Virtual machine on VMware	Creates a virtual machine instance on VMware

Managing categories

Create and manage categories to organize your services in the library.

- Creating categories
- Deleting a category

Creating categories

Create a category to organize your services in the library.

About the task

The "Cluster Lifecycle Services" category is preloaded for you and you cannot delete it.

Procedure

To create a category, follow these steps:

1. In the navigation bar, click **Automate Infrastructure** > **Library**. Click the **Services** tab.
2. In the **Service categories** pane, click **Add category**.
3. Enter a name for the category and click **Add**. When the category is created, a confirmation message displays.

Alternatively, when you create a service, select the **Add a category** item in the **Category** drop-down to create a new category. The naming convention for category name is as follows:

- Must start with a letter
- May contain alphanumeric, underscore, hyphen, and space characters

Deleting a category

You can delete a category from the library.

About the task

The "Cluster Lifecycle Services" category is preloaded for you and you cannot delete it.

Procedure

To remove an empty category, follow these steps:

1. In the navigation bar, click **Automate Infrastructure** > **Library**. Click the **Services** tab.
2. Hover over the category you wish to delete and move your cursor to the right until the minus icon appears. Click the minus icon. A message displays asking you to confirm the remove operation. If any services use the category, then the remove operation will fail. Move all services in this category to another category and then remove it.
3. Click **Remove** in the confirmation message. After the category is successfully removed from the library, a message displays.
4. Click **Close**.

Bookmarking Service Library URL with preselected category

This feature is included to navigate to a specific category in the Manage service library page.

Procedure

1. In the navigation bar, click **Automate Infrastructure** > **Library**. Click the **Services** tab.
2. Click a category in the **Services** pane. For example, click the "Cluster Lifecycle Services" category.

   The selected category name is appended to Managed services user interface URL.
3. Copy that URL.

   For example, `https://<TSA_HOSTNAME>/cam/portal/#!/servicelibrary/category/Cluster%20Lifecycle%20Services`. Where, `Cluster Lifecycle Services` is the name of the selected category.
4. Save or share the URL for future use.
5. Use that URL to navigate to the specific category in the Manage service library.

Creating a service

You can create or import a service from the Managed services service library page.

About the task

If there are any problems while you create, save, or publish your service, then warning or error messages display. For more information on these service validations, see Service validations.

Procedure

1. In the navigation bar, click **Automate Infrastructure** > **Library**. Click the **Services** tab.
2. Click **Create service**.
3. In the **Create service** window, enter the following details:
   - Select either of the following options in **Assign access** section:
     - **Make this service globally accessible (available for all users)** - Services created globally are accessible to all users.
     - **Make this service part of a namespace** - Associate the service with a specific namespace. For this option, you must select a namespace from the drop-down list to which the service will be assigned.

     Notes:
     - Based on the value selected in the namespace drop-down list of the **Library** > **Services** page, the **Assign access** and **Namespace** values are automatically selected. Modify the values if you want.
     - If the service is defined as globally accessible, then only globally accessible resources are available in the composer. For example, globally accessible cloud connections, shared parameters, and content runtimes are only available in the service composition tab for a service that is defined as globally accessible.
     - If the service is defined in a namespace context, then only globally accessible resources and resources defined in the same namespace context are available in the composition tab of the service.
   - Enter the service name.
   - Enter the version name. This version is used as a default version if not specified. The version format must follow **V.R.M.F** where the letters are integers in range 0-99.
   - Optionally, select a category.

     If you do not specify any category, then the service is assigned to the **Cloud Services** category. You can select **Add a category** from the **Category** drop-down list to create a new category. If you select **Add a category**, then enter the name of the new category and click **Create**. The **Select from list** allows

you to go back to the original list of categories.

For information about categories, see Creating a category.

Notes:

- You can create a service with the same name in a different namespace, but it is not allowed within the same namespace.
- Service name must follow the Kubernetes naming convention, or else the published services do not get listed in IBM Cloud Pak for AIOps catalog:
  - Alphanumeric, underscore, hyphen, and space
  - Starts with a letter
- If you plan to publish a service, ensure that its name is less than 64 characters long. If you have more than 64 characters, then publishing the service to IBM Cloud Pak for AIOps may cause issues.

4. Click **Create**. The service details page is displayed. It includes **Overview**, **Composition**, **Parameters**, **Plans and form**, and **Source code** tabs.
5. In the service details page, a drop-down list of all service versions is displayed next to the service name. Select the version to view service details for that service version.
6. In the **Overview** tab, enter **Service name**, **Short description**, and **Long description** in the **Quick overview** section.
7. In the **Select icon** section, you can select or change the existing icon for the service.
8. In the **Version details** section, you can view or edit the version details from the overflow menu. You can also set a particular version as default by clicking **Set default version** from the overflow menu. By default, the version created during the **Create service** modal is the default service version.
9. In the **Change version** drop-down list, you can change the version and view/load the details of that service version.
10. Click **Create version** to create a new version based on any of the existing versions. See Adding a Service Version. The created version is added to the drop-down list displayed next to the service name.
11. In the **Tags** section, select **System tags** to include all predefined tags. You cannot delete system tags. In edit mode, you can only change the value of **Name**.

    Notes:

    - The following parameters are available as system tags:
      - `environment` - The environment in which this service is running.
      - `Name` - The name you provide for the service instance at the time of request.
      - `request_group` - The current context group id of the current user that requested the provisioning of the template. This is important because a user may be part of more than one group and this identifies the group for which the user made the request.
      - `request_user` - The user id of the current user that requested the provisioning of the template.
      - `service_identifier` - Unique identifier generated by Managed services, which is mapped to the service instance of the template provisioned.
      - `service_name` - The name you provide for the service instance at the time of request.
    - Managed services converts the following non-permissible characters in the system tag definition to permissible characters:
      - Special characters - They are converted to "_". For example, if the key value is "a*b&c@d", then it gets converted to "a_b_c_d".
      - Upper case characters - They are converted to lower case characters automatically. For example, if the key value is "ABCD", then it gets converted to "abcd".
12. Click **Add tags** to create new user defined tags. The **Add tags** window is displayed. Tags are metadata that is directly persisted back to the actual cloud. They are useful in external system integration through the cloud. Before you use tags, see Prerequisites for tags.
13. Enter the following details of a tag:

    - **Name** - Enter a unique name for the tag. These tags are key value pairs where the **Name** is the key.

      Notes:

      - Consider the provider specific limitations when you name the tag or enter a key for it. For more information about IBM Cloud provider naming conventions, see Working with tags.
      - General naming conventions to be followed for the tag name:
        - Only alphanumeric, underscore, and hyphen characters are allowed.
        - Must start with a letter.
    - **End-user permission** - Select **Invisible**, **Read-only**, or **Read-write**.
    - **Type** - Select type from drop-down list. It supports only string type.
    - **Value required** - Determines whether a value is required for the tag.
    - **Specify options** - Select this option for a drop-down list of string values.
    - **Display name** - Enter the display name of the tag.
    - **Description** - Enter description of the tag.
    - **Default value** - Enter the default value. If you select, **Specify options**, then enter values for the **Label** and **Value** pair fields. Select a record to mark it as the default value. You can click the cross mark icon to delete a value record.
14. Click **Add**. The newly created tag gets added to the **Tags** section of the **Overview** tab. You can edit and delete an existing tag from the overflow menu.
15. Click **Add feature** and in the **Features** section to add a service feature. Enter the **Title** and **Description**, then click **Add**. From the overflow menu of an existing feature, you can edit or delete a feature.

16. Open the **Composition** tab and drag the various activities inside the composition canvas.

    To understand the layout and functionality of the **Composition** tab, see Working with Composition tab.

17. Open the **Parameters** tab. From this tab, you can add, edit, and delete an existing parameter. To work with the **Parameters** tab, see Working with the Parameters tab.

18. Open **Plans and form** tab. It has **Plans** and **Plan parameters** sections. Multiple plans are supported. Plans are combination of form or exposed parameters which are overridden to create a form.

19. Click **Add plan**. The **Add plan** window displays.

20. Enter the **Plan name** and **Description**.

    For example, create two plans, namely **`VMware`** and **`Powervc`**. There is a **`hypervisordecision`** input parameter in the **Parameters** tab that takes two values:

    ```
    [["value": "VMware"],["value": PowerVC]]
    ```

    Note: The plan name must follow the Kubernetes naming convention, or else the published services do not get listed in the IBM Cloud Pak for AIOps catalog: - Alphanumeric (lower case), underscore, hyphen, and space - Starts with a letter

21. Click **Add**. The newly added plan is added to the **Plans** section. From the overflow menu, you can edit, delete, or preview a plan.

Note: Optionally, you can associate pricing with a plan. However, you have to add pricing in the **Source code**. For more information about the pricing definitions in Service Composition Language, see plans section in Editing a service file page.

19. In the **Plan parameters** section, expand the plan name. All input parameters are listed here so you can override the parameters that are persisted for this plan.

    For example, expand the plan **`VMware`**. The input parameter **`hypervisordecision`** is listed.

20. To override a input parameter, click the overflow menu of a parameter and select **Edit**. The **Edit parameter** window is displayed. Change the permission to invisible and enter a **Default value**.

    For example, enter **Default value** as **`PowerVC`** for the parameter under the **`Powervc`** plan and enter **`VMware`** for the parameter under the **`VMware`** plan. When you create a service instance, the plans are displayed both in IBM Cloud Pak for AIOps and Managed services user interface.

21. Click the **Source code** tab to view, modify, or delete source code for a service.

Note: During service publishing on IBM Cloud Pak for AIOps catalog, if you want to display values for **Details**, **Documentation** and **Support Links** in the **Overview** > **Useful Links** section, then update **`documentationUrl`** and **`supportUrl`** attributes in the **`catalog_metadata`** section of the service template Source Code.

Example:

```
"longDescription": "\nService to deploy EC2 VM (Verified)",
"documentationUrl": "https://www.myibm.com/cam_creating_service.html",
"supportUrl": "http://www.myibm.com",
```

22. Click **Import source file** to import a service file from the local machine. For more information about the service file syntax, see Editing a service file.
23. Save your changes. The **Save** button is disabled if there are validation errors in the service.
24. The service is displayed in the Manage service library. The overflow menu for the service has **Assign access**, **Add Version**, **Duplicate**, **Rename service**, **Change category**, and **Delete**.
25. Expand the service to view the service versions. The overflow menu for a service versions has **Edit**, **Assign custom actions**, **Copy to...**, **Test deploy**, **Publish**, and **Delete**.
26. Test your service by creating a service instance and verifying whether it works correctly. You can deploy services in draft state, but they can be used only for testing purpose. For information about creating a service instance, see Creating a service instance.
27. If the service deployment ends in **`Error`** status, check the deployment logs by clicking the deployed service instance and then the **Log file** tab. When you find out the cause of the error, edit the service by accessing it from the Manage service library, save the changes, and test the service again.
28. If you want to save this service to a Git or Bitbucket repository, see Saving a service to different repositories.

Prerequisites for tags

If you create a service by using a template that includes tags, then the tags are sent to all the deployed instances of the service. Each of the deployed instances in turn passes the tags to the Terraform template. Ensure that your template is capable of consuming tags as Managed services only passes the tags to the Terraform template.

You can use the Managed services to consume the tags.

To use this module, import it and then use it.

For example, if you have packaged the module inline, do the following:

```
module "camtags" {
source = "./Modules/camtags"
}
```

Then the tags can be accessed as a map variable:

```
${module.camtags.tagsmap}
```

or can be accessed as a list:

```
${module.camtags.tagslist}
```

For a sample usage of tags, see the git repository.

For more information about tags module, see Defining the structure of Managed services template.

Working with the Parameters tab

From the **Parameters** tab, you can add new parameters, edit existing parameters, and delete existing parameters.

The tab has **Input Parameters**, **Activity Parameters**, and **Output Parameters** sections. Input and Output Parameters are not defined by any template, but are user-defined parameters to simplify the experience of creating a service instance. They are global variables limited within the scope of this service. You can define them for mapping back values in the activity parameter. Activity Parameters provide the data to deploy a particular template.

- To create new input and output parameters, see Creating new input and output parameters.
- To update or delete an existing input and output parameter, see Managing existing input and output parameters.
- To update an existing activity parameter, see Editing an existing activity parameter

Creating new input and output parameters

From the **Parameters** tab, you can create new parameters for **Input parameters** and **Output parameters**.

Procedure

1. From the drop-down menu, select **Provision action**, **Bind action**, or a custom action.

   Notes:

   - Based on the selection, the parameters change in the **Input parameters** section, **Activity parameters** section, and **Output parameters** section.
   - **Bind action** and custom actions appear in the drop-down list only if created in the **Composition** tab.
2. Click **Create parameter** to add a new input or output parameter. See Creating parameter.

5. Click **Add**. The parameter is added to the appropriate input or output section. You can edit and delete an existing parameter from the overflow menu. You can also verify the parameters in the **Source code** tab.

Creating parameter

1. In the **Create parameter** page, enter the **Parameter key**.

   Note: The naming convention for a parameter key is as follows:

   - Alphanumeric, underscore, and hyphen
   - Starts with a letter
2. Select **End-user permission**.

   The three different types of permissions are as follows:

   - **Invisible** - During parameter creation, enter a value for the **Value**. This parameter is not visible while creating an instance of the service.

     Note: For the Invisible parameter, if you enter incorrect data in the value field, then the Service instance deployment of the content run time fails.

   - **Read-only** - When you create a service instance, you cannot make changes to the value that was defined during creation. Enter or select the following values:

     - **Parameter type** - Select a type. It determines the type of parameter. The available parameter types are string, password, list, boolean, counter, map, connection, and shared parameter.
     - **Display name** - The label or display name of the parameter.
     - **Description** - The description appears as a tooltip when you create the service instance.
     - **Value** - The value of the parameter. When you create the service instance, this parameter is visible to you in read-only format.
     - For the list type, you can click **Add new** to add values to the list.
     - For the map type, you can click **Add new** to add **Key Value** pairs to the map. Click the cross icon to delete a pair.
     - For password types, toggle between **Show** and **Hide** to view or hide the password characters.
   - **Read-write** - When you create a service instance, you can make changes to the value that was defined during creation. Enter or select the following values for **Read-write** permission:

     - **Editable** - If checked, this parameter can be edited while editing a service instance.

     - **Parameter type** - Select a type. It determines the type of parameter. The available parameter types are string, password, list, boolean, counter, map, connection, and shared parameter.

     - **Value required** - Determines whether a value is required for the parameter.

- **Specify options** - For the string type, you can select this option to create a drop-down list of string values. It is not available for other data types.
- **Display name** - The label or display name of the parameter.
- **Description** - The description appears as a tooltip when you create the service instance.
- **Dynamic** - Enables an input parameter to fetch possible values dynamically in real time depending on the selected values of the dependent parameters.
- **Pass by name** - Check this if the name should be used instead of the value. If not checked, parameter value is used.

  Note: Parameters of asset type `regions` should not be defined as pass by name. A region should always be passed by a value as per provider implementation.
- **Source** - A collection of dynamic input parameter implementations. Each source is associated with a cloud provider type.

  For more information about supported providers, see Dynamic parameters supported providers
- **Asset type** - Select the required asset type from this drop-down list. The asset type list is based on the selection of the **Source**.
- **Depends on** - These input fields change based on the **Asset type** selection and should be linked to the appropriate input parameters.

  Notes:

  - Two plans with dynamic parameters are not supported yet. They are only supported with the one, standard plan only.
  - Dynamic input parameters must be created sequentially as connection, region, vpc and a subnet.
- **Validation rule** - The validation rule is an optional field that is available only if you select string or password in **Parameter type** drop-down list. A validation rule (regex) provides an ability to the service composer to restrict the values of an input parameter. If regex is provided during service composition, then the value of the string input parameter must satisfy the regex criteria during service deployment. For example, (\w+?@\w+?\x2E.+). This is not applicable if **Dynamic** is selected.
- **Validation rule description** - A description that provides information about the validation rule. For example, "Enter a valid email address". Here, (\w+?@\w+?\x2E.+) is the regular expression for an email address. If you enter “abc.xyz.com” as the value for string input parameters, then service deployment fails due to an invalid email address. This is not applicable if **Dynamic** is selected.

  Note: For more information about regex, see regexlib.com.
- **Default value** - Enter a default value. If you select, **Specify options**, then enter values for **Label** and **Value** pair fields. Select a record to mark it as default value. You can click the cross mark icon to delete a value record. This is not applicable if **Dynamic** is selected.

Managing existing input and output parameters

From the **Parameters** tab, you can edit or delete existing input and output parameters.

Procedure

1. Go to the appropriate **Input parameters** or **Output parameters** section.
2. From the overflow menu of the parameter record, click **Edit**.
3. In the **Edit parameters** page, modify the parameter values. For more details on the parameter values, see Creating new input and output parameters.
4. Click **Save**.
5. To delete an existing parameter, select **Delete** from the overflow menu of the parameter record.
6. In the confirmation message, click **Delete**. The parameter record is removed from the list.

Managing an existing activity parameter

In the **Activity Parameters** section, you can update, link, or create a new parameter.

Edit an existing parameter

In the **Edit Parameters** page, you can update values of an existing parameter.

Procedure

1. Go to **Activity parameters** section.
2. Expand the activity and search for your parameter record within it.
3. From the overflow menu of the parameter record, click **Edit**.
4. In the **Edit parameters** page, select the default **Update** tab.
5. Enter or select a new value to update the parameter.
6. Click **Save**.

Link parameter

In the **Edit Parameters** page, link the value to a parameter.

Procedure

1. Go to **Activity parameters** section.
2. Expand the activity and search for your parameter record within it.
3. From the overflow menu of the parameter record, click **Edit**.
4. In the **Edit parameters** page, select the **Link** tab.
5. Select a linking option. You can map parameter values using the **Input parameters** and **Templates** menu options in the **Link parameters** dialog box:

   Note: Not all options are available for a parameter. It varies based on the activities used in the service.

   - **Input parameters** - The **Input parameters** menu option lists all of the parameters that are available in the **Input parameters** section of the main **Parameters** tab of a service.
   - **Shared parameters**

     Note: If you link the attribute of a shared parameter, then an input parameter is automatically created. During service deployment, select the dataobject for the datatype. The data attribute value of the selected dataobject is used during provisioning.
   - **Templates**
   - **Helm Charts**
   - **Business Process Manager** - If you have configured a Business Process Manager connection, then all Business Process Manager activities are available for association.
6. Map values with the parameter:
   1. Click to select an option. The values displayed change based on the options that you select and the activities that you have used in your service workflow.

      Notes: For example, if there are two templates A and B placed in sequence in the **Provision action** of the **Composition** tab, then parameters of both the templates are available in the **Activity parameters** section of the **Parameters** tab. If you want to link a parameter of template B, then a list of all parameters of the template A and shared parameters are available for association. If your service involves Business Process Manager activities and helm charts, then they are also available for linking. For the very first activity, template A, you can only link input parameters and shared parameters.
   2. Expand the parameter menu and hover over the parameters to see a plus icon.
   3. Click the plus icon to select it. A green tick mark indicates your selection and also the **Value** is refreshed. You can also use the **Search Parameter** to filter and find a parameter.

Create a new parameter

In the **Edit Parameters** page, you can create service parameter and link to it at the same time.

Procedure

1. Go to **Activity parameters** section.
2. Expand the activity and search for your parameter record within it.
3. From the overflow menu of the parameter record, click **Edit**.
4. In the **Edit parameters** page, select the **Create** tab.
5. Enter a value for the **Parameter key**.
6. Enter or select values for the new parameter.

   Notes:

   - You can only use the **End-user permissions** value of the parameter record from which you opened the **Create** tab. You cannot change the value.

The three different types of permissions are as follows:

- **Hidden** - During parameter creation, enter a value for the **Value**. This parameter is not visible while creating an instance of the service.

  Note: For the hidden parameter, if you enter incorrect data in the value field, then the Service instance deployment of the content run time fails.
- **Read-only** - When you create a service instance, you cannot make changes to the value that was defined during creation. Enter or select the following values:
  - **Parameter type** - This value cannot be changed. It is set to the parameter type of the parameter you are editing.
  - **Display name** - The label or display name of the parameter.
  - **Description** - The description appears as a tooltip when you create the service instance.
  - **Value** - The default value of the parameter. When you create the service instance, this parameter is visible to you in read-only format.
  - For the list type, you can click **Add new** to add values to the list.
  - For the map type, you can click **Add new** to add **Key Value** pairs to the map. Click the cross icon to delete a pair.
  - For the password type, toggle between **Show** and **Hide** to view or hide the password characters.

- **Read and Write** - When you create a service instance, you can make changes to the value that was defined during creation. Enter or select the following values:
    - **Parameter type** - This value cannot be changed. It is set to the parameter type of the parameter you are editing.
    - **Value required** - Determines whether a value is required for the parameter.
    - **Specify options** - For the string type, you can select this option to create a drop-down list of string values. It is not available for other data types.
    - **Display name** - The label or display name of the parameter.
    - **Description** - The description appears as a tooltip when you create the service instance.
    - **Default value** - The default value.

7. Click **Save** to create and save the new parameter.

Working with the Composition tab

The Service Composition tab has the following sections:

- A palette to drag the different service components.
- A canvas where you can draw your workflow.
- A Parameter details pane that changes based on the activity you select in the canvas.

Palette of service components

The palette includes templates, helm charts, flow components, notifications, and integration components that you can drag and drop on the canvas.

To work with the different service components, see Service components in the Composition tab. For details about the supported interpolation expression of these service components, see Supported interpolation expressions.

Canvas in the middle

The canvas has the following sections within it:

- **Provision action** and **Create action** actions

  When you create a service, you can define actions for the service from the composition tab. The actions drop-down list of the canvas includes **Provision action** and **Create action** options. You can create a **bind** action or **custom** actions by using the **Create action** option.

  Note: The **Provision action** is displayed by default in the action list.

  The **Provision action** provisions a resource instance. Optionally, if you want to execute some additional bind actions on a provisioned resource instance, you can create a **bind** or **custom** action.

  Note: The **bind** and custom actions you define are applicable across all plans defined for that service.

  Steps to create a action:

  1. In the action drop-down, select **Create action** to create a new action. By default, **Provision action** is selected in the **Composition** tab.
  2. In the **Type** drop-down, select the type of action.
     1. **bind**: The **Name** of the action is "Bind" and can not be modified.
     2. **custom**: Enter the name of the action in **Name** text box. The name can not be **bind** for the custom action.
  3. Enter the **Description** for the action.
  4. Click **Create**. You can create only one bind action. If you try to create a second bind action, the **Create** button is disabled. There is no limit for creating custom actions.
  5. You can now include a Terraform templates or other activities in the bind canvas. These activities run on a deployed instance of a service. It is recommended that you include only Terraform templates that do not deploy a resource instance. You can view the details of the bind and provision in the **Source code** tab.

     Note: You can also create and invoke stand-alone action independent of any service or service instance. For more information on the APIs, see Create Action and Invoke Action in the Common Managed services APIs page.

- **Primary flow** and **Error flow**

  The **Primary flow** and **Error flow** sections are positioned below the action drop-down list in the canvas. You can have primary flow and error flow for **Provision**, **bind**, and **custom** actions.

  The **Primary flow** is initiated when you initially request a service. You can drag the service components of the workflow here. In the canvas they are generally termed as "activities."

  The **Error flow** is initiated when an error occurs in the primary flow during deployment. Similar to the primary flow, you can drag service components from the palette.

  Notes:

  - You can collapse and expand the **Primary flow** and **Error flow** sections in the canvas.
  - You can use retry or resume for failed deployments. For the procedure to retry or resume, see Resuming or retrying a service instance.

- The instance details and the activity log section of the **Log file** tab do not show details of the activities executed in the error flow. In the **Log file** tab, the error flow execution details are reported in the **ON ERROR FLOW** part of the service log section.
- The error flow is intended to notify you through email or slack or update a service now ticket about the error. As a result, it is not recommended to provision new resources in this flow. If new resources are provisioned, then the instances from the error flow do not get terminated during the 'Terminate' action. Also, an error that occurs in the error flow sequence is not handled separately.
- In error flows, for more information about interpolations that can be used to identify details around the activity that failed, see Service instance level parameters.
- You can use the OR (||) operator for the service activities in the error flow.
- If you use interpolation in the error flow around a non executed decision from the primary flow, the resultant value is an empty string.
- Limitations in the **Error flow** section:
  - You cannot use a decision service component in the **Error flow** section.
  - Whenever a service deployment fails in Terraform plan, the error flow is not executed. It is executed only when the Terraform plan gets executed successfully and some failure occurs during apply.

Parameters section

The parameters on the **Composition** tab vary based on the current activity that is selected in the canvas. To work with the activity parameters, see the following topics:

- Service components in the Composition tab
- Supported interpolation expressions

Additional features

- You can hover over an activity in the canvas to clone or delete. Additionally, for a decision activity, you can collapse the activity view in the flow.

  Note: Before you delete a component activity, ensure that it is not linked to other activities in the flow. If it is linked, then manually update all mapping either in the **Composition** tab or the **Source** tab, otherwise, the service breaks.

- You can use the control buttons to search the canvas, fit-to-screen, and zoom.

- If there are no errors or warnings in your service, then the page displays a **No issues** message. Whenever errors and warnings occur, a notification panel is displayed with the count of errors and warnings. Click for more information about the context of errors and warnings. In addition, in the composer canvas, a small icon (error and/or warning) is displayed against the related activity that has a validation problem. When you click **Save**, the API validation messages are displayed, however, they go away whenever you try to modify the service or move to other tabs. For more information about service validations, Managed services validation approaches, and behavior, see Service validations.

Activities in the Composition tab

Flow components, notifications, integration components, applications, templates and Helm charts are the different service components that you can work with in the **Composition** tab.

- Flow components
  - Decision
- Email notification
  - Email notification
  - Configuring and managing SMTP server connection for Email notifications
- Integration components
  - Rest Hook
- Applications
- Templates
- Helm charts
- Ansible
  - Credential
  - Inventory
  - Job Templates

For input and output parameter mapping for these activities, see Supported interpolation expressions.

For troubleshooting and limitations in the service composer, see Troubleshooting Service Composer or Portal issues.

Decision

In the **Composition** tab, the decision component is available underneath the **Flow components** menu. It is used for the purpose of selecting a flow based on a decision.

Procedure

1. Drag **Flow Components** > **Decision** in the composition canvas.
2. Select or enter the following details:

- **Title** - Enter the title of the decision activity. The **Title** must have a unique value.
- **Description** - The description of the decision activity.
- **Mapped Parameters** - Click **Link parameter** to map an existing parameter or create a new parameter. Alternatively, click **Add parameter** and enter an interpolation value. Click the blue tick mark to save the value.
    - Steps to map an existing parameter or create a new parameter of type mapped parameter:
        - Click **Link parameter** in the **Activity details** pane to map a new parameter.
        - In the **Link parameter** dialog, click **Link** to map an existing parameter.
        - Map an existing parameter or create a new parameter and link it automatically:
            - Link parameters:
                - Select a linking option. You can map parameter values using the **Input Parameters** and **Templates** menu options in the **Link Parameter** dialog box:
                    - **Input Parameters** - This menu option lists all string parameters that have **Options required** set to true in the **Input Parameters** section of the main **Parameters** tab of a service.
                    - **Templates** - This option lists all parameters of all template activities that are available prior in sequence to this decision activity.

                  The values displayed in the **Activity details** pane change based on what you select and which activities you use in your service workflow.

                  Note: For example, if there are two templates A and B placed in sequence in the **Provision Action** of the **Composition** tab, then parameters of both the templates are available in the **Activity Parameters** section of the **Parameters** tab. If you want to link a parameter of template B, then a list of all parameters of the template A and shared parameters are available for association. If your service involves Business Process Manager activities and helm charts, then they are also available for linking. For the very first activity, template A, you can only link input parameters and shared parameters.
                - Expand the parameter menu and hover over the parameters to see a plus icon.
                - Click the plus icon to select it. A green tick mark indicates your selection and also the **Value** is refreshed. You can also use the **Search Parameter** to filter and find a parameter.
                - Click **Save**.
                - You can also click **Remove Link** in the **Link Parameter** dialog box to remove a mapping.
            - Create a new parameter and link it at the same time:
                - In the **Link Parameter** dialog box, click **Create**.
                - Enter a value for the **Parameter Key**.
                - Enter or select values for the new parameter.

                  Notes:
                    - You can only use the **End-User Permissions** value of the parameter record from which you opened the **Create New** tab. You cannot change the value.
                    - You cannot change the **Parameter Type** value. It is dependent on the parameter record type from which you opened the **Create New** tab.
                - Enter or select the following values for **Read and Write** permission:
                    - **Parameter Type** - This value cannot be changed and is set to the parameter type of the parameter from which you opened the **Link parameter** dialog.
                    - **Value Required** - Determines whether a value is required for the parameter.
                    - **Specify Options** - For string data type, you can select this option for a drop-down list of string values.
                    - **Display Name** - The label or display name of the parameter.
                    - **Description** - The description appears as a tooltip when the customer orders this service.
                    - **Default Value** - Enter values for **Label** and **Value** pair fields. Select a record to mark it as default value. You can click the cross mark icon to delete a value record.
                - Click **Save** to create and save the new parameter.
- **Cases** - The value of **Cases** depends on the selected **Mapped parameter**.

  An example of **Cases** can be `case 0: VMware` and `case 1: IBM Cloud`.

Email notification

In the **Composition** tab, the **Email Notification** is available underneath the **Notification** menu.

It triggers an email notification at the specified point in the flow. Before using email notification, you must configure a connection to the SMTP server. For more information, see Configuring SMTP server connection for Email notifications using Managed services console and Configuring a connection for notifications using API.

Procedure

1. Drag **Notification** > **Email Notification** in the composition canvas.
2. Check **Editable** if you want to edit these parameters while editing the service instance.
3. Enter values for **Title**, **To**, **Cc**, and **Content**.

   Note: If running behind a proxy server, make sure the proxy SMTP server is configured and its values are set in the email configuration.
4. Optionally, in **Body**, enter the input value for the Email Notification activity in JSON format.

   Tip: The assistive user interface provides suggestions when you type "$". You can select from the interpolation options, such as ${input_parameters, ${svc_instance, ${datatypes. After you select the interpolation option, enter "." for the user interface to list all probable input parameters that are defined prior to this email notification activity. This feature is available for **To**, **Cc**, **Content**, and **Body**.

Managing Email Configuration

You can configure primary and secondary SMTP Email servers and manage their configurations.

Managing Email Configuration:

- Configure Email Server
- Searching SMTP Configuration
- Editing SMTP Configuration
- Deleting SMTP Configuration

Note: If you close the window without saving during create or manage operations, then the values are reset to empty.

Configure Email Server

From the **Email configuration** page, you can create an email server configuration.

1. In the navigation bar, click **Automate Infrastructure** > **Manage**. Click the **Email configuration** tab.
2. Click **Create configuration**.
3. Select either of the following options in the **Assign access** section:
   - **Make email server globally accessible (available to all users) -** Email servers created globally are accessible by all users.
   - **Make connection part of a namespace -** Associate the email server with a specific namespace. For this option, select a namespace from the drop-down list to which the email server will be assigned.

   Note:
   - Based on the value selected in the namespaces drop-down list on the **Email configuration** main page, the **Assign access** and namespace values are automatically selected. Modify the values if you want.
   - If there is already a configuration available for the selected namespace, then those details are automatically pre-filled.
4. Select **Primary** or **Secondary** type.
5. Enter the following details of the configuration:
   - **SMTP hostname -** Enter the host name of the SMTP server.

     Note: If running behind a proxy server, enter the proxy server host name or IP address.
   - **SMTP port -** Enter the port of the SMTP server.
   - **SMTP username -** Optionally, enter the user name of the SMTP server. **Note:** Whenever an email notification is sent, the **SMTP username** is used as the sender email address.
   - **SMTP password -** Optionally, enter the password of the SMTP user.
   - **Test email recipient -** Optionally, enter the email address to which a test email will be sent, if requested. **Note**: To send a test email, click the **here** link. A message appears confirming the success or failure of the test email.
6. Click **Save**.
7. SMTP server details are shown in the **Email server configurations** table.

Searching SMTP Configuration

From the **Email configuration** page, you can search for an email server configuration.

1. In the navigation bar, click **Automate Infrastructure** > **Manage**. Click the **Email configuration** tab.
2. Search for your email server configuration by using any of the following search filters:
   - Enter the host name in **Search email configurations**.
   - Click the **Namespace** column heading to sort the table by namespace.

- At the bottom of the table, you can use the **Email configurations per page** drop-down to select the number of records you want to display in a page at a time. Use the **<** and **>** to navigate to the previous and next page.
- You can select a namespace from the namespaces drop-down list. The list of email server configurations change based on the selected namespace. Along with the records for the selected namespace, all globally accessible records are also shown in the list. You can also select **All namespaces** to see all the configurations for which you have access. Each namespace can have a maximum of two configurations.

Editing SMTP Configuration

From the **Email configuration** page, you can edit an email server configuration.

1. In the navigation bar, click **Automate Infrastructure** > **Manage**. Click the **Email configuration** tab.
2. In the **Email server configurations** table, click the overflow menu of your SMTP server.
3. Click **Edit**. **Note**: You can also click the servers hostname to edit it.
4. The **Assign access** and **Type** are read-only and cannot be changed.
5. If you want to send a test email, provide a **Test email recipient** and click the **here** link. A test email is sent to this email address. A message appears confirming the success or failure of the test email.
6. Modify the details and **Save**.

Deleting SMTP Configuration

From the **Email configuration** page, you can delete an email server configuration.

1. In the navigation bar, click **Automate Infrastructure** > **Manage**. Click the **Email configuration** tab.
2. In the **Email server configurations** table, click the overflow menu of your SMTP server.
3. Click **Delete**.
4. In the **Remove email server** message box, click **Delete** to confirm the deletion.

Rest Hooks

In the **Composition** tab, the **Rest Hook** option is available within the **Integration** menu. It is used to make a REST call to an external system.

Procedure

Note: If running behind a proxy server, make sure the proxy environment variables (http_proxy, https_proxy) are set during the installation of Managed services.

1. Drag **Integration** > **Rest Hook** into your flow.
2. Check **Editable** if you want to edit these parameters while editing the service instance.
3. Enter the following values:
   - **Title** - Enter the name or the title for the Rest Hook.
   - **Activity ID** - The read-only activity ID is automatically generated.
   - **Input URL** - Enter the URL where the payload is delivered.

     Tip: The assistive user interface provides suggestions when you type "$". You can select from the interpolation options, such as ${input_parameters, ${datatypes. After you select the interpolation option, enter "." for the user interface to list all input parameters defined before this Rest Hook activity was created.
   - **Method** - Select the **Method**. The supported values are GET, POST, PUT, PATCH, and DELETE.
   - **Payload** - Enter the request body in JSON format. Quotes must be added for parameters with type String or Password. For Counter, List, and Map parameters, you must stringify the JSON data if a parameter value is a linked parameter.

     For example, name is a string parameter and amount is not:

     ```
     {
       \"name\": \"${param.name}\",
       \"amount\": "${param.amount}"
     }
     ```

     Tip: The assistive user interface is available for **Payload**. It enables you to easily enter multiple interpolations. Type "$" for the assistive user interface to provide you suggestions when you want to add an interpolation.
   - In the **Header/Auth** section, enter the following values:
     - The **Key** and **Value** are displayed for existing header keys and values. Click **Edit** to add or delete header keys. You cannot edit an existing header.
     - **Auth Type** - Select the authentication method. `basic` and `token` authentication methods are supported.
     - **Auth Username** - If you select `basic` authentication, enter the user name to be used for authentication with the Rest Hook authentication management system.

       Tip: The assistive user interface enables you to associate an input parameter with the user name so you can retrieve the user name dynamically during runtime. Type "$" for the assistive user interface to provide you suggestions.

- **Auth Password** - If you select `basic` authentication, enter the password for the user.
- **Bearer token** - If you select `token` authentication, enter a bearer token for the Rest Hook authentication management system.

4. Open the **Destroy** tab and enter values to define the Rest Hook that is run when the service instance is terminated. The parameters in the **Destroy** tab are the same as those in the **Create** tab.

For supported interpolations, see Input and output parameter mapping for REST Hook.

Applications

In the **Composition** tab, the published applications are displayed under the **Applications** menu.

Procedure

1. Browse through the list of published application or use the **Filter** to search for a particular application.
2. Drag the selected application to the pane.
3. Check **Editable** flag if you want to edit these parameters while editing the service instance.
4. Select or enter the following values for **Basic information**:
   - **Title** - Enter title of the application activity. It is a mandatory field. It is also the label name that appears in the application activity.
   - **Activity ID** - The ID is automatically generated and is not editable. Click **Copy** to copy the value of the activity ID to your clipboard.
   - **Template name** - It is the name of the application and is not editable.
   - **Template provider** - It is IBM Cloud Pak for AIOps and is not editable.
   - **Version** - It is `1.0` and is not editable.
   - **Instance name** - Enter the instance name of the application activity.
5. Update the details in **Parameters** tab. For more information, see Parameters tab of an activity.

Templates

In the **Composition** tab, **Templates** has a list of Terraform templates categorized based on the template provider. The number in parenthesis next to the provider name indicates the number of templates available for that provider.

Procedure

1. Browse through the list of Terraform templates or use the **Filter** to search for a particular template.
2. Drag a template into your flow. After the template has loaded you can set its parameter values.

   Note:

   - If you want to use IBM Business Process Manager (BPM) templates, you must have activated them during installation. For information about activating these templates after installation see Enabling or disabling IBM Business Process Manager.
   - This list contains templates that are globally accessible and templates that belong to the services namespace.
3. Check **Editable** if you want to edit these parameters while editing the service instance.
4. Select or enter the following values for **Basic information**:
   - **Title** - Enter title for the template activity.
   - **Activity ID** - The ID is automatically generated and is read-only.
   - **Template name** - The name of the template. This field is read-only.
   - **Template provider** - The name of the provider. This field is read-only.
   - **Version** - Select the version of the template. The templates default version is preselected.

     Note: If you switch versions, the service parameters are overwritten with the values from the selected version.
   - **Terraform version** - Select the Terraform version used to deploy the template.
   - **Use compatible version** - By default, this is checked. During deployment, if the selected Terraform version is not found, then the first compatible Terraform version is used based on the constraints that are defined in the template. You can uncheck this option if you want to use a specific Terraform version.
   - **Instance name** - Enter the instance name of the template activity.
   - **Connection** - Connections that are globally accessible or in the same namespace as the service are available for selection. There are different ways to enter values for the connection:

- Select an existing connection from the drop-down list. Support is extended for IBM Cloud Pak for AIOps connections and connections to an external IBM Cloud Kubernetes Service.
- You can create dynamic connections where the connection details are fetched at runtime. The output of a previous activity in the flow can be mapped to the connection field as follows:

  `${activity.id.output.paramname}`

  - To link the connection to an existing parameter:
    - Click **Link parameter** in the **Activity details** pane to map a new parameter.
    - In the **Link parameter** dialog, click **Link**.
    - Click **Input Parameters** to see a list of parameters available in the **Input parameters** section of the main **Parameters** tab.
    - Click **Templates** to see a list of parameters from all template activities in the flow before this template.

      The values displayed change based on what options you select and which activities you have used in your service workflow.

      Note: For example, if there are two templates A and B placed in sequence in the **Provision action** of the **Composition** tab, then parameters of both templates are shown in the **Activity parameters** section of the **Parameters** tab. If you want to link a parameter of template B, then the parameters of template A and shared parameters are available for linking. If your service includes Business Process Manager activities or Helm charts, then they are also available for linking. For the first activity, template A, you can only link to service level parameters and shared parameters.
    - You can use **Search parameter** to filter and find parameters.
    - Hover over a parameter to see a plus icon.
    - Click the plus icon to select it. A green tick mark indicates your selection and the **Value** is refreshed.
    - Click **Save**.
  - To create a parameter and link it at the same time:
    - In the **Link parameter** dialog, click **Create**.
    - Enter a value for the **Parameter key**.
    - The **End-user permission** is set based on the permission of the parameter being linked.
    - Enter the parameter values:
      - **Editable** - Check the box if you want to edit these parameters while editing the service instance.
      - **Parameter type** - Set to `connection` and is read-only.
      - **Display name** - The label or display name for the parameter.
      - **Default value** - Optionally, select a cloud connection. If you do not select a value during creation time, you must specify it during deployment.
      - **Cloud provider** - Set to the cloud provider for the template and is read-only.
      - **Description** - The description appears as a tooltip for this parameter when the customer orders this service.
    - Click **Save** to save the new parameter and link it to your connection.

  Note: For an IBM Business Process Manager (BPM) connection, you do not have create a connection explicitly in the **Manage** > **Cloud connections** page. You can directly select the "BPM Connection" value from the **Connection** drop-down list. You do not have to provide any credentials for the connection as the service deployment gets the IBM BPM connection details from environment variables.

- **Content runtime** - For middleware templates, you must enter values for content runtime. It is a required value.

  Note: For middleware templates, you can select an Automated Content Runtime that is not deployed on the same cloud provided proper network connectivity exists.

  Click **Link parameter** in the **Activity details** pane to link the value to a parameter:

  - To link to an existing parameter:
    - In the **Link parameter** dialog, click **Link**.
    - Select a linking option. You can link parameter values using the **Input parameters** and **Templates** menu options in the **Link Parameter** dialog:
      - **Input parameters** - The list of parameters available in the **Input parameters** section of the main **Parameters** tab
      - **Templates** - The list of parameters from all template activities in the flow before this template.

        The values displayed change based on what options you select and which activities you have used in your service workflow.

        Note: For example, if there are two templates A and B placed in sequence in the **Provision action** of the **Composition** tab, then parameters of both the templates are available in the **Activity parameters** section of the **Parameters** tab. If you want to link a parameter of template B, then a list of all parameters of the template A and shared parameters are available for association. If your service involves Business Process Manager activities and Helm charts, then they are also available for linking. For the first activity, template A, you can only link input parameters and shared parameters.
    - Expand the parameter menu and hover over a parameter to see a plus icon.
    - Click the plus icon to select it. A green tick mark indicates your selection and the **Value** is refreshed.
    - Click **Save**.

- You can also click **Remove link** in the **Link parameter** dialog box to remove a mapping.

- To create a parameter and link it at the same time:

  - In the **Link parameter** dialog, click **Create**.
  - Enter a value for the **Parameter key**.
  - The **End-user permission** is set based on the permission of the parameter being linked.
  - Enter the parameter values:
    - **Parameter type** - Set to `sharedparameter` and is read-only.
    - **Display name** - The label or display name for the parameter.
    - **Data type** - Set to `Advanced content runtime` and is read-only.
    - **Description** - The description appears as a tooltip for this parameter when the customer orders this service.
    - **Value** - Select a Data Object.
  - Click **Save** to create and save the new parameter.

- If any of the Terraform templates have shared parameters in their definition, then the Data Types are displayed in the **Basic information** tab. You must select values for the Data Objects that are associated with the Data Types.

  Instead of hard coding the value of a Data Object, link shared parameter values to parameters. To create a parameter:

  - Create a parameter in the **Parameters** tab with type `String`.

  - In the **Source code** tab, change the type to `sharedparameter` and provide a value for `datatype`. For example, this parameter has type `sharedparameter` and is associated to the `bastionhost` Data Type.

    ```
    "input_parameters": [
     {
      "name": "shared",
      "label": "shared",
      "customtype": "string",
      "type": "sharedparameter",
      "datatype": "bastionhost",
      "immutable": false,
      "hidden": false,
      "required": false,
      "secured": false
     }
    ],
    ```

  - For the Data Object value in the **Parameters** section of the **Composition** tab, you can enter a dynamic expression:

    The format of the expression is as follows:

    `${input_parameters.shared}`

    For the behavior of this dynamic Data Object, see Creating a service instance. You must define a default Data Object whenever the Data Type has multiple Data Objects.

    Click **Link parameter** in the **Activity details** pane to link the value to a parameter:

    - To link to an existing parameter:

      - In the **Link parameter** dialog, click **Link**.

      - Select a linking option. You can link parameter values using the **Input parameters** and **Templates** menu options in the **Link Parameter** dialog:

        - **Input parameters** - The list of parameters available in the **Input parameters** section of the main **Parameters** tab
        - **Templates** - The list of parameters from all template activities in the flow before this template.

        The values displayed change based on what options you select and which activities you have used in your service workflow.

        Note: For example, if there are two templates A and B placed in sequence in the **Provision action** of the **Composition** tab, then parameters of both the templates are available in the **Activity parameters** section of the **Parameters** tab. If you want to link a parameter of template B, then a list of all parameters of the template A and shared parameters are available for association. If your service involves Business Process Manager activities and helm charts, then they are also available for linking. For the very first activity, template A, you can only link input parameters and shared parameters.

      - Expand the parameter menu and hover over a parameter to see a plus icon.

      - Click the plus icon to select it. A green tick mark indicates your selection and the **Value** is refreshed.

      - Click **Save**.

      - You can also click **Remove Link** in the **Link parameter** dialog to remove a mapping.

    - To create a parameter and link it at the same time:

      - In the **Link parameter** dialog, click **Create**.
      - Enter a value for the **Parameter key**.
      - The End-user permission is set based on the permission of the parameter being linked.
      - Enter the parameter values:
        - **Parameter type** - Set to `sharedparameter` and is read-only.
        - **Display name** - The label or display name of the parameter.
        - **Data type** - The Data Type value is preselected. You cannot change the value.
        - **Description** - The description appears as a tooltip for this parameter when the customer orders this service.

- **Value** - Select a Data Object.
- Click **Save** to create and save the new parameter.

For information about shared parameters in interpolation expressions, see Using shared parameters in service interpolations and Data Types in Service Composition Language.

For information about Data Types and Data Objects, see Shared parameters.

For managing shared parameters from Managed services, see Managing Data Objects from the user interface.

5. Update the details in **Parameters** tab. For more information, see Parameters tab of an activity.

Notes:

- If you use a long running BPM template in your service that requires claim and approvals by the administrator of Business Process Manager, include the following parameters in the source code tab as follows:

```
"async_req": true
"long_running_delay": "<time in minutes>",
"long_running_timeout": "<time in hour>"
```

The async_req field is not shown in the **Parameters** tab. To change its value use the **Source code** tab.

For more details, see Example of a Business Process Manager template in Service Composition Language Structure topic.

- If a variable in a Business Process Manager template is not Boolean or String, then Managed services considers it as a String. For complex type input parameters, provide the JSON as string. For example:
  - Template input parameters in Business Process Manager:

```
{
  "inputString": {
    "type": "String",
    "isList": false
  },
  "inputInteger": {
    "type": "Integer",
    "isList": false
  },
  "inputBoolean": {
    "type": "Boolean",
    "isList": false
  },
  "parent": {
    "type": "ParentData",
    "isList": false
  }
}
```

  - Template input parameter values in Managed services:

```
inputString = Bob
inputInteger = 555
inputBoolean = false
parent = {"Name": "David", "Child": {"id": 21, "Name":"John"}}
```

Helm charts

The **Helm** section has a list of Helm charts available from the underlying IBM Cloud Pak for AIOps. If you want charts in the remote IBM Cloud Pak for AIOps to be available in Managed services, copy your charts to the local IBM Cloud Pak for AIOps.

The number mentioned within parenthesis next to the type indicates the number of Helm charts available from the underlying IBM Cloud Pak for AIOps. The number of charts visible is governed by the access defined by the IBM Cloud Pak for AIOps team for your user ID.

For a list of limitations, see the Helm limitations section of Troubleshooting Service Composer or Portal issues.

Procedure

1. Browse through the list of Helm charts or use the **Filter** to search for a particular Helm chart.
2. Drag a Helm chart into your flow. After the Helm chart has loaded you can set its parameter values.

   Note: The listed Helm charts do not have the IBM Cloud Pak for AIOps icons.
3. Check **Editable** if you want to edit these parameters while editing the service instance.
4. In the **Basic Information** tab, enter or select the following details:

   - **Title** - Enter a title for the Helm chart activity. It is a required field. It is also the label name that appears in the Helm chart activity.
   - **Activity Id** - The read-only ID is automatically generated.
   - **Helm Chart Name** - The name of the Helm chart. This field is read-only.
   - **Helm Chart Provider** - The name of the provider. This field is read-only.
   - **Version** - Select the Helm chart version. The Helm charts default version is preselected.

- **Release Name** - Enter the release name of the Helm chart activity.
- **Connection** - There are different ways to enter values for the connection:
  - If you want to select an existing connection, select a connection from the drop-down list. Support is extended for local IBM Cloud Pak for AIOps (MCM Connection) connection and connections to external IBM Cloud Kubernetes Service.
  - You can create dynamic connections where the connection details are fetched during runtime. The output of a previous activity in the sequence can be mapped to the connection field as follows:

    `${<activity>.<id>.output.<param-name>}`

    or to a service parameter: `${input_parameters.paramname}`
- **Chart License** - Select **I have read and agreed to the license agreements**.

5. Update the values in the **Parameters** tab. All parameters defined in the Helm chart are displayed. For more information, see Parameters tab of an activity.

Ansible

In the **Composition** tab, the Ansible component is available underneath the **Integration** menu.

- Credential
- Inventory
- Job Templates

Ansible Credential

Ansible credentials are utilized by Tower for authentication when launching jobs against machines.

After the service with credential activity is deployed on the Managed services, the credential is created in the Ansible.

Procedure

1. Select or enter the following values for **Basic information**:
   - **Title** - Enter title of the credential activity. It is a mandatory field. It is also the label name that appears in the credential activity.
   - **Activity Id** - The Id is automatically generated and is not editable. Click **Copy** to copy the value of the activity Id to your clipboard.
   - **Template name** - It is the name of the template and is not editable.
   - **Template provider** - It is the name of the provider and is not editable.
   - **Version** - Select the template version. A template is always at its default version.

     Note: If you select another version and again switch back to the original version, then service parameters gets overwritten by the values from the original template version.
   - **Instance name** - Enter the instance name of the template activity.
   - **Connection** - There are different ways to enter values for the connection:
     - Steps to map an existing parameter or create a new parameter of type connection:
       - Click **Link parameter** in the **Activity details** pane to map a new parameter.
       - In the **Link parameter** dialog box, click **Link** to map an existing parameter.
       - Map an existing parameter or create a new parameter and link it automatically:
         - Link parameters:
           - Select a linking option. You can map parameter values using the **Input parameters** and **Templates** menu options in the **Link Parameter** dialog box:
             - **Input parameters** - The **Input parameters** menu option lists all of the parameters that are available in the **Input parameters** section of the main **Parameters** tab of a service.
             - **Templates** - This option lists all parameters of all template activities that are available prior in sequence to this template activity.

             The values displayed in the in the **Activity details** pane change based on what you select and which activities you use in your service workflow.

             Note: For example, if there are two templates A and B placed in sequence in the **Provision Action** of the **Composition** tab, then parameters of both the templates are available in the **Activity parameters** section of the **Parameters** tab. If you want to link a parameter of template B, then a list of all parameters of the template A and shared parameters are available for association. If your service involves Business Process Manager activities and helm charts, then they are also available for linking. For the very first activity, template A, you can only link input parameters and shared parameters.
           - Expand the parameter menu and hover over the parameters to see a plus icon.

- Click the plus icon to select it. A green tick mark indicates your selection and also the **Value** is refreshed. You can also use the **Search parameter** to filter and find a parameter.
- Click **Save**.
- You can also click **Remove Link** in the **Link parameter** dialog box to remove a mapping.

- Create a new parameter and link it at the same time:
  - In the **Link parameter** dialog box, click **Create**.
  - Enter a value for the **Parameter Key**.
  - Enter or select values for the new parameter.
  - When you create a service instance, you can make changes to the values that were defined during creation. Enter or select the following values for **Read and Write** permission:
    - **Parameter type** - You cannot change the parameter type. It is connection by default.
    - **Display name** - The label or display name of the parameter.
    - **Description** - The description appears as a tooltip when the customer orders this service.
    - **Cloud provider** - The cloud provider is pre-selected. You cannot change the value.
    - **Default value** - Optionally, enter the value for connection. If you do not provide the value during design time, you must add it during deployment.
  - Click **Save** to create and save the new parameter.

- You can create a parameter of type string in the **Parameter** tab. In the **Source code** tab, change its type to connection and add provider value as shown in the following example:

```
"input_parameters": [
 {
 "name": "Conn",
 "label": "Conn",
 "Customtype": "string",
 "type": "connection",
 "provider": "VMware vSphere",
 "immutable": false,
 "hidden": false,
 "required": false,
 "secured": false
  }
 ]
```

  In **Connections**, enter `${input_parameters.Conn}`. For the behavior of this dynamic cloud connection at runtime, see Creating a service instance.

- The connection parameter type is not applicable for "Other" type of cloud connections because it is globally available.

2. Update the details in **Parameters** tab. For more information, see Parameters tab of Ansible Credentials activity.

   If a parameter has Read-Write user permission, then you can edit the values to override existing permission and parameter values.

Note: If the **Editable** flag is set to FALSE, this service does not contribute in the service instance deployment.

Parameters tab of Ansible Credential activity

You can set the parameter values for Ansible credentials from the **Composition** tab > Credential activity > **Parameters** tab.

Procedure

1. Select the activity in the **Composition** tab. The input parameters are displayed along with their name and value in your activity in the **Activity details** pane.

   Note: The Managed services and Ansible integration supports only the *Machine* credential type.

2. Enter the following values:
   - **credential_name_suffix**: Suffix is used while creating the credential on the Tower. Credential is created as ActivityInstanceName_suffix.
   - **user_name**: The user name for the credential.
   - **ssh_private_key**: The key for the credential.
   - **password**: The password for the credential.

   Note: Enter either the **ssh_private_key** or **password** or both for the credential.

3. Use **Search parameters** to filter and search for your parameter.
4. You can hard code the value of a parameter, link the value to a parameter or create a new parameter:
   - Link the parameter value:
     - Select a parameter. The following menu options are available for mapping the parameter values:

       Note: Not all options are available for a parameter. It varies based on the activities used in the service.

- **Input parameters**: The **Input parameters** menu lists all of the parameters that are available in the **Input parameters** section of the main **Parameters** tab of a service.
- **Shared parameters**

  Note: If you link the attribute of a shared parameter, then an input parameter is automatically created. During service deployment, select the dataobject for the datatype. The data attribute value of the selected dataobject is used during provisioning.

- Map the parameter values:
  - Expand the parameter menu and hover over the parameters to see a plus icon.
  - Click the plus icon to select it. A green tick mark indicates your selection and also the **Value** is refreshed. You can also use the **Search parameter** to filter and find a parameter.

- Create a new parameter:
  - Click **Link parameter** in the **Activity details** pane to map a new parameter.
  - In the **Link parameter** dialog box, click **Create**. You can create only a new parameter whose type exists in the template activity. For example, a template has string, Boolean, and map parameter types. If you want to create a new parameter of type counter, you must go to the main **Parameters** tab. To work with the main **Parameters** tab, see Working with the Parameters tab.
  - Select **End-User Permissions**.

    The three different types of permissions are as follows:

    - **Invisible** - During parameter creation, enter the following value:
      - **Default value**. This parameter is not visible while creating an instance of the service.

    Note: For the Invisible parameter, if you enter incorrect data in the default value field, then the Service instance deployment of the content run time fails.

    - **Read-only** - During parameter creation, enter or select the following values:
      - **Parameter type** - Select the type of parameter. The available parameter types are string, password, list, Boolean, counter, map, connection, and shared parameters.
      - **Display name** - The label or display name of the parameter.
      - **Description** - The description appears as a tooltip when the customer orders this service.
      - **Default value** - The default value of the parameter. When you create the service instance, this parameter is visible to you in read-only format.

      For list data type, you can click **Add New** to add a list of values.

      For map data type, you can click **Add New** to add a list of **Key Value** pairs. Click cross icon to delete a value record.

      For password data type, toggle between **Show** and **Hide** to view or hide the password characters.

      - **Read and Write** - When you create a service instance, you can make changes to the values that were defined during creation. Enter or select the following values for **Read and Write** permission:
    - **Parameter type** - Select a type. It determines the type of parameter. The available parameters are string, stringlist, password, list, boolean, counter, and map.
    - **Value required** - Determines whether a value is required for the parameter.
    - **Specify options** - For string data type, you can select this option for a drop-down list of string values.
    - **Display name** - The label or display name of the parameter.
    - **Description** - The description appears as a tooltip when the customer orders this service.
    - **Validation rule** - The validation rule is a non-mandatory field that is available only if you select "string" or "password" value in **Parameter type** drop-down list. Validation Rule (regex) provides an ability to the service composer to restrict the values of an input parameter. If regex is provided during service composition, then the value of the string input parameter must satisfy the regex criteria during service deployment. For example, (\w+?@\w+?\x2E.+).
    - **Validation rule description** - Validation Rule Description (regexdesc) provides information about the validation rule. For example, “Enter a valid email address”. Here, (\w+?@\w+?\x2E.+) is the regular expression for an email address. If you try to enter “abc.xyz.com” as the value for string input parameters, then service deployment fails due to invalid email address.

      Note: For more information about regex, see regexlib.com.

    - **Default value** - If you select, **Specify options**, then enter values for **Label** and **Value** pair fields. Select a record to mark it as default value. You can click the cross mark icon to delete a value record.

  - Click **Save**.

The output parameters are displayed at the end along with their names in read-only mode.

Ansible Inventory

An Ansible inventory is a collection of hosts against which jobs may be launched.

After the service with inventory activity is deployed on the Managed services, the inventory is created in the Ansible.

Procedure

1. Select or enter the following values for **Basic information**:
    - **Title** - Enter title of the template activity. It is a mandatory field. It is also the label name that appears in the template activity.
    - **Activity Id** - The Id is automatically generated and is not editable. Click **Copy** to copy the value of the activity Id to your clipboard.
    - **Template name** - It is the name of the template and is not editable.
    - **Template provider** - It is the name of the provider and is not editable.
    - **Version** - Select the template version. A template is always at its default version.

      Note: If you select another version and again switch back to the original version, then service parameters gets overwritten by the values from the original template version.
    - **Instance name** - Enter the instance name of the template activity.
    - **Connection** - Select the Ansible Connection value from the drop-down list.
2. Update the details in **Inventory** and **Hosts** tabs. For more information, see Inventory and Hosts tabs of Ansible Inventory activity.

Note: If the **Editable** flag is set to FALSE, this service does not contribute in the service instance deployment.

Parameters of Ansible Inventory activity

You can set the parameter values for the Ansible inventory from the **Composition** tab > Inventory activity > **Inventory** and **Hosts** tabs.

Procedure

1. Select the activity in the **Composition** tab. The parameters are displayed in the **Activity details** pane.
2. In the **Inventory** tab,
    1. **Inventory Name** - Enter the inventory name suffix. The suffix is used while creating the inventory on the Tower. The inventory is created as ActivityInstanceName_suffix.
    2. The Managed services only supports Default **Organization** at this time.
    3. **Group** - Based on the Ansible playbook, an inventory can target the multiple groups to have groups to host mapping depending on the Ansible playbook functionality.
        1. Click **Add Group** to add the a new group. Enter the name of the group and click ✔. The newly created group is added in the drop-down list.
        2. Click **Delete Group** to delete the selected group from the drop-down list.
    4. **Extra Variables** - These extra variables are the required extra variables by an inventory in the Ansible runbook.
        1. Click **Add Extra Vars** to add extra variables. Click ✔ after entering the **Key** and **Value**.
        2. Click **Delete Extra Vars** to delete the selected extra variable from the drop-down list.
    5. In **Hosts** tab,
        1. Select the **Group** from the drop-down list.
        2. **Host** - The hosts are added for the selected group.
            1. Enter a name of the host or the comma separated list of hosts in the **Host** field. Click **Add Host** to add new host. The newly created host is added in the drop-down list. The list of hosts is displayed at the bottom of the page.
            2. Click **Link Parameter** to link to the existing Managed services input parameter.

Ansible Job Templates

A job template is a definition and set of parameters for running an Ansible job.

The Ansible job templates are discovered on the Managed services after making the Ansible connection. After the service deployment, the job templates are executed on the Ansible.

Procedure

1. Check **Editable** flag if you want to edit these parameters while editing the service instance.
2. Select or enter the following values for **Basic Information**:
    - **Title** - Enter title of the credential activity. It is a mandatory field. It is also the label name that appears in the credential activity.
    - **Activity Id** - The Id is automatically generated and is not editable. Click **Copy** to copy the value of the activity Id to your clipboard.
    - **Template Name** - It is the name of the template and is not editable.
    - **Template Provider** - It is the name of the provider and is not editable.
    - **Version** - Select the template version. A template is always at its default version.

Note: If you select another version and again switch back to the original version, then service parameters gets overwritten by the values from the original template version.

- **Instance Name** - Enter the instance name of the template activity.
- **Connection** - There are different ways to enter values for the connection:
  - Steps to map an existing parameter or create a new parameter of type connection:
    - Click **Link Parameter** in the **Activity details** pane to map a new parameter.
    - In the **Link Parameter** dialog box, click **Link** to map an existing parameter.
    - Map an existing parameter or create a new parameter and link it automatically:
      - Link parameters:
        - Select a linking option. You can map parameter values using the **Input Parameters** and **Templates** menu options in the **Link Parameter** dialog box:
          - **Input Parameters** - The **Input Parameters** menu lists all of the parameters that are available in the **Input Parameters** section of the main **Parameters** tab of a service.
          - **Templates** - This option lists all parameters of all template activities that are available prior in sequence to this template activity.

          The values displayed in the **Activity details** pane change based on what you select and which activities you use in your service workflow.

          Note: For example, if there are two templates A and B placed in sequence in the **Provision Action** of the **Composition** tab, then parameters of both the templates are available in the **Activity Parameters** section of the **Parameters** tab. If you want to link a parameter of template B, then a list of all parameters of the template A and shared parameters are available for association. If your service involves Business Process Manager activities and helm charts, then they are also available for linking. For the very first activity, template A, you can only link input parameters and shared parameters.
        - Expand the parameter menu and hover over the parameters to see a plus icon.
        - Click the plus icon to select it. A green tick mark indicates your selection and also the **Value** is refreshed. You can also use the **Search Parameter** to filter and find a parameter.
        - Click **Save**.
        - You can also click **Remove Link** in the **Link Parameter** dialog box to remove a mapping.
      - Create a new parameter and link it at the same time:
        - In the **Link Parameter** dialog box, click **Create**.
        - Enter a value for the **Parameter Key**.
        - Enter or select values for the new parameter.
        - Enter values for **Read and Write** permission. When you create a service instance, you can make changes to the values that were defined during creation. Enter or select the following values for **Read and Write** permission:
          - **Parameter Type** - You cannot change the parameter type. It is connection by default.
          - **Display Name** - The label or display name of the parameter.
          - **Description** - The description appears as a tooltip when the customer orders this service.
          - **Cloud Provider** - The cloud provider is pre-selected. You cannot change the value.
          - **Default Value** - Optionally, enter the value for connection. If you do not provide the value during design time, you must add it during deployment.
        - Click **Save** to create and save the new parameter.
  - You can create a parameter of type string in the **Parameter** tab. In the **Source Code** tab, change its type to connection and add provider value as shown in the following example:

```
"input_parameters": [
{
"name": "Conn",
"label": "Conn",
"Customtype": "string",
"type": "connection",
"provider": "VMware vSphere",
"immutable": false,
"hidden": false,
"required": false,
"secured": false
 }
]
```

Update the details in **Parameters** tab. For more information, see Parameters tab of Ansible Job Template activity.

If a parameter has Read-Write user permission, then you can edit the values to override existing permission and parameter values.

Parameters tab of Ansible Credential activity

You can set the parameter values for Ansible Job Templates from the **Composition** tab > **Job Templates** activity > **Parameters** tab.

Procedure

1. Select the activity in the **Composition** tab. The input parameters are displayed along with their name and value in the **Activity details** pane.
2. **Inventory Name**: Enter the exact name of the inventory used in the Ansible.
3. **Credential Name**: Enter the exact name of the credential used in the Ansible.
4. **Extra Variables**: Enter the extra variables.
5. You can use the **Search Parameters** to filter and search for a parameter.
6. You can edit directly to hardcode the value of a parameter, link the value to a parameter or create a new parameter:

    - Link the parameter value:
        - Click the parameter, then click **Link Parameters** in the **Activity details** pane to map a parameter.
        - Select one of the following options for mapping parameter values: **Note**: Not all options are available for a parameter. It varies based on the activities used in the service.
            - **Input Parameters** - The **Input Parameters** menu option lists all of the available parameters of the main **Parameters** tab of a service.
            - **Shared Parameters Note**: If you link the attribute of a shared parameter, then an input parameter is automatically created. During service deployment, select the dataobject for the datatype. The data attribute value of the selected dataobject is used during provisioning.
            - **Templates** - The **Templates** menu option lists the templates available.
            - **Ansible** - The **Ansible** menu option lists the Ansible job templates.
        - Map values with the parameter:
            - Select an option in the **Link Parameter** dialog box. The values displayed in the **Activity details** pane change based on what you select and which activities you use in your service workflow.
            - Expand the parameter menu and hover over the parameters to see a plus icon.
            - Click the plus icon to select it. A green tick mark indicates your selection and also the **Value** is refreshed. You can also use **Search Parameter** to filter and find a parameter.
    - Create a new parameter:
        - Click **Link Parameter** in the **Activity details** pane.
        - In the **Link Parameter** dialog box, click **Create**. You can create only a new parameter whose type exists in the template activity. For example, a template has string, Boolean, and map parameter types. If you want to create a new parameter of type counter, you must go to the main **Parameters** tab. To work with the main **Parameters** tab, see Working with the Parameters tab.
        - Select **End-User Permissions**.

          The three different types of permissions are as follows:
            - **Invisible** - During parameter creation, enter a value for the **Default Value**. This parameter is not visible while creating an instance of the service. **Note:** For the Invisible parameter, if you enter incorrect data in the default value field, then the Service instance deployment of the content run time fails.
            - **Read-only** - During parameter creation, enter or select the following values:
                - **Parameter Type** - Select a type. It determines the type of parameter. The available parameter types are string, password, list, Boolean, counter, map, connection, and shared parameters.
                - **Display Name** - The label or display name of the parameter.
                - **Description** - The description appears as a tooltip when the customer orders this service.
                - **Default Value** - The default value of the parameter. When you create the service instance, this parameter is visible to you in read-only format.
                - For list data type, you can click **Add New** to add a list of values.
                - For map data type, you can click **Add New** to add a list of **Key Value** pairs. Click cross icon to delete a value record.
                - For password data type, toggle between **Show** and **Hide** to view or hide the password characters.
            - **Read and Write** - When you create a service instance, you can make changes to the values that were defined during creation. Enter or select the following values for **Read and Write** permission:
                - **Parameter Type** - Select a type. It determines the type of parameter. The available parameters are string, stringlist, password, list, boolean, counter, and map.
                - **Value Required** - Determines whether a value is required for the parameter.
                - **Specify Options** - For string data type, you can select this option for a drop-down list of string values.
                - **Display Name** - The label or display name of the parameter.
                - **Description** - The description appears as a tooltip when the customer orders this service.
                - **Validation Rule** - The validation rule is a non mandatory field that is available only if you select “string” or “password” value in **Parameter Type** drop-down list. Validation Rule (regex) provides an ability to the service composer to restrict the values of an input parameter. If regex is provided during service composition, then the value of the string input parameter must satisfy the regex criteria during service deployment. For example, (\w+?@\w+?\x2E.+).
                - **Validation Rule Description** - Validation Rule Description (regexdesc) provides information about the validation rule. For example, “Enter a valid email address”. Here, (\w+?@\w+?\x2E.+) is the regular expression for an email address. If you try to enter

"abc.xyz.com" as the value for string input parameters, then service deployment fails due to invalid email address.

Note: For more information about regex, see regexlib.com.

- **Default Value** - If you select, **Specify Options**, then enter values for **Label** and **Value** pair fields. Select a record to mark it as default value. You can click the cross mark icon to delete a value record.

- Click **Save** to save the changes.

7. The output parameters are displayed at the end along with their names in read-only mode. You can also view the output parameters in the **Source Code** tab at the same level as **`template_params`**.

Pricing for service plans

The cost of a service is represented as a price of the plan selected at the time of deployment and unit of its measure is on a monthly, hourly, and weekly basis.

Currently, pricing in Managed services is at service level and this is expected to be consumed by the third-party applications integrating with Managed services using APIs. Managed services does only syntactic validations. It does not check price entered against Cloud or any other providers.

- List of pricing rules/conditions
- Pricing attributes
- Examples of pricing attribute and their usage in Service Composition Language

List of pricing rules/conditions

- Managed services validations ensure that the parameters used in pricing rules are based on service plan parameters. For example, **`{"gt": ["vm_disk",100,"gb"]},`** here **`vm_disk`** is a service plan parameter with size greater than **`100 gb`** and **`vm_disk`** has to be exposed as a service plan parameter.
- The "any"/"all" condition - "all" specifies that all the conditions must satisfy for pricing. Whereas, "any" indicates that at least one condition must satisfy for pricing.
- Conditions can be defined only on exposed set of plan parameters. You can use only service plan input parameters in the pricing condition.
- List of supported operators supported are "gt", "lt", "ge", "le", "members". The convention to follow for operators are as follows:
  - First element must point to plan parameter. For example, "vm_disk".
  - Seconnd element is the value of that parameter. For example, "40".
  - Third optional element is the unit. For example, "gb".

  For example:

```
"condition":{
                "all":[
                 {"gt":["disk_size",0,"gb"]},
                 {"le":["disk_size",40,"gb"]},
                 {"eq":["instance_type","x2.small"]}
                ]
           },
```

- When defining an "amount", pricing can be a fixed value or it can have dependent plan parameters. You use the plan parameters with 'incr' of specified quantity and unit. For example:

```
"amount" : {"value" :49.0},
```

or

```
"amount" : {
             "value" :.99,
             "disk_size":["incr",1,"gb"]
           }
```

Pricing attributes

The Managed services captures the following attributes as a part of the Plan definition for the purpose of pricing:

- **`currency`** - It is a 3-character currency code. The default is "USD". For example:

```
"currency": "USD",
```

- **`paymentStrategy`** - The values of payment strategy are "MONTHLY", "HOURLY", "YEARLY", "ONCE". For example,

```
"paymentStrategy":"MONTHLY",
```

- **`pricingStrategy`** - The values of pricing strategy are as follows:
  - "FIXED" - The price is one time only and fixed for the plan.
  - "RECURRING" - The price is recurring and fixed for the plan.

- "USAGE" - The price is based on usage as per plan.

For example:

```
"pricingStrategy" :"RECURRING"
```

- **free** - It is a Boolean attribute at plan level and its default is 'false'. For example:

```
"free": false,
```

- **unitofMeasurement** and **unitValue** - The **unitValue** is "1" and **unitofMeasurement** is "gb" in this example **"disk_size":["incr",1,"gb"]**

Sample plan with pricing

The section provides two examples to illustrate pricing that is defined within plan parameters of a service. For more information about a plan structure, see Plans section in Managing service code structure.

- The following basic pricing sample sets a fixed amount of 99 USD for a virtual server with single CPU, 1 GB RAM, and 50 GB disk on a by-monthly recurring basis.

```
{
 "plans": [
   {
     "name": "Basic",
     "description": " Virtual Server with Single CPU, 1 GB RAM and 50 GB Disk.",
     "metadata": {
       "currency": "USD",
       "prices": {
         "base": {
           "amount": {
             "value": 99.0
           },
           "paymentStrategy": "MONTHLY",
           "pricingStrategy": "RECURRING"
         }
       },
       "bullets": [
         "Fixed pricing",
         "Small virtual machine",
         "Limited storage"
       ],
       "free": false
     }
   }
 ]
}
```

- The following sample plan defines a base price and one additional price for a virtual machine disk. The base price is at a flat cost of 49 USD for a virtual machine disk of size that is between 0 and 40 GB. If the usage goes beyond 40 GB, then additional pricing is considered based on the availability. The condition defines the amount charged for any extra usage of the resource. With the increment of each gb after the base pricing is exhausted, the additional pricing amount of 1 USD is charged.

```
"plans": [{
   "name": "The name of the plan. For example, Amsterdam",
   "description": "The description of the plan. For example, to deploy in Amsterdam",
   "plan_parameters" [
   // In conditions of base and additional pricing section, you can define only those parameters that are defined
here.
     { "name": "vm_disk",
        "label": "VM disk",
        "customtype": "string",
        "type": "string",
        "immutable": true,
        "hidden": true,
        "required": true,
        "secured": false,
        "description": "Virtual Machine disk",
        "default": "10"
       }
      ],
   "metadata": {
       "currency": "The currency used for the transaction. The default is USD.",
       "prices" :{    //This is the main section where you define the pricing.
       "base":{    //  The main pricing is defined in base section.
           "amount" : {"value" : For example, 49.0},
       // The charges for base pricing is mentioned in 'value' element under 'amount'.  As long as the conditions for
base pricing are met, this flat amount is charged. In this example,  49 USD is charged as long as the parameter
"vm_disk" is between 0 to 40 GB.
           "condition":{
        // This conditions section gives a set of rules which determines whether the base pricing is applicable or
not. If the condition is not met, then base pricing becomes invalid and additional pricing is considered based on its
availability.
               "all":[   // It implies the rule set for the price.
                      {"gt":["vm_disk",0,"gb"]},
                      {"le":["vm_disk",40,"gb"]}
                 //["resource name", value, unit of the resource] --->  {"le":["vm_disk",40,"gb"]}

                      //In this example, if the usage is between 0 to 40 GB, then this base pricing is applicable. If
it goes beyond 40 GB, then additional pricing is considered based on the availability.
```

```
                    ]
                },
                 "paymentStrategy":"The values could be "MONTHLY", "HOURLY", "YEARLY", "ONCE",
                 "pricingStrategy" : {
                   - "FIXED" : the price is one time only and fixed for the  plan.
                    - "RECURRING":  The price is recurring and fixed for the plan.
                  },
       "additional":[{    //Additional pricing is applicable whenever the base pricing is exhausted.
                "amount" : {    //Defines the amount charged for any extra usage of the resource. ---> "amount" : {
//Defines the amount charged for any extra usage of the resource under additional pricing.
                    "value" :1,
                    "vm_disk":["incr",1,"gb"]
              //[incr denotes incremental, value, unit]. With the increment of each gb after the base pricing is
exhausted, the additional pricing amount is charged.
                 },
                "condition":{
          // This condition section gives a set of rules to determine whether additional pricing is applicable. If
the condition is not met, then this additional pricing becomes invalid. In case another additional pricing is
defined, then it would be considered.
                    "all":[
                       {"gt":["vm_disk",40,"gb"]}
                     ]

                   }
             }
             ]
          },
           "bullets" :[ //Main features of pricing.
              "Flexible pricing",
              "Unlimited storage"
           ]
        "free": false,
    //  It is a boolean attribute at plan level and its default is 'false'. If there is no pricing attached to a
plan, set this is set to true.
                   }
       },
      };
     ]
```

Managing service code structure

The **Source Code** of a service follows Service Composition Language (SCL) V3 version. Use the correct syntax when importing or editing a service.

The Service Composition Language structure is as follows:

```
{
 "service": {
 "specVersion": "v3",
 "catalog_metadata": {
 "name": "",
 "description": "",
 "image": "serviceicon_1.svg",
 "category": "CloudServices",
 "bullets": [
  {
      "title": "Cloud Provider",
      "description": "IBM Bluemix Platform"
    }
 ],
 "providerDisplayName": "IBM",
 "longDescription": "",
 "documentationUrl": "",
 "supportUrl": "",
 "bindable": false,
 "updatable": ""
 "systemTags": true
 },
 "tags": [],
 "datatypes" :      [
   {
      "id" : "",
      "label": "",
      "description": "",
      "datatype": "",
      "default": "",
      "immutable": false
   },
 "actions": [
   {
      "type": "provision",
      "name": "Provision",
      "description": "Default action for deployment of service",
      "input_parameters": [],
      "flow": {
            "conditions": [],
            "templates": [],
            "resthooks": [],
```

```
            "notifications": [],
            "sequence": {}
        },
        "output_parameters": []
          }
        ],
        "plans": [
         {
           "name": "Standard",
           "description": "To deploy a Standard plan",
           "actions": [],
           "plan_parameters": []
                "free": It can be true or false. False indicates that it is not free.,
                "metadata": {
                   "currency": "USD",
                   "prices" :{
                     ...                    .
         }
       },
```

For information about the individual sections in the Service Composition Language V3 structure, see the following sections:

- catalog_metadata
- tags
- datatype
- actions
  - input_parameter
  - flow
    - conditions
    - templates
    - resthooks
    - notifications
    - sequence
    - error sequence
- plans

For Service Composition Language samples, see Service samples.

catalog_metadata

```
"catalog_metadata": {
   "name": "The name of the service",
   "description": "A short description of the service",
   "image": "The name of the icon file. For example: serviceicon_1.svg",
   "category": "The category to which the service is assigned. For example: My Category",
   "bullets": [{
        "title": "The name of the first feature",
        "description": "A description for the first feature"
    },
  ]
  "providerDisplayName": "The display name of the provider",
  "longDescription": "A long of description of the service",
  "documentationUrl": "The documentation URL",
  "supportUrl": "The support URL",
  "bindable": true or false,
  "updatable": "This is not supported in this release."
  "systemTags": true or fals. If systemTags flag is set to true, then system generated tags are automatically added to the
tags section of the service instance.
    },
}
```

The information in the **catalog_metadata** section is the information that you provided in the **Overview** tab when you create the service. This information is overwritten if you import a service file in the **Edit Source Code** tab.

The **image** attribute value is the file name of the icon associated to the service. The file name must be **serviceicon_<n>.svg** where **<n>** is a number from 1 to 10. If you specify another file name, the **image** attribute value is changed by default to **serviceicon_1.svg**.

The bullets attribute contains the list of features that you add in the **Overview** tab.

You can add additional fields in **catalog_metadata** to provide additional details about the service in the IBM Cloud Pak for AIOps Catalog.

tags

```
"tags": [
      {
        "name": "The tag name",
        "label": "The display name of the tag",
        "type": "The type of tag.",
        "immutable": Specify if the parameter is immutable. The value must be true or false,
        "hidden": Specify if the parameter is hidden. The value must be true or false,
        "required": Specify if the parameter is required. The value must be true or false,
```

```
        "secured": Specify if the parameter is secured. The value must be true or false,
        "description": "The description of the tag",
        "default": "The default value of the tag",
        "customtype": "The custom type of the tag.",
        "permission": "Specify whether the permission. For example, Read-Write",
        }
```

If you select **Specify Options**, then the following additional values are displayed:

```
"options": [
          {
            "label": "The label of the value",
            "value": "The value",
            "default": Specify if it is a default value. The value must be true or false.
          }
          {
          ...
          ...
          }
        ]
```

datatypes

```
 "datatypes" :      [
        {
           "id" : "is an identifier for your datatype instance.",
           "label": "label",
           "description": "Description",
           "datatype": "The Datatype to which it is mapped.",
           "default": "The default DataObject",
           "immutable": "If the definition has `"immutable": false`, then the deployment page shows a drop-down list of
all the DataObjects that are available for the DataType."
        },
]
```

An example for a datatype wherein the default dataobject is defined.

```
 "datatypes" :      [
        {
           "id" : "bastionhost1",
           "label": "Bastion Host Configuration",
           "description": "Select Bastion Host Configuration",
           "datatype": "bastionhost",
           "default": "DefaultNoBastionHostRequired",
           "immutable": false
        },
        {
          "id" : "httpproxy",
          "label": "Bastion Host Configuration",
          "description": "Select HTTP Proxy Configuration",
          "datatype": "httpproxy",
          "default": "DefaultNoProxyRequired",
          "immutable": true
        },
    ],
```

If you have only one DataObject associated to a Datatype, then you can directly use it in the interpolation without datatype mapping here. For interpolation syntax, see Using shared parameters in service interpolations.

actions

```
"actions": [
    {
      "type": "provision",
      "name": "Provision",

      input_parameter [{
        ...
        ...
        }]
        flow {
        ...
        ...
        }
        "output_parameters": []
    }
  ],
  "actions": [
    {
        "type": "bind",
        "name": "Bind",
        input_parameter [{
        ...
        ...
        }]
        flow {
        ...
        ...
```

```
        }
        "output_parameters": []
    }
  ],
```

input_parameter

```
"input_parameter": [{
                "name": "The name of the input parameter. For example: ssh_key",
                "label": "The label to be displayed in the user interface for this parameter",
                "description": "A short description of the parameter. For example, used to access your server",
                "customtype": "The type of the parameter. For example: String" ,
                "type": "The variable type of customtype. For example: text",
                "immutable": "Specify if the parameter is read-only or not. The value is true for read-only user
permissions and is false for read-write user permission.",
                "hidden": "Specify if the parameter is not displayed in the user interface. The value must be true or
false",
                "required": "Specify if the parameter is required. The value must be true or false",
                "secured": "Specify if the parameter value is shown as ********. The value can be true for `string` or
`password` `customtype` attribute and false for all other attributes.",
                "default": "Default value of the parameter.
                "plans": "

        },
        ...
]
```

If you select **Specify Options**, then the following additional values are displayed:

```
"options": [
          {
            "Default": "Is it a default value of the parameter",
            "value": "The value",
            "label": "The label of the value",
          }
          {
          ...
          ...
          }
        ]
```

flow

conditions

```
"conditions": [
          {
            "decision": {
              "title": "The unique title of the decision.",
              "options": [
                {
                  "case": "0",
                  "sequence": {
                  ...},
                  "case": "1",
                  "sequence":{
                  ...},
                }
              ],
              "id": "The generated id for this component. For example: decisionbbb53a59",
              "description": "The description of the component",
              "mapped_parameter": "The parameter to which this component is mapped. This is a mandatory parameter"
            }
          }
        ],
```

templates

```
"templates": [{
        "template_name": {
        "title": "The title of the template. For example: 1 Virtual Server with SSH Key",
        "id": "The id of the template component. For example:1virtual6ae83564",
        "template_name": "The name of the template",
        "version:"The version of the template",
        "template_provider: "The provider of the template. For example, IBM",
        "template_content_type": "The content type of the template. For example: prebuilt",
        "instance_name": "The name of the instance associated to this template when deployed",
        "cloud_connection_name": "The name of the cloud connection to be used to deploy the template",
        "content_runtime": "The runtime content",
        "template_params": [
        {
           "default": "The actual value of the parameter. For read",
           "description": "A description for this template parameter",
           "hidden": "Specify if the parameter is not displayed in the user interface. The value must be true or false",
           "immutable": "Specify if the parameter is read only. The value must be true or false",
           "label": "The label to be displayed in the user interface for this parameter",
           "name": "The name of the template parameter",
           "required": "Specify if the parameter is required. The value must be true or false",
```

```
            "secured": "Specify if the parameter value is shown as asterisk (*). The value must be true or false",
            "type": "The type of parameter. For example: text",
        },
        {
          ...
        }
      ]
   }
 ]
```

The **type** attribute can have **text** or **list** value. If the **type** value is **list**, in the **default** attribute specify the list of the values that can be assigned to the parameter in the format **["<First value>","<Second value>",...,"<Last value>"]**. For example, **["IBM Cloud","Amazon EC2"]**.

If you want to set a template parameter to the value of a input parameter, specify the **default** attribute value by using the following convention:

```
"default": "${input_parameters.<service_parameter_name>}
```

For example, you have the following input parameters:

```
"input_parameters": [{
   "name": "datacenter",
   "label": "datacenter",
   "description": "Target vSphere datacenter for VM creation",
   "type": "list",
   "default": ["vSphere datacenter 1","vSphere datacenter 2"],
   "hidden": "false",
   "immutable": "false",
   "required": "true",
   "secured": "false",
   "validation": "",
   "dependent": "",
   "dependent_attribute": "",
   "return_type": "text"
},
```

You can define the following template parameter to set its value to the related input parameter value that you select when ordering the service:

```
"template_params": [
                {
                "name": "datacenter",
                "label": "datacenter",
                "description": "Target vSphere datacenter for VM creation",
                "type": "text",
                "default": "${input_parameters.datacenter},
                "hidden": "true",
                "immutable": "false",
                "required": "true",
                "secured": "false",
                "validation": "",
                },
```

In the previous example, note that the **hidden** attribute value in the template parameter must be set to **true** to allow the template parameter value to be replaced with the input parameter value when ordering the service.

If you are using a Business Process Manager template, then the following parameters are added to the template:

```
"async_req": true  //flag to determine whether it is a long running template.
"long_running_delay": "<time in minutes>", //Delay after every poll. Value must be in minutes.
"long_running_timeout": "<time in hour>" //Total time for which polling must be run. The value must be in hours.
```

Example of a Business Process Manager template:

```
"templates": [
  {
    "SampleLongRunningProcess": {
      "title": "SampleLongRunningProcess_9de34f",
      "template_name": "SampleLongRunningProcess_25.00746596-7ced-4f98-b382-294e2f702e95_2063.5af7b495-770a-4408-a15b-
76ab6f3e890e",
      "version": "1.0"
      "id": "sample10139690a6",
      "template_type": "BPM",
      "template_content_type": "BPM",
      "template_provider": "BPM",
      "instance_name": "",
      "cloud_connection_name": "BPM Connection",
      "template_data_objects": {},
      "async_req": true,
      "long_running_delay": "5",
      "long_running_timeout": "24",
      "template_params": {
          "input1": ""
      },
      ...
      ]
```

Here, in 24 hours, poll happens at a frequency of 5 minutes and in total 288 times. if the Timeout is 24 and delay is 5, then poll happens 24*60/5 = 288 times.

resthooks

```
"resthooks": [{
        "resthook": {
        "title": "The title of the resthook",
        "id": "The unique id of the resthook",
        "header": {
                "accept": "
                "Content-Type: "application/json",
                The header of the resthook in JSON string format"
                },
                "url": "The URL of the external REST server",
                "method": "The method to poll the external REST server",
                "payload" : "The request payload if you specified a POST method"
                "timeout": 120,
        }
        "on_destroy":
                {
                "headers": {
                  "accept": "application/json",
                  "Content-Type": "application/json"
                },
                "auth": {
                  "type": "basic",
                  "username": "administrator@vsphere.local",
                  "password": "^(RGFuYzFuZyE=)"
                },
                "url": "https://example.com/create",
                "method": "POST",
                "payload": {
                  "id": "1"
                }
                "timeout": 120,
            }
      }
    ],
       ...
]
```

The service REST hooks are used to poll an external REST server.

Note: The `timeout` attribute suggests the maximum time of an URL connection. The default value for `timeout` is 120 seconds. As the `timeout` attribute is not available by default in Rest Hooks, you must add the timeout attribute and configure it as per your requirement. The resthook time out occurs either when the network timeout occurs or when the `timeout` value is reached.

notifications

```
"notifications": [{
        emailnotification":{
                "title": "The title of the email notification component",
                "type": "The type of the service notification. For example: email",
                "id": "The identifier of the email notification component",
                "sender": "The sender address",
                "receiverList": "The list of receiver email addresses",
                "subject": "The subject of the email",
                "body": "The notification body",

      },
      ...
]
```

Before using service notifications, you must configure a connection to the SMTP server. For more information, see Configuring a connection for notifications.

sequence

It defines the sequence of activities to deploy the service instance.

For example:

```
"sequence": {
            "0": "ibmchartf76699ee",
            "1": "emailnot43bfbb6f"
          }
```

error sequence

It defines the sequence of activities to deploy a error sequence defined in the **Error flow** section of the **Composition tab**.

For example:

```
"error_sequence":{
        "0": servicen247273d"
        }
```

plans

You can have multiple plans with or without pricing.

Example plan without pricing details:

```
"plans": [{
      "name": "The name of the plan. For example, Amsterdam",
      "description": "The description of the plan. For example, to deploy in Amsterdam",
      "actions": [],
      "plan_parameters" [{
            "name": "vm_cpu",
            "label": "Server CPU",
            "customtype": "string",
            "type": "string",
            "immutable": true,
            "hidden": true,
            "required": true,
            "secured": false,
            "description": "Virtual Machine CPU",
            "default": "1"
          }
        ]
            "free": true
          },
      };
     ]
```

Where

- `plan_parameters[]` - If your service has some input parameters in the provision action that you want to override at the time of deployment, use `plan_parameters`.
- `free` - Signifies whether pricing is associated to the plan or not. If it is associated, then the value is set to false.

For an example of a plan with pricing, see Sample pricing.

Supported interpolation expressions

Managed services service components have the capability to take an input parameter from another service component, hence links to all composer supported interpolation expressions are also included here.

The composer enables you to connect input parameters to service parameters or output parameters of other activities. These parameters are determined by composer supported expressions.

- Input and output parameter formats of all activities
- Inbuilt input and output formats of all activities
- Detailed information with examples for all activities
- Troubleshooting

Input and output parameter formats of all activities

Input and output parameter formats of the different activities are tabulated as follows:

Format	Example	Refers to
`${templates.<ID>.output.<PARAM_NAME>}`	`${templates.tomcat019453ac.output.TomcatNode01_ip}`	Output Parameter of a template. It is applicable only for terraform template as Helm does not support output parameters.
`${templates.<ID>.<PARAM_NAME>}` or `${templates.<ID>.input.<PARAM_NAME>}`	`${templates.tomcat019453ac.TomcatNode01-mgmt-network-public}`	Input Parameter of a template
`${input_parameters.<PARAM NAME>}`	${input_parameters.Conn}	Dynamic parameters for template activity. Here, `<PARAM NAME>` can be a variable of type `connection` or `sharedparameter` that you need to configure as input parameter during service definition. For more information about shared parameter, see Shared parameters in Templates topic. For more information about connection, see the Different ways of adding values for the cloud connection in Templates topic. For the behavior of these dynamic parameters at runtime, see Creating a service instance.
`${resthooks.<ID>.output.<PARAM_NAME>}`	`${resthooks.resthookf342a67e.output.body}`	Output parameter of a Rest Hook.
`${resthooks.<ID>.input}`		Payload of the Rest Hook.
`${resthooks.<ID>.output}`		Response or output or body parameter of Rest Hook.
`${notifications.<ID>.output.<PARAM_NAME>}`		Output parameter of notification.

Inbuilt input and output formats of all activities

The inbuilt input parameters for activities are tabulated as follows:

Format	Refers to
`${templates.<id>.instance_name}`	Name of the template instance
`${templates.<id>.template_name}`	Name of the template
`${templates.<id>.template_version}`	Version of the template
`${templates.<id>.title}`	Title of the template
`${templates.<id>.stack_id}`	Get the stack id of an activity
`${resthooks.<id>.url}`	URL of the Rest Hook.
`${resthooks.<id>.method}`	Method
`${resthooks.<id>.headers.<name>}`	Name of the header
`${resthooks.<id>.payload}`	Payload
`${resthooks.<id>.authentication.type}`	Authentication type
`${resthooks.<id>.authentication.username}`	User name
`${resthooks.<id>.headers.Content-Type}`	Content type headers
`${resthoooks.<id>.title}`	Title of Rest Hook
`${notifications.<id>.to}`	Receiver email address.
`${notifications.<id>.cc}`	Copy to email addresses.
`${notifications.<id>.bcc}`	Bcc to email addresses.
`${notifications.<id>.sender_name}`	Email id of the sender.
`${notifications.<id>.subject}`	Subject of the notification.
`${notifications.<id>.message}`	Notification message.
`${notifications.<id>.title}`	Title of the notification.
`${decisions.id.selection}`	Retrieve data about the decision that got selected at the time of deployment.

The inbuilt output parameters for the different activities are tabulated as follows:

Format	Refers to
`${templates.<id>.action}`: `CREATE` / `DELETE`	Create or delete action
`${templates.<id>.status}` : `SUCCESS` / `IN_PROGRESS` / `FAILED`	The status of a template. It can be success, in progress, and failed
`${templates.<id>.status_message}`	Additional message for the status
`${templates.<id>.stack_message}`	Template execution stack logs (from IAAS)
`${templates.<id>.stack_error_message}`	Template error message (from IAAS)
`${templates.<id>.created_at}`	Time of creation of the template. (from IAAS)
`${notifications.<id>.status}` : SUCCESS / FAILED	Status of the email notification.
`${notifications.<id>.status_message}`	Additional message for the status.

Detailed information with examples for all activities

The following table has links to input and output parameter mapping details of all activities along with their examples:

Service component / General	Input and output parameter mapping
Templates and helm charts	Input output mapping for templates and helm charts
Integration > Resthooks	Input and output parameter mapping for resthooks
Flow components > Decision	Parameter mapping for decision
Notifications > Email notification	Input and output parameter mapping for email notification
Service instance level parameters	Service instance level parameters
Interpolation parameters of Error flow	Service instance level parameters in Error flow
Shared parameters in service interpolations	Using shared parameters in service interpolations

Troubleshooting

If a service references a string literal, such as `${<text>}` in the parameter value of an activity, then use `$${<text>}` as a string to escape it in the service definition. For example, you have a helm chart that contains `${path.config/prospectors.d*.yml}` in **Filebeat.config.modules.path**. When you create a service to deploy this helm chart, the following error occurs:

```
Error: Invalid resource : ${path.config} (hint: 'path' not found)
{"error":{"statusCode":500,"message":"Internal Server Error"}}
```

To resolve this error, change `${path.config}` to `$${path.config}`.

For more troubleshooting information, see Troubleshooting Service Composer or Portal issues.

Input output mapping for templates and Helm charts

Mapping procedure in the Managed services user interface and their input output formats.

- Template / Helm input parameters
- Template / Helm output parameters
- For service instance level parameter details and service instance level parameters in Error flow, see Service instance level parameters.

Template / Helm chart input parameters

Representing input parameters and attributes of an activity within another activity.

Note: The `templates` word in the syntax is used for both template and helm activities.

If your source parameter is defined in the input parameters section of an activity, then use the following format to call its value within another activity:

```
${activity.id.paramname}
```

Examples:

- For example, `Apache Tomcat on a single virtual machine` template activity has `TomcatNode01-mgmt-network-public` parameter defined in the **INPUT PARAMETERS** section. Use the following format to call its value within another activity:

  ```
  ${templates.tomcat019453ac.TomcatNode01-mgmt-network-public}
  ```

  or

  ```
  ${templates.tomcat019453ac.input.TomcatNode01-mgmt-network-public}
  ```

  Where `tomcat019453ac` is the activity Id.

  - For example, mapping the output of `IPAM` template as an input to `Oracle Database 12c Enterprise Edition on a single virtual machine template`:

    ```
    OracleDBNode01_dns_suffixes": "${templates.ipam1467a9b92b6c.output.ipam_result_domain_list},
    OracleDBNode01_domain": "${templates.ipam1467a9b92b6c.output.ipam_result_domain_str},
    OracleDBNode01-name": "${templates.ipam1467a9b92b6c.output.ipam_result_host},
    OracleDBNode01_ipv4_address": "${templates.ipam1467a9b92b6c.output.ipam_result_ip_address},
    ```

    Where

    - `OracleDBNode01` is the ID of`Oracle Database 12c Enterprise Edition on a single virtual machine` template.
    - `ipam1467a9b92b6c` is the ID of `IPAM` template.

    The sample snippet of Service Composition Language wherein the output of one template activity is mapped as input into another template activity:

    ```
    "templates": [
        {
          "IPAM": {
            "title": "IPAM_b76b9c",
            "template_name": "IPAM",
            "version": "v1.0.0",
            "id": "ipam1467a9b92b6c",
            "template_type": "Terraform",
            "template_content_type": "Other",
            "template_provider": "Other",
            "instance_name": "",
            "cloud_connection_name": "Other",
            "template_data_objects": {},
            "template_params": {
              "ipam_ip_address": "9.9.9.9",
              "ipam_result_domain": "domain",
              "ipam_result_host": "hostname",
              "ipam_result_ip_address": "ipaddress"
            },
            "outputs": [
              "ipam_result_domain_list",
              "ipam_result_domain_str",
              "ipam_result_host",
              "ipam_result_ip_address"
            ]
          }
        },
        {
          "Oracle Database 12c Enterprise Edition on a single virtual machine": {
            "title": "Oracle Database 12c Enterprise Edition on a single virtual machine_6ec8ab",
            "template_name": "Oracle Database 12c Enterprise Edition on a single virtual machine - VMware vSphere",
            "version": "2.1",
            "id": "oracledaff0e8430",
            "template_type": "Terraform",
            "template_content_type": "VMware vSphere",
            "template_provider": "VMware vSphere",
            "instance_name": "",
            "cloud_connection_name": "VMware",
            "template_data_objects": {
              "bastionhost": "DefaultNoBastionHostRequired",
              "httpproxy": "DefaultNoProxyRequired",
              "advanced_content_runtime_chef": "VMware"
            },
            "template_params": {
              "OracleDBNode01_dns_servers": [
                "9.5.46.5",
                "9.5.48.5"
              ],
              "OracleDBNode01_dns_suffixes": "${templates.ipam1467a9b92b6c.output.ipam_result_domain_list}",
              "OracleDBNode01_domain": "${templates.ipam1467a9b92b6c.output.ipam_result_domain_str}",
              "OracleDBNode01-image": "terraform/managed_services/content/RHEL7-content",
              "OracleDBNode01-os_admin_user": "root",
    ```

```
          "OracleDBNode01-os_password": "aaaaaa",
          "OracleDBNode01_oracledb_version": "v12c",
          "OracleDBNode01_oracledb_port": "1521",
          "OracleDBNode01_oracledb_release_patchset": "0.0.0.0.0",
          "OracleDBNode01_oracledb_SID": "ORCL",
          "OracleDBNode01_root_disk_size": "250",
          "OracleDBNode01_oracledb_security_sys_pw": "aaaaaa",
          "OracleDBNode01_oracledb_security_system_pw": "aaaaaa",
          "OracleDBNode01-name": "${templates.ipam1467a9b92b6c.output.ipam_result_host}",
          "OracleDBNode01_root_disk_datastore": "datastore1",
          "OracleDBNode01_ipv4_gateway": "9.9.9.9",
          "OracleDBNode01_ipv4_address": "${templates.ipam1467a9b92b6c.output.ipam_result_ip_address}",
          "OracleDBNode01_memory": 8192,
          "OracleDBNode01_ipv4_prefix_length": "24",
          "OracleDBNode01_number_of_vcpu": 2,
          "OracleDBNode01_network_interface_label": "VM Network",
          "OracleDBNode01_cluster": "icm-vmware-nsx-2",
          "OracleDBNode01_datacenter": "NSX Manage To",
          "OracleDBNode01_folder": "terraform/test",
          "OracleDBNode01_adapter_type": "vmxnet3",
          "OracleDBNode01_resource_pool": "cam",
          "user_public_ssh_key": "ssh-rsa AAAABCCCCCCaaaaaaaLDCU3jpchru5Q== abc@in.ibm.com"
        },
        "outputs": [
          "OracleDBNode01_ip",
          "OracleDBNode01_name",
          "OracleDBNode01_roles",
          "stack_id"
        ]
      }
    }
```

- The following input parameters are common for all template/Helm activities:

  Format:

  ```
  ${templates.<id>.<attribute name>}
  ```

  ```
  ${templates.<id>.instance_name} \\ Name of the instance
  ${templates.<id>.template_name} \\ Name of the template activity
  ${templates.<id>.template_version} \\ Version of a template activity
  ${templates.<id>.title} \\ Title of a template activity
  ${templates.<id>.stack_id} \\ Stack id of an activity
  ```

Template / Helm output parameters

Representing output parameters and attributes of a template / helm activity within another activity.

Note: The `templates` word in the syntax is used for both template and helm activities.

- Use the following format for a specific template/helm activity:

  If you want to map your parameter to the output parameters of another template/helm activity, then prefix the word "output" when you reference it in the value field.

  ```
  ${activity.id.output.paramname}
  ```

  The `param_name` is the name of the parameter that is returned by a particular template activity or helm activity. It depends on the template definition for terraform templates, and for helm chart, it depends on the parameters defined in IBM Cloud Pak for AIOps.

  For example, `Apache Tomcat on a single virtual machine` template activity has `TomcatNode01_ip` defined in the **OUTPUT PARAMETERS** section. Use the following format to call its value within another activity:

  ```
  ${templates.tomcat019453ac.output.TomcatNode01_ip}
  ```

  Where, `tomcat019453ac` is the template activity Id and `TomcatNode01_ip` is the parameter.

- The following output parameters are common for all template/helm activities:

  Format:

  ```
  ${templates.<id>.<attribute name>}
  ```

  ```
  ${templates.<id>.action} : **`CREATE`** / **`DELETE`**
  ${templates.<id>.status} : **`SUCCESS`** / **`IN_PROGRESS`** / **`FAILED`**
  ${templates.<id>.status_message} :  additional message for the status
  ${templates.<id>.stack_message} : template execution stack logs (from IAAS)
  ${templates.<id>.stack_error_message} : template error message (from IAAS)
  ${templates.<id>.created_at} : template created at. (from IAAS)
  ```

Input and output parameter mapping for REST Hook

The mapping of input and output parameters for REST Hook and their formats.

- REST Hook input parameters

- REST Hook output parameters
- Example scenarios to call the input and output parameters
- For service instance level parameter details and service instance level parameters in Error flow, see Service instance level parameters.

REST Hook input parameters

The following input parameters are common to all REST Hook activities:

Format:

```
${resthooks.<id>.<attribute name>}
```

```
${resthooks.<id>.url}
${resthooks.<id>.method}
${resthooks.<id>.headers.<name>}
${resthooks.<id>.payload}
${resthooks.<id>.authentication.type}
${resthooks.<id>.authentication.username}
${resthooks.<id>.headers.Content-Type}
${resthoooks.<id>.title}
```

```
${resthooks.<ID>.<input>}
```

REST Hook output parameters

Representing output parameters and attributes of a REST Hook activity within another activity.

- Response or output or body parameter of REST Hook:

  ```
  ${resthooks.<ID>.output.body}
  ```

  To get the ID of an activity, see the **Source Code** tab. The `param_name` is the name of the parameter that is returned by a particular REST Hook activity.

  For example, the output of REST Hook `resthook_f4c71a` is referenced in email notification `emailnotification_c5ee13`:

  ```
  "resthooks": [
          {
            "resthook": {
              "title": "resthook_f4c71a",
              "id": "resthookf342a67e",
              "headers": {
                "accept": "application/json",
                "Content-Type": "application/json"
              },
              "url": "http://9.5.28.173:3000/posts/test_on_error_flow",
              "method": "GET"
            }
          }
        ],
        "notifications": [
          {
            "emailnotification": {
              "title": "emailnotification_c5ee13",
              "type": "email",
              "receiverList": "${input_parameters.to}",
              "id": "emailnot745071d6",
              "sender": "CAMadmin",
              "copyToList": "",
              "subject": "Rest server is accessible",
              "body": "${resthooks.resthookf342a67e.output.body}"
  }
  ```

- The following output parameters are common to all REST Hook activities:

  Format:

  ```
  ${resthooks.<id>.<attribute name>}
  ```

  ```
  ${resthooks.<id>.status} : SUCCESS / FAILED
  ${resthooks.<id>.body} : response body, JSON object
  ${resthooks.<id>.status_code} :http status code. For example, 200 OK
  ${resthooks.<id>.status_message} : http status. For example, 200 OK
  ```

Example scenarios to call the input and output parameters

The following example scenarios illustrate the various conventions that you must use to call the input and output parameters:

- Example 1

  ```
  {
    "ip" : "9.9.9.9",
    "hostname" : "vm1"
   }
  ```

  Syntax:

```
${resthooks.id.body.ip}
```

Result is "9.9.9.9

- Example 2

```
{
  "data" : {
  "ip" :  "9.9.9.9",
   "hostname" : "vm1"
   }
 }
```

Syntax:

```
${resthooks.id.body.data.ip}
```

Result is "9.9.9.9

- Example 3

```
{
  "zones" : [
     {
       "name" : "east",
       "percentage" : "25"
      },
      {
        "name" : "west",
        "percentage" : "70"
  }
   ]
  }
```

Syntax:

```
${resthooks.id.body.zones[name=east].percentage}
```

or

```
${resthooks.id.body.zones[0].percentage}
```

Result: 25

Note: In the following example, **dns_servers** is a variable of list type that is an output from a REST Hook activity:

```
{
  "id": "8",
  "domain": "domain.kstart.com",
  "hostname": "hostname-cam-local",
  "ipaddress": "9.9.9.9",
  "domain_suffix": [
  "domain.kstart.com",
  "domain.kstart.com"
   ],
  "dns_servers": [
  "9.9.9.0",
  "9.9.9.1"
   ]
 }
```

The value for the list type is an element of a list and is not a list by itself, so do not enter the following value in the **Value** field of **Edit Parameter** > **Update** tab for a list parameter type:

```
"vm_1_dns_servers": ["${resthooks.resthookc15774af.output.body.dns_servers}"
        ],
```

If you enter the reference JSON value in the **Value** field, then the following error message is displayed:

```
Could not parse value for param [vm_1_dns_servers] of type [list] with value : ["["9.9.9.0","9.9.9.1"]"]
```

Instead, go to the **Source** tab to reference a value of type list/map.

Parameter mapping for decision

Parameter mapping for decision activity.

If you want to retrieve data about the decision that got selected at the time of deployment, use the expression `${decisions.id.selection}`. For example `${decisions.decision6d43ee5f.selection}`.

OR (||) Parameter mapping in decision

The cases defined within a decision activity have different output string expressions and the actual output is decided during runtime. As you are not aware of the case that gets selected beforehand, use a OR (||) operator as a delimiter between the output of the cases. The OR (||) operator returns a single first non-nil value. The

non-selected parameters always have a nil value and are not considered for further processing.

For example, there is a decision activity that has two cases:

- The output of the first case is `templates.template4ce5b4be.user`
- The output of the second case is `templates.template105c1603.user`

The OR (||) operator expression for this example is as follows:

```
${templates.template4ce5b4be.output.user || templates.template105c1603.output.user}
```

If the first case is selected during runtime, then `templates.template4ce5b4be.user` is used for further processing in the workflow as it is the first non-nil value. The `templates.template105c1603.user` has a nil value and is not considered.

If an activity parameter is from inside a decision block and the decision block is not selected, then the parameter (output or input parameter) evaluates to an empty value.

If an activity parameter is from a selected decision block having an empty-value string, then the next parameter having a value string is considered.

If you use interpolation in the error flow around a non executed decision from the primary flow, the resultant value is an empty string.

Input and output parameter mapping for email notification

The output and input parameters for email notification.

Email notification output parameters:

- The following output parameters are common to all email notification activities:

  ```
  ${notifications.<id>.<attribute name>}
  ${notifications.<id>.status} : SUCCESS / FAILED
  ${notifications.<id>.status_message} : additional message for the status
  ```

  Note: The `status` is the send request for the email that was successfully accepted by the SMTP server.

Email notification input parameters:

- Use the following format for input parameters of notification activity:

  ```
  ${notifications.<id>.to}
  ${notifications.<id>.cc}
  ${notifications.<id>.bcc}
  ${notifications.<id>.sender_name}
  ${notifications.<id>.subject}
  ${notifications.<id>.message}
  ${notifications.<id>.title}
  ```

Service instance level parameters

The conventions to be followed for service instance level input and output parameters.

The `svc_instance` represents a JSON request object that is used to initiate a "provision" or a "bind" action instance.

- `${svc_instance.name}` - Name of the "provision" or a "bind" action instance that is entered in the deployment page.
- `${svc_instance.instance_parameters}` - The action parameter JSON object with key/values as entered in the deployment page. The Keys depend on the service definition. For example:

  ```
  {
    "host" : "some-name",
    "region" : "us-west"
  }
  ```

- `${svc_instance.instance_parameters.host}` - The particular action parameter key value. Using a subquery to drill down to a particular value.
- `${svc_instance.service}` - The service definition JSON object as available in the service composer source tab.

  Note: The `${svc_instance.service}` interpolation interpolates the whole source of the service. The service source might contain other interpolations, the Service composer tries to resolve these nested interpolations, which might sometimes cause undesired errors. So it is not recommended to use `${svc_instance.service}`, if used, should be used with caution.

- `${svc_instance.service.actions[name=provision].input_parameters[name=HybridCloud].options[label=AWS].value}` - Using a subquery to drill down to a particular value in the service definition. It gets the value of one of the input parameter options. In this example, it is "HybridCloud", "AWS".
- `${svc_instance.service.catalog_metadata.category}` - Using subquery to drill down to a particular value in the service definition. In this example, it gets the category of the service, "CloudServices".

- `${svc_instance.owner}` - Owner of the service. For example, "admin".
- `${svc_instance.instance_plan}` - Plan name in use for the current instance. For example, "Standard".
- `${svc_instance.tags}` - Tags JSON object with key/value pairs of tag name and values as entered in the Deployment page. Tag key names depend on the service definition. For example:

  ```
  {
   "dept" : "FIN"
   "org" : "AAA"
  }
  ```

- `${svc_instance.service_action_name}` - Current action has been performed. Name maps to `action.name` in the service definition. For example, "Provision".
- `${svc_instance.output_parameters.<parameterName>}` - Key/value pairs of output parameters received from 'Provision' action. Keys are defined in service definition. These output parameters are available in 'Bind' action. For example:

  ```
  {
    "host" : "test01.ibm.com",
    "ipaddress: "9.9.9.9"
  }
  ```

  You can drill down to a particular key in the output parameters as in the following example:

  ```
  `${svc_instance.output_parameters.ipaddress}`
  ```

  This returns the IP address "9.9.9.9"

  For more information on how to define output parameters, see Creating a service.

- `${svc_instance.namespace}` - The namespace value for a deployed instance.

Service instance level parameters in Error flow

- In addition to the listed service instance level parameters, the error flow section of the **Composition** tab supports these interpolations:
  - `${svc_instance.error.message}` - Error message for failure
  - `${svc_instance.error.activity_id}` - Activity id of the failed activity
  - `${svc_instance.error.activity_type}` - Type of failed activity
  - `${svc_instance.error.created_at}` - Creation time of the failed activity
  - `${svc_instance.primaryflow.decisions.<decision_id>.selection}` - Retrieve data about the decision that got selected at the time of deployment. For example, `${svc_instance.primaryflow.decisions.decision6d43ee5f.selection}`.
- Interpolation of primary flow activity parameters in Error flow:

  The interpolation expression for primary flow activity parameters in Error flow is as follows:

  ```
  ${svc_instance.primaryflow.<activity>.<activity_id>.<attribute name>}
  ```

  Where, `activity` can be REST Hook, templates, or notifications.

  The 'svc_instance.primaryflow.' prefix can be used with any parameter of REST Hook/template/notification activity from the primary flow. If an `${svc_instance.primaryflow.xxx.xxx.xxx}` expression does not exist, then an empty string value is used.

  Note: The `${svc_instance.primaryflow.xxx.xxx.xxx}` expression works only from within an error flow section.

- Example interpolation expressions for the different activities:
  - REST Hook:
    - `${svc_instance.primaryflow.resthooks.resthook8a5f70ec.payload}` - REST Hook payload
    - `${svc_instance.primaryflow.resthooks.resthook8a5f70ec.status}` - REST Hook status
    - `${svc_instance.primaryflow.resthooks.resthook8a5f70ec.headers.Content-Type}` - REST Hook Headers
    - `${svc_instance.primaryflow.resthooks.resthook8a5f70ec.authentication.type}` - REST Hook authentication mechanism
    - `${svc_instance.primaryflow.resthooks.resthook8a5f70ec.authentication.username}` - The username for REST Hook authentication management system.
    - `${svc_instance.primaryflow.resthooks.resthook8a5f70ec.title}` - The title of the REST Hook.

    For REST Hook related input and output interpolation expressions, see Input and output parameter mapping for REST Hook.
  - Templates:
    - `${svc_instance.primaryflow.templates.testtemp53db922a.status}` - Template status
    - `${svc_instance.primaryflow.templates.testtemp53db922a.output.selected-region}` - Template Output: Selected Region
    - `${svc_instance.primaryflow.templates.testtemp53db922a.template_name}` - Template Name
    - `${svc_instance.primaryflow.templates.testtemp53db922a.input.sleep}` - Template: Input Param Sleep

    For template-related input and output interpolation expressions, see Input output mapping for templates and Helm charts.
  - Notification Status:
    - `${svc_instance.primaryflow.notifications.emailnotbf32ca47.status}`
    - `${svc_instance.primaryflow.notifications.emailnotbf32ca47.sender_name}`
    - `${svc_instance.primaryflow.notifications.emailnotbf32ca47.title}`

    For notification-related input and output interpolation expressions, see Input and output parameter mapping for email notification.

Manually using shared parameters in service interpolations

Shared parameters can be manually linked and used in service interpolations.

For linking shared parameters from the user interface, see Link parameter section in Managing an existing activity parameter and Read-write End-User Permissions in Parameters tab of Helm charts / Templates activity section.

The shared parameter interpolation syntax that you can use to manually link:

```
${datatypes.<DATATYPE_ID>.<attribute name>}
```

Where,

- `DATATYPE_ID` is an identifier of Data Type to Data Object mapping that is defined in the service file.
- `attribute name` is the attribute name from the Data Type definition.

For example:

```
"actions": [
      {
        "type": "provision",
        "name": "Provision",
        "description": "Default action for deployment of service",
        "input_parameters": [
        {
            "name": "bastionhost1",
            "label": "Bastion Host Configuration",
            "customtype": "sharedparameter",
            "type": "sharedparameter",
            "immutable": false,
            "hidden": false,
            "required": true,
            "secured": false,
            "description": "Bastion Host Configuration",
            "default": "DefaultNoBastionHostRequired",
            "datatype": "bastionhost"
         }
```

For more information on the attributes and a detailed example, see Data Types in Service Composition Language.

In this example, `the DATATYPE_ID` is "bastionhost1" and it is mapped to `bastionhost` Data Type.

If there are multiple DataObjects created for a DataType, then a Data Object must be identified as a default object. In this example, the default DataObject is `DefaultNoBastionHostRequired`. In the following interpolation syntax, you override the default Data Object and make use of `bastion_host` Data Object:

```
${datatypes.bastionhost1.bastion_host}
```

The element `datatypes` is included in SCL V3 to support Shared Parameters in service definition, that is, DataObject to Datatype mapping. For more information, see datatypes section of Editing a service file topic.

Note: Only the Data Types that are created as string are supported in service context.

Service validations

Whenever you work with your service in the Managed services user interface, service validation is performed to raise early warnings and errors. These preemptive warnings and errors are displayed in the navigator panel. They enable you to create a service that is free of any errors or warnings.

User interface validations are triggered when you make changes to the service and API validations are triggered when you click **Save** or **Publish** buttons. Click the validation in the notification panel to find out more information about the context of error messages and warnings. In addition, in the composer canvas, a small icon (error and/or warning) is displayed against the related activity that has a validation problem.

Service validation approaches are as follows:

- User interface validation - It occurs as soon as you edit a new service or already existing service.
- API validation - It occurs as soon as you save the service. The API validation errors are no longer displayed if you try to modify the service or move away from the composer tab. Some validation results in error, while others result in warning. API can return either errors or warning at a time, so if a service has both errors and warnings, then the user interface does not show both at the same time. You must first fix the errors and click save to see the warnings. For a list of probable API validation messages, see API Validations.
- Publish time validation - It occurs as soon as you publish a service.

The validation messages are categorized in the following manner for the first two approaches:

- Warnings and problems that do not prevent you from saving a service.
- Errors and critical problems that prevents you from saving a service

List of all probable validation messages that occur when you create, save, or publish a service:

- Validations in composer
- Warnings in composer
- Errors on Save

- API Validations

Validations in composer

- These warnings check the source code for various false conditions, such as empty values, mandatory values for decision, Rest Hook, email notification, and templates .
- The source code is validated whenever there is a change anywhere in the service.
- The JSON syntax errors that are editor errors are also taken care, but the message does not show the exact point of failure.
- REST API errors and validation framework errors at the time of save.

Warnings in composer

{: #warnings]

- When service 'catalog_metadata.name' key is missing - Error is thrown from API
- When name of the service 'catalog_metadata.name' value is missing - Error is thrown from API
- Template key 'catalog_metadata' is missing from the SCL - Error is thrown from API
- If 'longDescription' in overview has length more than 400 chars.
- When service 'description' has length more than 150 characters
- When feature 'bullet's description' has length more than 150 characters
- When there is decision key missing - Error is thrown from API
- When title of the decision, that is, `decision.title` value is missing.
- When `decision.mapped_parameter` value is incorrect, that is, it does have interpolation syntax error.
- When `decision.mapped_parameter` value is missing from SCL.
- If there is no condition array in the SCL or "conditions" + " key is missing - Error is thrown from API
- If notifications array "notifications" + " key is missing" - Error is thrown from API
- Parameters of email notification like title and receiver list key or value is missing.
- The Rest Hook array or key is missing. - Error is thrown from API
- The Rest Hook URL is missing for create/on_delete.
- The Rest Hook URL value is missing from the SCL for create/on delete.
- URL is missing from both the create or delete definition of resthook.
- Templates array or 'templates' key is missing. - Error is thrown from API.
- Templates title key and value is missing.
- Templates cloud connection key or value is missing.
- The `template_params` are there but name key or value is missing from the template_params.
- Validation for hidden parameters for template_params.
- Template is not a valid JSON - Error is thrown from API.
- Parsing errors for SCL JSON - Error is thrown from API.

Errors on Save:

- REST error responses from various rest calls.
- Validation for using same name for the service in a namespace.
- Empty JSON values for different data structure object like json, array, map etc,
- Mandatory parameters missing from the various flow components - REST Hook, Decision, Email, Templates etc,
- Syntax errors.
- Publish time validations.

API Validations

Validations at the time of service creation

- Check whether service name is present or not - error
- Duplicating a service with same name not possible - error
- Tag present is invalid - error and if it is empty, then assign it to cloud services - warning (at the time of save and edit)
- Image provided is valid or not, if image is invalid replace it with a valid one - warning (at the time of save and edit)
- Check the overall json structure in source code, which will include checks for the presence of service attribute, spec_version, catalog_metadata, name, actions attribute of type array, flow attribute of type json, conditions, Rest Hook, notifications, plans and templates section of type array, sequence attribute of type json) - error
- Checking if sequence object has valid ids and is not empty - error
- Check if plan name is unique. - error
- Check if service name is unique. - error
- Check if parameters present in the source code are of correct Managed services variable format (check if name, hidden, required, immutable, secured type etc are present or not). - warning (to be generated through schema json) custom type : warning
- Error wont be thrown if an unknown element is added.
- Check if template_name, template_version, template_type, template_provider are present in the source code (Validation framework has added this check) - error
- Cloud connection checked - warning if not found
- Rest Hook - url and headers - warning if not found
- If 'longDescription' in overview has length more than 400 chars. - warning
- When service 'description' has length more than 150 characters. - warning
- When feature 'bullet's description' has length more than 150 characters. - warning
- When title of the decision, that is, `decision.title` value is missing. - warning

- The `decision.mapped_parameter` value is missing from SCL - warning
- Parameters of email notification like title and receiver list key or value is missing. - warning - The Rest Hook URL is missing for create/on_delete. - warning
- The Resthook URL value is missing from scl for create/on delete - warning
- Templates title key and value are missing. - warning

Validations at the time of service publish:

- All the checks present in case of service creation.
- Check if atleast 1 executable section (resthook/templates/email notification) is present in the source code. - error
- Check the data type defined for each template variable and verify if values provided in the source code are compliant. - error
- Check if template name is valid or not - error
- Check if a valid cloud connection name is present. - error
- Check if dynamic binding for parameters is done correctly or not. - error - Check if mapped parameter in decision is present in the source code or not. -error - Check if Rest Hook section has "url" and "method" section. - error - Check if email notification has "recieverlist" and "body" elements. - error - Check if "subject" is mandatory in email notification. - error
- Validate template parameter type provided in the source code with the one defined in template : boolean, password type parameter should have string value, map type value should be of object type, counter type value should be a number of type counter, valid value as per regex defined, valid value as per options defined, catch missing parameters where value is required, check parameter mapping in template parameter. - error
- The Activity Ids in flow.sequence should be unique. - error
- The Activity Ids should be valid in `flow.sequence`. - error
- The Activity Ids in `flow.conditions.decisions.options.sequence` should be unique. - error
- The Activity Ids should be valid in `flow.conditions.decisions.options.sequence`. - error
- Pricing Parameter should be valid. It should be from plan parameter list - error
- Operator used in the pricing object should be valid. Use from gt/lt/ge/le/eq/members - error
- Condition validation for pricing object. - error
- Base condition in pricing object should be validated . Use any/all only. - error
- Plan should not have multiple pricing. - error
- Method and Headers are a must when URL is present in resthook. - error
- Rest Hook - create without URL or `on_destroy.url` should not be provided. - error
- Method and Headers are a must when `on_destroy` URL is present in resthook. - error
- Error Flow can not have Resthook with destroy enabled. - error
- Action array should have 1 type 'provision' . - error
- Validate mapped parameter in `input_parameters` - error
- Interpolation Validation - error
- Template does not have cloud connection name - error

Viewing service details

After you create a service, you can view its details from the Services Library page.

Procedure

1. In the navigation bar, click **Library > Services**.

   In the services page, you can see a list of all the services. Each service record has name, number of versions, and the date modified.

2. Search for your service by using any of the following search filters:

   - Enter your service name in **Search services**.
   - Click the show filter menu icon to filter records based on the status of a service. The different statuses of a service are **Draft**, **Published**, **Retired**.
   - You can also filter the services by clicking **Show globally accessible**. You can also include/exclude the globally accessible services by checking/unchecking the **Show globally accessible**.
   - You can click **Name** and **Date modified** column headers to sort records.
   - You can select a namespace from the **All namespaces** drop-down list. The list of services in the page changes based on the selected namespace. You can select "All namespaces" to see all of the services for which you have access.
   - You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.
3. You can select the following actions from the overflow menu of a service: **Add version**, **Duplicate**, **Rename service**, **Change Category** and **Delete**.
4. Expand the service to view the following details: **Version name**, **Status**, **Associated instances** and **Created**. You can select the following actions from the overflow menu:

   - Draft : Edit/Copy/Deploy/Publish/Delete
   - Published: View/Copy/Deploy/Retire
   - Retired: View/Copy/Delete
5. Click the service for which you want to see the details.

   The name of the service and the status of the service is displayed. From the overflow menu, you can **Add Version**, **Duplicate**, **Change category** and **Delete** actions. This menu changes as per the status of the service version.

   - The **Overview** tab of the service is displayed by default, and has the following sections:

     - Service details.
     - **Service version** - You can select the version of this service from the drop-down list.
     - **Features** - You can order the service using the chosen features.

- The **Versions** tab of the service has the following sections:
  - **Default version** - You can change the default version of a service from this drop-down list.
  - **Search** version based on the status of a service version **Draft**, **Published**, **Retired**.
  - You can click **Version name** or **Created** column headers to sort the records.
  - Each version has the following actions from the overflow menu: **View details**, **Edit details**, **Edit version** and **Delete**.
  - You can click a service version to edit it. For service details, see Creating a Service.
- The **Associated instances** page displays the details of all the instances that are associated with a particular version of a service. In this tab, click the **Actions** overflow menu of the associated instance record to **View Details** of that instance, **Edit**, **Custom actions**, **Retry**, **Resume**, **Terminate** or **Delete**. The menu options are based upon the status of the associated instance.

Importing a service

You can import a service from your git repository.

About the task

You can import a service that is in service composition language version V3. However if you try to import a service that is in service composition language version V1 or V2, then an error message is displayed.

After importing a service, a service gets created with all the versions. If the service does not have any versions, it gets imported with a default version *1.0.0.0*.

Note: Services are provided by Managed services in the Manage service library of GIT repository for you to download and use. For the entire list of services, see Managing services in service library.

Before you begin

Before you import a service, do the following tasks:

- Fix the service definition that has a non-existent template version.
- Ensure that the service is free of any errors.

Procedure

1. In the navigation bar, click **Library** > **Services**. The Manage service library is displayed.
2. Click **Import service**.
3. Select either of the following options in **Assign access** section:
   - **Make this service globally accessible** - Services created globally are accessible to all users.
   - **Make this service part of a namespace** - Associate the service with a specific namespace. For this option, you must select a **Namespace** from the drop-down list to which the template must be assigned.

     Based on the value selected in the namespace drop-down list on the **Services** main page, the **Assign access** and **Namespace** values are automatically selected. Modify the values if you want.
4. From **Import service source** drop-down list, select any of the following values:
   - **GitHub**
   - **GitLab**
   - **Bitbucket server**
5. Enter the following details of your selected repository:
   - For both **GitLab** or **GitHub**, enter the following details:
     - Enter a repository URL, an access token, the relative directory of your service, and the related branch.

       The service must be in JSON format. For example, if the service is stored in a GitHub repository at **`vsphere/vsphere-example.json`**, then you must specify the following values:
       - **GitHub repository URL**: **`https://github.com/geekbass/terraform`**
       - **GitHub access token**: It is the token required to access GitHub template files. You can find it in your GitHub user account, and is not required for public projects. For example, **`aaa`**.
       - **GitHub repository sub-directory**: **`vsphere`**
       - **GitHub reference (branch or tag)**: **`master`**
   - For **Bitbucket server**, enter the following details:
     - **Bitbucket repository URL** - The location where Bitbucket service files can be referenced from.
     - **Bitbucket access token** - The token used to access the Bitbucket service files.
     - **Bitbucket repository sub-directory** - The path relative to the Bitbucket location where service files can be referenced from.
     - **Bitbucket reference** - Select **Branch** or **Tag** option and enter the name of the tag or branch.
6. Click **Import**. The import is successful unless there are errors in the service.

Editing a service

You can edit a service from the Manage service library page.

About the task

You cannot edit published services. To modify a published service, make a copy of the service and then modify it.

Procedure

To edit a service, follow these steps:

1. In the navigation bar, click **Library** > **Services**. The Manage service library is displayed.
2. Search for your service by using any of the following search filters:
   - Enter your service name in **Search services**.
   - Click the show filter menu icon to list services based on their status.
   - You can click the column headings of **Name** and **Created** to sort the list.
   - You can also select the provider or type to list services based on your selection.
   - You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.
   - You can select a namespace from the **All namespaces** drop-down list. The list of service in the page changes based on the selected namespace. You can also select "All namespaces" to see all the service for which you have access.
3. Expand the service to see the list of versions. For the service version record you want to modify, select **Edit** option in the **Actions** overflow menu of a version.
4. Edit service details. For service details, see Creating a service. From the Edit service actions overflow menu, you can do the following actions:
   - Draft : Edit/Copy/Deploy/Publish/Delete
   - Published: View/Copy/Deploy/Retire
   - Retired: View/Copy/Delete
5. Save the changes.

Assigning access to a service

Procedure to assign access to multiple namespaces of a service.

Procedure

1. In the navigation bar, click **Library** > **Services**. The Manage service library is displayed.
2. In the overflow menu of the service, click **Assign access**.
3. In the **Assign access** dialog box, select the namespaces. You can select a single or multiple namespaces to which the user has access.
4. Click **Assign**.

Scenarios

- You can set or change a single or multiple valid namespaces to a service. The valid namespaces are those which the user has access to.
- A change in service namespace reflects in all its versions too.
- A service with multiple namespaces can be deployed only in any of the user accessible namespaces to which a service belongs.
  - **Example**: A service `S` belongs to namespaces `N1`, `N2`, and `N3`. User `U` has access to `N2`, `N3`, `N4`. Allowed namespaces for deployment are `N2` and `N3`.
- For a service, removal (multiple namespaces), change (single namespace) or add (Global to single or multiple namespaces) is allowed if the namespace of the associated service instance is present in the new namespace list.
  - **Example 1**: If service `S1` (globally accessible) is deployed in namespaces `N1` and `N2` (one service instance in `N1` and one in `N2`) then you can allow to update the namespaces of `S1` only if it includes `N1` and `N2`. That is, `S1` can be updated to `N1` and `N2` but not to `N2` and `N3`.
  - **Example 2**: If a service instance `SI` of service `S` is deployed in namespace `N2`, then service `S` won't be allowed to change namespaces from `N1`, `N2`, and `N3` to `N1` and `N3`, removing `N2` until service instance `SI` is deleted.
- Cloud connections, shared parameters, and templates should either be global in nature or of a namespace to which a service belongs (service instance, in the case of SMTP connection).

Note: It is recommended to avoid composing a service with multiple namespaces that has templates or cloud connections from multiple namespaces. Even though the service belongs to multiple namespaces, it can be deployed in only one namespace and the activities by using or belonging to other namespaces fail.

Duplicating a service

Procedure to duplicate a Managed services service and all of its versions.

About the task

There are two ways by which you can access the duplicate feature:

- Click **Duplicate** in the overflow menu of a service record in the **Library** > **Services** page.
- In the **Overview** page of service deployment, click **Duplicate** from the overflow menu.

Procedure

1. In the navigation bar, click **Library** > **Service**. The Manage service library is displayed.
2. In the overflow menu of the service you want to duplicate, click **Duplicate**.
3. Enter the **Service Name**.
4. In the **Duplicate service** page, select either of the following options in **Advanced > Assign access** section:
   - **Make the service globally accessible** - Services created globally are accessible by all users.
   - **Make this service part of a namespace** - Associate the service with a specific namespace. For this option, you must select a **Namespace** from the drop-down list to which the service must be assigned.

   Note: If you create a service in a specific namespace, then you can deploy the service only to that namespace.
5. Click **Duplicate**. All the versions of this service are duplicated as Draft.
6. Modify the details of the service based on your requirement. For more information to update the tabs, see Editing a service.
7. Click **Save**.

Changing a service category

You can change a service category from the Manage service library page.

To change a service category, follow these steps:

1. In the navigation bar, click **Library > Services**. The Manage service library opens.
2. Search for your service by using any of the following search filters:
   - Enter your service name in **Search services**.
   - Click the show filter menu icon on the right of the search instance filter to list services based on their status.
   - You can click the column headings of **Name** and **Created** to sort the list.
   - You can also select the provider or type from the list to filter services based on your selections.
   - You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.
   - You can select a namespace from the **All namespaces** drop-down list. The list of services in the page changes based on the selected namespace. Along with the records of the selected namespace, all globally accessible records are available in the list. You can select "All namespaces" to see all of the services for which you have access.
3. Select **Change category** option from the overflow menu for the service record you want to change category.
4. In the **Change category** window, select a category from the **Category** drop-down list. There must be more than one category to move the service. From this page, you cannot create a new category.
5. Click **Change category**. The category of the service is changed based on your selection.

Deleting a service

You can delete an existing service from the Manage service library.

Procedure

1. Go to the Manage service Library page.
2. From the overflow menu of a service record, select **Delete**.
3. In **Delete service** page, enter "delete" and click **Delete**.
4. All the versions associated with that service gets deleted.

   Notes:

   - The default version of the service can not be deleted.
   - Service deletion deletes all the versions of the service if there are no associated instances.

Saving a service to different repositories

You can create or edit a service and save it to a GitHub, GitLab, or Bitbucket Server repositories.

Procedure

1. From the overflow menu of the service, click **Push to GIT**.
2. In the **Push Service To Git** page, select any of the following values from the **Import template source** drop-down list:
   - **From GitLab**
   - **From GitHub**
   - **Bitbucket Server**
3. Enter details of the selected repository:
   - For **From GitLab** or **From GitHub**, enter a repository URL, an access token, the relative directory of your service, and the related branch. The service must be in JSON format. For example, if the service is stored in a GitHub repository at **`vsphere/vsphere-example.json`**, you must specify the following values:
     - **GitHub Repository URL**: `https://github.com/geekbass/terraform`
     - **GitHub Access Token**: `aaaaaaaaaa` It is the token required to access GitHub template files. You can find it in your GitHub user account.
     - **GitHub Repository path to service**: `vsphere`
     - **GitHub Ref (branch)**: `master`
     - **Commit Message** - Enter a commit message to push the changes into the GIT hub repository.
   - For **Bitbucket**, enter the following details:
     - **Bitbucket Repository URL** - The location where Bitbucket service files are stored.
     - **Bitbucket Access Token** - The token used to store the service in Bitbucket.
     - **Bitbucket Repository sub-directory** - The path relative to the Bitbucket location where the service is stored.
     - **Bitbucket Reference** - Select **Branch** or **Tag** option and enter the name of the tag or branch.
4. Click **Push to GIT**.

Service level actions

The following actions are handled at the service level.

Tasks that you can perform to manage services are as follows:

- Creating a service
- Viewing service details
- Assigning access to a service
- Editing a service
- Importing a service
- Duplicating a service
- Changing category
- Deleting a service

Service version level actions

The following actions are handled at the service version level.

Tasks that you can perform to manage service versions are as follows:

- Adding a service version
- Copying a service version
- Deleting a service version
- Publishing a service version
- Deleting a service version
- Retiring a service version

Adding a service version

You can create multiple versions of a single service, providing flexibility when managing a service and the supporting end user needs.

About the task

There are three ways by which you can add a service version:

- Click **Add version** in the overflow menu of a service record in the **Library** > **Services** pane.
- In the **Overview** pane of a service, select **Add version** from the overflow menu.
- **Version details** section on Overview tab when you create/edit service.

Procedure

1. In the navigation bar, click **Library** > **Services**. The Manage service library is displayed.
2. In the overflow menu of the service you want to add version, click **Add version**.
3. Enter the **Version name**.
4. Select the version from the drop-down list of **Based on** version.
5. Click **Add**.
6. Modify the details of the service based on your requirement. For more information to update the tabs, see Editing a service.
7. Click **Save**.

Copying a service

You can copy a service version to a new service.

About the task

You can copy a retired service version record to a new service. The copied version is in Draft mode, and you can further edit it using the Edit service option.

Procedure

1. Go to the **Library** > **Services** pane.
2. Expand the service to see the service versions or click on the service to open the service details pane.
3. From the overflow menu of a retired service version record, select **Copy**.
4. Enter the new service version in the **Name** field.
5. Enter the service name in the **Copy to destination** field.
6. From the advanced options, select **Assign access**.
7. Click **Copy**.

Editing a service version

You can edit version details and also can upgrade/downgrade service instance to different service versions.

About the task

Notes:

- The upgrade/downgrade and edit flow is applicable only for active instances. If the active instance is in Error state, then Retry/Resume is performed first before upgrade/downgrade of a version.
- The edit flow of an active instance only considers the changes in input-parameter values, changes in the activity definition are not considered. If you need to apply changes in the activity definition, upgrade or downgrade flow must be used.
- All the defined activities are executed with the new input parameters values:
    - In case of unchanged activity, a modify/plan apply action is executed using new input parameters values.
    - In case you removed an existing activity and specified a new one, the previous activity is destroyed and the new one installed on upgrade or downgrade only.

Procedure

1. In the navigation bar, click **Library** > **Service**. The Manage service library is displayed.
2. In the overflow menu of the service you want to edit, click **Edit**.
3. In the **Version details** section on Overview tab, click **Edit details**.
4. Modify the **Version name**.
5. In the **Upgrade** tab, select the version to be upgraded. You can upgrade from a lesser than a current version.
6. In the **Downgrade** tab, select the version to be downgraded. You can downgrade from a higher version.
7. Click **Save**.

Publishing a service version

You can publish a service version and perform operations on it.

Procedure

1. Go to the **Library** > **Services** pane.

2. Expand the service record to see all the versions.
3. From the overflow menu of a service version record, select **Publish** option. If there are errors in your service version, then **Service failed to publish** message is displayed with details of the error. Fix those errors and retry the publish operation. Alternatively, you can open the service in edit mode and click **Publish**. If your service has validation errors, then the **Publish** button is disabled.
4. In **Publish service** confirmation message, click **Publish** to proceed. On successful completion of publish, a confirmation message is displayed. The published service is displayed in the Service library.

   Note: In **Library** > **Services** pane, a published service version has **View**, **Copy**, **Deploy**, and **Retire** options in the actions overflow menu. You cannot delete or edit a published service version, but you can retire the service version and delete it. After you retire a service version from the Manage service library, refresh the library page for the status to show up in the user interface.
5. To view and deploy the published service, click **View published service** in the success confirmation message.

   In the **Library** > **Services** pane, click **View** option or **Deploy** option in the overflow menu of the published service record to view or deploy the service respectively. You can also deploy the published service from the **View** page. To create a service instance, see Creating a service instance.

Deleting a service version

You can delete an existing service version from the Manage service library.

Procedure

1. Go to the Manage service Library page.
2. Expand the service record to see the list of versions.
3. From the overflow menu of a service version record, select **Delete**.
4. In **Delete service version** page, enter "delete" and click **Delete**.

   Notes:

   - A default service version cannot be deleted. To delete a default version, make other version as default version.
   - The deployed instances that are associated with this version cannot be modified after deleting service version.
   - In a service where upgrade/downgrade path is mentioned for a particular version, on deleting that version, an error message is displayed to the user. The user needs to manually remove the entries from the source code for the missing version.

Retiring a service version

You can retire a published service version.

About the task

You cannot retire a draft service version from the user interface, however, you can retire it by using API commands. For the API details, see Service and service instance APIs.

You can retire a particular service version by using the following methods:

- Manually retire a service version
- Auto-retire a service version

Manually retire a service version

1. Go to the **Library** > **Services** pane.
2. Expand the service to see the service versions or click the service to open the service details pane.
3. From the overflow menu of a published service version record, select **Retire** option. On successful completion, a **Retire service** confirmation message is displayed.
4. In the **Retire service** confirmation message box, click **Retire**. The status of the record changes to "Retired".

   Note: The overflow menu of a retired service version has **View**, **Copy**, **Delete** options.

Auto-retire a service version

You can set a retirement date for a published service version. The service version is retired on that particular date and the status of service version is changed to `Retired`. This is useful where you want to keep a service version available for the user to deploy for a certain period only. A retired service version cannot be deployed.

1. Go to the **Library** > **Services** pane.
2. Expand the service to see the service versions or click the service to open the service details pane.
3. From the overflow menu of a published service version record, select **Set retirement** option.
4. Select the retirement date.
5. Click **Save**.

Unretiring a service version

You can unretire a retired service version.

About the task

For the API details, see Service and service instance APIs.

Procedure

1. Go to the **Library** > **Services** page.
2. Expand the service to see the service versions or click on the service to open the service details page.
3. From the overflow menu of a retired service version record, select **Unretire** option. On successful completion, a **Unretire service version** confirmation message is displayed.
4. In the **Unretire service version** confirmation message box, click **Unretire**. The status of the record changes to "Published".

Managing service instances

Create and manage the service instance details. Terminate or delete the service instances that are not needed anymore.

- Creating a service instance
- Creating bind instances for service instances
- Managed services Kubernetes resource controller for services
- Editing a service instance
- Upgrading or downgrading a service instance
- Viewing service instance details
- Terminating and deleting a service instance
- Resuming or retrying a service instance

Creating a service instance

You can search and create service instances of published offerings from the Managed services catalog. You can customize the service instances based on your requirement and use it in the overall application development.

Before you begin

If you are using tags in your service, see Prerequisites for tags.

Procedure

To create a service instance, follow these steps:

1. In the navigation bar, click **Library > Services**. The Manage service library is displayed.
2. Search for your service by using any of the following search filters:
   - Enter your service name in **Search services**.
   - Click the show filter menu icon to list services based on their status.
   - You can click the column headings of **Name** and **Created** to sort the list.
   - You can also select the provider or type to list services based on your selection.
   - You can use the pagination drop-down to select the number of records you want to display in a page at a time.
   - You can select a namespace from the **All namespaces** drop-down list. The list of services in the page changes based on the selected namespace. You can select "All namespaces" to see all of the services for which you have access.
3. Click **Deploy** in the overflow menu of your service tile.

As an alternative, you can click the service to preview its **Overview** and **Associated instances** details.

The **Associated instances** page displays the details of all the instances that are associated with the service. In this tab, click the **Actions** overflow menu of the associated instance record to **View details** of that instance.

4. Go through the details of the service. You can see the following details of the service in the **Overview** page:
   - Chart version, published date, and type
   - **Details** section has a long description of the service.
   - For additional information about the service, see the **Useful links** section. It has **Documentation** and **Support link**.
5. Select your plan and click **Next**.
6. Enter the **Name** of the service instance.

   Notes:
   - The service instance name must begin with an alphabet and must have a combination of only these characters: [a-zA-Z][a-zA-Z0-9_-].
   - If service instance has an application activity then the service instance name should consist of lower case alphanumeric characters, '-' or '.', and must start and end with an alphanumeric character.
7. For globally accessible services, you can select a namespace from the **Namespace** drop-down list. For other namespaces, the option is not enabled for selection.
8. Consider the following for dynamic cloud connections in the service definition:
   - If you have defined a parameter of type connection in the service definition and linked it to the **Cloud connections** parameter value, then the parameter is displayed here as a drop-down list. For example, you have created "Conn" as a parameter of type connection, then "Conn" drop down list is displayed. For the complete input_parameter format for "conn" definition in the **Source code** tab, see Different ways of adding values for the cloud connection in Templates topic. This drop down list fetches all global cloud connections of the provider mentioned in the input_parameter. For example, if the provider is VMware vSphere, then the drop down list includes all global cloud connections of VMware vSphere provider. If you change the **Namespace** value, the drop-down value contains a list of global cloud connections that are tagged to the selected namespace and are associated to the provider.
9. Consider the following for dynamic shared parameters in the service definition:
   - If you have defined a parameter of type sharedparameter in the service definition and linked it to a Data Object value, then the parameter is displayed here as a drop-down list. For example, you have created "shared" as a parameter of type sharedparameter, then "shared" drop down list is displayed. For the complete input_parameter format for "shared" definition in the **Source code** tab, see Shared parameters in Templates topic. This drop down list fetches all globally defined Data Objects of the Data Type that is mentioned in the input_parameter. If there are more than one Data Object for the selected Data Type, then you must define a default Data Object. By default, this default value is preselected for the "shared" parameter drop down. If you change the **Namespace** value, the drop-down value contains a list of global Data Objects that are tagged to the selected namespace and are associated to the Data Type.
10. Enter the values for the selected plan parameters.

    Note: If a value is not available for a non mandatory service or activity parameter referenced within a plan parameter, the service instance fails with an error message. For example, you have referenced the `cc` parameter of an email notification activity in a plan parameter. If the value for the non-mandatory `cc` parameter is not available, then the service instance fails with the following error message:

    ```
    Service deploymentError: Invalid resource : ${parameters.cc} (hint: 'cc' not found)
    {"error":{"statusCode":500,"message":"Internal Server Error"}}
    ```
11. If you have any tags created for the service, then select your tag.
12. Click **Create instance**. A message confirming the successful submission of a service instance request is displayed. You can go to **Deployed instances** page to view the status of the current deployment or go to **Library** to create more instances.

Results

- If your service instance completes successfully, then the deployed instance status changes from `In Progress` to `Active`. If an activity component of a service instance fails, then the deployed service instance is marked as error.
- If you use a long running Business Process Manager template in your service that requires human intervention for claim and approval, the status of the service instance deployment changes to "Wait" state and in the activity instances, the status changes to "Waiting" state. To know the state and piid number, go to **Log file** tab > **Activity log** of the service instance. This piid is the stack id in Managed services. The Business Process Manager administrator logs in to the ProcessPortal dashboard to claim and approve the pending tasks. When the polling activity detects that the process is complete, the service instance state moves from "Wait" to "In progress" and then subsequently to the "Active" state based on the service flow. The activity instances of the service instance also move from "Waiting" to "Created" state.
- If SMTP connection is used in your service, then a primary connection for the selected namespace is retrieved first and in the absence of that connection, search is done for a globally accessible primary connection. If both primary connections do not exist, then a secondary connection is attempted in the same sequence as the primary connection. In the absence of both primary and secondary connections, an error message is added to the logs.

Creating bind and custom action instances for service instances

From the deployed service instance page, you can perform the bind or custom action.

About this task

Limitations:

- You can create any number of bind instance records for a service instance. However, only one bind instance can be created at a time. - You must wait for a bind instance to complete before you create another.
- Bind is available only for services instances that are in active state.
- You cannot deploy a bind instance before the service instance creation is complete.

For more bind related limitations, see Troubleshooting Service Composer or Portal issues.

Procedure

1. Navigate to the deployed instances page, by using one of these methods:
   - In the navigation bar, click **Deployed instances** > **Services** tab.
   - Alternatively, any operational user can access the instances page through the service library. From the IBM Cloud Pak for AIOps console, click **Automate infrastructure** > **Service library**. The **Instances** tab shows the deployed instances.
2. Search for your service instance.

   Note: You can also use the following search filters:

   - Enter the name of the instance in the search instance filter.
   - Click the show filter menu icon to filter records based on the status of a record. The different statuses of a service instance are **Active**, **In progress**, **Error**, and **Terminated**.

     Note: The **Wait** status is available whenever you use long running Business Process Manager template in your service.
   - You can click **Name** and **Ordered on** column headers to sort records. The **Name** also includes the namespace details. In addition, you have **Service offering** and **Status** column headers.
   - You can select a namespace from the **All namespaces** drop-down list. The list of service instances in the page changes based on the selected namespace. You can select "All namespaces" to see all of the service instances for which you have access.

   You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.
3. There are two ways to select **Custom actions**:
   - From the overflow menu of the service instance, select **Custom actions**.
   - Click on the service instance to view the details and select **Custom actions** from the overflow menu.
4. A **Custom actions** dialog box opens with the list of bind and custom actions.
5. Select the action and click **Next**, a service deployment page is displayed. It is called **Bind service instance** page for bind action.
6. Optionally, update the parameter values as required.
7. For Bind action, Click **Bind instance**. For custom actions, click action name button for executing this custom action. A new instance record is included in the **Overview** tab > **Custom action instances** section of the deployed instance. In the **Overview** > **Action** section, you can view the status of the operation. Click **View log** to view the log information of the bind action.
8. You can select **UnBind** action from the overflow menu of the bind instance records. The bind instance record changes from Active state to Terminated state.
9. From the **Overflow** tab > **Action** section, you can track the unbind operation. Click **View log** to view the log information of the unbind action.

Managed services Kubernetes resource controller for services

The Managed services Kubernetes custom resource definition and controller provides you with the ability to deploy and delete Managed services service instances using Kubernetes yaml resource files. With this capability, a single Kubernetes yaml can be created to deploy a composite application that consists of both Kubernetes deployable resources and traditional infrastructure resources, which are deployed with Terraform in Managed services. A typical containerized application is an example of a Kubernetes deployable resource. Examples of traditional infrastructure resources are virtual machines, storage, and so on.

About the task

The Managed services Kubernetes resource controller deploys the Managed services service and waits for Active status. If the deployment Fails, then the controller continues to issue Resume requests until the service becomes Active.

Before you begin

A role binding must be defined for a user or group to have the authority to deploy a service in Managed services.

The following is an example for the `icp:camgroup:operator` user group:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
   name: icp:camgroup:operator:service
roleRef:
```

```
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: cam-controller-manager-role
subjects:
- apiGroup: rbac.authorization.k8s.io
  kind: Group
  name: icp:camgroup:operator
```

Procedure

- Deploying a Managed services service
- Displaying the status of a Managed services service
- Deleting a deployed Managed services service

Deploying a Managed services service

1. Go to your Kubernetes environment that is the same as Managed services.
2. Create your YAML file. The file allows the definition of the service deployment to be placed under the source control, which allows changes to be tracked. An example Managed services Kubernetes service resource controller yaml file is:

```
apiVersion: cloudautomationmgr.ibm.com/v1alpha1
kind: Service
metadata:
  name: service-test-vsphere-1
  namespace: "default"
spec:
  connection: "camDc2Rtp"
  service:
    name: "LrhNodeOnSingleVM-vsphere"       //Instance that you are going to deploy
    instance_plan: "host-164"
    action: "Provision"                      //The action is provision.
    parameters:
      templateParameters: []
      specifications:
        parameters:                          //The parameters that are passed with the instance
          vSphereConfig: vSphere-CAMDC2
          vm_ipv4_address: "9.9.9.9"
          vm_name: "camc-vis232c-vm-164"
          vm_dns_servers:
          - "9.9.9.9"
          vm_dns_suffixes: ["rtp.raleigh.ibm.com"]
```

   - **parameters** - It is a collection of name-value pairs that map to the Managed services Service Input Parameter Key and Value. For example:

```
parameters:
  vSphereConfig: vSphere-CAMDC2
  vm_ipv4_address: "9.9.9.9"
  vm_dns_suffixes: ["rtp.raleigh.ibm.com"]
```

   - **secretParameters** - (Optional) List of Managed services secret parameter data objects to use with the deployed service. For example:

```
secretParameters:
        name: vm_password_lrh
        secretKeyRef:
                name: vm-password-lrh-secret
                key: password
```

     where

     name: name of service parameter

     secretKeyRef:

     name: Name of the Kubernetes secret

     key: key is the name of the secret data defined in the secret

3. Run the following kubectl command to deploy a Managed services service:

```
kubectl apply -f <yaml file name>
```

Displaying the status of a Managed services service

1. Verify the status of a deployed Managed services service by using either of the following commands:

```
kubectl describe -f <yaml file name>
```

   or

```
kubectl describe services.cloudautomationmgr.ibm.com service-test-vsphere-1 -n default
```

   Example:

```
Name:         service-test-vsphere-1
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
```

```
                {"apiVersion":"cloudautomationmgr.ibm.com/v1alpha1","kind":"Service","metadata":{"annotations":
{},"name":"service-test-vsphere-1","namespa...
 API Version:  cloudautomationmgr.ibm.com/v1alpha1
 Kind:         Service
 Metadata:
   Creation Timestamp:  2019-08-09T19:50:52Z
   Finalizers:
     Service.cloudautomationmgr.ibm.com
   Generation:        2
   Resource Version:  6549804
   Self Link:         /apis/cloudautomationmgr.ibm.com/v1alpha1/namespaces/default/services/service-test-vsphere-1
   UID:               feadd3c9-bade-11e9-a019-00163e01cbab
 Spec:
   Secrets:
     Env:
   Service:
     Action:         Provision
     instance_plan:  Standard
     Name:           LrhNodeOnSingleVM-vsphere
     Parameters:
       Specifications:
         Parameters:
           V Sphere Config:  vSphere-CAMDC2
           vm_datacenter:    CAMDC2
           vm_dns_servers:
             9.42.106.3
           vm_dns_suffixes:
             rtp.raleigh.ibm.com
           vm_ipv4_address:  9.46.126.166
           vm_name:          camc-vis232c-vm-166
 Status:
   Action:  provision
   Conditions:
     Last Transition Time:  2019-08-09T19:53:43Z
     Reason:                Active
     Status:                True
     Type:                  provision
   Message:
   Service ID:              5d4dce9d5b972d001dc804d8
   Status:                  Active
 Events:
   Type    Reason                 Age    From                     Message
   ----    ------                 ----   ----                     -------
   Normal  provision:Submitted    2m51s  cam-controller-service  provision status changed for default/service-test-
vsphere-1
   Normal  provision:In Progress  2m32s  cam-controller-service  provision status changed for default/service-test-
vsphere-1
   Normal  provision:Active       1s     cam-controller-service  provision status changed for default/service-test-
vsphere-1
```

- The Status fields returned from the **kubectl describe** command:
  - Action - Last action performed, that is provision, resume, delete
  - Message - Last error message, blank if no error message.
  - Service ID - Managed services service ID of the deployment.
  - Status - Status of the last action performed.
  - Conditions
    - Last Transition Time - Last update time of the condition.
    - Reason - The status of the Managed services action.
    - Status - It is 'True' when the condition is valid.
    - Type - The type of the condition - the Managed services action (For example, provision, resume, delete).
  - Outputs
    - Name - Name of the output parameter.
    - Type - The type of the parameter, that is, string, list, map.
    - Value - The value of the output parameter in JSON format.
- The Event fields returned from the **kubectl describe** command are Type, Reason, Age, and From. Example:

```
Type    Reason                 Age    From                     Message
----    ------                 ----   ----                     -------
Normal  provision:Submitted    6m53s  cam-controller-service  provision status changed for default/service-test-
vsphere-1
Normal  provision:In Progress  6m34s  cam-controller-service  provision status changed for default/service-test-
vsphere-1
Normal  provision:Active       4m3s   cam-controller-service  provision status changed for default/service-test-
vsphere-1
```

2. Optionally, you can also use Managed services Kubernetes controller startup parameters - controller parameter. They are defined in **cam-controller-statefulset.yaml** file. The args parameters are specified in the pod definition.

   The **-syncPeriod** is a controller parameter for the time duration between resource status checks. Value units are 's', 'm', 'h'." (Default is 2m).

   For example:

   - -syncPeriod=2h30m
   - -syncPeriod=300s
   - -syncPeriod=30m

Deleting a deployed Managed services service

If you no longer require the deployed instance of a service instance, run either of the following commands to delete it:

```
kubectl delete -f <yaml file name>
```

or

```
kubectl delete services.cloudautomationmgr.ibm.com service-test-vsphere-1 -n default
```

Note: The command deletes the Managed services instance. After the Managed services instance is successfully deleted, the Kubernetes resource that represents the Managed services instance is also deleted.

Editing a service instance

You can edit any active deployed service instance after selecting the required service instance and editing the parameters.

The following table shows how the different activities are managed during the Edit action when the Editable flag is checked for an activity:

Activity	Action on Edit
Terraform template	Modified (Depends on the template provider)
Rest Hook	Destroyed and re-created
Email notification	Executed again
Helm Chart	Destroyed and re-created
Decision	Not supported
BAW/BPM template	Not supported
Ansible credential	Destroyed and re-created
Ansible inventory	Destroyed and re-created
Ansible template	Executed again

Notes:

- The activity parameters, which are parameterized by using the service input parameters can only be edited by using this feature.
- If you change an activity instance from `Editable` to `non-Editable` or vice versa after the service is deployed, then Edit service instance action is not affected due to this change.
- If there are no input parameters or if the values of input parameters are not changed during the edit service instance, the edit action does not take place.
- If a service includes Helm and/or Ansible job activities, after editing the deployed service instance where input parameters are changed for other activity and not for Helm and Ansible job activities, the Helm and Ansible activities are also destroyed and re-created.
- In case where one activity depends on another activity, after an Edit action, if the first activity is destroyed and re-created then the other activity also gets destroyed and re-created. If you want to edit only the first activity, make the other activity as non-editable so that it does not participate in the Edit action. After Edit action, only the first activity gets destroyed and re-created.

To edit a service instance:

1. Navigate to the deployed instances page, by using one of these methods:
   - In the navigation bar, click **Deployed instances** > **Services** tab.
   - Alternatively, any operational user can access the instances page using the service library. From the IBM Cloud Pak for AIOps console, click **Automate infrastructure** > **Service library**. The **Instances** tab shows the deployed instances.
2. In the Deployed Instances page, you can see a list of all deployed instances. Each instance record has name, service offering, status, and the time of order.
3. Edit the deployed active instance by using any of the following methods:

   a. Search for your deployed instance by using any of the following search filters:

   - Enter your instance name in **Search instances**.
   - Click the show filter menu icon to filter records based on the status of a record. The different statuses of a service instance are **Active**, **In progress**, **Error**, and **Terminated**.

     Note: The **Wait** status is available whenever you use long running Business Process Manager template in your service.
   - You can click **Name** and **Ordered On** column headers to sort records. The **Name** also includes the namespace details. In addition, you have **Service Offering** and **Status** column headers.
   - You can select a namespace from the **All namespaces** drop-down list. The list of deployed services in the page changes based on the selected namespace. You can select "All namespaces" to see all of the deployed services for which you have access.
   - You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.
   - Click the **Edit** in the overflow menu. You can edit parameters of any Active service instance.

   b. The service instance edit action can also be selected from the service instance details page.

   - Click the service instance to be edited.
   - Click **Edit** from the Actions overflow menu of the service instance details page.

   c. Alternatively, you can also edit the service instance by selecting the service first and then its associated instance.

- From the menu bar, click **Library** > **Services**.
- Click the wanted service from the list of services.
- Click the **Associated instances** tab and select the instance and click **Edit** from the overflow menu.

4. Confirm **Edit** in the **Edit service instance** dialog box.
5. You can Modify or Delete the service tags. For more information about adding tags, see Creating a service.

   Notes:

   - You can modify only user added tags and not system tags.
   - To **Delete** the service tag, click the delete icon on the right side of the text box.

6. Modify the required parameters. For more information about creating user-defined parameters, see Creating new input and output parameters.

   Notes: The service input parameters, which are marked as Editable during creation can only be updated here.

   If the **Editable** is not checked for an activity and the user edits the service instance, then the service input parameter values are updated in the service instance but in actual resource the parametrized property value is not be changed.

7. Click **Perform action**. The **Planned changes** page is displayed.
8. Verify the log output and then click **Edit instance**. The service instance is redeployed with the latest modifications.

Upgrading or downgrading a service instance

You can upgrade or downgrade a particular active service instance. The upgrade or downgrade service version must be selected while creating or editing a service version. See Adding a service version or Editing a service version for more details.

Note: You can upgrade or downgrade a particular active service instance only by using the plan selected during initial service deployment. Upgrade and downgrade of an active service instance from Plan A to Plan B is not supported.

The following table shows how the different activities are managed during the Upgrade/downgrade action when any value of the activity changes between versions:

Activity	Action on Upgrade/downgrade
Terraform template	Modified (Depends on the template provider)
Rest Hook	Executed again
Email notification	Executed again
Helm Chart	Destroyed and recreated
Decision	Executed again
BAW/BPM template	Executed again
Ansible credential	Destroyed and recreated
Ansible inventory	Destroyed and recreated
Ansible template	Executed again

Note: If the activity ID of an activity changes, the activity is destroyed and recreated.

Procedure

1. Navigate to the deployed instances page, by using one of these methods:

   - In the navigation bar, click **Deployed instances** > **Services** tab.
   - Alternatively, any operational user can access the instances page through the service library. From the IBM Cloud Pak for AIOps console, click **Automate infrastructure** > **Service library**. The **Instances** tab shows the deployed instances.

     In the deployed instances page, you can see a list of all deployed instances. Each instance record has name, status, service offering, user ordered, and the time of order.

2. Search for your deployed instance by using any of the following search filters:

   - Enter your instance name in **Search instances**.
   - Click the show filter menu icon to filter records based on the status of a record. The different statuses of a service instance are **Active**, **In progress**, **Error**, and **Terminated**.

     Note: The **Wait** status is available whenever you use long running Business Process Manager template in your service.

   - You can click **Name** and **Ordered On** column headers to sort records. The **Name** also includes the namespace details. In addition, you have **Service offering** and **Status** column headers.
   - You can select a namespace from the **All namespaces** drop-down list. The list of deployed services in the page changes based on the selected namespace. You can select "All namespaces" to see all of the deployed services for which you have access.
   - You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.

3. Click **Upgrade** or **Downgrade** from the overflow menu of the service instance. The other way to upgrade or downgrade is to click the service instance and click **Upgrade** or **Downgrade**. These options are available only when Upgrade or Downgrade is specified while adding a new service version or editing a service version.
4. Click **Upgrade** or **Downgrade** in the confirmation dialog box.
5. A **Upgrade service instance** page is displayed where you can edit service input parameters before upgrading or downgrading an instance.
6. A **Planned changes** page is displayed with the log output. Verify the output and click **Upgrade** or **Downgrade** if the log output looks ok.
7. The service instance is upgraded or downgraded to the desired service version.

Viewing service instance details

After you order a service, you can view its details from the Deployed Instance page.

Procedure

1. Navigate to the deployed instances page, by using one of these methods:
   - In the navigation bar, click **Deployed instances** > **Services** tab.
   - Alternatively, any operational user can access the instances page through the service library. From the IBM Cloud Pak for AIOps console, click **Automate infrastructure** > **Service library**. The **Instances** tab shows the deployed instances.

     In the deployed instances page, you can see a list of all deployed instances. Each instance record has name, status, service offering, user ordered, and the time of order.
2. Search for your deployed instance by using any of the following search filters:
   - Enter your instance name in **Search instances**.
   - Click the show filter menu icon to filter records based on the status of a record. The different statuses of a service instance are **Active**, **In progress**, **Error**, and **Terminated**.

     Note: The **Wait** status is available whenever you use long running Business Process Manager template in your service.
   - You can click **Name** and **Ordered on** column headers to sort records. The **Name** also includes the namespace details. In addition, you have **Service Offering** and **Status** column headers.
   - You can select a namespace from the **All namespaces** drop-down list. The list of deployed services in the page changes based on the selected namespace. You can also select "All namespaces" to see all deployed services for which you have access.
   - You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.
3. Click the service instance for which you want to see the details. Alternatively, you can click the **View details** in the overflow menu.

   The name of the order and status of the order is displayed. From the overflow menu, you can **Rename** an order name or **Reorder** the service.
   - The **Overview** tab of the instance is displayed by default, and it has the following sections:
     - Service offering section from where you can **Redeploy instance**.
     - Instance Details section that has information about the owner, order time, created time, and plan name.
     - Action section that has the statuses of all deployments and bind/custom operations. Click **View log** to view the log of an operation.
     - Activity Instances section that has a list of all template instances that are used by the service. When you create a service, you provide an instance name for the template in the **Composition** tab. The name of the instance is prefixed by the order name followed by the instance position. For example, if the order name is `R001` and it is the first instance of the template, then the name of the record in this section is `R001_00_<template instance name>`.
     - Custom Action Instances section that has all the created bind as well as custom instances along with their status. You can unbind a **Bind** action, from the overflow menu. For more information, see Creating bind instances for service instances. Every action has input or output parameters.
     - Output parameters tab lists all the output parameters of a deployed service.
     - Service parameters tab lists all the deployment parameters of the service.
   - Tags tab displays all tags that were created while defining the service.
   - In the **Log file** tab, you can view the service deployment log file and the template deployment log file. Use the **Copy logs** if you want to copy the logs in to a text file.

Note: If the Log exceeds the maximum size of 200 KB, then only the last 200 KB of the Log is displayed.

Terminating and deleting a service instance

You can terminate a service instance from the deployed service instances. After you terminate a service instance, it goes to the `Destroyed` state and then the **Delete** action is enabled. If you delete the instance that is in `Destroyed` state, then all the IDs are cleaned up from Terraform jobs database and the IaaS database.

Procedure

1. Navigate to the deployed instances page, by using one of these methods:
   - In the navigation bar, click **Deployed instances** > **Services** tab.
   - Alternatively, any operational user can access the instances page through the service library. From the IBM Cloud Pak for AIOps console, click **Automate infrastructure** > **Service library**. The **Instances** tab shows the deployed instances.
2. In the service instances list, click the **Actions** overflow menu of an active or error instance that you want to terminate. The action list displays.
3. Click **Terminate**.
4. In the Terminate Service confirmation window, click **Terminate**. All resources are destroyed from the Terraform and the service instance is in 'Destroyed' state.

   Success:
   - If all the activities / template of the deployed service instance are destroyed successfully, then the **STATUS** of the service instance changes from `Active` to `Terminated`. The **STATUS** of the templates in the template instance section changes from `Created` to `Terminated`.

   Failure:
   - If a template in the template instance section is already in `Failed` state, then the **STATUS** of the service instance remains in error state. The template remains in `Failed` state even after the completion of terminate operation.
   - Templates that are not destroyed during a service instance termination are never reattempted.

   For information about deleting template instances, see Deleting a template instance.
5. From the **Actions** overflow menu of a terminated service instance, click **Delete**. You can do a force delete on service instances that are in active or error states.
6. In the Delete Service confirmation window, click **Delete** for terminated service instances. For error or active service instances, enter "delete" in the confirmation window and then click **Delete** to force delete. A message confirming the initiation of delete action is displayed.
7. Click **Close** in the confirmation window. The successfully deleted service instance is no longer available in the deployed service instance list.

Note: If you attempt the `Terminate` action on the service instance, then the retry, resume, and bind options are not available in the user interface irrespective of the status of the terminate action.

Resuming or retrying a service instance

You can resume or retry a service instance that is in error state.

About this task

Resume and Retry actions are the redeployments of a service instance from the point of failure. However, Retry action destroys partially completed resources before proceeding with the deployment.

Note: If Managed services orchestration has multiple templates and a template fails in the workflow, then all subsequent templates are also not considered for deployment.

Example scenarios for a service that is defined to create two virtual machines:

- The deployment fails after it creates the first virtual machine. The Resume and Retry actions do not re-create the first virtual machine instead proceeds only with the second virtual machine.
- The deployment fails after it creates the first virtual machine and partially creates the second virtual machine. The Resume action resumes from the exact point of failure but Retry action destroys the partially created virtual machine and then proceeds with the redeployment.

Resume

Resume action works only with Terraform template. Only for Terraform template, it does plan and apply. For other activities, it performs retry action.

1. Navigate to the deployed instances page, by using one of these methods:
   - In the navigation bar, click **Deployed instances** > **Services** tab.
   - Alternatively, any operational user can access the instances page through the service library. From the IBM Cloud Pak for AIOps console, click **Automate infrastructure** > **Service library**. The **Instances** tab shows the deployed instances.
2. In the service instances list, click the **Actions** overflow menu of an error instance that you want to resume. The action list is displayed.
3. Click **Resume**. A **Resume service instance** confirmation box is displayed.
4. Click **Resume**. A **Resume service instance** page is displayed.
5. Select **True** to resume all the activities with updated values including those that are executed successfully. Select **False** to resume with values provided during the original deployment for the successfully executed activities and use the updated values from the point of failure.
6. Click **Resume instance**.

7. From the list of deployed instances, click **View details** for this record from the overflow menu. In the **Overview** page of the service instance, the status changes to "In Progress", and after successful resume operation, the status changes to "Active" state. If the deployment of the service instance fails, then an error message informing about the failure is displayed.

   Note: If you get a 401 error during resume operation, then clean the cache and retry.

Retry

1. In the navigation bar, click **Deployed instances > Services**.
2. In the service instance list, click the **Actions** overflow menu of an error instance that you want to retry. The action list is displayed.
3. Click **Retry**. A **Retry service instance** confirmation box is displayed.
4. Click **Retry**. A **Retry service instance** page is displayed.
5. Select **True** to retry all the activities with updated values. Select **False** to retry with values provided during original deployment for the successfully executed activities and use the updated values from the point of failed activity.
6. Click **Retry instance**.
7. From the list of deployed instances, click **View details** for this record from the overflow menu. In the **Overview** page of the service instance, the status changes to "In Progress", and after successful retry operation, the status changes to "Active" state. If the deployment of the service instance fails, then an error message informing about the failure is displayed.

Creating and managing custom action

Custom action helps to perform day-to-day actions on the provisioned service instance when attached to a service version.

For troubleshooting and limitations in the service composer, see Troubleshooting Service Composer or Portal issues.

Tasks that you can perform to custom actions is as follows:

- Creating a custom action
- Creating a custom action category
- Viewing custom action details
- Editing a custom action
- Assigning custom action to a service version
- Assigning access to a custom action
- Deleting a custom action

Creating a custom action

You can create a custom action from the Managed services service library page.

About the task

If there are any problems while you create, save, or lock your custom action, then warning or error messages display.

Procedure

1. In the navigation bar, click **Library** > **Custom Action**. The Manage service library displays.
2. Click **Create custom action**.
3. In the **Create custom action** window, enter the following details:
   - Select either of the following options in **Assign access** section:
     - **Make this custom action globally accessible** - Custom actions created globally are accessible to all users.
     - **Make this custom action part of a namespace** - Associate the custom action with a specific namespace. For this option, you must select a namespace from the dropdown list to which the template must be assigned.

     Notes:
     - Based on the value selected in the namespace dropdown list of the **Library** > **Custom Action** window, the **Assign access** and **namespace** values are automatically selected. Modify the values if you want.
     - If the custom action is defined as globally accessible, then only globally accessible resources are available in the composer. For example, globally accessible cloud connections, shared parameters, and content runtimes are only available in the custom action composition tab for a custom action that is defined as globally accessible.
     - If the custom action is defined in a namespace context, then only globally accessible resources and resources defined in the same namespace context are available in the composition tab of the custom action.
   - Enter the custom action name.
   - Optionally, select a category.

     If you do not specify any category, then the custom action is assigned to Cloud Actions category with custom action. You can select **Add a category** from the **Category** dropdown list to create a new category. If you select **Add a category**, then enter the name of the new category and click **Create**. The

Select from list allows you to go back to the original list of categories.

For information about categories, see Creating a custom action category.

Notes:

- The composer does not allow you to create duplicate custom action names.
- Custom action name must follow the Kubernetes naming convention, or else the locked custom action do not get listed in IBM Cloud Pak® for AIOps catalog:
  - Alphanumeric, underscore, hyphen, and space
  - Starts with an alphabet
- If you plan to lock a custom action, ensure that its name is less than 64 characters long. If you have more than 64 characters, then locking the custom action to IBM Cloud Pak® for AIOps may cause issues.

4. Save your changes. The custom action is displayed in a `Unlock` status in the Manage service library. The overflow menu of the unlock service record in the Manage service library page has **Edit**, **Assign access**, **Lock**, and **Delete**. The **Save** button is disabled if there are validation errors in the service.
5. If you want to assign custom action to service version, see Assigning custom action to a service version

Creating custom action categories

Create a category to organize your custom actions in the library.

Procedure

To create a category, follow these steps:

1. In the navigation bar, click **Automate Infrastructure** > **Library**. Click the **Custom Action** tab.
2. In the **Custom Action categories** pane, click **Add category**.
3. Enter a name for the category and click **Add**. When the category is created, a confirmation message displays.

Alternatively, when you create a service, select the **Add a category** item in the **Category** drop-down to create a new category. The naming convention for category name is as follows:

- Must start with a letter
- May contain alphanumeric, underscore, hyphen, and space characters

Viewing custom action details

After you create a custom action, you can view its details from the Services Library page.

Procedure

1. In the navigation bar, click **Library > Custom Action**.

   In the custom action page, you can see a list of all the custom action. Each custom action record has associated services and the date modified.

2. Search for your custom action by using any of the following search filters:

   - Enter your custom action name in **Search Custom Action**.
   - Click the show filter menu icon to filter records based on the status of a custom action. The different statuses of a custom action are **Locked** and **Unlocked**.
   - You can also filter the custom action by clicking **Show globally accessible**. You can also include or exclude the globally accessible custom action by checking or unchecking the **Show globally accessible**.
   - You can click **Name** and **Date modified** column headers to sort records.
   - You can select a namespace from the **All namespaces** dropdown list. The list of custom action in the page changes based on the selected namespace. You can select "All namespaces" to see all of the custom action for which you have access.
   - You can use the pagination dropdown to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.

3. Click the custom action for which you want to see the details.

   The name of the custom action and the status of the custom action is displayed. From the overflow menu, you can **Edit**, **Assign access**, **Lock**, **Unlock**, and **Delete** actions. This menu changes as per the status of the custom action.

Editing a custom action

You can edit a custom action from the Manage service library page.

About the task

You can edit locked custom action by changing the status to unlocked. Unlocked custom action can be performed only when the custom action is unassigned from all the service versions that was assigned previously.

Procedure

To edit a custom action, follow these steps:

1. You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.
2. You can select a namespace from the **All namespaces** dropdown list. The list of custom action in the page changes based on the selected namespace. You can also select "All namespaces" to see all the service for which you have access.
3. Edit custom action details. For custom action details, see Creating a custom action.

From the Edit custom actions overflow menu, you can do the following actions based on the status as mentioned below:

- Unlocked: Edit/Assign access/Lock/Delete
- Locked: Edit/Assign access/Unlock/Delete

4. Save the changes.

Assigning a custom action to a service version

Custom actions that are in locked state can only be assigned for a service version.

About the task

Procedure

1. In the navigation bar, click **Library** > **Service Library**. The Manage service library is displayed.
2. In the overflow menu of the service, expand the service and select the service version for which you want to assign the custom action.
3. Click **Assign custom action**.
4. All the custom actions are displayed.

   Note: If the service is assigned to a namespace, then you are displayed with the custom actions that are in the same namespace and global namespace. If the service is assigned to a global namespace, then you see the custom actions of global namespace.
5. Click **Next**
6. Expand the custom actions to add or link the provison action output parameters to the input parameters.
7. You can follow either one of the steps as per the requirement for input parameter.

   a. Click **Add** to add the value (**Note**: Add the correct value depending upon the data type of the input parameters).

   b. Click **Select** and choose from the dropdown list of the interpolated output parameter of the provison action to map the provison action output parameter.
8. Click **Assign**.

Note: If you wish to unassign a particular custom action, then click **Assign custom action** > deselect **Custom action** > click **Next** and **Assign**.

Assigning access to a custom action

Procedure to assign access to multiple namespaces of a custom action.

About the task

Procedure

1. In the navigation bar, click **Library** > **Service Library**. The Manage service library is displayed.
2. Select the overflow menu of the custom action for which you need to assign the access.
3. Click **Assign access**.
4. In the **Assign access** dialog box, select the namespaces. You can select a single or multiple namespaces to which the user has access.
5. Click **Assign**.

Scenarios

- You can set or change a single or multiple valid namespaces to a custom action. The valid namespaces are those which the user has access to.
- A custom action (in locked status) with multiple namespaces can be assigned to service version which has the same namespace associated with it. Global custom actions(in locked status) are available for all the service versions.

Deleting a custom action

You can delete an existing custom action from the Manage service library.

Procedure

1. Go to the Manage service Library page > select the **Custom Action** page.
2. From the overflow menu of a custom action record, select **Delete**.
3. In **Delete** page, enter "delete" and click **Delete**.
4. Custom action gets deleted.

   Notes: Delete action can be performed only when the custom action is not assigned with any service version.

About Managed services Content

The Managed services library comes pre-populated with sample Terraform templates to help you get started quickly. These templates can be deployed across supported clouds that include IBM Cloud, AWS, Azure, Google Cloud Platform, and VMware. The pre-populated sample templates are fully supported by IBM. The Supported Terraform Templates page lists all the supported templates and their repository location in GitHub.

In addition to these pre-populated templates, the GitHub repository contains templates that are provided as-is with no support. You can import these as-is templates using the instructions in Import Template section. If these templates do not satisfy your requirements, then you can fork the repository and change the template to suite your requirements.

The Terraform template content in Managed services library can be classified into starterpack, middleware, and integration contents.

Managed services Starterpack Library

The starterpack library content contains automation building blocks that deploy a select set of cloud-native payloads. Some automated deployments that you can perform with the included templates are:

- MEAN stack
- LAMP stack

The sources for the starterpack library templates are available at GitHub location. You can deploy the starterpack content templates using these instructions.

Managed services Kubernetes cluster templates

The starterpack library content also contains a set of templates to deploy Kubernetes cluster based on native Kubernetes services on public cloud and Import these clusters to the hub cluster.

The GitHub repository also contains as-is templates to deploy Red Hat OpenShift 3.x and 4.2 on VMware and AWS.

Managed services Middleware Library

The middleware templates are available at GitHub location. You can import them using the instructions in Import Template section. Some automated deployments that you can import from this location includes:

- IBM WebSphere Liberty V17
- IBM WebSphere Application Server ND V9
- IBM Db2 V11 or V10.5 stand-alone
- IBM MQ Series V8 or V9

The middleware library templates depend on Chef automation to perform the installation of the middleware products. The chef automation is driven by the Content Runtime environment.

A summary of available middleware templates and associated Chef cookbooks is available at GitHub.

The following links provide more information on the middleware templates.

- Middleware Templates Description: This page details the relevant aspects of Terraform templates used in Middleware library.
- Deploying Middleware Template: This page explains how to deploy a middleware library content.

Managed services Integration Library

Integration library templates provide examples on how to integrate with third party services using Terraform templates. These templates can be wrapped in Service Composer to control the execution.

Integration examples:

- InfoBlox Integraton
- ServiceNow CMDB Configuration Template
- IBM Cloud App Management integration. For more information about IBM Cloud App Management, see IBM Cloud App Management documentation.

Content Runtime Environment

The Content Runtime Environment is set up by deploying the content runtime templates. The following links provide more information on the Content Runtime Environment.

- Content Runtime Environment Overview: This page explains the concepts and architecture of Content Runtime Environment.
- Managing the Content Runtime: This page explains how to set up and manage the Content Runtime Environment.
- Content Runtime in Offline mode: This page details how to install Content Runtime Environment in offline mode (air-gapped system with no-internet).
- Managed services Content APIs - This page details APIs to manage Chef cookbooks and roles.
- Troubleshooting issues and useful links - This page details how to troubleshoot the issues related to Content Runtime environment and Middleware Templates.
- FIPS compliant Content Runtime Environment - This page details how to enable FIPS compliant Content Runtime Environment.

Custom Terraform providers provided by Managed services

CAMC provider

The middleware templates that leverage Chef cookbooks to deploy middleware uses Terraform CAMC provider to perform following Chef related operations:

- Chef bootstrap operation on the target node
- Deploys one or more Chef cookbooks and Chef roles on the target node
- Makes use of the chef-vault gem to store secrets, such as passwords and user names to be defined and used by cookbooks during the software deployment process.

In addition to these operations, Terraform CAMC provider can execute scripts and store the output for use by other resources in your Terraform template.

What's Next

Proceed to Offline Content Installation to know more about offline content template installation and content runtime installation.

Proceed to Starterpack and Integration Content to know more about starterpack and integration library content.

Proceed to Managing the Content Runtime to know more about Content Runtime Environment.

Proceed to Understanding and Deploying Middleware Content Templates to know more about middleware content.

Offline Content Installation

If you do not have internet connectivity while you are installing and configuring Managed services, you can clone the content templates from GitHub and then import them into IBM Cloud Pak for AIOps Managed services library.

IBM Cloud Pak for AIOps provides helper scripts that can be used to clone the content templates and download the prerequisites to setup offline Content Runtime.

To clone the templates, you need internet connection. After cloning the templates, you can:

- Load the cloned templates into your local Guithub Enterprise or GitLab behind the firewall and then import the templates into IBM Cloud Pak for AIOps Managed services

or

- Import the templates directly from cloned file or folder into IBM Cloud Pak for AIOps Managed services.

It is recommended that you load the cloned templates into your local Guithub Enterprise or GitLab and then import from the repository rather than importing them directly from file or folder. If you choose to import directly from file or folder, following helper scripts can be used to bulk import the templates.

- Bulk import starter library
- Bulk import content runtime

The Provisioning an offline Content Runtime provides detailed information on importing content runtime templates and other pre-requisites in an environment with limited or no internet connectivity.

Deploying a starterpack and integration templates

You can deploy the predefined templates in the Starterpacks and Integration Library to your cloud environment including VMware, IBM Cloud, Google Cloud, and AWS.

Deploying Starterpack and Integration Templates Overview

The templates that are pre-loaded during installation, can be deployed using the steps in the Deploying a template. If the template is not loaded you can import the template using the instructions in Importing a template and then deploy them. For an example on how to deploy a starter library template, see Deploying a Single Virtual Machine template.

The integration template ServiceNow CMDB Configuration Template is the only integration template that is pre-loaded. For information on how to deploy this integration template, see Integrating with ServiceNow CMDB.

Starterpack library also contains number of templates to create kubernetes cluster and import them as managed cluster. For information on how to deploy these templates read the following topics

- Deploying Kubernetes cluster
- Deploying OpenShift Container Platform
- Importing Kubernetes target cluster to hub cluster

Validate the deployment

After you deploy the template, you can validate the deployment by checking the logs displayed in the **`Log file`** panel of the deployed instance. You can also check the **`Output variables`** tab of the deployed template and confirm you see the desired output.

Troubleshooting

For details about troubleshooting issues when deploying templates, see Troubleshooting issues and useful links.

Deploying a VMware Single Server template

Deploy the **`SingleVirtualMachine for Terraform 1.x.x`** template in your environment.

Before you begin

VMware templates need to have vmware-tools installed or else the operating system configuration post the deployment is not possible.

Procedure

To deploy the **`SingleVirtualMachine for Terraform 1.x.x`** template, follow these steps:

1. In the navigation bar, click **Library** > **Terraform templates**. The template library is displayed.
2. Click **Starterpacks**.
3. Click **SingleVirtualMachine for Terraform 1.x.x**.
4. Read the information about the template and click **Deploy template**.
5. Enter the required parameters:
   - Specify the **Instance name**.
   - Select the **VMware** cloud connection.
   - Complete **Template parameters**
6. Click **Deploy**. The template instance window is displayed.

In the template instance window, you can see the instance status, the instance information, the related resource details, and the related input and output variables. You can view or copy the instance logs and you can also access the template from which the instance was deployed.

Integrating with ServiceNow CMDB

ServiceNow CMDB Configuration Template allows you to manage the creation and deletion of CMDB records as a part of deploying a Virtual Machine.

You can run this template after the successful execution of a Terraform template that creates a virtual machine. On deployment of this template CMDB Record is created or updated for the virtual machine. On destroy of the template, the CMDB Record is deleted. Ideally you would use this template as an activity in a service composed using service composer. This sample service illusrates how to use this template in a service.

Prerequisites

- A working version of Service Now addressable from the Terraform Engine.

Template Inputs

Variable	Description
cmdb_pass	User to connect to Service Now
cmdb_user	Administrative user password.
cmdb_instance	Target Service Now instance.
cmdb_key	Key value for the Server, this may be the host name. This field relates to the cmdb_ci_server name field.
cmdb_record	A Map of values that constitute the CMDB Record. The structure is user defined and must follow the fields described in the ServiceNow ci_cmdb_server record. The only mandatory value is the name field.

Creating a Change Risk Assessment

Complete the following steps to create and view a change request.

1. Within the IBM Cloud Pak® for AIOps WebUI, make sure ServiceNow Integration is set to the *Live data for continuous ticket data collection* mode. For more information, see step 11 of Creating a ServiceNow integration.
2. You also need a ServiceNow integration and a trained and deployed Change Risk model. For more information, see Training a Change Risk model.
3. Within your ServiceNow instance, go to **Change** > **All** to view all existing change requests.
4. Click **New** > **Create Normal Change**. Add a short description for your change. Then, click **Submit**. If ServiceNow sends you to another page, select **Change** > **All** and find the change ticket that you created.

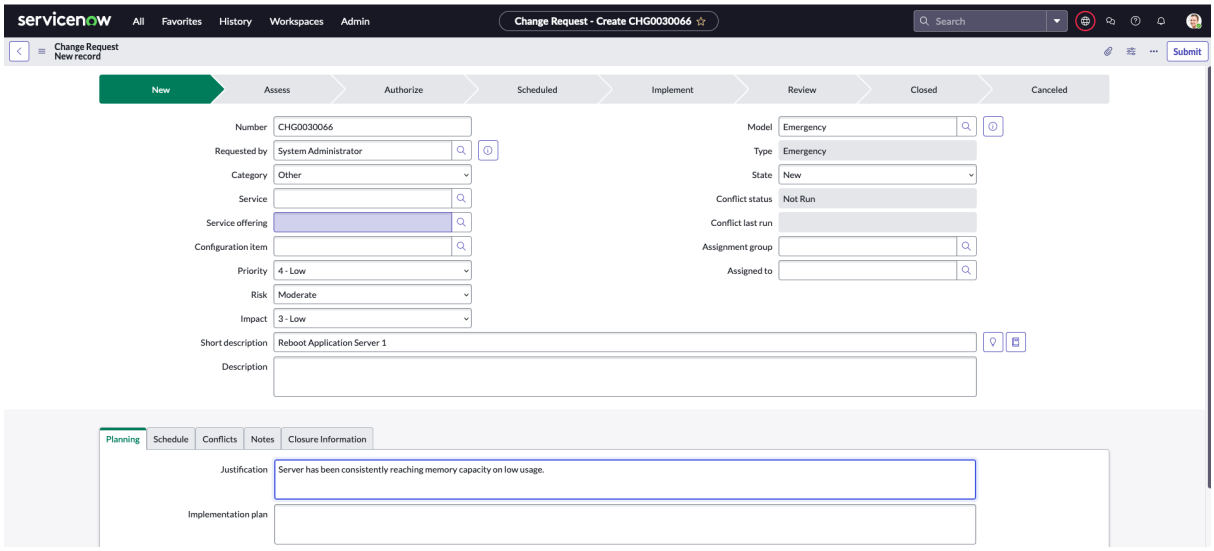

Figure. Change request short description

5. View the Change Request and the Change Risk Assessment tab.

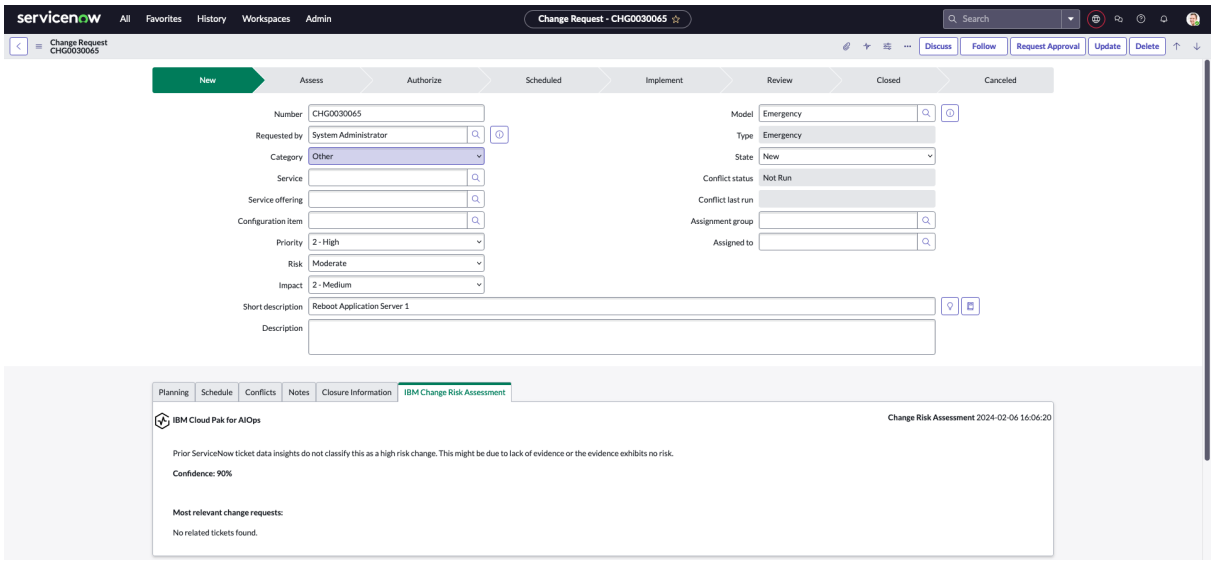

Figure. Change Request Assessment tab

Deploying OpenShift Container Platform on Managed services

There are many as-is OpenShift Container Platform templates available for deployment on Managed services.

The following table lists the templates that are available in Managed services, however, you must import it from Git repository:

Template name in Managed services Library	Description
OpenShift Container Platform Enterprise Installer for OpenShift 3.11	It install enterprise ready HA version of OpenShift Container Platform within your VMware Hypervisor and AWS environment.
OpenShift Container Platform Enterprise Installer for OpenShift 4.2	It install enterprise ready HA version of OpenShift Container Platform within your VMware Hypervisor environment.
OpenShift Container Platform Single Node Installation	It is a deployment wherein all OpenShift nodes are deployed in a single server.
OpenShift modules	OpenShift modules

The supported version of OpenShift Container Platform is 3.11 and 4.2.

Deploying Kubernetes Service cluster on public cloud

You can deploy Kubernetes Service cluster into public clouds, such as IBM Cloud, Amazon Web Services, Microsoft Azure and Google Cloud, and Red Hat OpenShift Kubernetes Service into IBM Cloud using the following templates.

As a first step to integrate, deploy the Kubernetes cluster service with Managed services, create a connection to the Cloud Provider. After you create the connection, you can either deploy one of the following templates or you can create a custom service by using one of the following templates. You can also publish the service in IBM Cloud Pak for AIOps catalog to allow other users a simplified way to create their own clusters.

Template name in Managed services Library	Location and name in Git repository	Description
Managed Kubernetes Service within Microsoft Azure	The `template_kubernetes_aks` Terraform template is available at Git repository.	This template deploys a Kubernetes cluster within Microsoft Azure's Kubernetes Service (AKS).
Managed Kubernetes Service within Google Cloud	The `template_kubernetes_gks` Terraform template is available at Git repository.	This template deploys a Kubernetes cluster within Google's Kubernetes Engine (GKE).
Managed Kubernetes Service within IBM Cloud	The `template_kubernetes_iks` Terraform template is available at Git repository.	This template deploys a Kubernetes cluster within IBM Cloud's Kubernetes Service (IKS).
Managed Kubernetes Service within Amazon Web Services	The `template_kubernetes_eks` Terraform template is available at Git repository.	This template deploys a Kubernetes cluster within Amazon Web Services (EKS).
Red Hat OpenShift single zone cluster on IBM Cloud	The `template_kubernetes_roks` Terraform template is available at Git repository.	The template deploys a Red Hat OpenShift on IBM Cloud (ROKS).

- Refer to Deploying IBM Cloud Kubernetes service template from Managed services for a sample usage on how to use a kubernetes cluster template in a Managed services service.
- Refer to Scaling nodes on IBM Cloud Kubernetes service for a sample usage on how to modify the number of worker nodes to scale up or down.

Working with IBM Cloud Kubernetes Service Template

As a prerequisite to deploying an IBM Cloud Kubernetes Service cluster, verify whether the resource group exists in IBM Cloud and the user ID that is used in IBM Cloud Provider cloud connection has access to this resource group.

As a first step to deploy IBM Cloud Kubernetes Service with Managed services, create a connection to the IBM Cloud Provider. This connection makes use of your IBM Cloud account's API key to communicate between Managed services and IBM Cloud.

After you create the connection, create a custom service by using the Managed Kubernetes Service within IBM Cloud template to deploy an IBM Cloud Kubernetes Service cluster. Deploying IBM Cloud Kubernetes Service template from Managed services describes how to create a custom service from the template. If you choose to add the optional VPN connection, refer to strongSwan Helm Chart on IBM Cloud Pak for AIOps.

After the cluster is created, you can use Deploying helm-tiller template to add Helm and tiller to the cluster.

You can modify the number of nodes in the default pool to scale up and down. For more information, see Scaling nodes on IBM Cloud Kubernetes Service.

Deploying IBM Cloud Kubernetes Service template

Deploy and configure **`IBM Cloud Kubernetes Service for Terraform 1.x.x`** template in Managed services.

Before you begin

- You must have administrator privileges for the deployment of IBM Cloud Kubernetes Service cluster and charts into that cluster. If you do not have the privileges, contact your administrator.
- If you need to initialize helm for clusters that were not created by Managed services, then see Deploying helm-tiller template to add the tiller deployment. For more information about Helm init, see public Helm documentation for Helm init.

Procedure

1. Log in to Managed services.
2. From Managed services menu, go to **Library** > **Services**.
3. In the **Services** pane, click **Create a Service**.
4. Enter your service name and category and click **Create**.
5. Go to the **Composition** tab, drag **`IBM Cloud Kubernetes Service for Terraform 1.x.x`** from the **Templates** > **IBM** section. In Managed services **`IBM Cloud Kubernetes Service for Terraform 1.x.x`** is available in the **Library** > **Terraform templates** page.
6. In the **Basic information** tab > **Connections**, select the IBM Cloud connection from the drop-down list. For more information about IBM Cloud connection, see Configuring an IBM Cloud connection. Use this connection to deploy IBM Cloud Kubernetes Service cluster from Managed services. If you are using a IBM Cloud Kubernetes cluster that is already available in IBM public cloud, see Configuring IBM Cloud Kubernetes Service.
7. Drag any Helm chart based on your requirement.
8. In the **Basic information** tab > **Connection**, pass the output of **`IBM Cloud Kubernetes Service for Terraform 1.x.x`** Terraform template activity in the **Connection** field. The format to provide the value is **`${templates.<activity id>.output.cluster_name`**. For example, **`${templates.ibmcloudcf954ae7.output.cluster_name}`**. The cloud connection is auto-generated.
9. In the **Parameters** tab, select your **namespace**. The values vary based on your connection.

   Note: The **image-repository** is a read-only value. As long as the file is accessible by the cluster, it is usable by the Helm chart. You can deploy a chart that point to images in the public cloud repository. IBM Cloud Kubernetes Service has its own repository of Helm charts. If you want to integrate that, then go to IBM Cloud Pak for AIOps console and add the repository. To configure repositories in IBM Cloud Pak for AIOps, do the following steps:

   1. Go to IBM Cloud Pak for AIOps.
   2. Click **Manage** > **Helm repositories**. You can see a list of Helm repositories that are configured for IBM Cloud Pak for AIOps. You can click **Sync repositories** to add new repositories. For more information about configuring your repositories in IBM Cloud Pak for AIOps, see IBM Cloud Pak for AIOps IBM Documentation.
10. Save and deploy the service. It creates an IBM Cloud Kubernetes Service cluster and installs Helm tiller on the cluster automatically. This fully integrated and initialized cluster is available for Managed services to deploy Helm charts.

Note: If the following error message is displayed in the activity logs, then ensure that the helm tiller is configured on their IBM Kubernetes Service cluster: **`Error: could not find tiller`**

11. Optionally, when you want to connect workloads in public and private cloud, then deploy VPN Helm charts into the IBM Cloud Kubernetes cluster. You can also create a new service to do the VPN Helm charts deployment and configure a secure connection between the external cluster and IBM Cloud Pak for AIOps.

    Note**: Workaround for strongSwan Helm Chart to work on IBM Cloud Pak for AIOps, see strongSwan Helm Chart on IBM Cloud Pak for AIOps section.
12. Manage clusters from Kubernetes dashboard:

    1. After you deploy the service, go to **Deployed instances** and open your service.
    2. Go to the **Overview** tab > **Activity instances** section.
    3. Click the instance name link. It takes you to the IBM Cloud console where the cluster is running.
    4. Click **Kubernetes dashboard**.
    5. Select your namespace. All of the active workloads are displayed. You can view running pods, discover and perform load balancing, scale deployments, and add replicas from the dashboard.

Deploying helm-tiller template

Deploy helm-tiller template on existing IBM Cloud Kubernetes Service cluster.

Procedure

1. Log in to IBM Cloud: https://console.bluemix.net/containers-kubernetes/clusters.
2. Create a cluster and wait until the cluster is in ready state.
3. Log in to IBM Cloud Pak for AIOps console and click **Automate infrastructure>Managed services**.
4. Create IBM Cloud Kubernetes service connection and connect to the deployed IBM Cloud Kubernetes Service cluster. For the actual steps, see Configuring IBM Cloud Kubernetes Service.
5. Retrieve the IBM Cloud Kubernetes Service cluster and Auth info for the helm-tiller template deployment.
   1. Go to https://console.bluemix.net/containers-kubernetes/clusters.
   2. Follow all the steps there to configure IBM Cloud Kubernetes Service cluster access by using CLI.
   3. Run the export command to export an API key and then log in to bluemix through CLI.

```
export BLUEMIX_API_KEY=<Bluemix Api Key>
```

The output of **ibmcloud cs cluster-config <cluster name>** gives the location of your cluster configuration files. For example:

```
export KUBECONFIG=/home/developer/.bluemix/plugins/container-service/clusters/<cluster name>/<tiller yml file>
```

4. Go to folder that contains the configuration file. For example:

   ```
   cd /home/developer/.bluemix/plugins/container-service/clusters/<cluster name>
   ```

   There are two files in this folder.

   For example:

   ```
   ca-dal13-jeff-iks-tiller.pem
   kube-config-dal13-jeff-iks-tiller.yml
   ```

5. In Mac OS, open the following configuration files

   ```
   base64 xxxxxxx.yml > config
   base64 xxxxx.pem > auth
   ```

   In Unix/Linux, open the following configuration files:

   ```
   base64 -w 0 xxxxxx.yml > config
   base64 -w 0 xxxxxx.pem > auth
   ```

   When you deploy helm tiller template from starterlibrary, do the following steps:

   - Enter the contents of **config** file in the **Cluster configuration** field
   - Enter the contents of **auth** file in the **Cluster certificate authority** field

6. Submit deploy and ensure that the deployment completes successfully:

   Run the following command to verify whether the tiller is installed on IBM Cloud Kubernetes Service cluster that is located in the same environment as your configured IBM Cloud Kubernetes Service cluster:

   ```
   kubectl get pods -n kube-system -l app=helm
   ```

   Example output:

   ```
   NAME                             READY     STATUS    RESTARTS   AGE
   tiller-deploy-6cddf6cc56-8hk22   1/1       Running   0          22h
   ```

strongSwan Helm Chart on IBM Cloud Pak for AIOps

Procedure to get strongSwan Helm Chart working on IBM Cloud Pak for AIOps.

Procedure

1. Connect to IBM Cloud Pak for AIOps virtual machine using SSH credentials.
2. Copy the **etcd-secret** as **calico-etcd-secrets** with a command:

   ```
   kubectl -n kube-system get secrets etcd-secret -o json |  jq '.metadata.name = "calico-etcd-secrets"' |  kubectl -n
   kube-system  create -f -
   ```

   Note: If you do not have **jq** installed, run the following command to install:

   ```
   apt install jq
   ```

3. Update **calico-config configMap** to add the etcd endpoint details.

   Example snippet to add the etcd_endpoints into calico-config configMap:

   ```
   Get the etcd endpoint details
   ~# etcd_ep=kubectl -n kube-system get cm etcd-config -ojsonpath={.data.etcd_endpoints} -n kube-system; echo
   "$etcd_ep"
   https://9.9.9.9:4001 <===== This is just in our example.
   Execute the following command to edit the calico-config
   kubectl -n kube-system edit cm calico-config
   scroll down in the editor to see the contex
   etcd_ca: /calico-secrets/etcd-ca
   etcd_cert: /calico-secrets/etcd-cert
   etcd_key: /calico-secrets/etcd-key
   ```

   The following is an example when you add **etcd_endpoints**:

   ```
   etcd_ca: /calico-secrets/etcd-ca
   etcd_cert: /calico-secrets/etcd-cert
   etcd_key: /calico-secrets/etcd-key
   etcd_endpoints: https://9.9.9.9:4001 <===== This is just in our example. Use the value specific to your env found
   through $etcd_ep
   ```

4. Save and close the editor.

5. When installing the helm chart, set the parameter `privilegedVpnPod` to true in the config file of strongSwan.

Scaling nodes on IBM Cloud Kubernetes Service

Modify the number of nodes in the default pool to scale up and down.

About this task

Group of Worker nodes with identical configuration are added to a worker pool. A worker pool can be associated with multiple zones. Both single zone and multi-zone clusters are supported. A default zone is automatically created so you do not have to explicitly create one. For this release, only the default worker pool is supported.

Procedure

1. Go to **Library** > **Terraform templates**.
2. Search for `IBM Cloud Kubernetes Service` template and deploy it.

   For the steps to deploy the cluster, see Deploying IBM Cloud Kubernetes service template from Managed services.
3. Go to **Deployed instance** > **Terraform templates**.
4. Open the deployed instance of your template.
5. Go to **Modify** tab.
6. Select the version of the template and click **Next**.
7. In the **Additional options** section, select a value in **Number of workers** to scale up the worker nodes.
8. Click **Plan changes**.
9. Check the log output to ensure that the worker node has scaled up or down correctly.
10. In the Apply Changes page, enter apply in **Confirm changes** and click **Apply**.
11. In the **Overview** > **Activity** section, check the status of the plan and apply.

Importing Kubernetes target cluster to hub cluster

You can import Kubernetes clusters from different cloud providers as targets to be managed by Infrastructure management. You can find more information on import in Importing a target managed cluster to the hub cluster.

Managed services provides the following templates to import clusters created on different Kubernetes cloud providers. Managed services provides a set of import templates that can be used on Infrastructure management installed with Red Hat® Advanced Cluster Management for Kubernetes and a set that can be used on Infrastructure management installed without Red Hat Advanced Cluster Management.

These templates are available in Managed services online version automatically. However, you must download it from Git repository for offline version. When you download the templates from the Git repository, ensure you download the right version of the template, as the branch is relative to Infrastructure management version.

Cluster import templates to be used on Infrastructure management installed with Red Hat Advanced Cluster Management

Template name	Location and name in Git repository	Description
Import Microsoft Azure Kubernetes Service into RHACM enabled IBM Cloud Pak for AIOps	The template is available at Git repository	This Terraform template imports an existing Microsoft Azure Kubernetes Service (AKS) Kubernetes cluster into your Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.
Import Amazon EC2 Kubernetes Service into RHACM enabled IBM Cloud Pak for AIOps	The template is available at Git repository	This Terraform template imports an existing Amazon EC2 Kubernetes Service (EKS) Kubernetes cluster into your Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.
Import Google Kubernetes Engine cluster into RHACM enabled IBM Cloud Pak for AIOps	The template is available at Git repository	This Terraform template imports an existing Google Cloud Kubernetes Engine (GKE) Kubernetes cluster into your Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.
Import IBM Cloud Kubernetes Service into RHACM enabled IBM Cloud Pak for AIOps	The template is available at Git repository.	This Terraform template imports an existing IBM Cloud Kubernetes Service (IKS) Kubernetes cluster into your Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.

Template name	Location and name in Git repository	Description
Import Red Hat OpenShift Kubernetes Service on IBM Cloud into RHACM enabled IBM Cloud Pak for AIOps	The template is available at Git repository.	This Terraform template imports an existing Red Hat OpenShift Kubernetes Service on IBM Cloud Kubernetes cluster into your Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.
Import OpenShift Container Platform Kubernetes cluster into RHACM enabled IBM Cloud Pak for AIOps	The template is available at Git repository.	This Terraform template imports an existing Red Hat OpenShift Container Platform (OCP) into your Red Hat Advanced Cluster Management enabled Infrastructure management hub cluster.
Import a Kubernetes cluster into RHACM enabled IBM Cloud Pak for AIOps	The template is available at Git repository	This Terraform template is a generic template that imports an existing Kubernetes cluster into RHACM enabled Infrastructure management.

Note: If you are using offline version of Infrastructure management, then you must use the template from repository template_import_rhacm and branch 5.2.0.

Managing Content Runtime

Before you can deploy virtual machines with Middleware Content installed and configured, run the following prerequisite steps.

Before starting, ensure that the System Requirements are met.

1. Starting from IBM Cloud Pak® for AIOps 4.6.0 release, terraform engine 0.11.x is not shipped with the product. The content runtime and middleware content requires terraform engine 0.11.x. You must use Create a version steps to first import the 0.11.x terraform engine before you deploy a content runtime.
2. Create a cloud connection. For information about creating a connection, see Managing connections.
3. Create the Content Runtime. For more information, see Provisioning and managing your Content Runtime infrastructure.
4. Set up the Software repository. For more information, see Managing a software repository
5. Check that the Middleware Templates are loaded.
6. Check that the IBM Middleware Cookbooks are loaded. For more information, see Kinfe Command Configuration.
7. The Content Runtime template scripts depend on Python for Operating System checks, so ensure that the Operating System image that is provided in the template has Python.

What to do next

Deploy a Middleware Template.

System requirements

Review the minimum system requirements for setting up and running the middleware Content Runtime within a virtual machine.

- Hardware requirements
- Supported operating systems and platforms
- Network requirements
- Port information for Content Runtime virtual machine

Hardware requirements

You must meet the following hardware minimum requirements:

- 4 CPU cores
- 8 GB memory
- 20 GB disk for Operating System
- 100 GB disk for Software Repository
- 40 GB disk for Docker production configuration (optional). For more information, see Production Docker.
- Content Runtime supports only x86 architecture.

Supported operating systems and platforms

The following operating systems and platforms are supported.

- Ubuntu 18.04 LTS
  - VMware Tools must be enabled in the image for VMWare template.
  - Ubuntu Repos with correct configuration must be enabled in the images.
  - Sudo User and password must exist and be allowed for use.
  - Firewall (through iptables) must be disabled.
  - SELinux must be disabled.
  - The system umask value must be set to 0022.
- Red Hat Enterprise Linux (RHEL) 7 (requires Docker-EE)
  - Needs RHEL 7.x image to be created, at least.
  - VMware Tools must be enabled in the image.
  - RHEL Satellite Repos with correct configuration must be enabled in the images.

        - Red Hat Enterprise Linux 7 Server (RPMs)
        - Red Hat Enterprise Linux 7 Server - RH Common (RPMs)
        - Red Hat Enterprise Linux 7 Server - Optional (RPMs)
        - Red Hat Enterprise Linux 7 Server - Supplementary (RPMs)
        - Red Hat Enterprise Linux 7 Server - Extras (RPMs)
    - Sudo user and password must exist and be allowed for use.
    - Firewall (through iptables/firewalld) is disabled.
    - SELinux must be disabled.
    - The system umask value must be set to 0022.
- CentOS 7
    - VMware Tools must be enabled in the image.
    - Sudo user and password must exist and be allowed for use.
    - Firewall (through iptables/firewalld) is disabled.
    - SELinux must be disabled.
    - The system umask value must be set to 0022.

Network requirements

- Static IPv4 address is assigned to each VM. No DHCP is used.
- A static IPv4 address is allocated and reserved prior to its usage.
- The IPv4 address is an IP in a private network that has egress-only access to Internet.
- In addition to IPv4 address, the Gateway, Prefix Length, DNS Suffixes, and DNS Servers need to be obtained prior to the deployment.
- Managed services instance is deployed in the same private network, so deploying from Managed services Instance to VMware environment is truly through private networking.
- The virtual machine must have a connection to the internet for the duration of the configuration process.

Port information for Content Runtime virtual machine

The following table lists the suggested settings for network and firewall:

Table 1. Port Information for Content Runtime

Network Environment	Private IP Only	Port Details
Private	Yes	Allow the following access for all sources on private interface: - SSH - ICMP - HTTP - HTTPS - TCP 8888 (non-secure software repository) - TCP 9999 (secure software repository) - TCP 5443 (pattern manager port)

Chef Versions

The following Chef Server and Client versions have been validated to be used for IBM provided cookbooks within CAM.

- Chef Server : 12.18.14
- Chef Client : 14.1.1

Docker and Docker Compose Versions

- Docker latest version, at the time of this document is : 20.10
- Docker Compose version, 1.11.2

VMWare ESXi Configuration

On an ESX/ESXi host, enable Network Time Protocol (NTP) Client, configure NTP Server, and ensure that the NTP Service is running.

Managed services Content

The Content Runtime environments consist of three key components: a pattern manager, a Chef server, and a software repository. These runtime environments run in your location and space on a single virtual machine (VM). You can have more than one runtime environment to serve different purposes, such as development, test, and production. There must be bidirectional network access between these runtime environments and the Managed services environment.

These advanced Content Runtime environments must be set up before you can deploy a pattern or template. The setup process is a one time step which is performed through the Managed services user interface by using Terraform templates.

As part of the Managed services installation, there is a Terraform Provider container that must have network access to communicate with the VM and network in which the runtime environments operate. It must also be able to communicate with the managed VMs. This container can communicate with the Content Runtime environments over either the public network or a virtual private network (VPN). If communication takes place over a private network, which can be either Amazon or IBM Cloud, the container must also include VPN services. The following Figure 1 illustrates this Managed services Content overview.

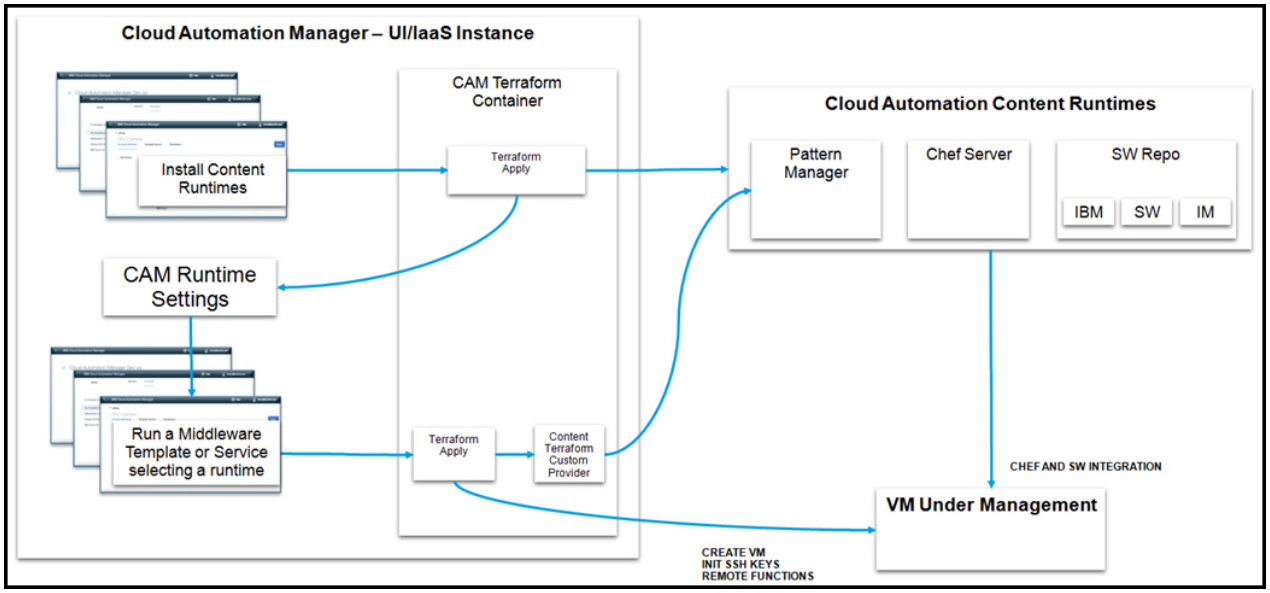

Figure. Managed services Content overview

For optimal performance, the runtime environments should be set up in a location that is geographically close to where you want to deploy your templates. After you configure a runtime environment, the settings are stored in a secure location in Managed services that identifies the deployed **`RUNTIME`** name and the associated settings, such as data center, IP address, and credentials. The settings are later injected as an input to a template during deployment when you select the **`RUNTIME`** name to use to deploy a template. All variables must be modeled in **`camvariables`** of the template that is being deployed to ensure the expected behavior during deployment. When you deploy a template, you select the target runtime environment and the system injects the associated values for that runtime environment into the pattern or template.

Important notes

- Consider where (for example, the region, the data center, and the environment) you want to deploy templates as you plan the setup of your runtime environment.
- Be sure to have a well-defined plan of your desired topology, taking into account available network communication.
- Be sure that the outputs that are stored from the runtime environment align with the expected inputs for your templates. If these outputs and inputs are not aligned, you are prompted to define the runtime parameters for each deployment, which can be difficult and error prone.

Managed services Content frameworks

The Managed services Content Middleware Template Library was built around a set of non-proprietary frameworks which are openly available.

Terraform and Chef were chosen for standardizing the IBM-created content due to the following key advantages:

- Popularity and growth with users.
- A community Model for development, support, and third-party tools.
- They are proven for Enterprises at scale.
- Support for hybrid environments (environments that are based both in the cloud and on-premises).
- Consistent automation format and management for IBM content.

Both communities provide learning resources:

- Terraform: https://www.terraform.io/intro/index.html
- Chef: https://learn.chef.io/#/

Note: Although the IBM Content is created using Terraform and Chef, Managed services does not preclude the use of other popular tools.

What to do next

The topics and tasks in this section guide you through configuring these runtime environments and deploying templates from the Middleware Template Content library. For more information, see Provisioning and managing the Content Runtime.

Enabling FIPS on Pattern Manager and Software Repository containers deployed by Advanced Content Runtime

FIPS is supported on Pattern Manager and Software Repository container deployed by Advanced Content Runtime starting from Advanced Content Runtime template version 2.5.

To enable FIPS, when you deploy the Advanced Content Runtime, set the value of attributes **Enable FIPS on pattern manager** and **software repository containers** to True. It configures the Pattern Manager and Software Repository container to operate in FIPS mode. After you deploy the template, you cannot change the FIPS

configuration on Pattern Manager and Software Repository container. To enable FIPS for Chef Server or Chef Client, you must provision the Chef Server and middleware templates that use chef client on a Red Hat 6 or 7 system. Chef do not support FIPS on Ubuntu. For more details on Chef FIPS support, see Chef documentation.

Provisioning and managing your Content Runtime infrastructure

Complete the following steps to configure your Content Runtime environment.

About this task

The Content Runtime is a virtual machine. A Chef server is installed on the virtual machine as part of the configuration of the Content Runtime. Two docker containers are installed on the machine to help communicate with the Chef server and to manage the software repository.

There are four templates:

- VMware
- Other
- IBM
- Amazon

The **`VMware`** template deploys a virtual machine to the target VMware vSphere cloud. The **`Other`** template deploys the Content Runtime to an existing virtual machine. This allows you to instantiate a virtual machine and perform as much or as little configuration as needed to create the Content Runtime. IBM and Amazon templates use a cloud provided Ubuntu 14.04 image as a deployment virtual machine.

The configuration process installs the following components on the Content Runtime virtual machine:

- Chef server
- Docker runtime
- Pattern manager docker container
- Software repository docker container

These components are illustrated in Figure 2. Components on the Content Runtime virtual machine.

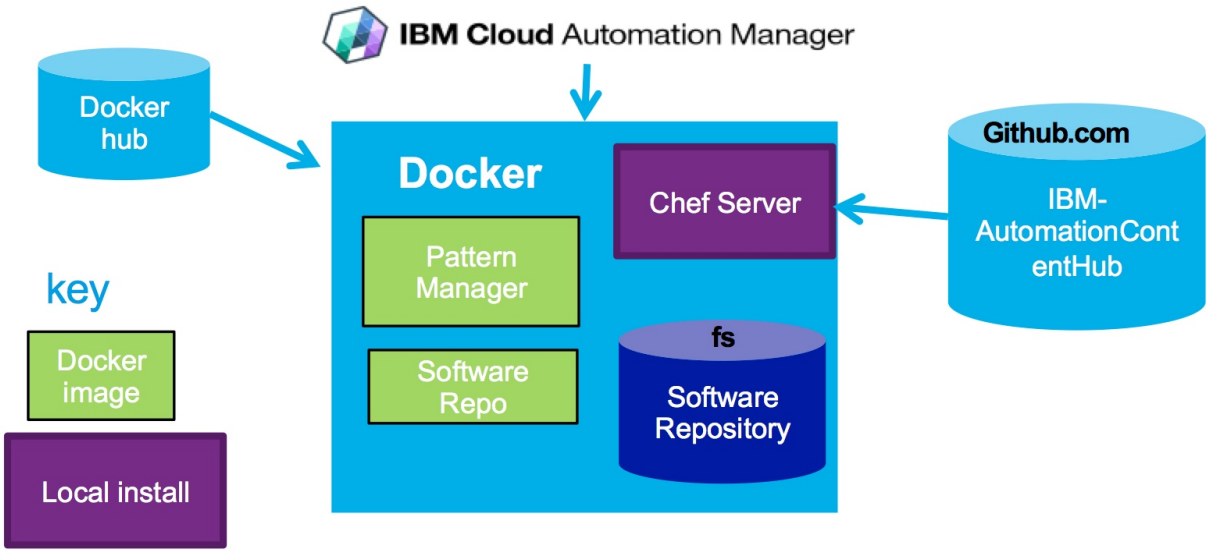

Figure. Components on the Content Runtime virtual machine

After you complete the task, you must populate the software repository on the file system of the Content Runtime virtual machine. See Populating the Software Repository and Populating the Install Manager Repository for more details.

Selecting a template

Before selecting a template, consider the following:

- VMware

  Beside the common parameters listed in the following section, you must have all the information needed to instantiate a virtual machine through the VMware vCenter. This information is entered in the Content Runtime template. The parameters are listed in the following Common Parameter Values section.

- Amazon Web Services

  When deploying an AWS EC2 instance, information such as the region (for example **`us-east-1`**), a VPC subnet ID and a security group ID will be required besides the common parameters. A private IP address associated to the provided subnet is optional.

  Note When providing a **`Key Name for Pattern Manager key set`**, the key needs to be created manually in the AWS EC2 dashboard. This can be done by accessing the **Key Pairs** page. Click **Import Key Pair** and provide the public key associated to the Pattern Manager. Selecting **Create Key Pair** will generate

a key which is not supported by the system.

- IBM Cloud

  An IBM Datacenter, such as **dal09** for Dallas 09, will be required alongside hardware specifications. The default values for these specifications are the minimum recommended for a Content Runtime deployment, but they can be tweaked. Optional settings include the ability to associate a portable IP address to the virtual machine.

- Other

  Beside the common parameters, the **Other** template allows you to provide the IP address of an existing virtual machine and login credentials to the Content Runtime template. An existing VMware vCenter, Amazon Web Services or IBM Cloud account can be used to manually create a virtual machine to be used. This may be the easiest solution for first time users.

Input parameter

For more information about public and private keys, see SSH Keys and related input required while deploying content runtime. Deploying a content runtime requires the following categories of parameters:

- For the cloud connection name, see Managing connections
- Connection information for the virtual machine: operating system credentials for the template
- New passwords and passphrases for the software repository content and pattern manager REST services
- SSH public and private keys for the pattern manager. It can be generated with the following commands:
  - In Mac OS:

    ```
    ssh-keygen -t rsa -f [output_keyfile] -N "" -C "";base64 [output_keyfile] > [output_keyfile].enc
    ```

  - In Unix:

    ```
    ssh-keygen -t rsa -f [output_keyfile] -N "" -C ""; base64 -w 0 [output_keyfile] > [output_keyfile].enc
    ```

  The [output_keyfile].enc output file is the encoded private key used. The [output_keyfile].pub file is the public key. The content of these files are used as input to the template.

  Note:

  - Pattern manager can only communicate with Linux guests. Even if cygwin is present, the Windows operating system is not supported.
  - For AWS and IBM Cloud, the generated public key must be imported as an SSH key pair. The name of this key pair will be used for part of the deploy process.
  - The pattern manager SSH public and private key must be a RSA key. The ED25519 algorithm (OpenSSH key) is not supported.

Parameter values which are grayed out are immutable values that are displayed as part of the Content Runtime template for informational value only.

The virtual machine must have a connection to the internet for the duration of the configuration process.

Template variables

The following tables contain a list of values which are required for creating the Content Runtime. In the first table, there are the values which are common for all providers followed by a table for specific values for each cloud provider.

- VMware Content Runtime template variables
- Other Content Runtime template variables
- IBM Content Runtime template variables
- Amazon Content Runtime template variables

Procedure

1. Start the creation process by displaying the menu in the Managed services user interface.
2. Select **Manage** > **Content runtimes**.
3. Click **Create content runtime**.
4. Select a namespace value from the **Namespace** drop-down list.
5. Enter a name for your Content Runtime. This name is used for selecting environment value to inject, so the name should be descriptive of the environment.
6. Select the Cloud Provider.
7. Select a value from the **Runtime** drop-down list. The values populated in the list are dependent on your cloud provider.
8. Click **Create**.
9. Select a cloud connection from the **Cloud connection** drop-down list.
10. Enter the remaining values for your Cloud Provider.
11. Click **Deploy**.

Result

- A virtual machine is created. The Content Runtime is configured on the virtual machine.
- Two disks are created:
  - 100 GB disk with mount point **/opt/ibm/docker/software-repo**
  - 25 GB root/boot disk

    - Optional: 40 GB Docker `direct-lvm` mode (only supported in the `Other` template, see Production Docker for more information)
- Docker-compose is installed on the machine to manage Docker images.
- Docker runs on the machine, with the following containers:
    - Pattern manager Docker container
    - Software Repository Docker container
- Cookbooks are pulled from GitHub and uploaded to the Chef server.
- When you deploy a new advanced content runtime, a data object containing it's meta-data is created. The name of the data object is same as the content runtime name and is of type `advanced_content_runtime_chef` Data Type. The namespace of the data object is same as the namespace of the content runtime. Optionally, if you want this data object to be available to middleware template deployments that are in a different namespaces, then make this data object as globally accessible.

If any problem occurs, see Troubleshooting and known issues.

Search for content runtimes

In **Content runtimes** page, you can use the following methods to search for content runtimes:

- When you want to view **Content runtimes** of a particular namespace, select a namespace from the drop-down list. The list of content runtimes in the page changes based on the selected namespace. You can also select "All namespaces" to see all content runtimes for which you have access.
- You can enter text in **Search items** to filter the content runtime list.
- You can use the show filter icon next to search text to filter records based on provider type.

Production Docker

Docker recommends configuring direct lvm mode for production environments.

The following two methods can be used to allow the Content Runtime to configure production docker:

1. `Other` template
    - Define a third disk of 40 GB before configuring the Content Runtime virtual machine. This method only works on machines that are not already configured.
2. On an existing Content Runtime virtual machine.
    - Add a 40 GB disk.
    - Delete the `daemon.json` with the command `sudo rm /etc/docker/daemon.json`.
    - Execute the command `~/advanced-content-runtime/launch-docker-compose.sh`.

Note: There is an underlying option missing on the `lvcreate` command on Ubuntu 14.04, therefore the Content Runtime does not attempt to configure `direct-lvm` on Ubuntu 14.04.

What to do next

- After the Content Runtime is deployed, you can log in to the Content Runtime virtual machine either by using the password or by using the SSH key.

  VMWare Cloud

  To log in to the Content Runtime deployed on VMWare, use the password if you had provided one during the deployment or use the SSH private key that is associated with the SSH public key. This SSH public key is the value you provided for input *User's Public Key*.

  IBM Cloud

  To log in to the content runtime deployed on IBM Cloud, do the following steps:

  1. Click the **Output variables** link in the Content Runtime deployed instance details page.
  2. Copy the value of Private Key for Content Runtime virtual machine by using the copy icon.
  3. Save the copied contents to a file and use this private key to SSH into the virtual machine. Alternatively, if you had provided a value for *User's Public Key*, then you can use the private key associated with this value.

  Amazon Cloud

  To log in to the content runtime deployed on IBM Cloud, do the following steps:

  1. Click the Output Variables link in the Content Runtime deployed instance details page.
  2. Copy the value of Private Key using the copy icon.
  3. Save the copied contents to a file and use this private key to SSH into the virtual machine. Alternatively, if you had provided a value for *User's Public Key*, then you can use the private key associated with this value.
- You must complete the Software Repository configuration step as described in Software repository configuration.

IBM Content Runtime template variables

The following tables list the IBM template variables.

Cloud Provider

The following table lists the parameters for a cloud provider.

Parameter	Default Value	Description
Virtual Machine's domain name		Virtual Machine's domain name for the Content Runtime Virtual Machine.
Public Key Name	cam_public_key	Provide a public key name. The key will be created and stored in the IBM Cloud as a resource with the name Hostname_PrivateKeyName. The private portion of the key can be found in the log file in the Terraform data.
OS Image Name	UBUNTU_16_64	An operating system reference code that is used to provision the computing instance.
Data Center		Specify the data center to create the Content Runtime virtual machine.
Private subnet		Private subnet for the private network interface of the instance. Accepted values are primary private networks and can be found in the subnets doc.
Private VLAN name		Private VLAN name for the network interface of the instance.
Dedicated Account Host		Specify whether or not the instance must only run on hosts with instances from the same account
Billing Type		Specify the billing type for the instance. The computing instance can be billed based on an hourly or monthly usage basis.
Network Connection Speed		Specify the connection speed for the instance's network components.
CPU cores		The number of CPU cores to allocate. The default value is sufficient for the Content Runtime.
RAM		The amount of RAM to allocate for the virtual machine. The default value is sufficient for the Content Runtime.

Cloud Provider Optional Settings

The following table lists the optional settings parameters for a cloud provider.

Parameter	Default Value	Description
Portable private IP address		Portable private IPv4 address to be assigned to this network interface for the Content Runtime virtual machine. If provided, the address needs to be static.
Portable private netmask		Portable private netmask for the private IP added to the new Content Runtime virtual machine. Required when assigning a portable IP address.
Portable private gateway		Portable private gateway address to be assigned to the new Content Runtime virtual machine. Required when assigning a portable IP address.

Additional Settings

The following table lists the additional settings parameters.

Parameter	Default Value	Description
Network Visibility		The network connection associated with the Content Runtime virtual machine instance. If network visibility is private, connection must exist from the IBM Cloud Pak for AIOps to the network connection associated with the Content Runtime virtual machine being created.

Managed services Parameters

The following table lists the parameters for Managed services.

Parameter	Default Value	Description
Enable FIPS on pattern manager and software repository containers	False	True to enable FIPS on pattern manager and software repository container.
Pattern Manager Access Passphrase		Passphrase used to access the REST API calls to the Pattern Manager.
Pattern Manager Administration Passphrase		Administration passphrase that is used to access the administrative REST API calls to the Pattern Manager.
Key Name for Pattern Manager key set		For Amazon and IBM clouds, the key must exist as a resource. For other provider types, the content is simply the name associated with the key.
Private Key for Pattern Manager - Base 64 encoded		Private key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must be base64 encoded and must be associated with the public key named by the Key Name for Pattern Manager key set.
Public Key for Pattern Manager		Public key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must match the public key named by the Key Name for Pattern Manager key set.
User's Public Key		Public key that is added to the Content Runtime virtual machine's `authorized_keys` file so as to allow access using the associated private key.
Content Runtime Host Name	ibm-content-runtime	The host name of the virtual machine being created to be used as the Content Runtime. The name is just the host name and not the fully qualified host name.

Note: For more information about generating public and private keys, see SSH Keys and related input required while deploying content runtime.

Docker & Chef Settings

The following table lists the parameters for Docker and Chef settings.

Parameter	Default Value	Description
Docker Registry	hub.docker.com	Docker registry to pull the Content Runtime Docker images. The images by default reside on the public Docker hub. The value is read only. It provides you the location where an image is pulled.
Chef License Agreement		Newer Chef Server, Client, Chef DK require license agreement with Chef for commercial. By typing Agree to this field you confirm that you are either using old chef version or you have the required license agreement.
ChefDK version	3.0.36	Stable version of Chef DK that will be installed on pattern manager container.
Docker Enterprise Edition Repository URL		This is an optional parameter. It is mandatory only if you use RHEL as the base image without Docker installed. RHEL supports Docker Enterprise Edition only. After you purchase the license, get the Docker Enterprise Edition Repository URL from https://store.docker.com/my-content. Docker Community Edition is used by default on other supported operating system.
Chef server Organization Name	chef-org	Chef server Organization name that is associated with the configuration of the Chef server.
Chef Administrator User name	chef-admin	Chef administrator user name that is associated with the configuration of the Chef server.
Chef Server version	12.11.1	Stable version of Chef server to install

Software Repository Settings

The following table lists the parameters for software repository settings.

Parameter	Default Value	Description
Software Repository User name	repouser	User name to access the Software Repository.
Password for Software Repository		Password for Software Repository User. The combination of user name and password is required to access the Software Repository.
Software Repository Port Number	8888	Port number for Software Repository HTTP access.
Software Repository Secure Port Number	9999	Port number for Software Repository HTTPS access.

Amazon Web Services Content Runtime template variables

The following tables list the Amazon template variables.

Cloud Provider

Parameter	Default Value	Description
AWS User ID	ubuntu	An internal field that is needed wherever an ID is required for an image.
Security Group ID		The ID of security group that exists in Amazon cloud. The security group is used while creating the Content Runtime virtual machine.
VPC Subnet ID		The VPC Subnet ID to use while creating Content Runtime. The subnet must exist in Amazon.
Amazon EC2 Instance Type	m3.large	The type of the Amazon EC2 Instance. The default setting is the recommended size for running the Content Runtime.
AWS region		The AWS region to create Content Runtime virtual machine

Cloud Provider Optional Settings

Parameter	Default Value	Description
Private IP Address		Static IPv4 address to be assigned to Content Runtime virtual machine. The provided IP address must be associated to the subnet id. If empty, AWS assigns an IP address that is associated to the subnet id.

Additional Settings

Parameter	Default Value	Description
Network Visibility		The network connection that is associated with the Content Runtime virtual machine instance. If network visibility is private, connection must exist between IBM Cloud Pak for AIOps and the network connection. The network connection is associated with the Content Runtime virtual machine that is being created.

Managed services Parameters

Parameter	Default Value	Description
Enable FIPS on pattern manager and software repository containers	False	True to enable FIPS on pattern manager and software repository container.

Parameter	Default Value	Description
Pattern Manager Access Passphrase		Passphrase used to access the REST API calls to the Pattern Manager.
Pattern Manager Administration Passphrase		Administration passphrase that is used to access the administrative REST API calls to the Pattern Manager.
Key Name for Pattern Manager key set		For Amazon cloud, the key must exist as a resource. For other provider types, the content is simply the name associated with the key.
Private Key for Pattern Manager - Base 64 encoded		Private key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must be base64 encoded and must be associated with the public key named by the Key Name for Pattern Manager key set.
Public Key for Pattern Manager		Public key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must match the public key named by the Key Name for Pattern Manager key set.
User's Public Key		Public key that is added to the Content Runtime virtual machine's `authorized_keys` file so as to allow access using the associated private key.
Content Runtime Host Name	ibm-content-runtime	The host name of the virtual machine being created to be used as the Content Runtime. The name is just the host name and not the fully qualified host name.

Note: For more information about generating public and private keys, see SSH Keys and related input required while deploying content runtime.

Docker & Chef Settings

Parameter	Default Value	Description
Docker Registry	hub.docker.com	Docker registry to pull the Content Runtime Docker images. The images by default reside on the public Docker hub. The value is read only. It provides you the location where an image is pulled.
Chef License Agreement		Newer Chef Server, Client, Chef DK require license agreement with Chef for commercial. By typing Agree to this field you confirm that you are either using old chef version or you have the required license agreement.
ChefDK version	3.0.36	Stable version of Chef DK that will be installed on pattern manager container.
Docker Enterprise Edition Repository URL		This is an optional parameter. It is mandatory only if you use RHEL as the base image without Docker installed. RHEL supports Docker Enterprise Edition only. After you purchase the license, get the Docker Enterprise Edition Repository URL from https://store.docker.com/my-content. Docker Community Edition is used by default on other supported operating system.
Chef server Organization Name	chef-org	Chef server Organization name that is associated with the configuration of the Chef server.
Chef Administrator User name	chef-admin	Chef administrator user name that is associated with the configuration of the Chef server.
Chef Server version	12.11.1	Stable version of Chef server to install

Software Repository Settings

Parameter	Default Value	Description
Software Repository User name	repouser	User name to access the Software Repository.
Password for Software Repository		Password for Software Repository User. The combination of user name and password is required to access the Software Repository.
Software Repository Port Number	8888	Port number for Software Repository HTTP access.
Software Repository Secure Port Number	9999	Port number for Software Repository HTTPS access.

VMware Content Runtime template variables

The following tables list the VMware template variables.

Cloud Provider

Parameter	Default Value	Description
vSphere Datacenter		The name of a Datacenter in which to launch the virtual machine.
vSphere Disk Datastore		Datastore for the created disks. Two disk are created, one for the OS template, the other for the data including the software repository content.
vSphere Default Resource Pool		Name of the default resource pool for the cluster. Specified as 'cluster_name/resource_pool'
vSphere Network Adapter Type	vmxnet3	Network interface type
Domain name		Content Runtime Virtual Machine's domain name
CPU cores		The number of CPU cores to allocate for the Content Runtime. The default value is sufficient for the Content Runtime.
RAM		The amount of RAM to allocate for the virtual machine. The default value is sufficient for the Content Runtime.

Parameter	Default Value	Description
OS Template Name		The folder/template name to use to configure the OS on the Content Runtime Virtual Machine.
Size of image disk (in GBs)	25	The size of the disk for the Content Runtime. It must be equal or larger than the provided image
Size of data disk (in GBs)	100	The size of the data disk for the Content Runtime, and Software Repository.
Network interface label		Label to assign to this network interface.
Static IPv4		Static IPv4 address to be assigned to this network interface for the Content Runtime virtual machine. The address must be a static IP.
Gateway IP address		IPv4 gateway address to be used.
IPv4 prefix length (CIDR)	24	Integer value between 1 and 32 for the prefix length, CIDR, to use when statically assigning an IPv4 address
Template image's user name		The user name to use while configuring the Content Runtime virtual machine.
Template image's password		The password to use for the provided SSH user name while configuring the Content Runtime virtual machine. The password is optional if an SSH key is provided.
Template image's private key for SSH connection - Base 64 encoded		A base 64 encoded SSH private key used for configuring the Content Runtime virtual machine. This key is optional if a password is specified.

Cloud Provider Optional Settings

Parameter	Default Value	Description
vSphere Folder		Name of the vSphere folder where the virtual machine is created.
Keep Disks On Remove	false	Should disks be kept on vSphere even if the virtual machine is destroyed?
DNS servers		List of DNS servers for the virtual network adapter. For more than one DNS, the values can be entered by adding more fields.
DNS suffix list		List of DNS suffixes for the virtual network adapter. For more than one suffix, the values can be entered by adding more fields.

Additional Settings

Parameter	Default Value	Description
Network Visibility	public	The network connection associated with the Content Runtime virtual machine instance. If network visibility is private, connection must exist from the IBM Cloud Pak for AIOps to the network connection associated with the Content Runtime virtual machine being created.
Prerequisite checker strictness		If set to strict, the prerequisite checker stops execution if one or more requirements is not installed. If set to lenient, If set to lenient, the prerequisite checker proceeds to install any missing requirement.

Managed services Parameters

Parameter	Default Value	Description
Enable FIPS on pattern manager and software repository containers	False	True to enable FIPS on pattern manager and software repository container.
Pattern Manager Access Passphrase		Passphrase used to access the REST API calls to the Pattern Manager.
Pattern Manager Administration Passphrase		Administration passphrase that is used to access the administrative REST API calls to the Pattern Manager.
Key Name for Pattern Manager key set		For Amazon and IBM clouds, the key must exist as a resource. For other provider types, the content is simply the name associated with the key.
Private Key for Pattern Manager - Base 64 encoded		Private key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must be base64 encoded and must be associated with the public key named by the Key Name for Pattern Manager key set.
Public Key for Pattern Manager		Public key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must match the public key named by the Key Name for Pattern Manager key set.
User's Public Key		Public key that is added to the Content Runtime virtual machine's `authorized_keys` file so as to allow access using the associated private key.
Content Runtime Host Name	ibm-content-runtime	The host name of the virtual machine being created to be used as the Content Runtime. The name is just the host name and not the fully qualified host name.

Note: For more information about generating public and private keys, see SSH Keys and related input required while deploying content runtime.

Docker & Chef Settings

Parameter	Default Value	Description
Docker Registry	hub.docker.com	Docker registry to pull the Content Runtime Docker images. The images by default reside on the public Docker hub. The value is read only. It provides you the location where an image is pulled.
Chef License Agreement		Newer Chef Server, Client, Chef DK require license agreement with Chef for commercial. By typing Agree to this field you confirm that you are either using old chef version or you have the required license agreement.
ChefDK version	3.0.36	Stable version of Chef DK that will be installed on pattern manager container.

Parameter	Default Value	Description
Docker Enterprise Edition Repository URL		This is an optional parameter. It is mandatory only if you use RHEL as the base image without Docker installed. RHEL supports Docker Enterprise Edition only. After you purchase the license, get the Docker Enterprise Edition Repository URL from https://store.docker.com/my-content. Docker Community Edition is used by default on other supported operating system.
Chef server Organization Name	chef-org	Chef server Organization name that is associated with the configuration of the Chef server.
Chef Administrator User name	chef-admin	Chef administrator user name that is associated with the configuration of the Chef server.
Chef Server version	12.11.1	Stable version of Chef server to install

Software Repository Settings

Parameter	Default Value	Description
Software Repository User name	repouser	User name to access the Software Repository.
Password for Software Repository		Password for Software Repository User. The combination of user name and password is required to access the Software Repository.
Software Repository Port Number	8888	Port number for Software Repository HTTP access.
Software Repository Secure Port Number	9999	Port number for Software Repository HTTPS access.

Other Content Runtime template variables

The following tables list the Other template variables.

Cloud Provider

Parameter	Default Value	Description
Static IPv4 address		Static IPv4 to assign to this network interface. This must be a static IP, and it is the IP address of the machine as known to the network.
Virtual Machine's Domain Name		Content Runtime Virtual Machine's domain name
Operating System User name		The user name which can be used to sign on to the system to configure the machine as a Content Runtime.
Operating System password		Password for signing onto the system to configure the machine as a Content Runtime. If an SSH key is provided this parameter is not needed.
OS SSH Private Key - Base64 encoded		The SSH key to connect to the virtual machine to allow for configuration of the Content Runtime. The key is optional if the password is provided for the operating system user name. The key is base64 encoded.

Additional Settings

Parameter	Default Value	Description
Network Visibility	public	The network connection associated with the Content Runtime virtual machine instance. If network visibility is private, connection must exist from the IBM Cloud Pak for AIOps to the network connection associated with the Content Runtime virtual machine being created.
Prerequisite checker strictness		If set to strict, the prerequisite checker stops execution if one or more requirements is not installed. If set to lenient, the prerequisite checker proceeds to install any missing requirement.
File system encryption passphrase		Passphrase for encrypted drives.

Managed services Parameters

Parameter	Default Value	Description
Enable FIPS on pattern manager and software repository containers	False	True to enable FIPS on pattern manager and software repository container.
Pattern Manager Access Passphrase		Passphrase used to access the REST API calls to the Pattern Manager.
Pattern Manager Administration Passphrase		Administration passphrase that is used to access the administrative REST API calls to the Pattern Manager.

Parameter	Default Value	Description
Key Name for Pattern Manager key set		For Amazon and IBM clouds, the key must exist as a resource. For other provider types, the content is simply the name associated with the key.
Private Key for Pattern Manager - Base 64 encoded		Private key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must be base64 encoded and must be associated with the public key named by the Key Name for Pattern Manager key set.
Public Key for Pattern Manager		Public key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must match the public key named by the Key Name for Pattern Manager key set.
User's Public Key		Public key that is added to the Content Runtime virtual machine's `authorized_keys` file so as to allow access using the associated private key.

Note: For more information about generating public and private keys, see SSH Keys and related input required while deploying content runtime.

Docker & Chef Settings

Parameter	Default Value	Description
Chef Client Installation Binaries Path		Provide the local path to chef client installation binaries. The format must be `/path/to/chef-clients` without any trailing slash. This value is required for offline install.
Docker Registry	hub.docker.com	Docker registry to pull the Content Runtime Docker images. The images by default reside on the public Docker hub. The value is read only. It provides you the location where an image is pulled.
Chef License Agreement		Newer Chef Server, Client, Chef DK require license agreement with Chef for commercial. By typing Agree to this field you confirm that you are either using old chef version or you have the required license agreement.
ChefDK Version	3.0.36	Stable version of Chef DK that will be installed on pattern manager container.
Docker Enterprise Edition Repository URL		This is an optional parameter. It is mandatory only if you use RHEL as the base image without Docker installed. RHEL supports Docker Enterprise Edition only. After you purchase the license, get the Docker Enterprise Edition Repository URL from https://store.docker.com/my-content. Docker Community Edition is used by default on other supported operating system.
Chef server Organization Name	chef-org	Chef server Organization name that is associated with the configuration of the Chef server.
Chef Administrator User name	chef-admin	Chef administrator user name that is associated with the configuration of the Chef server.

Optional Settings for Offline Installation

Parameter	Default Value	Description
Docker installation file		Optional file location of a docker .deb/.rpm file to be installed on the system. If the installation package has been stored within the content runtime system, for example, docker.deb saved to /tmp, then the input would be file:///tmp/docker.deb. If the installation package is stored in a server with HTTP access, then the input would be http://<server_IP>/path/to/docker.deb.
Docker Compose installation file		Optional file location of a Docker Compose executable file to be installed on the system. If the installation package has been stored within the content runtime system, for example, docker-compose saved to /tmp, then the input would be file:///tmp/docker-compose. If the installation package is stored in a server with HTTP access, then the input would be http://<server_IP>/path/to/docker-compose.
Software Repository Docker image location		Optional file location of the Software Repository Docker image to be loaded to the system. If the installation package has been stored within the content runtime system, for example, camc-sw-repo saved to /tmp, then the input would be file:///tmp/camc-sw-repo. If the installation package is stored in a server with HTTP access, then the input would be http://<server_IP>/path/to/camc-sw-repo.
Pattern Manager Docker image location		Optional file location of the Pattern Manager Docker image to be loaded to the system. If the installation package has been stored within the content runtime system, for example, camc-pattern-manager saved to /tmp, then the input would be file:///tmp/camc-pattern-manager. If the installation package is stored in a server with HTTP access, then the input would be http://<server_IP>/path/to/camc-pattern-manager.
Chef Server Installation File		Binary installation file for Chef server. Note: the installation package is OS dependent. This entry may contain an http://, https://, or file:// link to an installation package (.deb/.rpm). If the installation package has been stored within the content runtime system, for example, chef.rpm saved to /tmp, then the input would be file:///tmp/chef.rpm. If the installation package is stored in a server with HTTP access, then the input would be http://<server_IP>/path/to/chef.rpm.

Software Repository Settings

Parameter	Default Value	Description
Software Repository User name	repouser	User name to access the Software Repository.
Password for Software Repository		Password for Software Repository User. The combination of user name and password is required to access the Software Repository.
Software Repository Port Number	8888	Port number for Software Repository HTTP access.
Software Repository Secure Port Number	9999	Port number for Software Repository HTTPS access.

Using an existing Chef server when deploying a Content Runtime

Using the Content Runtime templates, you can provide an existing Chef server to which the Pattern Manager will connect.

Requirements

To use an existing Chef server when deploying a Content Runtime, the following are needed:

- The Chef server needs to have a static IP address assigned to it.

  Note: This IP address must be accessible from the Content Runtime.

- A user has to be created in the existing Chef server and associated to an organization. For more information on how to perform these steps, see Chef's documentation.

  Note: When creating a user, by default, the **`chef-server-ctl user-create`** command will print the certificate file for the new user to the standard output. To store this result in a file, use the **`-f`** option.

Procedure

To deploy a Content Runtime that will connect to an external Chef server, a custom template needs to be selected.

1. Start the creation process by selecting **Manage** > **Content runtimes** in the Managed services.
2. Click **Create content runtime**.
3. Enter a descriptive name for your Content Runtime.
4. Select the Cloud Provider. (Note: Select Other as cloud provider for offline install).
5. From the dropdown select the option **CAM Content Runtime with existing Chef Server**
6. The additional fields that need to be filled in are:
   - **Chef Server FQDN**: This is the fully qualified domain name of the Chef server.
   - **Chef Server IP Address**: The static IPv4 address of the existing Chef server.
   - **Chef Server Certificate - Base 64 Encoded**: The certificate (usually **`.pem`** format) containing the private key associated to the provided Chef user in the server. This key allows the Pattern Manager to perform requests to the Chef server.
   - **Install Chef Cookbooks** This input represents the option to install the set of cookbooks that are usually bundled on a Content Runtime deployment. If needed, this value can be set to *False* and cookbooks can be loaded manually into the server by following Managed services Content APIs.
7. Click **Deploy**.

Input Parameters

The following tables contain a complete list of all the input parameters available in these templates

- VMware Content Runtime with Existing Chef Server template variables
- Other Content Runtime with Existing Chef Server template variables
- IBM Content Runtime with Existing Chef Server template variables
- Amazon Content Runtime with Existing Chef Server template variables

Obtaining the Chef server FQDN

The fully qualified domain name of the existing Chef server can be obtained from the **`/etc/hosts`** file. It contains the machine's hostname and its associated domain name.

Obtaining the Chef server certificate

When a new user is created with the **`user-create`** option in **`chef-server-ctl`**, its private key is displayed in the standard output. This value can be copied into a file or the **`-f`** option can be used to automatically store it in a specific location.

If the existing Chef server was created using a Content Runtime deployment, then by default the created organization would be named **`chef-org`** and its user **`chef-admin`**. The **`.pem`** file in this case can be found at **`/etc/opscode/chef-admin.pem`**.

Base 64 encoding

To encode the **`.pem`** file into base 64, use the following command in a terminal window:

```
bash
base64 <filename>.pem -w 0
```

The resulting value must be provided in the **Chef Server Certificate - Base 64 Encoded** field.

Verifying Installation

The verification script bundled with the Content Runtime deployment should be able to establish a connection to the external Chef server and obtain the number of existing cookbooks and roles. If this step is successful, the **`Logs`** section displays the following messages:

```
bash
null_resource.call_launcher (remote-exec): [INFORMATIONAL] An external Chef server was configured on installation
...
null_resource.call_launcher (remote-exec): [SUCCESS] Chef Cookbooks verified successfully
null_resource.call_launcher (remote-exec): [SUCCESS] Cookbooks response verified successfully
```

```
null_resource.call_launcher (remote-exec): [SUCCESS] Total Chef Cookbook count 13
null_resource.call_launcher (remote-exec): [SUCCESS] Total Chef role count 38
```

IBM Content Runtime with Existing Chef Server template variables

The following tables list the IBM template variables.

Cloud Provider

Parameter	Default Value	Description
Virtual Machine's domain name		Virtual Machine's domain name for the Content Runtime Virtual Machine.
Public Key Name	cam_public_key	Provide a public key name. The key will be created and stored in the IBM Cloud as a resource with the name Hostname_PrivateKeyName. The private portion of the key can be found in the log file in the Terraform data.
OS Image Name	UBUNTU_16_64	An operating system reference code that is used to provision the computing instance.
Data Center		Specify the data center to create the Content Runtime virtual machine.
Private subnet		Private subnet for the private network interface of the instance. Accepted values are primary private networks and can be found in the subnets doc.
Private VLAN name		Private VLAN name for the network interface of the instance.
Dedicated Account Host		Specify whether or not the instance must only run on hosts with instances from the same account
Billing Type		Specify the billing type for the instance. The computing instance can be billed based on an hourly or monthly usage basis.
Network Connection Speed		Specify the connection speed for the instance's network components.
CPU cores		The number of CPU cores to allocate. The default value is sufficient for the Content Runtime.
RAM		The amount of RAM to allocate for the virtual machine. The default value is sufficient for the Content Runtime.

Cloud Provider Optional Settings

Parameter	Default Value	Description
Portable private IP address		Portable private IPv4 address to be assigned to this network interface for the Content Runtime virtual machine. If provided, the address needs to be static.
Portable private netmask		Portable private netmask for the private IP added to the new Content Runtime virtual machine. Required when assigning a portable IP address.
Portable private gateway		Portable private gateway address to be assigned to the new Content Runtime virtual machine. Required when assigning a portable IP address.

Additional Settings

Parameter	Default Value	Description
Network Visibility		The network connection associated with the Content Runtime virtual machine instance. If network visibility is private, connection must exist from the IBM Cloud Pak for AIOps to the network connection associated with the Content Runtime virtual machine being created.

Managed services Parameters

Parameter	Default Value	Description
Enable FIPS on pattern manager and software repository containers	False	True to enable FIPS on pattern manager and software repository container.
Pattern Manager Access Passphrase		Passphrase used to access the REST API calls to the Pattern Manager.
Pattern Manager Administration Passphrase		Administration passphrase that is used to access the administrative REST API calls to the Pattern Manager.
Key Name for Pattern Manager key set		For Amazon and IBM clouds, the key must exist as a resource. For other provider types, the content is simply the name associated with the key.
Private Key for Pattern Manager - Base 64 encoded		Private key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must be base64 encoded and must be associated with the public key named by the Key Name for Pattern Manager key set.
Public Key for Pattern Manager		Public key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must match the public key named by the Key Name for Pattern Manager key set.
User's Public Key		Public key that is added to the Content Runtime virtual machine's `authorized_keys` file so as to allow access using the associated private key.
Content Runtime Host Name	ibm-content-runtime	The host name of the virtual machine being created to be used as the Content Runtime. The name is just the host name and not the fully qualified host name.

Docker & Chef Settings

Parameter	Default Value	Description
Docker Registry	hub.docker.com	Docker registry to pull the Content Runtime Docker images. The images by default reside on the public Docker hub. The value is read only. It provides you the location where an image is pulled.
Chef License Agreement		Newer Chef Server, Client, Chef DK require license agreement with Chef for commercial. By typing Agree to this field you confirm that you are either using old chef version or you have the required license agreement.
ChefDK version	3.0.36	Stable version of Chef DK that will be installed on pattern manager container.
Docker Enterprise Edition Repository URL		This is an optional parameter. It is mandatory only if you use RHEL as the base image without Docker installed. RHEL supports Docker Enterprise Edition only. After you purchase the license, get the Docker Enterprise Edition Repository URL from https://store.docker.com/my-content. Docker Community Edition is used by default on other supported operating system.
Chef server Organization Name	chef-org	Chef server Organization name that is associated with the configuration of the Chef server.
Chef Administrator User name	chef-admin	Chef administrator user name that is associated with the configuration of the Chef server.
Install Chef Cookbooks	true	Should the Chef cookbooks be installed on the provided Chef server?
Chef Server FQDN		Fully qualified domain name of a remote Chef server. Consists of the server's hostname and domain.
Chef Server IP Address		IPv4 address of a remote Chef server.
Chef Server Certificate - Base 64 encoded		Certificate (.pem file) of the remote Chef server encoded in base64.

Software Repository Settings

Parameter	Default Value	Description
Software Repository User name	repouser	User name to access the Software Repository.
Password for Software Repository		Password for Software Repository User. The combination of user name and password is required to access the Software Repository.
Software Repository Port Number	8888	Port number for Software Repository HTTP access.
Software Repository Secure Port Number	9999	Port number for Software Repository HTTPS access.

Amazon Web Services Content Runtime with existing Chef Server template variables

The following tables list the Amazon template variables.

Cloud Provider

Parameter	Default Value	Description
AWS User ID	ubuntu	An internal field that is needed wherever an ID is required for an image.
Security Group ID		The ID of security group that exists in Amazon cloud. The security group is used while creating the Content Runtime virtual machine.
VPC Subnet ID		The VPC Subnet ID to use while creating Content Runtime. The subnet must exist in Amazon.
Amazon EC2 Instance Type	m3.large	The type of the Amazon EC2 Instance. The default setting is the recommended size for running the Content Runtime.
AWS region		The AWS region to create Content Runtime virtual machine

Cloud Provider Optional Settings

Parameter	Default Value	Description
Private IP Address		Static IPv4 address to be assigned to Content Runtime virtual machine. The provided IP address must be associated to the subnet id. If empty, AWS assigns an IP address that is associated to the subnet id.

Additional Settings

Parameter	Default Value	Description

Parameter	Default Value	Description
Network Visibility		The network connection that is associated with the Content Runtime virtual machine instance. If network visibility is private, connection must exist between IBM Cloud Pak for AIOps and the network connection. The network connection is associated with the Content Runtime virtual machine that is being created.

Managed services Parameters

Parameter	Default Value	Description
Enable FIPS on pattern manager and software repository containers	False	True to enable FIPS on pattern manager and software repository container.
Pattern Manager Access Passphrase		Passphrase used to access the REST API calls to the Pattern Manager.
Pattern Manager Administration Passphrase		Administration passphrase that is used to access the administrative REST API calls to the Pattern Manager.
Key Name for Pattern Manager key set		For Amazon and IBM clouds, the key must exist as a resource. For other provider types, the content is simply the name associated with the key.
Private Key for Pattern Manager - Base 64 encoded		Private key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must be base64 encoded and must be associated with the public key named by the Key Name for Pattern Manager key set.
Public Key for Pattern Manager		Public key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must match the public key named by the Key Name for Pattern Manager key set.
User's Public Key		Public key that is added to the Content Runtime virtual machine's `authorized_keys` file so as to allow access using the associated private key.
Content Runtime Host Name	ibm-content-runtime	The host name of the virtual machine being created to be used as the Content Runtime. The name is just the host name and not the fully qualified host name.

Docker & Chef Settings

Parameter	Default Value	Description
Docker Registry	hub.docker.com	Docker registry to pull the Content Runtime Docker images. The images by default reside on the public Docker hub. The value is read only. It provides you the location where an image is pulled.
Chef License Agreement		Newer Chef Server, Client, Chef DK require license agreement with Chef for commercial. By typing Agree to this field you confirm that you are either using old chef version or you have the required license agreement.
ChefDK version	3.0.36	Stable version of Chef DK that will be installed on pattern manager container.
Docker Enterprise Edition Repository URL		This is an optional parameter. It is mandatory only if you use RHEL as the base image without Docker installed. RHEL supports Docker Enterprise Edition only. After you purchase the license, get the Docker Enterprise Edition Repository URL from https://store.docker.com/my-content. Docker Community Edition is used by default on other supported operating system.
Chef server Organization Name	chef-org	Chef server Organization name that is associated with the configuration of the Chef server.
Chef Administrator User name	chef-admin	Chef administrator user name that is associated with the configuration of the Chef server.
Install Chef Cookbooks	true	Should the Chef cookbooks be installed on the provided Chef server?
Chef Server FQDN		Fully qualified domain name of a remote Chef server. Consists of the server's hostname and domain.
Chef Server IP Address		IPv4 address of a remote Chef server.
Chef Server Certificate - Base 64 encoded		Certificate (.pem file) of the remote Chef server encoded in base64.

Software Repository Settings

Parameter	Default Value	Description
Software Repository User name	repouser	User name to access the Software Repository.
Password for Software Repository		Password for Software Repository User. The combination of user name and password is required to access the Software Repository.
Software Repository Port Number	8888	Port number for Software Repository HTTP access.
Software Repository Secure Port Number	9999	Port number for Software Repository HTTPS access.

VMware Content Runtime with Existing Chef Server template variables

The following tables list the VMware template variables.

Cloud Provider

Parameter	Default Value	Description
vSphere Datacenter		The name of a Datacenter in which to launch the virtual machine.
vSphere Disk Datastore		Datastore for the created disks. Two disk are created, one for the OS template, the other for the data including the software repository content.
vSphere Default Resource Pool		Name of the default resource pool for the cluster. Specified as 'cluster_name/resource_pool'
vSphere Network Adapter Type	vmxnet3	Network interface type
Domain name		Content Runtime Virtual Machine's domain name
CPU cores		The number of CPU cores to allocate for the Content Runtime. The default value is sufficient for the Content Runtime.
RAM		The amount of RAM to allocate for the virtual machine. The default value is sufficient for the Content Runtime.
OS Template Name		The folder/template name to use to configure the OS on the Content Runtime Virtual Machine.
Size of image disk (in GBs)	25	The size of the disk for the Content Runtime. It must be equal or larger than the provided image
Size of data disk (in GBs)	100	The size of the data disk for the Content Runtime, and Software Repository.
Network interface label		Label to assign to this network interface.
Static IPv4		Static IPv4 address to be assigned to this network interface for the Content Runtime virtual machine. The address must be a static IP.
Gateway IP address		IPv4 gateway address to be used.
IPv4 prefix length (CIDR)	24	Integer value between 1 and 32 for the prefix length, CIDR, to use when statically assigning an IPv4 address
Template image's user name		The user name to use while configuring the Content Runtime virtual machine.
Template image's password		The password to use for the provided SSH user name while configuring the Content Runtime virtual machine. The password is optional if an SSH key is provided.
Template image's private key for SSH connection - Base 64 encoded		A base 64 encoded SSH private key used for configuring the Content Runtime virtual machine. This key is optional if a password is specified.

Cloud Provider Optional Settings

Parameter	Default Value	Description
vSphere Folder		Name of the vSphere folder where the virtual machine is created.
Keep Disks On Remove	false	Should disks be kept on vSphere even if the virtual machine is destroyed?
DNS servers		List of DNS servers for the virtual network adapter. For more than one DNS, the values can be entered by adding more fields.
DNS suffix list		List of DNS suffixes for the virtual network adapter. For more than one suffix, the values can be entered by adding more fields.

Additional Settings

Parameter	Default Value	Description
Network Visibility	public	The network connection associated with the Content Runtime virtual machine instance. If network visibility is private, connection must exist from the IBM Cloud Pak for AIOps to the network connection associated with the Content Runtime virtual machine being created.
Prerequisite checker strictness		If set to strict, the prerequisite checker stops execution if one or more requirements is not installed. If set to lenient, If set to lenient, the prerequisite checker proceeds to install any missing requirement.

Managed services Parameters

Parameter	Default Value	Description
Enable FIPS on pattern manager and software repository containers	False	True to enable FIPS on pattern manager and software repository container.
Pattern Manager Access Passphrase		Passphrase used to access the REST API calls to the Pattern Manager.
Pattern Manager Administration Passphrase		Administration passphrase that is used to access the administrative REST API calls to the Pattern Manager.
Key Name for Pattern Manager key set		For Amazon and IBM clouds, the key must exist as a resource. For other provider types, the content is simply the name associated with the key.
Private Key for Pattern Manager - Base 64 encoded		Private key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must be base64 encoded and must be associated with the public key named by the Key Name for Pattern Manager key set.
Public Key for Pattern Manager		Public key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must match the public key named by the Key Name for Pattern Manager key set.

Parameter	Default Value	Description
User's Public Key		Public key that is added to the Content Runtime virtual machine's `authorized_keys` file so as to allow access using the associated private key.
Content Runtime Host Name	ibm-content-runtime	The host name of the virtual machine being created to be used as the Content Runtime. The name is just the host name and not the fully qualified host name.

Docker & Chef Settings

Parameter	Default Value	Description
Docker Registry	hub.docker.com	Docker registry to pull the Content Runtime Docker images. The images by default reside on the public Docker hub. The value is read only. It provides you the location where an image is pulled.
Chef License Agreement		Newer Chef Server, Client, Chef DK require license agreement with Chef for commercial. By typing Agree to this field you confirm that you are either using old chef version or you have the required license agreement.
ChefDK version	3.0.36	Stable version of Chef DK that will be installed on pattern manager container.
Docker Enterprise Edition Repository URL		This is an optional parameter. It is mandatory only if you use RHEL as the base image without Docker installed. RHEL supports Docker Enterprise Edition only. After you purchase the license, get the Docker Enterprise Edition Repository URL from https://store.docker.com/my-content. Docker Community Edition is used by default on other supported operating system.
Chef server Organization Name	chef-org	Chef server Organization name that is associated with the configuration of the Chef server.
Chef Administrator User name	chef-admin	Chef administrator user name that is associated with the configuration of the Chef server.
Install Chef Cookbooks	true	Should the Chef cookbooks be installed on the provided Chef server?
Chef Server FQDN		Fully qualified domain name of a remote Chef server. Consists of the server's hostname and domain.
Chef Server IP Address		IPv4 address of a remote Chef server.
Chef Server Certificate - Base 64 encoded		Certificate (.pem file) of the remote Chef server encoded in base64.

Software Repository Settings

Parameter	Default Value	Description
Software Repository User name	repouser	User name to access the Software Repository.
Password for Software Repository		Password for Software Repository User. The combination of user name and password is required to access the Software Repository.
Software Repository Port Number	8888	Port number for Software Repository HTTP access.
Software Repository Secure Port Number	9999	Port number for Software Repository HTTPS access.

Other Content Runtime template variables

The following tables list the Other template variables.

Cloud Provider

Table. Cloud provider

Parameter	Default Value	Description
Static IPv4 address		Static IPv4 to assign to this network interface. This must be a static IP, and it is the IP address of the machine as known to the network.
Virtual Machine's Domain Name		Content Runtime Virtual Machine's domain name
Operating System User name		The user name which can be used to sign on to the system to configure the machine as a Content Runtime.
Operating System password		Password for signing onto the system to configure the machine as a Content Runtime. If an SSH key is provided this parameter is not needed.
OS SSH Private Key - Base64 encoded		The SSH key to connect to the virtual machine to allow for configuration of the Content Runtime. The key is optional if the password is provided for the operating system user name. The key is base64 encoded.

Additional Settings

Table. Additional settings

Parameter	Default Value	Description
Offline	False	Is this offline installation.
Network Visibility	public	The network connection associated with the Content Runtime virtual machine instance. If network visibility is private, connection must exist from the IBM Cloud Pak for AIOps to the network connection associated with the Content Runtime virtual machine being created.
Prerequisite checker strictness		If set to strict, the prerequisite checker stops execution if one or more requirements is not installed. If set to lenient, the prerequisite checker proceeds to install any missing requirement.
File system encryption passphrase		Passphrase for encrypted drives.

Managed services Parameters

Table. Managed services parameters

Parameter	Default Value	Description
Enable FIPS on pattern manager and software repository containers	False	True to enable FIPS on pattern manager and software repository container.
Pattern Manager Access Passphrase		Passphrase used to access the REST API calls to the Pattern Manager.
Pattern Manager Administration Passphrase		Administration passphrase that is used to access the administrative REST API calls to the Pattern Manager.
Key Name for Pattern Manager key set		For Amazon and IBM clouds, the key must exist as a resource. For other provider types, the content is simply the name associated with the key.
Private Key for Pattern Manager - Base 64 encoded		Private key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must be base64 encoded and must be associated with the public key named by the Key Name for Pattern Manager key set.
Public Key for Pattern Manager		Public key to be used by Pattern Manager to communicate with the newly instantiated virtual machine. The key must match the public key named by the Key Name for Pattern Manager key set.
User's Public Key		Public key that is added to the Content Runtime virtual machine's `authorized_keys` file so as to allow access using the associated private key.

Docker and Chef Settings

Table. Docker and Chef Settings

Parameter	Default Value	Description
Chef Client Installation Binaries Path (Required only for Offline install)		Provide the local path to chef client installation binaries. The format must be /path/to/chef-clients without without any trailing slash. This value is required if Offline is set to True.
Docker Registry	hub.docker.com	Docker registry to pull the Content Runtime Docker images. The images by default reside on the public Docker hub. The value is read only. It provides you the location where an image is pulled.
Chef License Agreement		Newer Chef Server, Client, Chef DK require license agreement with Chef for commercial. By typing Agree to this field you confirm that you are either using old chef version or you have the required license agreement.
ChefDK version	3.0.36	Stable version of Chef DK that will be installed on pattern manager container.
Docker Enterprise Edition Repository URL		This is an optional parameter. It is mandatory only if you use RHEL as the base image without Docker installed. RHEL supports Docker Enterprise Edition only. After you purchase the license, get the Docker Enterprise Edition Repository URL from https://store.docker.com/my-content. Docker Community Edition is used by default on other supported operating system.
Chef server Organization Name	chef-org	Chef server Organization name that is associated with the configuration of the Chef server.
Chef Administrator User name	chef-admin	Chef administrator user name that is associated with the configuration of the Chef server.
Install Chef Cookbooks	true	Should the Chef cookbooks be installed on the provided Chef server?
Chef Server FQDN		Fully qualified domain name of a remote Chef server. Consists of the server's hostname and domain.
Chef Server IP Address		IPv4 address of a remote Chef server.
Chef Server Certificate - Base 64 encoded		Certificate (.pem file) of the remote Chef server encoded in base64.

Optional Settings for Offline Installation

Table. Optional Settings for Offline Installation

Parameter	Default Value	Description
Docker installation file		Optional file location of a docker .deb/.rpm file to be installed on the system. If the installation package is stored within the content runtime system, for example, docker.deb saved to /tmp, then the input is file:///tmp/docker.deb. If the installation package is stored in a server with HTTP access, then the input is `http://<server_IP>/path/to/docker.deb`.

Parameter	Default Value	Description
Docker Compose installation file		Optional file location of a Docker Compose executable file to be installed on the system. If the installation package is stored within the content runtime system, for example, docker-compose saved to /tmp, then the input is **`file:///tmp/docker-compose`**. If the installation package is stored in a server with HTTP access, then the input is **`http://<server_IP>/path/to/docker-compose`**.
Software Repository Docker image location		Optional file location of the Software Repository Docker image to be loaded to the system. If the installation package has been stored within the content runtime system, for example, camc-sw-repo saved to /tmp, then the input is **`file:///tmp/camc-sw-repo`**. If the installation package is stored in a server with HTTP access, then the input is **`http://<server_IP>/path/to/camc-sw-repo`**.
Pattern Manager Docker image location		Optional file location of the Pattern Manager Docker image to be loaded to the system. If the installation package is stored within the content runtime system, for example, camc-pattern-manager saved to /tmp, then the input is **`file:///tmp/camc-pattern-manager`**. If the installation package is stored in a server with HTTP access, then the input is **`http://<server_IP>/path/to/camc-pattern-manager`**.

Software Repository Settings

Table. Software Repository Settings

Parameter	Default Value	Description
Software Repository User name	repouser	User name to access the Software Repository.
Password for Software Repository		Password for Software Repository User. The combination of user name and password is required to access the Software Repository.
Software Repository Port Number	8888	Port number for Software Repository HTTP access.
Software Repository Secure Port Number	9999	Port number for Software Repository HTTPS access.

Provisioning an offline Content Runtime

It is possible to deploy a Content Runtime on an existing virtual machine with limited or no internet connectivity.

To provision an offline Content Runtime, a virtual machine must exist with a static IP address and the installed operating system in the virtual machine must be one of the supported Linux distributions. In addition, either manually download software prerequisites by using the steps in Download prerequisite software section or install the software prerequisites on the virtual machine before the deployment as described in Pre-install prerequisite software manually.

General steps

- Deploy a system to host the Content Runtime
- Download prerequisite software
- Copy software to the Content Runtime host system
- Load Content Runtime Templates
- Deploy an offline Content Runtime
- Optional - Pre-install prerequisite software manually (follow this step if you do not want to use the helper script that is described in Download prerequisite software to download the prerequisite software.)

Deploy a system to host the Content Runtime

For an offline deployment of the Content Runtime, a virtual machine must meet the general infrastructure requirements and the offline template installation requirements.

After your content runtime virtual machine is setup, follow the instructions in Download prerequisite software to download the software prerequisite and make them available during automation, or proceed to Pre-install prerequisite software manually to install the software prerequisite yourself before the offline content runtime deployment.

Download prerequisite software

When you deploy an offline content runtime as described in Deploy an offline Content Runtime, the automation installs all the software prerequisites. But you are required to download the binary and provide the location of the binary during deployment. A set of helper scripts is available in a public GitHub repository to assist you in gathering the supported versions of the required software prerequisites. This helper script downloads the following required software:

- Docker
- Docker Compose
- Chef server
- Chef client
- Chef DK
- CAMC Pattern Manager Docker Image
- CAMC Software Repository Docker Image

Follow the steps to execute the helper script that downloads the required software prerequisites.

- Clone helper repository

```
bash
git clone https://github.com/IBM-CAMHub-Open/IBM-CAMHub-Open.git
```

- Execute prereq-downloader.sh

The **prereq-downloader.sh** script that is cloned in the previous step can be used to download all software prerequisites for an offline Content Runtime deployment.

```
bash
cd IBM-CAMHub-Open/bin/prereqDownloader
./prereq-downloader.sh <platform> <platform_version> <optional:release>
```

Where **<platform>** and **<platform_version>** are the Linux distribution and version of the virtual machine to which the Content Runtime is being deployed. The optional parameter **<release>** provides a way to obtain the required software for the older versions based on the environment's needs.

For example, downloading requirements for a Content Runtime installation on a virtual machine running Ubuntu 18.04

```
./prereq-downloader.sh ubuntu 18.04 4.0
```

Requirements get downloaded to a folder named **prereqs_<platform>_<platform_version>_<release>** which can later be copied to an HTTP server or the target virtual machine.

Known issues and workarounds

- If the script execution fails with the following error, then you may have encountered a GitHub API rate hit limit:

  "No repositories found, possibly the connection to the host https://github.com/IBM-CAMHub-Open failed"

  To overcome the rate limit, set the following environment variable and rerun the script:

  ```
  export CloneWithToken=YOUR_GITHUB_TOKEN@
  ```

  Note: You must append @ to your GitHub token.

- If **prereq-downloader.sh** execution fails due to curl auth error, then add **--insecure** parameter at the end of the curl.

Copy software to the Content Runtime host system

Copy software from the **prereqs_<platform>_<platform_version>_<release>** directory created in the previous step to the system which hosts the Content Runtime.

The file directory where the software is copied is used as input during Content Runtime deployment.

The deployment process requires the **IBM-CAMHub-Open.tar** produced in the previous step to be copied to **/var/** directory on the system that hosts the Content Runtime.

Alternatively, files can be placed on an accessible HTTP Server. In this case, the HTTP location is used as input to the Content Runtime deployment.

Running on a Chef 12 environment

If a Content Runtime is meant to be deployed using Chef client version 12, a version which is no longer officially supported, a third parameter can be specified when downloading requirements. If the **release** parameter is set to **1.0**, Chef client version 12 is downloaded along with other compatible versions of the requirements.

Load Content Runtime Templates

The Content Runtime templates need to be manually loaded into a Managed services environment that does not have access to github.com.

The recommended path is to first import the Content Runtime templates to a local GitLab or GitHub Enterprise. Content Runtime templates are available in Git repositories downloaded in the previous step and saved in **IBM-CAMHub-Open_advanced_content_runtime.tar**.

After the templates are imported to GitLab or GitHub Enterprise, the desired Content Runtime templates can be loaded into Managed services by creating a template in the user interface.

If GitLab or GitHub Enterprise are not available, the script **loadContentRuntimeTemplates.sh** in **IBM-CAMHub-Open_advanced_content_runtime.tar** can be executed to load the Content Runtime templates into Managed services.

After the Content Runtime templates have been loaded into Managed services, confirm whether they appear in the dropdown under **Manage** > Content runtimes > Create content runtime.

Deploy an offline Content Runtime

Before you deploy your offline content runtime, make sure your content runtime virtual machine meets all the requirement specified in general infrastructure requirements page and offline template installation requirements section.

1. Select the **Other** Cloud Provider after you click **Create content runtime**. Name the instance and click **Create**.
2. Provide the information required for establishing a connection with the existing virtual machine, the Docker and Chef settings, and other parameters.

Note: The value for **`Chef Client Installation Binaries Path`** must be provided. The value must be a local path to the binary without trailing slash. If your chef client binary is in directory /tmp/chef-clients then the value is as follows:

```
/tmp/chef-clients
```

3. In the section **`7. Optional Settings for Offline Installation`**, five optional fields are displayed: Docker installation file, Docker Compose installation file, Chef Server installation file, Pattern Manager Docker image location and Software Repository Docker image location. These inputs must be filled out by either providing the file path to the installation binaries or the HTTP location from where they can be downloaded.

    - **File location**: If the installation package has been stored in a location within the system, for example, **`docker.deb`** saved to **`/tmp`**, the correct input would be **`file:///tmp/docker.deb`**. The full path, including file name, has to be provided.
    - **HTTP location**: Similar to the file location, if the installation package was stored in a server with enabled HTTP access, the correct input would be **`http://<server_IP>/path/to/docker.deb`**.

Optional - Pre-install prerequisite software manually

Instead of using the helper script described in Download prerequisite software, you may choose to download the prerequisite software manually and provide the location of the binary during content runtime deployment. Alternatively, you may choose to download the prerequisite software manually, install them and during content runtime deployment, leave the section **`Optional Settings for Offline Installation`** empty. The following section describes the software you need to download in both the cases. After you download or download and installed the listed software, you can follow the steps in Deploy an offline Content Runtime to deploy the offline content runtime.

Before you proceed, make sure your content runtime virtual machine meets all the requirements specified in general infrastructure requirements page and offline template installation requirements section.

Installation binaries

An internet connection is required to obtain the required software packages. These installation binaries need to either be installed previously on the virtual machine or stored in locations that can be accessed during the deployment. These files are:

- Docker
- Docker Compose
- Chef server

These installation binaries need to be downloaded and stored in a location on content runtime virtual machine that can be accessed during the deployment

- Chef client
- Chef DK

Docker, Chef Server, Chef DK and Chef Client need to be obtained in a **`.deb`** (Ubuntu) or **`.rpm`** (RHEL/CentOS) format depending on the Linux distribution to which the Content Runtime is deployed. Content runtime deploy has been validated with Chef Server 12.17.33 and Chef Client 14.0.190.

In addition to the programs mentioned previously, two Docker images from DockerHub need to be manually downloaded from a machine with Docker installed:

- CAMC Pattern Manager
- CAMC Software Repository

Obtaining Docker images

The two docker images can be downloaded from the public DockerHub repository by running the following commands:

```
bash
$ podman pull ibmcom/camc-pattern-manager:3.0-current
$ podman pull ibmcom/camc-sw-repo:2.0-current
```

This downloads and installs the Docker images in the current machine, to obtain a file that can be shared with another machine, the **`podman save`** command can be used as follows

```
bash
$ podman save ibmcom/camc-sw-repo:3.0-current > camc-sw-repo
$ podman save ibmcom/camc-pattern-manager:2.0-current > camc-pattern-manager
```

This creates two files **`camc-sw-repo`** and **`camc-pattern-manager`** that contains the images.

Offline template deployment installation requirements

The deployment process can handle the installation of the provided **`.deb`** or **`.rpm`** files. However, these packages may have requirements that need to be manually installed before starting the process. These packages can be installed through **`apt-get install`** or **`yum install`** commands.

Requirements can be obtained from each **`.deb`** installation package by running the following commands:

```
bash
# Ubuntu
dpkg -I <package>.deb

# Red Hat and CentOS
yum deplist <package>.rpm
```

Docker installation

Ubuntu:

```
    iptables
    init-system-helpers
    lsb-base
    libapparmor1
    libc6
    libdevmapper
    libltdl7
    libseccomp2
    libsystemd0
```

Red Hat and CentOS:

```
    device-mapper-devel
    glibc-static
    libseccomp
    libseccomp-devel
    libselinux-devel
    libtool-ltdl-devel
    selinux-policy
    selinux-policy-devel
    systemd-devel
```

Note: You can obtain the selinux related packages if you download container-selinux rpm.

Local Knife Configuration

Configuring the Knife command to work with CAM.

After the Content Runtime is deployed, a Chef Server is available with an initial set of Chef Recipes and Roles deployed. To manage Chef Content, install the Chef DK on a local Workstation. The Chef DK installs the Knife tool which is the primary tool for managing the installed Chef Server.

Before you begin

Prior to beginning, identify the following information from the Content Runtime deployment.

Parameter	Description
User	User to connect to the Chef Server
Password	Password to connect to the Chef Server
Chef Hostname	Full Host name of the Chef Server, property=chef_fqdn
Chef Org	Default Chef Organization, property=chef_org
Chef Admin Name	Chef administration user, property=chef_admin

Ensure the fully qualified Chef Server is resolvable from the local workstation.

Installing the Chef DK

The Knife Command is packaged with the Chef Development Kit (Chef DK) which must first be installed on a local workstation. The Chef DK package will make the knife command available.

To begin, follow the instructions published by opscode on this topic here -> Install the Chef DK.

Configuring Knife

Understanding Knife configuration

Review the following documentation on the Chef DK and knife command:

- Workstation Configuration
- Knife Documentation

Creating the chef-admin.pem file

Knife requires authentication for the Chef Admin user to properly manage the Chef Server. Knife authenticates with a .pem file which must be copied from the chef server.

1. From the Chef Server, locate the /etc/opscode/{Chef Admin}.pem file.
2. Copy to your local workstation.

Minimal knife.rb

1. Create a directory to hold the knife configuration, you may need one per Content Runtime.
2. Copy the {Chef Admin}.pem file to this directory (such as `chef-admin.pem`).
3. Create a file called knife.rb with the following minimal values.

```
current_dir = File.dirname(__FILE__)
log_level                :info
```

```
log_location              STDOUT
node_name                 '{Chef Admin}'
client_key                "{Knife Dir}/{Chef Admin}.pem"
chef_server_url           "https://{Chef Hostname}/organizations/{Chef Orgname}"
```

Testing Knife

Knife commands will by default require the certificate of the server present in the trusted_cert directory. In order to force this, run the following command.

```
knife ssl fetch
```

You can now test simple knife functions.

- Listing cookbooks:

  ```
  knife cookbook list
  ```

  Output:

  ```
  db2                 1.0.4
  httpd               1.4.0
  ibm_cloud_utils     1.0.4
  ihs                 1.0.5
  im                  1.0.3
  linux               1.0.4
  oracle_mysql        1.0.4
  oracledb            1.0.4
  tomcat              1.0.3
  was                 1.0.6
  wasliberty          1.0.5
  wmq                 1.0.4
  ```

- Listing Chef Roles:

  ```
  knife role list
  ```

  Output:

  ```
  db2_create_db
  db2_v105_install
  db2_v111_install
  httpd24-base-install
  httpd24-ssl-vhosts
  ihs-liberty-admin
  ihs-liberty-nonadmin
  ihs-wasmode-admin
  ihs-wasmode-nonadmin
  liberty_core_install
  ```

- Viewing deployed nodes:

  ```
  knife node list
  ```

  Output:

  ```
  nschambu-mq-01
  nschambu-mq-02
  nschambu-was-01
  nschambu-was-02
  ```

For more knife commands refer to the Knife Documentation

The Pattern Manager has exposed an API to automate the management of Chef Cookbooks. For more information, see Pattern Manager API.

Modifying a deployed content runtime

Modifying a content runtime after it has been deployed.

You can redeploy an existing content runtime instance after selecting the desired template version and modifying the parameters. Full instructions for modifying a deployed instance can be found at modifying a deployed template instance.

The taint request described on that page might not be necessary for modifying your content runtime instance. Not all properties are eligible for modification. Some properties might be unavailable while others might not trigger a resource update during the plan request.

Modifying an existing deployment can take two paths: change or destroy and re-create. A change request updates the property in Terraform and makes a request to the affected resources in the content runtime. A destroy and re-create request destroys your content runtime virtual machine and create a new one with the updated properties.

Modify scenarios

Most of property updates require the content runtime virtual machine to be destroyed and re-created, which is destructive. For this reason, you are recommended to use modify in the following scenarios.

Redeploying a failed or destroyed instance

Template modification can be used for more than just modifying deployed content runtime instances. It can also be used to redeploy a failed or destroyed content runtime. Update the parameters that caused the deployment to fail and try the deployment again without having to reenter all of the parameters. Similarly, if a content runtime is accidentally destroyed, it can be redeployed with all of the same parameters from the destroyed copy.

Note: Redeploying a destroyed instance does not re-create the Chef server contents and you must recover the Content Runtime.

Updating the pattern manager key pair or software repository password

The content runtime allows modification of some Managed services properties in addition to the hardware-specific properties. These include the software repository password and the pattern manager key pair properties, which are the pattern manager private key, pattern manager public key, and the key name for pattern manager key set. Updating these properties runs an update script

Troubleshooting destroy and add in the plan output

It is important that you pay attention to the output of the plan request as it includes whether the existing content runtime virtual machine gets destroyed as part of the modify process. Destroying the content runtime virtual machine results in the creation of a new Chef server that is unaware of any node virtual machines that have been previously deployed to this content runtime instance. If you have mistakenly destroyed your content runtime virtual machine as part of a modify process and want to reregister your existing template instances, see Recovering the Content Runtime.

If the destroy and add is related to a resource that contains singlenode or single-node, then your modify action destroys your content runtime VM. It is not recommended that you continue this action unless you are redeploying a failed instance or if your content runtime has no nodes assigned to it. Here is a sample plan output that destroys the content runtime virtual machine in an IBM Cloud content runtime:

```
The following execution plan has been generated.
Resource actions are indicated with the following symbols:
-/+ destroy and then create replacement

Terraform will perform the following actions:
-/+ ibm_compute_vm_instance.single-node (new resource required)
id: "46145801" => (forces new resource)

wait_time_minutes: "90" => "90"

-/+ null_resource.call_launcher (new resource required)
id: "2023496446251967403" => (forces new resource)
triggers.%: "4" => (forces new resource)
triggers.cr_instance_ids: "46145801" => "" (forces new resource)
triggers.private_key_changed: "******" => "" (forces new resource)
triggers.public_key_changed: "ssh-rsa
AAAAB3NzaC1yc2EAAAADAQABAAABAQCunj1Un1T9s1FNdHl+yY9ta5b71ldQahM7CKYnSKf+Y8baXmEejajSM+cc2WXhcXZPscjate8P7oLdQfFg/zAr1MzbKU
7sTvupA6Qx+hlneweL0KKhGpMFLhsp9lgFzGLW4424k+WvKlUf3o59SbLwaMIVeMM/0DlOGLfh2Z2e7o39fsLIg6D5ptr8hBnsQZ9zwReh9qbwiAW9bbl/5tYg
it0HSucrYiZRTss8unHCeuVvRwxK6KeVoqzNRxx2UtL0eb62TzVM+IIm4JlsXr1Nx6IvLf/z6icaMViu3GPKtf4Gz5zbZv3PI/EF/7CJf03S5F5vYuDCi4CKa0
OhKh9d" => "" (forces new resource)
triggers.repo_pass_changed: "repopass" => "" (forces new resource)

Plan: 2 to add, 0 to change, 2 to destroy.
------------------------------------------------------------------------
This plan was saved to: terraform_execution_plan
To perform exactly these actions, run the following command to apply:
terraform apply "terraform_execution_plan"
```

In the preceding output, there are two resources being destroyed and then redeployed: ibm_compute_vm_instance.single-node and null_resource.call_launcher. As stated before, destroying ibm_compute_vm_instance.single-node destroys your content runtime VM. It is not recommended that you apply this plan.

IBM Cloud and the private VLAN ID

Looking more closely at the output from the previous section, you can see that the property change that is forcing a new resource is the private_vlan_id being set from 1601131 to -1. The private VLAN name was not set during the initial deploy so the IBM Cloud assigned our instance a default private VLAN based on the datacenter. If this is the only reason why the content runtime virtual machine is set to be destroyed, then find out the VLAN name associated with that ID in the IBM Cloud to set that parameter for our content runtime deploy.

Using the ID, log into the IBM Cloud to find the VLAN name associated with our deploy. Find and select your virtual machine in the Device List to open the Device Details page. There will be a network section on this page, which includes the private network information. Find the private VLAN assigned to your device and click it to open the VLAN Details page. The VLAN Details page contains the name of your private VLAN. Copy that name and go back to the Managed services UI.

Go back to your content runtime instance and click the modify tab. Find the Private VLAN name field for your content runtime and set it to the VLAN name that was found in the IBM cloud. Update any other parameters that you had previously updated and click plan. The resulting plan should no longer include destroying the ibm_compute_vm_instance.single-node instance.

Updating the Content Runtime Docker Containers

Updating the pattern manager and software repository Docker containers after is has been deployed.

The Content Runtime consists of a virtual machine with two Docker containers - one for the pattern manager and one for the software repository. There are times where you may want to update these Docker containers manually rather than redeploying a new content runtime. The Content Runtime provides a helper script to assist in updating the Docker containers so that you don't need to manually run Docker commands.

Image upgrade script

The image upgrade script is called **image-update.sh** and is found in the **~/advanced-content-runtime** directory on the Content Runtime. Usage syntax is:

```
~/advanced-content-runtime/image-upgrade.sh <container> <version>
```

The container and version variables can be retrieved from the image column of the output of the **podman ps** command. For example, in the following output, the container is **camc-pattern-manager** and the version is 1.0-current.

```
$ podman ps
CONTAINER ID        IMAGE                                       COMMAND                  CREATED             STATUS
PORTS                                       NAMES
a14ae0bd4ae6        ibmcom/camc-pattern-manager:1.0-current   "bin/bash /opt/ibm/p…"   6 hours ago         Up 6 hours
0.0.0.0:5443->443/tcp                       camc-pattern-manager
f0e7aa1c3c41        ibmcom/camc-sw-repo:1.0-current           "/bin/bash /tmp/inst…"   6 hours ago         Up 6 hours
0.0.0.0:8888->8888/tcp, 0.0.0.0:9999->9999/tcp   camc-sw-repo
```

Using these values in the image-upgrade command results in the following request:

```
~/advanced-content-runtime/image-upgrade.sh camc-pattern-manager 1.0-current
```

This will pull the latest 1.0-current podman container and a new image will appear in the output of **podman images** for the specified container.

Deploying a GDPR enabled Content Runtime

As part of GDPR enablement, it is recommended that you encrypt specific directories that may contain personal information. These include directories that contain Content Runtime configuration information and Content Runtime Pattern Manager logs.

Provisioning a GDPR enabled Content Runtime requires using an existing virtual machine with mounted encrypted block devices.

General steps

- Deploy a system to host the Content Runtime
- Encrypt volumes using dm-crypt
- Deploy Content Runtime

Additional information

- Pattern Manager and Software Repository Logs

Deploy a system to host the Content Runtime

For a GDPR enabled deployment of the Content Runtime, a virtual machine meeting infrastructure requirements must exist and be accessible by Managed services. In addition to the general infrastructure requirements, two unformatted disks must be attached to the virtual machine.

The following set of steps contains example commands for configuring a virtual machine where a Content Runtime instance will be deployed. In this example, two logical volumes are created and mounted in well-known locations used by the Pattern Manager.

Encrypt and mount volumes

dm-crypt provides transparent encryption of block devices. You can access the data immediately after you mount the device. For more information about dm-crypt, see https://wiki.archlinux.org/index.php/dm-crypt.

Prerequisites

Ensure that the following packages are installed on all the nodes of your Content Runtime VM:

- On Red Hat Enterprise Linux (RHEL), the following packages must be installed:
  - cryptsetup
  - device-mapper
  - util-linux

    If the packages are not installed, run these commands as a root user to install them:

    ```
    yum install cryptsetup-luks util-linux
    ```
- On Ubuntu, the following packages must be installed:
  - cryptsetup
  - libdevmapper1
  - util-linux
  - lvm2
  - xfsprogs

    If the packages are not installed, run these commands as a root user to install them:

    ```
    apt-get install cryptsetup util-linux lvm2 xfsprogs
    ```

Create a partition table

Before encrypting volumes, a label and at least one partition must be created in the drive.

1. Use the **parted** tool on the disk

   ```
   parted <full path and name of the physical volume>
   ```

   Example commands and output

   ```
   parted /dev/sdb
   GNU Parted 3.2
   Using /dev/sdb
   Welcome to GNU Parted! Type 'help' to view a list of commands.
   (parted)
   ```
2. Add a partition table to the volume using **mklabel**

   Example commands

   ```
   (parted) mklabel gpt
   ```
3. Create a partition, in this case a single partition will be created using all available space. **Note:** Multiple logical volumes can later be defined inside a single partition.

   Example commands

   ```
   (parted) mkpart primary 1 -1
   ```
4. Exit parted by typing **quit**
5. Repeat steps 1-4 for other disks. In this example, repeat for **/dev/sdc**

Encrypting the volumes

These commands will create and encrypt a logical volume. That logical volumes will be mounted to the corresponding directories the may contain personal information.

Run these commands as root.

1. Configure logical volume management (LVM) to store the encrypted data:
   1. Create a physical volume.

      ```
      pvcreate <full path and name of the partition>
      ```

      Example commands and outputs:

      ```
      pvcreate /dev/sdb1
      Physical volume "/dev/sdb1" successfully created.
      ```

```
pvcreate /dev/sdc1
Physical volume "/dev/sdc1" successfully created.
```

2. Create a volume group.

   ```
   vgcreate <name of the volume group> <full path to the physical volume>
   ```

   Example commands and outputs:

   ```
   vgcreate pmvg /dev/sdb1
   Volume group "pmvg" successfully created.

   vgcreate pmlogvg /dev/sdc1
   Volume group "pmlogvg" successfully created.
   ```

3. Create a logical volume.

   ```
   lvcreate -L <amount of space required> <name of the volume group> -n <name of the logical volume>
   ```

   Example commands and outputs:

   ```
   lvcreate -L1G pmvg -n pmlv
   Logical volume "pmlv" created.

   lvcreate -L5G pmlogvg -n pmloglv
   Logical volume "pmloglv" created.
   ```

2. Create a dm-crypt LUKS Container in the volume.

   ```
   cryptsetup -y luksFormat <full path to the logical volume>
   ```

   If you want to use a passphrase for decrypting, you can specify it now. This passphrase will be needed for deploying the Content Runtime later. The passphrase needs to be common for both logical volumes.

   The following is an example command and output:

   ```
   cryptsetup -y luksFormat /dev/pmvg/pmlv

   WARNING!
   ========
   This will overwrite data on /dev/pmvg/pmlv irrevocably.

   Are you sure? (Type uppercase yes): YES
   Enter passphrase:
   Verify passphrase:

   cryptsetup -y luksFormat /dev/pmlogvg/pmloglv

   WARNING!
   ========
   This will overwrite data on /dev/pmlogvg/pmloglv irrevocably.

   Are you sure? (Type uppercase yes): YES
   Enter passphrase:
   Verify passphrase:
   ```

3. (Optional) Add LUKS key to your encrypted device.

   cryptsetup supports adding a key to your logical volume using a keyfile. This keyfile can be added to /etc/crypttab to allow your encrypted drives to be auto-unlocked at boot time. Your keyfile can be random data or something specific. It is recommended that the permissions on your keyfile be set to root only.

   Create keyfile examples:

   ```
   dd if=/dev/random bs=32 count=1 of=/etc/keys/pm_key
   printf "This is a plaintext passphrase key file" > /etc/keys/pmlog_key
   ```

   Add the keyfile to your LUKS partition:

   ```
   cryptsetup luksAddKey <full path to logical volume> <full path to key file>
   ```

   The following is an example command and output:

   ```
   cryptsetup luksAddKey /dev/pmvg/pmlv /etc/keys/pm_key
   Enter any passphrase:

   cryptsetup luksAddKey /dev/pmlogvg/pmloglv /etc/keys/pmlog_key
   Enter any passphrase:
   ```

4. Open the LUKS container and map the logical volume to the volume group.

   ```
   cryptsetup  luksOpen <full path to the logical volume> <name of the logical volume>
   ```

   The following is an example command and output:

   ```
   cryptsetup luksOpen /dev/pmvg/pmlv pmlv
   Enter passphrase for /dev/pmvg/pmlv:

   cryptsetup luksOpen /dev/pmlogvg/pmloglv pmloglv
   Enter passphrase for /dev/pmlogvg/pmloglv:
   ```

5. Create a file system on the logical volume. You can use any file system. The command here is for using an XFS file system.

```
$ mkfs.xfs /dev/mapper/<name of the logical volume>
```

The following is an example command and output:

```
$ mkfs.xfs /dev/mapper/pmlv

meta-data=/dev/mapper/pmlv       isize=512    agcount=4, agsize=65408 blks
         =                       sectsz=512   attr=2, projid32bit=1
         =                       crc=1        finobt=0, sparse=0
data     =                       bsize=4096   blocks=261632, imaxpct=25
         =                       sunit=0      swidth=0 blks
naming   =version 2              bsize=4096   ascii-ci=0 ftype=1
log      =internal log           bsize=4096   blocks=855, version=2
         =                       sectsz=512   sunit=0 blks, lazy-count=1
realtime =none                   extsz=4096   blocks=0, rtextents=0

$ mkfs.xfs /dev/mapper/pmloglv

meta-data=/dev/mapper/pmloglv     isize=512    agcount=4, agsize=327552 blks
         =                        sectsz=512   attr=2, projid32bit=1
         =                        crc=1        finobt=0, sparse=0
data     =                        bsize=4096   blocks=1310208, imaxpct=25
         =                        sunit=0      swidth=0 blks
naming   =version 2               bsize=4096   ascii-ci=0 ftype=1
log      =internal log            bsize=4096   blocks=2560, version=2
         =                        sectsz=512   sunit=0 blks, lazy-count=1
realtime =none                    extsz=4096   blocks=0, rtextents=0
```

6. Create a mount location to mount the file systems for the pattern manager config directory and docker container log directories

   ```
   mkdir <mount location>
   ```

   The following is an example command

   ```
   mkdir -p /opt/ibm/docker/pattern-manager
   mkdir -p /var/log/ibm/docker
   ```

7. Mount the pattern manager config and docker container log filesystems

   ```
   mount /dev/mapper/<name of the logical volume> <mount location>
   ```

   The following is an example command:

   ```
   mount /dev/mapper/pmlv /opt/ibm/docker/pattern-manager
   mount /dev/mapper/pmloglv /var/log/ibm/docker
   ```

   To automatically mount between system restarts, add the following lines to the /etc/crypttab and /etc/fstab files:

   - Add the following line to /etc/crypttab file, where is a unique name of your choosing:

     ```
     <target name> <full path to the logical volume> {none|<absolute_path_to_keyfile>} luks
     ```

     Where, add **none** if you used a passphrase for decrypting, or add the full path to the key file, if you used a key file for decrypting.

     The following are example lines in /etc/crypttab:

     ```
     pm_crypt /dev/pmvg/pmlv /etc/keys/pm_key luks
     pmlog_crypt /dev/pmlogvg/pmloglv /etc/keys/pmlog_key luks
     ```

   - Add the following line to the /etc/fstab file, where matches the unique name added to /etc/crypttab:

     ```
     /dev/mapper/<target name> <full path to the volume group> xfs defaults 0 2
     ```

     The following are example lines in /etc/fstab:

     ```
     /dev/mapper/pm_crypt /opt/ibm/docker/pattern-manager xfs defaults 0 2
     /dev/mapper/pmlog_crypt /var/log/ibm/docker xfs defaults 0 2
     ```

8. Reboot the virtual machine

Deploy Content Runtime

1. In the CAM UI, click **Manage** > **Content runtimes**.
2. Select the **Other** Cloud Provider after clicking the **Create content runtime** button. Choose any of the three Runtime options as they will all support encrypted volumes. Name the instance and press the **Create** button.
3. Provide the information required for establishing a connection with the existing virtual machine and other parameters. Include the encryption passphrase for the encrypted volumes in the **File system encryption passphrase** field.

Pattern Manager and Software Repository Logs

The Content Runtime's Pattern Manager and Software Repository logs can be found on the content runtime virtual machine under the **/var/log/ibm/docker** directory in the **pattern-manager** and **software-repository** directories, respectively. Should it be required to delete personal data from the Content Runtime logs, this is where you will find them.

Broadcast messages

The following message may be broadcast on your system during the content runtime installation process. It can be ignored.

```
Broadcast message from root@ibm-cam-runtime (Mon 2018-05-14 15:46:50 UTC):

Password entry required for 'Please enter passphrase for disk pmlogvg-pmloglv (pmlogvg)!' (PID 32283).
Please enter password with the systemd-tty-ask-password-agent tool!
```

Troubleshooting and known issues

Troubleshoot your Content Runtime infrastructure and read the known issues.

Failed to create the Content Runtime

The console log displays the following error message which is caused by the issue. You must correct the error and configure the Content Runtime again.

```
null_resource.singlenode: Still creating... (3m40s elapsed)
null_resource.singlenode: Still creating... (3m40s elapsed)
null_resource.singlenode: Still creating... (3m40s elapsed)
null_resource.singlenode: Still creating... (3m40s elapsed)
null_resource.singlenode: Still creating... (3m40s elapsed)
null_resource.singlenode: Still creating... (3m50s elapsed)
null_resource.singlenode: Still creating... (4m0s elapsed)
null_resource.singlenode: Still creating... (4m10s elapsed)
null_resource.singlenode: Still creating... (4m20s elapsed)
null_resource.singlenode: Still creating... (4m30s elapsed)
null_resource.singlenode: Still creating... (4m40s elapsed)
null_resource.singlenode: Still creating... (4m50s elapsed)
null_resource.singlenode: Still creating... (5m0s elapsed)
Error applying plan:

1 error(s) occurred:

* null_resource.singlenode: 1 error(s) occurred:

* ssh: handshake failed: ssh: unable to authenticate, attempted methods [none password], no supported methods remain

Terraform does not automatically rollback in the face of errors. Instead, your Terraform state file has been partially
updated with any resources that successfully completed. Please address the error above and apply again to incrementally
change your infrastructure.
```

If you are unable to determine the cause of the failure from the logs, it is possible to log in to the Content Runtime virtual machine and run the configuration process manually using the following command which is located in the home directory of the OS user:

```
advanced-content-runtime/launch-docker-compose.sh
```

Additional debug information can be captured from the `./advanced-content-runtime/launch-docker-compose.sh` script by editing the `./advanced-content-runtime/.advanced-runtime-config/.launch-docker-compose.sh` file and adding the line `--debug` to the end of the file. Rerun the `./advanced-content-runtime/launch-docker-compose.sh` command to capture the additional information. Parameters may be updated in the `./advanced-content-runtime/.advanced-runtime-config/.launch-docker-compose.sh` file if the parameter values were the cause of the failure.

If you are successful when completing the creation of a Content Runtime from the command line, you need to complete the following steps to add it to the Content Runtime creation panel:

1. Go back to the Content Runtime creation panel and recreate the Content Runtime from the beginning.
2. Leave the virtual machine intact, go back to the Content Runtime panel, select create Content Runtime's `Other` template. You must enter all the parameters as they appear in the `~/advanced-content-runtime/.advanced-runtime-config/.launch-docker-compose.sh` file in the create panel so that the existing virtual machine is reused. Managed services then stores its information so that it can be used later in pattern deployment.

Common issues when deploying a Content Runtime

The following are a set of input issues that would result in a failed deployment of a Content Runtime, how to identify them by reading the provided `Log File` and the steps to solve them.

All cloud providers

The following errors can occur independently of the selected cloud provider.

```
ssh: unable to authenticate, attempted methods [none password], no supported methods remain
```

- This error is displayed when the credentials (user name and password or private key) provided for the SSH connection to the virtual machine were incorrect.

  ```
  [ERROR] Platform <distribution> not supported
  ```

- If a Content Runtime is trying to be deployed to an unsupported operating system, this error is displayed.

  ```
  [ERROR] This OS version (<version>) is not supported
  ```

- The error occurs when a Content Runtime is trying to be deployed to a supported operating system but an unsupported version.

```
[ERROR] This script requires root permissions with the NOPASSWD option enabled for executing
```

- This error is displayed when the user account provided for connecting to the Content Runtime has no **sudo** permissions or creates a prompt for password when executing as **sudo**:
- To remove the password prompt, the file **/etc/sudoers** must be changed to include **user_name ALL=(ALL:ALL) NOPASSWD: ALL**

```
[ERROR] This script requires <package manager> permissions for executing
```

- This error occurs when the user account provided for connecting to the Content Runtime has no permissions to use the OS's package manager. A different user account with higher permissions can be provided to solve it.

```
[ERROR] This script requires at least 5GB of available disk space
```

- This error is displayed when the hard drive being used for installing the necessary software and downloading additional packages does not contain at least 5GB of empty space. An image containing a larger hard drive or freeing up more space should solve this issue.

```
[ERROR] The provided encoded private key contains a password. Pattern Manager requires the use of a passwordless private key.
```

- This error is displayed when the provided private key was password-encrypted when generated. In order to solve this issue, generate another private key without providing a password.

```
[ERROR] The provided SSH public and private keys for Pattern Manager do not match, please provide a matching pair of keys.
```

- This error message indicates that the provided pair of private and public keys provided for the Pattern Manager installation do not match. In order to fix it, create a new Content Runtime deployment while making sure that they were generate generated together or, if unsure, generate a new pair of keys.

```
[ERROR] The server's hostname can not contain uppercase letters
```

- This error occurs when the provided host name for the virtual machine contains an uppercase letter and the setup prerequisite checker was set to **strict** mode. When set to **lenient**, the script automatically converts the current host name to lower case. This issue originates from limitations in **Chef**.

```
[ERROR] Docker CE for Red Hat Enterprise is not supported, please provide a valid Docker EE repository URL
```

- This error is displayed when a RHEL template image is provided without a valid Docker EE repository URL. Docker Community Edition is installed by default on all the other distributions but it does not support RHEL officially.

```
[ERROR] There was an error validating the certificate validation when obtaining Docker Compose from the provided URL.
```

- When downloading the Docker compose installer, **curl** command is used for obtaining it. This issue is shown when the **curl** command wasn't able to validate the certificate for downloading the file, usually due to a required update in the system. To fix this issue, perform an update on the system and reboot, or skip the certificate verification in **curl** by adding the word **insecure** to **~/.curlrc**. For security reasons, updating the system is the recommended solution path.

```
[ERROR] There is an error with the default permissions (umask) for new users and folders. The recommended value is 022, found <mask>
```

- The OS image being used contains a UMASK that will limit the required images' permissions when reading or writing files. The default UMASK value can usually be found and changed in the **/etc/login.def** file.

```
[ERROR] Failed while installing <package>
```

- During the prerequisite checking phase of the process, a failure when installing a software package displays this error. If encountered, reviewing the logs can provide more insight on the reason.
- This issue can sometimes be caused by internet connectivity problems or custom setup of repositories which does not include the packages being installed.

VMware vSphere

- The following error is displayed when a virtual machine with the same **name** already exists in the provided VMware vSphere cloud. By default, this **name** is pre-populated to **ibm-content-runtime**. To solve this issue, provide a new unique name for the Content Runtime instance.

```
Error applying plan:
1 error(s) occurred:
* vsphere_virtual_machine.singlenode: 1 error(s) occurred:
* vsphere_virtual_machine.singlenode: The attempted operation cannot be performed in the current state (Powered on).
```

- The followings error varies according to the setup of the vSphere server in use. Some of the optional fields in the **Optional Cloud Provider Settings** might be required in order to achieve a successful deployment.

```
Error applying plan:
1 error(s) occurred:
* vsphere_virtual_machine.singlenode: 1 error(s) occurred:
* vsphere_virtual_machine.singlenode: default resource pool resolves to multiple instances, please specify
```

Troubleshooting Docker EE installation

RHEL

The installation of Docker EE requires access to the **container-selinux** package, located by default in the **rhel-7-server-extras-rpms** repository in **/etc/yum.repos.d/redhat.repo**. If the provided Virtual Machine image contains customized RHEL repositories and there is no access to the mentioned **extras-rpms**, the following error is displayed when attempting to install Docker EE.

```
vsphere_virtual_machine.singlenode (remote-exec): Loaded plugins: product-id, search-
vsphere_virtual_machine.singlenode (remote-exec):               : disabled-repos,
vsphere_virtual_machine.singlenode (remote-exec):               : subscription-manager
vphere_virtual_machine.singlenode (remote-exec): Error loading certificate

vsphere_virutal_machine.singlenode (remote-exec): Error getting repository data for rhel-7-server-extras-rpms, repository
not found
vsphere_virtual_machine.singlenode (remote-exec): [ERROR] There was an error installing Docker EE from the provided
repository
vsphere_virtual_machine.singlenode (remote-exec): [ERROR] Repo: https://storebits.docker.com/ee/rhel/sub-b5

Error applying plan:

1 error(s) occurred:

* vsphere_virtual_machine.singlenode: 1 error(s) occurred:

*Script exited with non-zero exit status: 1

Terraform does not automatically rollback in the face of errors. Instead, your Terraform state file has been partially
updated with any resources that successfully completed. Please address the error above and apply again to incrementally
change your infrastructure.
```

Remote installation verification

A verification of the installation can be done by executing the following command:

```
ssh <user>@<content-runtime> advanced-content-runtime/verify-installation.sh
```

The information returned to the screen should help to diagnose the issue.

Known issues

- **CentOS and RHEL**

  The default firewall on the CentOS must be modified to allow for the `docker0` network connection to communicate back to the docker host. The connection `docker0` must be added to the firewall configuration, and port 443 must be enabled for communication.

  ```
  firewall-cmd --permanent --zone=public --change-interface=docker0
  firewall-cmd --permanent --zone=public --add-port=443/tcp
  firewall-cmd --zone=public --list-all
  firewall-cmd --reload
  systemctl status podman
  systemctl restart podman
  podman exec -it camc-pattern-manager /bin/bash -c "nc -v -z <hostip> 443"
  podman exec -it camc-pattern-manager /bin/bash -c "ping google.com"
  ```

  Disabling the firewall causes an issue with the default docker DNS failing to resolve any hosts.

- **localhost.localdomain host name**

  `localhost` is not supported as a host name for Content Runtime virtual machine. `nmtui` can be used to set the host name on RHEL and CentOS.

- **Mixed case host name**

  The host name of the Content Runtime virtual machine is restricted to lower case. In the case of `other` template, the name is lower cased as part of the Content Runtime configuration process.

- **curl command fails on download of chef-server with SSL certificate error**

  ```
  curl: (60) SSL certificate problem: certificate is not yet valid
  More details here: http://curl.haxx.se/docs/sslcerts.html
  ```

  The Content Runtime virtual machine time is too far out of synch with the current time. Set the time of the virtual machine to the current time.

- **Failed connection to external sites**

  The Content Runtime configuration process relies on external sites to download install content for the virtual machine. If a connection to the internet is not available or if one of the sites is down, the Content Runtime installation and configuration process fails. These sites include:

  - Chef
  - Docker Hub
  - GitHub
  - OS update service for the base operating `systemctl`

Health check

If the Content Runtime experiences an unknown issue, read the following sections to know some commands which may help to isolate the problem.

A script on the Content Runtime virtual machine can be executed to display current status for running services.

The script can be executed by running the command:

```
ssh <user>@<content-runtime> advanced-content-runtime/verify-installation.sh
```

where **user** is the user used to create the Content Runtime. The path to the script can be adjusted based on the user to find the correct location of the script.

content-runtime is the IP address or host name of the Content Runtime virtual machine.

```
[SUCCESS] Chef server nodes are running correctly
[SUCCESS] Docker is installed
[SUCCESS] Docker is currently running
[SUCCESS] The Pattern Manager image is running correctly
[SUCCESS] The Software Repository image is running correctly
[SUCCESS] Connection to the Software Repo image was established correctly
[SUCCESS] Connection to the Pattern Manager image was established correctly
Connection to 192.168.122.89 443 port [tcp/https] succeeded!
[SUCCESS] Connection from Pattern Manager to host has been established successfully
[SUCCESS] /opt/ibm/docker/software-repo/var/swRepo/private is setup as expected
```

Connection to the Content Runtime virtual machine

The virtual machine running the Content Runtime can be connected using **ssh** and the private key associated with the **User's Public Key** parameter.

Docker

Ensure that the Docker service is running:

```
sudo systemctl status podman
```

or

```
sudo service podman status
```

The service can be started by using the **start** option with the previous command.

If you have installed Docker, you must enable the service to start on reboot. You can check the enablement of the service by running:

```
sudo systemctl is-enabled podman
```

Platforms running **service** should have the service to start by default.

Docker containers

Ensure that the Docker containers are running:

```
sudo podman ps
```

The command output should display two active containers as, for example:

```
CONTAINER ID    IMAGE                                COMMAND                  CREATED         STATUS        PORTS
NAMES
93e4607e889a    ibmcom/camc-sw-repo:latest           "/bin/bash /tmp/in..."   3 days ago      Up 3 days     0.0.0.0:8888-
>8888/tcp, 0.0.0.0:9999->9999/tcp    camc-sw-repo
24866ee2426d    ibmcom/camc-pattern-manager:latest   "bin/bash /opt/ibm..."   3 days ago      Up 3 days     0.0.0.0:5443-
>443/tcp                             camc-pattern-manager
```

If the containers are not running, run the **advanced-content-runtime/launch-docker-compose.sh** command from the ~ directory to restart the containers.

Note that the **docker-compose** command controls stopping and starting the container.

Chef server status

Check the status of the Chef server by using the **/usr/bin/chef-server-ctl status** command.

If there are failed processes, take the appropriate action to recover.

Ubuntu apt-get fails

The configuration of the Content Runtime virtual machine can fail with an **apt-get** lock error. The issue is that a background process holds the lock on the **/var/lib/dpkg/lock** file. The timed upgrade does not complete within a limited amount of time.

```
null_resource.singlenode (remote-exec): Checing lock file /var/lib/dpkg/lock
null_resource.singlenode: Still creating... (18m30s elapsed)
null_resource.singlenode (remote-exec): E: Could not get lock /var/lib/dpkg/lock - open (11: Resource temporarily
unavailable)
null_resource.singlenode (remote-exec): E: Unable to lock the administration directory (/var/lib/dpkg/), is another
process using it?
null_resource.singlenode (remote-exec): [ERROR] This script requires apt-get permissions for executing
```

Ubuntu 16.04 may be configured to run unattended updates. The lock which is held by that process might cause delays to occur with the Content Runtime configuration process.

Disk allocation

The logic within the configuration code takes the largest available non-formatted disk for the Software Repository. If no disk is available, the primary partition is used, with the assumption that it has enough space to hold the Software Repository.

If there is a second disk available, the disk is used as the Docker disk. Usage of the second disk is recommended for production environments.

The configuration code does not support using a separate disk for Docker, but not for the Software Repository.

Disk space

If there is not enough space for the Software Repository, you can allocate new space, and move the content of the Software Repository to that space. Complete this action according to the operating system you selected. When completed, you can run the **`advanced-content-runtime/verify-installation.sh`** script to determine if the base file structure is correct.

File system

A file directory structure is created for the Software Repository on the **`/opt/ibm/docker/software-repo/var/swRepo/`** file system.

If you delete or rename any of the file directories, restart the docker container to pick up the changes by running the following command:

```
advanced-content-runtime/launch-docker-compose.sh
```

Managing a software repository

Pattern Management at its core involves the installation and configuration of software packages. In Managed services, the software repository is the node which serves the installation files to the Middleware Template Library installation. The software repository is used to store product binaries that are in compressed format or Installation Manager based repositories.

The software repository currently can hold two different types of product installation files. Product files that are compressed format (zip, tgz) and product binaries that require IBM Installation Manager to perform the installation.

Before you begin

You must have a software repository that is provisioned in the target cloud environment. By default, when the advanced content runtime is provisioned, a software repository is configured.

You must know the following values for the virtual system that is hosting the software repository.

- IP address
  - In the navigation bar, click **Manage > Content Runtimes**.
  - Select the content runtime instance and from the **Actions** overflow menu, click **View Details**
  - In the Overview section, scroll down and click on **Output Variables**.
  - Search for *ibm_sw_repo* and this will contain the IP address of the software repository.
- SSH Key or password to access the virtual system.
- The root directory of the software repository on the virtual system. Default value is **`/opt/ibm/docker/software-repo/var/swRepo/private`**.
- URL for the software repository. For example, **`https://<IP_address>:<port>/`**

Access to the necessary source software repositories from which installation and fix pack files are downloaded:

- IBMid
- Passport Advantage
- Fix Central
- Installation Manager repository

You must have a method to copy files externally to the software repository, either through a direct Internet facing connection or through an appropriate proxy server.

Software Repository Directory Structure

Product binary files must be placed in the correct location within the software repository for the Middleware Template Library content to locate the product binaries. The directory structure is determined by the Enterprise middleware Chef based cookbooks.

The root directory is **`/opt/ibm/docker/software-repo/var/swRepo/private`** and all software binaries reside within this directory structure. The correct directories may be found in the README.md for each of the cookbooks and must be manually created within the software repository. If you do not have access to the middleware Chef cookbooks, see Populating the software repository article for details.

The structure of the repository is as follows:

```
── <product_a>           Name of the software product
    ── <version 1>         Version of the software product
        ── base            Directory that contains the binaries for the full installation of the product.
        ── maint           Directory that contains the fixpack or product updates for the product.
    ── <version 2>
        ── base
        ── maint
── <product b>
    ── <version>
        ── base
        ── maint
── IMRepo                   Directory for Installation Manager binaries
    ── repository.config
```

What to do next

See Populating the software repository for uploading product binaries.

Populating the software repository

Population of the software repository is a manual process which involves creating the directories for each software product and copying the files to these locations.

About this task

This task explains the overall software repository directory structure for products that used compressed format for their installation binaries. For Installation Manager based repositories, see Populating the Installation Manager repository.

Before you begin

1. Understand how to access the advanced content runtime repository so that product binaries can be transferred to the repository.
2. Identify which product binaries need to be transferred to the repository. The product binaries that are needed are based on which Middleware Template are used.
3. Download the product binaries from the appropriate location.
4. Transfer the product binaries to the software repository. See the following diagram for the proper layout.

Software repository directory structure that is properly populated

Product binary files must be placed in the correct location within the software repository for the Middleware Template content to locate the product binaries. The directory structure is determined by the Middleware Template Chef based cookbooks.

The root directory is **`/opt/ibm/docker/software-repo/var/swRepo/private`** and all software binaries reside within this directory structure. For the current supported software products, the software repository directory layout looks like:

- apache > tomcat > v80 > base > apache-tomcat-8.0.15.tar.gz
- db2 > v105 > base > DB2_Svr_10.5.0.8_Linux_x86-64.tar.gz
- db2 > v105 > maint > v10.5fp9_linuxx64_server_t.tar.gz
- db2 > v111 > base > DB2_Svr_11.1_Linux_x86-64.tar.gz
- db2 > v111 > license > DB2_ESE_AUSI_Activation_11.1.zip
- db2 > v111 > maint > v11.1.2fp2_linuxx64_server_t.tar.gz
- im > v1x > base > agent.installer.linux.gtk.x86_64_1.8.6000.20161118_1611.zip
- im > v1x > base > agent.installer.linux.gtk.x86_64_1.8.8000.20171130_1105.zip
- oracle > ee > v12c > base > 12.1.0.2.0 > V46095-01_1of2.zip
- oracle > ee > v12c > base > 12.1.0.2.0 > V46095-01_2of2.zip
- oracle > ee > v12c > base > 12.2.0.1.0 > V839960-01.zip
- oracle > ee > v12c > grid > 12.1.0.1.0 > V38501-01_1of2.zip
- oracle > ee > v12c > grid > 12.1.0.1.0 > V38501-01_2of2.zip
- oracle > ee > v12c > grid > 12.1.0.2.0 > V46096-01_1of2.zip
- oracle > ee > v12c > grid > 12.1.0.2.0 > V46096-01_2of2.zip
- oracle > ee > v12c > grid > 12.2.0.1.0 > V840012-01.zip
- oracle > mysql > v5.7.17 > base > mysql-5.7.17-1.el6.x86_64.rpm-bundle.tar
- oracle > mysql > v5.7.17 > base > mysql-5.7.17-1.el7.x86_64.rpm-bundle.tar
- oracle > mysql > v5.7.17 > base > mysql-server_5.7.17-1debian8_amd64.deb-bundle.tar
- oracle > mysql > v5.7.17 > base > mysql-server_5.7.17-1ubuntu14.04_amd64.deb-bundle.tar
- oracle > mysql > v5.7.17 > base > mysql-server_5.7.17-1ubuntu16.10_amd64.deb-bundle.tar
- wmq > v8.0 > base > WS_MQ_LINUX_ON_X86_64_V8.0_IMG.tar.gz
- wmq > v8.0 > maint > 8.0.0-WS-MQ-LinuxX64-FP0008.tar.gz
- wmq > v9.0 > base > IBM_MQ_9.0.0.0_LINUX_X86-64.tar.gz
- wmq > v9.0 > maint > 9.0.0-IBM-MQ-LinuxX64-FP0002.tar.gz

Downloading IBM software from Passport Advantage and Fix Central

- How to download software from Passport Advantage

IBM WebSphere Application Server

Note: The following links also include details for the IBM HTTP Server and Java SDK.

- Downloading WebSphere Application Server
- Downloading WebSphere Application Server 9.0
- Downloading WebSphere Application Server 8.5.5

IBM DB2 Enterprise Server Edition

- Downloading IBM DB2 11.1
- Downloading IBM DB2 11.5
- How do I download my DB2 license from Passport Advantage
- Recommended Fixes for DB2

IBM MQ

- Downloading IBM MQ 9.0
- Recommended Fixes for IBM MQ

Example: Loading the IBM WebSphere MQ assets into the software repository

After retrieving the product binaries from Passport Advantage (for example):

- IBM MQ V9.0 Long Term Support Release for Linux on x86 64bit Multilingual: **CN9GDML**
- MQ V8.0.0.5 for Multiplatform Multilingual eAssembly: **CJ0CYML**

1. Copy the downloaded files to the software repository:
   - For version 9.0: `/opt/ibm/docker/software-repo/var/swRepo/private/wmq/v9.0/base`
   - For version 8.0: `/opt/ibm/docker/software-repo/var/swRepo/private/wmq/v8.0/base`
2. Download the available fix packs:
   - `9.0.0-IBM-MQ-LinuxX64-FP0002.tar.gz`
   - `8.0.0-WS-MQ-LinuxX64-FP0008.tar.gz`
3. After you download the latest fixes, copy the downloaded files to the software repository:
   - For version 9.0: `/opt/ibm/docker/software-repo/var/swRepo/private/wmq/v9.0/maint`
   - For version 8.0: `/opt/ibm/docker/software-repo/var/swRepo/private/wmq/v8.0/maint`

Example: Loading the IBM DB2 Enterprise Server Edition into the software repository

After retrieving the product binaries from Passport Advantage:

- IBM® DB2® Server 10.5 for Linux® on AMD64 and Intel® EM64T systems (x64): **CNEB9ML**
- IBM® DB2® Server 11.1 for Linux® on AMD64 and Intel® EM64T systems (x64): **CNB0AML**
- IBM® DB2® Enterprise Server Edition Authorized User Single Install Option Quick Start and Activation V11.1 for Linux, UNIX and Windows Multilingual **CNB23ML**

1. Copy the downloaded files to the software repository:
   - For version 11.0: `/opt/ibm/docker/software-repo/var/swRepo/private/db2/v111/base`
   - For version 10.5: `/opt/ibm/docker/software-repo/var/swRepo/private/db2/v105/base`
2. Download the available fix packs:
   - `v10.5fp9_linuxx64_server_t.tar.gz`
   - `v11.1.2fp2_linuxx64_server_t.tar.gz`
3. After you download the latest fixes, copy the downloaded files to the software repository:
   - For version 10.5: `/opt/ibm/docker/software-repo/var/swRepo/private/db2/v105/maint`
   - For version 11.1: `/opt/ibm/docker/software-repo/var/swRepo/private/db2/v111/maint`
4. Copy the Activation file to the software repository:
   - For version 11.0: `/opt/ibm/docker/software-repo/var/swRepo/private/db2/v111/license`

What to do next

See Populating the Installation Manager repository for setting up the Installation Manager repository for WebSphere Application Server offerings.

Populating the Installation Manager repository

This article explains how to setup the local software repository for products that are based on the IBM WebSphere Application Server family of products. The Installation Manager (IM) repository is served by the content runtime software repository container.

Overview

There are three ways you can populate the Installation Manager repository with the proper WebSphere Application Server offerings.

IBM Installation Manager live repositories

The Installation Manager live repositories enable you to directly install the product and supplemental software over the internet. All fix packs levels are available. Access to the initial release requires the proper entitlement. For a list of Installation Manager repositories, see Online product repositories for WebSphere Application Server offerings.

This method will require you to use the IBM Package Utility to build a local Installation Manager repository.

IBM Fix Central

IBM Fix Central contains all fix packs and interim fixes for the product parts. For example, you can download the latest fix pack for WebSphere Application Server or an earlier level according to your needs. Applicable parts for each version of WebSphere Application Server are listed in the download documents. For a list of updates, see Recommended updates for WebSphere Application Server.

This method allows you to use download the fix packs from IBM Fix Central and copy them to the Advanced Content Runtime software repository. This is a good choice if you already have the fix packs downloaded.

Passport Advantage

IBM® Passport Advantage® customers can download the initial release of the product parts from Passport Advantage. To obtain current code levels, these downloads must be supplemented with fix pack repositories from IBM Fix Central. For parts available from Passport Advantage, see Download WebSphere Application Server from Passport Advantage.

Which method you choose depends on what you are most familiar with.

When working with IBM Installation Manager, you should be familiar with the following terminology:

- **Installation Manager repository**

  A repository that Installation Manager uses to locate the files for installing, modifying, rolling back, updating, or uninstalling WebSphere Application Server products. You specify these repositories in the Installation Manager preferences. When you download a product from Passport Advantage or IBM Fix Central, the extracted installation files contain the repository for the product.

- **Composite repository**

  A repository that references one or more other Installation Manager repositories. By editing this single file, you can quickly and easily change which products and versions the repository includes.

- **External repository**

  A user-created repository that typically exists behind a firewall and can be accessed only by systems within your enterprise's intranet. The external repository can be a composite repository that consists of multiple WebSphere Application Server versions, fix packs, or interim fixes. An external repository is also known as a enterprise repository.

- **IBM Packaging Utility**

  A no-cost companion tool to Installation Manager that you can use to create new repositories that contain one or more WebSphere Application Server product offerings. The tool can accept web repositories or local repositories as input, and it produces a local repository as output. This option is needed if you are using the IBM Installation Manager live repositories.

Procedure

1. Download the Installation Manager toolkit to a local machine and transfer the file to the proper location in the software repository. For more information, see Installation Manager Toolkit
2. Build the Installation Manager repository for the WebSphere Application Server products. For more information, see one of the following:
   - IBM Installation Manager live repositories
   - IBM Fix Central
3. Setup the composite repository. For more information, see Setting up a composite repository
4. Verify that the Installation Manager is setup correctly. For more information, see Validating the Installation Manager repository

What to do next

Deploying a predefined template

Installation Manager toolkit binaries

This article explains how to setup the Installation Manager toolkit product in binaries within the software repository.

Procedure

1. Download the Installation Manager to a local machine. For more information about downloading these files, see Installation Manager and Packaging Utility download documents. See the following table to determine which version of the Installation Manager should be downloaded based on which middleware template version is being used. If you are not sure which version of the cookbooks being used, download all versions of the toolkit.
2. Transfer the Installation Manager toolkit file(s) to the Advanced Content Runtime software repository. The file(s) should be copied to the **`/opt/ibm/docker/software-repo/var/swRepo/private/im/v1x/base`** directory.

Version of Installation Manager Toolkit to download

Installation Manager toolkit 1.8.6 or 1.8.8 are required depending on the version of the cookbooks you are using. Cookbook versions 1.0.2 or earlier require IBM Installation Manager 1.8.6 and versions 1.0.3 or higher require 1.8.8.

The cookbook version, toolkit version, and the corresponding file names are listed in the following table:

Cookbook version	Installation Manager Toolkit version	File Name
1.0.1 or lower	1.8.6	agent.installer.linux.gtk.x86_64_1.8.6000.20161118_1611.zip
1.0.2 or higher	1.8.8	agent.installer.linux.gtk.x86_64_1.8.8000.20171130_1105.zip

What to do next

Continue with the one of the methods for populating the Installation Manger repositories.

Using the Installation Manager live repositories

One of the simplest ways to create an Installation Manager repository that works with WebSphere Application Server family of offerings is to use the IBM Installation Manager live repositories. You can build a single repository that contains a specific WebSphere fix pack version by using the IBM Package Utility.

Before you begin

The Installation Manager toolkit binaries step have been completed.

About this task

Set up the software repository with the proper Installation Manager toolkit and IBM Package Utility that are used to create the Installation Manager enterprise repositories.

Complete the following steps to install the Installation Manager toolkit and the IBM Package Utility product.

Procedure

1. Log in to the Content Runtime virtual machine.
2. Change to the **/opt/ibm/docker/software-repo/var/swRepo/private** directory.

   ```
   cd /opt/ibm/docker/software-repo/var/swRepo/private
   ```

3. Make a directory named **IMTemp**.

   ```
   mkdir IMTemp
   ```

4. Change to the **IMTemp** directory.

   ```
   cd IMTemp
   ```

5. Copy the installer file to the **IMTemp** directory.

   ```
   cp /opt/ibm/docker/software-
   repo/var/swRepo/private/im/v1x/base/agent.installer.linux.gtk.x86_64_1.8.8000.20171130_1105.zip
   /opt/ibm/docker/software-repo/var/swRepo/private/IMTemp
   ```

6. Extract the files from the **agent.installer.linux.gtk.x86_64_1.8.8000.20171130_1105.zip** file.

   ```
   unzip agent.installer.linux.gtk.x86_64_1.8.8000.20171130_1105.zip -d imtoolkit
   ```

7. Change to the **/opt/ibm/docker/software-repo/var/swRepo/private/IMTemp/imtoolkit/tools** directory.

   ```
   cd /opt/ibm/docker/software-repo/var/swRepo/private/IMTemp/imtoolkit/tools
   ```

8. Install the package utility from the IBM public installation manager repository.

   ```
   ./imcl install com.ibm.cic.packagingUtility_1.8.8000.20171130_1136 -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.cic.packagingUtility  -installationDirectory
   /opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL -dataLocation /opt/ibm/docker/software-
   repo/var/swRepo/private/IMProducts/datalocation -sharedResourcesDirectory /opt/ibm/docker/software-
   repo/var/swRepo/private/IMProducts/IMshared -log /opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/IMlogs -
   prompt -showProgress  -acceptLicense
   ```

9. Change to the IBM Package Utility directory.

   ```
   cd /opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL
   ```

10. Using the IBM Package Utility, build the required Installation Manager repositories based on the product offerings you require. Follow the instructions that follow.

Build the Installation Manager 1.8.6.1 fix pack repository

It is recommended that the Installation Manager 1.8.6.1 be used as it has additional security fixes. This fix pack level is retrieved from the IBM hosted repositories. This is only needed if you are using the Middleware cookbooks version 1.0.2.

1. Copy the Installation Manager 1.8.6.1 fix pack into the repository using the IBM hosted repositories

   ```
   ./PUCL copy com.ibm.cic.agent_1.8.6001.20170428_1156 -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.cic.agent  -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/im186fp1 -prompt  -showProgress -acceptLicense
   ```

Build the WebSphere v9.0.0.x repository

The commands in the following procedure create a set of installation binaries that supports direct installation to the latest WebSphere Application Server Network Deployment v9.0.0.x fix pack level. If a particular fix pack level is required, the offering name and version number must be specified in the copy command.

The middleware templates are defaulted to install version 9.0.0.6 but they can be changed to use a different fix pack during deployment of the template.

The following table lists the offering IDs that should be used in the Package Utility copy command for various fix pack levels.

Table. WebSphere Application Server

WebSphere Application Server Network Deployment Release	Offering ID
9.0.0.6	com.ibm.websphere.ND.v90_9.0.6.20171205_1311
9.0.0.7	com.ibm.websphere.ND.v90_9.0.7.20180302_0440
latest	com.ibm.websphere.ND.v90

Table. IBM HTTP Server

IBM HTTP Server Release	Offering ID
9.0.0.6	com.ibm.websphere.IHS.v90_9.0.6.20171205_1311
9.0.0.7	com.ibm.websphere.IHS.v90_9.0.7.20180302_0440
latest	com.ibm.websphere.ND.v90

Table. Web server plug-ins

Web server plug-ins Release	Offering ID
9.0.0.6	com.ibm.websphere.PLG.v90_9.0.6.20171205_1311
9.0.0.7	com.ibm.websphere.PLG.v90_9.0.7.20180302_0440
latest	com.ibm.websphere.PLG.v90

Table. Java 8 SDK

Java 8 SDK Release	Offering ID
8.0.5.7	com.ibm.java.jdk.v8_8.0.5007.20171218_1035
8.0.5.10	com.ibm.java.jdk.v8_8.0.5010.20180320_0647
latest	com.ibm.java.jdk.v8

If you do not see the fix pack offering ID, you can use the following command to view the live repositories. You will be prompted for your IBMid.

```
/opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL/PUCL listAvailablePackages -repositories
http://www.ibm.com/software/repositorymanager/V9WASND -prompt
```

The commands in the following procedure build the latest available WebSphere Application Server Network Deployment V9 fix pack level that is available using the IBM hosted repositories. Repeat these commands for each of the fix pack releases that you want to use by replacing the latest offering ID with the appropriate product offering ID.

1. Change your directory to the IBM Package Utility:

   ```
   cd /opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL
   ```

2. Copy the latest available WebSphere Application Server Network Deployment binaries:

   ```
   ./PUCL copy com.ibm.websphere.ND.v90  -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.ND.v90 -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/WAS9   -prompt -showProgress -acceptLicense
   ```

3. Copy the latest available IBM HTTP Server binaries:

   ```
   ./PUCL copy com.ibm.websphere.IHS.v90 -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.IHS.v90  -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/WAS9   -prompt -showProgress -acceptLicense
   ```

4. Copy the WebSphere Web Server Plug-ins binaries:

   ```
   ./PUCL copy com.ibm.websphere.PLG.v90 -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLG.v90/WAS9 -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/WAS9  -prompt -showProgress -acceptLicense
   ```

5. Copy the Java 8 SDK binaries:

   ```
   ./PUCL copy com.ibm.java.jdk.v8 -repositories http://www.ibm.com/software/repositorymanager/com.ibm.java.jdk.v8  -
   target /opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/jdk8   -prompt  -showProgress -acceptLicense
   ```

Build the Liberty repository

The commands in the following procedure create a set of installation binaries that supports direct installation to the latest WebSphere Application Server Liberty fix pack level. If a particular fix pack level is required, the offering ID must be used in place of the latest offering ID on the copy command.

The following table lists the WebSphere Liberty core releases and their offering IDs:

Table. WebSphere Liberty Core

WebSphere Liberty Core Release	Offering ID
17.0.0.4	com.ibm.websphere.liberty.CORE_17.0.4.20171206_1447
18.0.0.1	com.ibm.websphere.liberty.CORE_18.0.1.20180309_2209
latest	com.ibm.websphere.liberty.CORE

The following table lists the WebSphere Liberty releases and their offering IDs:

Table. WebSphere Liberty

WebSphere Liberty Release	Offering ID
17.0.0.4	com.ibm.websphere.liberty.BASE_17.0.4.20171206_1447
18.0.0.1	com.ibm.websphere.liberty.BASE_18.0.1.20180309_2209
latest	com.ibm.websphere.liberty.BASE

Table. WebSphere Liberty Network

WebSphere Liberty Network Deployment	Offering ID
17.0.0.4	com.ibm.websphere.liberty.ND_17.0.4.20171206_1447
18.0.0.1	com.ibm.websphere.liberty.ND_18.0.1.20180309_2209
latest	com.ibm.websphere.liberty.ND

The following table lists the Java 8 SDK releases and their offering IDs:

Table. Java 8 SDK

Java 8 SDK Release	Offering ID
8.0.5.7	com.ibm.java.jdk.v8_8.0.5007.20171218_1035
8.0.5.10	com.ibm.java.jdk.v8_8.0.5010.20180320_0647
latest	com.ibm.java.jdk.v8

If you do not see the fix pack offering ID, you can use the following command to view the WebSphere Liberty live repositories. The command prompts for your IBMid.

```
/opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL/PUCL listAvailablePackages -repositories
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.CORE -prompt
```

The commands in the following procedure build the latest available WebSphere Application Server Liberty fix pack level that is available using the IBM live repositories. Repeat these commands for each of the fix pack releases that you want to use by replacing the latest offering ID with the appropriate product offering ID.

1. Change your directory to the IBM Package Utility:

   ```
   cd /opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL
   ```

2. Copy the WebSphere Liberty Core binaries:

   ```
   ./PUCL copy com.ibm.websphere.liberty.CORE -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.CORE -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/Liberty   -prompt -showProgress -acceptLicense
   ```

3. Copy the WebSphere Liberty Network Deployment binaries:

   ```
   ./PUCL copy com.ibm.websphere.liberty.ND -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/Liberty -prompt  -showProgress -acceptLicense
   ```

4. Copy the WebSphere Liberty binaries:

   ```
   ./PUCL copy com.ibm.websphere.liberty.BASE -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.BASE -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/Liberty   -prompt   -showProgress -acceptLicense
   ```

5. Copy the Java 8 SDK binaries:

   ```
   ./PUCL copy com.ibm.java.jdk.v8 -repositories http://www.ibm.com/software/repositorymanager/com.ibm.java.jdk.v8  -
   target /opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/jdk8   -prompt  -showProgress -acceptLicense
   ```

Build WebSphere Application Server 8.5.5.x repository

When building this repository, you need the WebSphere Application Sever 8.5.5.0 Installation Manager repositories in order to build a fully functional repository that is capable of installing the product. You have the following two options:

- Using IBM hosted repositories
- Using IBM hosted repositories and Passport Advantage repositories

If your target repository is already built based upon the 8.5.5.0 code base, you can just use the IBM live repositories.

Using IBM hosted repositories

You can also use the Package Utility **-connnectPassportAdvantage** parameter option to connect to the Passport Advantage repository which allows you to not have to download the V8.5.5.0 product binaries. You must have the appropriate IBMid that is entitled to the WebSphere 8.5.5.0 product binaries.

For example, use the following command to download WebSphere Application Server Network Deployment v8.5.5.12 where your IBMid is entitled to use the Passport Advantage repositories that are IBM hosted:

```
./PUCL copy com.ibm.websphere.ND.v85_8.5.5012.20170627_1018 -repositories
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.ND.v85 -target /opt/ibm/docker/software-
repo/var/swRepo/private/IMRepo/WAS8 -showProgress -acceptLicense -prompt -connnectPassportAdvantage
```

Using IBM hosted repositories and Passport Advantage repositories

This option uses a combination of using two source repositories to build a single repository that contains the appropriate fix pack level. This method is used when your IBMid is not entitled to access the Passport Advantage repositories that are configured in the IBM hosted repository site.

For more information, see How to download WebSphere Application Server Network Deployment V8.5.5 from Passport Advantage. The required part numbers are listed in the following table:

Note: IBM WebSphere SDK Java Technology Edition 7.1 is not available on the product media or on Passport Advantage. IBM hosted repository can be used to retrieve the Java 7.1 SDK binaries.

After downloading these files, unpackage each product offering file into a separate directory structure, one for the supplements and one for the network deployment. Then use the IBM Package Utility to use two source repositories to create a single new repository. For example:

```
./PUCL copy com.ibm.websphere.ND.v85_8.5.5012.20170627_1018 -repositories
<path_to_8.5.5.0_repostories,http://www.ibm.com/software/repositorymanager/com.ibm.websphere.ND.v85 -target
/opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/WAS8 -showProgress -acceptLicense -prompt
```

The following table lists the offering IDs that must be used in the Package Utility copy command for a particular fix pack level.

Table. WebSphere Application Server

WebSphere Application Server Release	Offering ID
8.5.5.12	com.ibm.websphere.ND.v85_8.5.5012.20170627_1018
8.5.5.13	com.ibm.websphere.ND.v85_8.5.5013.20180112_1418
latest	com.ibm.websphere.ND.v85

Table. IBM HTTP Server

IBM HTTP Server Release	Offering ID
8.5.5.12	com.ibm.websphere.IHS.v85_8.5.5012.20170627_1018
8.5.5.13	ccom.ibm.websphere.IHS.v85_8.5.5013.20180112_1418
latest	com.ibm.websphere.IHS.v85

Table. Web server Plug-ins

Web server Plug-ins Release	Offering ID
8.5.5.12	com.ibm.websphere.PLG.v85_8.5.5012.20170627_1018
8.5.5.13	com.ibm.websphere.PLG.v85_8.5.5013.20180112_1418
latest	com.ibm.websphere.PLG.v85

Table. WebSphere Java 7.1 SDK

WebSphere Java 7.1 SDK	Offering ID
8.5.5.12	com.ibm.websphere.IBMJAVA.v71_7.1.4005.20170626_0531
8.5.5.13	com.ibm.websphere.IBMJAVA.v71_7.1.4015.20171219_1604
latest	com.ibm.websphere.IBMJAVA.v71

If you do not see the fix pack offering ID, you can use the following commands to view the WebSphere Liberty live repositories

```
/opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL/PUCL listAvailablePackages -repositories
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.ND.v85  -prompt
```

```
/opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL/PUCL listAvailablePackages -repositories
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.IBMJAVA.v71  -prompt
```

```
/opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL/PUCL listAvailablePackages -repositories
http://www.ibm.com/software/repositorymanager/com.ibm.websphere.IHS.v85  -prompt
```

The following example illustrates the commands that are used to build a functional WebSphere Application Server Network Deployment repository that is based on the latest fix pack available on IBM hosted repositories:

1. Change your directory to the IBM Package Utility:

   ```
   cd /opt/ibm/docker/software-repo/var/swRepo/private/IMProducts/PUCL
   ```

2. Copy the WebSphere Application Server Network Deployment offering:

   ```
   ./PUCL copy com.ibm.websphere.ND.v85 -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.ND.v85 -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/WAS8 -showProgress -acceptLicense -prompt
   ```

3. Copy the IBM HTTP Server offering:

   ```
   ./PUCL copy com.ibm.websphere.IHS.v85 -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.IHS.v85 -target  /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/WAS8 -acceptLicense -prompt
   ```

4. Copy the Web Server Plug-ins offering:

   ```
   ./PUCL copy com.ibm.websphere.PLG -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLG.v85 -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/WAS8 -acceptLicense -prompt
   ```

5. Copy the WebSphere Java 7.1 SDK:

   ```
   ./PUCL copy com.ibm.websphere.IBMJAVA.v71 -repositories
   http://www.ibm.com/software/repositorymanager/com.ibm.websphere.IBMJAVA.v71  -target /opt/ibm/docker/software-
   repo/var/swRepo/private/IMRepo/WAS8 -acceptLicense -prompt
   ```

What to do next

Set up the composite repository. For more information, see Setting up a composite repository.

- Creating custom installation repositories with IBM Packaging Utility for WebSphere Application Server 8.5.5

Configuring the Installation Manager repository

WebSphere Application Server family of offerings uses an IBM Installation Manager repository to contain WebSphere Application Server offerings, fix packs, and interim fixes. You can download fix packs and interim fixes from IBM Fix Central and add them to the Advanced Content Runtime software repository composite repository.

Before you begin

The Advanced Content Runtime software repository composite repository contains the WebSphere base product offering that will allow you to perform a full installation of the fix pack. See Download WebSphere Application Server from Passport Advantage for instructions.

Procedure

1. Download the appropriate fix pack from IBM Fix Central. See Recommended updates for WebSphere Application Server

   Log in to the Content Runtime virtual machine.

2. Transfer the compressed IBM Installation Manager packages to the /opt/ibm/docker/software-repo/var/swRepo/private/IMRepo directory.

3. Extract the compressed repository files to a directory underneath /opt/ibm/docker/software-repo/var/swRepo/private/IMRepo. Each product offering should be extracted into their own directory.

4. Update the composite repository configuration file **`/opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/repository.config`** to contain the new directory.

What to do next

For more information, see Setting up a composite repository.

Setting up a composite repository

A composite repository is one that is reference to one or more other repositories. It allows you to provide one repository to your end users, while being able to quickly and easily change what products and versions that repository includes. The Managed services Installation Manager Repository is set up to be a composite repository.

Product binary files reside in their own directory and have a master **`repository.config`** file that aggregates all of the product binary files. The advantage that this configuration has over a single repository is that you can more easily add or remove product binary files from the overall Installation Manager repository.

The composite repository has the following directory structure:

- **`/opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/`**
- **`/opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/repository.config`**
- **`/opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/<product A>`**
- **`/opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/<product B>`**
- **`/opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/<product C>`**

The **`repository.config`** file resembles the following example:

```
#Thu Mar 09 21:59:57 UTC 2017
LayoutPolicyVersion=0.0.0.1
LayoutPolicy=Composite
repository.url.was9=./WAS9
repository.url.was855=./WAS8
repository.url.liberty=./Liberty
repository.url.jdk8=./jdk8
repository.url.imcl186fp1=./im186fp1
```

What to do next

Validate the Installation Manager repository. For more information, see Validating the Installation Manager repository.

Validating the Installation Manager repository

Use the Installation Manager command line and list the contents of the Managed services Installation Manager repository to validate the Installation Manager repository.

1. Change directory to Installation Manager toolkit directory:

   ```
   cd /opt/ibm/docker/software-repo/var/swRepo/private/IMTemp/imtoolkit/tools
   ```

2. List the available packages that are available:

   ```
   ./imcl listAvailablePackages -repositories /opt/ibm/docker/software-repo/var/swRepo/private/IMRepo/
   ```

If the repository is setup properly, you will see output that should contain the WebSphere Application Server offerings that were built using the IBM Package Utility. Here is an example output of a Installation Manager repository that contains the Installation Manager 1.8.6.1, JDK 8 and WebSphere fix pack 9.0.0.4.

com.ibm.cic.agent_1.8.6001.20170428_1156
com.ibm.java.jdk.v8_8.0.5000.20170906_1259

com.ibm.websphere.ND.v90_9.0.4.20170523_1327
com.ibm.websphere.IHS.v90_9.0.4.20170523_1327
com.ibm.websphere.PLG.v90_9.0.4.20170523_1327

Content Runtime Backup Considerations

After a Content Runtime is provisioned, it is recommended customers implement a backup solution.

The following sections will specify the process or file systems that you are recommended to be backed up.

Chef Server Backup

Follow the recommended Chef Server backup and restore steps

- CHEF Backup and Restore

IBM Software Repository Binaries

All the software binaries needed by the Middleware Content Library are located under the file system '**/opt/ibm/docker/software-repo/var/swRepo/private**'.

Customers should backup the file system once populated or have procedure on how to repopulate.

Also backup the software repository configuration under the file system '**/opt/ibm/docker/software-repo/**'.

IBM Pattern Manager

Backup the IBM Pattern Manager configuration under the file system '**/opt/ibm/docker/pattern-manager/**'.

Updating the Content Runtime SSL Certificates

You can update the Chef server certificate on a content runtime deploy. Communication with components of the content runtime is performed with self-signed SSL certificates that are created during deploy. One of these certificates is used by the Chef server for communication with its clients.

The recommended method to replace this certificate with your own certificate is to follow the instructions available at the Chef Security page. Alternatively, you can create a virtual machine and pre-populate the SSL certificate before deploying the content runtime:

1. Create a virtual machine in the cloud.
2. Copy your `.key` and `.pem` files into `/etc/opscode/ca` on the virtual machine.

   Note: If you have a .crt file, ensure that it is in PEM format and rename the suffix to `.pem`.

3. Deploy the type "other" content runtime to your virtual machine.

Middleware Content Templates

After you configure your runtime environments, you can proceed to the content in the Middleware Template Library in the Managed services interface to deploy middleware content. Middleware Content automation is represented in Managed services by the Terraform Template format. These templates are made available through a set of private GitHub repositories.

Before you begin

Read the Managed services Content topic and complete the steps to configure your content runtime environments.

Middleware Template Library

The Middleware Content automation leverages two types of content from this repository:

`template_<template_description>`:

This library repository contains predefined Terraform templates that are used when provisioning a Middleware Template.

This repository contains separate directories for available middleware. For example:

- This repository might be named **`ibm_wasndv9_standalone`**, which contains the templates for a WebSphere standalone topology.
- This **`ibm_wasndv9_standalone`** repository contains these child directories: **`amazon`**, **`ibmcloud`**, and **`vmware`**.
- These child directories contain a **`terraform`** directory, which contains the template for the WebSphere Application Server deployment.
- This directory also contains the **`camvariables.json`** file, which is the parameters file that is used to customize the deployment experience.

`cookbook_<middleware_product>`:

These repositories contain the Chef based automation that is used for the installation and configuration of the corresponding software.

- The **`cookbook_<middleware_product>`** directory contains the required files: **`README.md`**, **`attributes.json`**, **`components.json`**, **`metadata.rb`**, and **`recipes.json`**.
- It also contains several subdirectories which contain the required files for the cookbook:
  - **`attributes`**: This directory contains the attributes files: **`default.rb`** and **`internal.rb`**.
  - **`libraries`**: This directory contains chef libraries to extend the cookbook functionality.
  - **`providers`**: This directory contains cookbook Lightweight Resource Providers (LWRPs) to extend cookbook functionality
  - **`recipes`**: This directory contains the recipes for the cookbook, such as **`prereq.rb`**, **`install.rb`**, **`gather_evidence.rb`**, **`fixpack.rb`**, **`harden.rb`**, and more.
  - **`resources`**: This directory contains resources to be used with the LWRPs under the provider directory.

Chef cookbooks

IBM-created Chef cookbooks use a common structure to provide a consistent experience. Each cookbook repository holds the automation for a single product. When possible, a cookbook will support multiple versions of a product offering as well as support for multiple operating systems.

Cookbook and Template Versions

For current templates supported and versions, see IBM-CAMHub-Open/IBM-CAMHub-Open repository.

What's Next

Proceed to Deploying a Middleware template to know more about deploying a middleware template.

Proceed to the following section if you want to know more about middleware templates in GitHub repositories and and how it relates to Terraform.

- Terraform Template Overview
- Template Cloud Parameters
- Template Middleware Parameters

Deploying a middleware templates

You can deploy the predefined middleware templates in GitHub repository by first importing them using the steps in Import page. Once you import, you can then deploy them to your cloud environment including VMware, IBM Cloud, and AWS.

Starting from IBM Cloud Pak® for AIOps 4.6.0 release, terraform engine 0.11.x is not shipped with the product. The middleware content requires terraform engine 0.11.x. You must use the Create a version steps to first import the 0.11.x terraform engine before you deploy middleware templates.

General deployment guidelines

- Each predefined template was tested with the default values for its variables. See the README file for the template for details on possible customizations to the template.

Deployment guidelines for VMware

- Consult the README file for the template to learn what additional configuration steps might be required to deploy that template.
- No additional general configuration steps are required for VMware.

Deploy the template

For steps to deploy the template, see Deploying a WebSphere Application Server V9 Standalone template.

Validate the deployment

After you deploy a predefined template, you can validate the deployment by checking the log files for Terraform, Chef, and the middleware product. You can also check the Output variables tab of the deployed template and confirm you see the desired output.

Troubleshooting

For details about troubleshooting issues when deploying templates, see Troubleshooting content related issues and useful links.

Deploying a WebSphere Application Server V9 Standalone template

Deploy the WebSphere Application Server V9 Standalone template in your environment.

Starting from IBM Cloud Pak® for AIOps 4.6.0 release, terraform engine 0.11.x is not shipped with the product. This template requires terraform engine 0.11.x. You must use the Create a version steps to first import the 0.11.x terraform engine before you deploy this template.

Procedure

To deploy the WebSphere Application Server V9 Standalone template, follow these steps:

1. In the navigation bar, click **Library** > **Terraform templates**. The template library is displayed.
2. Import the template from GitHub repository
3. Click **Middleware**.
4. Click **IBM WebSphere Network Deployment V9 on a single virtual machine - VMware vSphere**.
5. Read the information about the template and click **Deploy template**.
6. Enter the required parameters:
   - Specify the **Instance name**.
   - Select the **VMware** cloud connection.
   - Select the **Advanced content runtime** Namespace.
7. Specify the instance name, a connection to the cloud provider where you want to deploy the template, and enter the required deployment parameters.

   The cloud connection list only contains the connections defined for the type of cloud provider where you can deploy the template. For information about cloud connections, see Managing connections.
8. Click **Deploy**. The template instance window is displayed.

   In the template instance window, you can see the instance status, the instance information, the related resource details, and the related input and output variables. You can view or copy the instance logs and you can also access the template from which the instance was deployed.

Cloud Input Variables Group

Table. Cloud Input Variables Group

Parameter	Default Value	Description
vSphere Cluster		The name of the target vSphere cluster to host virtual machine.
vSphere Datacenter		The name of the target vSphere Datacenter to host virtual machine.
vSphere Folder		The name of the target vSphere folder to host virtual machine.

Virtual Machine Input Variables Group

Table. Virtual Machine Input Variables Group

Parameter	Default Value	Description
DNS servers		List of DNS servers for the virtual network adapter. For more than one DNS, the values can be entered by adding more fields.
DNS Suffixes		List of DNS Suffixes for the virtual network adapter. For more than one DNS, the values can be entered by adding more fields.
Domain Name		Virtual Machines domain name
Operating System ID/Template		The vSphere Template Name to be cloned
Operating System Username	root	The username to log into the Template System ID / Template

Parameter	Default Value	Description
Operating System Password		The password for the Operating System Username to log into the Template System ID/Template
Short Hostname		The short hostname of the virtual machine
Template Disk Controller	scsi	A drop-down of the vSphere template disk controller types.
Template Disk Datastore		Data store or storage cluster name for target virtual machine's disks
Template Disk Type	Thick Provision Eager-zeroeed	A drop-down list of vSpghere Disk types
Virtual Machine Gateway Address		IPv4 gateway for vNIC configuration
Virtual Machine IP Address		IPv4 address for vNIC configuration
Virtual Machine Memory		Memory assigned to the virtual machine in megabytes. This value is required to be an increment of 1024
Virtual Machine Netmask Prefix		IPv4 prefix length for vNIC configuration. The value must be a number between 8 and 32
Virtual Machine vCPU's		Number of virtual CPU for the virtual machine, which is required to be a positive Integer
Virtual Machine vSphere Port Group		vSphere port group or network label for virtual machine's vNIC

SSH Keys Group

Table. SSH Keys Group

Parameter	Default Value	Description
User Public SSH Key		User defined public SSH key used to connect to the virtual machine. The format must be in openSSH.

WASNode01 Group

Table. WASNode01 Group

Parameter	Default Value	Description
WebSphere Application Server Version	9.0.0.4	The release and fix pack level of WebSphere Application Server to be installed
WebSphere Application Server maximum JVM Heap Size	512	WebSphere Application Server maximum JVM Heap Size
WebSphere Application Server minimum JVM Heap Size	256	WebSphere Application Server minimum JVM Heap Size
WebSphere Application Server profile name	standalone1	WebSphere Application Server Profile name
WebSphere Java SDK Version	8.0.4.70	The Java SDK version that should be installed with the WebSphere Application Server
WebSphere administrative user name	wasadmin	The username for securing the WebSphere administrative console
WebSphere administrative user password	xxxx	The password for the WebSphere administrative account
WebSphere default keystore password	xxxx	Specifies the password to use on all keystore files created during profile creation
WebSphere product installation directory	/opt/IBM/WebSphere/AppServer	The installation root directory for the WebSphere Application Server product binaries"
WebSphere profile location	/opt/IBM/WebSphere/AppServer/profiles	The directory path that contains WebSphere Application Server profiles

Deploying content and content runtime from Managed services that is behind a firewall

Deployment of content and content runtime in Infrastructure Automation - Managed services that is behind a firewall.

About the task

Two scenarios are supported for this deployment:

- Deploy the content and content runtime on to a cloud that is outside the firewall. For example, IBM Cloud, AWS and vSphere from the Managed services that is inside the firewall. For this deployment, you need a Bastion Server that is capable of SSH calls. The Terraform template uses this server to make any remote execution calls.
- Deploy the content and content runtime to a vSphere cloud that is inside a firewall from the Managed services that is also inside a firewall. For this deployment, you need a HTTP proxy server that can forward any HTTP or HTTPS calls. The limitations for this scenario are as follows:
  - For middleware content, support is available only for Ubuntu.
  - For Content Runtime, Bring Your Own Chef is not supported.
  - Starter library MEAN stack template is not supported.

Procedure

1. In Managed services, go to **Manage** > **Shared parameters**.

2. You can view the shared parameters that are included to support the scenarios mentioned in the "About the task" section.

   - The following Data Types are created to capture Bastion host details and HTTP configuration details:
     - `Bastion Host Configuration` - Configuration that contains information to connect outbound through a Bastion host.
     - `HTTP Proxy Configuration`- Proxy configuration that is to be used for both HTTP and HTTPS outbound communication by the virtual machine that is deployed inside a proxy.
   - The following Data Objects that are provided can be used whenever you do not need a Bastion host or HTTP proxy host:
     - `DefaultNoBastionHostRequired`
     - `DefaultNoProxyRequired`
3. If you need a Bastion host or HTTP proxy, then you must create your own Data Objects that capture the details of the Bastion host or HTTP proxy server. For steps to create Data Types and Data Objects, see Managing shared parameters from Managed services console.

4. Open a Content Runtime, Terraform template, or middleware template to deploy:

   - To deploy from the Managed services that is not behind a firewall and also wherein both Bastion host and HTTP proxy are not required:
     - Select the cloud connection.
     - In the **Select data object** section, select `DefaultNoBastionHostRequired` for Bastion Host Configuration.
     - Select `DefaultNoProxyRequired` for **HTTP Proxy Configuration**.
   - To deploy to a public cloud from Managed services that is behind a firewall:
     - Select the cloud connection.
     - In the **Select data object** section, for **Bastion Host Configuration**, select the Bastion host data object that encapsulates your bastion host data.
     - Select `DefaultNoProxyRequired` for **HTTP Proxy Configuration**.
   - Deploy Content Runtime, middleware, and other templates on to a private VMware cloud that is behind a firewall from Managed services that is also behind a firewall: To deploy to a private VMware, additional HTTP Proxy Configuration details are required.
     - Select the cloud connection.
     - In the **Select data object** section, select `DefaultNoBastionHostRequired` for **Bastion Host Configuration**.
     - For **HTTP Proxy Configuration**, select the **HTTP Proxy Configuration** data object that encapsulates your HTTP proxy server.
5. Click **Deploy**.

Terraform Template Overview

The following is a description of a typical Terraform template focusing on the elements which may be modified.

The following elements are considered:

- Variables - SSH keys
- Variables - Cloud specific
- Variables - Environment variables
- Variables - Pattern variables
- Variables - Image variables
- IBM-specific Terraform resources

Variables - SSH keys

SSH keys for injection and Pattern Manager remote control.

```
variable "user_public_ssh_key" {
  type = "string"
  description = "User defined public SSH key used to connect to the virtual machine, whose format is required to be the
openSSH key format with optional comment"
  default = "None"
}
```

Variables - Cloud specific

Cloud specific variables that may be different for each cloud type. Cloud specific variables are likely injected by Managed services and not exposed to the deployer. The following examples are for VMware-based cloud.

```
variable "vsphere_user" {
  description = "vSphere user"
}

variable "vsphere_password" {
  description = "vSphere password"
}

variable "vsphere_server" {
  description = "vSphere server"
}

variable "ibm_pm_public_ssh_key" {
  description = "Public CAMC SSH key value which is used to connect to a guest, used on VMware only"
}

variable "ibm_pm_private_ssh_key" {
  description = "Private CAMC SSH key (base64 encoded) used to connect to the virtual guest"
}
```

```
variable "allow_unverified_ssl" {
  description = "Communication with vSphere server with self-signed certificate"
  default = "true"
}
```

Variables - Environment variables

Environment variables relate to the injected variables, which in turn relate to the selected Content Runtime, and are not exposed to the deployer. A typical set of variables is:

```
variable "vsphere_user" {
  description = "vSphere user"
}

variable "vsphere_password" {
  description = "vSphere password"
}

variable "vsphere_server" {
  description = "vSphere server"
}

variable "ibm_pm_public_ssh_key" {
  description = "Public CAMC SSH key value which is used to connect to a guest, used on VMware only"
}

variable "ibm_pm_private_ssh_key" {
  description = "Private CAMC SSH key (base64 encoded) used to connect to the virtual guest"
}

variable "allow_unverified_ssl" {
  description = "Communication with vSphere server with self-signed certificate"
  default = "true"
}
```

Variables - Pattern variables

This set of variables contains the specific variables that relate to the software pattern. Variables are typically defined on a per-node basis and relate to specific software concepts such as ports, users and directories.

This type of variable is the most applicable for editing. You can create custom templates for specific situations and hide variables from the deployer if necessary. It is noteworthy that each of these parameters appears in the Managed services Variables section and may be defaulted or hidden by Managed services Variable modification.

```
##### centralnode variables #####

#Variable : centralnode_was_liberty_base_version
variable "centralnode_was_liberty_base_version" {
  type = "string"
  description = "The release and fixpack level for WebSphere Liberty to be installed. Example formats are 8.5.5.11 or
17.0.0.2"
  default = "17.0.2"
}

#Variable : centralnode_was_liberty_edition
variable "centralnode_was_liberty_edition" {
  type = "string"
  description = "Indicates which Liberty offering should be installed. Valid values are: base, core, nd"
  default = "base"
}
```

Variables - Image variables

A template describes one or more compute instances and other cloud resources. These resources are cloud specific and may include the definition of virtual machines, networks, disk or security groups. The templates have different resources for each cloud defined.

This category of variables may be extremely relevant for an administrator to modify, to ensure that template deployers do not have too many decisions to make at deploy time.

```
#########################################################
##### Resource : centralnode
#########################################################

variable "centralnode-os_password" {
  type = "string"
  description = "Operating System Password for the Operating System User to access virtual machine"
}

variable "centralnode_folder" {
  description = "Target vSphere folder for virtual machine"
}

variable "centralnode_datacenter" {
```

```
  description = "Target vSphere Datacenter for virtual machine creation"
}

variable "centralnode_number_of_vcpu" {
  description = "Number of virtual CPU for the virtual machine, which is required to be a positive Integer"
  default = "2"
}
```

It is noteworthy that these resources often use Managed services Variables to set values at deploy time. For example, the amount of memory assigned to a virtual machine is defined and may be modified by an administrator using Managed services Variables.

IBM-specific Terraform resources

IBM has extended the standard Terraform provider to expose methods provided by the Pattern Manager, which participates in software deployment. The following resources are exposed:

camc_bootstrap

camc_bootstrap bootstraps the target node with a Chef client and register the client with the relevant Chef server. A Chef vault item is also created at this time to handle Pattern Secrets. Standard IBM Variables such as **stack_id** and **stack_name** are created as Node Attributes during **camc_bootstrap**. An example of **camc_bootstrap** is:

```
resource "camc_bootstrap" "centralnode_chef_bootstrap_comp" {
  depends_on = ["camc_vaultitem.VaultItem","vsphere_virtual_machine.centralnode"]
  name = "centralnode_chef_bootstrap_comp"
  camc_endpoint = "${var.ibm_pm_service}/v1/bootstrap/chef"
  access_token = "${var.ibm_pm_access_token}"
  skip_ssl_verify = true
  trace = true
  data = <<EOT
{
  "os_admin_user": "${var.centralnode-os_admin_user}",
  "stack_id": "${random_id.stack_id.hex}",
  "environment_name": "_default",
  "host_ip": "${vsphere_virtual_machine.centralnode.network_interface.0.ipv4_address}",
  "node_name": "${var.centralnode-name}",
  "node_attributes": {
    "ibm_internal": {
      "stack_id": "${random_id.stack_id.hex}",
      "stack_name": "${var.ibm_stack_name}",
      "vault": {
        "item": "secrets",
        "name": "${random_id.stack_id.hex}"
      }
    }
  }
}
EOT
}
```

camc_softwaredeploy

camc_softwaredeploy instructs the Pattern Manager to execute a Chef role on the target node. An important facet of this operation is the creation of Node Attributes on the Chef node, which are used when the Chef client is executed.

```
resource "camc_softwaredeploy" "centralnode_liberty_install" {
  depends_on = ["camc_bootstrap.centralnode_chef_bootstrap_comp","camc_bootstrap.libertynode_chef_bootstrap_comp"]
  name = "centralnode_liberty_install"
  camc_endpoint = "${var.ibm_pm_service}/v1/software_deployment/chef"
  access_token = "${var.ibm_pm_access_token}"
  skip_ssl_verify = true
  trace = true
  data = <<EOT
{
  "os_admin_user": "${var.centralnode-os_admin_user}",
  "stack_id": "${random_id.stack_id.hex}",
  "environment_name": "_default",
  "host_ip": "${vsphere_virtual_machine.centralnode.network_interface.0.ipv4_address}",
  "node_name": "${var.centralnode-name}",
  "runlist": "role[liberty_install]",
  "node_attributes": {
    "ibm": {
      "im_repo": "${var.ibm_im_repo}",
      "im_repo_user": "${var.ibm_im_repo_user}",
      "sw_repo": "${var.ibm_sw_repo}",
      "sw_repo_user": "${var.ibm_sw_repo_user}"
    },
    "ibm_internal": {
      "roles": "[liberty_install]"
    },
    "was_liberty": {
      "base_version": "${var.centralnode_was_liberty_base_version}",
      "edition": "${var.centralnode_was_liberty_edition}",
      "im_install_dir": "${var.centralnode_was_liberty_im_install_dir}",
      "install_dir": "${var.centralnode_was_liberty_install_dir}",
      "install_grp": "${var.centralnode_was_liberty_install_grp}",
      "install_user": "${var.centralnode_was_liberty_install_user}",
```

```
      "java_version": "${var.centralnode_was_liberty_java_version}",
      "wlp_user_dir": "${var.centralnode_was_liberty_wlp_user_dir}"
    }
  },
  "vault_content": {
    "item": "secrets",
    "values": {
      "ibm": {
        "im_repo_password": "${var.ibm_im_repo_password}",
        "sw_repo_password": "${var.ibm_sw_repo_password}"
      }
    },
    "vault": "${random_id.stack_id.hex}"
  }
}
EOT
}
```

In the previous example note the following items:

- `runlist`: The Chef Runlist to execute.
- `host_ip`: The IP address of the node to execute the Chef client on.
- `node_attributes`: A Chef structure list of node attributes to be created.
- `vault_content`: Chef vault items to create.

  Note: A single Chef vault is created per template or stack. In this way, all nodes from the same template can share secrets and exclude nodes from other templates.

Template Cloud Parameters

The following sections detail common and standard template parameters and how they are used in Managed services. Note that the predominant classification is by cloud type, which reflects the differences among cloud types when provisioning cloud resources.

Global variables

Global variables appear once on a Terraform template and effect the template as a whole. Templates that deploy to specific clouds may have variables unique to that cloud type.

Table 1. Global Variables

Attribute	Description	Scope
ibm_stack_name	A unique stack name which is appended as a Chef Node Attribute. System generated.	all
allow_unverified_ssl	Boolean. Communication with vSphere server with self-signed certificate.	VMware
client_debug	True or False. If you enable it to true in the provider section, the logs are written to `/home/terraform/.govmomi/debug` directory.	VMware
aws_ami_owner_id	The AMI owner ID, injected by the cloud connection.	AWS
aws_region	The AWS region, injected by the cloud connection. For example, us-east-1.	AWS
aws_sg_camc_name	The name of the AWS security group for automation content, injected by the cloud connection.	AWS
aws_vpc_name	The name of the AWS VPC, injected by the cloud connection.	AWS

Content Runtime injected variables

The Content Runtime predefines a specific set of variables that are injected to the template at deployment time. These variables can not be modified in CAM Variables. They are listed as a reference only.

Table 2. Content Runtime Injected Variables

Attribute	Description	Scope
ibm_sw_repo	IBM Software Repository root, described by a URL.	all
ibm_sw_repo_password	IBM Software Repository password, set by the HTTP Server on the software repository.	all
ibm_sw_repo_user	IBM Software Repository user name, used to secure the HTTP Server.	all
ibm_pm_private_ssh_key	Private CAMC SSH key (base64 encoded) used to connect to the virtual guest.	all
ibm_pm_public_ssh_key	Public CAMC SSH key name used to connect to the virtual guest.	all
ibm_pm_access_token	IBM Pattern Manager access token.	all
ibm_pm_service	IBM Pattern Manager service.	all

Node variables - All clouds

Node variables appear once per node and can therefore appear multiple times on the same template. Node variables also have a name which is a merging of the variable name and the node name. For example, the os_admin_user field may appear in the template as MQV9Node01-os_admin_user, which is a combination of the variable and node name.

Table 3. Node Variables - All Clouds

Attribute	Description	Scope
domain	Domain Name of virtual machine. It is used in DNS searching on the node (resolv.conf on Linux devices).	all
runtime_domain	Domain Name of virtual machine. It is used in DNS searching on the node (resolv.conf on Linux devices).	all
image	Operating system image ID/template that should be used when creating the virtual image.	all
name	Short host name of the virtual machine.	all
user_public_ssh_key	User-defined public SSH key used to connect to the virtual machine. Set to None if not required.	all

Node variables - VMware

The following is a list of node parameters that effect VMware-based templates only.

Table 4. Node Variables - VMware

Attribute	Description	Scope
os_password	Operating system password for the operating system user to access virtual machine, used by Terraform to bootstrap the node.	VMware
root_disk_controller_type	Type of template disk controller. For example, scsi-lsi-parallel.	VMware
root_disk_datastore	Data store or storage cluster name for target virtual machine's disks.	VMware
root_disk_type	Type of template disk volume. For example, eager_zeroed.	VMware
ipv4_gateway	IPv4 gateway for vNIC configuration.	VMware
ipv4_address	IPv4 address for vNIC configuration.	VMware
memory	Memory assigned to the virtual machine in megabytes. This value is required to be an increment of 1024.	VMware
ipv4_prefix_length	IPv4 prefix length for vNIC configuration. The value must be a number between 8 and 32.	VMware
number_of_vcpu	Number of virtual CPU for the virtual machine. The value must be a positive integer.	VMware
folder	Target vSphere folder for virtual machine.	VMware
datacenter	Target vSphere datacenter for virtual machine creation.	VMware
cluster	Data store or storage cluster name for target virtual machine's disks.	VMware
network_interface_label	vSphere port group or network label for virtual machine's vNIC.	VMware

Node variables - AWS

The following table lists node parameters that effect AWS-based templates only.

Table 5. Node Variables - AWS

Attribute	Description	Scope
root_block_device_delete_on_termination	Boolean. AWS root block device delete on termination.	AWS
root_block_device_volume_size	AWS root block device volume size in gigabytes.	AWS
root_block_device_volume_type	AWS root block device volume type. For example: gp2, io1, st1, sc1.	AWS
subnet_name	AWS subnet name.	AWS
associate_public_ip_address	Boolean. Assign a public IP address.	AWS
flavor	AWS flavor of the virtual machine. For example, t2.small.	AWS
mgmt-network-public	Boolean. Expose and use public IP address of virtual machine for internal communication.	AWS

Node variables - IBM Cloud

The following table lists node parameters that effect IBM Cloud-based templates only.

Table 6. Node Variables - IBM Cloud

Attribute	Description	Scope
local_disk	Boolean. User local disk or SAN disk.	ibm
datacenter	IBM Cloud datacenter where infrastructure resources is deployed.	ibm
dedicated_acct_host_only	Shared or dedicated host, where dedicated host usually means higher performance and cost.	ibm
hourly_billing	Billing cycle: hourly billed or monthly billed	ibm
network_speed	Bandwidth of network communication applied to the virtual machine. For example, 10.	ibm
private_network_only	Boolean. Provision the virtual machine with only private IP address.	ibm
memory	Amount of Memory (MBs), which is required to be one or more times of 1024.	ibm
number_of_cores	Number of CPU cores, which is required to be a positive integer.	ibm
root_disk_size	Root disk size in GB. For example, 25.	ibm
mgmt-network-public	Boolean. Expose and use public IP address of virtual machine for internal communication.	ibm

Template Middleware Parameters

Managed services variables are definitions of variables that are presented to the deployer when a Template is deployed. This section will describe the format and uses of these variables.

Managed services variables provide the opportunity for an administrator to hardcode certain values for a parameter and make them relevant for a specific organization. Additionally, the deployment properties of variables may be modified to make it suitable for a specific situation.

Managed services variables may be accessed and edited from the **Templates** tab in the Template Editor.

From GIT, the *camvariables.json* file describes a set of Managed services variables for a specific template.

Managed services Variables example

The following example shows a sample Managed services variable as it is described in the **Parameters** section of the Template Editor. To understand the context of this variable, the Terraform template must be inspected.

```
python
  {
    "name": "referenced-image-image",
    "type": "string",
    "description": "referenced-image OS Image",
    "default": "RHEL-7.3_HVM_GA",
    "hidden": false,
    "label": "referenced-image Image",
    "secured": false,
    "system": false,
    "required": true,
    "immutable": false
  }
```

This example describes an input variable to a **Terraform Template** that gets interpreted by Managed services when the template is deployed.

Managed services variables structure

The following is the meta-structure of a Managed services variables file, this in general represents the different sections contained within the file.

Section	Definition
input_datatypes	input_datatypes are a collection of attributes. This section defines one or more input_datatypes collections to inject to the template at deploy time the most common being advanced_content_runtime_chef. <\br> You can also use input_datatypes to define Data Types.
output_datatypes	After deployment, the this section defines the name of the namespace to be updated post deployment.
input_groups	Variables are divided into logical groups. One such use of variable groups is to more efficiently display variables to a deployer in a logical format. This section defines one or more Input Groups associated with a Template.
output_groups	This section defines one or more Output Groups associated with a Template.
template_input_params	Templates will accept one or more parameters in order to deploy. As a general rule, these parameters will help populate the Terraform Variables (.tfvars) file. The input parameters define a list of parameters to be inputted to the Terraform Template during the deployment process. The field definition will dictate how CAM handles these variables at deploy time. <\br> If you want to get a value from datatype, then you can define the default value, for example, "default": "${datatypedemo1.ipaddress}", where datatypedemo1 is the name of the datatype and ipaddress is the attribute.
template_output_params	A list of variables calculated during the deployment process and stored for future reference.

Input Parameter Definition

The following are the relevant field definitions for defining Input Parameters:

Field	Definition
name	The name of the service parameter.
label	The label to be displayed in the user interface for this parameter
description	A description for this parameter.
type	The type of parameter. Such as "list, string, map.
default	The default value of the parameter. An example default value for shared parameter is `"default": "${datatypedemo1.ipaddress}"`, where `datatypedemo1` is the name of the Data Type and `ipaddress` is an attribute.
hidden	Specify if the parameter is not displayed in the user interface. The value must be true or false.
immutable	Specify if the parameter is read only. The value must be true or false.
immutable_after_create	Specify a value and deploy it for the first time. You cannot edit it in subsequent plan changes. The value must be true or false.
required	Specify if the parameter is required. The value must be true or false.
secured	Specify if the parameter value is shown as ********. The value must be true or false.
regex	Define the regular expression (regex) - A-Za-z0-9-[1]{1,52}$. The value you provide must match this regular expression.

Field	Definition
group_name	The group to locate this parameter in when displaying on the UI" Such as "myGroup".
options	in place of "default" for a list to select from

Output Parameter Definition

The following are the relevant field definitions for defining Output Parameters:

Field	Definition
name	The name of the service parameter.
label	The label to be displayed in the user interface for this parameter
description	A description for this parameter.
type	The type of parameter. Such as "list, string, map
hidden	Specify if the parameter is not displayed in the user interface. The value must be true or false.
secured	Specify if the parameter value is shown as ********. The value must be true or false.
return_type	The type of the parameter that is returned.
group_name	The group to locate this parameter in when displaying on the UI" Such as "myGroup".

Relationship to templates

Generally, Managed services variables directly relate to the parameters exposed in a Terraform template. Managed services variables are used by Managed services to inject Terraform parameters at deploy time.

---

1. A-Za-z0-9- ↩

Customizing a predefined template

The Managed services Middleware templates can be customized to fit your organizational requirements. Updating the templates is a multi-step process which involves cloning the private GitHub repositories and modifying the template input parameters.

Follow these steps to customize the Middleware templates:

1. Clone the Middleware templates.
2. Update template parameters file.
3. Modify Template.
4. Modify CAM Variables.

What to do next

Deploy a Middleware template.

Template modification

Template modification is possible by cloning catalog items from within the Managed services user interface and directly modifying the template inline.

Consider the following use cases:

- Hardcoding template parameters
- Template modification - BYO script
- Template modification - BYO Chef role

Hardcoding template parameters

At a template level, you can hardcode predefined parameters and set them within the template. The following changes must be made:

- Remove Terraform parameter.
- Hardcode value in the **camc_softwaredeploy** resource.

As an example, consider the following **camc_softwaredeploy** resource and associated parameter, **install_dir**:

```
#Variable : centralnode_was_liberty_install_dir
variable "centralnode_was_liberty_install_dir" {
  type = "string"
  description = "Liberty install dir"
  default = "/opt/IBM/WebSphere/Liberty"
}

resource "camc_softwaredeploy" "centralnode_liberty_install" {
...
```

```
    "runlist": "role[liberty_install]",
    "node_attributes": {
      "was_liberty": {
        "install_dir": "${var.centralnode_was_liberty_install_dir}",

  ...
```

In the previous example, if you want to hardcode the value of the **install_dir** parameter, you must first remove the variable and secondly modify the resource with the correct value as, for example, **/opt/liberty**.

```
  "node_attributes": {
    "was_liberty": {
      "install_dir": "/opt/liberty",
```

Subsequent deployments of the template ignore parameters injected, and instead always use your custom value.

Template modification - BYO script

The BYO script resource allows for the inclusion of a custom script into an existing template. To perform this modification, the Managed services user interface may be used.

Note that the addition of custom scripts uses the standard Terraform **remote-exec** resource. The following sample shows how this may be used with standard IBM-provided variables.

- **Custom script snippet**

  Use the following Terraform snippet in a VMware based template to add a custom script to the template.

```
#########################################################
##### Resource : Sample Script
#########################################################

resource "null_resource" "NODENAME_Sample Script" {
  depends_on = ["vsphere_virtual_machine.NODENAME"]

  # Specify the ssh connection
  connection {
    user = "${var.NODENAME-os_admin_user == "" ? lookup(var.default_os_admin_user, var.NODENAME-image) : var.NODENAME-
os_admin_user}"
    private_key = "${base64decode(var.ibm_pm_private_ssh_key)}"
    host = "${vsphere_virtual_machine.NODENAME.network_interface.0.ipv4_address}"
  }

  provisioner "file" {
    destination = "NODENAME_Sample Script.properties"
    content     = <<EOF
export custom_property=""

EOF
  }

  provisioner "file" {
    destination = "NODENAME_Sample Script.sh"
    content     = <<EOF
#!/bin/bash

++SCRIPTLINES++
EOF

  # Execute the script remotely
  provisioner "remote-exec" {
    inline = [
      "sudo bash -c 'chmod +x NODENAME_Sample Script.properties'",
      "sudo bash -c '. ./NODENAME_Sample Script.properties'",
      "sudo bash -c 'chmod +x NODENAME_Sample Script.sh'",
      "sudo bash -c './NODENAME_Sample Script.sh  >> centralnode_Sample Script.log 2>&1'",
      "sudo bash -c 'rm NODENAME_Sample Script.properties'"
    ]
  }

}
```

The following variables must be substituted:

- **NODENAME**: The logical name of the node within the Terraform template.
- **SCRIPTLINES**: The injected script.

Template modification - BYO Chef role

The BYO Chef role provides the capability to insert a customer provided Chef role into the orchestration. The following snippet must be added to a Terraform template:

```
resource "camc_softwaredeploy" "NODENAME_ROLE" {
  depends_on = ["vsphere_virtual_machine.NODENAME"]
  name = "NODENAME_ROLE"
  camc_endpoint = "${var.ibm_pm_service}/v1/software_deployment/chef"
```

```
  access_token = "${var.ibm_pm_access_token}"
  skip_ssl_verify = true
  trace = true
  data = <<EOT
{
  "os_admin_user": "${var.NODENAME-os_admin_user}",
  "stack_id": "${random_id.stack_id.hex}",
  "environment_name": "_default",
  "host_ip": "${vsphere_virtual_machine.NODENAME.network_interface.0.ipv4_address}",
  "node_name": "${var.NODENAME-name}",
  "runlist": "role[ROLE]",
  "node_attributes": {
    "ibm_internal": {
      "roles": "[ROLE]"
    }
  }
}
EOT
}
```

The following variables must be substituted:

- **`NODENAME`**: The logical name of the node within the Terraform template.
- **`ROLE`**: The name of the Chef role to be executed.

Template variables modification

Managed services Variables update guidance.

Managed services Variables provide the opportunity for an administrator to hardcode certain values for a parameter and make them relevant for a specific organization. Additionally, the deployment properties of variables may be modified to make suitable for a specific situation.

Managed services Variables may be accessed and edited from the **Templates** tab in the Template Editor.

Figure. Variables editing

When to customize

Managed services templates are designed to multi-cloud and multi-purpose environments. The correct way to use CAM Variables is to customize a template for a specific use case, for example:

- Specific cloud endpoint
- Specific Middleware configuration (Development/Test/Production)

A systems administrator can set in advance and hide deployment details from the deployer to achieve a specific effect during the deployment.

Hiding a Managed services Variable from the deployer

To hide a Managed services Variable from the deployer and therefore set the variable for a specific template, you must modify the following fields in CAM Variables. The **`default`** value is injected in the Terraform template at deploy time.

- **`hidden`**: Set this field to **`true`**.
- **`default`**: Set this value to be the default value.

Setting default value

Default values for Managed services Variables are a common use case and provide meaningful advice to the deployer on the correct value.

- **`default`**: Set this value to be the default value.

Field validation

Field validation occurs through a Regular Expression described in the **validation** parameter.

- **validation**: Set to the relevant Regular Expression.

Chef guidelines with Managed services

The following is a general advice and guidance on how to integrate Chef Cookbooks with Managed services and the essential structural elements of Chef as used within CAM.

Fundamentals

Role based orchestration

The most important aspect of integrating existing Chef cookbooks with Managed services is that all orchestration from the template is based upon the Chef Role. Chef Roles are the primary artifact for orchestration.

When you examine the Terraform Resource responsible for calling Chef through the Pattern Manager, you notice that the Chef Role is mentioned as the runlist. Subsequent calls to Chef appends the Role to the RunList in order.

```
resource "camc_softwaredeploy" "centralnode_liberty_install" {
  depends_on = ["camc_bootstrap.centralnode_chef_bootstrap_comp","camc_bootstrap.libertynode_chef_bootstrap_comp"]
  name = "centralnode_liberty_install"
  camc_endpoint = "${var.ibm_pm_service}/v1/software_deployment/chef"
  access_token = "${var.ibm_pm_access_token}"
  skip_ssl_verify = true
  trace = true
  data = <<EOT
{
  "os_admin_user": "${var.centralnode-os_admin_user}",
  "stack_id": "${random_id.stack_id.hex}",
  "environment_name": "_default",
  "host_ip": "${vsphere_virtual_machine.centralnode.network_interface.0.ipv4_address}",
  "node_name": "${var.centralnode-name}",
  "runlist": "role[liberty_install]",
  "node_attributes": {
    "ibm": {
      "im_repo": "${var.ibm_im_repo}",
      "im_repo_user": "${var.ibm_im_repo_user}",
      "sw_repo": "${var.ibm_sw_repo}",
      "sw_repo_user": "${var.ibm_sw_repo_user}"
    },
    "ibm_internal": {
      "roles": "[liberty_install]"
    },
    "was_liberty": {
      "base_version": "${var.centralnode_was_liberty_base_version}",
      "edition": "${var.centralnode_was_liberty_edition}",
      "im_install_dir": "${var.centralnode_was_liberty_im_install_dir}",
      "install_dir": "${var.centralnode_was_liberty_install_dir}",
      "install_grp": "${var.centralnode_was_liberty_install_grp}",
      "install_user": "${var.centralnode_was_liberty_install_user}",
      "java_version": "${var.centralnode_was_liberty_java_version}",
      "wlp_user_dir": "${var.centralnode_was_liberty_wlp_user_dir}"
    }
  },
  "vault_content": {
    "item": "secrets",
    "values": {
      "ibm": {
        "im_repo_password": "${var.ibm_im_repo_password}",
        "sw_repo_password": "${var.ibm_sw_repo_password}"
      }
    },
    "vault": "${random_id.stack_id.hex}"
  }
}
EOT
}
```

In this example, the **roles** field is populated with the role to be run. The *Pattern Manager* appends the role to the runlist of the node and runs the chef-client to complete the execution of the component.

Chef Cookbooks must therefore be designed in such a way as to be orchestrated by the running and subsequent running of Chef Roles. It is important to note the relationship between *Attributes* passed from Managed services and the Chef Role. As a general rule, hide all attributes that are not to be changed within a Role and expose only *Node* based attributes to Managed services.

Chef Client and Server version

When a *Content Runtime* is deployed, a pre-approved version of the Chef Client and Server are deployed. As Chef is an open source tool, only specific versions of the Chef Client and server are approved for deployment. The current versions are as follows:

- Chef Server: v12.11.1
- Chef Client: v12.12.13

Language linting

IBM provided Chef Cookbooks use the following tools to standardize on the language and structure of Chef Cookbooks:

-Rubocop -FoodCritic

Testing tooling

IBM tests all cookbooks with the following tools that are automated as part of a Devops Toolchain.

- ChefSpec
- Test Kitchen

README generation

All Chef Cookbook *README.md* files are generated with the knife readme plugin that is located at Chef.

Structural elements

The following section is a summary of the structural elements of standard IBM provided cookbooks. It is not necessary for customer provided cookbooks to follow these standards, they are included as a reference only.

Standard Chef attributes

Chef Node Attributes are commonly used to define cross-cookbook attributes, which may be used to describe common features. A single *Chef Node* might consume multiple cookbooks, so standardize those standard variables that affect all cookbooks.

The following is the list of standard Chef Attributes used in IBM provided cookbooks. These may be referenced in a customer provided cookbook only if there is a need to re-use these standard variables.

Note: This is not mandatory but required only for consistency and simplicity.

Attribute	Definition
default['ibm']['expand_area']	Home directory for Open Patterns unfold directory, this is a global variable that may be set in the Environment. This path is absolute and all other paths are relative to it.
force_override[ ]['expand_area']	Cookbook based ExpandArea which will be relative to the global expandArea. This value will be set in the internal.rb file.
default['ibm']['sw_repo_root']	URL location of the Repository Server.
force_override[' ']['archive_names']	The correct version attribute name to describe the archive to install a product from is [' ']['v ']['archive_names']. This attribute may be represented by an array if necessary, each element having a reasonable descriptor of the function of the installer in question. The SHA Value must also be represented for each file.
force_override[' ']['fixpack_names']	ARRAY of file names of the installer.
force_override[ibm][evidence_path]['windows']	Root path for the Evidence files on Windows systems, this variable will be defined in a role on the customer chef server.
force_override[ibm][evidence_path]['unix']	Root path for the Evidence files on Unix systems, this variable will be defined in a role on the customer chef server.
default[ ]['evidence_zip']	ZIP File which contains the evidence.
default[' ']['fixpack_id']	Identifier for the fix pack to be applied. This attribute is necessary for all products that support the notion of applying fix packs. The precise fix pack must never be hard-coded in the Recipe.
force_override[' ']['os_users']	The data structure should include a hash for every operating system user including related settings such as username, home directory, password, ldap_user etc.
Base directory for a product to be installed into.	Home directory for Open Patterns unfold directory, this is a global variable that may be set in the Environment. This path is absolute and all other paths are relative to it.
force_override[' ']['sw_repo_path']	One or more attributes defining the relative location of product related files on the software repository (such as default['ibm']['sw_repo_root']).
force_override[' ']['fp_repo_path']	One or more attributes defining the relative location of fix pack related files on the software repository (such as default['ibm']['sw_repo_root']).

Attribute	Definition
force_override[' '] ['os_libraries']	The value should contain a list of operating system libraries to install.
default['ibm'] ['temp_dir']	An absolute path to a temporary location on the filesystem to store any temporary files.
default['ibm'] ['log_dir']	Any logfiles that should persist on the system should be written to this location.

Avoiding namespace clashes

As a node might run one or more cookbooks, seperate similar attributes from different cookbooks. The following rule applies when naming attributes.

```
['<cookbookName>']['<attribute>']
```

Internal.rb vs Default.rb

IBM categorizes Chef variables based on whether they are to be exposed in CAM or not, the general structure applies.

```
|- chef
|   |- cookbooks
|   |   |- <cookbook_name>
|   |- attributes
|       - default.rb              # All product attributes
|       - internal.rb             # force_override attributes that may never be changed.
```

Attribute Precedence

Chef supports a wide variety of attribute precedence, the following is a summary of the supported and the relevant use cases.

Standard Chef Recipes

The following is the set of standard recipes that should exist in all IBM provided cookbooks. Product specific cookbooks to configure and control are added separately.

Receipe Name	Definition
prereq	OS Pre-requisite provisioning.
prereq-check	Recipe to ensure that pre-requisites are in place for a cookbook to run.
fixpack	Product un-installation only. (Not necessary by default, however, should it be required, then use this name)
uninstall	OS Pre-requisite provisioning.
harden	Product hardening only. Note, this is inherently customer specific and must therefore be separated from other recipes.
install	Product installation only.
gather_evidence	Recipe to gather artifacts to prove an installation has occurred successfully. These artifacts are to be packed in a single archive.
cleanup	Recipe to remove all unwanted files such as install media and temp files.
default	Standard default recipe which will implement the minimal functionality to stand up the cookbook.

Chef Cookbook Principles

The following is a list of principles used in the construction of Chef Cookbooks.

The Granularity Principle

Granularity in the CHEF context refers to the care taken to expose recipes in a granular enough fashion to ensure Orchestration and Pattern designers can assemble the component pieces in such a way as to gain the desired result. There are no hard and fast rules here, the general principal to apply is this:

```
Recipes should seek to encapsulate a single software function.
```

Recipes represent the lowest representation of functionality provided by the Chef Cookbook and as such should contain with them a single operation that may be combined into a Role as a Pattern is defined based on these recipes. Standard CHEF Recipes represent both a minimal default and also encapsulate this principle.

Configuration of software products is in general difficult to generalize, however, consider a similar principle when deciding on Recipes that seek to implement software configuration. As a general rule, a single recipe should implement a single configuration concept.

When evaluating a Software Product to try to find the correct level of Granularity, it is important to be aware of the following general principles.

- How Recipes relate to Roles.
- How Roles are used in Pattern definition.

- How Roles are used in Pattern Orchestration.
- An understanding of the standard Recipes required for any software product.

  An understanding of where Recipes sit in relation to the overall Open Pattern construct is essential to an understanding of the best way to find the correct level of granularity.

The Idempotency Principle

The Idempotency principal is in essence the practice of running an action more than once producing the same result. From a CHEF perspective, assume that a recipe will fail at some point and needs to be re-run.

`All CHEF Cookbook's and Recipe's must be inherently idempotent.`

Recipes must be designed with re-entry in mind. This can be as a result of failure, or as a result of the chef client being run at unexpected times. Cookbooks should make no assumption's as to the start state of the system and always check that an action can be run before it is run.

Touch points include:

- Only download files where necessary, for example, do not download installer files if the installation is already complete.
- Only execute configuration changes.
- All LWRP and other CHEF artefacts for example Recipes must be inherently idempotent.
- Cookbooks should never produce errors based on a state of the running software.

Data Driven Principle

Data Driven refers to the exposing as many options as CHEF variables as possible and therefore reducing the number of hard coded values. The general principle is as follows: CHEF Cookbooks should be highly dependent on attributes when executing, changing the outcome should be driven by modifying the attributes through the use of Roles and Node Attributes. The following generalizations apply:

- Maximize CHEF Attributes.
- Minimize hard coding.
- CHEF Attributes should be represented as arrays where possible.

Maximizing Attributes / Minimize Hard Coding As a general rule, values that are consumed by a cookbook should be represented as Attributes. Attribute definition and consumption by CHEF should follow the guidelines set out in the Attribute Precedence section of this document. As a general Rule all attributes are changeable, however, there are circumstances where certain variables are to remain fixed, these are given the force_override operator and defined in the internal.rb file.

Standard Attributes Attributes that implement standardized concepts should be named as per the Naming Standards described in this guide. Standard Attributes are defined to maximize readability of our Chef Cookbooks, but also to allow for attributes to be standardized across an environment.

Attribute Arrays Software products that implement multiple configuration items of the same type should be represented in an Array from a definition perspective. A reasonable example of this is the definition of database, which may be described in terms of 1..n databases. It is best practice in these cases to define the attributes in an array rather than singleton attributes, for example:

```
default['was']['os_users'] = {
  'wasadmin'  =>  {
      'name' =>     'wasadmin',
      'gid' =>      'wasgrp',
      'comment' =>  'WAS administrative user',
      'home' =>     "/home/wasadmin",
      'shell' =>    '/bin/bash'
  },
  'wasowner'  =>  {
      'name' =>     'wasowner',
      'gid' =>      'wasgrp',
      'comment' =>  'WAS owner',
      'home' =>     "/home/wasowner",
      'shell' =>    '/bin/bash'
  }
}
```

The previous example defines the os_users attribute as an Hash Table rather than as singleton attributes. It is therefore possible to add or remove users based on data alone, without the need to define any new attributes or change the code in general.

Modularity Principle

The principle of Modularity relates to creating re-usable components that may be utilized within a single cookbook, or to external cookbooks.

`CHEF Cookbooks should be modular in nature and take advantage where possible of Libraries, LWRP and other CHEF Cookbooks.`

An important consideration when designing a cookbook is whether to use an LWRP or not. A Chef Lightweight Resource Provider can be created to encapsulate the functionality of Software Configuration items to be treated as an object. A clear identifier of an object that should be represented as an LWRP is that it may be modified, exhibits internal state, applies across Operating Systems and is in general version independent. As a guide, consider existing CHEF Resources, each of these are in fact an implementation of a LWRP.

Never attempt to re-create an existing Chef Resource if one already exists. Open Patterns should maximize the use of LWRP for the following situations.

- Fix pack installation.
- State control (For example, stop/start) Software configuration.

LWRP should exhibit the following characteristics.

- Operating System neutral.
- Software version neutral.
- State neutral. (For example, start a Software Product that is already started will not cause an error)
- Idempotent.

Modifying a deployed middleware template instance

Managed services middleware template modification

You can redeploy an existing instance after selecting the desired template version and modifying the input parameters. Instructions for doing so can be found on the modifying a deployed template instance. There are a few restrictions with modifying the middleware templates. Those restrictions are listed here.

Chef assets cannot be updated

The Chef cookbooks in the Managed services (CAM) middleware templates are not written to support modification after deploy. This fits with the cloud model of quickly destroying and recreating entities as needed. When attempting to modify a deployed middleware instance, you will see the node properties are not able to be edited.

The properties are not editable due to a property in the template's CAM variables file called immutable_after_create. If you are writing your own templates and would like to prevent properties from being modified after deploy, then the immutable_after_create property is what you would use. Similarly, if you have cloned the middleware templates to your own git repository and would like to be able to modify these parameters, you would update the immutable_after_create property in the template's CAM variables file.

For more information on Managed services variables, see Template variables modification

Terraform Provider Configuration

Starting from Terraform 0.13.0 a new hierarchical namespace for providers was introduced by Terraform. For more information on this refer to Terraform documentation. This new feature requires explicit source information for any providers that are not maintained by Hashicorp. Terraform 0.13.0 and above provides a new nested block **`required_providers`** inside the **`terraform`** configuration block to specify the provider source location. The value for **`source`** attribute is in the format **`<REGISTRY_HOST>/<NAMESPACE>/<PROVIDER_TYPE>`**

The starterlibrary provides the following templates that showcase how to use this new source syntax.

- Google Cloud Single Virtual Machine Example for Terraform 1.x.x This template shows how to source the provider maintained by hashicorp and hosted in default hashicorp registry. The value **`hashcorp/google`** assigned to attribute **`source`** refers to the location of provider binary which is packaged by default under **`$HOME/.terraform.d/plugins/registry.terraform.io/hashicorp/google`** in the **`cam-provider-terraform`** pod. The name **`hashicorp`** in the source value indicates that the provider is maintained by Hashicorp. The value **`registry.terraform.io`** in the binary path refers to the default provider registry host which can be ommitted in the source value as the provider is in the default regisity.
- Virtual Server in a new VPC with SSH key For Terraform Engine 13 and 14 This template shows how to source the provider maintained by a third party vendor which in this case is IBM and hosted in default hashicorp registry. The value **`IBM-Cloud/ibm`** assigned to attribute **`source`** refers to the location of provider binary which is packaged by default under **`$HOME/.terraform.d/plugins/registry.terraform.io/IBM-Cloud/ibm`** in the **`cam-provider-terraform`** pod. The name **`IBM-Cloud`** in the source value indicates that the provider is a thrid-party provider. The value **`registry.terraform.io`** in the binary path refers to the default provider registry host which can be ommitted in the source value as the provider is in the default registry.

For the templates that use the IBM Cloud Pak for AIOps Managed services provided Terraform providers, you must use the **`required_providers`** section as shown in the following sample.

```
terraform {
  required_version = ">= 0.13"

  required_providers {
    camc = {
      #Source attribute value is in format <REGISTRY_HOST>/<NAMESPACE>/<PROVIDER_TYPE>
      source  = "registry.ibm.com/cam/camc"
      version = "~> 0.2"
    }
  }

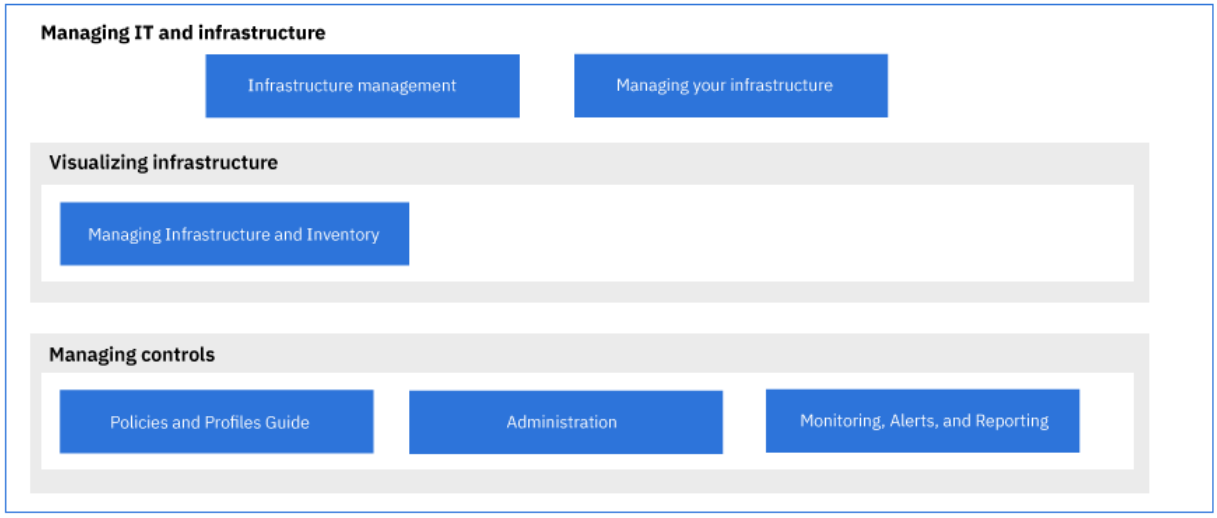
}
```

The above sample defines the source location for IBM Cloud Pak for AIOps Managed services provided CAMC Provider. The value **`registry.ibm.com/cam/camc`** assigned to attribute **`source`** refers to the location of provider binary which is packaged under **`$HOME/.terraform.d/plugins/registry.ibm.com/cam/camc`** in the **`cam-provider-terraform`** pod. The name **`registry.ibm.com/cam`** in the source value indicates that the provider is a IBM Cloud Pak for AIOps Managed services provided provider. The value **`registry.ibm.com`** in the binary path refers to a local dummy non-existent domain to indicate that this provider is a local in-house provider.

For a different IBM Cloud Pak for AIOps Managed services provided provider say UCD provider, you would change only the value for **`PROVIDER_TYPE`** as shown below.

```
terraform {
  required_version = ">= 0.13"

  required_providers {
    ucd = {
      #Source attribute value is in format <REGISTRY_HOST>/<NAMESPACE>/<PROVIDER_TYPE>
      source  = "registry.ibm.com/cam/ucd"
      version = "~> 0.5"
    }
  }



}
```

Refer to Shipped Terraform providers for complete set of provider binaries (which are compatiable with Terraform 0.13.0 or higher) bundled with IBM Cloud Pak for AIOps Managed services.

Managing IT and infrastructure

Infrastructure Management

Infrastructure Automation – Infrastructure Management delivers the insight, control, and automation enterprises need to address the challenges of managing virtual environments, which are far more complex than physical ones. This technology enables enterprises with existing virtual infrastructures to improve visibility and control, and those just starting virtualization deployments to build and operate a well-managed virtual infrastructure.

Infrastructure Management includes the following feature sets:

- Insight: discovery, monitoring, utilization, performance, reporting, analytics, chargeback, and trending.
- Control: security, compliance, alerting, policy-based resource and configuration management.
- Automate: IT process, task and event, provisioning, workload management and orchestration.
- Integrate: systems management, tools and processes, event consoles, CMDB, RBA, and web services.

Note: When the Infrastructure Management component of Infrastructure Automation is installed, you can access the Infrastructure Management UI from the IBM Cloud Pak for AIOps console UI by browsing to the menu: **Automate Infrastructure > Infrastructure management**. The documentation for Infrastructure Management, including the menu navigation for documented procedures, is written from the context of first browsing to the Infrastructure Management UI.

This documentation is delivered by various sources in the ManageIQ open source community. IBM accepts support tickets, and corrects documentation errors. Support and enhancement updates can also come from the open source community.

Managing Infrastructure and Inventory

Clusters

Clusters provide high availability and load balancing for a group of hosts. The **Clusters** page under **Compute > Infrastructure** displays the clusters discovered in your enterprise environment.

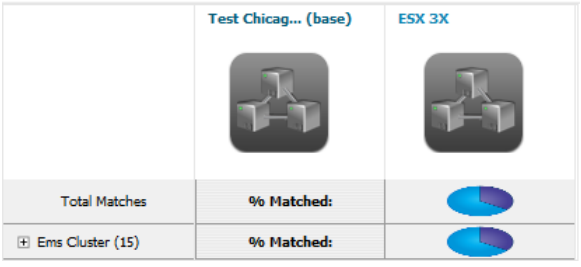
Note:

Any filter applied will be in effect here.

Use the **Clusters Taskbar** to manage the analysis and tagging of your clusters. These buttons manage multiple clusters at one time. To manage one cluster, click on that cluster in the main area of the screen.

Performing SmartState Analysis on Clusters

Analyze a cluster to gather historical data to compare with previous points in time.



1. Browse to menu: **Compute > Infrastructure > Clusters**.
2. Check the clusters to analyze.
3. Click **Configuration**, and then (**Perform SmartState Analysis**).
4. Click **OK**.

The SmartState Analysis begins and returns the current data.

Comparing Clusters

Infrastructure Automation provides features to compare properties of clusters.

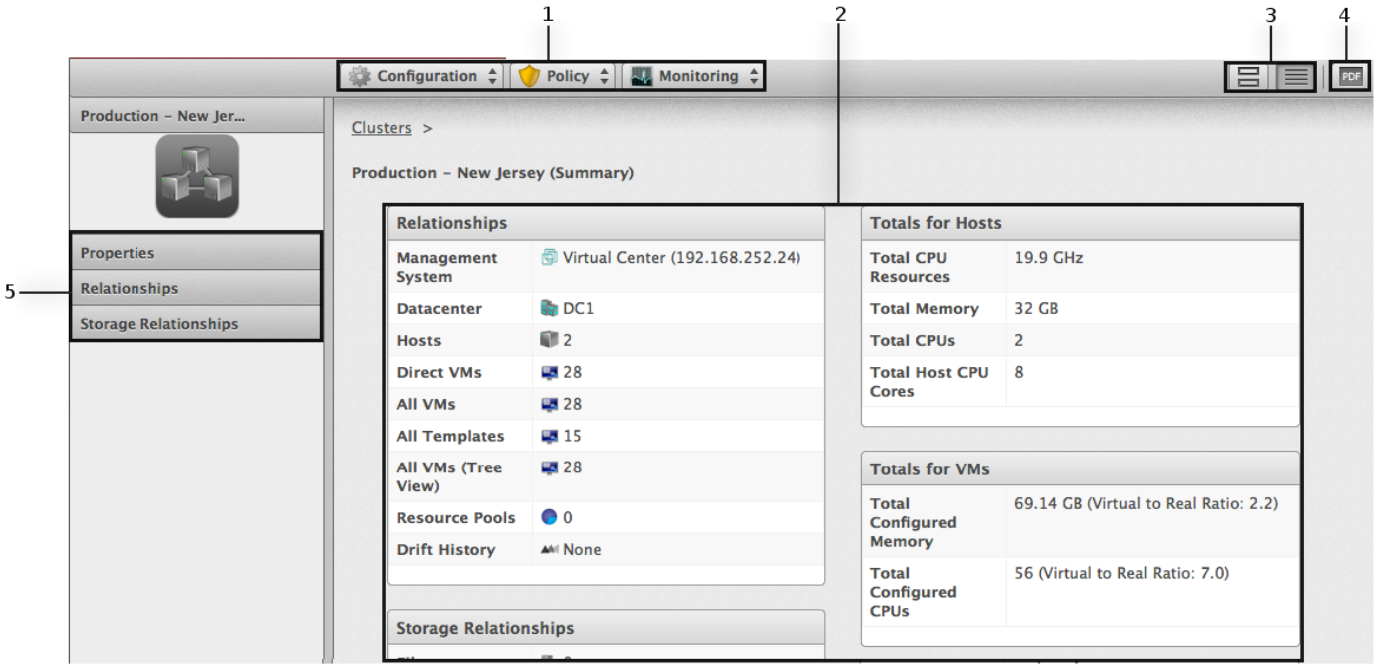
1. Browse to menu: **Compute > Infrastructure > Clusters**.
2. Check the clusters to compare.
3. Click **Configuration**, and then (**Compare Selected items**). The comparison displays in a default expanded view and lists a limited set of properties.

4. To delete a cluster from the comparison, click (**Remove this Cluster from the Comparison**).
5. To go to a compressed view, click (**Compressed View**). To return to an expanded view, click (**Expanded View**).
6. To change the base cluster that all other clusters compare to, click its label at the top of its column.
7. To go to the cluster summary screen, click its virtual thumbnail or icon.
8. There are three buttons in the taskbar to limit the type of views:
   - Click (**All attributes**) to see all attributes.
   - Click (**Attributes with different values**) to see only the attributes that are different across clusters.
   - Click (**Attributes with the same values**) to see only the attributes that are the same across clusters.

9. To limit the mode of the view, there are two taskbar buttons.
    - Click (**Details Mode**) to see all details for an attribute.
    - Click (**Exists Mode**) to only see if an attribute exists compared to the base or not. This only applies to attributes that can have a Boolean property. For example, a user account exists or does not exist, or a piece of hardware that does or does not exist.

This creates a comparison between clusters. Export this data or create a report from your comparison for analysis using external tools.

Creating a Cluster Comparison Report



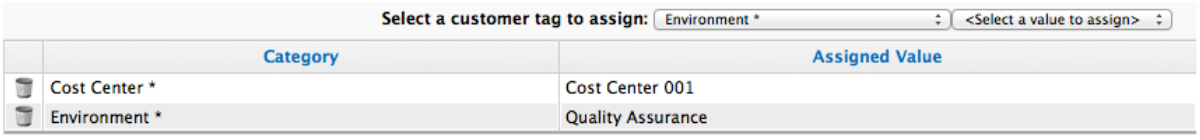
Create a quick report of to compare clusters in CSV, TXT, or PDF formats.

1. Create the comparison to analyze.
2. Click (**Download**).
3. Click the output button for the type of report.
    - Click (**Download comparison report in TXT format**) for a text file.
    - Click (**Download comparison report in CSV format**) for a comma-separated file.
    - Click (**Download comparison report in PDF format**) for a PDF file.

Viewing a Cluster

You can click on a specific cluster to view its details. The screen provides you with a cluster taskbar, a cluster accordion, and a cluster summary.

Cluster Management Screen.

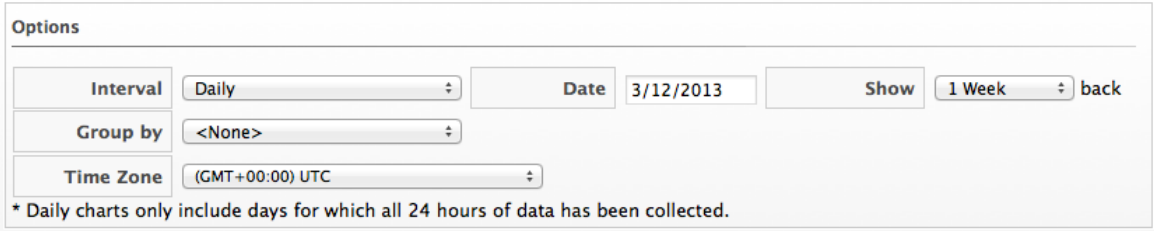


1. **Cluster Taskbar**: Choose between **Configuration**, **Policy** and **Monitoring** options for the selected cluster
2. **Cluster Summary**: See cluster summary such as **Relationships**, **Totals for Hosts**, **Totals for VMs**
3. **Cluster Summary Views**: Choose between graphical or text view of the cluster summary
4. **Cluster Summary PDF**: Generates cluster summary in PDF format
5. **Cluster Accordion**: See details about **Properties**, **Relationships**, **Storage Relationships** for the selected cluster

Tagging Clusters

Use tags to categorize clusters.

1. Browse to menu: **Compute > Infrastructure > Clusters**.
2. Check the Clusters to tag.
3. Click **Policy**, and then **Edit Tags**.



* Only a single value can be assigned from these categories

4. Select a customer tag from the first dropdown, and then a value for the tag.
5. Select more tags or click **Save** to save your changes.

Viewing Capacity and Utilization Charts for a Cluster

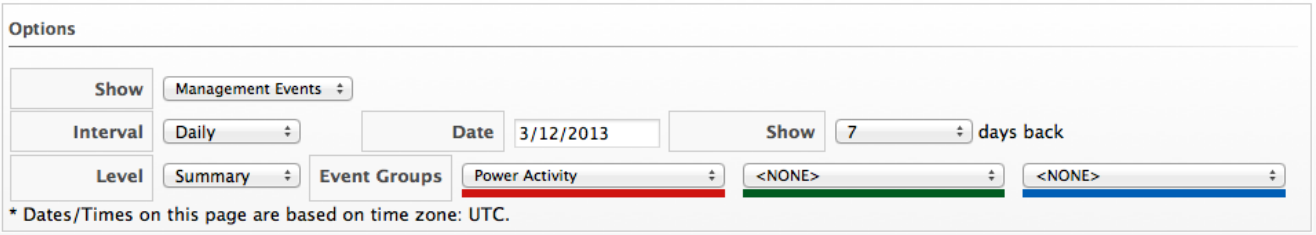
View capacity and utilization for a cluster.

1. Browse to menu: **Compute > Infrastructure > Clusters**.
2. Click the cluster to view Capacity and Utilization data.
3. Click (**Monitoring**), and then (**Utilization**) or from the accordion menu, click **Properties > Capacity & Utilization**.

4. From **Interval**, select to view hourly or daily data points and the dates to view data. Use **Group by** to group the lines by SmartTags. Use **Time Profiles** to select a time range for the data.

The **Capacity & Utilization** charts display

Note:



Daily charts only include full days of data. If a day does not include all the 24 data points for a day, the data does not show for that day.

For information about data optimization including utilization trend reports, see Data Optimization.

Viewing Cluster Timeline

Use the cluster timeline to see a graphical depiction of operational and configuration events over time.

1. Browse to menu: **Compute > Infrastructure > Clusters**.
2. Click the cluster to view the timeline.
3. Click (**Monitoring**), and then (**Timelines**) or from the accordion menu, click menu: **Properties > Timelines**.
4. From **Options**, customize the period of time to display, and the types of events to see.

   - Use the **Interval** dropdown to select hourly or daily data points.
   - Use **Date** to type the date for the timeline to display.
   - If you select to view a daily timeline, use **Show** to set how many days back to go. The maximum history is 31 days.
   - The three **Event Group** dropdowns allow the selection of different groups of events to display. Each has its own color.
   - From the **Level** dropdown, select a **Summary** event if needed, or a **Detail** list of events. For example, the detail level of a *Power On* event might include the power on request, the starting event, and the actual **Power On** event. If you select **Summary**, the timeline only displays the Power On event.
5. To see more detail on an item in the timeline, click on it. A balloon appears with a clickable link to the resource.

Detecting Drift on Clusters

Over time, a cluster's configuration might change. Drift is the comparison of a cluster to itself at different points in time. The cluster requires analysis at least twice to collect information. Detecting drift provides users with the following benefits:

- See the difference between the last known state of a cluster and its current state
- Review the configuration changes that happen to a particular cluster between multiple points in time.
- Capture the configuration drifts for a single cluster across a time period.

Detect drift on clusters:

1. Browse to menu: **Compute > Infrastructure > Clusters**.
2. Click on the cluster to view drift.
3. Click **Relationships** in the cluster accordion.
4. Click **Drift History**.
5. Check the analyses to compare.
6. Click (**Drift Analysis**) at the top of the screen. The results are displayed.
7. Check the **Comparison** sections on the left to view in your comparison.
8. Click the plus sign next to the section name to expand it.
   - An item displayed on red text shows a change from the base analysis. An item displayed in black text shows no change from the base analysis.
   - A (**Changed from previous**) shows there has been a change since the last analysis.
   - A (**Same as previous**) means there has been no change since the last analysis.

- Click (**Remove from drift**) at the bottom of a column to remove a specific analysis. The drift is then recalculated and the new results display.

9. Click (**Expanded View**) to see the expanded view. Click (**Compressed View**)] to compress the information.
10. Click the minus sign next to the section name to collapse it.
11. To limit the type of views, there are three buttons in the taskbar.
    - Click (**All attributes**) to see all attributes of the sections selected.
    - Click (**Attributes with different values**) to see only the attributes different across drifts.
    - Click (**Attributes with the same values**) to see only the attributes the same across drifts.

The drift displays for your cluster. Download the data or create a report from the drift for analysis using external tools.

Creating a Drift Report for Clusters

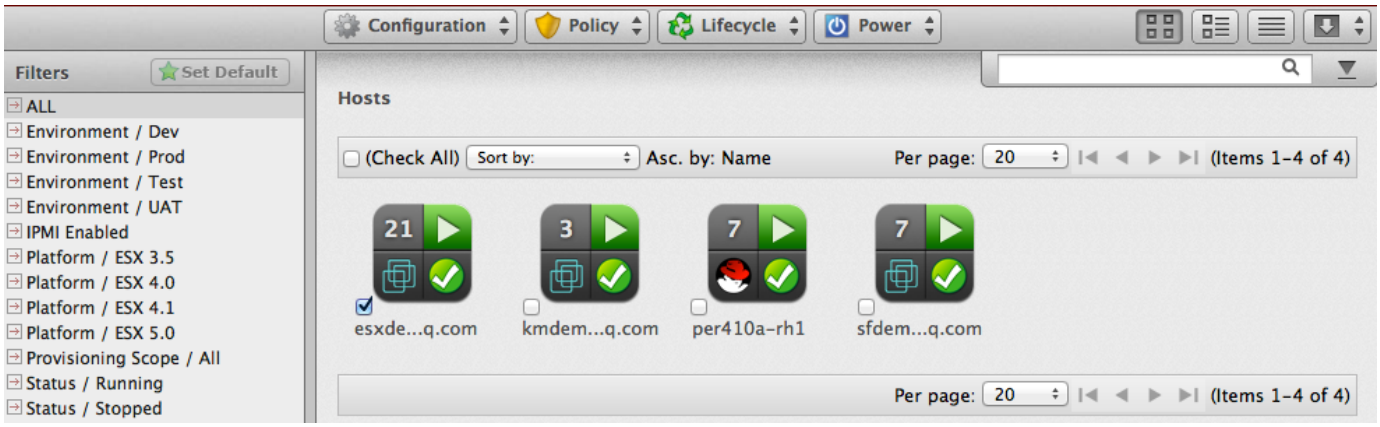
Use the drift report feature to export information about your cluster's drift.

1. Create a drift of a cluster.
2. Click (**Download**).
3. Click the output button for the type of report you want.
   - Click (**Download drift report in TXT format**) for a text file.
   - Click (**Download drift report in CSV format**) for a comma-separated file.
   - Click (**Download drift report in PDF format**) for a PDF file.

Removing Clusters

If a cluster has been decommissioned or requires troubleshooting, it might require removal from the VMDB.

1. Browse to menu: **Compute > Infrastructure > Clusters**.
2. Check the clusters to remove.
3. Click **Configuration**, and then (**Remove Clusters from the VMDB**).
4. Click **OK**.



The clusters are deleted. Any virtual machines or hosts associated with these clusters remain, but are no longer associated with them.

Hosts

The **Hosts** page under **Compute > Infrastructure** displays the hosts discovered in your enterprise environment.

Note:

Any applied filters will be in effect here.

After adding or sorting your hosts, click on one to examine it more closely and see its virtual machines, SmartProxy settings, and properties.

1. Top left quadrant: Number of virtual machines on this host
2. Bottom left quadrant: Virtual machine software
3. Top right quadrant: Power state of host
4. Bottom right quadrant: Authentication status

Icon	Description
	Validated: Valid authentication credentials have been added.
	Invalid: Authentication credentials are invalid
	Unknown: Authentication status is unknown or no credentials have been entered.

Filtering Hosts

The Host Filter accordion is provided to easily navigate through the hosts. Use the ones provided or create your own. In addition, you can set a default filter.

Setting a Default Host Filter

Set the default filter for viewing your hosts.

1. From the **Filters** accordion on the left, click on the filter to use.
2. Click **Set Default** at the top of the filters list.

The default filter is set and marked by a green star next to its name.

Creating a Host Filter

Create a filter for viewing your hosts.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click (**Advanced Search**) to open the expression editor.
3. Use the expression editor to choose the appropriate options for your criteria.
4. Click **Save**.
5. Type in a name for the search expression in **Save this search as**.

   Note:

   This title depends on the type of resource you are searching.
6. Click **Save**.

The filter is saved and displays in the **My Filters** area of the **Filter** accordion.

Performing SmartState Analysis on Hosts

Perform a SmartState analysis on a host to collect additional information about it, such as patches, CPU, and memory.

Note:

- SmartState analysis on hosts is processed by the **Provider Operations** role. It is enabled by default.
- For ESX or ESXi hypervisors, consider the following: ESX hosts utilize a service console for host management and can be accessed using SSH. ESXi hosts lack a service console and therefore SSH cannot be used to obtain information sets for patches, services, Linux packages, user groups, SSH Config, and FS Files.
- `root` or administrator credentials are required to get patch information.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Check the hosts to analyze.
3. Click **Configuration**, and then (**Perform SmartState Analysis**).
4. Click **OK**.

Comparing Hosts

Infrastructure Automation allows you to compare hosts and check operating systems, host software and version information, and hardware.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Check the hosts to compare.
3. Click **Configuration**, and then (**Compare selected Hosts**). The comparison displays in a default expanded view, which lists a limited set of properties.
4. To remove a host from the comparison, click (**Remove this Host from the comparison**) at the bottom of the column.
5. To go to a compressed view, click (**Compressed View**). To return to an expanded view, click (**Expanded View**).
6. To limit the mode of the view, there are two buttons in the taskbar.
   - Click (**Details Mode**) to see all details for an attribute.
   - Click (**Exists Mode**) to limit the view to if an attribute exists compared to the base or not. This only applies to attributes that can have a Boolean property. For example, a user account exists or does not exist, or a piece of hardware that does or does not exist.
7. To change the base host that compare to the other hosts, click its label at the top of its column.
8. To go to the summary screen for a host, click its virtual thumbnail or icon.

Host Comparison Sections

Section	Description
Host Properties	Use this section to see basic information of the host, such as hostname, product, build number, hardware, and network adapters.
Security	Use this to see users and groups for the host, and firewall rules.
Configuration	Use this to see the operating system, applications, services, patches, vSwitches, vLANS, and advanced settings.
My Company Tags	Use this to see all tags.

Using the Host Comparison Sections

The following procedure describes how to use the host comparison sections.

1. On the left of a comparison screen, select the categories of properties to display.
2. Click the plus sign next to the sections name to expand it.
3. The following descriptions pertain to the **Expanded View** . Either the value of a property or an icon representing the property displays depending on the properties type.
   - A property displayed in the same color as the base means that the compared host matches the base for that property.
   - A property displayed in a different color from the base means that the compared host does not match the base for that property.

4. If you are in the **Compressed View** , the values of the properties do not display. All items are described by the icons shown below.
    - A (**checkmark**) means the compared host matches the base for that property. Hover over it and the value of the property displays.
    - A (**x**) means the compared host does not match the base for that property. Hover over it and the value of the property displays.
5. Click the plus sign next to the section name to collapse it.

This comparison is viewable in multiple ways. Export the data or create a report from your comparison for analysis using external tools.

Creating a Host Comparison Report

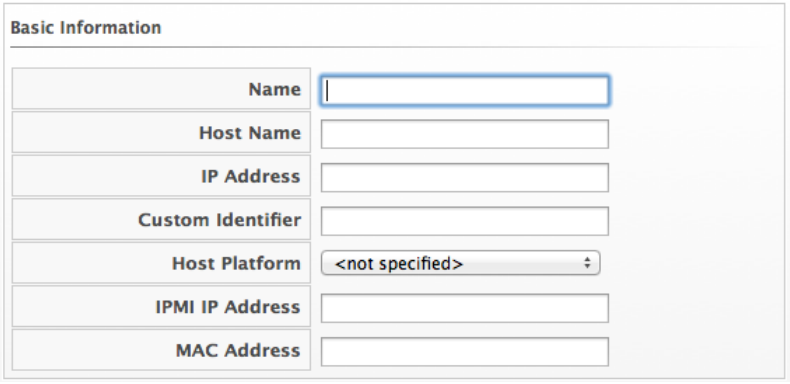
Create a quick report to compare clusters in CSV, TXT, or PDF formats.

1. Create the comparison to analyze.
2. Click (**Download**).
3. Click the output button for the type of report.
    - Click (**Download comparison report in TXT format**) for a text file.
    - Click (**Download comparison report in CSV format**) for a comma-separated file.
    - Click (**Download comparison report in PDF format**) for a PDF file.

Refreshing Multiple Hosts

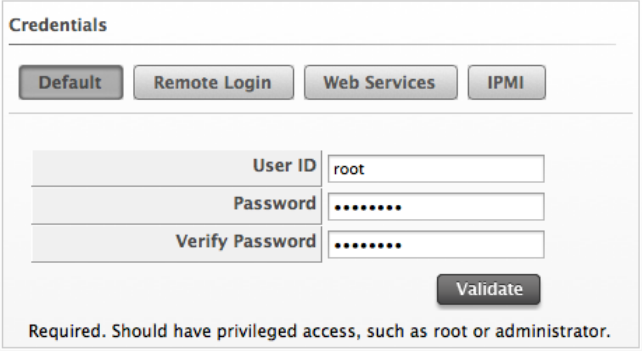
Manually refresh a host for its properties and related infrastructure components.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Check the hosts to refresh.
3. Click **Configuration**, and then (**Refresh Relationships and Power States**).
4. Click **OK**.



When a host is refreshed and a new virtual machine is discovered on that host, Infrastructure Automation checks to see if the virtual machine is already registered with another host. If this is the case, the host that the virtual machine is associated with switches to the new host. If the SmartProxy is monitoring a provider, this happens automatically. If not, the next refresh of the host addresses this.

Adding a Single Host

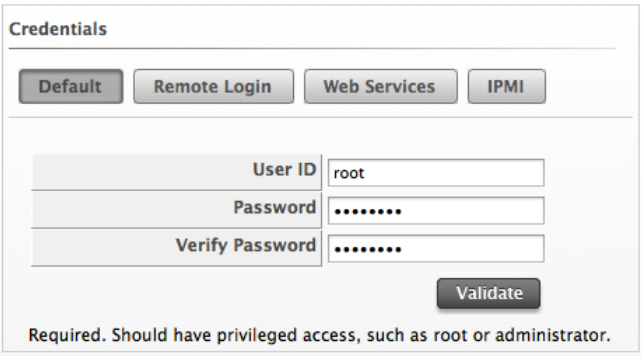


To analyze a host for more detailed information, add it to the VMDB first. If the host has not been found during **Host Discovery** or **Provider Refresh**, and the host's IP address is known, use the **Add a New Host** button.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click **Configuration**, then click (../images/1862.png)**Add a New item**.
3. Type the **Name**, **Host Name**, and **IP Address** of the host to add. **Name** is how the device is labeled in the console. Select the type of operating system from the **Host Platform** dropdown. If the Host has been found during **Discovery** or **Refresh** and the host's operating system has been identified, the **Host Platform** selector remains disabled. If adding an IPMI server for provisioning, add in the IP address of that host.

    Important: The **Host Name** must use a unique fully qualified domain name.

4. In the **Credentials** box, the **Default** tab provides fields to type a user name with elevated security credentials and the user's password. If using domain credentials, the format for **User ID** is in the format of `[domainname]\[username]`. On ESX hosts, if the `SSH` login is disabled for the **Default** user, type in a user with remote login access on the **Remote Login** tab.



5. Click **Validate** to check the credentials.
6. Click **Save**.

Editing Hosts

If multiple hosts have the same settings or credentials, edit them at the same time.

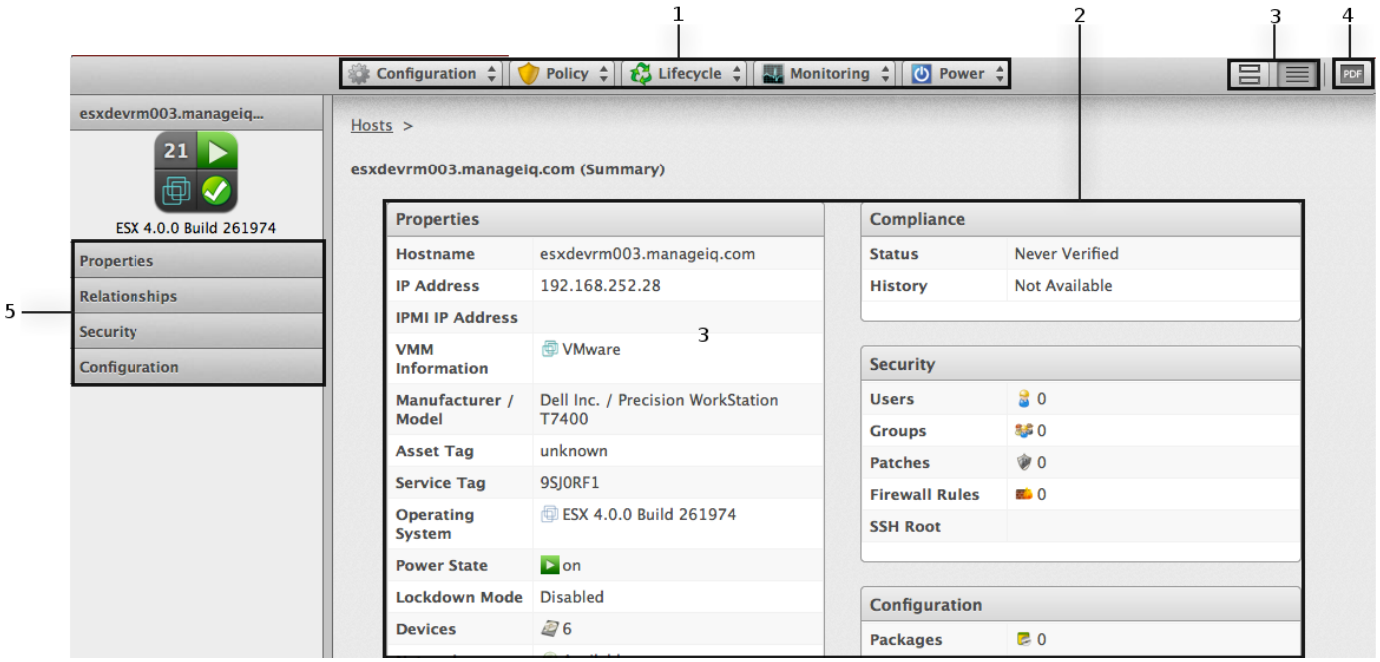
1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click **Configuration**.
3. Check the Hosts to edit.
4. Click (**Edit Selected items**).
5. Use **Credentials** to provide login credentials required for this host.

- On the **Default** tab, type a user name with elevated security credentials and the users password. If you are using domain credentials, the format for User ID must be in the format of `[domainname]\[username]`.
- On `ESX` hosts, if `SSH` login is disabled for the **Default** user, type in a user with remote login access on the **Remote Login** tab. If this is not supplied, *Default* credentials will be used.
- Use **Web Services** to supply credentials for any web service calls made directly to the host system. If this is not supplied, **Default** credentials are used.

Note:

Login credentials are required for performing SmartState Analysis on the host's virtual machines and templates.

For each type of credential used, the following information is required:



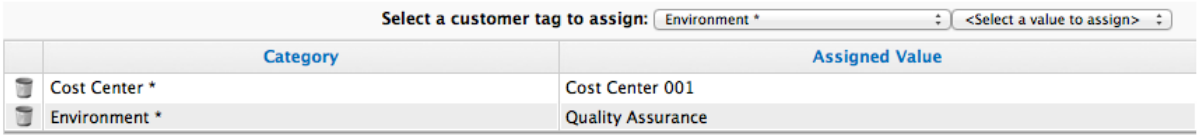
- Use **User ID** to specify a login ID.
- Use **Password** to specify the password for the User ID.
- Use **Verify Password** to confirm the password.

6. Test the credentials by using the *Select Host to validate against* drop down and click **Validate**.
7. Click **Save**.

Viewing a Host

You can click on a specific host to review it. The screen shows a host virtual thumbnail, a host taskbar, a host accordion, and a host summary.

Host Management Screen.



1. **Host Taskbar**: Use the host taskbar to take actions on the selected host
2. **Host Summary**: Use the host summary to see the properties of a host, drill down to a host's information, and view its installed virtual machines
3. **Host Summary Views**: Choose between graphical or text view of the provider summary
4. **Host PDF**: Generates host summary in PDF format
5. **Host Accordion**: See details about **Properties**, **Relationships**, **Security** and **Configuration** for the selected host

Tagging Multiple Hosts

To categorize hosts together, apply tags to multiple hosts at the same time.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Check the hosts to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. Select a customer tag from the first dropdown, and then a value for the tag.

* Only a single value can be assigned from these categories

5. Select more tags or click **Save** to save your changes.

Removing Hosts

If a host is decommissioned or requires troubleshooting, it might require removal from the VMDB.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Check the hosts to remove.
3. Click **Configuration**, and then (**Remove items from the VMDB**).
4. Click **OK**.

The hosts are removed. The virtual machines remain in the VMDB, but are no longer associated with their respective hosts.

Scaling Down Compute Hosts

Through Infrastructure Automation, you can perform a *Compute scale down* on a Red Hat OpenStack infrastructure provider. This process involves decreasing its Compute nodes used by an OpenStack infrastructure provider. Doing so involves putting a Compute node into *maintenance mode* and removing it from the provider afterwards. Once a node is in maintenance mode, it can be repurposed (for examle, re-provision it as a Controller node), repaired, or decommissioned altogether.

Before scaling down, evacuate or migrate any instances hosted on the node you are removing. For instructions on either procedure, see Migrating a Live Instance or Evacuating an Instance.

After migrating or evacuating instances from the node, set the node to maintenance mode. To do so:

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click the OpenStack compute node to be removed from the provider.
3. Click **Configuration**, and then (**Toggle Maintenance Mode**).

   Note:

   This option can only be used with OpenStack providers with at least two Compute nodes.

Repeat this procedure for every node you want to remove from the cloud provider.

After setting a Compute node to maintenance mode, you can scale down its provider:

1. Browse to menu: **Compute > Infrastructure > Providers**.
2. Click the provider to be scaled down.
3. Click **Configuration**, and then (**Scale Down**).
4. From the **Scale Infrastructure Provider Down** section, check the nodes to be removed from the provider. You can only do this for nodes where **Maintenance** is set to **true**.
5. Click **Scale Down**.

Refreshing Relationships and Power States for a Host

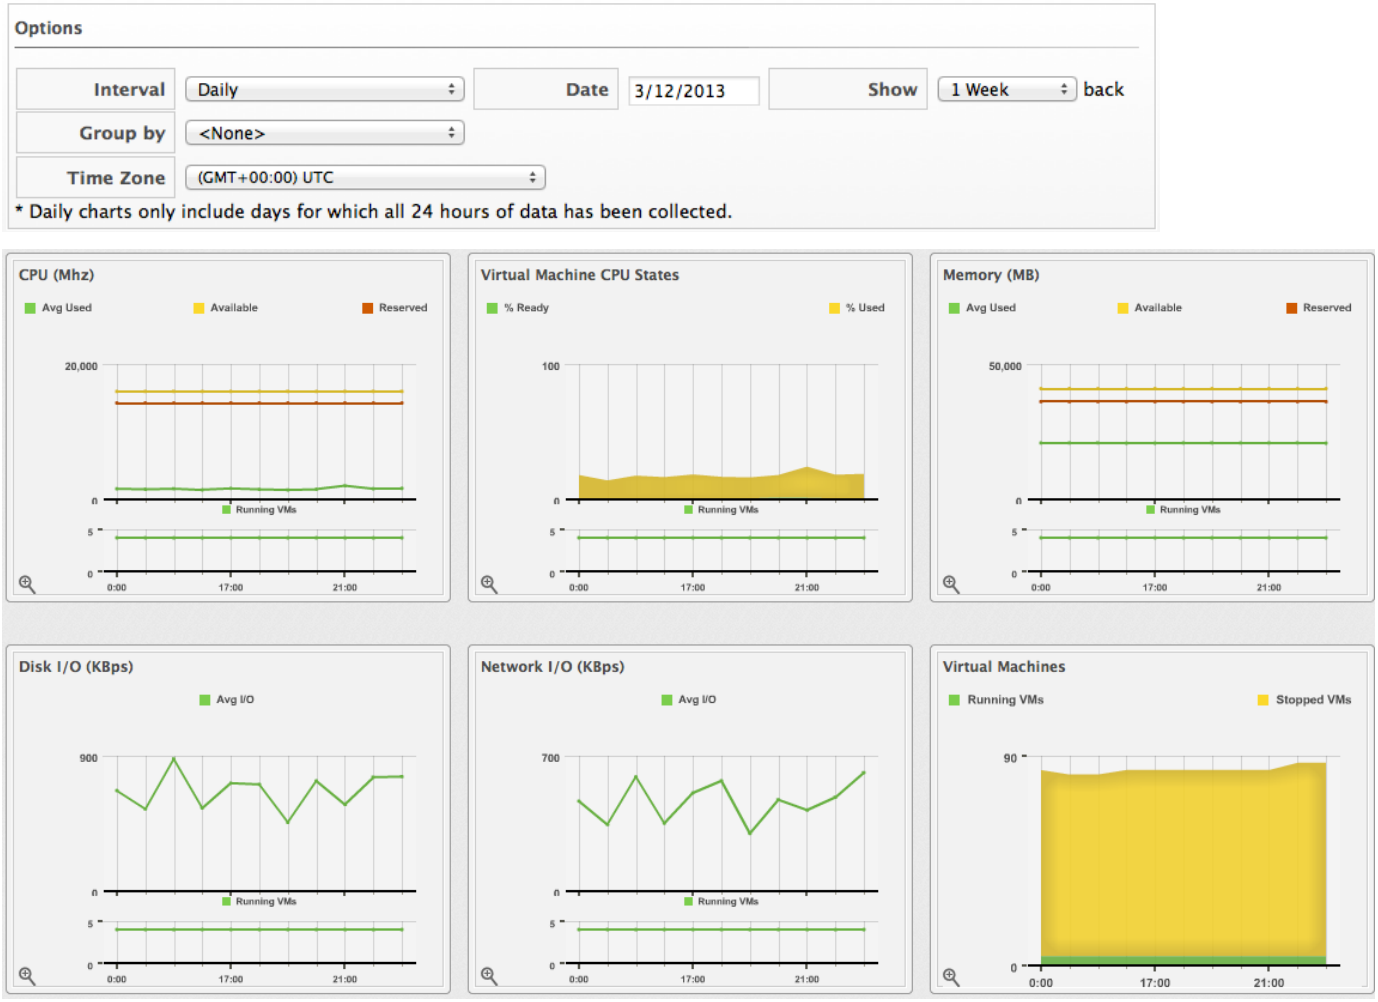
Refresh the relationships and power states of the items associated with your hosts from the Host Taskbar.

Note:

`root` or administrator credentials are required to get patch information.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click on the host to refresh.
3. Click **Configuration**, and then (**Refresh Relationships and Power States**) on the Host Taskbar.

Infrastructure Automation determines the state (running, stopped, or paused) of all virtual machines registered to the host.



Viewing Capacity and Utilization Charts for a Host

View Capacity & Utilization data for hosts that are part of a cluster.

Note:

Your Infrastructure Automation server requires network visibility to the provider assigned the **Server Role** of **Capacity & Utilization Collector** to enable this feature.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click the Host to view capacity data.
3. Click (**Monitoring**), and then (**Utilization**) or from the Host accordion, click **Properties > Capacity & Utilization**.
4. From **Interval**, select to view hourly or daily data points and the dates to view data. Use **Group by** to group the lines by SmartTags. Use **Time Profiles** to select a time range for the data.

The charts are displayed for CPU, memory, disk, network, and running virtual machines.

Note:

Daily charts only include full days of data. If a day does not include all the 24 data points for a day, the data does not show for that day.

For information about data optimization including utilization trend reports, see Data Optimization.

Viewing the Host Timeline

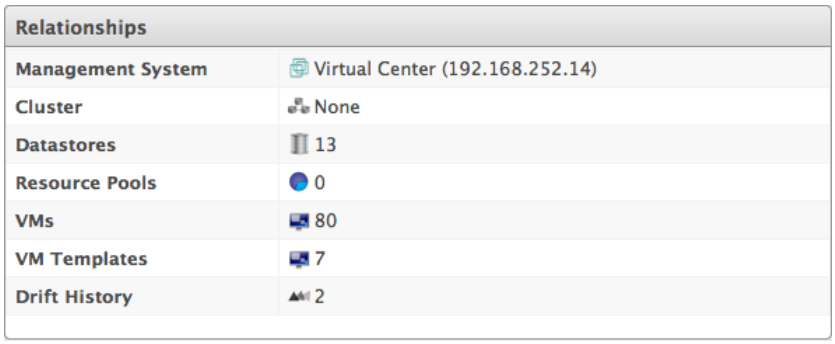
View the timeline of events for the virtual machines registered to a host.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click the host to view the timeline.

3. Click (**Monitoring**), and then (**Timelines**) or from the host accordion, click **Properties > Timelines**.
4. From **Options**, customize the period of time to display and the types of events to see.
    - Use **Show** to select types of events to show on the timeline.
    - Use the **Interval** dropdown to select hourly or daily data points.
    - Use **Date** to type the date the timeline displays.
    - If you select to view a daily timeline, use **Show** to set how many days back to go. The maximum history is 31 days. If selecting **Hourly**, select the interval to see.
    - From the **Level** dropdown, select either a **Summary** event or a **Detail** list of events. For example, the detail level of a **Power On** event might include the power on request, the starting event, and the actual **Power On** event. If you select **Summary**, only the Power On event appears in the timeline.
    - The three **Event Group** dropdowns allow selection of different groups of events to display. Each group has its own color.
5. To see more detail on an item in the timeline, click on it. A balloon appears with a clickable link to the resource.

Host Virtual Summary

Clicking on a specific host shows the Host's Virtual Thumbnail and an `operating system-sensitive` screen of host information, called the Host Summary. Where applicable, click on a subcategory of the Host Summary to see more detail on that section.



A **Refresh** provides some basic information on the Host. To get more detail, enter credentials for the host and perform a SmartState Analysis.

The Summary divides into the following categories.

- **Properties** include information such as base operating system, hostname, IP addresses, devices attached to the system, and storage adapters. Some categories can be clicked on for additional detail. For example, click **Network** to view the network adapters connected to the host.

Properties	
Hostname	per410a-t5.manageiq.com
IP Address	192.168.252.4
IPMI IP Address	
VMM Information	VMware
Manufacturer / Model	Dell Inc. / PowerEdge R410
Asset Tag	unknown
Service Tag	BBR8TK1
Operating System	ESXi 4.0.0 Build 504850
Power State	on
Lockdown Mode	Disabled
Devices	6
Network	Available
Storage Adapters	5
Number of CPUs	2
Number of CPU Cores	8
CPU Cores Per Socket	4
Memory	40 GB
Manangement Engine GUID	a55d2e44-8828-11e2-9abc-005056af00b4

- **Relationships** include information on the provider, cluster, datastores, resource pools, and installed virtual machines.

- **Security** shows the number of users, groups, patches installed, and firewall rules on the host. Click on any of these items to see further details.

  Note:

  Run a SmartState Analysis on the host to retrieve this information.

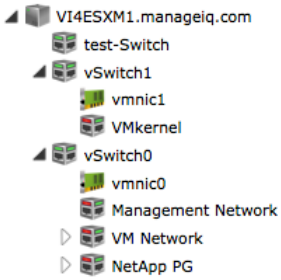
- **Storage Relationships** shows the relationship the host has to LUNs, volumes, and file shares. The **Storage Inventory Role** must be enabled in the zone for these items to be populated.
- **Configuration** shows the number of packages and services installed. Click on any of these items to see more details.

  Note:

  Run a SmartState Analysis on the host to retrieve this information.

- **Smart Management** shows all tags assigned to this host.
- **Authentication Status** shows all the types of credentials entered for this host and the whether those credentials are valid.

Viewing Host Device Information

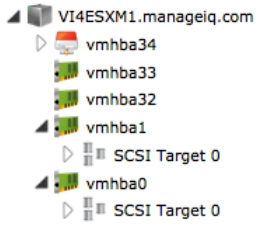


Access information on the hardware devices including processor, CPU type and speed, and memory for each host.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click the host to view the network information.
3. From the host accordion, click menu: **Properties > Devices**.

Viewing Host Network Information

Access information on networking including switches, network interfaces, and local area networks for each host.



1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click the host to view the network information.
3. From the host accordion, click menu: **Properties > Network**.

Viewing Storage Adapters

Access information on the storage adapters including storage type for each host.

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click the host to view the network information.
3. From the host accordion, click menu: **Properties > Storage Adapters**.

Detecting Drift on Hosts

Over time, the configuration of a host might change. Drift is the comparison of a host to itself at different points in time. The host requires analysis at least twice to collect information. Detecting drift provides you the following benefits:

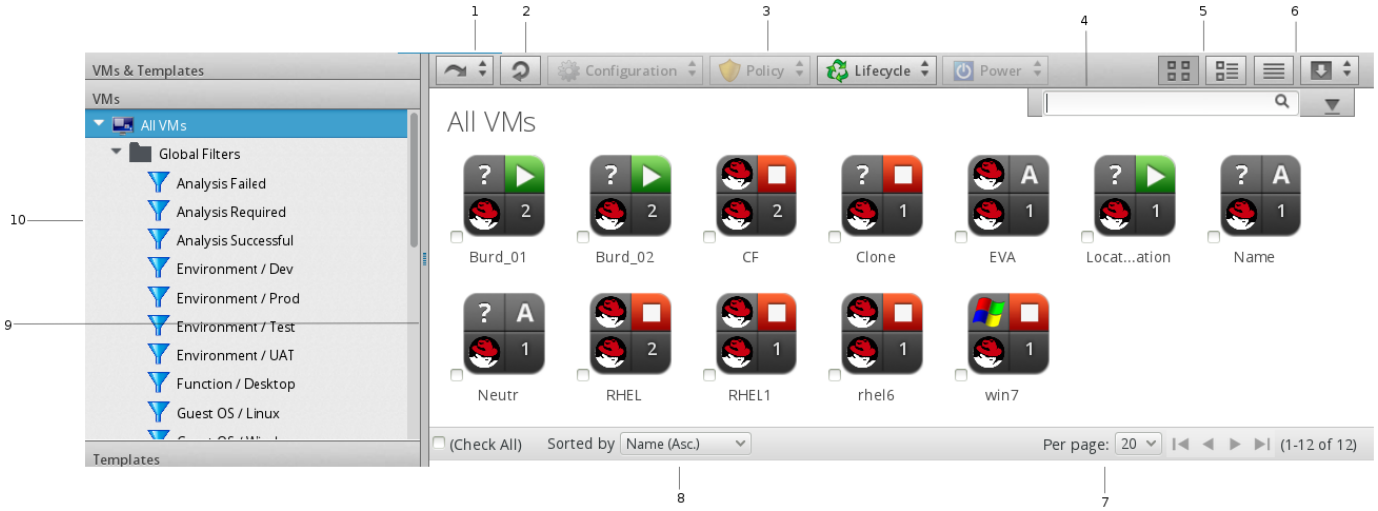
- See the difference between the last known state of a host and its current state.
- Review the configuration changes that happen to a particular host between multiple points in time.
- Capture the configuration drifts for a single host across a time period.

Detect drift on hosts:

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Click on the host to view drift.
3. Click **Relationships** in the host accordion.
4. Click **Drift History**.
5. Check the analyses to compare.
6. Click (**Drift**) at the top of the screen. The results display.
7. Check the **Comparison** sections on the left to view in your comparison.
8. Click **Apply**.
9. Click the plus sign next to the sections name to expand it.
    - An item displayed on red text shows a change from the base analysis. An item displayed in black text shows no change from the base analysis.
    - A (**Changed from previous**) shows a change since the last analysis.
    - A (**Same as previous**) means no change since the last analysis.
    - Click (**Remove from drift**) at the bottom of a column to remove a specific analysis. The drift recalculates and the new results display.
10. Click (**Expanded View**) to see the expanded view. Click (**Compressed View**) to compress the information.
11. Click the minus sign next to the sections name to collapse it.
12. To limit the type of views, you have three buttons in the taskbar:
    - Click (**All attributes**) to see all attributes of the sections you selected.
    - Click (**Attributes with different values**) to see only the attributes that are different across the drifts.
    - Click (**Attributes with the same values**) to see only the attributes that are the same across drifts.

The drift comparison displays. Download the data or create a report from your drift for analysis using external tools.

Creating a Drift Report for Hosts



Use the drift report feature to export information about your host's drift.

1. Create the comparison to analyze.
2. Click (**Download**).
3. Click the output button for the type of report you want.
   - Click (**Download drift report in TXT format**) for a text file.
   - Click (**Download drift report in CSV format**) for a comma-separated file.
   - Click (**Download drift report in PDF format**) for a PDF file.

Virtual Machines

The heterogeneous virtual machine container and guest support combined with the ability to analyze information inside the virtual machine - such as disk space, patch level or installed applications - provides in-depth information across the virtual environment. This rich set of information enables Infrastructure Automation users to improve problem resolution times and effectively manage virtual machines.

The **Virtual Machines** pages display all virtual machines that were discovered by your server. Note that if you have applied a filter to a user, it will be in effect here. The **Virtual Machines** taskbar is a menu driven set of buttons that provide access to functions related to virtual machines.

1. History button
2. Refresh screen button
3. Taskbar
4. Name search bar/Advanced Search button
5. View buttons
6. Download buttons
7. Navigation bar
8. Sort dropdown
9. Main area in Grid View
10. Provider/Filter Navigation

The console uses **Virtual Thumbnails** to describe virtual machines and templates. Each thumbnail contains four quadrants by default. This allows you to glance at a virtual machine for a quick view of its contents.

1. Top left quadrant: Operating system of the Virtual Machine
2. Bottom left quadrant: Virtual Machine Hosts software
3. Top right quadrant: Power state of Virtual Machine or Status icon
4. Bottom right quadrant: Number of Snapshots for this Virtual Machine

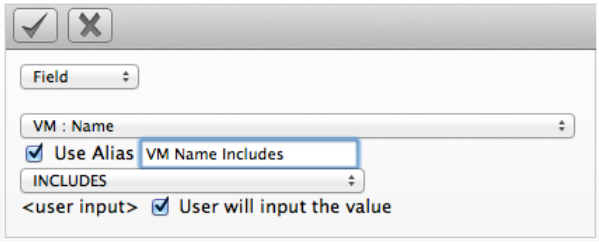
Icon	Description
	Template: Virtual Template
	Retired: When a virtual machine or instance is no longer required, it can be retired. Once a virtual machine or instance reaches its retirement date and time, it is immediately shut down and not allowed to restart. If an attempt to restart is made, Infrastructure Automation will shut down the virtual machine or instance.
	Archived: An archived virtual machine has no host or datastore associated with it. Archiving is done to move virtual machines to a low cost storage, either on demand or during retirement, if requested, to avoid incurring extra cost on a virtualized infrastructure due to virtual machine sprawl.
	Orphaned: An orphaned virtual machine has no host but has a datastore associated with it. Orphaned virtual machines are those that have been removed from their providers but still exist on the storage. An orphaned virtual machine is unable to identify the associated host. A virtual machine also shows as orphaned if it exists on a different host than the host expected by the provider's server.
	Disconnected: A disconnected virtual machine is one that has lost connection to either the provider's storage, host, or both. A disconnect is usually a result of network issues on the provider side. For instance, if during virtual machine provisioning the storage is not set up or deleted, the virtual machine will still exist on the provider, but will not run on the host as it has lost connection to its provider's storage.
	On: Virtual Machine is powered on.
	Off: Virtual Machine is powered off.
	Suspended: Virtual Machine has been suspended.

The **Virtual Machines** page has three accordions organizing your virtual machines and templates in different ways. All of these accordions share a set of common controls:

- Use **VMs and Templates** to view your virtual machines and templates organized by Provider. In addition, you can see archived and orphaned items here.
- Use **VMs** to view, apply filters, and collect information about all of your virtual machines.
- Use **Templates** to view, apply filters, and collect information about all of your templates.

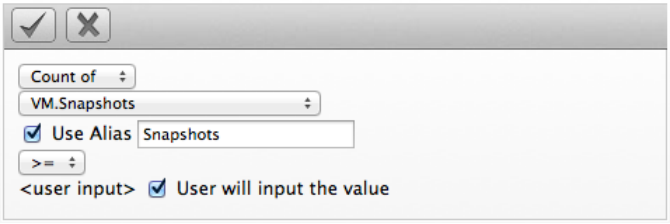
Through the console, you are able to view your virtual machines in multiple ways. For your virtual machines, you can:

- Filter virtual machines
- Change views
- Sort
- Create a report
- Search by MyTags
- Search by collected data



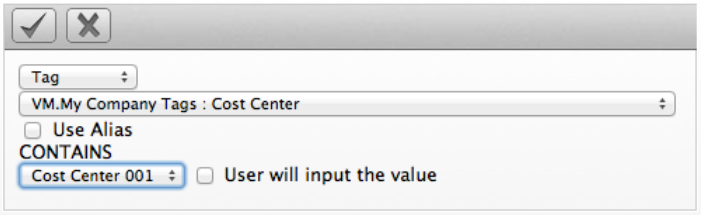
Filtering Virtual Machines and Templates

The **Virtual Machine Filter** accordion is provided so that you can easily navigate through groups of virtual machines. You can use the ones provided or create your own through **Advanced Filtering** capabilities.

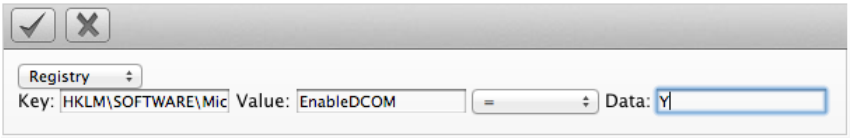


1. Navigate to **Compute > Infrastructure > Virtual Machines**.
2. Go to the **VMs** or **Templates** accordion.
3. Click on the desired filter from the left pane.

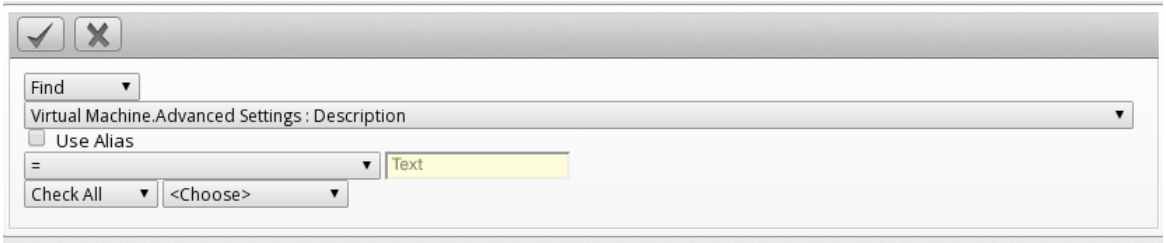
Creating a Virtual Machine or Template Filter



1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Go to the **VMs** or **Templates** accordion.
3. Click **All VMs** or **All Templates**, then click (**Advanced Search**) to open the expression editor.
4. Use the expression editor to choose the appropriate options for your criteria. Based on what you choose, different options will show.
    - For all of the types of searches, you have the options of creating an alias and requested user input. Select **Use Alias** to create a user friendly name for the search. If you are requested user input for the search, this text will show in the dialog box where the input is requested.
    - Click **Field** to create criteria based on field values.



- Click **Count of** to create criteria based on the count of something, such as the number of snapshots for a virtual machine, or the number of virtual machines on a host.



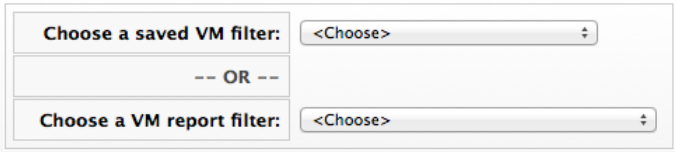
- Click **Tag** to create criteria based on tags assigned to your virtual infrastructure, such as for power states or production tagging.

- Click **Registry** to create criteria based on registry values, such as the DCOM status of a Windows system. Note this criteria applies only to Windows operating systems.

- Click **Find** to seek a particular value, and then check a property.

5. Click ✓ (**Commit Expression Element Changes**) to add the expression.
6. Click **Save**.
7. Type in a name for the search expression in **Save this VM** search as. (Note that this title depends on the type of resource you are searching.) To set the filter to show globally, check **Global search**.
8. Click **Save**.

The filter is saved and will show in the **My Filters** area of the **Filter** accordion. If you checked **Global search**, the filter will show under **Global Filters**.



Loading a Report Filter or Search Expression

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to search either **VMs** or **Templates**.
3. Click (**Advanced Search**) to open the expression editor.
4. Click **Load**.

5. Select either a saved virtual machine search or a virtual machine report filter.

   Note:

   The set of items to select will depend on the type of resource you are searching.

6. Click **Load** to load the search expression.
7. If you want to edit the expression, click on it and make any edits for the current expression.
   - Click (**Commit expression element changes**) to add the changes.
   - Click (**Undo the previous change**) to remove the change you just made.
   - Click (**Redo the previous change**) to put the change that you just made back.
   - Click AND (**AND with a new expression element**) to create a logical AND with a new expression element.
   - Click OR (**OR with a new expression element**) to create a logical OR with a new expression element.
   - Click NOT (**Wrap this expression element with a NOT**) to create a logical NOT on an expression element or to exclude all the items that match the expression.
   - Click (**Remove this expression element**) to take out the current expression element.
8. Click **Load**.
9. Click **Apply**.

Changing Views for Virtual Machines and Templates

While you can set the default view for different pages from the settings menu, then **Configuration > My Settings > Default Views**, the current view can also be controlled from the Virtual Machines pages.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to view.
3. Click the appropriate button for the desired view.
   - Click for **Grid View**.
   - Click for **Tile View**.
   - Click for **List View**.

Sorting Virtual Machines and Templates

Virtual machines and templates can be sorted by Name, Cluster, Host, Datastore, Compliance, Last Analysis Time, Total Snapshots, or Region.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to sort.
3. To sort virtual machines or templates when in grid or tile view:
   - From the **Sort by** dropdown, click the attribute to sort.
4. To sort virtual machines or templates when in list view:
   - Select the **List View**.
   - Click on the **Column Name** to sort. For example, click on **Cluster** to sort by the name of the cluster.

Creating a Virtual Machine or Template Report

For a listing of virtual machines and templates, you can create a quick report in CSV, TXT, or PDF formats.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items for report creation.
3. Click (**Download**).
   - Click for a **TXT** file.
   - Click for a **CSV** file.
   - Click for a **PDF** file.

Searching for Virtual Machines or Templates

To the right of the taskbar on the *Virtual Machines* page, you can enter names or parts of names for searching. You can search in the following ways:

- Type characters that are included in the name. For example, if you type **`sp1`**, all Virtual Machines whose names include **`sp1`** appear, such as **`Windows2003sp1`** and **`Sp1clone`**.
- Use **`*`** at the end of a term to search for names that begin with specific characters. For example, type **`v*`** to find all virtual machines whose names begin with the letter **`v`**.
- Use **`\*`** at the beginning of a term to search for names that end with specific characters. For example, type **`*sp2`** to find all virtual machines whose names end with **`sp2`**.
- Erase all characters from the search box to go back to viewing all virtual machines.

Search for virtual machines or templates:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to search.

   
3. In the **Name Filter** bar in the upper right corner of the window, type your criteria.
4. Click (**Search by Name within results**) or press **Enter**.
5. Type in other criteria to filter on what is currently displayed.
6. Click (**Search by Name within results**) or press **Enter**.

Analyzing Virtual Machines and Templates

Analyze a virtual machine to collect metadata such as user accounts, applications, software patches, and other internal information. If Infrastructure Automation is not set up for automatic analysis, perform a manual analysis of a virtual machine. To perform a SmartState analysis, Infrastructure Automation requires a running SmartProxy with visibility to the virtual machine's storage location. If the virtual machine is associated with a host or provider, ensure the virtual machine is registered with that system to be properly analyzed; the server requires this information since a snapshot might be created.

Note:

SmartState Analysis of a virtual machine requires access to its host. To perform a successful analysis, edit the virtual machine's host and enter the host's authentication credentials.

1. Navigate to **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to analyze.
3. Check the **Virtual Machines** and **Templates** to analyze.
4. Click (**Configuration**), then (**Perform SmartState Analysis**).
5. Click **OK**.

Red Hat Enterprise Virtualization Prerequisites

SmartState Analysis on Red Hat Enterprise Virtualization Manager 3.1 and Above - Storage Support Notes

Note the following requirements when performing SmartState Analysis on Red Hat Enterprise Virtualization Manager 3.1 and above.

- NFS
  - The Infrastructure Automation appliance requires a mount to the NFS datastore.
- iSCSI / FCP
  - For Red Hat Enterprise Virtualization 3.1 and 3.2, clusters must use full Red Hat Enterprise Linux hosts and not Red Hat Enterprise Virtualization Hypervisor hosts. You can use either type of host in Red Hat Enterprise Virtualization 3.3 and above.
  - Each Infrastructure Automation appliance performing SmartState Analysis requires sharable, non-bootable DirectLUN access to each attached iSCSI/FCP storage domain. In order to perform smart analysis, the appliance must mount the data storage as a DirectLUN disk.
  - A Infrastructure Automation appliance **must** reside in each datacenter with the iSCSI / FCP storage type.
  - If your storage domain is using Logical Volume Manager (LVM), you will need to manually activate your volume groups and logical volumes before performing the SmartState Analysis.
    1. Edit the **`/etc/lvm/lvm.conf`** file on the appliance and add volume groups to activate as read-only:

       ```
       activation {
           read_only_volume_list = ["volume_group_0", "volume_group_1", etc...]
       }
       ```

       Note: the volume group names are the storage domain UUIDs
    2. Activate volume groups:

       ```
       vgchange -ay
       ```
- Other Notes
  - The **Edit Management Engine Relationship** option enables the VM SmartState Analysis job to determine the datacenter where a Infrastructure Automation appliance is running and thus to identify what storage it has access to in a Red Hat Enterprise Virtualization environment.
    - After setting up a Infrastructure Automation appliance and performing a refresh of the provider, find the Infrastructure Automation appliance in the **Virtual Machine** accordion list and view its summary screen.
    - Click **Configuration > Edit Management Engine Relationship**.
    - Select the server that relates to this instance of the Infrastructure Automation appliance.

If you attach a DirectLUN disk after configuring the Infrastructure Automation database, access the appliance in a terminal and run `pvscan` to detect the DirectLUN disk. Alternatively, in Infrastructure Automation 5.2.1 and above, you can restart the appliance to detect the disk automatically.

SmartState Analysis on Red Hat Enterprise Virtualization Manager 3.0 - Storage Support Notes

There are two additional steps required to perform a SmartState Analysis on Red Hat Enterprise Virtualization Manager 3.0 using **`iSCSI`** or **`FCP`** storage. NFS storage does not have these requirements.

1. Enable **`DirectLUN`** support for the host and Infrastructure Automation appliance that performs the analysis.
   - Enable **`DirectLUN`** on host.
   - Enable **`DirectLUN`** on the Infrastructure Automation appliance. To do this, edit the desired Red Hat Enterprise Virtualization storage and get the **`LUNID`** value. Then, on the Infrastructure Automation appliance virtual machine in the Red Hat Enterprise Virtualization user interface, right-click and select **Edit > Custom Properties** and enter the following in the **Custom Properties** edit box:

     `directlun=<LUN ID>:readonly`

     If you have multiple storage domains, separate them by a comma, similar to:

     `directlun=<LUN ID 1>:readonly,<LUN ID 2>:readonly,<LUN ID N>:readonly`

     Note:

     The Infrastructure Automation appliance must reside in the same data center as the storage you are trying to connect. If you have multiple data centers with **`iSCSI`** or **`FCP`** storage, you need a Infrastructure Automation appliance in each data center to support virtual machine scanning.
2. **Set Server Relationship** - This is required to allow the virtual machine SmartState analysis job to determine which data center a Infrastructure Automation appliance is running and therefore identify what storage it has access to in a Red Hat Enterprise Virtualization environment.
   1. After setting up a Infrastructure Automation appliance and performing a refresh of the Provider, find the Infrastructure Automation appliance in the **Virtual Machine** accordion list and view its summary screen.
   2. Click  (**Configuration**), and then  (**Edit Server Relationship**).
   3. Select the server that relates to this instance of the Infrastructure Automation appliance.

3. If your storage domain is using Logical Volume Manager (LVM), you will need to manually activate your volume groups and logical volumes before performing the SmartState Analysis.

    1. Edit the **/etc/lvm/lvm.conf** file on the appliance and add volume groups to activate as read-only:

    ```
    activation {
        read_only_volume_list = ["volume_group_0", "volume_group_1", etc...]
    }
    ```

    Note: the volume group names are the storage domain UUIDs

    2. Activate volume groups:

    ```
    vgchange -ay
    ```

    For more information, please refer to the Red Hat Enterprise Linux documentation.

VMware vSphere Prerequisites

Installing VMware VDDK on appliances

Execution of SmartState Analysis on virtual machines within a VMware environment requires the Virtual Disk Development Kit (VDDK) to be installed.

To install VMware VDDK:

1. Download the required VDDK version (**VMware-vix-disklib-[version].x86_64.tar.gz**) from the VMware website.

    Note:

    - If you do not already have a login ID to VMware, then you will need to create one. At the time of this writing, the file can be found by navigating to **Downloads > vSphere**. Select the version from the drop-down list, then click the **Drivers & Tools** tab. Expand **Automation Tools and SDKs**, and click **Go to Downloads** next to the **VMware vSphere Virtual Disk Development Kit** version. Alternatively, find the file by searching for it using the **Search** on the VMware site.
    - See VMware documentation for information about their policy concerning backward and forward compatibility for VDDK.

2. Download and copy the **VMware-vix-disklib-[version].x86_64.tar.gz** file to the **/root** directory of the appliance.

3. Start an SSH session into the appliance.

4. Extract and install the **VMware-vix-disklib-[version].x86_64.tar.gz** file using the following commands:

    ```
    # cd /root
    # tar -xvf VMware-vix-disklib-[version].x86_64.tar.gz
    # cp vmware-vix-disklib-distrib/ -rf /usr/lib/vmware-vix-disklib/
    # ln -s /usr/lib/vmware-vix-disklib/lib64/libvixDiskLib.so /usr/lib/libvixDiskLib.so
    # ln -s /usr/lib/vmware-vix-disklib/lib64/libvixDiskLib.so.6 /usr/lib/libvixDiskLib.so.6
    # ln -s /usr/lib/vmware-vix-disklib/lib64/libvixDiskLib.so.6.7.0 /usr/lib/libvixDiskLib.so.6.7.0
    ```

5. Run **ldconfig** to verify that the application can find the newly installed VDDK library.

    Note:

    Use the following command to verify the VDDK files are listed and accessible to the appliance:

    ```
    # ldconfig -p | grep vix
    ```

6. Restart the appliance.

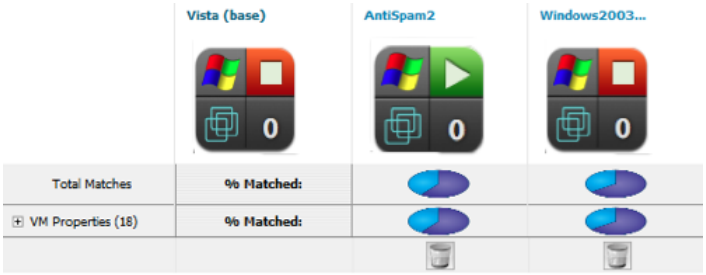
The VDDK is now installed on the appliance. This enables use of the SmartState Analysis server role on the appliance.

Comparing Virtual Machines and Templates

The Infrastructure Automation Server allows you to compare multiple virtual machines. This allows you to see how different virtual machines are from their original template. This helps detect missing patches, unmanaged user accounts, or unauthorized services.

Use the comparison feature to:

- Compare multiple virtual machines from different hosts.
- Compare multiple virtual machines side-by-side.
- Quickly see similarities and differences among multiple virtual machines and a base.
- Narrow the comparison display to categories of properties.
- Print or export in the comparison results to a PDF or CSV file.



Compare virtual machines and templates:

1. Navigate to **Compute > Infrastructure > Virtual Machines**.

2. Click the accordion for the items to analyze.

3. Check the items to compare.

4. Click btn:[(Configuration)], and then btn:[(Compare Selected items)]. The comparison displays in a compressed view with a limited set of properties listed.

5. To delete an item from the comparison, click btn:[(Remove this item from Inventory)] at the bottom of the items column. This option is only available when comparing more than two virtual machines.
6. To view many items on one screen, go to a compressed view by clicking btn:[(Compressed View)]. To return to an expanded view, click btn:[(Expanded View)].
7. To limit the mode of the view, there are two buttons in the task bar.
   - Click btn:[(Details Mode)] to see all details for an attribute.
   - Click btn:[(Exists Mode)] to limit the view to if an attribute exists compared to the base or not. This only applies to attributes that can have a boolean property. For example, a user account exists or does not exist, or a piece of hardware that does or does not exist.
8. To change the base virtual machine that all the others are compared to, click its label at the top of its column.
9. To go to the summary screen for a virtual machine, click its btn:[Virtual Thumbnail] or icon.

Virtual Machine and Templates Comparison Sections

The following table describes the different sections for comparison information.

Section	Description
Properties	Use this section to see basic information on the file location of the virtual machine, its name, and the virtual machine monitor vendor. Hardware, disk, CD/DVD drives, floppy drive, network adapter, and volume information is also included.
Security	Use this to see users and groups for the virtual machine, including those which may be unauthorized compared to a template.
Configuration	Use this to see Guest Applications, Win32 services, Linux Init Processes, Kernel Drivers, File System Drivers, and Patches.
My Company Tags	Use this to see all tags.

Using the Virtual Machine Comparison Sections

Use the comparison sections to view various comparison data and display the data in different ways.

1. On the left of a comparison screen, select what categories of properties to display.
2. Click **Apply**.
3. Click the plus sign next to the sections name to expand it.
4. The following descriptions pertain to the **Expanded View** . Whether you see the value of a property or an icon representing the property depends on the properties type.
   - A property displayed in the same color as the base means that the compared virtual machine matches the base for that property.
   - A property displayed in a different color from the base means that the compared virtual machine does not match the base for that property.
5. If you are in the **Compressed View** , the values of the properties will not be displayed. The icons shown below will describe all items.
   - A (**checkmark**) means that the compared virtual machine matches the base for that property. If you hover over it, the value of the property will display.
   - A (**x**) means that the compared virtual machine does not match the base for that property. If you hover over it, the value of the property will display.
6. Click the minus sign next to the sections name to collapse it.

Your comparison can be viewed in multiple ways. Export the data or create a report from your comparison for analysis using external tools.

Creating a Virtual Machine Comparison Report

Output the data from a comparison report in TXT, CSV or PDF formats.

1. Create the comparison for the report.
2. Click the output button for the chosen report type.
   - Click (**Download comparison report in TXT format**) for a text file.
   - Click (**Download comparison report in CSV format**) for a CSV file.
   - Click (**Download comparison report in PDF format**) for a PDF file.

Controlling the Power State of Red Hat Virtualization Virtual Machines

Follow this procedure to control the power states of Red Hat Virtualization VMs through the Infrastructure Automation console.

1. Navigate to **Compute > Infrastructure > Virtual Machines**.
2. Click on a VM to change the power state.
3. Click **Power Operations**, then click the button for the desired power operation. Available operations will depend on the current power state of the VM.
   - Click (**Shutdown Guest**) to shutdown the guest OS on the VM.
   - Click (**Restart Guest**) to restart the guest OS on the VM.
   - Click (**Power On**) to power on the VM.
   - Click (**Power Off**) to power off the VM.
   - Click (**Suspend**) to suspend the VM.
   - Click (**Reset**) to reset the VM.
4. Click **OK**.

Refreshing Virtual Machines and Templates

Refresh your virtual machines to get the latest data the provider or host can access. This includes information such as the power state, container, and hardware devices attached to the virtual machine.

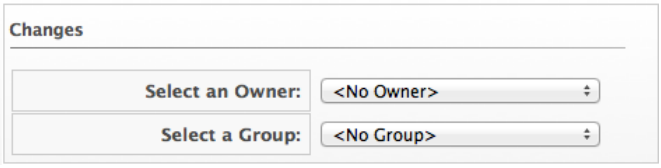
1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to analyze.
3. Check the items to refresh.
4. Click **Configuration**, and then (**Refresh Relationships and Power States**) on the **Virtual Machine Taskbar**.

The console returns a refreshed list of the data associated with the selected virtual machines.

Extracting Running Processes from Virtual Machines and Templates

Infrastructure Automation can collect processes running on Windows virtual machines. To do this, enter domain credentials for the zone where the virtual machine is located.

The virtual machine must be running and must have an IP address in the VMDB, usually obtained from a SmartState Analysis.



1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Check the Virtual Machines to collect the processes.
3. Click **Configuration**, and then (**Extract Running Processes**) on the Taskbar.
4. Click **OK**.

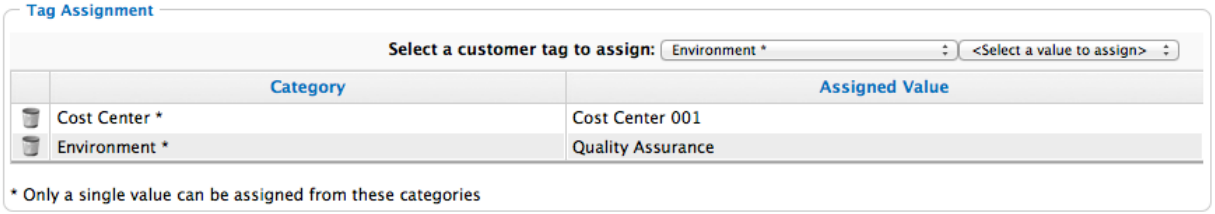
The server returns the running processes. View the summary of the virtual machine to see the details.

Setting Ownership for Virtual Machines and Templates

You can set the owner of a group of virtual machines and templates by either individual user or group. This allows you an additional way to filter and can be used to enforce quotas.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to change.
3. Check the items to set ownership.
4. Click **Configuration**, and then (**Set Ownership**) on the **Virtual Machine Taskbar**.
5. From the **Select an Owner** dropdown, select a user, and from the **Select a Group** dropdown, select a group.

6. Click **Save**.



Removing Virtual Machines and Templates from the VMDB

If a virtual machine has been decommissioned or you need to perform some troubleshooting, you might need to remove a specific virtual machine from the VMDB. This does not however remove the virtual machine or template from its Datastore or Provider.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to remove.
3. Check the items to remove.
4. Click **Configuration**, and then (**Remove from the VMDB**) button.
5. Click **OK**.

Tagging Virtual Machines and Templates

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to tag.
3. Check the items to tag.
4. Click (**Policy**), and then (**Edit Tags**).
5. Select a customer tag from the first dropdown, and then a value for the tag.

Viewing a VMware Virtual Machine's Storage Profile

VMware storage profiles allow you to assign policies to datastores. Storage profiles are used to tag virtual machines to ensure they operate in compliance with settings in the datastore.

Infrastructure Automation retrieves VMware virtual machine storage profile information in the inventory, and associates the virtual machines and disks with them.

To view a virtual machine's storage profile:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click a VMware virtual machine to open its summary page.
3. The VMware **Storage Profile** is listed under **Properties**.

You can assign a storage profile when provisioning a VMware virtual machine in Infrastructure Automation, by using the virtual machine as a template to clone. See Provisioning Virtual Machines in *Provisioning Virtual Machines and Hosts* for instructions.

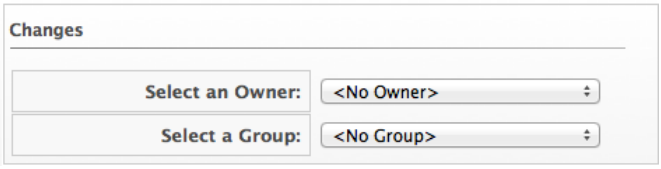
Viewing Running Processes after Collection

1. Click a virtual machine with collected processes.
2. From the **Diagnostics** area, click **Running Processes**.

	Name	PID	Memory %	Memory Usage	CPU %	CPU Time
	AppleMobileDeviceService.e	1,360	0.54	2,883,584	0.00	0
	EarthAgent.exe	1,412	1.36	7,278,592	0.00	409
	NSClient++.exe	1,524	1.70	9,093,120	0.00	176
	SoftwareUpdate.exe	2,028	3.37	18,075,648	0.00	0
	SpntSvc.exe	1,640	1.13	6,041,600	0.00	695
	StOPP.exe	2,052	0.50	2,658,304	0.00	0
	StWatchDog.exe	3,672	0.40	2,125,824	0.00	0
	VMwareService.exe	1,664	14.34	76,918,784	0.00	108
	VMwareTray.exe	2,368	0.14	749,568	0.00	0
	VMwareUser.exe	3,276	0.13	696,320	0.00	2
	csrss.exe	332	1.21	6,475,776	0.00	5
	csrss.exe	3,304	1.24	6,647,808	0.00	3

The most recent collection of running processes is displayed. Sort this list by clicking on the column headers.

Editing Virtual Machine or Template Properties



Edit the properties of a virtual machine or template to set parent and child virtual machines. SmartState Analysis also can detect this.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to edit.
3. Click the item to edit properties.
4. Click **Configuration**, and then (**Edit selected item**) on the Taskbar.
5. From the **Parent VM** dropdown, select the parent virtual machine.
6. From **Child VM** selection, select virtual machines that are based on the current virtual machine from the list of **Available VMs**.
7. Click **Save**.

Setting Ownership of a Virtual Machine or Template

Set the owner of a virtual machine or template by either individual user or group. This allows you an additional way to filter configuration items.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the items to analyze.
3. Click the item to set ownership.
4. Click **Configuration**, and then (**Set Ownership**) on the taskbar.
5. From the **Select an Owner** dropdown, select a user.

6. From the **Select a Group** dropdown, select a group.
7. Click **Save**.

Right Sizing a Virtual Machine

Infrastructure Automation uses collected statistics to recommend the best size for a virtual machine. Infrastructure Automation uses the information from the **Normal Operating Range** to calculate the recommendations.

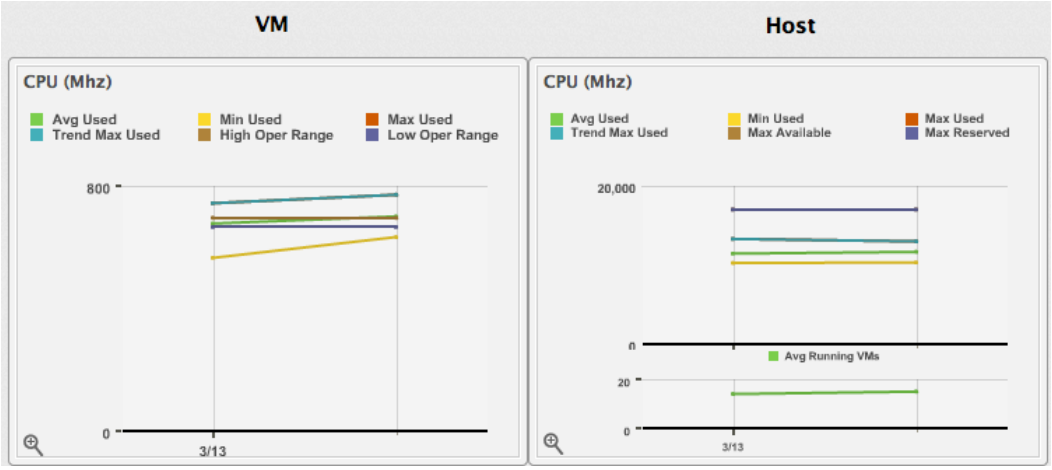
1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click a virtual machine for right-sizing.
3. Click **Configuration**, and then (**Right-Size Recommendations**) button.

A new page appears with three levels of Memory and CPU recommendations, Conservative, Moderate, and Aggressive, next to the Normal Operating Range statistics.

Viewing Capacity and Utilization Charts for a Virtual Machine

You can view capacity and utilization data for virtual machines that are part of a cluster. Note that daily charts only include full days of data. If all 24 data points for a day are not available, daily charts are not displayed. For some capacity and utilization data, Infrastructure Automation calculates and shows trend lines in the charts which are created using linear regression. The calculation uses the capacity and utilization data collected by Infrastructure Automation during the interval you specify.

Note:



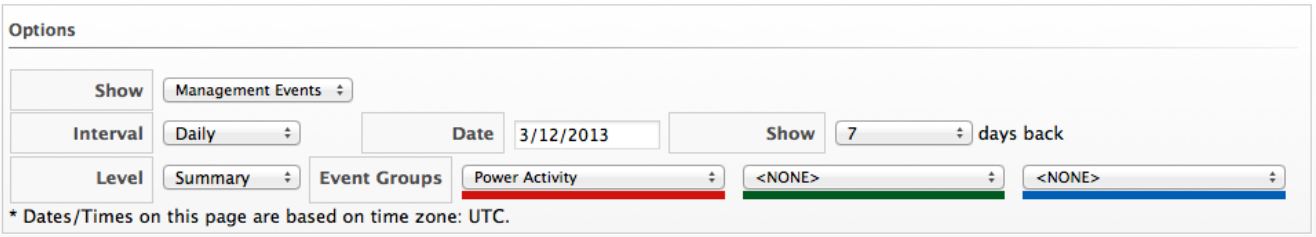
You must have a server with network visibility to your provider assigned the server role of **Capacity & Utilization Collector** to use this feature.

The virtual machine must be powered on to collect the data.

1. From **Compute > Infrastructure > Virtual Machines**, click the accordion that you want to view capacity data for.
2. Click the item you want to view.
3. Click (**Monitoring**), and then (**Utilization**).
4. From **Interval**, select to view **Daily**, **Hourly**, or **Most Recent Hour** data points. When choosing **Daily**, you can also select the **Date**, and how far back you want to go from that date. When selecting **Hourly**, you can select the date for which you want to view hourly data. If you are using **Time Profiles**, you will be able to select that as an option, also.

5. From **Compare to**, select **Parent Host** or **Parent Cluster**. The capacity and utilization charts for both items will show simultaneously.

Note:



Daily charts only include full days of data. This means Infrastructure Automation does not show daily data for a day without a complete 24 data point range for a day.

For information about data optimization including utilization trend reports, see Data Optimization.

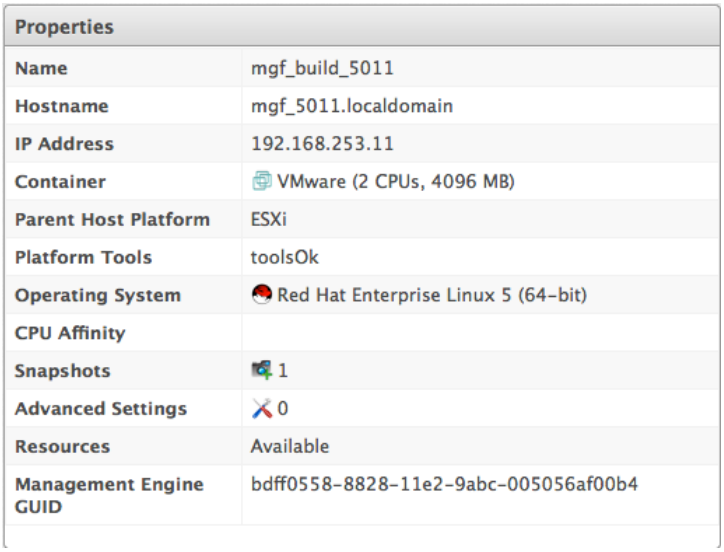
Viewing the Virtual Machine or Template Timeline

View the timeline of events for a virtual machine or template if registered to a Host.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the virtual machine to view the timeline.
3. Click (**Monitoring**), and then (**Timelines**) on the taskbar.
4. From **Options**, customize the period of time to display, and the types of events to view.

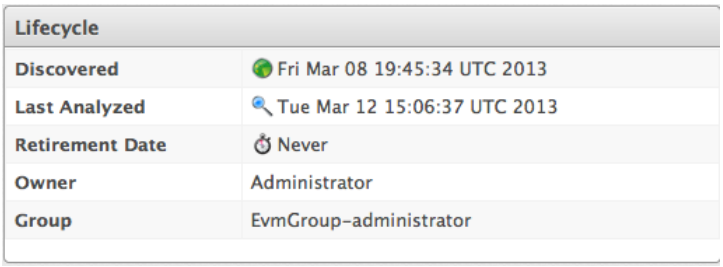
- Use the **Interval** dropdown to select hourly or daily data points.
- Use **Date** to type the date of the timeline to display.
- If viewing a daily timeline, use **Show** to set how many days back to go. The maximum history is 31 days.
- The three **Event Group** dropdowns allow selection of different event groups to display. Each has its own color.
- From the **Level** dropdown, select either a **Summary** event or a **Detail** list of events. For example, the detail level of a **Power On** event might include the power on request, the starting event, and the actual **Power On** event. If you select **Summary**, you only see the **Power On** event in the timeline.

5. To see more detail on an item in the timeline, click on it. A balloon appears with a clickable link to the resource.



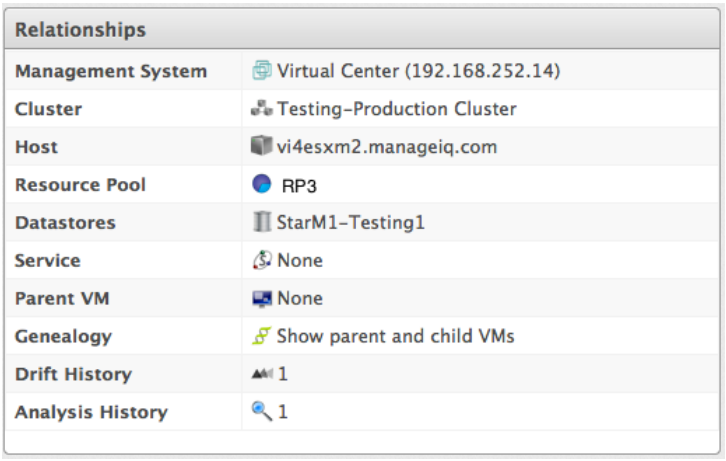
Virtual Machine or Template Summary

When you click on a specific virtual machine or template, you will see the **Virtual Thumbnail**, and an operating system-specific screen of the item, called the **Summary**. Where applicable, click on a subcategory of the **Summary** to see more detail on that section.

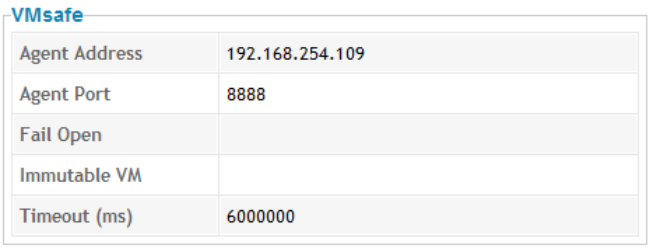


Note:

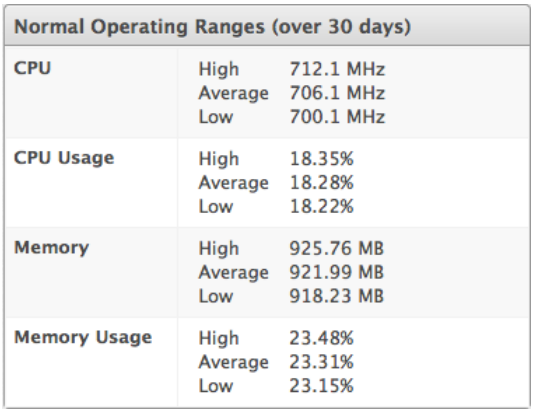
When you perform a SmartState Analysis on a virtual machine or template, you get more detailed information in these categories.



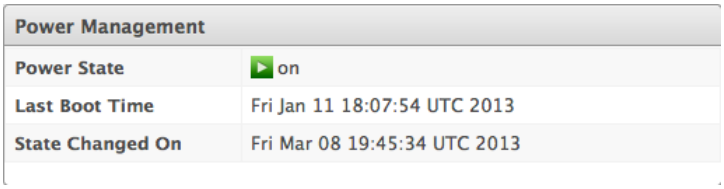
- **Properties** include information such as the base operating system, hostname, IP addresses, Virtual Machine vendor, CPU Affinity, devices attached to the system, and snapshots. This includes the ability to analyze multiple partitions, multiple disks, Linux logical volumes, extended partitions, and Windows drives. Some categories can be clicked on for additional detail. For example, click **Container** to view notes associated with a virtual machine.



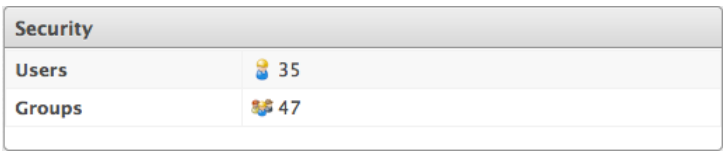
- **Lifecycle** shows the date of discovery and the last analysis. If a retirement date and time or owner has been set, these display as well.



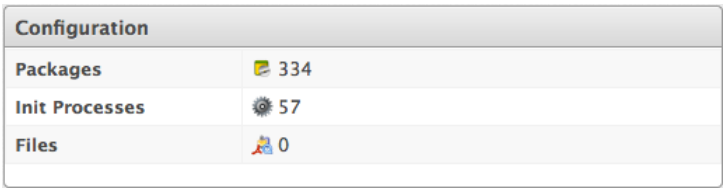
- **Relationships** include information on the parent host, genealogy such as parent and child virtual machines, and drift.



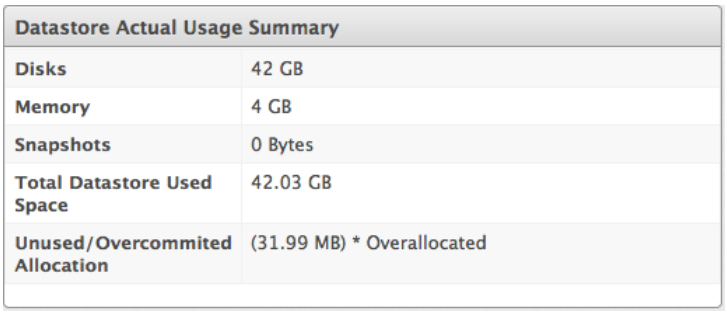
- **Storage Relationships** shows relationships to Filers, LUNs, Volumes and File Shares.
- **VMsafe** shows properties of the VMsafe agent if it is enabled.



- **Normal Operating Ranges** shows the values for the normal operating range for this virtual machine. These statistics are used in calculating right sizing recommendations.



- **Power Management** displays the current power state, last boot time, and last power state change. **State Changed On** is the date that the virtual machine last changed its power state. This is a container view of the power state, therefore a restart of the operating system does not cause the container power state to change and will not update this value.



- **Security** includes information on users, groups, and security patches. Recall that the items shown on the **Summary** screen change based on the guest operating system.

- **Configuration** includes information on applications, services, packages, and init processes. This section changes depending on the base operating system.

- **Datastore Allocation Summary** shows how many and how much disk space has been allocated to this virtual machine as well as disk alignment and thin provisioning information.
- **Datastore Actual Usage Summary** shows how much disk and memory the virtual machine is actually using.

- **Diagnostics** provides a link to viewing running processes and the information from the latest collected event logs.
- **Smart Management** shows all tags assigned to this virtual machine.

Viewing the Operating System Properties

View details of the operating system from the **Virtual Machine Summary** or the accordion. For Windows systems, see **Account Policies** for the virtual machine.

1. From **Compute > Infrastructure > Virtual Machines**, click on the item to view its **Summary**.
2. From the **Properties** section, click **Operating System**.

An expanded view of the operating systems properties and **Account Policies** displays. This varies based on the operating system.

Viewing Virtual Machine or Template Snapshot Information

View the list of snapshots to see a history of their creation and size. Infrastructure Automation provides the description, size, and creation time of the snapshot as well as a view of the genealogy of the snapshots.

Note:

Snapshot size is only available after the successful completion of a **SmartState Analysis**.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the appropriate accordion containing the item you wish to view the snapshots of.
3. Click on the item to view its **Summary**.
4. From the **Summary**, click *Snapshots* in the **Properties** area.
5. The list of snapshots show in a tree format and captures their genealogy.

Viewing User Information for a Virtual Machine or Template

Infrastructure Automation's **SmartState Analysis** feature returns user information. Drill into the user to get details on the user's account, including group memberships.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the item to view user information.
3. Click on the item to view its **Summary**.
4. From the **Security** section of the **Virtual Machine Summary**, click **Users**.
5. Click the user to view details.

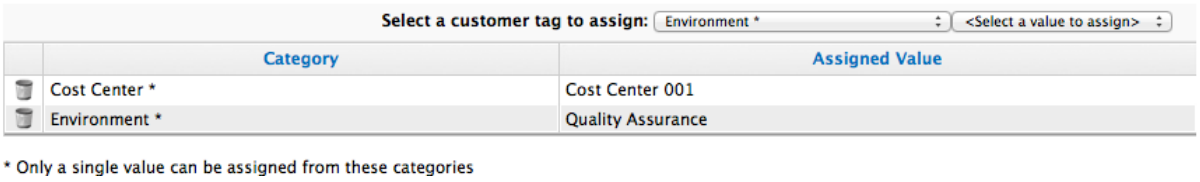
Viewing Group Information for a Virtual Machine or Template

Infrastructure Automation's **SmartState Analysis** feature returns group information. Explore a group to get a list of its users.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the item to view user information.
3. Click on the item to view its **Summary**.
4. From the **Security** section of the **Virtual Machine Summary**, click **Groups**.
5. Click the group to view users.

Viewing Genealogy of a Virtual Machine or Template

Infrastructure Automation detects the lineage of a virtual machine. View a virtual machine's lineage and compare the virtual machines that are part of its tree. This also allows tagging of virtual machines that share genealogy.



1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the item to view genealogy.
3. Click on the item to view its **Summary**.
4. From the **Relationships** area in the **Summary**, click **Genealogy**.

Comparing Genealogy of a Virtual Machine or Template

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the item to view genealogy.
3. Click on the item to view its **Summary**.
4. From the **Relationships** area in the **Summary**, click **Genealogy**.
5. Check the items to compare.
6. Click (**Compare Selected VMs**).

Tagging Virtual Machines or Templates with a Common Genealogy

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the item to view genealogy.
3. Check the items to tag.
4. Click (**Policy**), and then (**Edit Tags**).
5. Select a customer tag from the first dropdown, and then a value for the tag.

Detecting Drift on Virtual Machines or Templates

The configuration of a virtual machine might change over time. **Drift** is the comparison of a virtual machine to itself at different points in time. The virtual machine needs analysis at least twice to collect this information. Detecting drift provides you the following benefits:

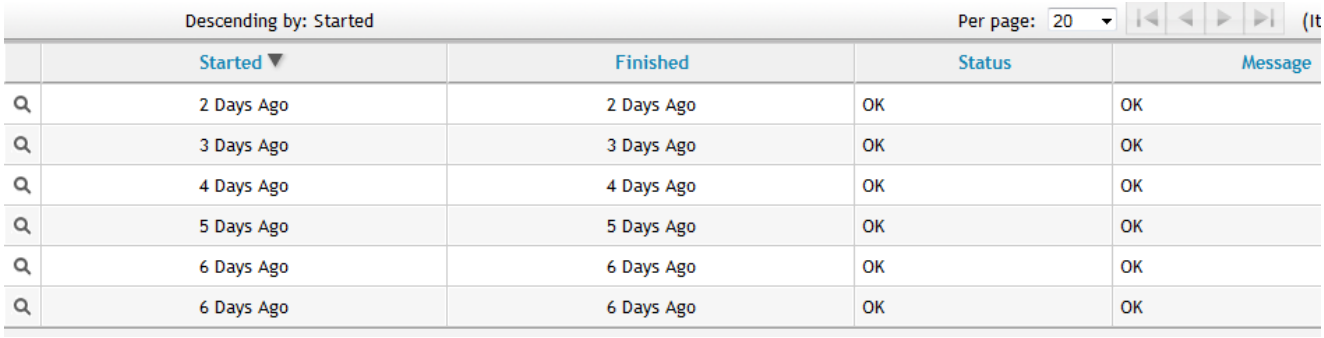
- See the difference between the last known state of a machine and its current state.

- Review the configuration changes that happen to a particular virtual machine between multiple points in time.
- Review the host and datastore association changes that happen to a particular virtual machine between multiple points in time.
- Review the classification changes that happen to a virtual machine between two time checks.
- Capture the configuration drifts for a single virtual machine across a time period.

Detect drift on virtual machines or templates:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click on the item to view its **Summary**.
3. From the **Relationships** area in the **Summary**, click **Drift History**.
4. Check the analyses to compare.
5. Click  (**Select up to 10 timestamps for Drift Analysis**) at the top of the screen. The results display.
6. Check the **Drift** sections on the left to view in your comparison.
7. Click **Apply**.
8. The following descriptions pertain to the **Expanded View**  . Whether you see the value of a property or an icon representing the property depends on the properties type.
    - A property displayed in the same color as the base means the compared analysis matches the base for that property.
    - A property displayed in a different color from the base means the compared analysis does not match the base for that property.
9. If you are in the **Compressed View**  , the values of the properties are not displayed. All items are described by the icons shown below.
    - A  (**checkmark**) means that the compared analysis matches the base for that property. If you hover over it, the value of the property will display.
    - A  (**triangle**) means the compared analysis does not match the base for that property. If you hover over it, the value of the property displays. Click the minus sign next to the sections name to collapse it.
10. To limit the scope of the view, you have three buttons in the **Resource** button area.
    - Click  (**All attributes**) to see all attributes of the sections you selected.
    - Click  (**Attributes with different values**) to see only the attributes that are different across the drifts.
    - Click  (**Attributes with the same values**) to see only the attributes that are the same across drifts.
11. To limit the mode of the view, there are two buttons in the **Resource** button area.
    - Click  (**Details Mode**) to see all details for an attribute.
    - Click  (**Exists Mode**) to only see if an attribute exists compared to the base or not. This only applies to attributes that can have a Boolean property. For example, a user account exists or does not exist, or a piece of hardware that does or does not exist.

This creates a drift analysis. Download the data or create a report from your drift for analysis using external tools.



Creating a Drift Report for a Virtual Machine or Template

1. Create the comparison to analyze.
2. Click  (**Download**).
3. Click the output button for the type of report you want.
    - Click  (**Download drift report in text format**) for a text file.
    - Click  (**Download drift report in CSV format**) for a csv file.
    - Click (**Download drift report in PDF format**) for a PDF file.

Viewing Analysis History for a Virtual Machine or Template

Each time a SmartState Analysis is performed on a virtual machine, a record is created of the task. This information is accessed either from the virtual machine accordion or the virtual machine summary. Use this detail to find when the last analysis was completed and if it completed successfully. If the analysis resulted in an error, the error is shown here.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the item to view genealogy.
3. Click on the item to view its **Summary**.
4. From the **Relationships** area in the **Summary**, click **Analysis History**. A history of up to the last 10 analyses is displayed.

Descending by: Started Per page: 20 (It

	Started ▼	Finished	Status	Message
	2 Days Ago	2 Days Ago	OK	OK
	3 Days Ago	3 Days Ago	OK	OK
	4 Days Ago	4 Days Ago	OK	OK
	5 Days Ago	5 Days Ago	OK	OK
	6 Days Ago	6 Days Ago	OK	OK
	6 Days Ago	6 Days Ago	OK	OK

5. Click on a specific analysis to see its details.

Viewing Disk Information for a Virtual Machine or Template

Each time a SmartState Analysis is performed on a virtual machine or template, information on the disks associated with the item is collected. This includes free and used space information as well as the type of disk and file system.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click on the item to view its **Summary**.
3. From **Datastore Allocation Summary**, click **Disks**.

A list of the disks for the item with type, file system, size, and usage information is displayed.

Reconfiguring Virtual Machines

Memory, processors, disks, ISOs, and CD/DVD Drives can be reconfigured on existing VMware and Red Hat Virtualization virtual machines using the **Reconfigure this VM** button.

You can reconfigure multiple components on a virtual machine using one request, or make each reconfiguration separately. Confirm your changes using the **Submit** button.

The following restrictions apply to adding and removing Red Hat Virtualization virtual machine disks: - Supported by Red Hat Virtualization 4.0 and above. - Only a single bootable disk is supported. - The virtual machine requires at least one existing disk to allow adding additional disks. This is because the destination storage cannot be specified from the Infrastructure Automation dialog, so the storage associated with the existing disk is reused.

Adding a Disk to a Virtual Machine

A disk can be added to a VMware or Red Hat Virtualization virtual machine with the following steps:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**, and then (**Reconfigure this VM**).
4. Click **Add Disk**.
5. Specify the disk type, mode, size, and dependency options.
6. Click **Submit**.

After the disk has been added, you can view the new disk by navigating to **Compute > Infrastructure > Virtual Machines**. . Open the target virtual machine, then click **Devices** to view the new disk.

Removing a Virtual Machine Disk

A disk can be removed from a VMware or Red Hat Virtualization virtual machine with the following steps:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**, and then (**Reconfigure this VM**).
4. Click **Delete** next to the disk to remove.
5. Click **Submit**.

Resizing a Virtual Machine Disk

Note:

This functionality is available on VMware virtual machines only.

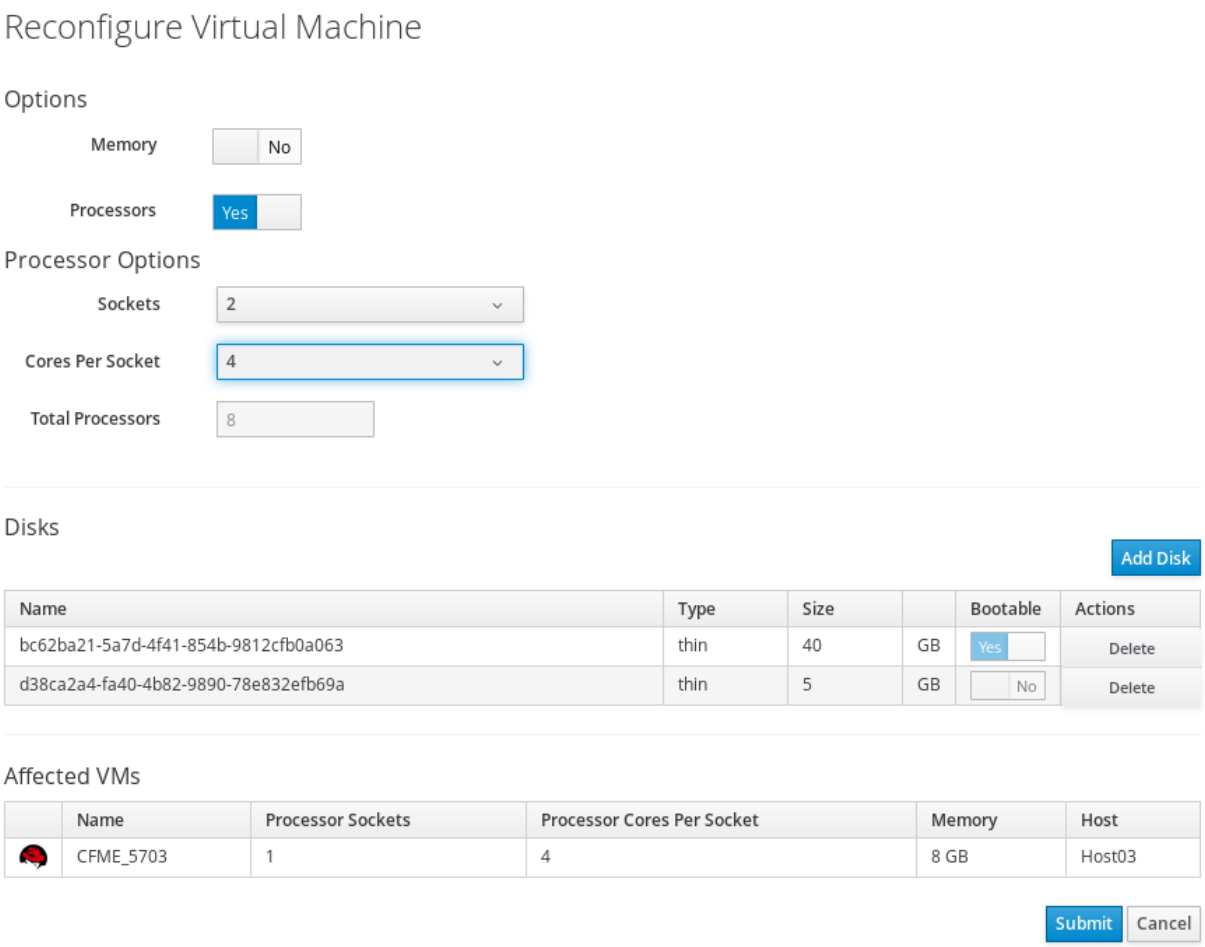
You can extend a VMware virtual machine's disk with the following steps:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**), and then (**Reconfigure this VM**).
4. Click **Resize** next to the disk you want to resize to show resizing options.
5. Specify the desired memory size and units (MB or GB). A disk can only be extended in size.
6. Click **Confirm Resize** to select the values. Alternatively, selecting **Cancel Resize** shows the original values.
7. Click **Submit**.

The disk resizing request is then processed for the virtual machine.

Increasing or Decreasing a Virtual Machine's Memory Size

You can increase or decrease a VMware or Red Hat Virtualization virtual machine's memory size with the following steps:



1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**, and then (**Reconfigure this VM**).
4. Select **Yes** next to **Memory** to show memory options.
5. Specify the desired memory size and units (MB or GB).
6. Click **Submit**.

The memory add request is then processed for the virtual machine.

Reconfigure a Virtual Machine's Processors

You can reconfigure a VMware or Red Hat Virtualization virtual machine's processors with the following steps:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**, and then **Reconfigure this VM**.
4. Select **Yes** next to **Processors** to show processor options.

5. Specify the number of sockets and the number of cores per socket. The reconfiguration screen will calculate the **Total Processors**.
6. Click **Submit**.

The virtual machine's processors are then reconfigured.

Adding or Removing Virtual Machine Network Adapters

Note:

This functionality is available on VMware virtual machines only.

You can add or remove network adapters on a VMware virtual machine from the **Reconfigure this VM** button.

Adding a Network Adapter to a VMware Virtual Machine

To add a network adapter to a virtual machine:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**, and then (**Reconfigure this VM**).
4. Click **Add Network** next to the disk you want to resize to show resizing options.
5. Select the type of adapter from the list under **vLan**.
6. Click **Confirm Add**.
7. Click **Submit**.

A request to add the network adapter is then processed for the virtual machine. You can view the details for the new network adapter by navigating to the **Reconfigure this VM** area. When the network adapter is added, a name and MAC address are assigned to the adapter.

Removing a Network Adapter from a VMware Virtual Machine

To remove a network adapter from a virtual machine:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**, and then (**Reconfigure this VM**).
4. Click **Delete** next to the network adapter you want to remove.
5. Click **Submit**.

Attach or Remove an ISO (VMware Virtual Machines Only)

You can attach an ISO to a VMware virtual machine using following steps:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**, and then (**Reconfigure this VM**).
4. Under **CD/DVD Drives**, click **Connect**.
5. Select the **Host File** from the list to attach and click **Confirm Connect**.
6. Click **Submit**.

The ISO is now attached to the VMware virtual machine.

You can remove an ISO on VMware virtual machine using following steps:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine.
3. Click **Configuration**, and then (**Reconfigure this VM**).
4. Under **CD/DVD Drives**, locate the **Host File** and click **Disconnect**.
5. Click **Confirm**.
6. Click **Submit**.

The ISO is removed from the VMware virtual machine.

Viewing Event Logs for a Virtual Machine or Template

Using an **Analysis Profile**, collect event log information from your virtual machines.

Note:

This feature is only available for Windows.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click the accordion for the item to view event logs.
3. Click on the item to view its **Summary**.
4. From **Diagnostics** click **Event Logs**.

The collected event log entries are displayed. Sort this list by clicking on the column headers.

Remote Consoles

A console is a graphical window that allows you to view the start up screen, shut down screen, and desktop of a virtual machine, and to interact with that virtual machine in a similar way to a physical machine.

Infrastructure Automation offers the following support for HTML5-based VNC, SPICE, and WebMKS consoles:

- VNC and SPICE consoles for Red Hat Virtualization Manager with websocket proxy.
- VMware's WebMKS HTML5-based console type.
- VNC consoles for OpenStack using OpenStack-supplied websocket proxy.

Note:

- VMware no longer supports the MKS console type. Also, VMRC is no longer a browser plugin but a native desktop application. As a result, the VMware MKS and the VMRC plugin options have been disabled in Infrastructure Automation.
- Currently, attempting to connect to the VMware WebMKS console for a virtual machine fails when the server security type is set to **2** for that virtual machine.
- Due to VMware licensing restrictions, Red Hat cannot ship the WebMKS SDK in Infrastructure Automation. For information on how to configure WebMKS support in Infrastructure Automation, see Configuring WebMKS Support in Infrastructure Automation.

All of the above make use of the websocket protocol supported by all recent versions of browsers, and can use SSL to encrypt the websocket connection.

- OpenStack Infrastructure Automation only makes an API call to get the URL for the console and open that console in a web browser; see Directly Connect to a VNC Console in the Red Hat OpenStack Platform *Instances and Images Guide* for more details.
- Red Hat Enterprise Virtualization Manager and VMware By default, the websocket connection runs over HTTPS or HTTP based on how the application was accessed. Under an appliance, you will most likely use HTTPS, and, therefore, the websocket connection will be wss:// (websocket with SSL).

  When configuring Red Hat Virtualization Manager for virtual machine console access, set the display type for each virtual machine to **noVNC** or **SPICE HTML5**. For more information on configuring console options, see Configuring Console Options in the Red Hat Virtualization *Virtual Machine Management Guide*.

Configuring Console Access to VMware ESXi Hosts At A Network Layer

When configuring access to the VNC or HTML5 console, make sure that at a network layer:

- All VNC ports (5900-6000) are opened from the machine on which you access the Infrastructure Automation Console to the Infrastructure Automation.
- All VNC ports (5900-6000) are opened from the Infrastructure Automation to each VMware ESXi host running virtual machines that you want to access.
- The firewall on VMware ESXi hosts is enabled and that the VMware ESXi host firewall ports are opened.
- The VNC service (**gdbserver**) is running and that the **gdbserver** service has an association with ports 5900-6000 usually defined with a **/etc/vmware/firewall/service.xml** firewall rules configuration.

  The **gdbserver** ruleset must be enabled on each ESXi host running virtual machines that will be accessed through the HTML5 console or VNC console on the Infrastructure Automation. The ruleset can be configured on the host itself, or using the VMware vCenter web user interface.

The following procedures apply to VMware vCenter 5.0 and later.

Using SSH to Configure VMware ESXi Hosts to Enable Console Access

Configure the **gdbserver** ruleset on the host using SSH.

1. Access the host:

   ```
   # ssh host@example.com
   ```

2. Set the **gdbserver** parameter:

   ```
   # esxcli network firewall ruleset set --ruleset-id gdbserver --enabled true
   ```

3. Confirm that the ruleset is active:

   ```
   # esxcli network firewall ruleset list
   ```

Using the VMware vCenter Web Interface to Configure ESXi Hosts to Enable Console Access

Configure the **gdbserver** ruleset on the host using the VMware vCenter web user interface.

1. Select the ESXi host in the VMware vCenter web interface.
2. Click the **Manage** tab.
3. Click the **Settings** sub tab.
4. Click **System > Security Profile** from the list on the left.
5. Click **Edit**.
6. Select the **gdbserver** ruleset, and then click **OK**.

Configuring the VMware ESXi Host Firewall Ports for Console Access

Follow these steps to configure the VMware ESXi host firewall ports for HTML5 or VNC console access to guest virtual machine consoles. The firewall ports must be enabled on each VMware ESXi host running virtual machines that will be accessed through the HTML5 or VNC console on the Infrastructure Automation.

1. Log in to your vSphere Client and select **Home > Inventory > Hosts and Clusters**.
2. In the **Hosts/Clusters** tree view, select the VMware ESXi host you want to configure for HTML5 or VNC console access.

3. Select the **Configuration** tab and open the **Software** box.
4. Select **Security Profile**.
5. Browse to the **Firewall Properties** dialog window by selecting the **Properties** link from the **Firewall** section.
6. In the **Firewall Properties**, scroll down to **GDB Server** and select it.
7. Click **OK**.

Configuring WebMKS Support in Infrastructure Automation

Complete the following steps to enable WebMKS support in Infrastructure Automation.

1. Log in to the Infrastructure Automation user interface appliance console as the root user.
2. On the Infrastructure Automation user interface appliances, create a folder titled **`webmks`** in the **`/var/www/miq/vmdb/public/`** directory.

   `/var/www/miq/vmdb/public/webmks`
3. Download and extract the contents of VMware WebMKS SDK into the **`webmks`** folder.

Opening a Console for a Virtual Machine

Open a web-based VNC or SPICE console for a virtual machine.

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click on the virtual machine that you want to access.
3. Click (**Access**) and select **VM Console** or **Web Console**.

The virtual machine console opens in a new tab in your browser.

Managing Virtual Machine Snapshots

A snapshot is a view of a virtual machine's operating system and applications on any or all available disks at a given point in time. Take a snapshot of a virtual machine before you make a change to it that may have unintended consequences. You can use a snapshot to return a virtual machine to a previous state.

View virtual machines by infrastructure providers by navigating to **Compute > Infrastructure > Providers**.

Creating a Virtual Machine Snapshot

To create a snapshot of a virtual machine:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine, and open it to view its details.
3. Under **Properties**, click **Snapshots** to show information about the virtual machine's snapshots.
4. Click (**Create a new snapshot for this VM**).
5. Enter snapshot details in **Description**.
6. (Optional) Select **Snapshot VM memory** for the snapshot to preserve the virtual machine's current runtime state. This option will appear only if the VM **Power State** is (**On**).
7. Click **Create**.

Deleting a Virtual Machine Snapshot

To delete a virtual machine snapshot:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the target virtual machine, and open it to view its details.
3. Under **Properties**, click **Snapshots** to show information about the virtual machine's snapshots.
4. Select the snapshot to delete under **Available Snapshots**.

5. Click and select **Delete Selected Snapshot**.
6. Click **OK**.

Reverting a Virtual Machine to a Snapshot

A virtual machine can be reverted to a previous state using a snapshot.

The virtual machine state must be powered `off` for the **Revert to selected snapshot** option to be available.
To revert a virtual machine to a snapshot:

1. Power the virtual machine off.
2. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
3. Select the target virtual machine, and open it to view its details.
4. Under **Properties**, click **Snapshots** to show information about the virtual machine's snapshots.
5. Select the snapshot to revert to under **Available Snapshots**.
6. Click (**Revert to selected snapshot**).
7. Click **OK**.

Creating a Template Based on a Virtual Machine

A template is a copy of a virtual machine (VM) that you can use to simplify the subsequent, repeated creation of similar VMs. Templates capture the configuration of software, configuration of hardware, and the software installed on the VM on which the template is based.

Note:

Virtual machines must meet the following criteria to publish as templates:

- The VM must not be blank, archived or orphaned.
- The VM must be associated with a oVirt / RHV provider.
- oVirt / RHV provider 4.0 or higher, with `use_ovirt_engine_sdk` set to `true` in `/var/www/miq/vmdb/config/settings.yml` on your Infrastructure Automation appliance.
- The VM power state is `OFF`.
- Sealing a template is not supported for Windows OS VMs.

To create a template based on an existing VM:

1. Browse to menu: **Compute > Infrastructure > Providers**.
2. Click on a oVirt / RHV provider.
3. Select a VM.
4. Click (**Lifecycle**), then click (**Publish selected VM to a Template**).
5. Under the **Request** tab, provide **Request Information** and identify a **Manager**:
    1. Enter an **E-Mail** address.
    2. Provide a **First** and **Last** name in the individual fields.
    3. Enter a **Manager** name.
6. Assign tags to the new template in the **Purpose** tab.
    1. Click on a tag category and check applicable tags.
7. Use fields in the **Catalog** tab to identify the source VM and provide details for the template:
    1. Select the source VM from the **Name** field.
    2. (Optional) Check **Seal Template**.

        Note:

        Sealing, which uses the `virt-sysprep` command, removes system-specific details from a virtual machine before creating a template based on that VM. This prevents the original VM's details from appearing in subsequent VMs that are created using the same template. It also ensures the functionality of other features, such as predictable vNIC order.

3. The **Number of VMs** indicates the output will be a single template.
4. Provide a **Name** and **Description** for the created template.

8. Under the **Environment** tab, specify information for the storage domain in which to create the template's disks.
    1. Check **Choose Automatically** to allow Infrastructure Automation to determine the destination cluster and datastore.

       Or, manually enter cluster and datastore information using the following steps:
    2. Select the cluster with which to associate the template from the **Cluster** list. By default, this is identical to the cluster of the source VM.
    3. Choose a **Datastore** for the destination to create the template's disks.
9. Provide provisioning and retirement information for VMs based on the template in the **Schedule** tab.
    1. Select **Schedule** or **Immediately on Approval** for **Schedule Info** to determine when to provision the VM.
    2. Set the **Time to Retirement** under **Lifespan** using the drop-down menu.
10. Click **Submit**.

Retiring Virtual Machines

Specify a retirement date and time for virtual machines or instances using Infrastructure Automation.

To set retirement date and time:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the virtual machines or instances for retirement.
3. Click (**Lifecycle**), then select **Set Retirement Date**.
4. Under **Enter Retirement Date as**, select **Specific Date and Time**.
5. Select a date using the calendar control, then click (**Select Time**).
6. Specify the hour and minute for retirement.
7. Select a **Retirement Warning** from the list.
8. Click **Save**.

Migrating Virtual Machines

Infrastructure Automation supports migrating virtual machines between datacenters, clusters, resource pools, folders and hosts. Create and submit a request with detailed environment information to which to migrate the VM.

To create a request to migrate a virtual machine:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Click **VMs & Templates** on the accordion menu.
3. Select the VM to migrate.
4. Click **Configuration**, and then **Lifecycle**.
5. Click **Migrate selected items**. The Migrate Virtual Machine form will appear.
6. Under the **Request** tab:
    1. Provide an **E-mail** address, **First Name** and **Last Name**.
    2. Include any **Notes** and a Manager's **Name**.
7. Under the **Environment** tab:
    1. Select a **Datacenter** to migrate the VM to.
    2. Select a **Cluster** from the list.
    3. Choose a **Resource Pool**.
    4. Select a **Folder** to migrate the VM to.

5. Under **Host** choose a **Filter** and click on a **Name** from the list that appears.
6. **Filter** the **Datastore** and click a **Name** from the results.

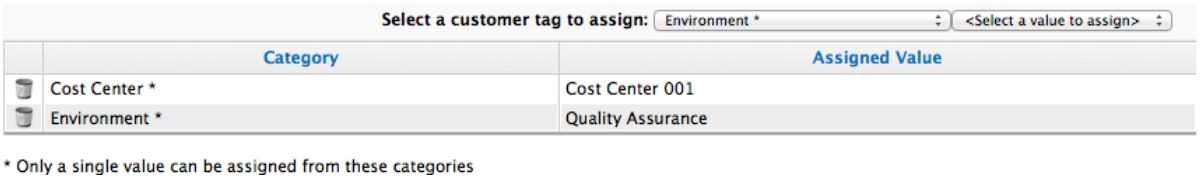
8. Under the **Schedule** tab:
    1. Select **Schedule Info** for migrating the virtual machine. Provide a **Provision on** date if selecting **Schedule**.
9. Click **Submit**.

Resource Pools

Resource pools are used to allocate CPU and memory across a group of virtual machines.

Removing a Resource Pool

If a resource pool is decommissioned or requires troubleshooting, it might require removal from the VMDB.



1. Browse to menu: **Compute > Infrastructure > Resource Pools**.
2. Click on the resource pool to remove.
3. Click **Configuration**, and then (**Remove from the VMDB**).
4. Click **OK**.

The resource pool is removed. The virtual machines remain in the VMDB, but are no longer associated with this resource pool.

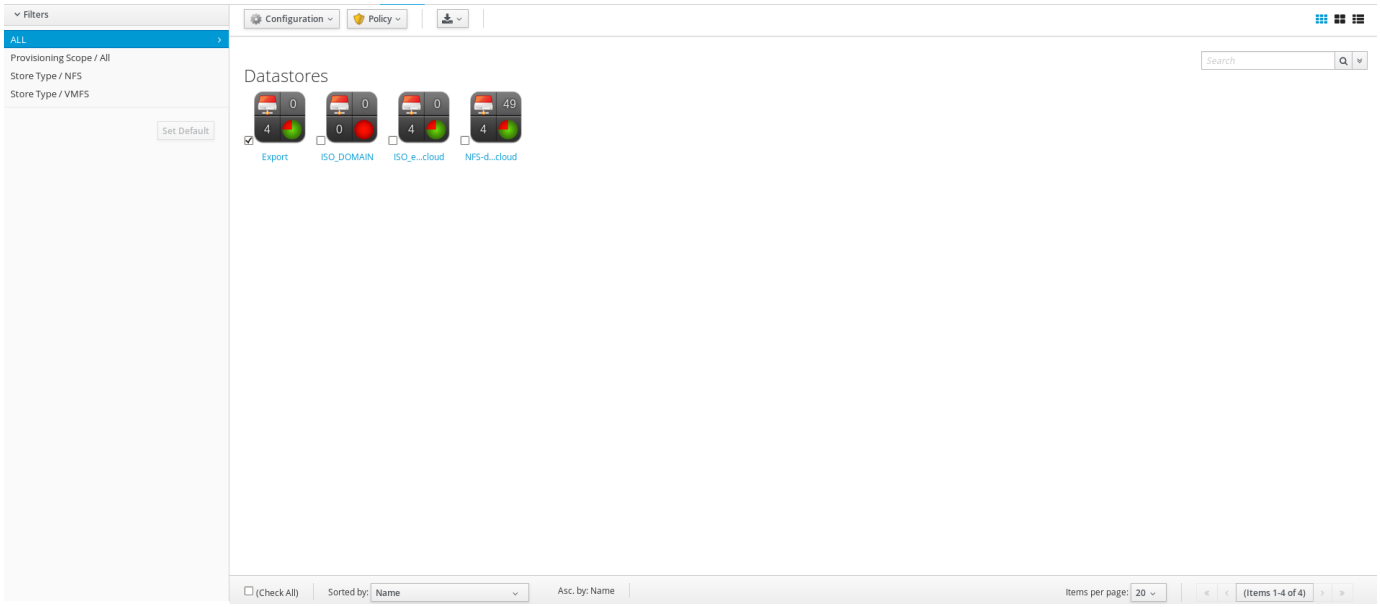
Tagging a Resource Pool

Use tags to categorize a resource pool.

1. Browse to menu: **Compute > Infrastructure > Resource Pools**.
2. Click the resource pool to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. Select a customer tag from the first dropdown, and then a value for the tag.

Viewing the Resource Pool Summary

Use the Resource Pool Summary to see the number of discovered virtual machines, the parent host, and the parent cluster. It is the default view when you click on one resource pool.



Resource Pools Accordion

Use the **Resource Pools** accordion to access the properties and objects associated with the resource pool.

- Click **Properties** to view the Resource Pools summary screen.
- Click **Relationships** to see the clusters, virtual machines, and hosts related to this resource pool.

Datastores

A storage location is considered a device where digital information resides and is connected to a resource. Infrastructure Automation detects, analyzes, and collects capacity and utilization data for both VMFS and NFS datastores. Datastores connected to a provider are automatically created on discovery. On creation of a repository, a datastore is automatically created.

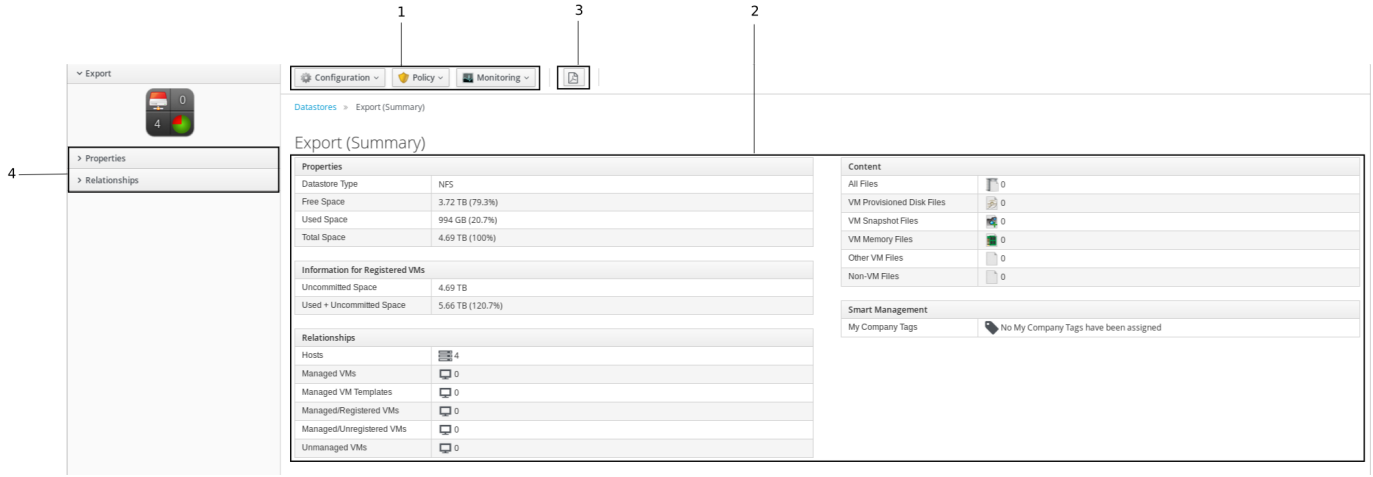
After detecting datastores, you might want to examine them more closely to see virtual machines, hosts, and available space.

1. File system type
2. Number of hosts
3. Number of virtual machines
4. Available space

Performing SmartState Analysis on Datastores

Analyze a datastore to collect information on the types of files on a datastore, and to see the number of managed/registered, managed/unregistered, and unmanaged virtual machines. To perform a SmartState analysis, the datastore is accessible from a running host and valid security credentials are supplied for that host.

Note:



- SmartState analysis on datastores is processed by the **Provider Operations** role. It is enabled by default.
- Be aware that executing a SmartState analysis on a datastore from the console takes a while to return data on the content. If capacity and utilization roles are enabled, Infrastructure Automation performs the analysis automatically on a scheduled basis approximately every 24 hours.

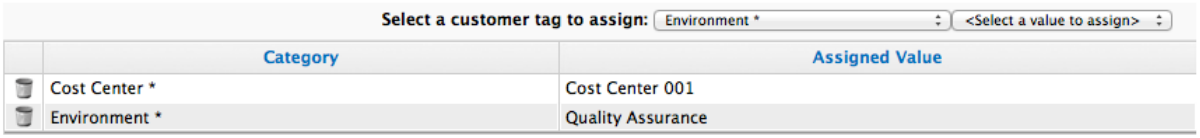
1. Browse to menu: **Compute > Infrastructure > Datastores**.
2. Select the datastores to analyze.
3. Click **Configuration**, and then (**Perform SmartState Analysis**).
4. Click **OK**.

Viewing a Datastore

You can click on a specific datastore to view its details. The screen provides you with a datastore taskbar, virtual thumbnail, accordion, and summary.

Datastore Management Screen.

1. **Datastore Taskbar**: Choose between **Configuration**, **Policy** and **Monitoring** options for the selected datastore.
2. **Datastore Summary**: See summary such as datastore properties, storage, VM information.
3. **Datastore PDF**: Generates datastore summary in PDF format.
4. **Datastore Accordion**: See details about **Properties**, **Relationships**, **Storage Relationships** and **Content** for the chosen datastore.



Note:

To view **Content** section details, run a SmartState Analysis on the datastore. For information on how to perform SmartState Analysis, see Performing SmartState Analysis on Datastores.

Tagging a Datastore

Use tags to categorize a datastore.

1. Browse to menu: **Compute > Infrastructure > Datastores**.
2. Click the datastore to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. Select a customer tag from the first list, and then a value for the tag from the second list.

5. Select more tags as required.
6. Click **Save**.

Viewing Capacity and Utilization Charts for a Datastore

You can view capacity and utilization data for a datastore.

Note:

Infrastructure Automation requires network visibility to your provider assigned the server role of *Capacity & Utilization Collector* to enable this feature.

1. Browse to menu: **Compute > Infrastructure > Datastores**, then click the Datastore for which to view Capacity and Utilization data.
2. Click (**Monitoring**), and then (**Utilization**).
3. From **Interval**, select to view hourly or daily data points and the dates to view data.
4. Use **Show VM Types** to include only managed/registered, managed/unregistered, or unmanaged virtual machines.

- **Managed/Registered VM** - A virtual machine connected to a host and exists in the VMDB. Also, a template connected to a management system and exists in the VMDB.

  Note:

  Templates cannot be connected to a host.

- **Managed/Unregistered VM** - A virtual machine or template that resides on a repository that is no longer connected to a management system or host, but exists in the VMDB. A virtual machine previously considered registered might become unregistered if the virtual machine is removed from management system inventory.
- **Not Managed** - Files discovered on a datastore that do not have a virtual machine associated with them in the VMDB. These files might be registered to a management system that Infrastructure Automation does not have configuration information. Possible causes might be the management system has not been discovered or the management system has been discovered but no security credentials are provided.

5. Use **Time Profiles** to select a time range for the data.

Note:

Daily charts only include full days of data. If a day does not include all the 24 data points for a day, the data does not show for that day.

For information about data optimization including utilization trend reports, see Data Optimization.

Removing a Datastore

If a datastore no longer contains any files associated with the virtual environment, remove it from the VMDB. This button is enabled only if a datastore is completely empty.

1. Browse to menu: **Compute > Infrastructure > Datastores**.
2. Click on the Datastore to remove.
3. Click **Configuration**, and then (**Remove Datastore from Inventory**).
4. Click **OK**.

Data Optimization

Infrastructure Automation optimization functions allow you to view utilization trends in your environment. In addition, you can predict where you have capacity for more virtual machines, see Planning Where to Put a New Virtual Machine in the *Deployment Planning Guide*.

Note: To access the utilization report features, you will first need to enable data collection in Infrastructure Automation; see the following sections in the *Deployment Planning Guide*:

- Assigning the Capacity and Utilization Server Roles
- Capacity and Utilization Data Collected

Utilization Trends

Infrastructure Automation allows you to view the resource utilization of your clusters, providers, and datastores. You can choose from summary, details, or report view.

Viewing a Utilization Trend Summary

This procedure shows you how to view a utilization trend summary.

1. Browse to menu: **Overview > Utilization**.
2. Click **Summary** if it is not already selected.
3. Expand the tree on the left side until you can see the wanted providers, clusters, or datastores.
4. Click the item.
5. Use the **Options** section in the **Summary** tab to change the characteristics of the data.
   - Use **Trends** to select how far back you want to calculate the trend.
   - Use **Selected Day** for the date you want to see percent utilization for in the chart on the **Summary** tab.
   - Use **Classification** to see trends only for a specific applied tag.
   - Use **Time Profile** to select an existing time profile. If the logged on user does not have any time profiles available, this option will not show.
   - Select a **Time Zone**.

Viewing Detail Lines of a Utilization Trend

This procedure shows you how to view detail lines of a utilization trend.

1. Browse to menu: **Overview > Utilization**.
2. Expand the tree on the left side until you can see the wanted providers, clusters, or datastores.
3. Click the item.
4. Click **Details** if it is not already selected.
5. From the **Options** area, select how far back you want to view the trends for and any classifications you want to use.

Viewing a Report of a Utilization Trend

To find out more about resource utilization, view utilization trend reports.

1. Browse to menu: **Overview < Utilization**.
2. Expand the tree on the left side until you can see the wanted providers, clusters, or datastores.
3. Click the item.
4. Click **Report** if it is not already selected.
5. From the **Options** area, select how far back you want to view the trends for and any classifications you want to use.

PXE Servers

PXE servers are used by Infrastructure Automation to bootstrap virtual machines for the purpose of provisioning. They include images for different operating systems that can be customized using customization templates and are used in conjunction with IPMI Servers.

Availability Zones

An availability zone is a provider-specific method of grouping cloud instances and services. Infrastructure Automation uses Amazon EC2 regions and OpenStack Nova zones as availability zones.

Viewing an Availability Zone

You can click on an availability zone to view its details. The screen provides you with an availability zone accordion and an availability zone summary page.

- You can choose between graphical or text view of the datastore summary.
- Use the availability zone accordion to view the **Properties** of the zone and its **Relationships** to other cloud resources.
- Use the availability zone summary to see details on **Relationships** (**Cloud Provider**, **Instances**) and **Smart Management** (**Company Tags**).

Viewing Availability Zone Relationships

Use the availability zone accordion's **Relationship** section to see items related to an availability zone.

1. Browse to menu: **Compute > Clouds > Availability Zones**.
2. Click the availability zone to view the configuration.
3. From the availability zone accordion, click **Relationships**.
4. Click the type of resource relationship to view as a list.

Cloud Tenants

A tenant is an OpenStack term for an organizational unit or project. Infrastructure Automation creates cloud tenants to match existing OpenStack tenants for managing resources and controlling visibility of objects.

Note:

OpenStack tenant mapping must be enabled for cloud tenants to be created. See Tenant Mapping for details.

OpenStack uses tenants for the following reasons:

- Assigning users to a project
- Defining quotas for a project
- Applying access and security rules for a project
- Managing resources and instances for a project

This helps administrators and users organize their OpenStack environment and define limits for different groups of people. For example, one project might require higher quotas and another project might require restricted access to certain ports. OpenStack allows you to define these limits and apply them to a project.

Infrastructure Automation can abstract information from tenants including quotas and relationships to other OpenStack objects.

To see multiple tenants in Infrastructure Automation, the user authenticating to your OpenStack environment from Infrastructure Automation must be configured to have visibility into these tenants.

Note:

This section describes OpenStack cloud tenant usage. For information about tenants created in Infrastructure Automation for access and resource control, see Access Control in *General Configuration*.

Tenant Mapping

When adding an OpenStack cloud or infrastructure provider, enable *tenant mapping* in Infrastructure Automation to map any existing tenants from that provider.

This means Infrastructure Automation will create new cloud tenants to match each existing OpenStack tenant; each new cloud tenant and its corresponding OpenStack tenant will have identical resource assignments (including user and role synchronization) with the exception of quotas. Tenant quotas are not synchronized between Infrastructure Automation and OpenStack, and are available for reporting purposes only. You can manage quotas in Infrastructure Automation but this will not affect the quotas created in OpenStack.

During a provider refresh, Infrastructure Automation will also check for any changes to the tenant list in OpenStack. Infrastructure Automation will create new cloud tenants to match any new tenants, and delete any cloud tenants whose corresponding OpenStack tenants no longer exist. Infrastructure Automation will also replicate any changes to OpenStack tenants to their corresponding cloud tenants.

If you leave tenant mapping disabled, Infrastructure Automation will not create cloud tenants or tenant object hierarchy from OpenStack.

Viewing Cloud Tenant Relationships

From **Compute > Clouds > Tenants**, click on a specific cloud tenant to view its details.

The screen provides you with a cloud tenant accordion and a cloud tenant summary.

- Use cloud tenant summary views to change how you are looking at the **Summary**.
- Use the cloud tenant accordion to view the **Properties** of the tenant and its **Relationships**.
- Use the cloud tenant summary to see details on **Relationships** (**Cloud Provider**, **Security Groups**, **Instances**, and **Images**), **Quotas** (including all OpenStack **Compute**, **Network**, and **Volume** quotas) and **Smart Management** (**Company Tags**).

Volumes

A volume is a block storage device that you can attach to or detach from an instance to manage the storage available to that instance. Volumes are managed through storage managers, which are added automatically to Infrastructure Automation when the corresponding provider is added.

Amazon Elastic Block Store Manager Volumes

This section outlines the actions that you can perform on Amazon Elastic Block Store manager volumes.

Creating Volumes

You can create and attach volumes to your storage manager.

To create a volume:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Click **Configuration**, then click (**Add a new Cloud Volume**).
3. Select the Amazon Elastic Block Store manager from the **Storage Manager** list.

4. Select an availability zone from the **Availability Zone** list.
5. Enter a **Volume Name**.
6. Select the type of the volume from the **Cloud Volume Type** list.

   Note:

   See Amazon EBS Volume Types for more information on volume types.
7. Enter the size of the volume in gigabytes (GB).
8. Select whether the volume should be encrypted using the **Encryption** toggle.
9. Click **Add**.

The volume appears in the list of volumes after it has been provisioned.

Creating a Snapshot of a Volume

You can create a snapshot of a volume to preserve the state of the volume at a specific point in time. The snapshot can be used to create a duplicate of the volume.

To create a snapshot of a volume:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Click the volume to snapshot to open the volume's summary page.
3. Click **Configuration**, then click **Create a Snapshot of this Cloud Volume**.
4. Enter a name for the snapshot in **Snapshot Name**.
5. Click **Save**.

Click **Cloud Volume Snapshots** on the summary page of a volume to view the snapshots for that volume.

Attaching a Volume to an Instance

To attach a volume to an instance:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to attach.
3. Click **Configuration**, then click **Attach selected Cloud Volume to an Instance** to open the **Attach Cloud Volume** screen.
4. Select an instance from the list.
5. Optionally, enter a **Device Mountpoint**.
6. Click **Attach**.

Detaching a Volume from an Instance

To detach a volume from an instance:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to detach.
3. Click **Configuration**, then click **Detach selected Cloud Volume from an Instance** to open the **Detach Cloud Volume** screen.
4. Select an instance from the list.
5. Click **Detach**.

Editing a Volume

You can edit several properties of existing volumes.

To edit a volume:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to edit to open its summary page.
3. Click **Configuration**, then click (**Edit this Cloud Volume**).
4. Enter a new **Volume Name**.
5. Select a new volume type from the **Cloud Volume Type** list.

   Note:

   See Amazon EBS Volume Types for more information on each of the volume types.
6. Enter a new size in gigabytes.
7. Click **Save**.

Deleting a Volume

To delete a volume from a storage manager:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to delete.
3. Click **Configuration**, then click (**Delete selected Cloud Volumes**).

OpenStack Block Storage Manager Volumes

This section outlines the actions that you can perform on OpenStack Block Storage manager volumes.

Creating Volumes

You can create and attach volumes to your storage manager.

To create a volume:

After creating a volume, only the volume name can be edited.

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Click **Configuration**, then click (**Add a new Cloud Volume**).
3. Select the OpenStack Block Storage manager from the **Storage Manager** list.
4. Enter a **Volume Name**.
5. Enter the size of the volume in gigabytes (GB).
6. Under **Placement**, select the cloud tenant to attach it to.
7. Click **Add**.

The volume appears in the list of volumes after it has been provisioned.

Creating a Backup of a Volume

You can create a backup of a volume to protect against data loss, and restore it in the future.

For OpenStack Block Storage managers, the `openstack-cinder-backup` service must be enabled on the OpenStack Block Storage manager to create a volume backup.
To create a backup of a volume:

1. Browse to menu: **Storage < Block Storage < Volumes**.
2. Click the volume you want to back up to open the volume's summary page.
3. Click **Configuration**, then click (**Create a Backup of this Cloud Volume**).
4. Enter a name for the backup in **Backup Name**.
5. (Optional) Select **Incremental?** to take an incremental backup of the volume instead of a full backup.

Note:

You can take an incremental backup of a volume if you have at least one existing full backup of the volume. An incremental volume saves resources by capturing only changes made to the volume since its last backup. See Create an Incremental Volume Backup in the *Storage Guide* for more information.

6. (Optional) Select **Force?** to allow backup of a volume attached to an instance.

   Note:

   Selecting the **Force** option will back up the volume whether its status is *available* or *in-use*. Backing up an *in-use* volume ensures data is crash-consistent.

7. Click **Save**.

View a volume's backups by clicking **Cloud Volume Backups** on the volume's summary page.

Note:

See Back Up and Restore a Volume in the *Storage Guide* for more information about backups.

Restoring a Volume from a Backup

In case of data loss, you can restore a volume from a backup with the following steps:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Click the volume whose backup you want to restore. This will open the volume's summary page.
3. Click **Configuration**, then click (**Restore from a Backup of this Cloud Volume**).
4. Select the volume to restore from in the **Cloud Volume Backup** list.
5. Click **Save**.

Restoring a Cloud Volume from a Backup

In case of data loss, you can restore from a cloud volume backup with the following steps:

1. Browse to menu: **Storage > Block Storage > Volume Backups**.
2. Select a **Cloud Volume Backup** to restore.
3. Click **Configuration**, then click (**Restore backup to Cloud Volume**).
4. Select the **Volume** to restore from the backup.
5. Click **Save**.

Deleting a Cloud Volume Backup

Delete unnecessary cloud volume backups through the following steps:

1. Browse to menu: **Storage > Block Storage > Volume Backups**.
2. Select the **Cloud Volume Backups** to delete.
3. Click **Configuration**, then click (**Delete selected Backups**).
4. Click **OK** to confirm your choice.

Creating a Snapshot of a Volume

You can create a snapshot of a volume to preserve the state of the volume at a specific point in time. The snapshot can be used to create a duplicate of the volume.

To create a snapshot of a volume:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Click the volume to snapshot to open the volume's summary page.
3. Click **Configuration**, then click (**Create a Snapshot of this Cloud Volume**).

4. Enter a name for the snapshot in **Snapshot Name**.
5. Click **Save**.

Click **Cloud Volume Snapshots** on the summary page of a volume to view the snapshots for that volume.

Note:

See Create, Use, or Delete Volume Snapshots in the *Storage Guide* for more information about snapshots.

Attaching a Volume to an Instance

To attach a volume to an instance:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to attach.
3. Click **Configuration**, then click (**Attach selected Cloud Volume to an Instance**) to open the **Attach Cloud Volume** screen.
4. Select an instance from the list.
5. Optionally, enter a **Device Mountpoint**.
6. Click **Attach**.

Detaching a Volume from an Instance

To detach a volume from an instance:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to detach.
3. Click **Configuration**, then click **Detach selected Cloud Volume from an Instance** to open the **Detach Cloud Volume** screen.
4. Select an instance from the list.
5. Click **Detach**.

Editing a Volume

Only the volume name can be edited on an existing volume.

To edit a volume's name:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to edit to open its summary page.
3. Click **Configuration**, then click (**Edit this Cloud Volume**).
4. Enter the new **Volume Name**.
5. Click **Save**.

Deleting a Volume

To delete a volume from a storage manager:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to delete.
3. Click **Configuration**, then click (**Delete selected Cloud Volumes**).

IBM Power Systems Virtual Servers Block Storage Manager Volumes

This section outlines the actions that you can perform on IBM Power Systems Virtual Servers Block Storage manager volumes.

Creating Volumes

You can create and attach volumes to your storage manager.

To create a volume:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Click **Configuration**, then click **Add a new Cloud Volume**.
3. Select the desired IBM Power Systems Virtual Servers instance from the **Storage Manager** list.
4. Enter a **Volume Name**.
5. Select the type of the volume from the **Cloud Volume Type** list.

   Note:

   See Power Systems Virtual Servers documentation for more information on volume types.
6. Enter the size of the volume in gigabytes (GB).
7. Click **Add**.

The volume appears in the list of volumes after it has been provisioned.

Attaching a Volume to an Instance

To attach a volume to an instance:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to attach.
3. Click **Configuration**, then click (**Attach selected Cloud Volume to an Instance**) to open the **Attach Cloud Volume** screen.
4. Select an instance from the list.

   Note:

   Note: A VM cannot have disks from different storage types. Only VMs matching storage type will be available for selection.
5. The **Device Mountpoint** field is not used.
6. Click **Attach**.

Detaching a Volume from an Instance

To detach a volume from an instance:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to detach.
3. Click **Configuration**, then click **Detach selected Cloud Volume from an Instance** to open the **Detach Cloud Volume** screen.
4. Select an instance from the list.
5. Click **Detach**.

Deleting a Volume

To delete a volume from a storage manager:

1. Browse to menu: **Storage > Block Storage > Volumes**.
2. Select the volume to delete.
3. Click **Configuration**, then click (**Delete selected Cloud Volumes**).

Flavors

Flavors indicate the resource profiles available for instances. Each flavor contains a value set for CPUs, CPU cores and memory. Flavors allow you to pre-configure resource settings, which you can then apply during instance provisioning. You can also change the flavor of a provisioned instance; see Resizing an Instance for instructions.

Infrastructure Automation provides the ability to view individual flavor information and instances currently using the flavor.

Creating a Flavor

You can create a new flavor for the provider.

1. Browse to menu: **Compute > Clouds > Flavors**.
2. Click **Configuration**, then click (**Add a new Flavor**).
3. Select the provider from the **Provider** list.
4. Enter a **Name** for the flavor.
5. Enter **RAM size in MB**.
6. Enter **VCPUs**.
7. Enter **Disk size in GB**.
8. Enter **Swap size in MB**.
9. Enter **RXTX factor**. This is an optional property allows servers with a different bandwidth to be created with the RXTX factor. The default value is 1. That is, the new bandwidth will be the same as that of the attached network.
10. Click **Public** to set `True` or `False`. The default is `True`. If you set it to false, select cloud tenants from the **Cloud Tenant** list.
11. Click **Add**.

Viewing a Flavor

You can click on a specific flavor to view its details. The screen provides you with a flavor accordion and a flavor summary.

- Use flavor summary views to change how you are looking at the summary.
- Use the flavor accordion to view the **Properties** of the flavor and its **Relationships**.
- Use the flavor summary to see details on **Properties** (**CPUs**, **CPU Cores**, **Memory**), **Relationships** (**Cloud Provider**, **Instances**), and **Smart Management** (**Company Tags**).

Viewing Flavor Relationships

Use the **Relationship** section in the flavor accordion to see items related to the flavor.

1. Browse to menu: **Compute > Clouds > Flavors**.
2. Click a flavor to view the configuration.
3. From the flavor accordion, click **Relationships**.
4. Click the type of resource to see the flavor's relationships.

Deleting a Flavor

1. Browse to menu: **Compute > Clouds > Flavors**.
2. Select the flavors you want to remove from the list.
3. Click **Configuration**, then click **Remove selected Flavors**.
4. Cick **OK** on the warning window to remove selected flavors permanently.

Cloud Networks

Infrastructure Automation enables configuration and administration for the software-defined networking component of Red Hat OpenStack Platform. The virtual network infrastructure enables connectivity between instances and the physical external network.

This section describes common cloud network administration tasks, such as adding and removing subnets and routers to suit your Red Hat OpenStack Platform providers.

Creating and Administering Cloud Networks

Create a network to provide instances a place to communicate internally and receive IP addresses using Dynamic Host Configuration Protocol (DHCP). A network can also be integrated with external networks in your Red Hat OpenStack Platform deployment or elsewhere, such as the physical network.

Note:

- Keystone API v3 is required to create cloud tenants on Red Hat OpenStack Platform cloud providers. For more information, see OpenStack Identity (keystone) in the Red Hat OpenStack Platform *Architecture Guide*.
- For further details on cloud network objects and administration, see the *Networking Guide* in the Red Hat OpenStack Platform documentation..

Adding a Cloud Network

Add a new cloud network following the steps in this procedure:

1. Browse to menu: **Network > Networks**.
2. Click **Configuration** and then click **Add a new Cloud Network**.
3. In the **Network Providers** area, select a **Network Manager** from the drop-down menu.
4. Under **Placement**, select a **Cloud Tenant**.
5. In the **Network Provider Information** section, choose a **Provider Network Type**.
    - If **Local** is selected, provide a **Physical Network** name.
    - If **GRE** is selected, provide a **Physical Network** name and **Segmentation ID**.
6. In the **Network Information** area:
    1. Provide a descriptive **Network Name** based on the role the network will perform.
    2. Enable an **External Router**
    3. Set the **Administrative State** to control whether the network is immediately available.
    4. Establish **Shared** status of the network.
7. Click **Add**.

Editing Cloud Network Details

To edit network information details of a cloud network:

1. Browse to menu: **Networks > Networks**.
2. Select a network from the list view.
3. Click **Configuration**, then  (**Edit selected Cloud Network**).
4. Edit **Network Information** fields.
5. Click **Save**.

Deleting a Cloud Network

To delete a cloud network:

1. Browse to menu: **Networks > Networks**.
2. Select a cloud network from the list view.
3. Click **Configuration**, then click **Delete selected Cloud Networks**.

Creating and Administering Subnets

Infrastructure Automation enables creation and administration of subnets for your cloud networks. Create subnets in pre-existing networks as means to grant network connectivity to instances. Subnets are the means by which instances are granted network connectivity. Each instance is assigned to a subnet as part of the instance creation process.

Consider proper placement of instances to best accommodate their connectivity requirements:

- Tenant networks in OpenStack Networking can host multiple subnets.
- Subnets are isolated from one another.
- Host distinctly different systems on different subnets within the same network.
- Instances on one subnet that wish to communicate with another subnet must have traffic directed by a router.
- Place systems requiring a high volume of traffic amongst themselves in the same subnet, avoiding routing and subsequent latency and load issues.

Adding a Subnet

Add a subnet to an existing cloud network following the procedure below.

1. Browse to menu: **Networks > Subnets**.
2. Click **Configuration**, then click **Add a new Cloud Subnet**.
3. Select a **Network Manager**.
4. Under **Placement**, select a **Cloud Tenant**.
5. Provide the following **Cloud Subnet** details:
    1. A descriptive **Subnet Name**.
    2. The **Gateway** IP address of the router interface for the default gateway.
    3. **Enable DHCP** services for the subnet. DHCP allows automated distribution of IP settings to instances.
    4. Select the **IP Version**. The IP address range in the Network Address field must match whichever version you select.
    5. Input the **Subnet CIDR** address in CIDR format, which contains the IP address range and subnet mask in one value.

       Note:

       Determine the address by calculating the number of bits masked in the subnet mask and append that value to the IP address range. For example, the subnet mask 255.255.255.0 has 24 masked bits. To use this mask with the IPv4 address range 192.168.122.0, specify the address 192.168.122.0/24.

Editing a Cloud Subnet

To edit the details of a cloud subnet:

1. Browse to menu: **Networks > Subnets**.
2. Click on a subnet from the list view.
3. Click **Configuration**, then  **Edit this Cloud Subnet**.
4. Edit **Cloud Subnet details** fields.
5. Click **Save**.

Configuring Network Routers

Infrastructure Automation enables configuration for Red Hat OpenStack Platform provider cloud network routing services using an SDN-based virtual router.

- Routers are a requirement for your instances to communicate with external subnets, including those out in the physical network.
- Routers and subnets connect using interfaces, with each subnet requiring its own interface to the router.
- A router's default gateway defines the next hop for any traffic received by the router.
- A router's network is typically configured to route traffic to the external physical network using a virtual bridge.

Adding a Network Router

Add a network router to an existing cloud network by following the procedure below.

1. Browse to menu: **Networks > Network Routers**.
2. Click **Configuration** and click **Add a new Router**.
3. In the **Network Provider** area, select a **Network Manager**.
4. Provide a **Router Name**.
5. Under **External Gateway**:
    1. If **Yes** is selected, provide the following:

1. Choose to **Enable Source NAT**. In Source Network Address Translation (SNAT), he NAT router modifies the IP address of the sender in IP packets. SNAT is commonly used to enable hosts with private addresses to communicate with servers on the public Internet.
2. Select a **Network**.
3. Select a **Subnet**.

6. Select a **Cloud Tenant**.
7. Click **Add**.

Editing Network Router Details

To edit the details of a network router:

1. Browse to menu: **Networks > Network Routers**.
2. Select a network router from the list view.
3. Click **Configuration**, then **Edit selected Router**.
4. Edit required fields.
5. Click **Save**.

Adding an Interface to a Network Router

Interfaces allow you to interconnect routers with subnets. As a result, the router can direct any traffic that instances send to destinations outside of their intermediate subnet.

To add an interface to a network router:

1. Browse to menu: **Networks > Network Routers**.
2. Select a network router from the list view.
3. Click **Configuration**, then (**Add Interface to this Router**).
4. Select a **Subnet** from the list.
5. Click **Add**.

Removing a Network Router Interface

You can remove an interface to a subnet if you no longer require the router to direct its traffic.

To remove an interface:

1. Browse to menu: **Networks > Network Routers**.
2. Select a network router in the list view.
3. Click **Configuration**, then (**Remove Interface from this Router**).
4. Confirm your choice.

Deleting a Network Router

To delete a network router:

1. Browse to menu: **Networks > Network Routers**.
2. Select a network router from the list view.
3. Click **Configuration**, then click **Delete selected Routers**.

Creating Floating IPs

Floating IP addresses allow you to direct ingress network traffic to your cloud network instances. Define a pool of validly routable external IP addresses, which can then be dynamically assigned to an instance. All incoming traffic destined for that floating IP is routed to the instance to which it has been assigned.

Note:

Red Hat OpenStack Networking allocates floating IP addresses to all projects (tenants) from the same IP ranges/CIDRs. As a result, every subnet of floating IPs is consumable by any and all projects. Manage this behavior using quotas for specific projects.

Adding Floating IPs.

Floating IP addresses allow you to direct ingress network traffic to your instances.

Add floating IP addresses to an existing cloud network by following the procedure below.

1. Browse to menu: **Networks > Floating IPs**.

2. Click **Configuration** and click Add a new Floating IP.
3. Select a **Network Manager**.
4. Choose an **External Network**
5. Under **Association Information** provide the following:
    1. (Optional) An **Associated Port** for the floating IP.
    2. (Optional) The **Floating IP Address**.
6. Select a **Cloud Tenant**.
7. Click **Add**.

Managing Port Association of a Floating IP

To manage the port associations of a floating IP:

1. Browse to menu: **Networks > Floating IPs**.
2. Click on a floating IP from the list view.
3. Click **Configuration**, then **Manage the port association of this Floating IP**.
4. To associate a port, add a new **Port id**
5. To disassociate a port, delete the **Port id** field information.
6. Click **Save**.

Deleting a Floating IP

To delete a floating IP

1. Browse to menu: **Networks > Floating IPs**.
2. SClick on a floating IP from the list view to view its summary page.
3. Click **Configuration**, then click **Delete this Floating IP**.

Security Groups

You can group instances using security groups to restrict port or IP address accessibility. Security groups can be created and assigned to instances using Infrastructure Automation instance provisioning.

Cloud providers that currently support this function include: Amazon EC2, OpenStack, and Red Hat Enterprise Virtualization.

Editing Security Group Details

Editing security group information allows users to make changes to existing security group details and firewall rules, in additional to adding new firewall rules.

To edit details of a security group:

1. Browse to menu: **Networks > Security Groups**.
2. Click on a security group to view the summary page.
3. Click **Configuration**, then **Edit this Security Group**.
4. Under **Security Group Information**, edit the **Security Group Name** and the **Security Group Description**.
5. Edit existing **Firewall Rules** or add new firewall rules by clicking **Add a Firewall Rule**.
6. Click **Save**.

Viewing Security Groups

This procedure describes how to view security groups.

1. Browse to menu: **Networks > Security Groups**.
2. Click the desired security groups for viewing the details.
    - In **Properties**, you can view the basic information of the security group.
    - In **Relationships**, you can view the cloud provider and the instances associated with the security group.
    - In **Firewall Rules**, you can view a list of ports and IP ranges that are accessible.

      Note:

      This box is not available if you have not set any rules for your security group.

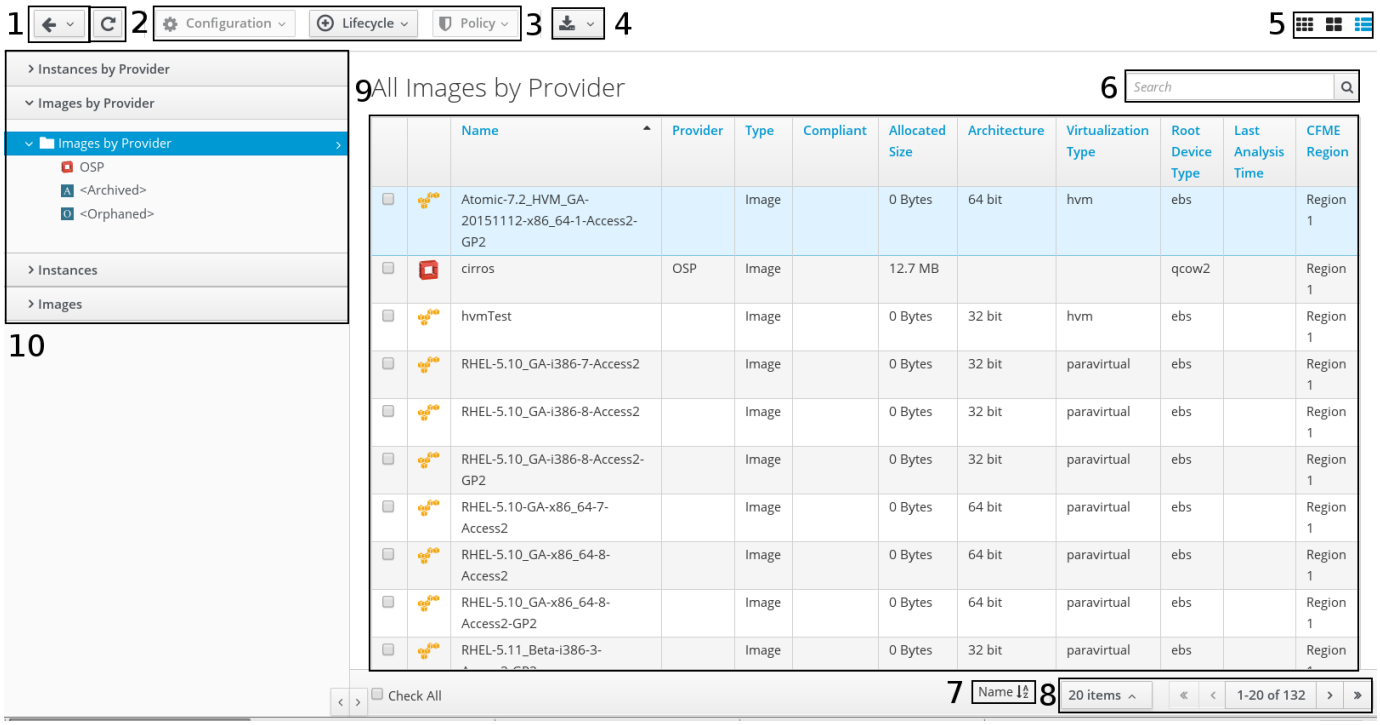
Tagging Security Groups

Apply tags to security groups to categorize them.

1. Browse to menu: **Networks > Security Groups**.
2. Select the security group to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. Select a customer tag to assign from the dropdown menu.
5. Select a value to assign.
6. Click **Save**.

Deleting a Security Group

To delete a security group:



1. Browse to menu: **Networks > Security Groups**.
2. Click on a security group in the list view to view its summary page.
3. Click on **Configuration**, then click **Delete this Security Group**.

Instances and Images

Images are the static templates containing the software configuration from which you provision a running **Instance** - a virtual machine, with which you can interact - on your cloud provider.

The **Instance** and **Images** containers, combined with the ability to analyze information inside each instance or image, provides in-depth information across the cloud environment. This rich set of information enables Infrastructure Automation users to improve problem resolution times and effectively manage instances and images in their cloud environment.

The **Instances** and **Images** pages display all instances and images the server discovered from your cloud providers. The taskbar on each page is a menu driven set of buttons that provide access to functions related to instances and images.

1. History button
2. Refresh screen button
3. Taskbar
4. Download buttons
5. View buttons
6. Name search bar/Advanced Search button

7. Sort dropdown
8. Navigation bar
9. Main area in List View
10. Cloud/Filter Navigation

Console uses Virtual Thumbnails to describe instances and images. Each thumbnail contains four quadrants by default. This allows you to glance at an instance or image for a quick view of its contents.

1. Top left quadrant: Operating system of the Instance
2. Bottom left quadrant: Instance Cloud Provider
3. Top right quadrant: Power state of Instance or Status icon
4. Bottom right quadrant: Number of Snapshots for this Instance

Icon	Description
	Template: Cloud Image
	Retired: Instance has been retired
	Archived: Instance has no provider or availability zone associated with it.
	Orphaned: Instance has no availability zone but does have a provider associated with it.
	Disconnected: Instance is disconnected.
	On: Instance is powered on.
	Off: Instance is powered off.
	Suspended: Instance has been suspended.

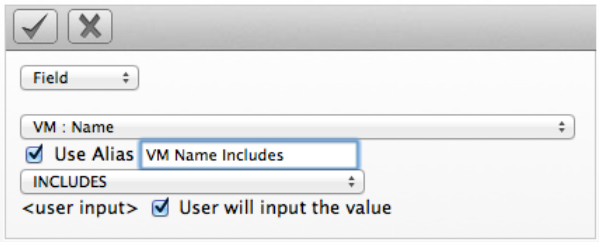
The **Instances** page has four accordions organizing your instances and images in different ways. All of these accordions share a set of common controls:

- Use **Instances by Provider** and **Images by Provider** to view your instances and images organized by provider. In addition, you can see archived and orphaned items here.
- Use the **Instances** to view, apply filters, and collect information about all of your instances.
- Use **Images** to view, apply filters, and collect information about all of your images.

Through the console, you can view your instances and images in multiple ways:

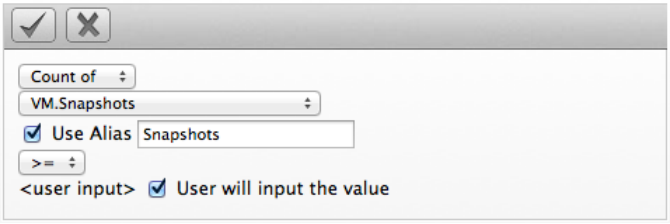
- Filter instances
- Change views
- Sort
- Create a report
- Search by Tags
- Search by collected data

Filtering Instances and Images



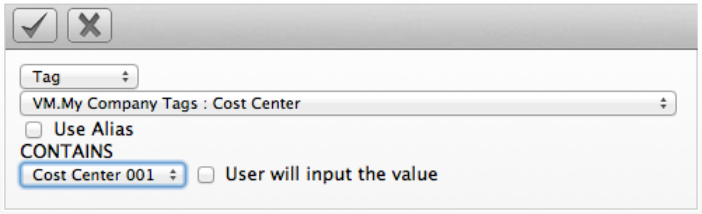
The **Instance Filter** accordion is provided so that you can easily navigate through groups of instances. You can use the ones provided or create your own through **Advanced Filtering** capabilities.

Using an Instance or Image Filter



1. Browse to menu: **Compute > Clouds > Instances**.
2. Click on the **Instances** or **Images** accordion.
3. Click on the desired filter from the left pane.

Creating an Instance or Image Filter



1. Browse to menu: **Compute > Clouds > Instances**.
2. Go to the **Instances** or **Images** accordion.
3. Click **All Instances** or **All Images**, then click (**Advanced Search**) to open the expression editor.
4. Use the expression editor to choose the appropriate options for your criteria. Based on what you choose, different options will show.
   - For all of the types of searches, you have the options of creating an alias and requested user input. Select **Use Alias** to create a user friendly name for the search. If you are requested user input for the search, this text will show in the dialog box where the input is requested.
   - Click **Field** to create criteria based on field values.

   - Click **Count of** to create criteria based on the count of something, such as the number of snapshots for an instance, or the number of instances on a host.

   - Click **Tag** to create criteria based on tags assigned to your virtual infrastructure, such as for power states or production tagging.

   - Click **Find** to seek a particular value, and then check a property.

5. Click (**Commit Expression Element Changes**) to add the expression.
6. Click **Save**.
7. Type in a name for the search expression in **Save this Instance search as**. To set the filter to show globally, check **Global Search**.
8. Click **Save**.

The filter is saved and shows in the **My Filters** area of the **Filter** accordion. If you checked **Global Search**, the filter shows there.

Loading a Report Filter or Search Expression

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the items to search (either **Instances** or **Images**).

3. Click (**Advanced Search**) to open the expression editor.
4. Click **Load**.
5. Select either a saved instance search or an instance report filter.

   Note:

   The set of items to select will depend on the type of resource you are searching.
6. Click **Load** to load the search expression.
7. If you want to edit the expression, click on it and make any edits for the current expression.
   - Click (**Commit expression element changes**) to add the changes.
   - Click (**Undo the previous change**) to remove the change you just made.
   - Click (**Redo the previous change**) to put the change that you just made back.
   - Click AND (**AND with a new expression element**) to create a logical AND with a new expression element.
   - Click OR (**OR with a new expression element**) to create a logical OR with a new expression element.
   - Click NOT (**Wrap this expression element with a NOT**) to create a logical NOT on an expression element or to exclude all the items that match the expression.
   - Click (**Remove this expression element**) to take out the current expression element.
8. Click **Load**.
9. Click **Apply**.

Changing Views for Instances and Images

While you can set the default view for different pages from the settings menu, then menu: **Configuration > My Settings > Default Views**, the current view can also be controlled from the Instances pages.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the items to view.
3. Click the appropriate button for the desired view.
   - Click for **Grid View**.
   - Click for **Tile View**.
   - Click for **List View**.

Sorting Instances and Images

Virtual machines and images can be sorted by Name, Availability Zone, Flavor, Cloud Provider, Compliant, Last Analysis Time, and Region.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the desired items to sort.
3. To sort instances or images when in grid or tile view:
   - From the **Sort by dropdown**, click the attribute to sort.
4. To sort instances or images when in list view:
   - Select the **List View**.
   - Click on the **Column Name** to sort. For example, click on **Availability Zone** to sort by the name of the availability zone.

Creating an Instance or Image Report

For a listing of instances and images, you can create a quick report in CSV, TXT, or PDF formats.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the desired items for report creation.
3. Click (**Download**).
   - Click for a **TXT** file.
   - Click for a **CSV** file.
   - Click for a **PDF** file.

Searching for Instances or Images

To the right of the taskbar on the **Instances** page, you can enter names or parts of names for searching. You can search in the following ways.

- Type characters that are **included** in the name. For example, if you type **`sp1`**, all Instances whose names include **`sp1`** appear, such as **`Windows2003`** and **`Sp1clone`**.
- Use **`*`** at the end of a term to search for names that begin with specific characters. For example, type **`v*`** to find all instances whose names begin with the letter **`v`**.
- Use **`*`** at the beginning of a term to search for names that end with specific characters. For example, type **`*\sp2`** to find all instances whose names end with **`sp2`**.
- Erase all characters from the search box to go back to viewing all instances.

Search for instances and images:

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the desired items to search.

   
3. In the **Name Filter** bar in the upper right corner of the window, type your criteria.
4. Click (**Search by Name within results**) or press **Enter**.
5. Type in other criteria to filter on what is currently displayed.
6. Click (**Search by Name within results**) or press **Enter**.

Analyzing Instances and Images with SmartState Analysis

Analyze an instance to collect metadata such as user accounts, applications, software patches, and other internal information. If Infrastructure Automation is not set up for automatic analysis, perform a manual analysis of an instance. To perform a SmartState Analysis, Infrastructure Automation requires a running SmartProxy with visibility to the instance's storage location so that a snapshot can be created.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the items to analyze.
3. Check the instances and images to analyze.
4. Click **Configuration**, and then **Perform SmartState Analysis** on the taskbar.
5. Click **OK**.

Note:

Restrictions on Displaying Files Collected

- File size bigger than 20k characters
- File with missing name
- Non MIME .conf file, with non ascii characters
- Non MIME .conf file, without content
- MIME .exe binary file
- MIME .txt non binary file

- Non MIME .conf ascii file

SmartState Analysis for instances runs as a process independent from providers. For example, a successful SmartState Analysis of a host does not mean SmartState Analysis for instances will be successful. Ensure to enter credentials for the provider that contains the instance for the SmartState Analysis to work.

Comparing Instances and Images

You can compare multiple instances in Infrastructure Automation server. This allows you to see how different instances are from their original image. This helps detect missing patches, unmanaged user accounts, or unauthorized services.

Use the comparison feature to:

- Compare multiple instances from different hosts
- Compare multiple instances side-by-side
- Quickly see similarities and differences among multiple instances and a base
- Narrow the comparison display to categories of properties
- Print or export in the comparison results to a PDF or CSV file

Compare instances and images:

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the items to analyze.
3. Click the checkboxes for the items to compare.
4. Click **Configuration**, and then (**Compare Selected items**). The comparison displays in a compressed view with a limited set of properties listed.
5. To delete an item from the comparison, click (**Remove this VM from the comparison**) at the bottom of the items column.
6. To view many items on one screen, go to a compressed view by clicking (**Compressed View**). To return to an expanded view, click (**Expanded View**).
7. To limit the mode of the view, there are two buttons in the task bar.
   - Click (**Details Mode**) to see all details for an attribute.
   - Click (**Exists Mode**) to limit the view to if an attribute exists compared to the base or not. This only applies to attributes that can have a boolean property. For example, a user account exists or does not exist, or a piece of hardware that does or does not exist.
8. To change the base instance that all the others are compared to, click its label at the top of its column.
9. To go to the summary screen for an instance, click its **Virtual Thumbnail** or icon.

Creating an Instance Comparison Report

Output a the data from a comparison report in TXT, CSV or PDF formats.

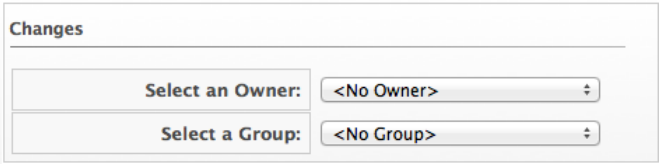
1. Create the comparison for the report.
2. Click (**Download**).
   - Click for a **TXT** file.
   - Click for a **CSV** file.
   - Click for a **PDF** file.

Refreshing Instances and Images

Refresh your instances to get the latest data the provider can access. This includes information such as the power state, container, and hardware devices attached to the instance.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the desired items to analyze.
3. Click the checkboxes for the items to refresh.
4. Click **Configuration**, and then (**Refresh Relationships and Power States**) on the **Instance Taskbar**.

Extracting Running Processes from Instances and Images



Infrastructure Automation can collect processes running on Windows instances. To do this, enter domain credentials for the zone where the instance is located. The instance must be running and must have an IP address in the VMDB, usually obtained from a SmartState Analysis.

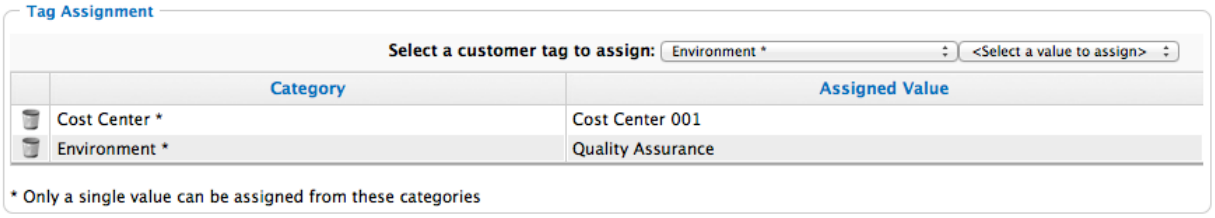
1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the checkboxes for the instances to collect processes.
3. Click **Configuration**, and then (**Extract Running Processes**) on the taskbar.
4. Click **OK**.

Setting Ownership for Instances and Images

You can set the owner of a group of instances and images by either individual user or group. This allows you an additional way to filter and can be used to enforce quotas.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the items to change.
3. Click the checkboxes for the items to set ownership.
4. Click **Configuration**, and then (**Set Ownership**) on the **Instance Taskbar**.
5. From the **Select an Owner** dropdown, select a user.

6. From the **Select a Group** dropdown, select a group
7. Click **Save**.



Removing Instances and Images from the VMDB

If an instance has been decommissioned or you need to perform some troubleshooting, you might need to remove a specific instance from the VMDB. This does not however remove the instance or image from its provider.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the items to remove.
3. Click the checkboxes for the items to remove.
4. Click **Configuration**, and then (**Remove from the VMDB**) button.
5. Click **OK**.

Tagging Instances and Images

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the items to tag.
3. Click the checkboxes for the items to tag.
4. Click (**Policy**), and then (**Edit Tags**).
5. Select a customer tag from the first dropdown, and then a value for the tag.

6. Click **Save**.

Reviewing an Instance or Image

After viewing your list of instances and images, click on a specific item to review a **Summary** screen of it. The **Summary** screen provides you with a **Virtual Thumbnail** and a **Taskbar**.

- Use the **Taskbar** to perform actions on the selected item.
- Use **Summary Views** to change the view type of the summary screen.
- Use **Virtual Thumbnails** for a quick glance at the item.
- Use the **Summary** screen to see a quick summary of the attributes of the item.

Viewing Running Processes after Collection

1. Click an instance with collected processes.
2. From the **Diagnostics** area, click **Running Processes**.

The most recent collection of running processes is displayed. Sort this list by clicking on the column headers.

Managing Security Groups for Cloud Instances

Manage security groups associated with cloud provider instances using Infrastructure Automation.

To add a security group to an instance:

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click on **Instances by Provider**, and select an instance.
3. Click **Configuration**, then click (**Add a Security Group**).
4. Select a **Security Group** from the drop-down menu to add to the instance.
5. Click **Save**.

To remove a security group from an instance:

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click on **Instances by Provider**, and select an instance.
3. Click **Configuration**, then click (**Remove a Security Group**).
4. Select a **Security Group** from the drop-down menu to remove from the instance.
5. Click **Save**.

Editing Instance or Image Properties

Edit the properties of an instance or image to set parent and child instances. SmartState Analysis also can detect this.

1. From **Compute > Clouds > Instances**.
2. Click the accordion for the items to edit.
3. Click the item to edit properties.

4. Click (**Configuration**), and then (**Edit this Instance or Edit this Image**) on the Taskbar.
5. From the **Parent Instance** dropdown, select the parent instance.
6. From **Child Instance** selection, select instances that are based on the current instance from the list of **Available Instances**.
7. Click **Save**.

Controlling the Power State of an Instance

Follow this procedure to control the power states of an instance through the Infrastructure Automation console.

1. Navigate to **Compute > Clouds > Instances**.
2. Click the instance to change the power state.
3. Click **Power Operations**, then click the button for the desired power operation.
   - Click (**Start**) to start the selected instances.
   - Click (**Terminate**) to terminate the selected instances.
   - Click (**Suspend**) to suspend the selected instances.
   - Click (**Reset**) to reset the selected instances.
   - Click (**Stop Guest**) to stop the guest operating system.
   - Click (**Restart Guest**) to restart the guest operating system.
4. Click **OK**.

Right Sizing an Instance

Infrastructure Automation uses collected statistics to recommend the best size for an instance. Infrastructure Automation uses the information from the **Normal Operating Range** to calculate the recommendations.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click an instance for right-sizing.
3. Click **Configuration**, and then (**Right-Size Recommendations**) button.

A new page appears with three levels of Memory and CPU recommendations, Conservative, Moderate, and Aggressive, next to the Normal Operating Range statistics.

Resizing an Instance

Infrastructure Automation allows you to resize an existing, active instance by changing its flavor. This is only possible if your OpenStack deployment has:

- At least two Compute nodes, or with resizing to the same host enabled
- Enough capacity to support the needs of the new flavor

Note:

Keep in mind that the instance will undergo a controlled shutdown when you change its flavor.

For more information about the requirements and underlying OpenStack process involved, see Resize an Instance in the Red Hat OpenStack Platform *Instances and Images Guide*.

To resize an instance through Infrastructure Automation:

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the instance whose flavor you want to change.
3. Click **Configuration**, and then (**Reconfigure this Instance**).
4. In the **Reconfigure Instance** section, select the new flavor you want from the **Choose Flavor** dropdown.
5. Click **Submit**. Doing so will initiate the flavor change, and it might take several minutes before Infrastructure Automation verifies whether the change was successful.

See Flavors and Manage Flavors in the Red Hat OpenStack Platform *Instances and Images Guide* for more information.

Migrating a Live Instance

Live migration involves moving a live instance between Compute nodes. Live migration is useful for avoiding instance downtime during cloud maintenance or load management. See How to Migrate a Live Instance in the Red Hat OpenStack Platform *Migrating Instances* guide for details on the underlying OpenStack process.

To migrate a live instance:

1. Browse to menu: **Compute > Clouds > Instances**.
2. On the right pane, click the instance to be migrated. Use the **Instances by Provider** accordion to filter instances by provider and/or availability zone.
3. Click (**Lifecycle**), then (**Migrate selected Instance**).
4. On the **Migrate Instance** section, select your preferred migration options:
   - **Auto-select Host?**: let the OpenStack provider automatically choose a destination Compute node. If you prefer to choose a specific node, uncheck this option and choose from the **Destination Host** dropdown.
   - **Block Migration**: check this option to perform a *block-based* migration. With this migration, the entire virtual machine image is moved from the source node to the destination node. If your OpenStack provider uses *shared storage*, leave this option unchecked. See Prerequisites in the Red Hat OpenStack Platform *Migrating Instances* guide for related information.
   - **Disk Over Commit**: check this option to prevent the OpenStack provider from verifying first whether the destination host has available disk space to host the instance.
5. Click **Submit**.

Once the migration initiates, the instance list will reload with a message indicating that the selected instance is being migrated. Upon completion, the instance list will reload and the evacuated instance will be displayed as (**On**).

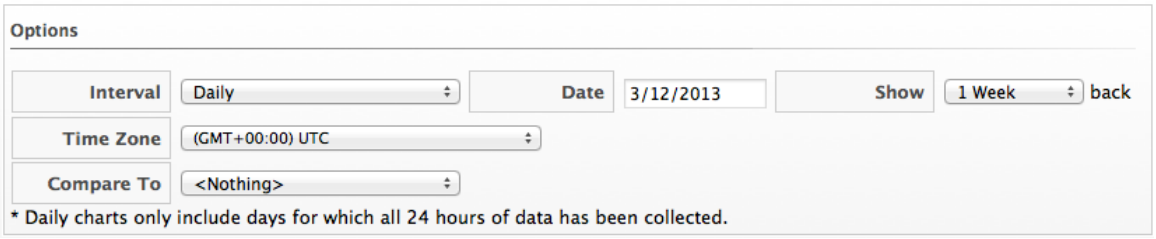
Evacuating an Instance

If a Compute node is shut down, you can *evacuate* instances hosted on it. This is only useful if the instances use shared storage or block storage volumes. See Evacuate Instances in the Red Hat OpenStack Platform *Instances and Images Guide* for details on the underlying OpenStack process.

To evacuate an instance:

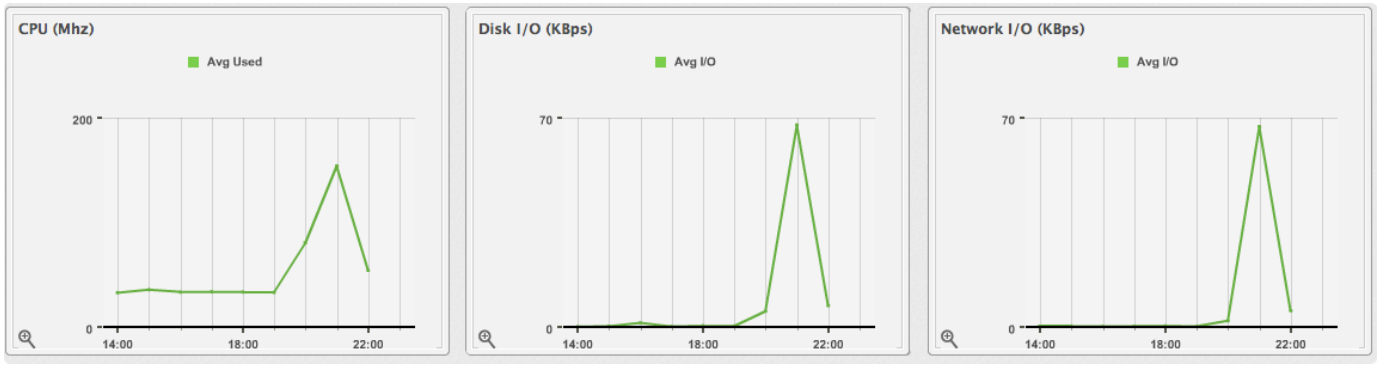
1. Browse to menu: **Compute > Clouds > Instances**.
2. On the right pane, click the instance to be evacuated. Use the **Instances by Provider** accordion to filter instances by provider and/or availability zone.
3. Click (**Lifecycle**), then (**Evacuate selected Instance**).
4. On the **Evacuate Host** section, select your preferred evacuation options:
   - **Auto-select Host?**: let the OpenStack provider automatically choose a destination Compute node. If you prefer to choose a specific node, uncheck this option and choose from the **Destination Host** dropdown.
   - **On Shared Storage**: leave this checked to indicate that all instance files are on shared storage.
5. Click **Submit**.

Once the evacuation initiates, the instance list will reload with a message indicating that the selected instance is being evacuated. Upon completion, the instance list will reload and the evacuated instance will be displayed as (**On**).



Viewing Capacity and Utilization Charts for an Instance

View capacity and utilization data for instances that are part of a cluster.



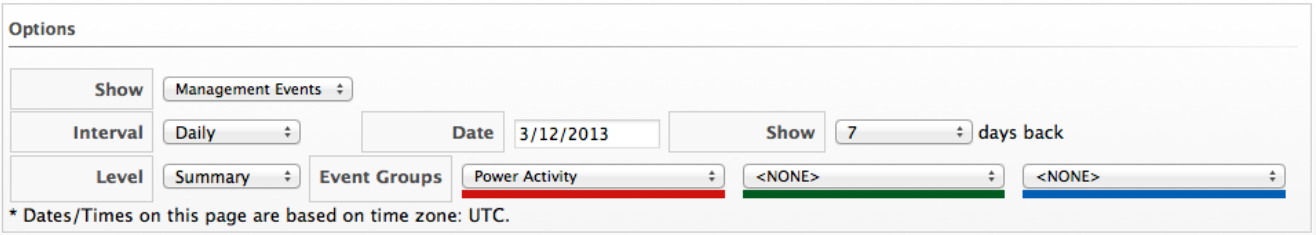
Note:

You must have a server with network visibility to your provider assigned the server role of **Capacity & Utilization Collector** to use this feature.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion to view capacity data.
3. Click the item to view.
4. Click (**Monitoring**), and then (**Utilization**) on the taskbar.
5. Select to view hourly, most recent hour, or daily data points for the dates to view data.

6. Select a **Time Profile**.

Note:



Daily charts only include full days of data. This means Infrastructure Automation does not show daily data for a day without a complete 24 data point range for a day.

For information about data optimization including utilization trend reports, see Data Optimization.

Viewing the Instance or Image Timeline

View the timeline of events for an instance or image if registered to a host.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the instance to view the timeline.
3. Click (**Monitoring**), and then (**Timelines**) on the taskbar.
4. From **Options**, customize the period of time to display, and the types of events to view.

- Use the **Interval** dropdown to select hourly or daily data points.
- Use **Date** to type the date of the timeline to display.
- If viewing a daily timeline, use **Show** to set how many days back to go. The maximum history is 31 days.
- The three **Event Group** dropdowns allow selection of different event groups to display. Each has its own color.
- From the **Level** dropdown, select either a **Summary** event or a **Detail** list of events. For example, the detail level of a **Power On** event might include the power on request, the starting event, and the actual **Power On** event. If you select **Summary**, you only see the **Power On** event in the timeline.

5. To see more detail on an item in the timeline, click on it. A balloon appears with a clickable link to the resource.

Viewing the Instance or Image Summary

When you click on a specific instance or image, you will see the **Virtual Thumbnail**, and an operating system-specific summary screen of the item. Where applicable, click on a subcategory of the summary to see more detail on that section.

The summary page contains the following categories:

- **Properties** include information such as the base operating system, hostname, IP addresses, instance vendor, cloud resources, and snapshots. This includes the ability to analyze multiple partitions, multiple disks, Linux logical volumes, extended partitions, and Windows drives. Some categories can be clicked on for additional detail. For example, click **Container** to view notes associated with an instance.
- **Lifecycle** shows the date of discovery and the last analysis. If a retirement date and time or owner has been set, these display as well.
- **Relationships** include information on the instance's cloud provider, genealogy such as parent and child instances, and drift.
- **VMsafe** shows properties of the VMsafe agent if it is enabled.
- **Compliance** shows the status of system compliance checks and history of past checks.
- **Power Management** displays the current power state, last boot time, and last power state change. **State Changed On** is the date that the instance last changed its power state. This is a container view of the power state, therefore a restart of the operating system does not cause the container power state to change and does not update this value.
- **Security** includes information on users and groups.
- **Configuration** includes information on applications, services, packages, init processes, and files. This section changes depending on the base operating system.
- **Diagnostics** provides a link to viewing running processes and the information from the latest collected event logs.
- **Smart Management** shows all tags assigned to this instance.

Performing a SmartState Analysis on an instance or image provides more detailed information in these categories.

Viewing User Information for an Instance or Image

Infrastructure Automation's **SmartState Analysis** feature returns user information. Explore the user to get details on the user's account, including group memberships.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click on the instance or image to open its summary page.
3. From the **Security** section of the summary page, click **Users**.
4. Click the user to view details.

Viewing Group Information for an Instance or Image

Infrastructure Automation's **SmartState Analysis** feature returns group information. Explore the group to get a list of its users.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the item to view user information.
3. Click on the item to view its **Summary**.
4. From the **Security** section of the **Instance Summary**, click **Groups**.
5. Click the group to view users.

Viewing Genealogy of an Instance or Image

Infrastructure Automation detects the lineage of an instance. View an instance's lineage and compare the instances that are part of its tree. This also allows tagging of instances that share genealogy.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the item to view genealogy.
3. Click on the item to view its **Summary**.
4. From the **Relationships** area in the **Summary**, click **Genealogy**.

Detecting Drift on Instances or Images

The configuration of an instance might change over time. **Drift** is the comparison of an instance to itself at different points in time. The instance needs to be analyzed at least twice to collect this information. Detecting drift provides you the following benefits:

- See the difference between the last known state of a machine and its current state.
- Review the configuration changes that happen to a particular instance between multiple points in time.
- Review the association changes that happen to a particular instance between multiple points in time.
- Review the classification changes that happen to an instance between two time checks.
- Capture the configuration drifts for a single instance across a time period.

Detect drift on instances or images:

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the item to view drift.
3. Click on the item to view its **Summary**.
4. From the **Relationships** area in the **Summary**, click **Drift History**.
5. Click the checkboxes for the analyses to compare.
6. Click  (**Select up to 10 timestamps for Drift Analysis**)] at the top of the screen. The results display.
7. Check the **Drift** sections on the left to view in your comparison.
8. Click **Apply**.
9. The following descriptions pertain to the **Expanded View**  . Whether you see the value of a property or an icon representing the property depends on the properties type.
    - A property displayed in the same color as the base means the compared analysis matches the base for that property.
    - A property displayed in a different color from the base means the compared analysis does not match the base for that property.
10. If you are in the **Compressed View**  , the values of the properties are not displayed. All items are described by the icons shown below.
    - A  (**checkmark**) means that the compared analysis matches the base for that property. If you hover over it, the value of the property will display.
    - A  (**triangle**) means the compared analysis does not match the base for that property. If you hover over it, the value of the property displays. Click the minus sign next to the sections name to collapse it.
11. To limit the scope of the view, you have three buttons in the **Resource** button area.
    - Click  (**All attributes**) to see all attributes of the sections you selected.
    - Click  (**Attributes with different values**) to see only the attributes that are different across the drifts.
    - Click  (**Attributes with the same values**) to see only the attributes that are the same across drifts.
12. To limit the mode of the view, there are two buttons in the **Resource** button area.
    - Click  (**Details Mode**) to see all details for an attribute.
    - Click  (**Exists Mode**) to only see if an attribute exists compared to the base or not. This only applies to attributes that can have a Boolean property. For example, a user account exists or does not exist, or a piece of hardware that does or does not exist.

This creates a drift analysis. Download the data or create a report from your drift for analysis using external tools.

Creating a Drift Report for an Instance or Image

1. Create the comparison to analyze.
2. Click  (**Download**).
3. Click the output button for the type of report you want.
    - Click  (**Download drift report in text format**) for a text file.
    - Click  (**Download drift report in CSV format**) for a csv file.
    - Click  (**Download drift report in PDF format**) for a PDF file.

Viewing Analysis History for an Instance or Image

Each time a SmartState Analysis is performed on an instance, a record is created of the task. This information is accessed either from the instance accordion or the instance summary. Use this detail to find when the last analysis was completed and if it completed successfully. If the analysis resulted in an error, the error is shown here.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the desired item to view analysis history.
3. Click on the item to view its summary.
4. From the **Relationships** area in the summary, click **Analysis History**. A history of up to the last 10 analyses is displayed.

Descending by: Started Per page: 20 (It

	Started ▼	Finished	Status	Message
🔍	2 Days Ago	2 Days Ago	OK	OK
🔍	3 Days Ago	3 Days Ago	OK	OK
🔍	4 Days Ago	4 Days Ago	OK	OK
🔍	5 Days Ago	5 Days Ago	OK	OK
🔍	6 Days Ago	6 Days Ago	OK	OK
🔍	6 Days Ago	6 Days Ago	OK	OK

5. Click on a specific analysis to see its details.

Viewing Event Logs for an Instance or Image

Using an **Analysis Profile**, collect event log information from your instances.

Note:

This feature is only available for Windows.

1. Browse to menu: **Compute > Clouds > Instances**.
2. Click the accordion for the item to view event logs.
3. Click on the item to view its **Summary**.
4. From **Diagnostics** click **Event Logs**.

The collected event log entries are displayed. Sort this list by clicking on the column headers.

Orchestration Stacks

Browse to menu: **Compute > Clouds > Stacks** to see a list of orchestration stacks along with information such as *Name*, *Provider*, *Type*, *Status*, *Instances*, *Security Groups*, and *Cloud Networks*. Click on a stack to see more information about it, including properties, retirement date and time, and relationships with the cloud provider and instances. You can click on instances to see details of all instances the stack relates to.

Tagging Orchestration Stacks

Apply tags to orchestration stacks to categorize them together at the same time. . Browse to menu: **Compute > Clouds > Stacks**. . Select the orchestration stacks to tag. . Click (**Policy**), and then (**Edit Tags**). . **Select a customer tag to assign** from the first list. . Select a value to assign from the second list. . Click **Save**.

Retiring Orchestration Stacks

You can either retire orchestration stacks on a set date and time, or retire them immediately.

To set a retirement date:

1. Browse to menu: **Compute > Clouds > Stacks**.

2. Select the orchestration stacks to retire on a set date and time.
3. Click (**Lifecycle**), and then (**Set Retirement Dates**).
4. On the **Retire Orchestration Stacks** page, set **Retirement Date and Time**.
5. Select **Retirement Warning** from the list. The default is *None*.
6. Click **Save**.

Note:

Saving a blank date will remove all retirement dates.

To retire selected stacks immediately:

1. Browse to menu: **Compute > Clouds > Stacks**.
2. Select the orchestration stacks to retire now.
3. Click (**Lifecycle**), and then (**Retire selected Orchestration Stacks**). A pop-up window appears to confirm the action.
4. Click **OK**.

Removing Orchestration Stacks

1. Browse to menu: **Compute > Clouds > Stacks**.
2. Select the orchestration stacks to remove from the VMDB. A warning pop-up window appears to confirm the action.
3. Click **Configuration**, and then (**Remove Stacks from the VMDB**).
4. Click **OK**.

Key Pairs

This tab lists key pairs and fingerprints for all cloud providers. Click on a key pair to see a summary and its relationship with instances. On this screen, click on instances to see details of all instances the key pair relates to. You can use the key pairs added during provisioning instances.

Note:

Adding a new key pair is currently only supported for OpenStack.

Adding a New Key Pair

1. Browse to menu: **Compute > Clouds > Key Pairs**.
2. Click **Configuration**, then click (**Add a new Key Pair**).
3. In **Basic Information**, enter a **Name** and the **Public Key (optional)** generated using **ssh-keygen** command.
4. Select your OpenStack provider from the **Provider** list.
5. Click **Add**.

Removing a Key Pair

1. Browse to menu: **Compute > Clouds > Key Pairs**.
2. Select the key pair you want to remove from the key pairs list. Or, click on the key pair to see the instances it relates to.
3. Click **Configuration**, then click (**Remove selected Key Pairs from Inventory**). A warning appears to confirm the action.
4. Click **OK**.

Downloading Key Pairs

1. Browse to menu: **Compute > Clouds > Key Pairs**. You will see a list of existing key pairs.
2. Click the  button, then select the option to download key pairs data in your preferred format:
    1. Download as Text
    2. Download as CSV
    3. Print or export as PDF

Object Stores

Browse to menu: **Storage > Object Stores** to see a list of all cloud object stores along with information including *Key*, *Size (bytes)*, *Object Count*, *Cloud Tenant*, and *Cloud Provider*. Click on an object store to see its properties and relationships with the cloud provider, tenant, and object store on the summary page.

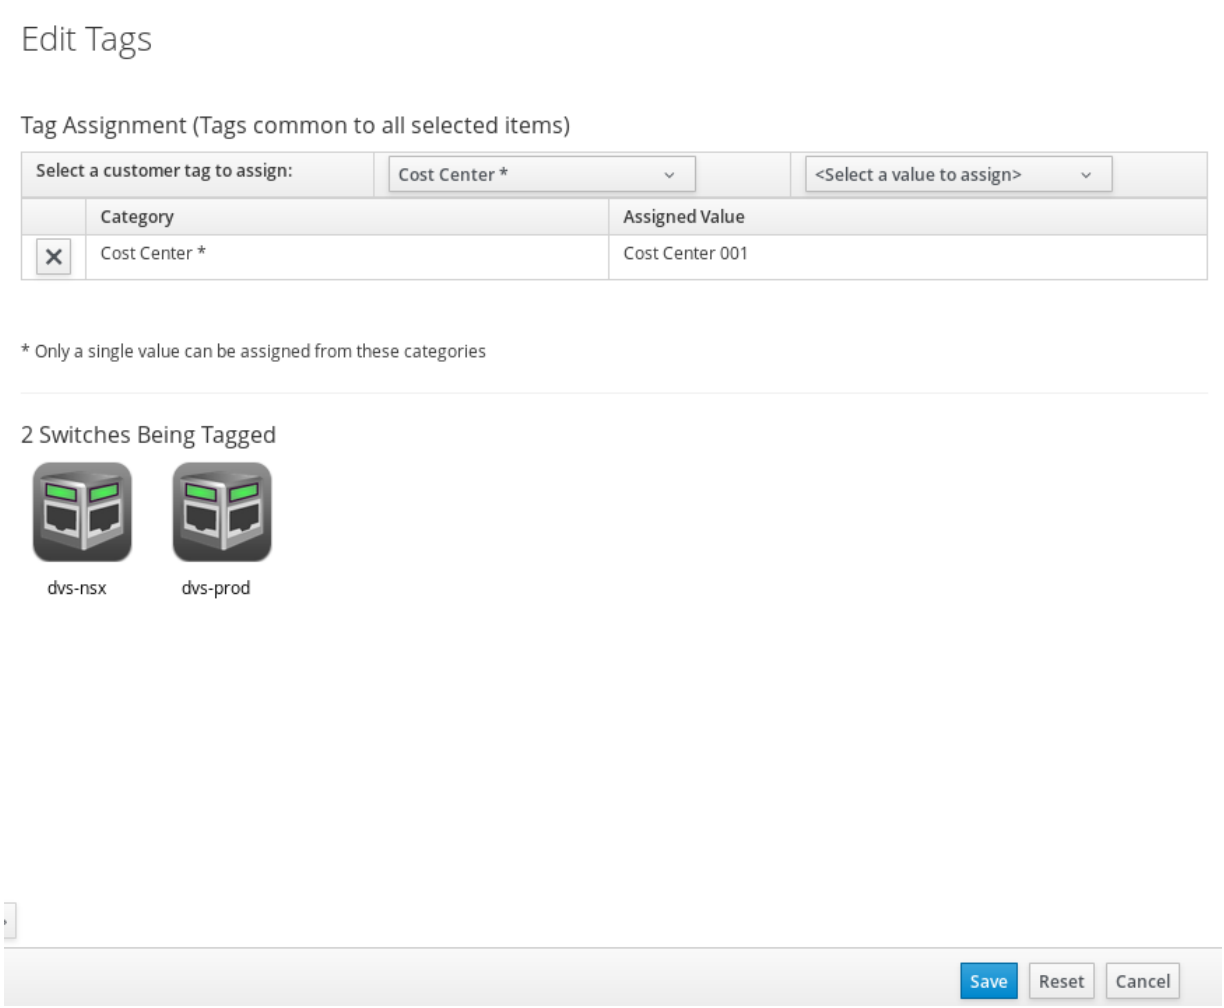
Tagging Object Stores

Apply tags to object stores to categorize them together at the same time.

1. Browse to menu: **Storage > Object Stores**.
2. Select the object stores to tag.
3. Click **Policy**, and then **Edit Tags**.
4. **Select a customer tag to assign** from the first list.
5. Select a value to assign from the second list.
6. Click **Save**.

VMware Networking Switches

After adding a VMware provider, Infrastructure Automation automatically discovers all vSphere distributed switches (vDS) on that provider and collects the information in the Infrastructure Automation inventory.



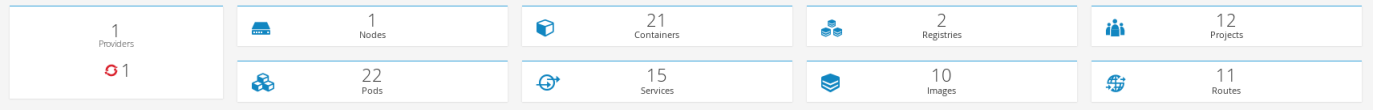
Browse to menu: **Compute > Infrastructure > Networking** to see a list of all VMware switches, along with information including *Name*, *Ports*, and *UUID*. Switches and port groups are listed by provider, then cluster on the sidebar.

Click on a switch to view its summary page, which displays relationships with hosts, and any tags.

Tagging VMware Networking Switches

Use tags to categorize vSphere distributed switches.

1. Browse to menu: **Compute > Infrastructure > Networking**.
2. Select the switches to tag.
3. Click (**Policy**), and then (**Edit Tags**).



4. Select a customer tag from the first dropdown, and then a value for the tag.
5. Select more tags or click **Save** to apply the tags.

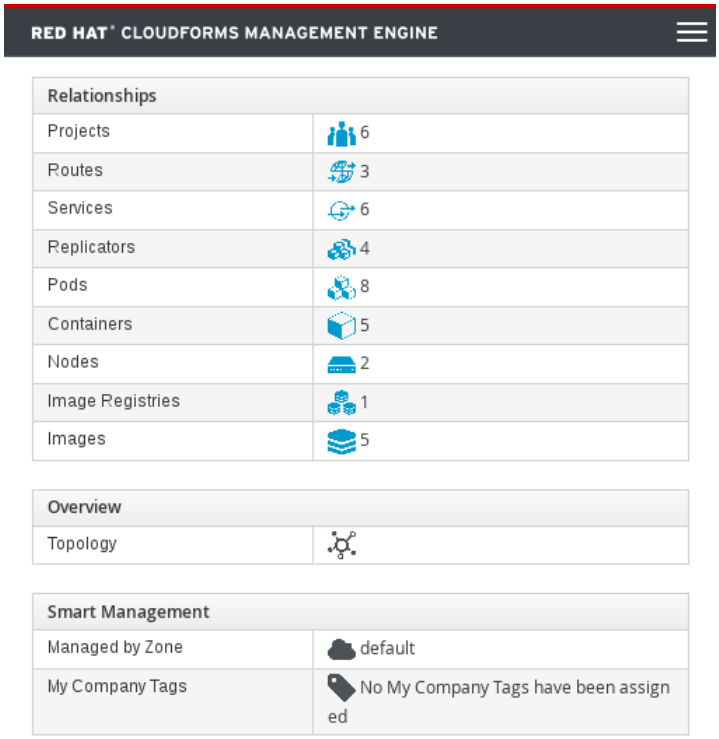
Container Entities

This chapter provides information on managing resources on your containers providers.

The Containers Overview Page

The containers overview page shows information on all containers providers and entities known to Infrastructure Automation. The **Overview** page provides links to other summary pages which contain further information on the containers providers and entities. The **Overview** page also provides metrics for **Aggregated Node Utilization**, **Network Utilization Trend**, **New Image Usage Trend**, **Node Utilization**, and **Pod Creation and Deletion Trends**.

1. Browse to menu: **Compute > Containers > Overview**.
2. Click the desired containers entity, or provider, if applicable, for viewing the summary with further information.



Note:

To reliably associate pods and images, Infrastructure Automation requires information from the `docker-pullable` field, added in OpenShift 3.3.1.2. This can affect the results of the **Chargeback by Image** report for older OpenShift providers, and potentially cause image inspection (done as part of Smart State Analysis) to fail due to associating a container to the wrong image. Consequently, Infrastructure Automation may not report accurate information about pods and images in OpenShift providers before version 3.3.1.2.

Viewing a Container Entity Summary

Container entity (object) summaries are found at menu: **Compute > Containers > Entity**, where you can view information about container entities and their components.

- Viewing a Containers Provider Summary Browse to menu: **Compute > Containers > Providers** to view information on different aspects of a containers provider. The summary includes:
    - The status of the provider and its components.
    - The relationships between different entities of the containers provider. These relationships are summarized in the **Relationships** box on the right-hand side of the summary page.

    - Additional information on aggregated capacity of all CPU cores of all nodes, and aggregated capacity of all memory of all nodes.
- Viewing a Container Nodes Summary Browse to menu: **Compute > Containers > Container Nodes** to view information on different aspects of a container node. The summary includes:
    - The number of entities on a node.
    - A node's capacity and utilization.
    - The version of the underlying operating system and software.

To view the timeline of events for a node from a container nodes summary page, click (**Monitoring**), and then (**Timelines**).

- Viewing a Containers Summary Browse to menu: **Compute > Containers > Containers** to view information on different aspects of a container. The summary includes:
    - The relationships of the container to a related node, pod, or image.
    - The node the container runs on.
    - The container ID.
    - Properties of the container image, such as name, tag, etc.
- Viewing a Container Images Summary Browse to menu: **Compute > Containers > Container Images** to view information on different aspects of a container image. The summary includes:
    - The containers currently using the images.
    - The image registry the image is from.
- Viewing an Image Registries Summary Browse to menu: **Compute > Containers > Image Registries** to view information on different aspects of an image registry. The summary includes:
    - Which images are from the registry.
    - The number of images that come from that registry.
    - Which containers use images from that registry.

    - The host and port of the registry.
- Viewing a Pods Summary Browse to menu: **Compute > Containers > Pods** to view information on different aspects of a pod. The summary includes:
    - The containers that are part of the pod.
    - The services that reference the pod.
    - The node the pod runs on.
    - If the pod controlled by a replicator.
    - The IP address of the pod.
- Viewing a Replicators Summary Browse to menu: **Compute > Containers > Replicators** to view information on different aspects of a replicator. The summary includes:
    - The number of requested pods.
    - The number of current pods.
    - The labels and selector for the replicator.
- Viewing a Container Services Summary Browse to menu: **Compute > Containers > Container Services** to view information on different aspects of a container service. The summary includes:
    - The pods that the container service provide traffic to.
    - The port configurations for the container service.
    - The labels and selector for the container service.
- Viewing a Volumes Summary Browse to menu: **Compute > Containers > Volumes** to view information on the persistent volumes of a container provider. The summary includes:
    - The pods the volume is connected to.
    - The volume's connection parameters.
    - The volume's storage capacity.
    - The volume's iSCSI target details (if applicable).
- Viewing a Container Builds Summary Browse to menu: **Compute > Containers > Container Builds** to view different aspects of a container build. The summary includes:
    - The build configuration the container build is based on.
    - Which build instances have been created.
    - Which phase in the build process the instance has completed.
    - Which pod a build instance reside in.
- Viewing a Container Templates Summary Browse to menu: **Compute > Containers > Container Templates** to view different aspects of a container template. The summary includes:
    - The project the template is associated with.
    - The objects the template contains.
    - The parameters that can be used with the template's objects.
    - The template's version number.

Using the Topology Widget

The **Topology** widget is an interactive topology graph, showing the status and relationships between the different entities of the containers providers and projects to which Infrastructure Automation has access.

- The topology graph includes pods, containers, services, nodes, virtual machines, hosts, routes, and replicators within the overall containers provider environment. - Each entity in the graph displays a color indication of its status.
- Hovering over any individual graph element will display a summary of details for the individual element.
- Double-click the entities in the graph to browse to their summary pages.
- It is possible to drag elements to reposition the graph.
- Click the legend at the top of the graph to show or hide entities.
- Click **Display Names** on the right-hand side of the page to show or hide entity names.

Viewing the Topology for Container Providers

1. Browse to menu: **Compute > Containers > Providers**.
2. Click the desired containers provider for viewing the provider summary.
3. On the provider summary page, click **Topology** in the **Overview** box on the right side of the page.

Viewing the Topology for Container Provider Projects

The project topology page displays the project as the center node, surrounded by its related entities.

1. Browse to menu: **Compute > Containers > Projects**.
2. Click on a project.
3. On the project summary page, click  (**Topology View**) on the top right side of the page.

Limiting the Number of Containers Shown in the Topology View

1. Navigate to the settings menu, then **My Settings**, and click on the **Visual** tab.
2. Select the number of container items from the drop-down under **Topology Default Items in View**.
3. Click **Save**.

Analyzing Container Images with SmartState Analysis

Perform a SmartState Analysis of a container image to inspect the packages included in an image.

1. Browse to menu: **Compute > Containers > Container Images**.
2. Check the container image to analyze. You can check multiple images.
3. Click **Configuration**, and then  **Perform SmartState Analysis**.

The container image is scanned. The process will copy over any required files for the image. After reloading the image page, all new or updated packages are listed.

To monitor the status of container image SmartState Analysis tasks, navigate to the settings menu, then **Tasks**. The status of each task is displayed including time started, time ended, what part of the task is currently running, and any errors encountered.

Note:

See *Scanning Container Images in with OpenSCAP* for details on scanning container images using OpenSCAP policies.

Configuring Automatic Tagging for Container Entities

Container object labels in OpenShift can be used to automatically create tags and tag categories in Infrastructure Automation. This is done by mapping Infrastructure Automation tags to existing OpenShift or Kubernetes labels.

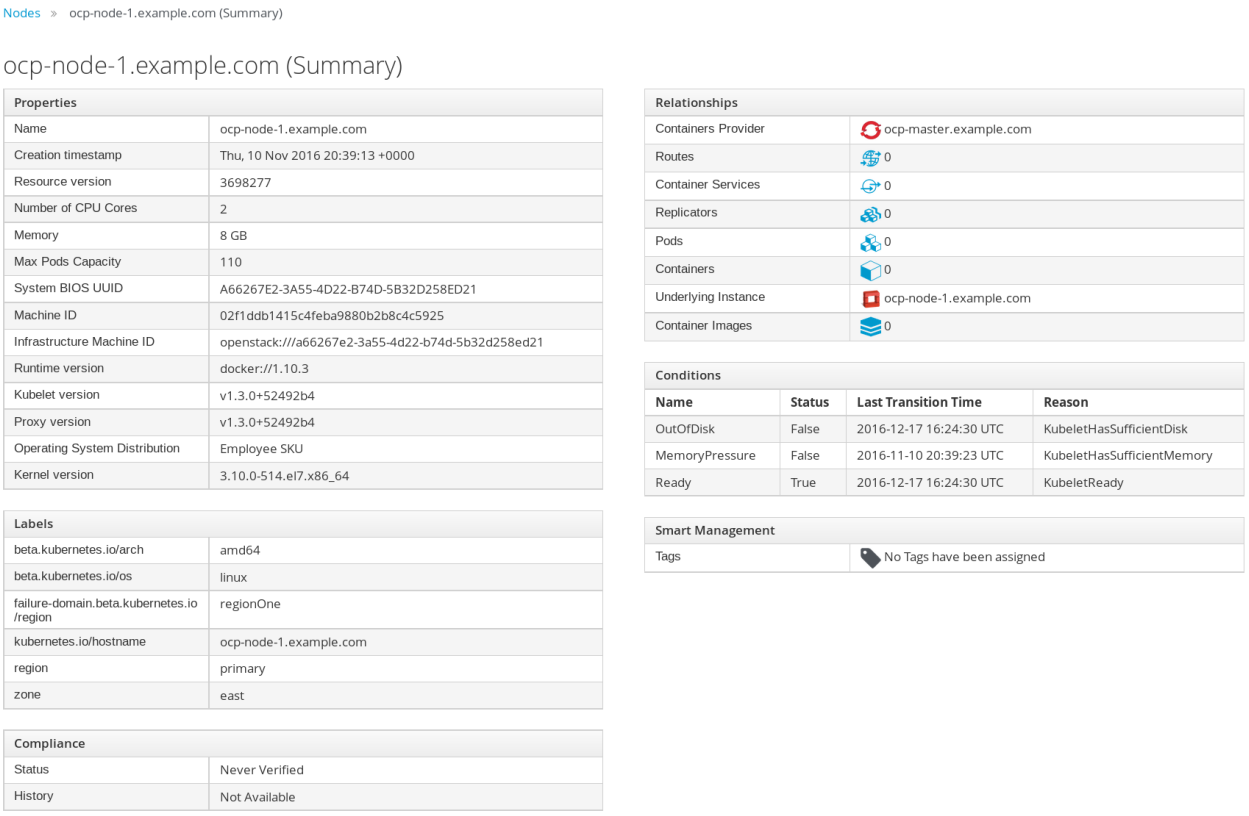
Labels from OpenShift can be mapped to Infrastructure Automation tags for the following container entities:

- Projects
- Nodes
- Routes
- Replicators
- Container services
- Pods
- Container builds

Note:

Tags automatically created from OpenShift labels are completely managed by the Infrastructure Automation system and cannot be manually assigned or unassigned. Deleting a mapping rule from Infrastructure Automation immediately deletes the resulting tags.

You can view a container entity's OpenShift labels on the entity's details page under **Labels**.



The following example shows how to configure tagging for a node, but the same steps can be used for mapping labels to tags on other container entities.

To configure automatic tagging on container entities using labels:

1. Note the *key* of the OpenShift label you want to map to a Infrastructure Automation tag. OpenShift labels consist of two parts: a *key* and a *value*.
    1. Browse to menu: **Compute > Containers > Container Nodes**.
    2. Select a node to open its summary page.

3. Under **Labels**, note the label(s) to map to Infrastructure Automation tag(s). Any OpenShift labels will list the *key* in the left column of the **Labels** table, and the *value* in the right column of the **Labels** table.

   This node has six labels (key/value pairs) that were created in OpenShift and collected in the Infrastructure Automation inventory:

Nodes » ocp-node-1.example.com (Summary)

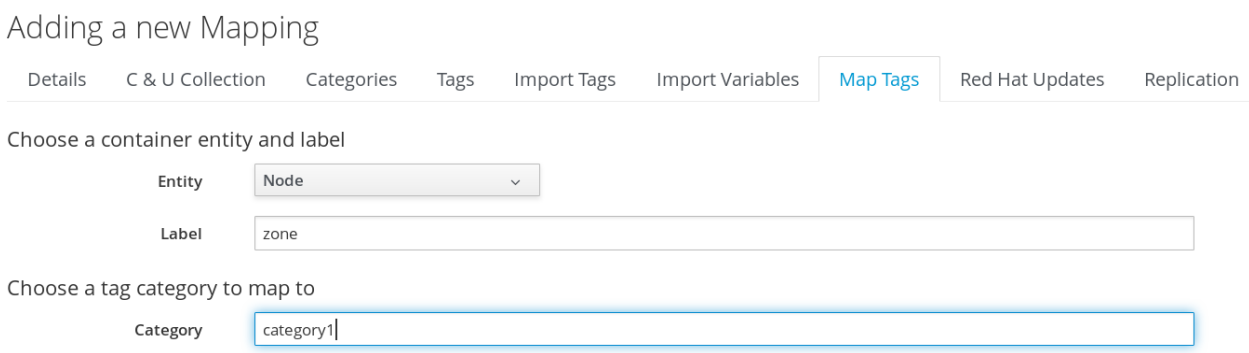
ocp-node-1.example.com (Summary)

Properties	
Name	ocp-node-1.example.com
Creation timestamp	Thu, 10 Nov 2016 20:39:13 +0000
Resource version	3698277
Number of CPU Cores	2
Memory	8 GB
Max Pods Capacity	110
System BIOS UUID	A66267E2-3A55-4D22-B74D-5B32D258ED21
Machine ID	02f1ddb1415c4feba9880b2b8c4c5925
Infrastructure Machine ID	openstack:///a66267e2-3a55-4d22-b74d-5b32d258ed21
Runtime version	docker://1.10.3
Kubelet version	v1.3.0+52492b4
Proxy version	v1.3.0+52492b4
Operating System Distribution	Employee SKU
Kernel version	3.10.0-514.el7.x86_64

Relationships	
Containers Provider	ocp-master.example.com
Routes	0
Container Services	0
Replicators	0
Pods	0
Containers	0
Underlying Instance	ocp-node-1.example.com
Container Images	0

Conditions			
Name	**Status**	**Last Transition Time**	**Reason**
OutOfDisk	False	2016-12-17 16:24:30 UTC	KubeletHasSufficientDisk
MemoryPressure	False	2016-11-10 20:39:23 UTC	KubeletHasSufficientMemory
Ready	True	2016-12-17 16:24:30 UTC	KubeletReady

Labels	
beta.kubernetes.io/arch	amd64
beta.kubernetes.io/os	linux
failure-domain.beta.kubernetes.io /region	regionOne
kubernetes.io/hostname	ocp-node-1.example.com
region	primary
zone	east

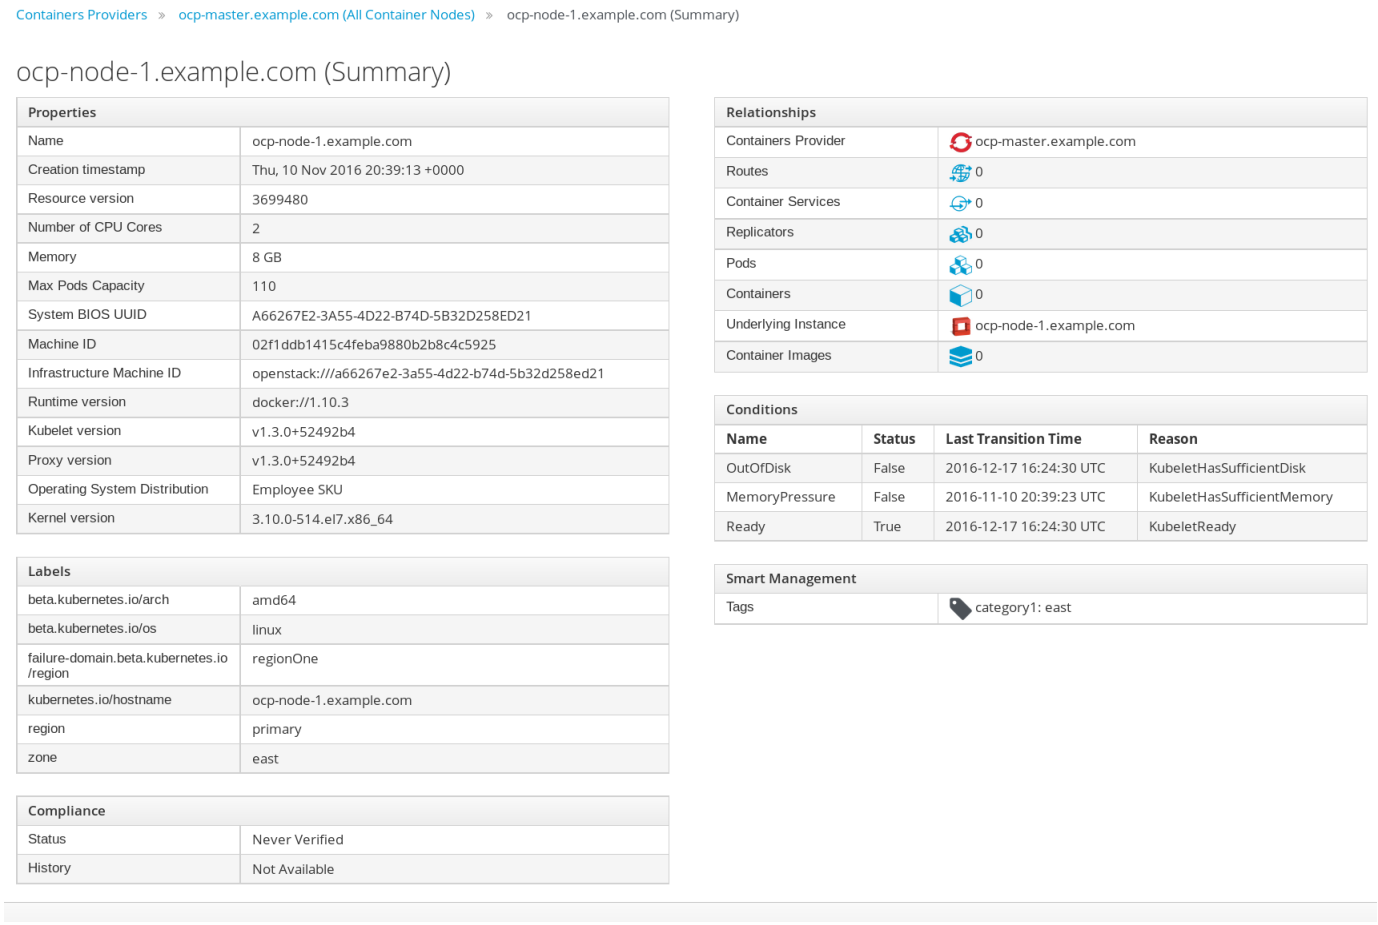


Smart Management	
Tags	No Tags have been assigned

Compliance	
Status	Never Verified
History	Not Available

   Note:

   To create an OpenShift label, see Developer CLI Operations in the OpenShift Container Platform *CLI Reference* guide. A new label added in OpenShift will only show up in Infrastructure Automation after the next OpenShift provider refresh.



2. Navigate to **Configuration** and select the region.
3. Click the **Map Tags** tab.
4. Click **Add** to create a new mapping rule.
   1. Select a container entity to tag from the **Entity** list, or select **All** to tag all entities.
   2. Specify the *key* from the OpenShift label you noted earlier in the **Label** field.
   3. Specify a Infrastructure Automation tag category in **Category** to map the label to. If the tag category does not exist yet in Infrastructure Automation, it will be created automatically.

   4. Click **Add**. The mapping will show in the table on the **Map Tags** tab.
5. Refresh the provider to complete the mapping:

1. Browse to menu: **Compute > Containers > Providers**.
2. Select the provider to refresh.
3. Click **Configuration**, and then **Refresh Items and Relationships**.

The label will display on the entity's summary page under **Smart Management** under **Company Tags** as `<Category> : <value>`.

Any container entity with the OpenShift `zone` label will be tagged automatically as `category1` in Infrastructure Automation. If the *value* for `zone` is `south`, for example, the entity will be tagged as `category1 south`.

You can use these tags to create reports. See Monitoring, Alerts, and Reporting for details on creating reports.

Policies and Profiles Guide

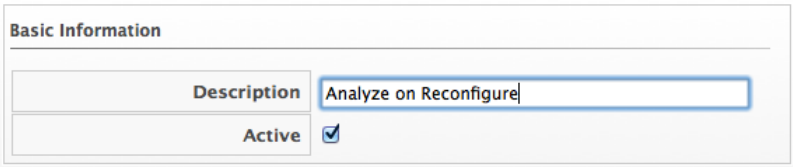
Policies

Policies are used to manage your virtual environment. There are two types of policies available: compliance and control. Compliance policies are used to harden your virtual infrastructure, making sure that your security requirements are adhered to. Control policies are used to check for a specific condition and perform an action based on the outcome. For example:

- Prevent virtual machines from running without an administrator account.
- Prevent virtual machines from starting if certain patches are not applied.
- Configure the behavior of a production virtual machine to only start if it is running on a production host.
- Force a SmartState Analysis when a host is added or removed from a cluster.

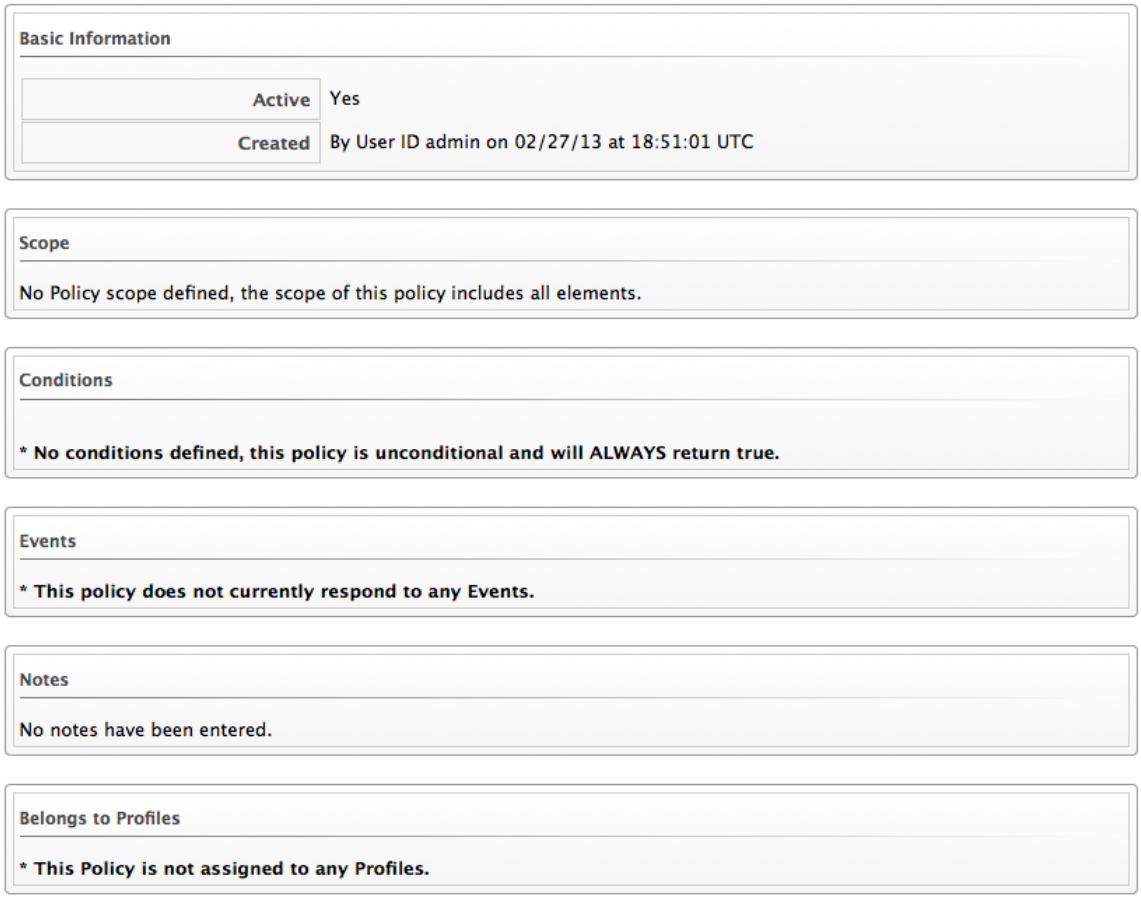
Control Policies

A control policy is a combination of an event, a condition, and an action. This combination provides management capabilities in your virtual environment.



- An event is a trigger to check a condition.
- A condition is a test that is triggered by an event.
- An action is an execution that occurs if a condition is met.

Creating Control Policies

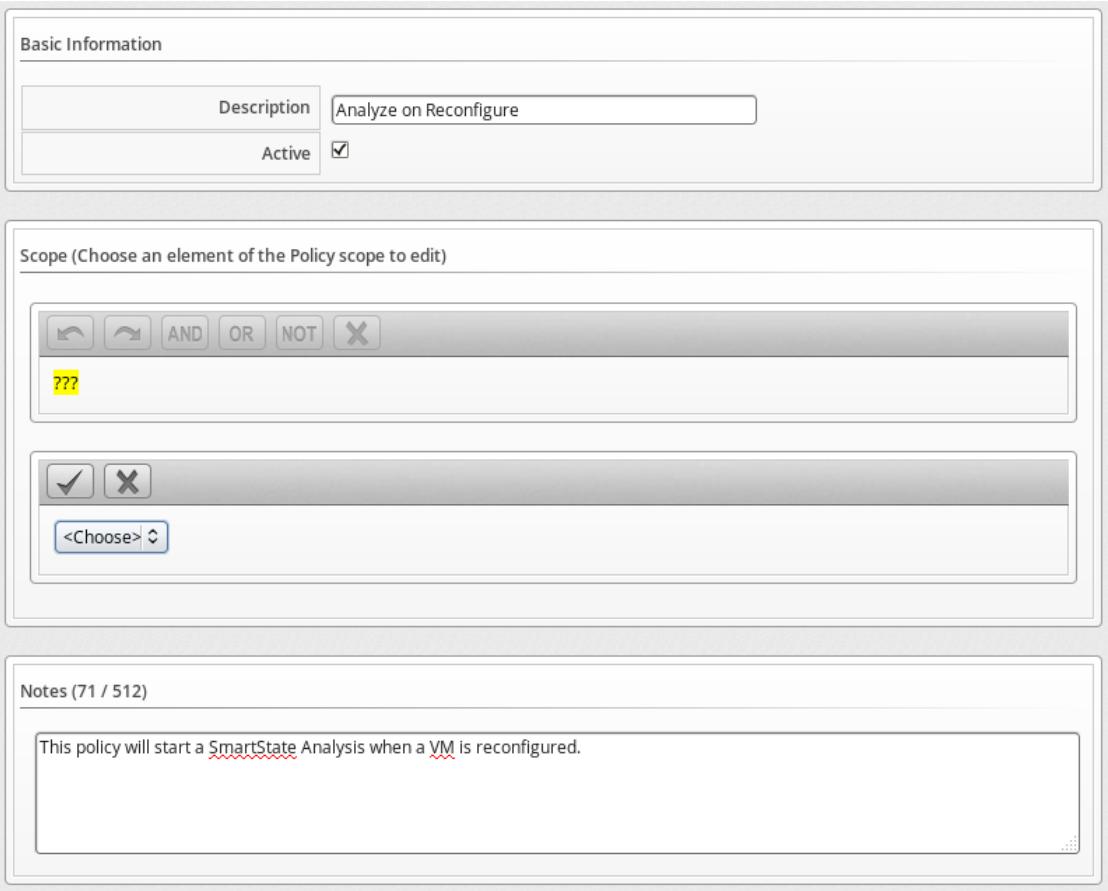


Create control policies by combining an event, a condition, and an action. Plan carefully the purpose of your policy before you create the policy. You can also use a scope expression that is tested immediately when the policy is triggered by an event. If the item is out of scope, then the policy does not continue on to the conditions, and none of the associated actions run.

This procedure describes how to create a control policy, its underlying conditions, and assign its events and actions in one process. Conditions and custom actions can be created separately as well. Those procedures are described in later sections in conditions and actions. Also, a description of all events is provided in events.

1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, and select **Control Policies**.
3. Select either **Host Control Policies** or **VM Control Policies** or **Replicator Control Policies** or **Pod Control Policies** or **Container Node Control Policies** or **Container Image Control Policies**.
4. Click **Configuration**, **Add a New Host / VM / Replicator / Pod / Node / Image Control Policy**.
5. Type in a **Description**.

6. Uncheck **Active** if you do not want this policy to be processed even when assigned to a resource.
7. You can enter a **Scope** here (You can also create a scope as part of a condition, or not use one at all). If the host or virtual machine is not included in the scope, no actions are run.
8. In the **Notes** area, add a detailed explanation of the policy.
9. Click **Add**. You are brought to the page where you add conditions and events to your new policy.

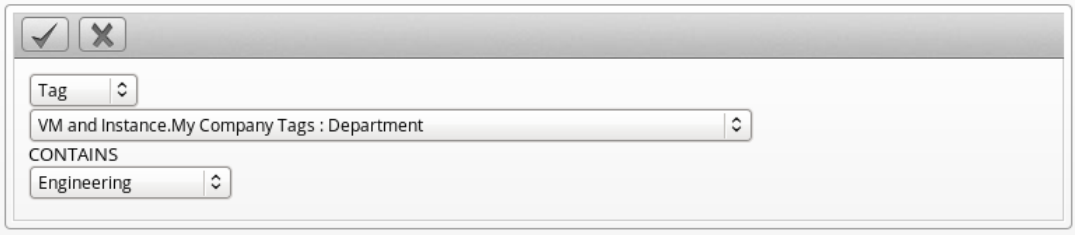


10. Click **Configuration** to associate conditions, events, and actions with the policy.

Editing Basic Information, Scope, and Notes for a Policy

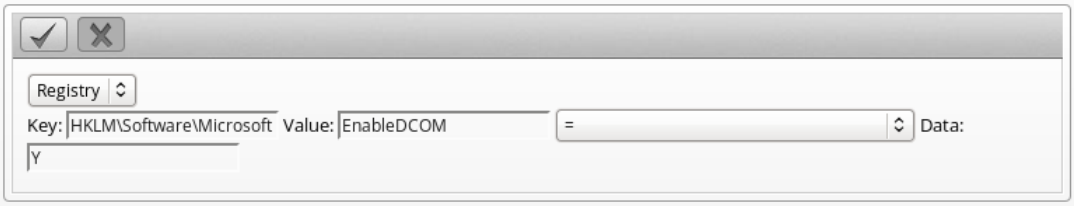
As your enterprise's needs change, you can change the name of a policy or its scope. If the items that are being evaluated are out of scope, policy processing stops and no actions run.

1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, and select the policy to edit.
3. Click **Configuration**, **Edit Basic Info, Scope, and Notes**.
4. In the **Scope** area, create a general condition based on a simple attribute. Or, click an existing expression to edit it. Based on what you choose, different options appear. Configuring a **Scope** is optional for a policy.



- Click **Field** to create criteria based on field values.

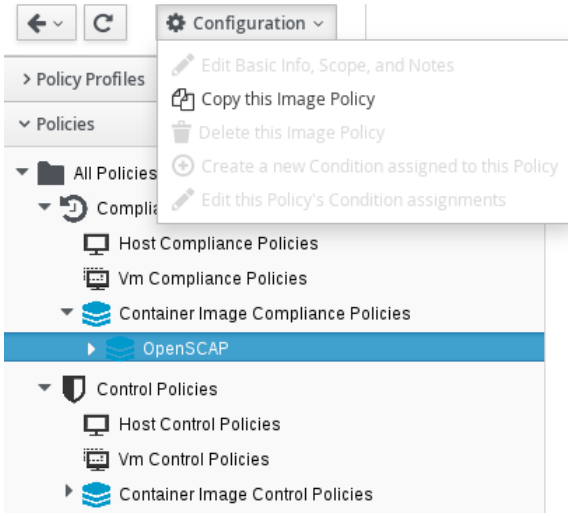
- Click **Count of** to create criteria based on the count of something, such as the number of snapshots for a virtual machine, or the number of virtual machines on a host.



- Click **Tag** to create criteria based on tags that are assigned to your resources. For example, you can check the power state of a virtual machine or see whether it is tagged as production.

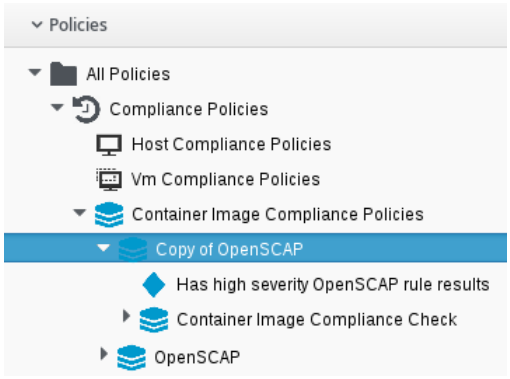
- Click **Find** to seek a particular value, and then check a property. For example, finding the **Admin** account and checking that it is enabled. Use the following check commands:
  - **Check Any**: The result is true if one or more of the find results satisfy the check condition.
  - **Check All**: All of the find results must match for a true result.
  - **Check Count**: If the result satisfies the expression in check count, the result is true.

- Click **Registry** to create criteria based on registry values. For example, you can check whether DCOM is enabled on a Windows System. Note that this applies only to Windows operating systems. Registry will only be available if you are editing a VM Control Policy.



5. Click **Commit Expression Element Changes** to add the scope.
6. In the **Notes** area, make the required changes.
7. Click **Save**.

Copying a Policy



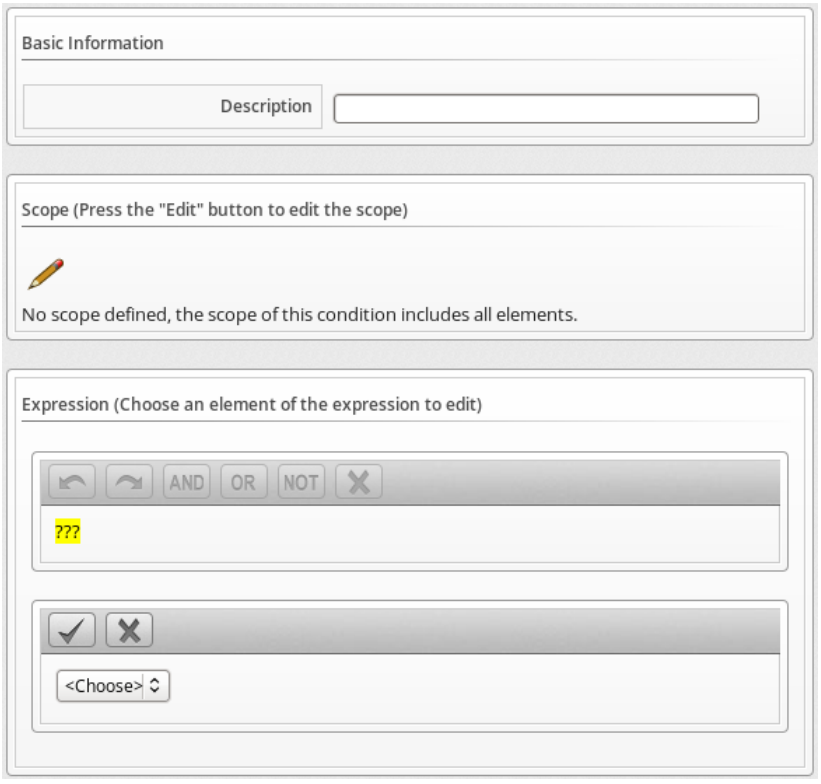
You can copy a policy if its contents are similar to a new one that you want to create, then change the condition or event associated with it. This enables you to make new policies efficiently.

1. Navigate to menu: **Control > Explorer**.
2. Click the **Policies** accordion, and select the policy that you want to copy.
3. Click **Configuration**, and an option to copy the policy appears; for example, **Copy this Image Policy**.

4. Click **OK** to confirm.

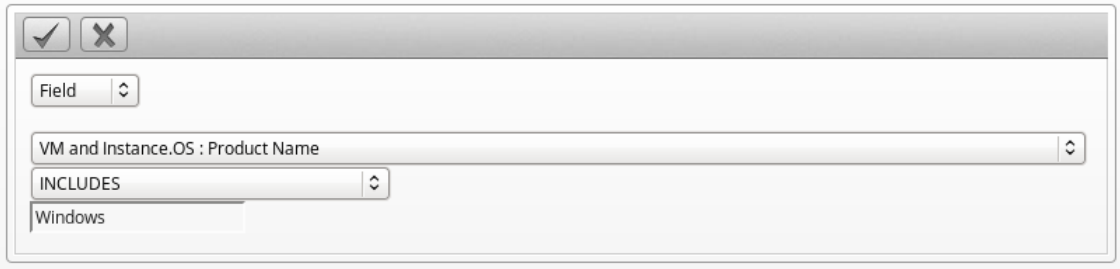
The new policy is created with a prefix of **Copy of** in its description, and it can be viewed in the Policy accordion.

Deleting a Policy



You can remove policies that you no longer need. You can remove only the policies that aren't assigned to a policy profile.

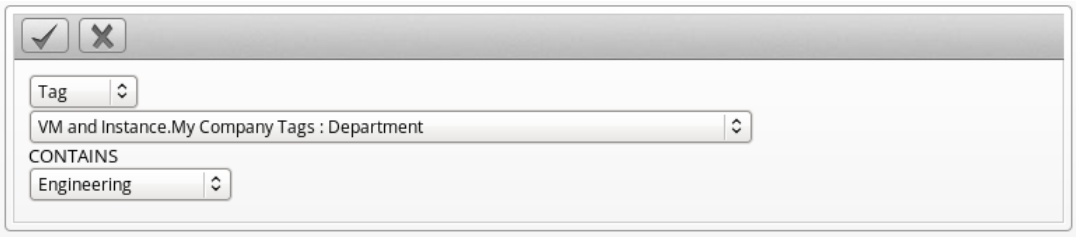
1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, and select the policy that you want to remove.
3. Click **Configuration**, **Delete this Host/VM and Instance/Replicator/Pod/Node/Image Policy**.
4. Click **OK** to confirm.



Creating a New Policy Condition

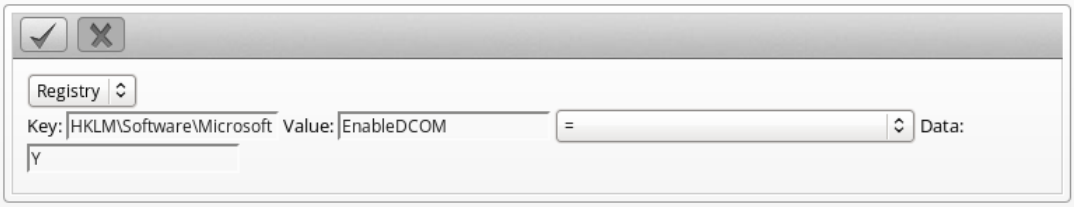
If you have not created a condition to use with this policy, you can create one directly from inside the policy. A condition can contain two elements: a scope, and an expression. The expression is mandatory, but the scope is optional. A scope is a general attribute that is quickly checked before evaluating a more complex expression. You can create a scope at either the policy or condition level.

1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, and select the policy that you want to create a new condition for.
3. Click **Configuration**, **Create a new Condition assigned to this Policy**.
4. Type in a **Description** for the condition. It must be unique to all the conditions.



5. Click **Edit this Scope** in the **Scope** area to create a general expression based on a simple attribute, such as operating system version. Based on what you choose, different options display. **Scope** is optional.
    - Click **Field** to create criteria based on field values.

- Click **Count of** to create criteria based on the count of something, such as the number of snapshots for a virtual machine, or the number of virtual machines on a host.

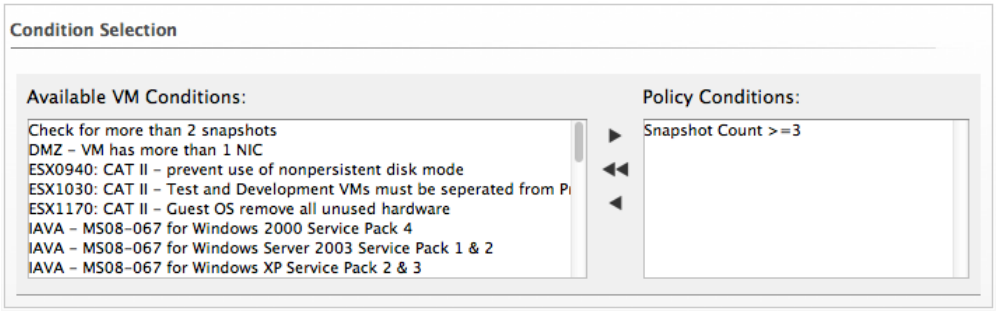


- Click **Tag** to create criteria based on tags that are assigned to your resources. For example, you can check the power state of a virtual machine or see whether it is tagged as production.

- Click **Find** to seek a particular value, and then check a property. For example, finding the Admin account and checking that it is enabled. Use the following check commands:
  - **Check Any**: The result is true if one or more of the find results satisfy the check condition.
  - **Check All**: All of the find results must match for a true result.
  - **Check Count**: If the result satisfies the expression in check count, the result is true.

- Click **Registry** to create criteria based on registry values. For example, you can check whether DCOM is enabled on a Windows System. This applies only to Windows operating systems. Registry is only available if you are creating a VM Control Policy.

6. Click **Commit expression element changes** to add the scope.
7. Click **Edit this Expression** in the **Expression** area. Based on what you choose, options display according to the choices that are presented in the **Scope** area.
8. Click **Commit Expression Element Changes** to add the expression.
9. In **Notes**, type in a detailed explanation of the condition.



10. Click **Add**.

The condition is created and is assigned directly to the policy. **Note**: The condition can be assigned to other policies.

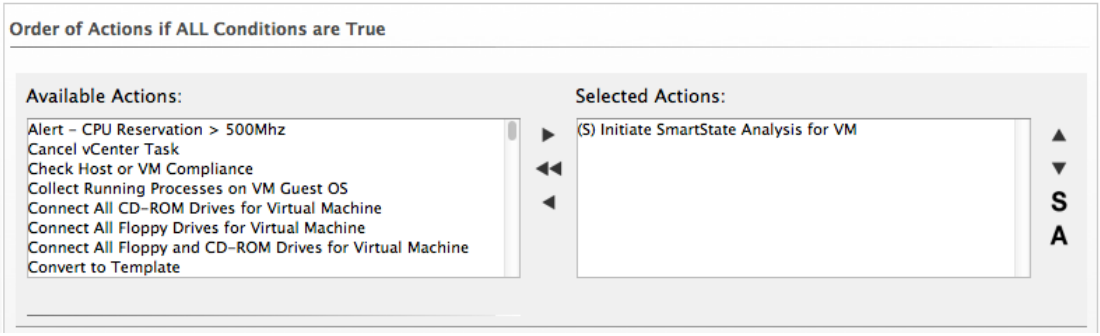
Editing Policy Condition Assignments

Use this procedure to use a condition that was created either separately or as part of another policy. You can also remove a condition from a policy that no longer applies.

1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, and select the policy that you want to assign conditions to.
3. Click **Configuration**, **Edit this Policy's Condition assignments**.
4. From the **Condition Selection** area, you can assign conditions to the policy, remove all conditions from the policy, or remove specific conditions from the policy.

   - To add one or several conditions, select all the conditions that you want to apply from the **Available Conditions** box. Use `Ctrl` to add multiple conditions to a policy. Then, click **Move selected Conditions into this Policy**.
   - Click **Remove all Conditions from this Policy** to unassign any conditions from this policy.
   - To remove one or some conditions, select all the conditions that you want to remove from the **Policy Conditions** box. Use `Ctrl` to select multiple conditions. Then, click **Remove selected Conditions from this Policy**.
5. Click **Save**.

Editing Policy Event Assignments



The policy evaluates its scopes and conditions when specified events occur in your virtual infrastructure. This procedure helps you to select those events and the actions that occur based on the evaluation of the scopes and conditions for the policy.

1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion and select the control policy that you want to assign events to.
3. Click **Configuration**, **Edit this Policy's Event assignments**.
4. Check all the events that you want to assign to this policy.
5. Click **Save**.

Assigning an Action to an Event

This procedure describes how to assign an action to an event.

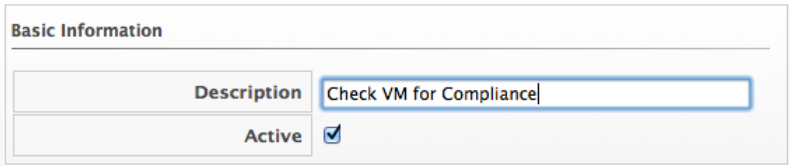
1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, and select the policy that you want to assign actions to.
3. From the **Events** area, click the description of the event you want to assign an action to.
4. Click **Configuration**, **Edit Actions for this Policy Event**.
5. Select all the appropriate actions from the **Available Actions** box, inside the **Order of Actions if ALL Conditions are True**. These are the actions that take place if the resources meet the Condition of the Policy.

Note:

Each selected action can be executed synchronously or asynchronously; synchronous actions will not start until the previous synchronous action is completed, and asynchronous action allows the next action to start whether the first action has completed or not. Also, at least one Infrastructure Automation server in the Infrastructure Automation zone must have the notifier server role that is enabled for the trap to be sent.

6. Click the add button ›, then:
   - Click the action, then click **A** **Set selected Actions to Asynchronous** to make it asynchronous.
   - Click the action, then click **S** **Set selected Actions to Synchronous** to make it synchronous. If creating a synchronous action, use the up and down arrows to identify in what order you want the actions to run.
7. Select all the actions from the appropriate **Available Actions** box, inside of the **Order of Actions if ANY Conditions are False**. These are the actions that take place if the resources do not meet the condition of the policy.
8. Click **Save**.

Compliance Policies



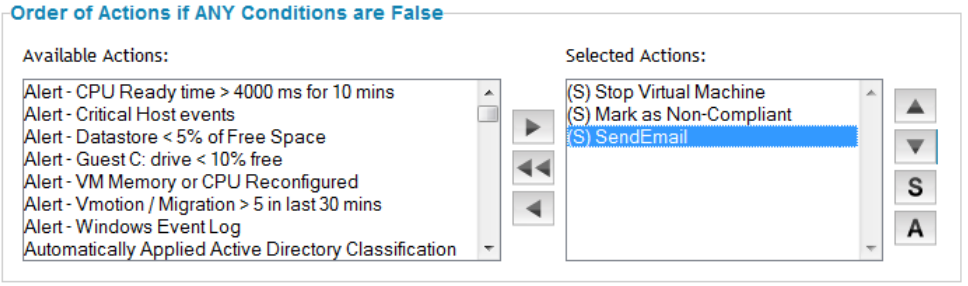
Compliance policies are designed to secure your environment by checking conditions that you create. These conditions can include the same conditions that you would use in a control policy, and most of the procedures are the same. However, a compliance policy automatically assigns the mark as a compliant action when the entity type (virtual machine or host, for example) to which the policy applies passes all of the conditions. If any of the conditions are not met, then the virtual machine or host is marked as non-compliant. The compliance status is shown in the summary screen for the entity type and on the compare and drift screens.

Creating a Compliance Policy

Create compliance policies by assigning or creating a condition. Infrastructure Automation automatically assigns the events and actions to the compliance policy as opposed to a control policy where you must define this yourself. The entity type (VM or host, for example) compliance check event is assigned to the compliance policy. A compliance policy runs the mark as compliant action when the virtual machine or host passes all of the conditions. If any of the conditions are not met, then the virtual machine or host is marked as non-compliant.

Carefully plan the purpose of your policy before creating it. You can also use a scope expression that is tested immediately when the compliance check event triggers the policy. If the item is out of scope, then the policy does not continue on to the conditions, and none of the associated actions run.

1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, and select **Compliance Policies**.
3. Select either **Host Compliance Policies** or **VM Compliance Policies** or **Replicator Compliance Policies** or **Pod Compliance Policies** or **Container Node Compliance Policies** or **Container Image Compliance Policies**.
4. Click **Configuration**, **Add a new Compliance Policy**.
5. Type in a **Description** for the policy.



6. Uncheck **Active** if you do not want this policy to be processed even when assigned to a resource.
7. You can enter a scope here. (You can also create a scope as part of a condition, or not use one at all.) If the host or virtual machine is not included in the scope, no actions run.
8. In the **Notes** area, add a detailed explanation of the policy.
9. Click **Add**.

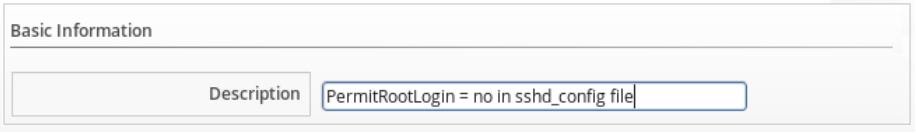
You must add one or several conditions:

- You can create a new condition by clicking **Configuration**, **Create a new Condition assigned to this Policy**, as described in Creating a New Policy Condition.
- You can use an existing condition by clicking **Configuration**, **Edit this Policy's Condition assignments**, as described in Editing Policy Condition Assignments.

By default, if any of the conditions are false, the virtual machine is marked as non-compliant. To add other actions, such as sending an email if the virtual machine fails the compliance test:

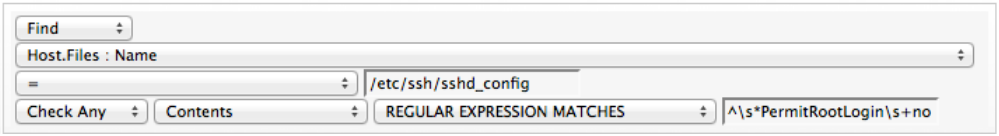
1. Click the **Compliance Check** event under the policy (exact name depends on entity type, for example **VM Compliance Check**.
2. Click **Configuration**, **Edit Actions for this Policy Event**.
3. Select **Stop Virtual Machine** and **Send Email** from the **Available Actions** area in **Order of Actions if ANY conditions are False**. (**Mark as Non-Compliant** should already be selected.)

4. Click **Move selected Actions into this Event**.
5. Click **Add**.



You can now make this part of a policy profile. After assigning the policy profile to the virtual machine, you can check it for its compliance status either on a schedule or on demand.

Creating a Compliance Condition to Check Host File Contents



Infrastructure Automation Control provides the ability to create a compliance condition that checks file contents. Use this to be sure that internal operating system settings meet your security criteria. Regular expressions are used to create the search pattern. Test your regular expressions thoroughly before using them in a production environment.

Note that to search file contents you need to have collected the file using a host analysis profile.

1. Browse to menu: **Control > Explorer**.
2. Click the **Conditions** accordion, and select **Host Conditions**.
3. Click **Configuration**, **Add a New Host Condition**.
4. In **Basic Information**, type in a **Description** for the condition.

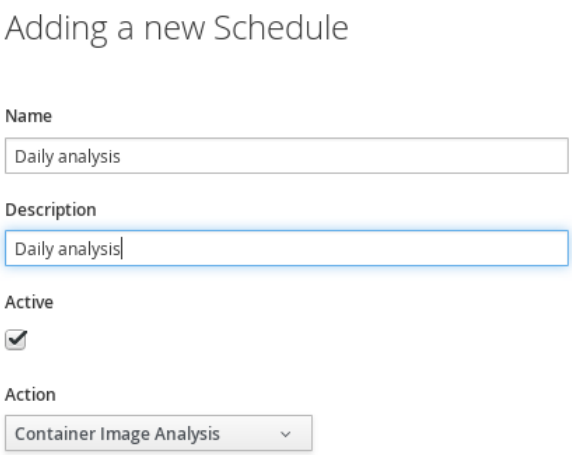
5. Editing the **Scope** area is not necessary for this procedure. Skip editing any **Scope** conditions.
6. If the **Expression** area is not automatically opened, click **Edit this Expression**, then edit the condition area to create a general condition based on a simple attribute. Based on what you choose, different options appear.
   - Click **Find**, then **Host.Files : Name**, and the parameters to select the file that you want to check.
   - Click **Check Any**, **Contents**, **Regular Expression Matches**, and type the expression. For example, if you want to make sure that permit root login is set to no, type `^\s*PermitRootLogin\s+no`.

7. Click **Commit expression element changes** to add the expression.
8. In **Notes** area, type in a detailed explanation of the condition.

9. Click **Add**.

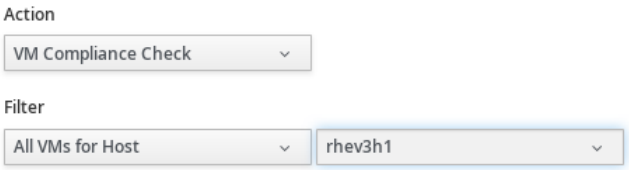
Checking for Compliance

After you have created your compliance policies and assigned them to a policy profile, you can check compliance in two ways. You can either schedule the compliance check or perform the check directly from the summary screen.



The compliance check runs all compliance policies that are assigned to the host or virtual machine. If the item fails any of the checks, it is marked as non-compliant in the item's summary screen.

Note:



To schedule, you must have **`EvmRole-administrator`** access to the Infrastructure Automation server.

Scheduling a Compliance Check

1. Click **Configuration**.
2. Click the **Settings** accordion, and select **Schedules**.
3. Click **Configuration**, **Add a new Schedule**.
4. In the **Adding a new Schedule** area, type in a name and description for the schedule.

5. Select **Active** if you want to enable this scan.
6. From the **Action** dropdown, select the type of compliance check you want to schedule. Depending on the type of analysis you choose, you are presented with one of the following group boxes:
   - If you choose **VM Compliance Check**, you are presented with **VM Selection** where you can choose to check all VMs, all VMs for a specific provider, all VMs for a cluster, all VMs for a specific host, a single VM, or you can select VMs by using a global filter.

   - If you choose **Host Compliance Check**, you are presented with **Host Selection** where you can choose to analyze all hosts, all hosts for a specific provider, all hosts for a cluster, a single host, or you can select hosts by using a global filter.
   - If you choose **Container Image Compliance Check**, you are presented with **Image Selection** where you can choose to analyze all images, all images for a specific provider, or a single image.

Note:

You can schedule a host analysis only for connected virtual machines, not repository virtual machines that were discovered through that host. Since repository virtual machines do not retain a relationship with the host that discovered them, there is no current way to scan them through the scheduling feature. The host is shown because it might have connected virtual machines in the future when the schedule is set to run.

1. From the **Run** menu, select how often you want the analysis to run. Your options after that depend on which run option you choose.

- Select **Once** to have the analysis run just one time.
- Select **Hourly** to run the analysis hourly. You're prompted to select how many hours you want between each analysis.
- Select **Daily** to run the analysis daily. You're prompted to select how many days you want between each analysis.
- Select **Weekly** to run the analysis weekly. You're prompted to select how many weeks you want between each analysis.
- Select **Monthly** to run the analysis monthly. You're prompted to select how many months you want between each analysis.

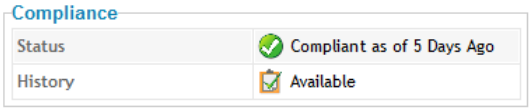
2. Select the time zone for the schedule.
3. Type or select a date to begin the schedule in **Starting Date**.
4. Select a starting time based on a 24-hour clock in the selected time zone.
5. Click **Add**.

Checking a Virtual Machine for Compliance from the Summary Screen

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**, select the virtual machine that you want to check for compliance.
2. Click **Policy**, and then **Check Compliance of Last Known Configuration**.
3. A confirmation message appears. Click **OK**.
4. To view the compliance history, click the virtual machine. Under **Compliance**, if **History** is **Available**, click it to see its compliance history.

Checking a Host for Compliance from the Summary Screen

1. Browse to menu: **Compute > Infrastructure > Hosts**, click the host that you want to check for compliance.
2. Click **Policy**, and then **Check Compliance of Last Known Configuration** or **Analyze then Check Compliance**.
3. To view the compliance history, click **Available** next to **History**.

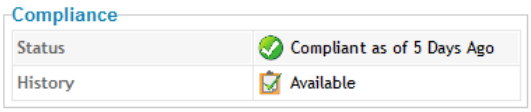


Checking a Replicator for Compliance from the Summary Screen

1. Browse to menu: **Compute > Containers > Replicators**, select the replicator that you want to check for compliance.
2. Click **Policy**, and then **Check Compliance of Last Known Configuration**.
3. A confirmation message appears. Click **OK**.
4. . To view the compliance history, click the replicator. Under **Compliance**, if **History** is **Available**, click to see its compliance history.

Checking a Pod for Compliance from the Summary Screen

1. Browse to menu: **Compute > Containers > Pods**, select the pod that you want to check for compliance.
2. Click **Policy**, and then **Check Compliance of Last Known Configuration**.
3. A confirmation message appears. Click **OK**.
4. To view the compliance history, click the pod. Under **Compliance**, if **History** is **Available**, click to see its compliance history.

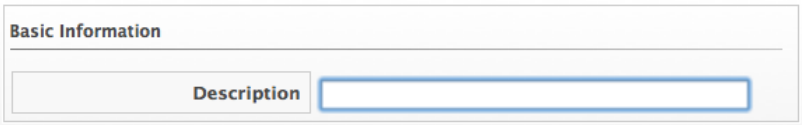


Checking a Container Node for Compliance from the Summary Screen

1. Browse to menu: Compute > Containers > Container Nodes**, click the node that you want to check for compliance.
2. Click **Policy**, and then **Check Compliance of Last Known Configuration**.
3. A confirmation message appears. Click **OK**.
4. To view the compliance history, click the node. Under **Compliance**, if **History** is **Available**, click to see its compliance history.

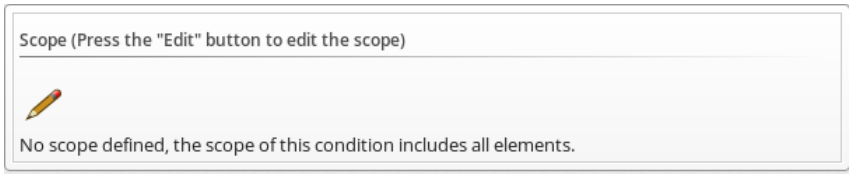
Checking a Container Image for Compliance from the Summary Screen

1. Browse to menu: **Compute > Infrastructure > Container Images**, select the container image that you want to check for compliance.
2. Click **Policy**, and then **Check Compliance of Last Known Configuration**.
3. A confirmation message appears. Click **OK**.
4. To view the compliance history, click the container image. Under **Compliance**, if **History** is **Available**, click to see its compliance history.



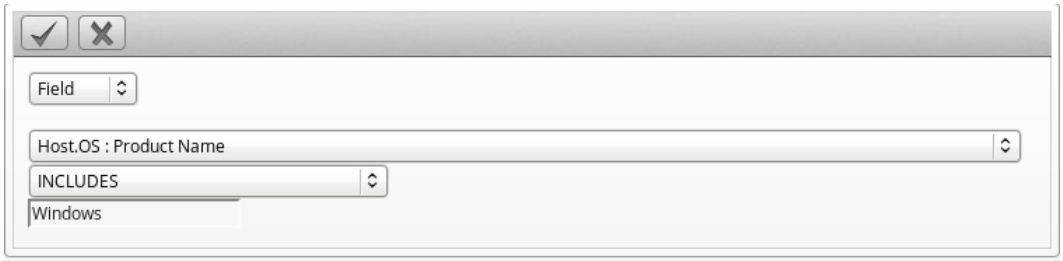
Conditions

Conditions are tests that are performed on attributes of virtual machines. A condition can contain two elements, a scope, and an expression. The expression is mandatory, but the scope is optional. A scope is a general attribute that is quickly checked before evaluating a more complex expression. For example, you might use a scope to check the operating system, and use an expression to check for a specific set of applications or security patches that only apply to the operating system referenced in the scope. If no conditions, scope, or expression, are defined for a policy, the policy is considered unconditional and returns a true value.



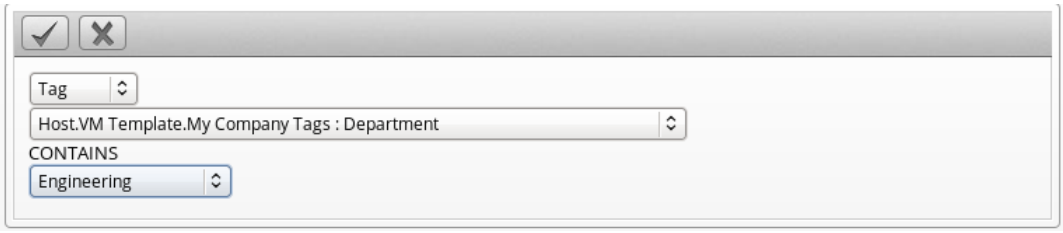
Creating a Condition

You can create a condition either from within a policy screen or by going directly to the expression editor in the Infrastructure Automation console. You need to define a description and an expression element. The expression element defines what criteria you want to use to test the condition.

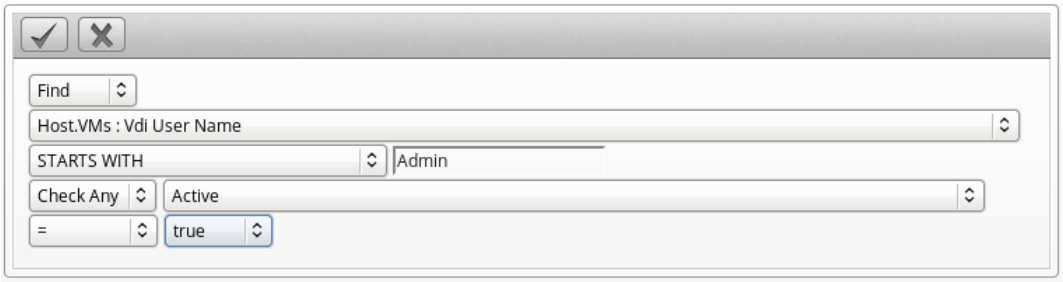


1. Browse to menu: **Control > Explorer**.
2. Click the **Conditions** accordion, and select either **Host / Node Conditions** or **VM and Instance Conditions** or **Replicator Conditions** or **Pod** or **Node Conditions** or **Image Conditions**.
3. Click **Configuration**, then **Add a New Host / VM / Replicator / Pod / Node / Image Condition**.
4. Enter a **Description** for the condition.

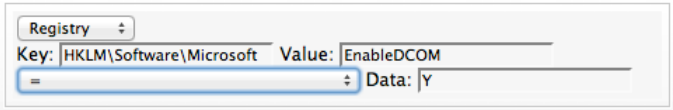
5. Click **Edit this Scope** in the **Scope** area to create a general condition based on a simple attribute. Based on what you choose, different options appear. Creating a scope is optional.



- Click **Field** to create criteria based on field values.

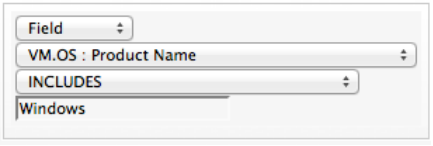


- Click **Count of** to create criteria based on the count of something, such as the number of network adapters on the host.



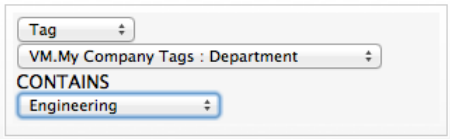
- Click **Tag** to create criteria based on tags that are assigned to your resources. For example, you can check the power state of a virtual machine or see whether it is tagged as production.

- Click **Find** to seek a particular value, and then check a property. For example, finding the Admin account and checking that it is enabled. Use the following check commands:
  - **Check Any**: The result is true if one or more of the find results satisfy the check condition.
  - **Check All**: All of the find results must match for a true result.
  - **Check Count**: If the result satisfies the expression in check count, the result is true.

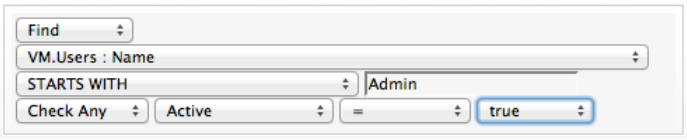


- Click **Registry** to create criteria based on registry values. For example, you can check whether DCOM is enabled on a Windows System. This applies only to Windows operating systems. Registry will only be available if you are creating a VM Condition.

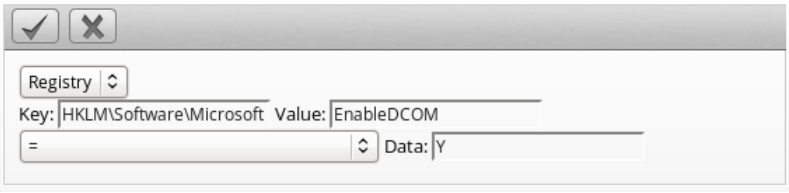
6. Click ✓ **Commit expression element changes** to add the scope.
7. Click **Edit this Expression** in the **Expression** area to create a general condition based on a simple attribute. Based on what you choose, different options appear.



- Click **Field** to create criteria based on field values.



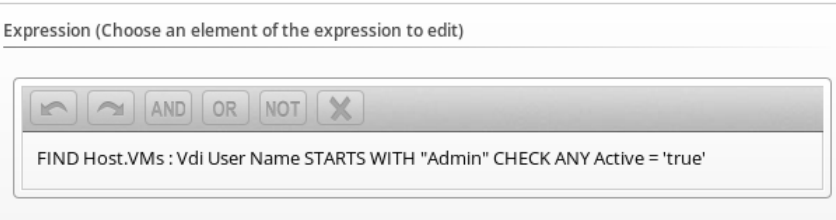
- Click **Count of** to create criteria based on the count of something, such as the number of snapshots for a virtual machine, or the number of virtual machines on a host.



- Click **Tag** to create criteria based on tags assigned to your resources. For example, you can check the power state of a virtual machine or see whether it is tagged as production.

- Click **Find** to seek a particular value, and then check a property. For example, finding the Admin account and checking that it is enabled. Use the following check commands.
  - **Check Any**: The result is true if one or more of the find results satisfy the check condition.
  - **Check All**: All of the find results must match for a true result.
  - **Check Count**: If the result satisfies the expression in check count, the result is true.

- Click **Registry** to create criteria based on registry values. For example, you can check whether DCOM is enabled on a Windows System. This applies only to Windows operating systems.



8. Click **Commit expression element changes** to add the expression.
9. In **Notes**, type in a detailed explanation of the condition.
10. Click **Add**.

Editing a Condition

Edit a condition to add more expressions to it or modify its properties. You can edit conditions that you created.

1. Browse to menu: **Control > Explorer**.
2. Click the **Conditions** accordion, and click the condition that you want to edit.
3. Click **Configuration**, **Edit this Condition**.
4. Click in either the **Scope** or **Expression** area, and click the part of the condition to edit.

5. Make the edits for the current expression.
   - Click **Commit expression element changes** to add the changes.
   - Click **Undo the previous change** to cancel the last action executed.
   - Click **Redo the previous change** to repeat the previous action executed.
   - Click **AND with a new expression element** to create a logical AND with a new expression element.
   - Click **OR with a new expression element** to create a logical OR with a new expression element.
   - Click **Wrap this expression element with a NOT** to create a logical NOT on an expression element.
   - Click **Remove this expression element** to take out the current expression element.
6. When you complete all of the changes to the condition, click **Save**.

Copying a Condition

You can copy a condition to create a similar condition, then change the values that are associated with it. You can copy the sample conditions that are provided to customize them to your environment.

1. Browse to menu: **Control > Explorer**.
2. Click the **Conditions** accordion, and select the condition that you want to copy.
3. Click **Configuration**, **Copy this Condition to a new Condition**.
4. Make all the changes that you need for the new condition. The description must be unique to all conditions.
5. Click **Add**.

Deleting a Condition

Remove conditions that are no longer applicable. You can delete only the conditions that are not part of a policy. To be able to delete the condition, you must remove the policy first.

1. Browse to menu: **Control > Explorer**.
2. Click the **Conditions** accordion, and click the condition that you want to remove.
3. Click **Configuration**, **Delete this VM and Instance Condition**.
4. Click **OK** to confirm.

Actions

Actions are performed after the condition is evaluated. Control comes with a set of default actions that you can choose from. You can also create some of your own.

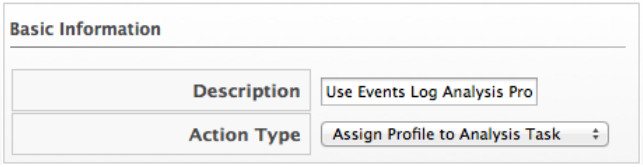
Action	Description
Cancel vCenter Task	Stop current vCenter Task. Due to limitations of vCenter, this applies only to cloning tasks.
Check Host or VM Compliance	Run compliance checks.
Collect Running Processes on VM Guest OS	Collect the list of running processes from the guest operating system.
Connect All CD-ROM Drives for Virtual Machine	Connect all the CD-ROM drives for the virtual machine.
Connect All Floppy Drives for Virtual Machine	Connect all the floppy drives for the virtual machine.
Connect All Floppy and CD-ROM Drives for Virtual Machine	Connect all of the floppy and CD-ROM drives for virtual machine.
Convert to Template	Convert this virtual machine to a template.
Delete all Snapshots	Remove all snapshots for a virtual machine.
Delete Most Recent Snapshot	Removes a virtual machine's most recent snapshot.
Delete VM from Disk	Remove the virtual machine from disk.
Disconnect All CD-ROM Drives for Virtual Machine	Disconnect all the CD-ROM drives for the virtual machine.
Disconnect All Floppy Drives for Virtual Machine	Disconnect all the floppy drives for the virtual machine.

Action	Description
Disconnect All Floppy and CD-ROM Drives for Virtual Machine	Disconnect all of the floppy and CD-ROM drives for virtual machine.
Execute an external script	Run an external script.
Generate Audit Event	Write an entry to the audit log and to the VMDB.
Generate log message	Write an entry to the Infrastructure Automation log.
Initiate SmartState Analysis for Host	Start a SmartState Analysis for a host.
Initiate SmartState Analysis for VM	Start a SmartState Analysis for a virtual machine.
Invoke a Custom Automation	For use with Infrastructure Automation automate. It enables you to run tasks and notifications automatically.
Mark as Non-Compliant	Used with compliance policies. Mark resource as non-compliant. (Compliance status is viewable in summary screens.)
Prevent current event from proceeding	Stop the current event from continuing.
Put Virtual Machine Guest OS in Standby	Put the virtual machines operating system in standby mode.
Raise Automation Event	Used with Infrastructure Automation automate.
Refresh data from vCenter	Perform a refresh of the vCenter.
Remove Virtual Machine from Inventory	Take the virtual machine out of inventory.
Retire Virtual Machine	Retire the virtual machine. (It remains in inventory, but cannot be started.)
Show EVM Event on Timeline	To show the EVM event on the timeline.
Shutdown Virtual Machines Guest OS	Shut down the virtual machine's operating system.
Start Virtual Machine	Power on the virtual machine.
Stop Virtual Machine	Power off the virtual machine.
Suspend Virtual Machine	Suspend the virtual machine.

Default Actions and Descriptions

Custom Actions

You can create a custom action by using the Infrastructure Automation console. Enter a description and action type. Procedures for each type of action are shown in the following sections. When you create a policy, you can associate actions with specific events.

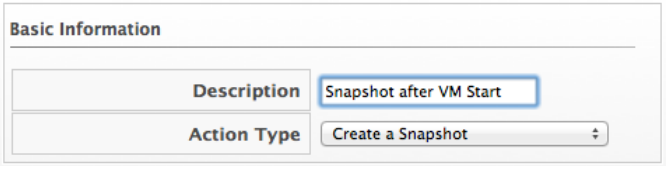


Custom Action	Description
Assign Profile to Analysis Task	When initiating a Smart State Analysis event, you can assign a specific analysis profile.
Create a Snapshot	Creates a snapshot with a name that you provide.
Delete Snapshots by Age	Removes snapshots based on how old they are.
Evaluate Alerts	Checks for alerts. This is required for the alert to be delivered.
Inherit Parent Tags	Assigns tags from the parent cluster, host, datastore, or resource pool.
Invoke a Custom Automation	For use with Infrastructure Automation automate.
Reconfigure CPUs	Reconfigure the number of CPUs for a virtual machine to the number you specify.
Reconfigure Memory	Reconfigure the amount of memory for a virtual machine to the amount you specify.
Remove Tags	Removes tags from the resource.
Run Ansible Playbook	Run an Ansible playbook against an inventory selection.
Send an E-mail	Send an email to an address that you provide. This type of action can be used in an alert.
Send an SNMP trap	Send an SNMP (Simple Network Management Protocol) trap to the host you specify. This type of action can be used for an alert.
Set a Custom Attribute in vCenter	Set the value of a custom attribute in vCenter.
Tag	Assign a company tag that you specify to a virtual machine.

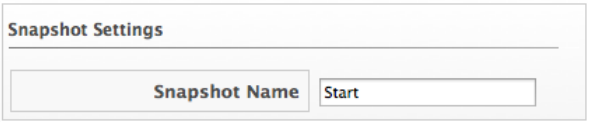
Custom Actions and Descriptions

Creating an Assign Profile to Analysis Task Action

Use this action for assigning specific analysis profiles to virtual machines. You must create an analysis profile before assigning it to an action. You can only assign this action to an analysis start event.



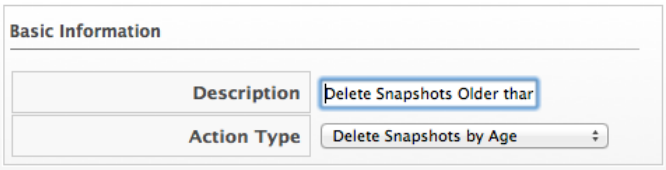
1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the **Action Type**.



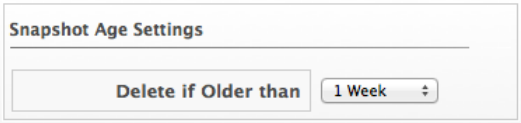
4. Select **Assign Profile to Analysis Task** from **Action Type**.
5. Select a profile from the **Analysis profiles**.
6. Click **Add**.

Creating a Snapshot Action

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.



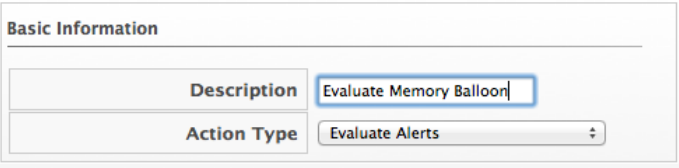
4. Select **Create a Snapshot** from **Action Type**.
5. Type in a **Snapshot Name**.



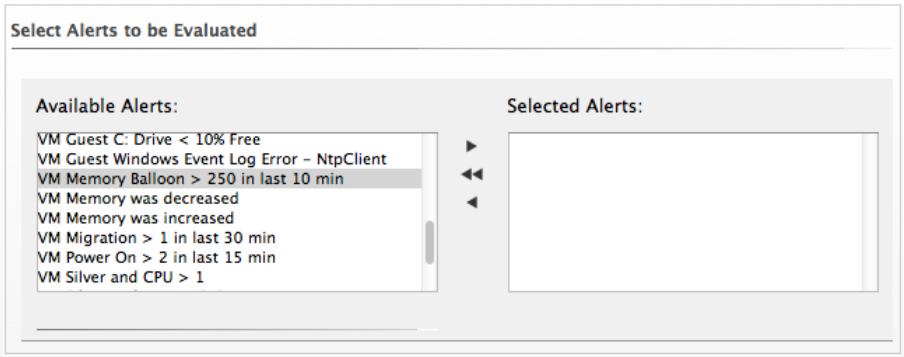
6. Click **Add** when you are finished.

Deleting Snapshots by Age

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.



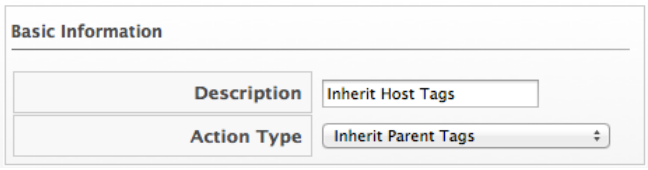
4. Select **Delete Snapshots by Age** from **Action Type**.
5. Select the age of snapshots to delete.



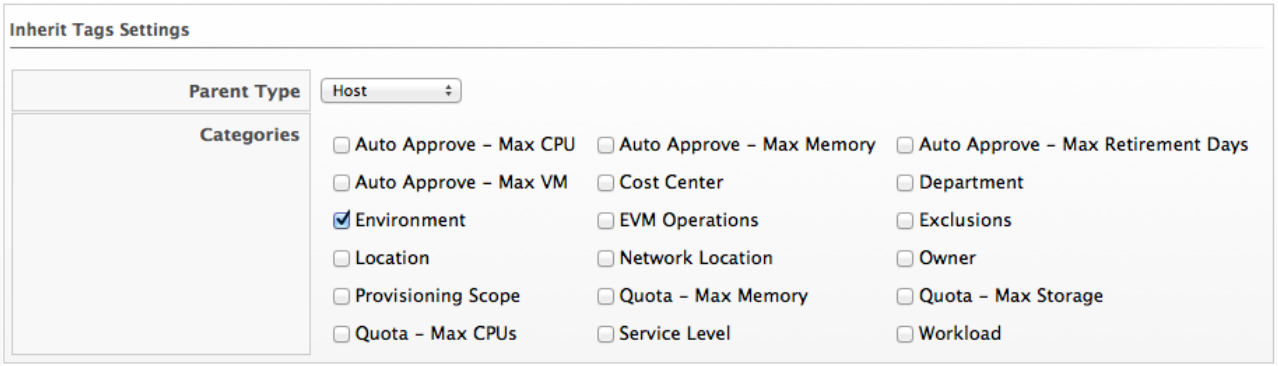
6. Click **Add**.

Evaluating an Alert

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.



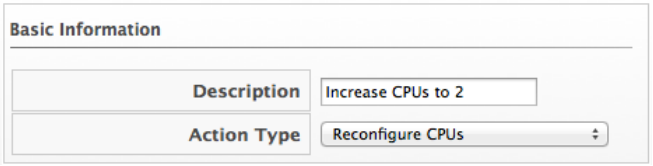
4. Select **Evaluate Alerts** from **Action Type**.
5. Select the alerts to be evaluated and click > (Move selected Alerts into this Action). Use the `Ctrl` key to select multiple alerts.



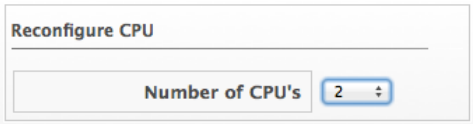
6. Click **Add**.

Creating an Inherit Tag Action

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, and click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.



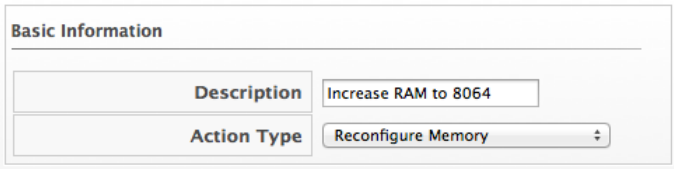
4. Select **Inherit Parent Tag** from **Action Type**.
5. Select the type of parent item to inherit from in **Parent Type**.
6. Check all categories that you want inherited.



7. Click **Add**.

Creating a CPU Reconfigure Action

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.

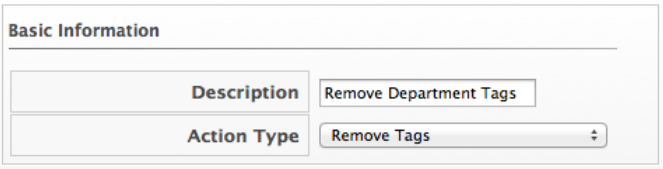


4. Select **Reconfigure CPUs** from **Action Type**.
5. Select a number from **Number of CPUs**.

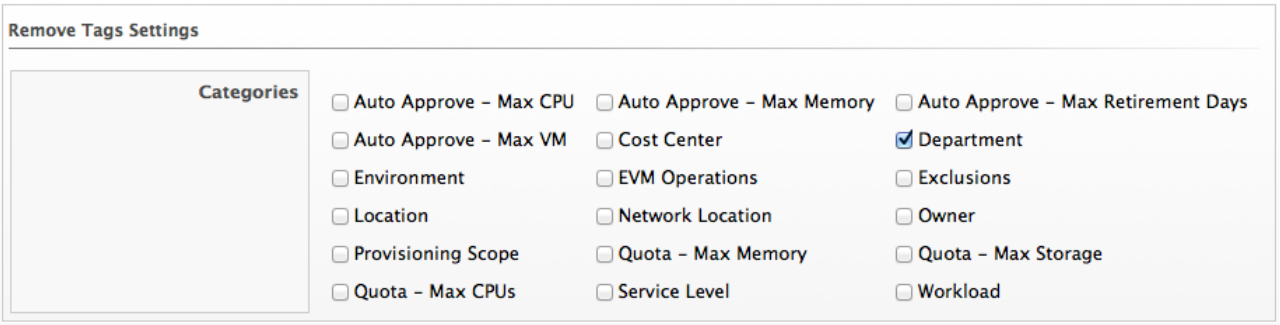
6. Click **Add**.

Creating a Memory Reconfigure Action

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.



4. Select **Reconfigure Memory** from **Action Type**.
5. Type in a new value for **Memory Size**.



6. Click **Add**.

Creating a Remove Tag Action

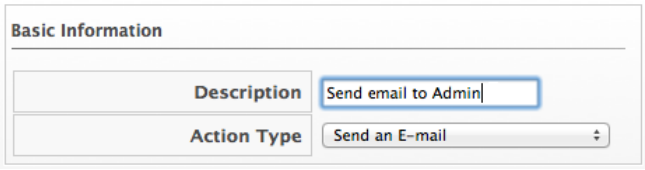
1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.

4. Select **Remove Tags** from **Action Type**.
5. Check the category of tags you want to remove.

6. Click **Add**.

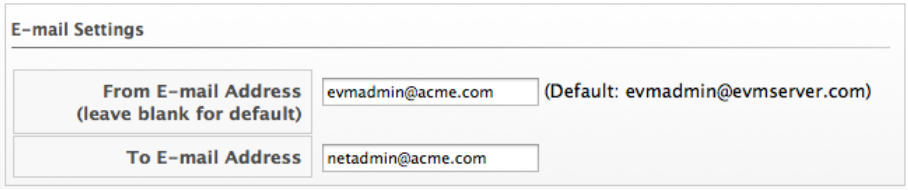
Creating an Ansible Playbook Run Action

Use this action to run an Ansible Playbook against your inventory. You must first sync a playbook repository and add an Ansible Playbook service catalog item.



1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, and click **Configuration**, **Add a new Action**.

3. Type in a **Description** for the action.
4. Select **Run Ansible Playbook** from **Action Type**.
5. Select the playbook catalog item to run from **Playbook Catalog Item**.
6. Check the inventory against which you run the Ansible playbook.
    - If **Specific Hosts** is selected, provide the IP or DNS names.
7. Click **Add**.



Creating an E-mail Action

To send emails from the Infrastructure Automation server, you must have the notifier server role enabled and have defined settings for SMTP email.

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.

4. Select **Send an E-mail** from **Action Type**.
5. Type in a **From E-mail Address** and **To E-mail Address**.

6. Click **Add**.

Creating an SNMP Action

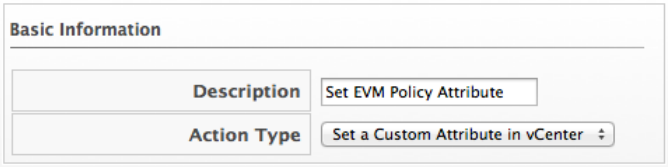
To send SNMP traps from the Infrastructure Automation server, you must have the **`Notifier`** server role and the SNMP daemons enabled.

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Enter a **Description** for the action.
4. Select **Send an SNMP** Trap from **Action Type**.
5. Type in the IP for the host to send the trap to, select the version of SNMP that you are using, and type in the Trap Object ID. Type in multiple hosts if you require the trap sent to multiple SNMP hosts.
    - If using SNMP V1, you are prompted for a Trap Number. Type 1, 2, or 3, based on the appropriate Suffix Number from table below.
    - If using SNMP V2, you are prompted for a Trap Object ID. Type info, warning, or critical, based on the table below.

Object ID	Suffix Number Added to PEN	PEN with the Suffix Added
info	1	1.3.6.1.4.1.33482.1
warn, warning	2	1.3.6.1.4.1.33482.2
crit, critical, error	3	1.3.6.1.4.1.33482.3

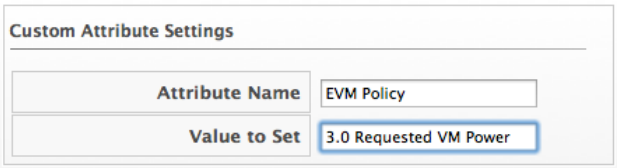
Trap Object ID and Suffix Number

6. Type in the variables that you require in your message.
7. Click **Add**.



Note: When adding an SNMP action, be sure to set it as asynchronous.

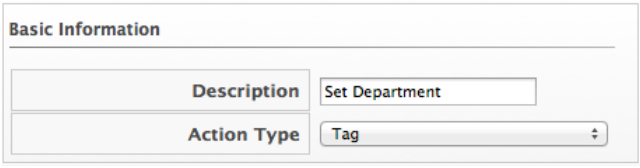
Creating a Set Custom Attribute Action



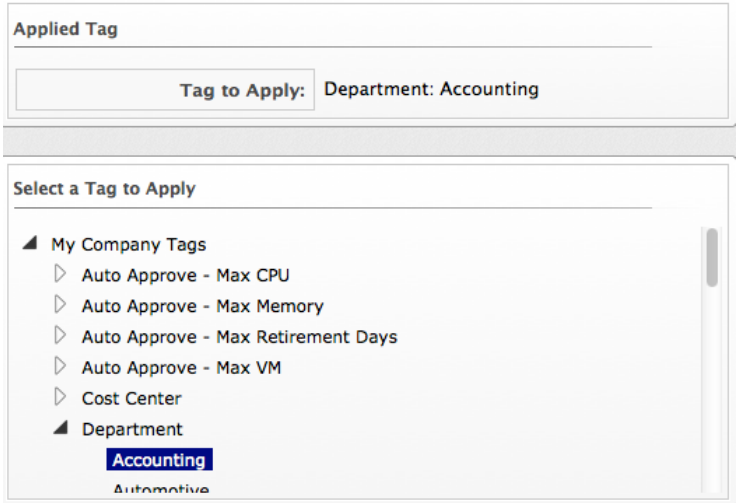
The custom attribute must already exist in vCenter. See vCenter documentation for instructions. In this example, an attribute called Infrastructure Automation policy already exists.

1. Browse to menu: **Control > Explorer**.

2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.



4. Select **Set a Custom Attribute in vCenter** from **Action Type**.
5. Type in the **Attribute Name** and **Value to Set**.



6. Click **Add**.

Creating a Tag Action

1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, then click **Configuration**, **Add a new Action**.
3. Type in a **Description** for the action.

4. Select **Tag** from **Action Type**.
5. Click on the appropriate tag to apply from the list provided.

6. Click **Add**.

Editing an Action

Edit an action to modify its properties. You can't edit any of the default actions that are supplied with Infrastructure Automation. Only actions that you create can be changed.

Note: When you view an action, you can see what policies it is assigned to.

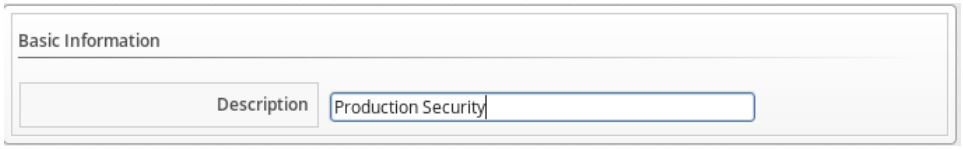
1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, and then click the action that you need to edit.

3. Click **Configuration**, **Edit this Action** on the detail view of the action.
4. Make any required changes.
5. Click **Save**.

The action is modified and can be added to a policy. If the action is already party of a policy, the policy is automatically updated.

Deleting an Action

Delete unused actions to keep your environment uncluttered. You can't delete default actions or actions that are currently assigned to a policy. The delete button is unavailable if the action is in use.

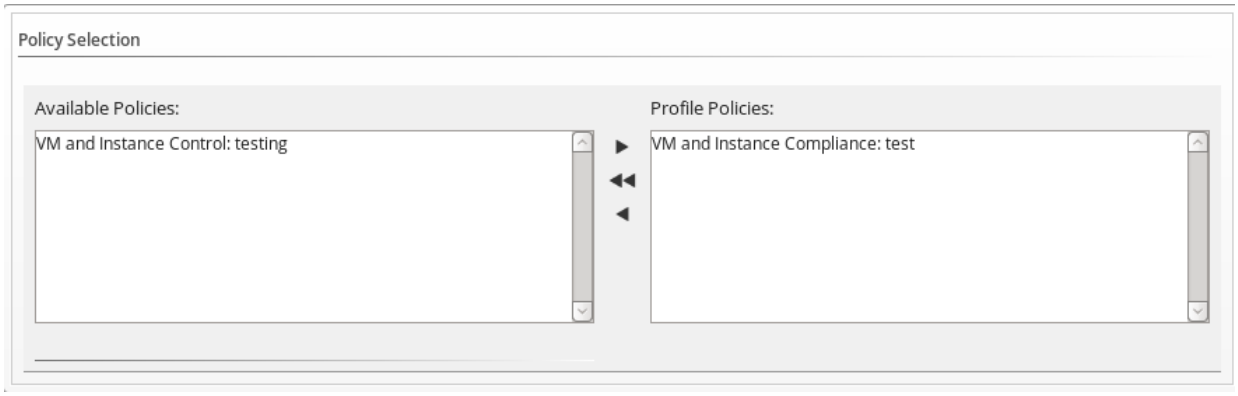


1. Browse to menu: **Control > Explorer**.
2. Click the **Actions** accordion, click the action that you need to remove.
3. Click **Configuration**, **Delete this Action** on the detail view of the tree.
4. Click **OK** to confirm.

Policy Profiles

Policy profiles are groups of policies that you can assign wholesale to virtual machines, providers, clusters, hosts, resource pools, replicators, pods, container nodes, and container images. Policy profiles provide a framework for easily managing and assigning different levels of security, across various types of cloud resources.

Creating Policy Profiles



1. Browse to menu: **Control > Explorer**.
2. Click on the **Policy Profiles** accordion, then click **Configuration**, then (**Add a New Policy Profile**).
3. In the **Basic Information** area, type in a unique description for the policy profile.

4. From **Available Policies** in the **Policy Selection** area select all the policies you need to apply to this policy profile. Use the `Ctrl` key to select multiple policies.

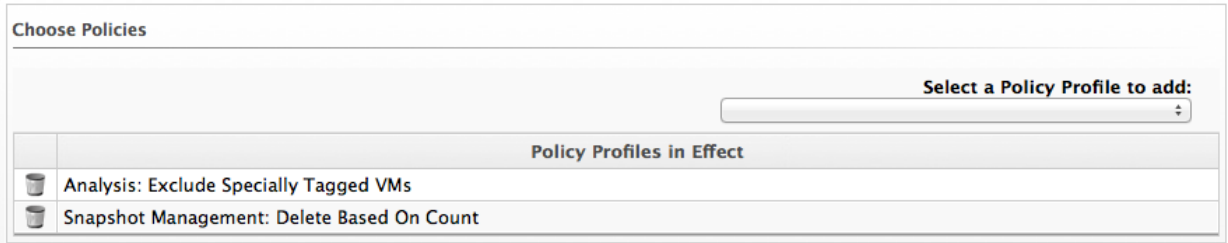
5. Click to add the **Policies**.

6. Add to the **Notes** area if required.
7. Click **Add**.

The policy profile is added. You can now assign the policy profile to providers, hosts, and repositories. In addition, you can verify that the virtual machine complies with the policy profile by using the **Resultant Set of Policy** feature.

Deleting a Policy Profile

Remove policy profiles that you no longer need. This doesn't remove the policies that are associated with the policy profile.



1. Browse to menu: **Control > Explorer**.
2. Click the **Policy Profile** accordion, and then click the policy profile that you want to remove.
3. Click **Configuration**, **Remove this Policy Profile**.
4. Click **OK** to confirm.

Simulating Policy

Before assigning a policy profile to a virtual machine, use the Infrastructure Automation controls policy simulation feature to determine if a virtual machine passes a policy profile.

Simulating Policy Profiles on Virtual Machines

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**, select the virtual machines that you need to evaluate.
2. Click **Policy**, and then click **Policy Simulation**.
3. From the **Select a Policy Profile to add** dropdown, click the policy that you need to apply to the selected virtual machines.

4. The virtual machine thumbnail displays in the **Policy Simulation** area.
   - A check sign in the virtual thumbnail shows that the virtual machine passes policy.
   - A minus sign in the virtual thumbnail shows that the virtual machine fails policy.
5. Click a virtual machine in the **Policy Simulation** area to see its details.
6. Expand a policy profile by clicking it to see its member policies and the status of the conditions.
   - Check **Show out of scope items** to show all conditions, whether the virtual machine passes the scope part of the condition. Uncheck it to hide conditions where the scope part fails.
   - Next to **Show policies**, check **Successful** to show policies that are passed and check **Failed** to see the policies that have failed. The default is to show both.
   - Items in green text passed the condition.
   - Items in red text failed the condition.
   - Items in red italics failed the condition, but do not change the outcome of the scope.

If you evaluate multiple policy profiles, you can see both policy profiles and a tree expanding down to their conditions.

Assigning Policy Profiles

After creating your policy profiles, you are ready to evaluate and assign them.

- Assign a policy profile to a virtual machine to apply the policy profile to a specific virtual machine, independent of its related host, provider, or repository.
- Assign a policy profile to a provider to apply the policy profile to all virtual machines, hosts, replicators, pods, container nodes or container images registered to that provider.
- Assign a policy profile to a replicator to apply the policy profile to that specific replicator.
- Assign a policy profile to a pod to apply the policy profile to that specific pod.
- Assign a policy profile to a container node to apply the policy profile to that specific node.
- Assign a policy profile to a container image to apply the policy profile to that specific image.

- Assign a policy profile to a cluster to apply the policy profile to all virtual machines or hosts assigned to that cluster.
- Assign a VM policy profile to a host to apply the policy profile to that specific host or all virtual machines registered to that host.
- Assign a VM policy profile to a resource pool to apply the policy profile to all virtual machines or hosts assigned to that resource pool.

Assigning Policy Profiles to an Infrastructure Provider

1. Browse to menu: **Compute > Infrastructure > Providers**, verify the provider you need to assign the policy profiles to.
2. Click (**Policy**), and then click (**Manage Policies**).
3. From the **Select Policy Profiles** area, you can click on the triangle next to a desired policy profile to expand it and see its member policies.
4. Check the policy profiles you require to apply to the provider. It turns blue to show its assignment state has changed.
5. Click **Save**.

Removing Policy Profiles from an Infrastructure Provider

1. Browse to menu: **Compute > Infrastructure > Providers**, check the providers that you want to remove the policy profile from.
2. Click **Policy**, and then click **Manage Policies**.
3. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
4. Click **Save**.

Assigning Policy Profiles to a Cluster

1. Browse to menu: **Compute > Infrastructure > Clusters**, check the clusters that you need to assign policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, you can click the triangle next to a desired policy profile to expand it and see its member policies.
4. Check the policy profiles that you need to apply to the cluster. It turns blue to show that its assignment state changed.
5. Click **Save**.

Removing Policy Profiles from a Cluster

1. Browse to menu: **Compute > Infrastructure > Clusters**, check the clusters that you need to remove the policy profiles from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, you can click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profiles that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to a Host

1. Browse to menu: **Compute > Infrastructure > Hosts**, check the hosts that you need to assign policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Check the policy profiles that you need to apply to the host. It turns blue to show that its assignment state changed.
5. Click **Save**.

Removing Policy Profiles from a Host

1. Browse to menu: **Compute > Infrastructure > Hosts**, check the hosts that you need to remove the policy profiles from.
2. Click **Policy**, and then click **Manage Policies**.
3. Uncheck the policy profiles that you need to remove. It turns blue to show that its assignment state changed.
4. Click **Save**.

Assigning Policy Profiles to a Virtual Machine

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**, check the virtual machines that you need to assign policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.

3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Check the policy profiles that you need to apply to the host. It turns blue to show that its assignment state changed.
5. Click **Save**.

Removing Policy Profiles from a Virtual Machine

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**, check the virtual machines that you want to remove the policy profile from.
2. Click **Policy**, and then click **Manage Policies**.
3. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
4. Click **Save**.

Assigning Policy Profiles to a Resource Pool

1. Browse to menu: **Compute > Infrastructure > Resource Pools**, check the resource pools that you need to assign policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Click the policy profiles that you need to apply to the resource pools. It turns blue to show that its assignment state changed.
5. Click **Save**.

Removing Policy Profiles from a Resource Pool

1. Browse to menu: **Compute > Infrastructure > Resource Pools**, check the resource pools that you need to remove the policy profiles from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profiles that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to a Cloud Provider

1. Browse to menu: **Compute > Clouds > Providers** and check the provider that you need to assign the policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a wanted policy profile to expand it and see its member policies.
4. Check the policy profiles that you need to apply to the provider. The ones that are different from the previous setting shows in blue.
5. Click **Save**.

Removing Policy Profiles from a Cloud Provider

1. Browse to menu: **Compute > Clouds > Providers**, check the providers that you need to remove the policy profile from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to a Network Provider

1. Browse to menu: **Networks > Providers**, check the network provider that you need to assign the policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a wanted policy profile to expand it and see its member policies.
4. Check the policy profiles that you need to apply to the provider. The ones that are different from the previous setting shows in blue.
5. Click **Save**.

Removing Policy Profiles from a Network Provider

1. Browse to menu: **Networks > Providers**, check the network providers that you need to remove the policy profiles from.

2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to a Container Provider

1. Browse to menu: **Compute > Containers > Providers** and select the provider that you need to assign the policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a wanted policy profile to expand and see its member policies.
4. Select the policy profiles that you need to apply to the provider. It turns blue to show the selection.
5. Click **Save**.

Removing Policy Profiles from a Container Provider

1. Browse to menu: **Compute > Containers > Providers**, select the container providers that you need to remove the policy profiles from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to a Replicator

1. Browse to menu: **Compute > Containers > Replicators** and select the replicator that you need to assign the policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a wanted policy profile to expand and see its member policies.
4. Select the policy profiles that you need to apply to the replicator. It turns blue to show the selection.
5. Click **Save**.

Removing Policy Profiles from a Replicator

1. Browse to menu: **Compute > Containers > Replicators**, select the replicators that you need to remove the policy profiles from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to a Pod

1. Browse to menu: **Compute > Containers > Pods** and select the pod that you need to assign the policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a wanted policy profile to expand and see its member policies.
4. Select the policy profiles that you need to apply to the pod. It turns blue to show the selection.
5. Click **Save**.

Removing Policy Profiles from a Pod

1. Browse to menu: **Compute > Containers > Pods**, select the pods that you need to remove the policy profiles from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to a Container Node

1. Browse to menu: **Compute > Containers > Container Nodes** and select the container node that you need to assign the policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a wanted policy profile to expand and see its member policies.
4. Select the policy profiles that you need to apply to the node. It turns blue to show the selection.
5. Click **Save**.

Removing Policy Profiles from a Container Node

1. Browse to menu: Compute > Containers > Container Nodes**, select the container nodes that you need to remove the policy profiles from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to a Container Image

1. Browse to menu: **Compute > Containers > Container Images** and select the image that you need to assign the policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a wanted policy profile to expand and see its member policies.
4. Select the policy profiles that you need to apply to the image. It turns blue to show the selection.
5. Click **Save**.

Removing Policy Profiles from a Container Image

1. Browse to menu: **Compute > Containers > Container Images**, select the container images that you need to remove the policy profiles from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

Assigning Policy Profiles to an Instance

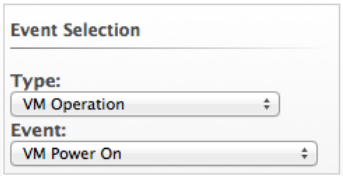
1. Browse to menu: **Compute > Clouds > Instances**, check the instances that you want to assign policy profiles to.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a wanted policy profile to expand it and see its member policies.
4. Check the policy profiles that you want to apply to the instances. It turns blue to show that its assignment state changed.
5. Click **Save**.

Removing Policy Profiles from an Instance

1. Browse to menu: **Compute > Clouds > Instances**, check the instances that you need to remove the policy profile from.
2. Click **Policy**, and then click **Manage Policies**.
3. From the **Select Policy Profiles** area, click the triangle next to a desired policy profile to expand it and see its member policies.
4. Uncheck the policy profile that you need to remove. It turns blue to show that its assignment state changed.
5. Click **Save**.

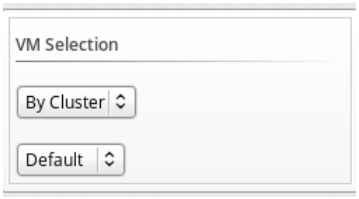
Disabling a Policy in a Policy Profile

You can disable one policy in a profile without removing it from the policy, perhaps for trouble shooting purposes or because the policy is not required temporarily.



1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, then navigate to the policy that you need to disable or navigate to the policy from the policy profile.

3. Click **Configuration**, **Edit Basic Info, Scope, Notes**.
4. Uncheck **Active**.
5. Click **Save**.



Viewing Policy Simulation - Resultant Set of Policy (RSOP)

After the Policy Profiles are assigned, you can see the final result of the resolution of all policies based on which Events occur. Based on the result, you can adjust your Policies. To view RSOP, go to the control area in the Infrastructure Automation console.

1. Browse to menu: **Control > Simulation**.
2. From the **Event Selection** area, select a type of event, and then the specific event you need the result for.

3. From the **VM Selection** area, select the virtual machine from a provider, cluster, host, or a single virtual machine.

4. Click **Submit**.

Exporting and Importing Analysis Profiles

Infrastructure Automation SmartState analysis requires an analysis profile to select the files to be scanned by a compliance policy. Infrastructure Automation allows the export and import of SmartState analysis profiles by using the command line and rake commands. As a result, approved configurations can be easily imported into customer environments, without having to manually recreate the profile through the user interface.

1. Change to the `vmdb` directory:

   ```
   cd /var/www/miq/vmdb
   ```

2. Create an export directory:

   ```
   $ mkdir exports
   ```

3. To export an analysis profile, run:

   ```
   bundle exec rake evm:export:scan_profiles -- --directory exports
   ```

4. To import the default analysis profile, run:

   ```
   bundle exec rake evm:import:scan_profiles -- --source exports/host_default.yaml
   ```

   Note:

   If the default profile exists in Infrastructure Automation, the new profile does not overwrite the old profile. Instead, it duplicates the file items in the default profile.

Appendix

Events

Events are triggers that cause a condition to be tested. Control provides several Events, that can be divided into functional types. Events cannot be modified.

Category	Description
Container Operation	Events related to container analysis.
Datastore Operation	Events related to datastore analysis.
Authentication Validation	Events related to credential validation for hosts and providers.

Category	Description
Company Tag	Events related to assigning and removing company tags from an infrastructure object.
Compliance	Events related to checking compliance policies.
Host Operation	Events related to the connection state of a host and status of a SmartState Analysis on a host.
Orchestration Lifecycle	Events related to orchestration lifecycle, such as retirement.
Physical Server Operation	Events related to the connection state of a physical server.
VM Configuration	Events associated with a change in configuration of a virtual machine. These include, but are not limited to, clone, create, template create, and settings change.
VM Lifecycle	Events such as virtual machine discovery, provisioning, and virtual machine retirement.
VM Operation	Events associated with power states or locations of virtual machines and virtual desktop machines. These include, but are not limited to, power off, power on, reset, resume, shutdown, and suspend.
Service Lifecycle	Events associated with service lifecycle. These include, but are not limited to, provisioning completed, start request, started, stop request, stopped, retirement warning, and retired.

Event Types

Each type has a set of events that you can select to trigger the checking of a condition.

Event	Description
Container Image Analysis Request	Check the condition when an analysis of a container image is requested.
Container Image Analysis Complete	Check the condition when an analysis of a container image completes.
Container Image Discovered	Check the condition when a new container image is discovered.
Container Image Compliance Check	Check the condition when a compliance check is performed on an image.
Container Image Compliance Passed	Check the condition when an image passes a compliance check.
Container Image Compliance Failed	Check the condition when an image fails a compliance check.
Container Node Failed Mount	Check the condition when a node fails to mount a volume for a pod.
Container Node Invalid Disk Capacity	Check the condition when a node's disk capacity is invalid.
Container Node Not Ready	Check the condition when a node is not ready.
Container Node Not Schedulable	Check the condition when a node is not schedulable.
Container Node Ready	Check the condition when a node is ready.
Container Node Schedulable	Check the condition when a node is schedulable.
Container Node Rebooted	Check the condition when a node reboots.
Container Node Compliance Check	Check the condition when a compliance check is performed on a node.
Container Node Compliance Passed	Check the condition when a node passes a compliance check.
Container Node Compliance Failed	Check the condition when a node fails a compliance check.
Pod Compliance Check	Check the condition when a compliance check is performed on a pod.
Pod Compliance Passed	Check the condition when a pod passes a compliance check.
Pod Compliance Failed	Check the condition when a pod fails a compliance check.
Pod Container Created	Check the condition when a container is created in a pod.
Pod Container Failed	Check the condition when a container in a pod fails.
Pod Container Killing	Check the condition when a container in a pod is killed.
Pod Container Started	Check the condition when a container in a pod is started.
Pod Container Stopped	Check the condition when a container in a pod is stopped.
Pod Container Unhealthy	Check the condition when a container in a pod is unhealthy.
Pod Deadline Exceeded	Check the condition when a pod with specified deadline exceeds it and is terminated.
Pod Failed Scheduling	Check the condition when scheduling a pod fails.
Pod Failed Sync	Check the condition when getting a pod to its desired state fails (a frequent reason is failure to download the image).
Pod Failed Validation	Check the condition when a pod validation fails.

Event	Description
Pod hostPort Conflict	Check the condition when a pod hostPort conflict occurs.
Pod Insufficient Free CPU	Check the condition when there is an insufficient free CPU in a pod.
Pod Insufficient Free Memory	Check the condition when there is an insufficient free memory in a pod.
Pod nodeSelector Mismatching	Check the condition when a pod nodeSelector mismatches.
Pod Out of Disk	Check the condition when a pod is out of disk space.
Pod Scheduled	Check the condition when a pod is scheduled onto the node.
Replicator Failed Creating Pod	Check the condition when a replicator fails creating a pod.
Replicator Successfully Created Pod	Check the condition when a replicator successfully creates a pod.
Replicator Compliance Check	Check the condition when a compliance check is performed on a replicator.
Replicator Compliance Passed	Check the condition when a replicator passes a compliance check.
Replicator Compliance Failed	Check the condition when a replicator fails a compliance check.
Database Failover Executed	Check the condition when a database failover is executed.
Datastore Analysis Complete	Check the condition when a SmartState Analysis of a datastore completes.
Datastore Analysis Request	Check the condition when a SmartState Analysis for a datastore is requested from the user interface.
Host Added to Cluster	Check the condition when a host is added to a cluster.
Host Analysis Complete	Check the condition when a SmartState Analysis of host completes.
Host Analysis Request	Check the condition when a SmartState Analysis is requested from the Infrastructure Automation console.
Host Auth Changed	Check the condition when host authentication credentials are changed in the Infrastructure Automation console.
Host Auth Error	Check the condition if there is any other error connecting to the host such as ssh/vim handshaking problems, timeouts, or any other uncategorized error.
Host Auth Incomplete Credentials	Check the condition if host authentication credentials are not complete in the user interface.
Host Auth Invalid	Check the condition if Infrastructure Automation is able to communicate with the host and the credentials fail.
Host Auth Unreachable	Check the condition if Infrastructure Automation is unable to communicate with the host.
Host Auth Valid	Check the condition when the host authentication credentials entered in the Infrastructure Automation console are valid.
Host C & U Processing Complete	Check the condition when the processing of capacity and utilization data has finished.
Host Compliance Check	Check the condition when a compliance check is performed on a host.
Host Compliance Failed	Check the condition when a host fails a compliance check.
Host Compliance Passed	Check the condition when a host passes a compliance check.
Host Connect	Check the condition when a host connects to a provider.
Host Disconnect	Check the condition when a host disconnects from a provider.
Host Maintenance Enter Request	Check the condition when a host requests to enter maintenance mode.
Host Maintenance Exit Request	Check the condition when a host requests to exit maintenance mode.
Host Provision Complete	Check the condition when the host provision is complete.
Host Reboot Request	Check the condition when someone tries to reboot a host from the Infrastructure Automation console.
Host Removed from Cluster	Check the condition when a host is removed from a cluster.
Host Reset Request	Check the condition when a host is restarted from the Infrastructure Automation console.
Host Shutdown Request	Check the condition when a host is shut down from the Infrastructure Automation console.
Host Standby Request	Check the condition when someone tries to put the operating system of a host in standby from the Infrastructure Automation console.
Host Start Request	Check the condition when a host is started from the Infrastructure Automation console.
Host Stop Request	Check the condition when a host is requested to stop from the Infrastructure Automation console.
Host Vmotion Disable Request	Check the condition when a request to disable vMotion on a host is created from the Infrastructure Automation console.
Host Vmotion Enable Request	Check the condition when a request to enable vMotion on a host is created from the Infrastructure Automation console.

Event	Description
Orchestration Stack Retire Request	Check the condition when an orchestration stack retirement request is created from Infrastructure Automation.
Physical Server Reset	Check the condition when a physical server is restarted from the Infrastructure Automation console.
Physical Server Shutdown	Check the condition when a physical server is shut down from the Infrastructure Automation console.
Physical Server Start	Check the condition when a physical server is started from the Infrastructure Automation console.
Provider Auth Changed	*For use only with Infrastructure Automation automate, for future use in policies.* Check the condition when provider authentication credentials are changed in the user interface.
Provider Auth Error	*For use only with Infrastructure Automation automate, for future use in policies.* Check the condition if there is any other error connecting to the provider such as ssh/vim handshaking problems, timeouts, or any other uncategorized error.
Provider Auth Incomplete Credentials	*For use only with Infrastructure Automation automate, for future use in policies.* Check the condition if provider authentication credentials are not complete in the Infrastructure Automation console.
Provider Auth Invalid	*For use only with Infrastructure Automation automate, for future use in policies.* Check the condition if Infrastructure Automation is able to communicate with the provider and the credentials fail.
Provider Auth Unreachable	*For use only with Infrastructure Automation automate, for future use in policies.* Check the condition if Infrastructure Automation is unable to communicate with the provider.
Provider Auth Valid	*For use only with Infrastructure Automation automate, for future use in policies.* Check the condition when the provider authentication credentials entered in the user interface are valid.
Provider Compliance Check	Check the condition when a compliance check is performed on a provider.
Provider Compliance Failed	Check the condition when a provider fails a compliance check.
Provider Compliance Passed	Check the condition when a provider passes a compliance check.
Service Provision Complete	Check the condition when the service provision is complete.
Service Retire Request	Check the condition when a service retirement request is created from Infrastructure Automation.
Service Retired	Check the condition when the service has been retired.
Service Retirement Warning	Check the condition when the service is about to retire.
Service Start Request	Check the condition when the service has been requested to start.
Service Started	Check the condition when the service has started.
Service Stop Request	Check the condition when the service has been requested to stop.
Service Stopped	Check the condition when the service has stopped.
Tag Complete	Check the condition after a company tag is assigned.
Tag Parent Cluster Complete	Check the condition after a company tag is assigned to a virtual machine's parent cluster.
Tag Parent Datastore Complete	Check the condition after a company tag is assigned to a virtual machine's parent datastore.
Tag Parent Host Complete	Check the condition after a company tag is assigned to a virtual machine's parent host.
Tag Parent Resource Pool Complete	Check the condition after a company tag is assigned to a virtual machine's parent resource pool.
Tag Request	Check the condition when assignment of a company tag is attempted.
Un-Tag Complete	Check the condition when a company tag is removed.
Un-Tag Parent Cluster Complete	Check the condition after a company tag is removed from a virtual machine's parent cluster.
Un-Tag Parent Datastore Complete	Check the condition after a company tag is removed from a virtual machine's parent datastore.
Un-Tag Parent Host Complete	Check the condition after a company tag is removed from a virtual machine's parent host.
Un-Tag Parent Resource Pool Complete	Check the condition after a company tag is removed from a virtual machine's parent resource pool.
Un-Tag Request	Check the condition when an attempt is made to remove a company tag.
VDI Connecting to Session	Check the condition when a VDI session is started.
VDI Disconnected from Session	Check the condition when a VDI session is disconnected.
VDI Login Session	Check the condition when a user logs on to a VDI session.
VDI Logoff Session	Check the condition when a user logs off from a VDI session.
VM Analysis Complete	Check the condition when a SmartState Analysis of virtual machine completes.
VM Analysis Failure	Check the condition when a SmartState Analysis of virtual machine fails.
VM Analysis Request	Check the condition when a SmartState Analysis is requested from the Infrastructure Automation console.
VM Analysis Start	Check the condition when a SmartState Analysis of virtual machine is started.
VM C & U Processing Complete	Check the condition when the processing of capacity and utilization data has finished.

Event	Description
VM Clone Complete	Check the condition when a virtual machine is cloned.
VM Clone Start	Check the condition when a virtual machine clone is started.
VM Compliance Check	Check the condition when a compliance check is performed on a virtual machine.
VM Compliance Failed	Check the condition when a virtual machine fails a compliance check.
VM Compliance Passed	Check the condition when a virtual machine passes a compliance check.
VM Create Complete	Check the condition when a virtual machine is created.
VM Delete (from Disk)	Check the condition when a disk on a virtual machine is deleted.
VM Delete (from Disk) Request	Check the condition when someone tries to delete a virtual machine from disk from the user interface.
VM Guest Reboot	Check the condition when a virtual machine is rebooted.
VM Guest Reboot Request	Check the condition when someone tries to reboot a virtual machine from the Infrastructure Automation console.
VM Guest Shutdown	Check the condition when the operating system of a virtual machine shuts down.
VM Guest Shutdown Request	Check the condition when someone tries to shut down the operating system of a virtual machine from the user interface.
VM Live Migration (VMOTION)	Check the condition when a vMotion migration is performed.
VM Pause	Check the condition when a virtual machine is paused.
VM Pause Request	Check the condition when someone tries to pause a virtual machine from the Infrastructure Automation console.
VM Power Off	Check the condition when a virtual machine is turned off.
VM Power Off Request	Check the condition when someone tries to power off a virtual machine from the Infrastructure Automation console.
VM Power On	Check the condition when a virtual machine is turned on.
VM Power On Request	Check the condition when someone tries to turn on a virtual machine from the Infrastructure Automation console.
VM Provision Complete	Check the condition when a virtual machine is provisioned.
VM Remote Console Connected	Check the condition when a virtual machine is connected to a remote console.
VM Removal from Inventory	Check the condition when a virtual machine is unregistered.
VM Removal from Inventory Request	Check the condition when a request is sent from the Infrastructure Automation console to unregister a virtual machine.
VM Renamed Event	Check the condition when a virtual machine is renamed on its provider.
VM Reset	Check the condition when a virtual machine is restarted.
VM Reset Request	Check the condition when a virtual machine is restarted from the Infrastructure Automation console.
VM Resume	Check the condition when a virtual machine is resumed.
VM Retire Request	Check the condition when a virtual machine retirement request is created from Infrastructure Automation.
VM Retired	Check the condition when a virtual machine is retired.
VM Retirement Warning	Check the condition when a warning threshold is reached for retirement.
VM Settings Change	Check the condition when the settings of virtual machine are changed.
VM Shelve	Check the condition when a virtual machine is shelved.
VM Shelve Offload	Check the condition when a virtual machine is removed and deleted with the shelve offload operation.
VM Shelve Offload Request	Check the condition when a shelve offload request is created from Infrastructure Automation for a virtual machine.
VM Shelve Request	Check the condition when a virtual machine shelve request is created from Infrastructure Automation.
VM Snapshot Create Complete	Check the condition when a snapshot is completed.
VM Snapshot Create Request	Check the condition when someone tries to create a snapshot of a virtual machine from the user interface.
VM Snapshot Create Started	Check the condition when a snapshot creation is started.
VM Standby of Guest	Check the condition when the operating system of a virtual machine goes to standby.
VM Standby of Guest Request	Check the condition when someone tries to put the operating system of a virtual machine in standby from the Infrastructure Automation console.
VM Suspend	Check the condition when a virtual machine is suspended.
VM Suspend Request	Check the condition when someone tries to suspend a virtual machine from the Infrastructure Automation console.
VM Template Create Complete	Check the condition when a virtual machine template is created.

Monitoring, Alerts, and Reporting

Overview Dashboard

Overview shows your virtual environment's events, reports, and configurable alerts. This information supports better information technology decision making and predictions for future virtual machine management.

When you log in to the console, it brings you directly to the **Overview Dashboard** page by default. The console uses widgets to organize this page, providing you with a default set of commonly used widgets. The configuration items on these widgets are clickable, allowing you to drill down directly to a referenced item.

Customize this page to include charts and reports you specifically want to see as soon as you log in to the console. You can add, remove, move, minimize, zoom into, and maximize widgets. Only users with the proper access can create widgets.

Adding a Widget

You can add widgets to the dashboard to accommodate the information you want to see upon login.

1. Navigate to **Overview > Dashboard**.
2. Click **(Add a Widget)**.
3. Select the widget you want to add from the list.

Note:

Only widgets that are not currently showing on the dashboard will appear in this list.

Resetting to the Default Set of Widgets

You can reset to default set of widgets according to your needs with the following steps:

1. Navigate to **Overview > Dashboard**.
2. Click **(Reset Dashboard Widgets to the defaults)**.

Removing a Widget

You can remove a widget when you no longer need the widget to be displayed in the dashboard.

1. Navigate to **Overview > Dashboard**.
2. From the widget that you want to remove, click **(Remove from Dashboard)** in the upper right corner of the widget.
3. Click **OK**.

The widget is removed from the dashboard, but it is not deleted. It can be added again if needed.

Zooming in to a Chart Widget

1. Navigate to **Overview > Dashboard**.
2. From the chart widget that you want to enlarge, click **(Zoom in)** in the upper right corner of the widget.

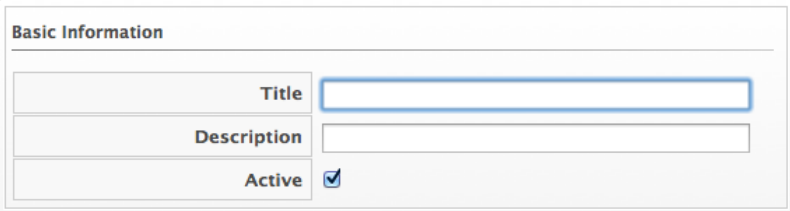
The enlarged chart is opened in its own pop-up window. To close this window, click **(Close)** in the upper right corner.

Opening a Chart or Report Widget in Full Screen View

1. Navigate to **Overview > Dashboard**.
2. From the chart or report widget that you want to enlarge, click **(Full Screen view)** in the upper right corner of the widget.
3. Click **OK**.

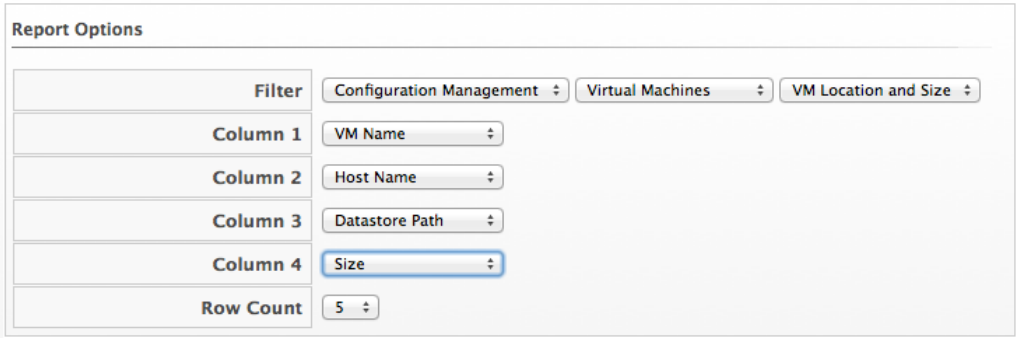
Minimizing or Maximizing a Widget

1. Navigate to **Overview > Dashboard**.
2. From the chart or report widget that you want to maximize, click **(Minimize)** or **(Full Screen)** in the upper right corner of the widget.



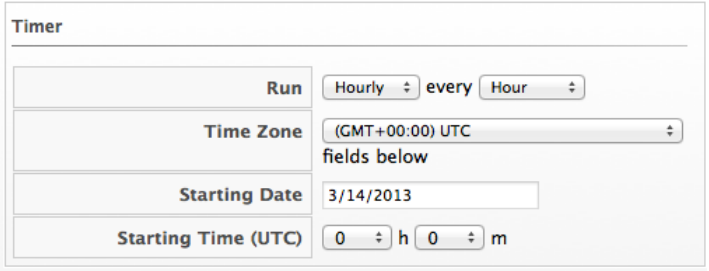
Downloading a Report Widget as a File

1. Navigate to **Overview > Dashboard**.
2. From the chart or report widget that you want to download as a PDF, click **[(Download PDF)** in the upper right corner of the widget.
3. Click **OK**.



Creating Dashboard Widgets

Creating a Report Widget



1. Navigate to **Overview > Reports**.
2. Click on the **Dashboard Widgets** accordion, then choose the **Reports** folder.
3. Click **(Configuration)**, then click **(Add a new Widget)**.
4. In the **Basic Information** area, type in a **Title** and **Description**. By default the widget will be active as soon as you create it. To make it inactive, uncheck the **Active** box.

5. From the **Report Options** area, select the filters until you are at the report you want for this widget. Select up to four columns from that report. Finally, for **Row Count**, select the number of rows that you want displayed.

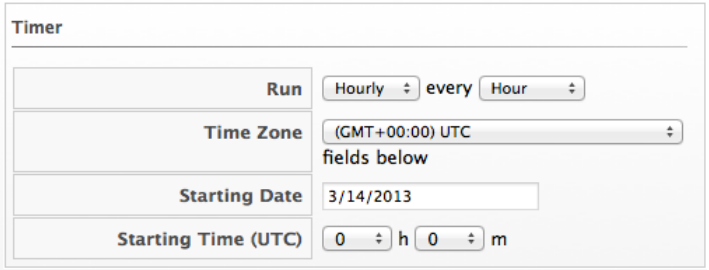
6. In the **Timer** area, click the **Run** drop down to specify how often you want the widget data to get updated. The options displayed will depend on which **Run** option you choose. Select **Hourly**, **Daily**, **Weekly**, or **Monthly**.

7. Select a **Time Zone**. Type or select a date to begin the schedule in **Starting Date**. Select a **Starting Time** based on a 24 hour clock in the selected time zone.

   Note:

   If you change the time zone, you will need to reset the starting date and time.

8. In the **Visibility** area, select **<To All Users>**, so that all users can use this widget no matter what user role they are assigned. Select **<By Role>** to assign this widget to specific user roles. Select **<By Group>** to assign this widget to specific groups.



9. Click **Add**.

Creating a Chart Widget

1. Navigate to **Overview > Reports**.
2. Click the **Dashboard Widgets** accordion and click the **Charts** folder.
3. Click **(Configuration)**, then click **(Add a new Widget)**.
4. In the **Basic Information** area, type in a **Title** and **Description**. By default the widget will be active as soon as you create it. To make it inactive, uncheck the **Active** box.
5. From the **Chart Report** area, select a chart to display in the widget.

6. In the **Timer** area, click the **Run** drop down to specify how often you want the widget data to get updated. The options displayed will depend on which **Run** option you choose. Select **Hourly**, **Daily**, **Weekly**, or **Monthly**.

7. Select a **Time Zone**. Type or select a date to begin the schedule in **Starting Date**. Select a **Starting Time** based on a 24 hour clock in the selected time zone.

   Note:

   If you change the time zone, you will need to reset the starting date and time.

8. In the **Visibility** area, select **<To All Users>**, so that all users can use this widget no matter what user role they are assigned. Select **<By Role>** to assign this widget to specific user roles. Select **<By Group>** to assign this widget to specific groups.

9. Click **Add**.

Creating a Menu Widget

1. Navigate to **Overview > Reports**.
2. Click the **Dashboard Widgets** accordion and click the **Menus** folder.
3. Click **(Configuration)**, then click **(Add a new Widget)**.
4. In the **Basic Information** area, type in a **Title** and **Description**. By default the widget will be active as soon as you create it. To make it inactive, uncheck the **Active** box.

5. In the **Menu Shortcuts** area, use the **Add a Shortcut** dropdown to select all the places in the console that you want to add to this widget.
6. In the **Visibility** area, select **<To All Users>**, so that all users can use this widget no matter what user role they are assigned. Select **<By Role>** to assign this widget to specific user roles. Select **<By Group>** to assign this widget to specific groups.
7. Click **Add**.

Editing a Widget

1. Navigate to **Overview > Reports**.
2. Click the **Dashboard Widgets** accordion and select the widget you want to edit.
3. Click **(Configuration)**, and then **(Edit this Widget)**.
4. Make the required changes.
5. Click **Save**.

Copying a Widget

1. Navigate to **Overview > Reports**.
2. Click the **Dashboard Widget** accordion, and select the widget you want to copy.
3. Click **(Configuration)**, and then **(Copy this Widget)**.
4. Type a unique name for the widget and edit its properties.
5. Click **Save**.

Deleting a Widget

Note:

Default widgets cannot be deleted, but they can be copied.

1. Navigate to **Overview > Reports**.
2. Click the **Dashboard Widget** accordion and select the widget you want to delete.
3. Click **(Configuration)**, and then **(Delete this Widget from the Database)**.
4. Click **OK**.

Importing a Widget

You can share widgets between appliances using the export and import features.

1. Navigate to **Overview > Reports**.
2. In the **Import/Export** accordion, click **Widgets**.
3. In the **Import** area, click **Browse** to select an import file.
4. Click **Upload**.

Exporting a Widget

You can share widgets between appliances using the export and import features.

1. Navigate to **Overview > Reports**.
2. In the **Import/Export** accordion, click **Widgets**.
3. In the **Export** area, select the widgets that you want to export.
4. Click **Export**.

Generating Widget Content Immediately

1. Navigate to **Overview > Reports**.
2. Click the **Dashboard Widgets** accordion and select the widget you want to generate.

3. Click **(Configuration)**, and then **(Generate Widget Content now)**.
4. Click **OK**.

The content is generated immediately instead of waiting for the next scheduled update. Generation of widget content is shown under **Tasks**, accessed from the settings menu.

Reports

Click the **Reports** accordion under **Overview > Reports** to see a list of reports available. These reports have been constructed to help you view the most commonly requested and significant data. From here, you can also create reports if you have appropriate access. Infrastructure Automation provides a large group of default reports organized into categories. Each category has its own set of subfolders.

- **Configuration Management**: hardware, application, network, service, user account, operating system, and snapshot information for all of your items.
- **Migration Readiness**: information related to items required to migrate a virtual machine.
- **Operations**: free space on registered and unregistered virtual machines, power states for virtual machines, and SmartState analysis status.

  This category also provides reports relating to the operation of Infrastructure Automation, such as user IDs and snapshots taken by Infrastructure Automation.
- **VM Sprawl**: usage information and disk waste.
- **Relationships**: virtual machine, folder, and cluster relationships.
- **Events**: operations and configuration management events.
- **Performance by Asset Type**: performance of your virtual infrastructure.

  You must be capturing capacity and utilization data to get this information.
- **Running Processes**: information on processes running on a virtual machine.

  You must have domain credentials entered for the zone to collect the information for these reports, and the virtual machine must have been analyzed at least once.
- **Trending**: projections of datastore capacity, along with host CPU and memory use.
- **Tenants**: quotas report aggregated by each tenant that shows quota name, total quota, in use, allocated, and available. The report currently lists all tenants and there is no nesting information available by parent and child tenants.
- **Provisioning**: provisioning activity based on the approver, datastore, requester, and virtual machine.

For a complete list of reportable fields in Infrastructure Automation, see Reportable Fields.

Running Reports

There are two different ways to generate a report: by scheduling the report, or running the report manually by clicking the report generation button on the **Reports** page. Infrastructure Automation uses interactive report generation so that reports are placed on a queue. A visual indicator of the reports status is shown. All reports are automatically saved so that they can be downloaded and analyzed later.

Generating a Single Report

1. Navigate to **Overview > Reports**.
2. Click the **Reports > All Reports** accordion. Navigate to the report you want to view by selecting the appropriate folder.
3. Click (**Queue**).
4. The report generation is placed on the queue and its status shows in the reports page.

	Queued At	Run At	Source	User ID	Status
	10/21/11 14:14:11 UTC		Requested by user	admin	Queued
	10/21/11 14:00:08 UTC	10/21/11 14:00:22 UTC	Requested by user	admin	Finished

5. Click **(Reload current display)** to update the status.
6. When a report has finished generating, click on its row to view it.

Scheduling a Report

You can view historical data by creating reports on a scheduled basis. In addition, scheduled reports can be emailed directly to users.

Note:

You may need to disable, change the report filter, or change the frequency of a schedule. To do this, you will need to edit the schedule.

There are two ways to schedule a report:

Add a new Schedule through the **Reports** accordion:

1. Navigate to **Overview > Reports**.
2. Select a report from the **Reports** accordion and click **Configuration**.
3. Click **Add a New Schedule** or click the Schedules accordion and click **Configuration** > **Add a New Schedule**.

or

Add a new Schedule through the **Schedules** accordion:

1. Navigate to **Overview > Reports**.
2. Click the **Schedules** accordion.
3. Click **Configuration**.
4. Click **Add a New Schedule**.

Adding new Schedule details.

1. In the **Basic Information** area, type in a **Name** and **Description** for the schedule.
   - By default, **Active** is checked to enable the scan.
2. The **Report Selection** area is pre-populated if you added the schedule directly from the report. If you are adding from the schedule according, use the **Filter** drop downs to select the report that you want to schedule.
3. In the **Timer** area, click the **Run** drop down to specify how often you want the analysis to run. Your options after that will depend on which run option you choose.
   - Click **Once** to have the analysis run just one time.
   - Click **Daily** to run the analysis on a daily basis. You will be prompted to select how many days you want between each analysis.
   - Click **Hourly** to run the analysis hourly. You will be prompted to select how many hours you want between each analysis.
   - Type or select a date to begin the schedule in **Starting Date**.
   - Select a **Starting Time** based on a 24 hour clock in the Infrastructure Automation appliance's Time Zone.
4. Use the **E-Mail after Running** feature to send an email after the report has been generated to selected users. The email will include a link to the report.
   - Check **Send an E-mail**.
   - In **From (leave blank for default)**, type in the sending email.
   - Use **Add a User**, to select a specific user. The user must have a valid email address entered under accounts.
   - Use **Add (enter manually)** to type in the address not registered to a User.
   - Then, click **(Add)**.
5. If you are sending an email after the report runs, then you can select further options under Email Options.
   - Check **Send if Report is Empty** if you want an email even if no records exist in the report.
   - Next to Attachments, check if you would like the report attached as a **Text**, **CSV**, or **PDF** file.
6. Click **Add**.

Note:

See Outgoing SMTP Email Settings in the *General Configuration* guide, to learn how to verify the address and validate outgoing email settings.

Modifying a Report Schedule

1. Navigate to **Overview > Reports**
2. Click the **Schedules** accordion and select the schedule you want to edit.
3. Click (**Configuration**), then click (**Edit this Schedule**).
4. Make the required changes.
5. Click **Save**.

Running a Scheduled Report Immediately

1. Navigate to **Overview > Reports**.
2. Click the **Schedules** accordion and select the schedule you want to run.

3. Click (**Configuration**), then click (**Queue up this Schedule to run now**).

Viewing Reports

Once you have run a report, you can view it at any time after the first scheduled time has occurred.

1. Navigate to **Overview > Reports**.
2. Click the **Saved Reports** accordion or the **Reports** accordion.
3. Click on the instance of the report you want to view.

Changing Report Views

After running a report, you can customize your view in several ways.

Some reports can be viewed as charts as well as lists. This will depend on the type of data and on how the report has been created. Where applicable, you will see these additional buttons:

1. Navigate to **Overview > Reports**.
2. Click a completed report to view. Click one of the following buttons for the view you want:
   - Click for **Graph View**.
   - Click for **Hybrid View**.
   - Click for **Tabular View**.

Filtering Report Data

To filter the report information you see, use the **Data View** button.

1. Navigate to **Overview > Reports**.
2. Click a completed report to view.
3. Click the button for **Data View**, which opens the search field.
4. Select the criteria from the dropdown menu to filter by, and enter your search term.
5. Press **Enter** to search.

Sorting Reports by Column

In tabular and hybrid view, you can sort a list of reports by column.

1. Navigate to **Overview > Reports > Saved Reports**.
2. Click a report name to show a list of completed reports.
3. Click any blue column heading to sort the reports by the values in that column.

Downloading a Report

Download reports to analyze the data using other tools or to print the report.

When you click on one of the supplied reports, you are presented with a group of buttons to download the report in one of three formats or to view the report in a full screen.

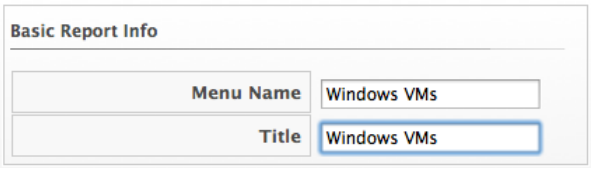
1. Navigate to **Overview > Reports**.
2. Click the report you want to view.
3. Click on the row for the instance of the report you want to download. If the report needs to be generated, see Running Reports.
4. Click on the report download buttons for the type of export you want.
   - Click **(Download this report in text format)** to download as text.
   - Click **(Download this report in csv format)** to download as a comma-separated file.
   - Click **(Download this report in PDF format)** to download as PDF.
   - The report is automatically named with the type of report and date.

Note:

Edit and delete buttons are only visible to administrators and super administrators. Edit and delete functions are only available to customer-created reports. The Infrastructure Automation pre-configured reports cannot be edited or deleted, but they can be copied.

Showing a Report in Full Screen

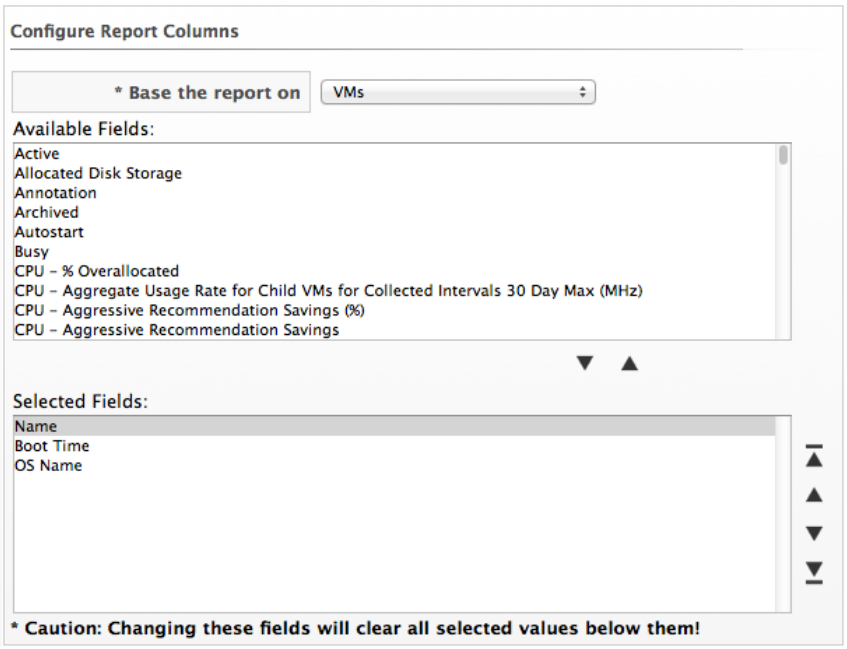
View the report in full screen to examine report details. From full screen, you can also print the chart that accompanies a report.



1. Navigate to **Overview > Reports**.
2. Click the **Reports > All Reports** accordion and select the report that you want to view.
3. Click the **Saved Reports** tab and select a report.
4. On the **Saved Report** detail screen, click (**Configuration**), and click (**Show full screen Report**).

The report will appear in full screen view. Click back on your browser to return to the reports explorer.

Adding a Report



Add reports if the default reports do not include what you need or you want to narrow the scope of a report. For example, you may want a report that shows only Windows virtual machines.

1. Navigate to **Overview > Reports**.
2. Click the **Reports > All Reports** accordion.
3. Click **(Configuration)**, then click **(Add a New Report)**.
4. In the **Columns** tab, edit the **Basic Report Info** area.

   - Type a unique name in **Menu Name** for how you want the report described in the menu list.
   - Type the **Title** you want displayed on the report in title.

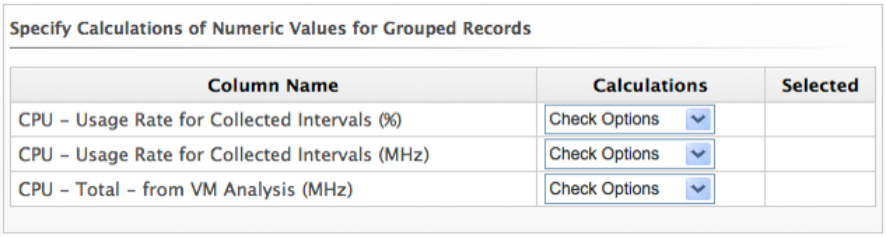
5. Add fields in the **Configure Report Columns** area.

   - Use the **Base the report on** table dropdown to choose a table to get fields from.

     Note:

     If you change the report base or the interval, all selections below will be reset.

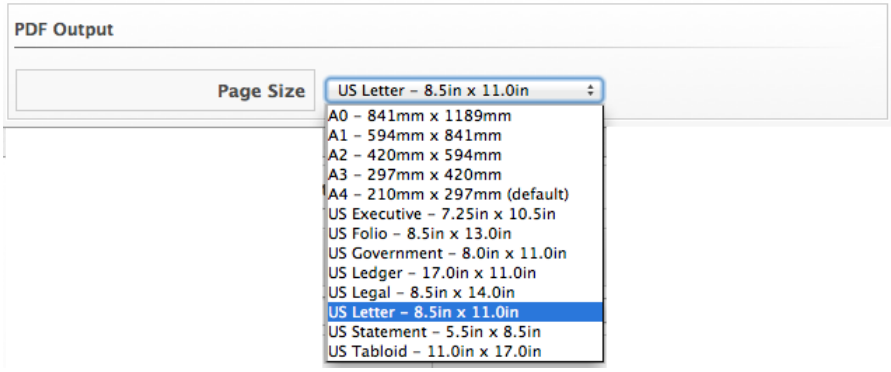
   - Select fields that you want in the report from **Available Fields**, and then click **(Move selected fields down)**. In addition to the fields, you can also select any tags that you have created and assigned.
   - Change the order of the fields in the report by clicking **(Move selected fields up)** or **(Move selected fields down)**.



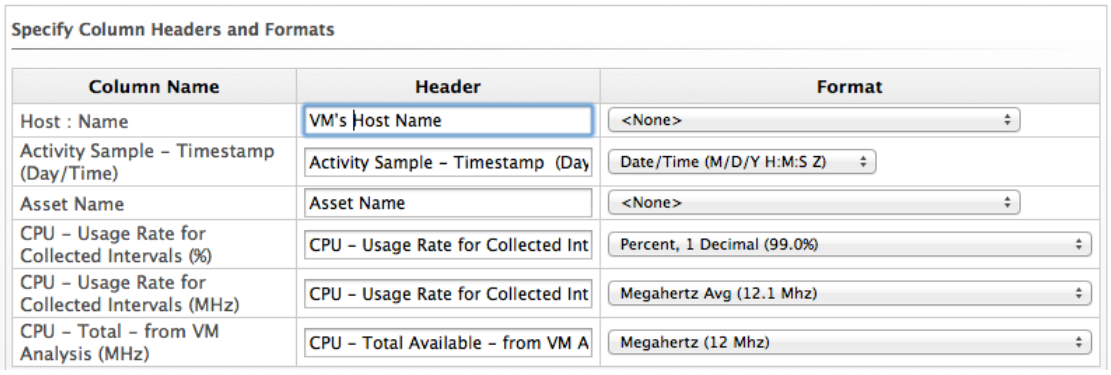
6. Click on the **Consolidation** tab to consolidate and aggregate data points into maximum, minimum, average, and total. Specifically, this would be useful for analyzing performance data over a specific period of time.

Note:

Please note that if you do this, you will not see individual records, but rather the calculation as a column header.

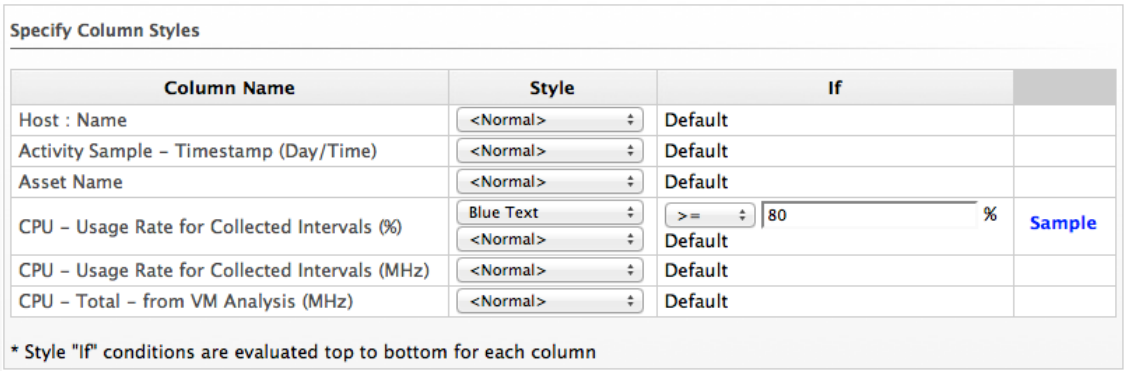


- Select the columns to group by.



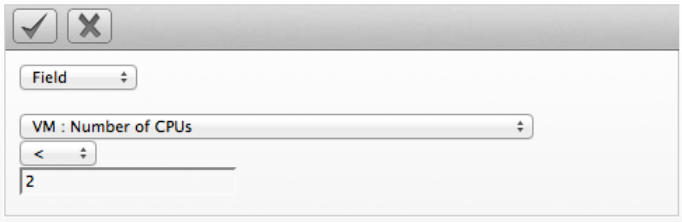
- For each numeric field selected in the report, you can click the dropdown under **Calculations**. Check the calculations you want to use.

7. Click on the **Formatting** tab to set the size of paper for a PDF and column header format.

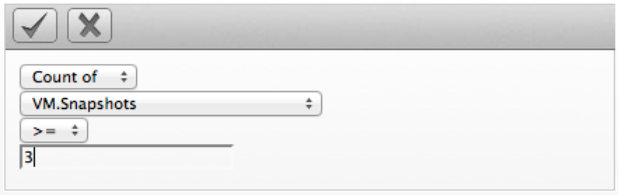


- From the **PDF Output** area, select the page size from the dropdown.

- From **Specify Column Headers and Formats**, type the text you want displayed for each field. For each numeric field, you can also set the numeric format.



8. Click on the **Styling** tab to change the color of the text or the background for a row based on a condition.



- Use **Style** to select the format for the value. You can choose to change the text color or the background.
- Use **If** to create a conditional statement for the style.

9. Click on the **Filter** tab to set filters for the data displayed in the report. There are two types of filters: the first is the **Record Filter** which is the primary filter of the main tables records, the second is also a **Display Filter**, which is a secondary filter of rows based on the fields of the child table. Click in the appropriate area to use the expression editor to choose the appropriate options for your criteria. Based on what you choose, different options will show.

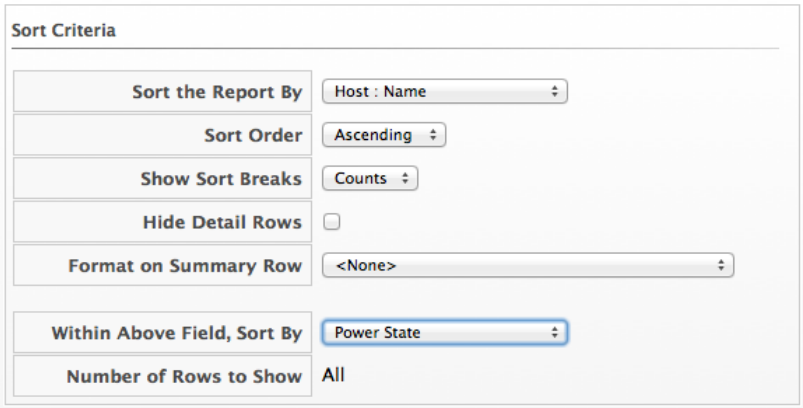
   - Click **Field** to create criteria based on field values.

   - Click **Count of** to create criteria based on the count of something, such as the number of snapshots for a virtual machine, or the number of virtual machines on a host.

   - Click **Tag** to create criteria based on tags assigned to your resources. For example, you may want to check the power state of a virtual machine or see if it is tagged as production.

   - Click **Registry** to create criteria based on registry values. For example, you may want to check if DCOM is enabled on a Windows system. (Note that this applies only to Windows operating systems.)

   - Click **Find** to seek a particular value, and then check a property. For example, finding the `Admin` account and checking that it is enabled.

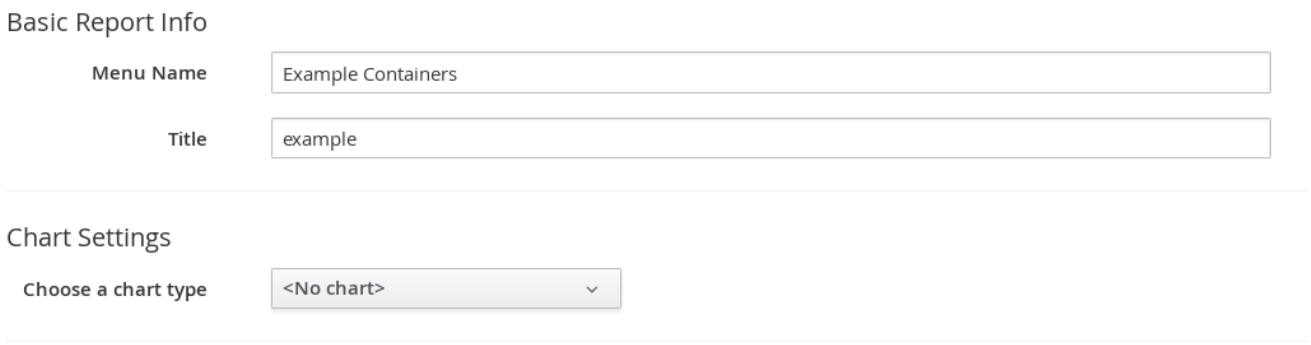


- Click ✓ **(Commit Expression Element Changes)** to add the expression.

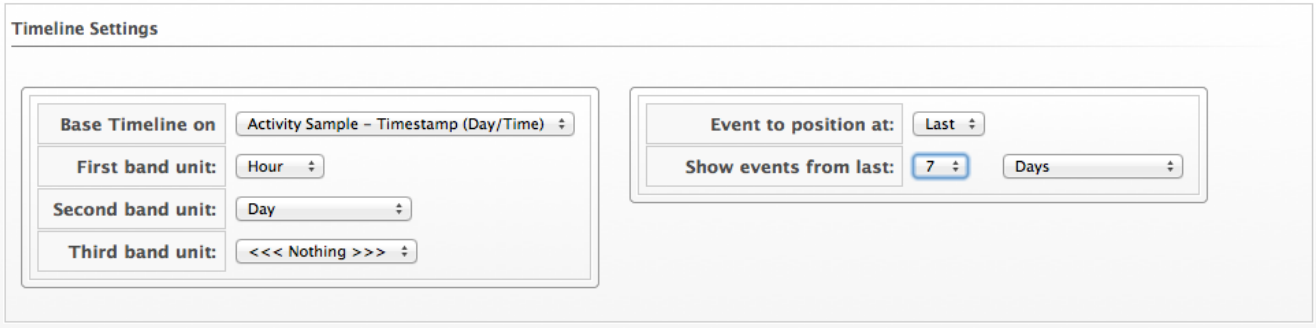
  Note:

  The filters that you apply will show at the bottom of the report so that you know which filters have been applied.

10. Click on the **Summary** tab to select sort order, sort type, groupings, and group calculations for the report. **Summary** groups rows of data based on the sort breaks. You can only sort by fields that display in the report.



- Set the primary sort in **Sort the Report by**.
- Set the next sorts in **Within Above Field, Sort By**.
- Select the type of sort, ascending or descending, in **Sort order**.
- In **Show Sort breaks**, select **Yes** to show the sort breaks, **Counts** to show sort breaks with the count, or **No** for no sort breaks.



- For any numeric field, you can select to show minimum, average, maximum, and total in the sort break.

11. Click on the **Charts** tab to create a chart for the report. This is not required.

- Use **Choose a chart type** to select a type of chart. Note that some charts may not produce the result you are looking for based on the types of fields in the report and its sort order.
- If you only want to see the top values, select the number of top values from **Top values to show**.
- If you want to see the total number of values that are not categorized or evaluated against others, check **Sum 'Other' values**.

12. Click on the **Timeline** tab to select a timeline for the report. You must have a field of time or date format to use this feature.

- Use **Base Timeline on** to select a column in date or time format for the report.
- Select a unit of time for the first band in **First band unit**.
- Select a unit of time for the second band in **Second band unit**.
- Select a unit of time for the third band in **Third band unit**.
- Select an **Event to position at**.
- Select the range for the event to position from **Show events from last**.

13. Click the **Previews** tab to see a sample of your report.
14. When you have the report that you want, click **Add** to create the new report.

Note:

After the new report is created, to make the report accessible from the report menu, you must add it to a report menu.

Copying a Report

Use this feature to copy a report that is similar to one that you want to create. By copying a report, you only need to make minor edits instead of creating an entirely new report.

1. Navigate to **Overview > Reports**.
2. Click the **Reports > All Reports** accordion and select the report that you want to copy.
3. Click (**Configuration**), then click (**Copy this report**).
4. On the Columns tab, edit the **Basic Report Info** area to include a new **Menu Name**. Each **Menu Name** must be unique.
5. Make any other changes you need. See "Adding a Report" for details on the changes you can make.
6. Click **Add**.

Editing a Report

If you find that a report is not giving you the data that you need, you can edit it after it has been created. Note that only reports that you have created can be modified. Only administrators and super administrators of Infrastructure Automation can add, copy, edit, and delete reports.

1. Navigate to **Overview > Reports**.
2. Click the **Reports > All Reports** accordion and select the report you want to edit.
3. Click (**Configuration**), (**Edit this Report**).
4. Make any changes you need.
5. Click **Save**.

Deleting a Report

Delete reports when you find that they are no longer useful. Only administrators and super administrators of Infrastructure Automation can add, copy, edit, and delete reports.

Note:

Please note that only customer-created reports can be deleted.

1. Navigate to **Overview > Reports**.
2. Click the **Reports > All Reports** accordion and select the report you want to delete.
3. Click (**Configuration**), (**Delete this Report from the Database**).

   Note:

   The **Delete this report from the Database** option will only appear on reports you have created. Default reports cannot be deleted.
4. Click **OK**.

Importing a Report

Reports are stored in the VMDB; however, you can share customized reports among VMDBs. To do this use the export and import feature of reports.

1. Navigate to **Overview > Reports**.
2. Select **Custom Reports** from the **Import/Export** accordion.
3. In the **Import** area, click **Browse** to select an import file.
4. To overwrite an existing report with the same menu name, select **Overwrite existing reports**.
5. Click **Upload** to import the report to the **Company-Custom** folder.

Exporting a Report

Reports are stored in the VMDB. Custom reports may be shared among VMDBs. Share your custom reports using the export and import features.

1. Navigate to **Overview > Reports**.
2. Select **Custom Reports** from the **Import/Export** accordion.
3. In the **Export** area, select the reports to export.
4. Click **Export**.

Managing Report Menus

By default, all account roles have the same reports available. If you have the super administrator or administrator role, you can customize the accordions, the folders within them, and the locations of your reports.

Note:

When you create your own report, the report is not automatically available. You must add it to a report menu.

The report menu is a hierarchical structure that consists of the following components:

- The top level, under which the accordions are shown. (Top level is only displayed when you are in the report menu editor.)
- Accordions that are general categories for the reports. The defaults supplied are **Configuration Management**, **Migration Readiness**, **Operations**, **VM Sprawl**, **Relationships**, **Events**, **Performance by Asset Type**, **Trending**, **Tenants**, **Provisioning**, and **Running Processes**.
- Folders that are used to further organize reports within an accordion. For example, under the **Configuration Management**, there are folders for virtual machines, hosts, and other virtual infrastructure components.
- Reports that are stored directly in the folders.

Managing Report Menu Accordions

1. Navigate to **Overview > Reports**.

2. Click the **Edit Report Menus** folder.
3. Click the role whose menus you want to customize.
4. Click on **Top Level** to organize, add, and delete folders.
    - Click  **(Move selected folder to top)** to move the folder to the top of the list.
    - Click  **(Move selected folder up)** to move the folder up.
    - Click  **(Move selected folder down)** to move the folder down.
    - Click  **(Move selected folder to bottom)** to move the folder to the bottom of the list.
    - Click  **(Delete selected folder and its contents)** to delete a folder.
    - Click  **(Add folder to selected folder)** to add an folder.

      Note:

      If you are creating a new folder, **Top Level** must be selected under **Reports**. Be sure to select the folder you want to create a subfolder for on the left pane. To name the folder, double-click on **New Folder**, then click on **Top Level** in the **Reports** area.
5. When you are finished adding folders, click **Commit**. To revert, click **Discard**.
6. Click **Save**.

The new folder is added, and you can add folders in which to store reports to it. You can also organize the reports into folder that are meaningful to you.

Managing Report Menu Folders

1. Log in to the console as a user who is assigned either the super administrator or administrator account role.
2. Navigate to **Overview > Reports**.
3. Click the **Edit Report Menus** accordion.
4. Click the role whose menus you want to customize.
5. Click on the accordion name you want to organize or add folders to.
    - Click  **(Move selected folder to top)** to move the folder to the top of the list.
    - Click  **(Move selected folder up)** to move the folder up.
    - Click  **(Move selected folder down)** to move the folder down.
    - Click  **(Move selected folder to bottom)** to move the folder to the bottom of the list.
    - Click  **(Delete selected folder and its contents)** to delete an folder.
    - Click  **(Add subfolder to selected folder)** to add a folder. When creating a subfolder, be sure to select the folder that you want the subfolder to show under. To name the folder, double-click on `New Folder`.
6. When you are finished making changes click **Commit**. To revert, click **Discard**.
7. Click **Save**.

Note:

Only reports that are not already in another folder can be assigned.

Organizing Reports in Report Menus

1. Log in to the console as a user who is assigned either the Super Administrator or Administrator Account Role.
2. Navigate to **Overview > Reports**.
3. Click the **Edit Report Menus** accordion.
4. Click the role whose menus you want to customize.

5. Expand the **Report** accordion and menus using the triangles to the left of the item name until you are able to select the subfolder where you want to put reports.
6. Choose one of the following actions:
   - To add a report, select a report from the **Available Reports** area on the right and click  **(Move selected reports left)**.
   - To remove a report from a folder, select the report from the **Selected Reports** area and click  **(Move selected reports right)**.
   - To move a report to the top of the folder, select the report and click  **(Move selected reports to top)**.
   - To move a report up one place in the folder, select the report and click  **(Move selected reports up)**.
   - To move a report down one place in the folder, select the report and click  **(Move selected reports down)**.
   - To move a report to the bottom of the folder, select the report and click  **(Move selected reports to bottom)**.
7. When you are finished making changes click **Commit**.
8. Click **Save**.

The changes are made. The next time a user with this Account Role logs in, the new report and menu structure will be displayed.

Chargeback

The chargeback feature allows you to calculate monetary virtual machine charges based on owner or company tag. To use this feature you must be collecting capacity and utilization data.

Chargeback Rates

Infrastructure Automation provides a default set of rates for calculating chargeback costs, but you can create your own set of computing and storage costs by navigating to **Overview > Chargeback** and clicking the **Rates** accordion.

You can configure chargeback rates for various resources by selecting either **Compute** or **Storage** in the **Rates** accordion. **Compute** sets chargeback rates for CPU, disk I/O, fixed compute cost, memory, and network I/O items, while **Storage** sets chargeback rates for fixed storage cost and disk storage.

Chargeback costs are computed using a set formula based on hourly cost per unit and hourly usage.

Chargeback can be calculated in the following currencies:

- Australian dollar (AUD)
- Brazilian real (BRL)
- Swiss franc (CHF)
- Chinese yuan renminbi (CNY)
- Euro (EUR)
- Pound sterling (GBP)
- Indian rupee (INR)
- Japanese yen (JPY)
- South Korean won (KRW)
- Mexican peso (MXN)
- Norwegian krone (NOK)
- Russian ruble (RUB)
- Swedish krona (SEK)
- Turkish lira (TRY)
- United States dollar (USD)
- South African rand (ZAR)

Chargeback rates can be assigned at a single rate or by tiers, where rates are assigned in ranges depending on level of usage.

Additionally, chargeback can be calculated at one fixed rate, or by a combination of fixed and variable rates per tier. Fixed rates are charged once per unit of time, and the variable rate is calculated by the level of usage multiplied by the number of resources used in a unit of time.

Memory Used Cost

Calculating the Memory Used Cost in dollars ($) for a day can be expressed in the following ways:

- Memory allocation per hour (in MB) * Hourly Allocation cost per megabyte * Number of Memory Allocation metrics available for the day
- Sum of Memory allocation for the day (in MB) * Hourly Allocation cost per megabyte
- Sum of Memory allocation for the day (in MB) * Daily Allocation cost per megabyte / 24

Memory costs can be measured in B, KB, MB, GB, or TB.

In a scenario where 9.29 GB of memory is used in a day with the chargeback rate set at one dollar ($1) per megabyte per day, the Memory Used Cost would be $396.42.

- 9.29 GB = 9514.08 MB
- 9514.08 MB * $1 (per MB per day) = $9514.08
- $9514.08 / 24 = $396.42 Memory Used Cost

CPU Total Cost

The CPU Total Cost is defined as the number of virtual CPUs over the selected interval (hour, day, week, month). CPU costs can be measured in units of Hz, KHz, MHz, GHz, or THz, as specified when creating a chargeback rate.

In a scenario where 16 CPUs are used in a day with the chargeback rate set at one dollar per CPU per day, the CPU Total Cost would be $16.

- 16 CPUs * $1 (per CPU per day) = $16 CPU Total Cost

CPU Used Cost

The CPU Used Cost is defined as the average CPU used in MHz over the selected rate interval (hour, day, week, month). CPU Used Cost is not supported for containers providers.

In a scenario where 2.5 GHz is used in a day with the chargeback rate set at $0.01 per MHz per day, the CPU Used Cost would be $25.

- 2.5 GHz = 2500 MHz
- 2500 MHz * $0.01 (per MHz per day) = $25 CPU Used Cost

Storage Allocated Cost

The Storage Allocated Cost is defined as the Allocated Disk Storage in bytes over the selected rate interval (hour, day, week, month). Storage costs can be measured in B, KB, MB, GB, or TB.

In a scenario where 500 GB are used in a day with the chargeback rate set at $0.10 per GB per day, the Storage Allocated Cost would be $50.

- 536,870,912,000 bytes = 500 GB
- 500 GB * $0.10 (per GB per day) = $50 Storage Allocated Cost

Storage Total Cost

The Storage Total Cost is defined as the Used Disk Storage in bytes over the selected rate interval (hour, day, week, month).

In a scenario where 250 GB are used in a day with the chargeback rate set at $0.10 per GB per day, the Storage Total Cost would be $25.

- 268,435,456,000 bytes = 250 GB
- 250 GB * $0.10 (per GB per day) = $25 Storage Total Cost

Storage Used Cost

The Storage Used Cost is defined as the Used Disk Storage in bytes over the selected rate interval (hour, day, week, month).

In a scenario where 250 GB are used in a day with the chargeback rate set at $0.10 per GB per day, the Storage Used Cost would be $25.

- 268,435,456,000 bytes = 250 GB
- 250 GB * $0.10 (per GB per day) = $25 Storage Used Cost

Note:

The following chargeback rates are not supported for containers providers:

- Allocated CPU count
- Used CPU
- Used disk I/O
- Allocated memory

Creating Chargeback Rates

Infrastructure Automation allows you to create your own set of computing and storage costs to use for billing.

Chargeback rates can be configured at a single rate or in tiers, where one rate is assigned to one usage range, and another rate is assigned to a different usage range. You can also assign fixed and variable rates per tier if desired.

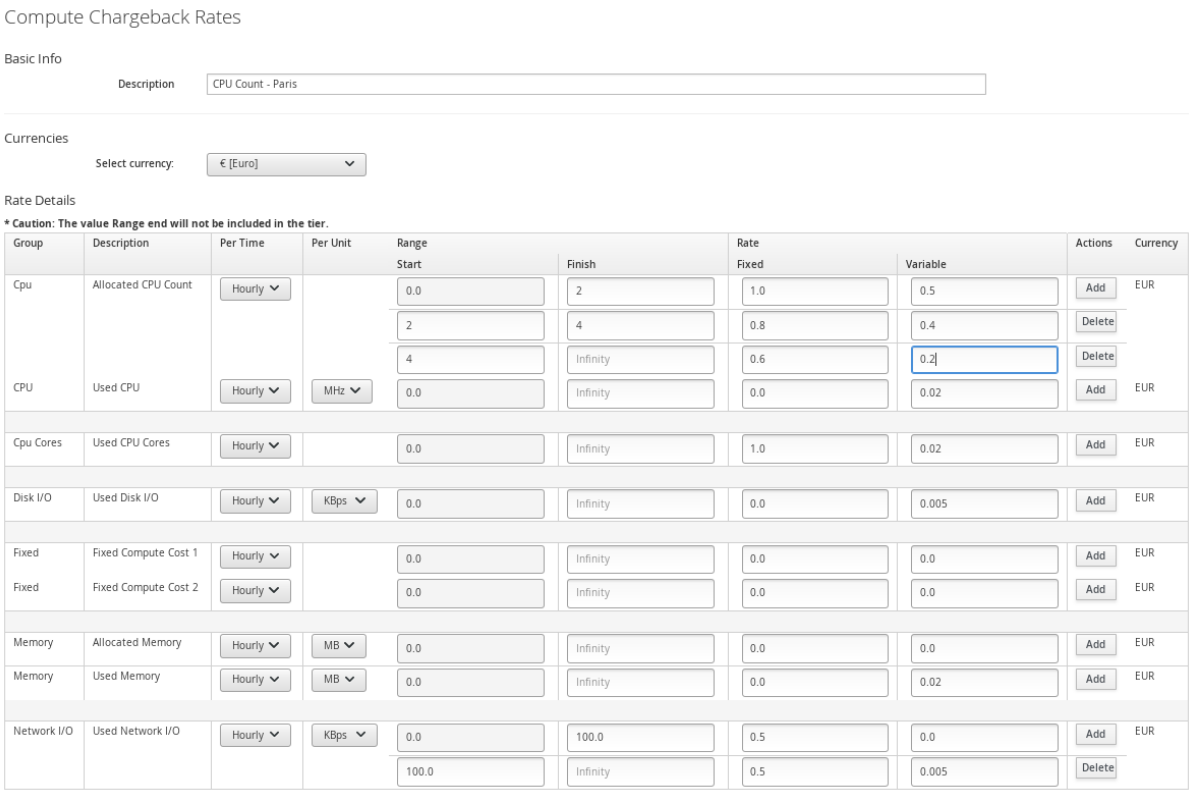
There are three methods to create a chargeback rate: editing or copying an existing rate, or creating a new rate.

Editing a Chargeback Rate

1. Navigate to **Overview > Chargeback**.
2. Click the **Rates** accordion and select an existing rate from under **Compute** or **Storage**.
3. Click **(Configuration)** and **(Edit this Chargeback Rate)**.
4. Edit the rate as desired.
5. Click **Save** at the bottom of the screen to save the chargeback rate.

Copying a Chargeback Rate

1. Navigate to **Overview > Chargeback**.
2. Click the **Rates** accordion and select an existing rate from under **Compute** or **Storage**.
3. Click **(Configuration)** and **(Copy this Chargeback Rate)**.
4. Edit the rate as desired.
5. Click **Add** at the bottom of the screen to save the chargeback rate.



Adding a Chargeback Rate

The following example shows a scenario to create a new chargeback rate for allocated CPU usage in Euro per week measured by the following tiers, calculating both fixed and variable costs:

- Tier 1: 0-2 CPU = 1 Euro fixed + 0.5 Euro variable
- Tier 2: 2-4 CPU = 0.8 Euro fixed + 0.4 Euro variable
- Tier 3: 4 CPU and above = 0.6 Euro fixed + 0.2 Euro variable

To configure this rate:

1. Navigate to **Overview > Chargeback**.
2. Click the **Rates** accordion and select **Compute** to create a CPU chargeback rate.
    1. Click **(Configuration)** and **(Add a new Chargeback Rate)**.
3. Type in a **Description** for the chargeback rate.
4. Select **Euro** for currency.
5. In **Rate Details**, select the time, and fill in the range and rates for each tier. Alternatively, a single chargeback rate can be configured by using only one tier. For this example, in **Allocated CPU Count**, configure:
    1. For tier 1, set:
        1. In **Per Time**, select **Hourly**.
        2. In **Range**, specify the CPU range: **Start** remains as `0.0` and **Finish** is `2`.
        3. In **Rate**, specify `1` for the **Fixed** rate, and `0.5` for the **Variable** rate.
        4. Click **Add** under **Actions** to create a new, blank **Allocated CPU Count** line for tier 2.
    2. For tier 2, set:
        1. In the new line in **Range**, specify the CPU range: **Start** is `2` and **Finish** is `4`.
        2. In **Rate**, specify `0.8` for the **Fixed** rate, and `0.4` for the **Variable** rate.
        3. Click **Add** under **Actions** to create another new, blank **Allocated CPU Count** line for tier 3.
    3. For tier 3, set:
        1. In the new line in **Range**, specify the CPU range: **Start** is `4` and leave **Finish** as `Infinity`.
        2. In **Rate**, specify `0.6` for the **Fixed** rate, and `0.2` for **Variable**.

6. Click **Add** at the bottom of the screen to save the chargeback rate.

The rate can now be assigned.

Assigning Chargeback Rates

Infrastructure Automation allows you to assign chargeback rates by choosing from **Compute** and **Storage**. You can assign either a custom chargeback rate, or a default rate for Compute, Storage, or Container Images.

Note:

The **Default Container Image Rate** can be useful when applied to a containers provider with multiple images, where only some of the images have a chargeback rate assigned; the images without a custom rate will then use the default rate.

1. Navigate to **Overview > Chargeback**.
2. Click the **Assignments** accordion, and click either **Compute** or **Storage**.

Configuring Chargeback for Compute

Use **Compute** to assign a compute chargeback rate. You can assign chargeback rates to **The Enterprise**, **Selected Cloud/Infrastructure Providers**, **Selected Clusters/Deployment Roles**, **Selected Containers Providers**, **Tagged VMs and Instances**, **Tagged Images**, **Labeled Images**, or **Tenants**.

1. From the **Basic Info** area, use the **Assign To** list to select a type of assignee to assign the rate set to.
2. For **Tagged VMs and Instances** and **Tagged Images** select a **Tag Category**.
3. For each item to set, select the chargeback rate to use. The options displayed vary based on the type you select.
4. Click **Save**.

Configuring Chargeback for Storage

Use **Storage** to assign a storage chargeback rate. You can assign chargeback rates to **The Enterprise**, **Selected Datastores**, **Tagged Datastores**, or **Tenants**.

1. From the **Basic Info** area, use the **Assign To** list to select a type of assignee to assign the rate set to.
2. For **Tagged Datastores** select a **Tag Category**.
3. For each item to set, select the chargeback rate to use. The options displayed vary based on the type you select.
4. Click **Save**.

The rate is assigned. The next time you generate a chargeback report, these values will be used.

Note:

When viewing chargeback, there is a rate for a virtual machine for the number of the CPUs. The chargeback for this parameter is calculated based on when the virtual machine is running. If the virtual machine is not running, then it is not charged for CPU allocation.

Creating a Chargeback Report

Infrastructure Automation allows you to create chargeback reports to monitor costs you charged.

Note:

When creating a chargeback report, the **Total Cost** is the complete cost for the chosen workload over the selected time frame. Total costs are calculated by adding the calculated costs for the amount used and the amount allocated for the time frame. When adding cost related columns to display on your report, be sure to select all rate assigned fields to present a comprehensive accounting of total costs.

1. Browse to menu: **Overview > Reports**.
2. Click the **Reports** accordion.
3. Click **Configuration**, then click **Add a new Report**.
4. On the **Columns** tab, fill out the **Basic Report Info** area.
   - Type a unique name in **Menu Name** for how you want the report described in the menu list.
   - Type the **Title** to display on the report.
5. Add fields in the **Configure Report Columns** area.
   - From the **Base the report on** list, select **Chargebacks**.
   - Select the fields to include in the report from the **Available Fields** list, then click **Move selected fields down**. In addition to the fields, you can also select any tags that you have created and assigned.
   - Change the order of the fields in the report by clicking **Move selected fields up** or **Move selected fields down**.
6. Click the **Formatting** tab to set the size of paper for a PDF and column header format.
   - From the **PDF Output** area, select the page size from the **Page Size** list.
   - From **Specify Column Headers and Formats**, type the text to display for each field. For each numeric field, you can also set the numeric format.
7. Click the **Filter** tab to set filters for the data displayed in the report.
   - From **Chargeback Filters**, select how you want the costs to show, the tag category, the tag, and how you want the items grouped.
   - From **Chargeback Interval**, select the time interval. You must have a full interval worth of data in order to select an option other than **Partial** in the **Daily Ending With** list.
8. Click the **Preview** tab, and then **Load** to see what the report will look like.
9. When you are satisfied that you have the report that you want, click **Add** to create the new report.

The new report is created. To make the report accessible from the **Report** menu, you must add it to a report menu.

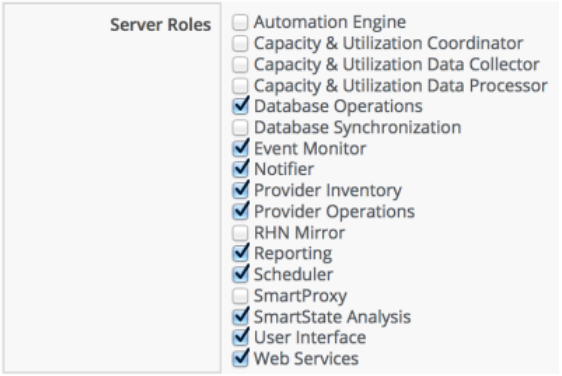
Optimization

Optimization provides administrators with a series of reports to provide meaningful information on areas for optimizing resources such as CPU, memory and disk and identify potential savings.

Running an Optimization Report

1. Navigate to **Overview > Optimization**.
2. Click **Queue Report** for each report type you choose to run.

Viewing Optimization Reports



1. Navigate to **Overview > Optimization**.
2. Click on the report type you wish to view details for.
3. On the report type screen, click on a report instance to view details.
4. Sort reports by clicking on the field names at the top of the report.

Alerts

Assigning the Notifier Role

1. Click (**Configuration**).
2. Click the **Settings** accordion, and select the Infrastructure Automation server.

3. From the **Server Control** tab, select the **Notifier** role.

4. Click **Save**.

Creating an Alert

This section outlines the basic procedure to create an alert.

Note:

To send emails or SNMP traps from the Infrastructure Automation server, you must enable the Notifier server role and set up SMTP email or SNMP traps. For more information, see *General Configuration*.

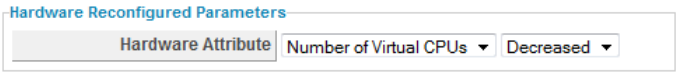
1. Navigate to **Control > Explorer**.
2. Click the **Alerts** accordion, then click (**Configuration**), (**Add a New Alert**).
3. Enter the basic details of the alert:
    1. Enter a description in the **Description** field.
    2. Select the **Active** check box to enable the alert after creation.
    3. Select the severity level from the **Severity** list.
    4. Select the inventory item on which to base the alert from the **Based On** list.
    5. Select the type of event that triggers the alert from the **What to Evaluate** list.
    6. Select the frequency with which to be notified if the event log threshold is reached from the **Notification Frequency** list.
4. Configure the parameters of the alert.

    Note:

    The available parameters depend on the options you selected in the **Based On** and **What to Evaluate** lists. See later sections for the details of these parameters.
5. Optionally, select **Send an E-mail** to configure options so that an email is sent when the alert is triggered:
    1. Enter the email address from which to send the email in the **From** field.
    2. Select a user from the **Add a User** list to add a user registered in Infrastructure Automation. The user must have a valid email address entered under accounts.
    3. Enter the email address of a user in the **Add (enter manually)** field and click + to add a user not registered in Infrastructure Automation.
6. Optionally, select **Send an SNMP Trap** to configure options so that an SNMP trap is sent when the alert is triggered:
    1. Enter the IP addresses of the hosts to send the trap in the **Host** fields.
    2. Select the version of SNMP to use from the **Version** list:
        1. If you select **v1**, enter a trap number in the **Trap Number** field. Enter **1**, **2**, or **3**, based on the appropriate suffix number in table_title.
        2. If you select **v2**, enter a trap object ID in the **Trap Object ID** field. Enter **info**, **warning**, or **critical** based on the values in table_title.

Object ID	Suffix Number Added to PEN	PEN with the Suffix Added
info	1	1.3.6.1.4.1.33482.1
warn, warning	2	1.3.6.1.4.1.33482.2
crit, critical, error	3	1.3.6.1.4.1.33482.3

SNMP Trap Identifiers



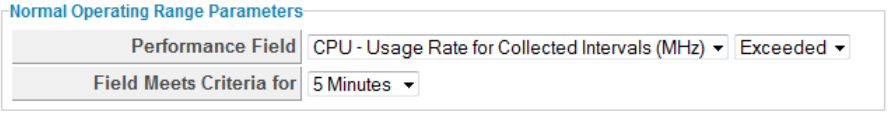
7. Optionally, select **Send a Management Event** to trigger an automation event:
    1. Enter the name of the event that exists in the **Process/Event Class** in the **Event Name** field.

8. Click **Add**.

Creating a Hardware Reconfigured Alert

Use a hardware reconfigure alert to detect changes to the amount of memory or the number of CPUs on a virtual machine.

1. Navigate to **Control > Explorer**.
2. Click the **Alerts** accordion, then click (**Configuration**), (**Add a new Alert**).
3. In the **Info** area:
   - Type in a description for the alert.
   - From **Based On**, select **VM and Instance**.
   - From **What to Evaluate**, select **Hardware Reconfigured**.
   - In **Notification Frequency**, select how often you want to be notified if hardware reconfiguration is detected.
4. From **Hardware Attribute**, select Number of CPUs. From the next dropdown, select **Decreased**.



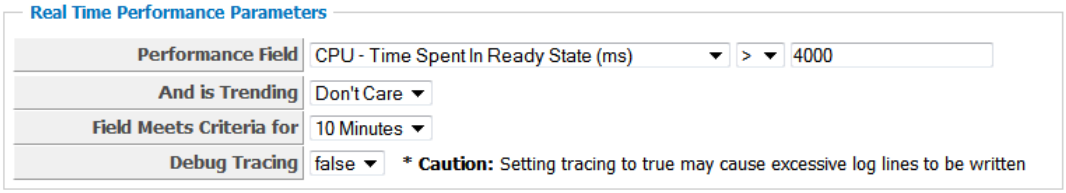
5. After setting the parameters, select what you want the alert to do. You can send an email, create an SNMP Trap, or send a management event to start an automation process.
6. Click **Add**.

Creating a Normal Operating Range Alert

Normal operating range alerts enables you to be notified when the normal operating range is exceeded, or falls below for a period of time from 1 minute to 2 hours. Capacity and utilization must be enabled for normal operating ranges to be calculated. See *General Configuration* for more information.

1. Navigate to **Control > Explorer**.
2. Click the **Alerts** accordion, then click (**Configuration**), (**Add a new Alert**).
3. In the **Info** area:
   - Type in a **Description** for the alert.
   - From **Based On**, select **VM and Instance**.
   - For **What to Evaluate**, select **Normal Operating Range**.
   - In **Notification Frequency**, select how often you want to be notified if the performance threshold is reached.
4. Set the threshold in the **Normal Operating Range Parameters** area.

   - From **Performance Field**, select the field to check and whether you want to be notified if the field is exceeded or fell below.
   - In **Field Meets Criteria for**, select the amount of time that the threshold requires to be met to trigger the alert.
5. After setting the parameters, you then select what you want the alert to do. You can send an email, create an SNMP Trap, or send a management event to start an automation process. See Creating an Alert.
6. Click **Add**.



Creating a Real Time Performance Alert

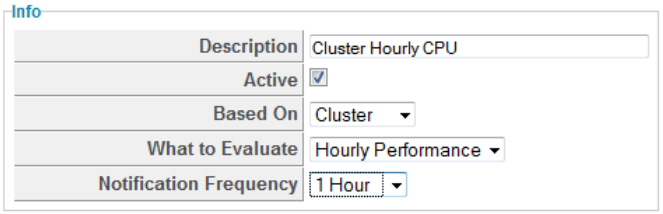
Real Time Performance alerts enables you to be notified immediately when a performance threshold has been met for a virtual machine, host, or cluster. Capacity and Utilization must be enabled for performance thresholds to be detected.

1. Navigate to **Control > Explorer**.
2. Click the **Alert** accordion, then click (**Configuration**), (**Add a new Alert**).
3. In the **Info** area:
   - Type in a **Description** for the alert.
   - From **Based On**, select **VM and Instance**.
   - For **What to Evaluate**, select **Real Time Performance**.

- In **Notification Frequency**, select how often you want to be notified if the performance threshold is reached.

4. Set the threshold in the **Real Time Performance Parameters** area.

   - From **Performance Field**, select the field to check and any other parameters required for that field.
   - In **And is Trending**, select **Don't Care** if it does not matter how the performance metric is trending. Otherwise, choose from the possible trending options.
   - In **Field Meets Criteria for**, select the amount of time that the threshold requires to be met to trigger the alert.
   - Set **Debug Tracing** to true only when directed to do so by Red Hat Support. This provides an extremely detailed level of logging and can result in many more log lines being written.



5. After setting the parameters, you then select what you want the alert to do. You can send an email, create an SNMP Trap, or send a management event to start an automation process.

6. Click **Add**.

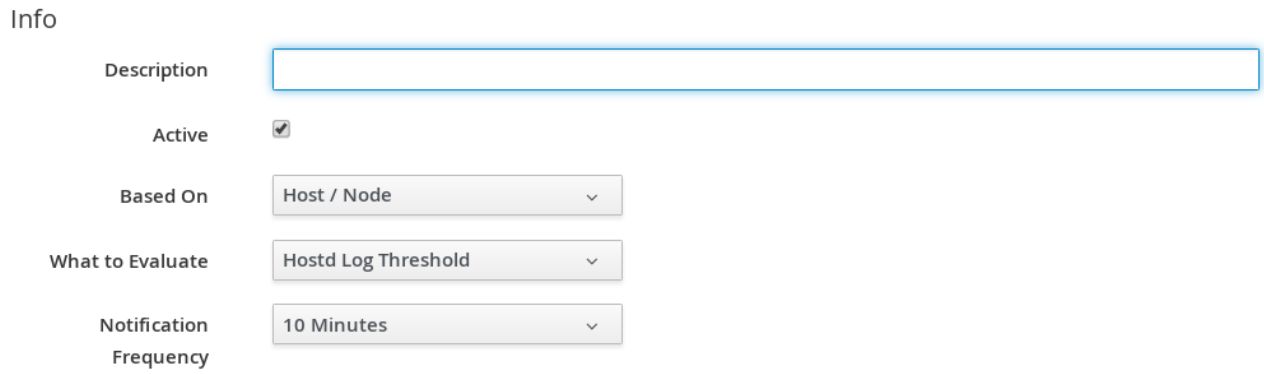
Creating an Hourly Performance Alert

Hourly performance alerts enable you to be notified immediately when an hourly performance threshold has been met for a cluster. Capacity and Utilization must be enabled for performance thresholds to be detected.

1. Navigate to **Control > Explorer**.
2. Click the **Alerts** accordion.
3. Click (**Configuration**), (**Add a new Alert**).
4. In the **Info** area:

   - Type in a **Description** for the alert.
   - From **Based On**, select **Cluster**.
   - For **What to Evaluate**, select **Hourly Performance**.
   - In **Notification Frequency**, select how often you want to be notified if threshold is met.

5. In the **Hourly Performance Parameters** area select performance field and the criteria. You can also select options from the **And is Trending** dropdown box and whether the **Debug Tracing** is true or false.



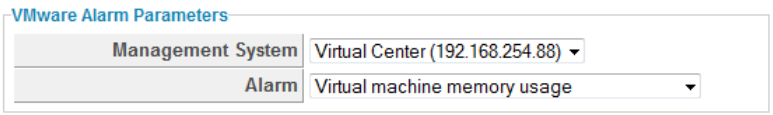
6. After setting the parameters, you then select what you want the alert to do. You can send an email, create an SNMP Trap, or send a management event to start an automation process.

7. Click **Add**.

Creating a hostd Log Threshold Alert

Use the **hostd Log Threshold** to send a notification when certain items are found in the event logs for a host. A default analysis profile with event log items is required for this feature. The following example shows steps to check the host's log for a failure to validate a virtual machine's IP address.

1. Navigate to **Control > Explorer**.
2. Click the **Alert** accordion.
3. Click (**Configuration**), (**Add a new Alert**).
4. In the **Info** area:



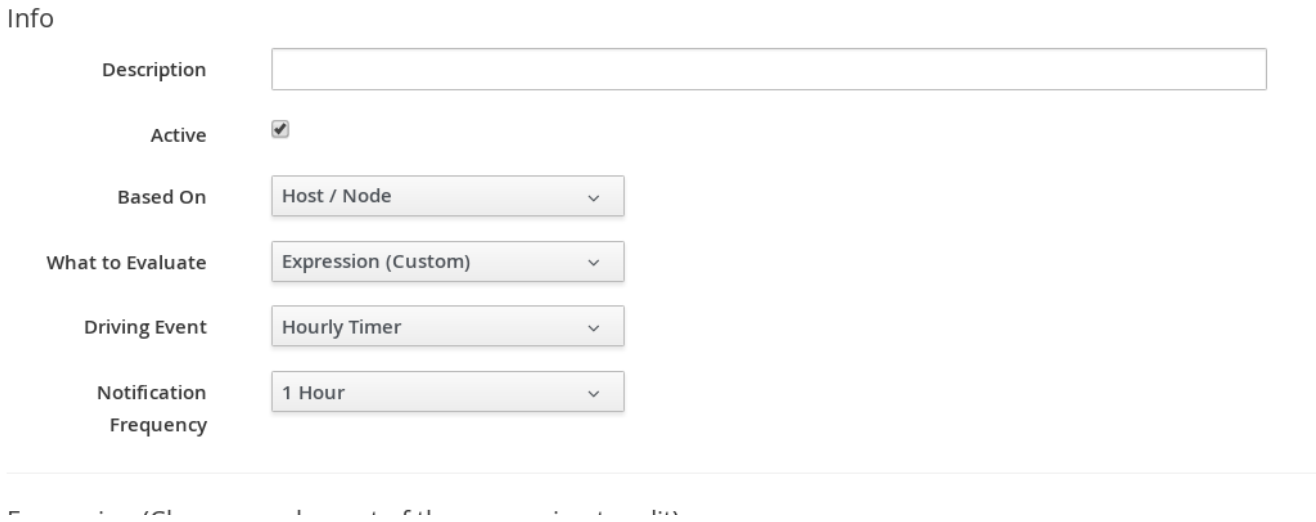
- Type in a **Description** for the alert.
- From **Based On**, select **Host/Node**.
- For **What to Evaluate**, select **Hostd Log Threshold**.
- In **Notification Frequency**, select how often you want to be notified if the log item is detected.

5. In the **Hostd Log Threshold Parameters** area, select the parameters for the event log message. You can set a threshold for a filter, level, or message source.
   - Use **Message Filter** to look for specific text in a message. Use **Message Level** to filter based on message level. Infrastructure Automation reports on the specified level and above. Use **Message Source** to filter log messages based on its source.
   - Set **How Far Back to Check** in days you want to look for this message.
   - If you only want an alert triggered when the log message has occurred a certain number of times, type the number in **Event Count Threshold**.
6. After setting the parameters, select what you want the alert to do. You can send an email, create an SNMP Trap, or send a management event to start an automation process.
7. Click **Add**.

Creating a VMware Alarm Alert

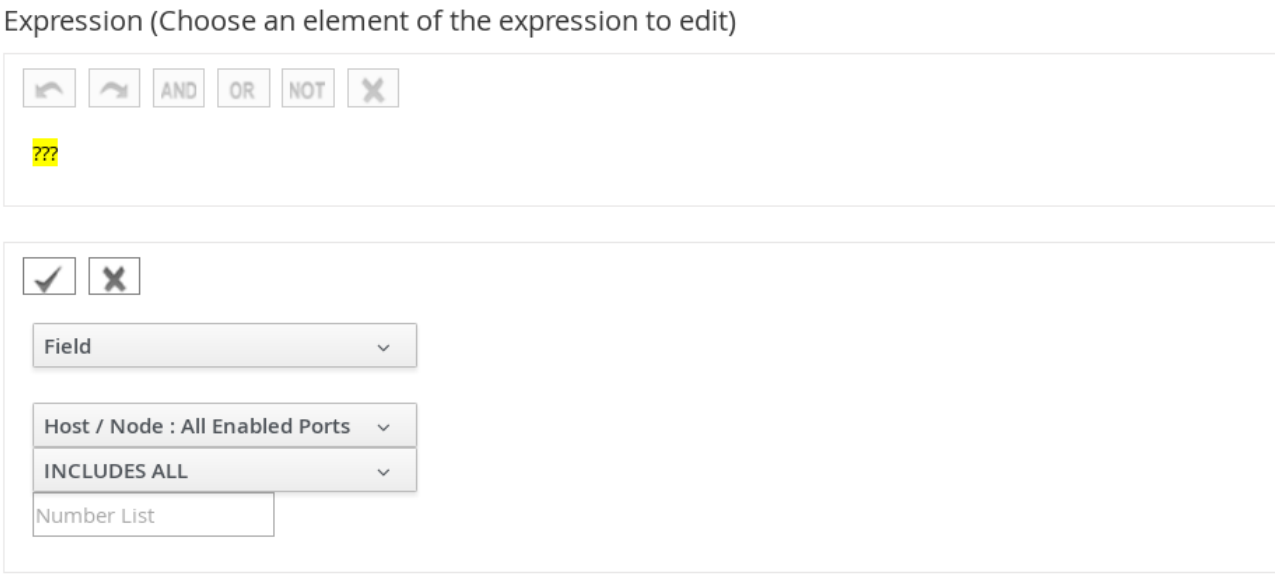
Infrastructure Automation can use VMware alarms as a trigger for an alert. This type of alert can be created for a cluster, host, or virtual machine.

1. Navigate to **Control > Explorer**.
2. Click the **Alerts** accordion, then click (**Configuration**), (**Add a new Alert**).
3. In the **Info** area:
   - Type in a description for the alert.
   - From **Based On**, select **Cluster**, **Host**, or **VM**.
   - For **What to Evaluate**, select **VMware Alarm**.
   - In **Notification Frequency**, select how often you want to be notified if the log item is detected.
4. In the **VMware Alarm Parameters** area select the provider and alarm.



5. After setting the parameters, you then select what you want the alert to do. You can send an email, create an SNMP Trap, or send a management event to start an automation process.
6. Click **Add**.

Creating an Expression Alert



Expression alerts enables you to create a notification based on any possible criteria for clusters, datastores, hosts, and virtual machines. The following procedure creates an alert for when a host's datastore has less than 5% free space.

1. Navigate to **Control > Explorer**.
2. Click on the **Alerts** accordion, then click (**Configuration**), (**Add a new Alert**).
3. In the **Info** area:

- Type in a description for the alert.
- From **Based On**, select **Host/Node**.
- For **What to Evaluate**, select **Expression (Custom)**.
- In **Notification Frequency**, select how often you want to be notified if the expression is evaluated to true.

4. Use the expression editor to create your expression. This is the same expression editor used to create **Conditions**.

5. Click ✓ (**Commit expression element changes**) to accept the expression.
6. After setting the parameters, you then select what you want the alert to do. You can send an email, create an SNMP Trap, or send a management event to start an automation process.
7. Click **Add**.

Create an Operational Alert

1. Navigate to **Control > Explorer**.
2. Click on the **Alerts** accordion, then click ⚙ (**Configuration**), ⊕ (**Add a new Alert**).
3. In the **Info** area:
   - Type in a description for the alert.
   - Check **Active** when you feel that the alert is ready to be enabled.
   - From **Based On**, select **Server**.
   - Select the appropriate driving event.

- In **Notification Frequency**, select how often you want to be notified if the event log threshold is reached.

4. After setting the parameters, select what you want the alert to do. You can send an email, create an SNMP Trap, or send a management event to start an automation process.

5. Click **Add**.

Operational Alert Types

Operational Alerts

Driving Event	Explanation (Thresholds, Description)	Proposed Action and Next Steps
EVM Server Start	Alert is raised when an server starts.	Send e-email. This is a notification.
EVM Server Stop	Alert is raised when a server stops.	Send e-mail. Review logs to see why the server stopped.
EVM Server Not Responding	Alert is raised when one server detects that another server has not responded in 2 minutes.	This is a sign of a problem that should be investigated. Check logs.
EVM Server Exceeded Memory Limit	Alert is raised when an server has exceeded its system memory limit and begins killing workers. Default is 80%. Threshold configured in Advanced Settings. server: :worker_monitor: :kill_algorithm: :name: :used_swap_percent_gt_value :value: 80	This may be caused by the following issues: The server is running with too few resources. The server is enabled with too many roles or number of workers. The server picked up all the roles because another server has failed. A runaway process has taken up most of the memory.
EVM Server is Master	When one server takes over as a master server.	Typically, this should only occur when first starting a set of servers, perhaps following expected outages. If a server picks up as master in other situations, the old master had an issue that needs to be researched (such as server not responding in time).
EVM Server High System Disk Usage	The server's system disk is 80% full. This check is run as part of a system schedule. Threshold configured in Advanced Settings. server: events: :disk_usage_gt_percent: 80	Temp files used by the operating system may be filling the disk. Yum updates, normal /tmp files, or temp files in /var/lib/data/miqtemp/ may cause the problem.
EVM Server High App Disk Usage	The server's app disk is 80% full. This check is run as part of a system schedule. Threshold configured in Advanced Settings. server: events: :disk_usage_gt_percent: 80	Server temp files may remain.
EVM Server High Log Disk Usage	The server's log disk is 80% full. This check is run as part of a system schedule. Threshold configured in Advanced Settings. server: events: :disk_usage_gt_percent: 80	Logs are getting too big or are not being log rotated properly every day. Review the most recent logs.
EVM Server High DB Disk Usage	The server's db disk is 80% full. This check is run as part of a system schedule. Applies if using PostgreSQL as the VDMB. Threshold configured in Advanced Settings. server: events: :disk_usage_gt_percent: 80	Database or database logging is getting too large. May require **full** vacuuming of PostgreSQL database.
EVM Worker Started	Alert is raised when a worker is about to start.	This is a notification. Failover may trigger this alert.
EVM Worker Stopped	Alert is raised when a worker is requested to stop.	Review logs for reason in the event the worker was not purposefully stopped.
EVM Worker Killed	Alert is raised when a non- responsive worker does not restart on its own and is killed.	Review logs for reason the worker was killed. May be the result of EVM Worker Not Responding.

Driving Event	Explanation (Thresholds, Description)	Proposed Action and Next Steps
EVM Worker Not Responding	Alert is raised when a worker has not responded for 2 minutes (:heartbeat_timeout) or has not started within 10 minutes (:starting_timeout).	An influx of events from the Virtual Center or Red Hat Virtualization causes an inability of EVM/CFME to handle the capacity at which they are being queued. Utilize the Event Handler Configuration to filter events that are causing problematic queue table growth.
EVM Worker Exceeded Memory Limit	Alert is raised when a worker exceeds the memory threshold. The default is 150 MB, but some workers have their own value in the :memory_threshold section for that specific worker.	Review logs for reason the worker is exceeding the memory limit. This may be the result of an overload to the worker process that requires further investigation.
EVM Worker Exceeded Uptime Limit	Alert is raised when a worker has been running longer than the :restart_interval. (Most workers are set to never restart using the 0.hours setting.) The EMS Refresh SmartProxy workers are set to restart every 2 hours.	Review logs for the reason the worker is exceeding the limit. This may be the result of an overload to the worker process that needs further investigation.
EVM Worker Exit File	Alert is raised when the scheduler worker exits due to a pending large ntp time change.	This is a notification.

Editing an Alert

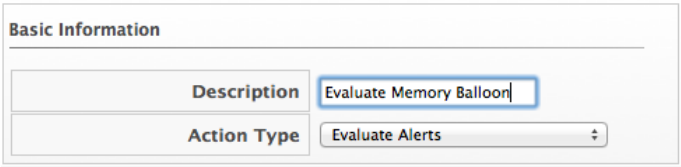
After creating an alert, you can edit the threshold, expression, or the notification type.

1. Navigate to **Control > Explorer**.
2. Click on the **Alerts** accordion, then click on the alert that you need to edit.
3. Click **(Configuration)**, **(Edit this Alert)**.
4. Make the required changes.
5. Click **Save**.

Copying an Alert

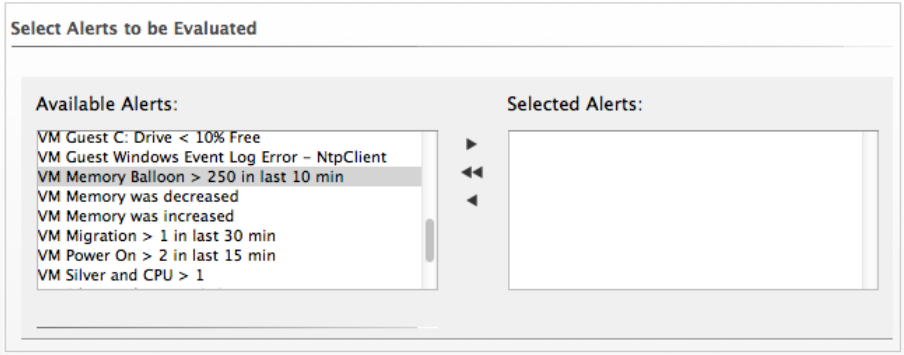
You can copy an existing alert to create a new alert that is similar to the existing one, then change the values associated with it.

1. Navigate to **Control > Explorer**.
2. Click on the **Alert** accordion, then click on the alert that you want to copy.
3. Click (**Configuration**), (**Copy this Alert**). Click **OK** to confirm.
4. Make the required changes.
5. Click **Add**.



Deleting an Alert

When an alert is no longer needed, you can remove it from your VMDB.



1. Navigate to **Control > Explorer**.
2. Click on the **Alerts** accordion, then click on the alert that you want to delete.
3. Click (**Configuration**), (**Delete this Alert**).
4. Click **OK** to confirm.

Evaluating an Alert

1. Navigate to **Control > Explorer**.
2. Click the **Actions** accordion, then click (**Configuration**), (**Add a new Action**).
3. Type in a **Description** for the action.

4. Select **Evaluate Alerts** from **Action Type**.
5. Select the alerts to be evaluated and click (**Move selected Alerts into this Action**). Use the `Ctrl` key to select multiple alerts.

6. Click **Add**.

Alert Profiles

Creating Alert Profiles

Alert profiles enable you to create groups of standard alerts. An alert profile can have as many alerts assigned as you need, and can be assigned to clusters, datastores, hosts, and virtual machines.

Note:

Each profile type under the **Alert Profile** accordion menu will have its own **Alert Selections** and subsequent **Assignments** choices.

1. Navigate to **Control > Explorer**.
2. Click on the **Alert Profiles** accordion, then click on the type of profile that you want to create.
3. Click (**Configuration**), (**Add a new Profile**).
4. In the **Basic Information** box, type in a unique **Description** for the alert profile.
5. Select the desired alerts from the **Alert Selection** area. Use the `Ctrl` key to select multiple alerts.
6. Click to add the Alerts.
7. Type in any additional description in the **Notes** area.
8. Click **Add**.

Editing an Alert Profile

You can edit an alert profile as your enterprise's needs change.

1. Navigate to **Control > Explorer**.
2. Click on the **Alert Profiles** accordion, then click the alert profile you want to edit.
3. Click (**Configuration**), (**Edit this Alert Profile**).
4. Make the required changes.
5. Click **Save**.

Deleting an Alert Profile

Remove alert profiles that you no longer need. This does not remove the alerts associated with the alert profile.

1. Navigate to **Control > Explorer**.
2. Click on the **Alert Profiles** accordion, then click the alert profile you want to remove.
3. Click (**Configuration**), (**Delete this Alert Profile**).
4. Click **OK** to confirm.

Assigning an Alert Profile

After an alert profile is created and verified, you can assign it directly to a resource.

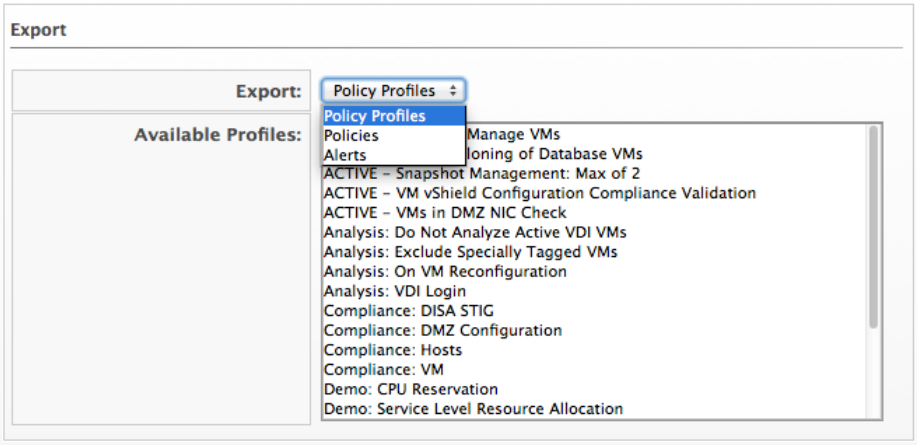
1. Navigate to **Control > Explorer**.
2. Click on the **Alert Profiles** accordion, then click on the alert profile that you want to assign.
3. Click (**Configuration**), (**Edit Assignments for this Alert Profile**).

4. The options presented change based on if the alert is for a cluster, datastore, Infrastructure Automation server, host, or virtual machine and instance. You can assign to the enterprise, to specific hosts, cluster, resource pools, and providers, or based on assign tags. For a Infrastructure Automation server alert profile, you can only assign to Infrastructure Automation servers in the current Region.
5. Click **Save**.

Importing and Exporting

Importing and Exporting Policies, Policy Profiles, and Alerts

If you have multiple VMDBs, you can export policies, policy profiles, or alerts from one to another. You can export and import for use with other Infrastructure Automation infrastructures.



Note:

The appliances you are exporting or importing data between must use the same Infrastructure Automation version.

1. Copy the file to import to a location that is accessible to your Infrastructure Automation console.
2. Navigate to **Control > Import/Export**.
3. Click **Choose file** to navigate to the location of the file.
4. Select the file, and then click **Open** from the file selection box.
5. Click **Upload**.
6. Verify that these are the policies or policy profiles that you want to import.
7. Click **Commit**.

Exporting a Policy, Policy Profile, or an Alert

1. Navigate to **Control > Import/Export**.
2. From the **Export dropdown**, select policy profiles, policies, or alerts, depending on what you want to export.

3. From the **Available Profiles** or **Available Policies** or **Available Alerts** list, select the items to export. Use the `Ctrl` key to select multiple items to export into one file.
4. Click **Export**.
5. Follow the prompts in your browser to save the file.

OpenShift Prometheus Alerts

Note:

This feature is currently available as a technology preview only. For more information on the support scope for features marked as technology preview, see Technology Preview Features Support Scope.

Prometheus is used as an external alerting component. Infrastructure Automation integrates Prometheus alerts for use with OpenShift Container Platform. Infrastructure Automation collects events from Prometheus, generates alerts based on these events, and then attaches alerts to inventory objects.

It is possible to view ongoing alerts in Infrastructure Automation by navigating to **Monitor > Alerts** and manage their life cycle, including the ability to:

- View active alerts per provider in the **Overview** screen.
- View alert data and related objects.
- Comment, assign, and acknowledge alerts in the **All Alerts** screen.

Network utilization metrics for OpenShift Container Platform are only collected for `eth0` network interfaces. Therefore, network utilization trend will not be displayed for network interfaces other than `eth0` on the overview screen of the provider.

Configuring Prometheus Alerts in Infrastructure Automation

Configuring and enabling Prometheus alerts in Infrastructure Automation comprises the following steps:

1. Deploying and configuring Prometheus on OpenShift.
2. Assigning Prometheus alert profiles to the enterprise in Infrastructure Automation.
3. Adding an OpenShift Containers Provider with a Prometheus alert endpoint in Infrastructure Automation.

Deploying and Configuring Prometheus on OpenShift

1. Deploy Prometheus on OpenShift by following the steps covered in Prometheus on OpenShift Container Platform.
2. Add Prometheus to an OpenShift cluster and configure alert definitions. See the example code block below for configuring alerts (currently must be done on the Prometheus side):

```
$ oc edit configmap -n openshift-metrics prometheus
# Supported labels:
# severity: ERROR|WARNING|INFO. defaults to ERROR.
# Supported annotations:
# description: The error message displayed on the screen
# miqTarget: ContainerNode|ExtManagementSystem, defaults to ContainerNode.
# miqIgnore: "true|false", should ManageIQ pick up this alert, defaults to true.
  prometheus.rules: |
    groups:
    - name: example-rules
      interval: 30s # defaults to global interval
      rules:
      - alert: "NodeDown" << Alert starts here
        expr: up{job="kubernetes-nodes"} == 0
        annotations:
          miqTarget: "ContainerNode"
          severity: "ERROR"

          description: "Too many authenticated requests"
```

3. Reload the Prometheus configuration. You can do this by deleting the Prometheus pod, then redeploying with the new configuration.

Assigning Prometheus Alert Profiles to the Enterprise

Complete the following procedure to assign Prometheus alert profiles to the enterprise using the Infrastructure Automation user interface.

Note:

Both Node and Provider alert profiles are created automatically during the installation, so it is not required to create these profiles.

1. Navigate to **Control > Explorer**, then click **Alert Profiles** in the accordion menu.
2. Click to expand **Node Alert Profiles**, then click **Prometheus Node Profile**.
3. Click  (**Configuration**), then click  (**Edit assignments for this Alert Profile**). Assign the profile to **The Enterprise** from the **Assign To** list.
4. Click **Save**.
5. Click to expand **Provider Alert Profiles**, then click **Prometheus Provider Profile**.
6. Click **Configuration**, then click **Edit assignments for this Alert Profile**. Assign the profile to **The Enterprise** from the **Assign To** list.
7. Click **Save**.

   Note:

   Alerts triggered before assigning the profiles to the enterprise will not appear in Infrastructure Automation at all.

Adding an OpenShift Containers Provider with a Prometheus Alert Endpoint

Complete the following procedure to add an OpenShift Containers Provider with a Prometheus Alert Endpoint using the Infrastructure Automation user interface.

1. Browse to menu: **Compute > Containers > Providers**.
2. Click **Configuration**, then click  (**Add a New Containers Provider**).
3. Enter a **Name** for the provider.
4. From the **Type** list, select **OpenShift Container Platform**.

5. Enter the appropriate **Zone** for the provider. If you do not specify a zone, it is set to **`default`**.
6. In the **Default** tab, configure the following for the OpenShift provider:
    1. Select a **Security Protocol** method to specify how to authenticate the provider:
        - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.
        - **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.

          Note:

          You can obtain your OpenShift Container Platform provider's CA certificate for all endpoints (default, metrics, alerts) from **`/etc/origin/master/ca.crt`**. Paste the output (a block of text starting with **`-----BEGIN CERTIFICATE-----`**) into the **Trusted CA Certificates** field.
        - **SSL without validation**: Authenticate the provider insecurely (not recommended).
    2. Enter the **Hostname** (or IPv4 or IPv6 address) of the provider.

       Important:

       The **Hostname** must use a unique fully qualified domain name.
    3. Enter the **API Port** of the provider. The default port is **`6443`**.
    4. Enter a token for your provider in the **Token** box.

       Note:

       To obtain a token for your provider, run the **`oc get secret`** command on your provider; see Obtaining an OpenShift Container Platform Management Token.

       For example:

       # oc get secret –namespace management-infra management-admin-token-8ixxs –template='' | base64 –decode
    5. Click **Validate** to confirm that Infrastructure Automation can connect to the OpenShift Container Platform provider.
7. In the **Metrics** endpoint tab optionally configure the metrics service details:
    1. Select a service type (e.g.: Prometheus) or leave disabled
    2. Select a **Security Protocol** method to specify how to authenticate the service:
        - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.
        - **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.
        - **SSL without validation**: Authenticate the provider insecurely using SSL. (Not recommended)
    3. Enter the **Hostname** (or IPv4 or IPv6 address) of the metrics service.

       In order to find the hostname you can use the **`oc get route`** command.

       You can retrieve the Prometheus route by running:

       ```
       oc get route prometheus-k8s -n openshift-monitoring
       ```

       Example:

       ```
       oc get route prometheus-k8s -n openshift-monitoring
       NAME              HOST/PORT                                          PATH              SERVICES   PORT
       TERMINATION          WILDCARD
       prometheus-k8s   prometheus-k8s-openshift-monitoring.ocp.example.com  prometheus-k8s   web
       reencrypt/Redirect   None
       ```

       In this example you would use **`prometheus-k8s-openshift-monitoring.ocp.example.com`** as the metrics hostname.
    4. Enter the **API Port** of your metrics endpoint uses a non-standard port for access. The default port is **`443`**.
    5. Click **Validate** to confirm that Infrastructure Automation can connect to the metrics endpoint.
8. In the **Virtualization** endpoint tab optionally configure the virtualization service details:
    1. Select a service type (OpenShift Virtualization / KubeVirt) or leave disabled
    2. Select a **Security Protocol** method to specify how to authenticate the service:
        - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.

- **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.
- **SSL without validation**: Authenticate the provider insecurely using SSL. (Not recommended)

3. Enter the **Hostname** (or IPv4 or IPv6 address) of the virtualization service.
4. Enter the **API Port** of your virtualization service. The default port is **`443`**.
5. Enter a token for your provider in the **Token** box.

9. Click the **Advanced** tab to add image inspector settings for scanning container images on your provider using OpenSCAP.

Note:

- These settings control downloading the image inspector container image from the registry and obtaining the Common Vulnerabilities and Exposures (CVE) information (for effective scanning) via a proxy.
- CVE URL that Infrastructure Automation requires to be open for OpenSCAP scanning: https://www.redhat.com/security/data/metrics/ds/. This information is based on the source code of OpenSCAP.

1. Enter the proxy information for the provider in either **HTTP**, **HTTPS**, or **NO Proxy** depending on your environment.
2. Enter the **Image-Inspector Repository** information. For example, **`openshift3/image-inspector`**.
3. Enter the **Image-Inspector Registry** information. For example, **`registry.access.redhat.com`**.
4. Enter the **Image-Inspector Tag** value. A tag is a mark used to differentiate images in a repository, typically by the application version stored in the image.
5. Enter **`https://www.redhat.com/security/data/metrics/ds/`** in **CVE location**.

10. Click **Add**.

Note:

You can also set global default image-inspector settings for all OpenShift providers in the advanced settings menu by editing the values under **`ems_kubernetes`**, instead of setting this for each provider.

For example:

```
:image_inspector_registry: registry.access.redhat.com
:image_inspector_repository: openshift3/image-inspector
```

Once you have completed the procedure, you will have OpenShift Prometheus alerts enabled in Infrastructure Automation, and can manage their life cyle from the **Monitor > Alerts** screen in the user interface.

Regular Expressions

In Infrastructure Automation, regular expressions can be used to search the contents of a file for a specific string for use in a condition. Below are listed the items most commonly used with Infrastructure Automation to search strings. These are a small subset of all the items available to use in regular expressions. If you are unfamiliar with regular expressions, there are many resources available on the Internet, including www.regular-expressions.info. Note that if you want to search a file, you must collect it as part of a host analysis profile.

Anchors		
^	start of string	
$	end of string	
Character Classes		
\s	white space including spaces, tabs, and line breaks	
\S	not white space	
\d	digit, same as [0-9]	
\D	not digit	
\w	word	
\W	not word	
Quantifiers		
*	0 or more of preceding characters	
+	1 or more of preceding characters	
?	0 or 1 of preceding character	
Escape Character		
\	put before a metacharacter to search for that actual character	
Metacharacters		
^ [. $ { * (\ +)	? < >	must be used with the Escape Character if you are searching specifically for it
Special characters		
\n	new line	

\t	tab	
Groups and Ranges		
.	any character except new line (\n)	
(a	b)	a or b
()	group	
[abc]	a or b or c	
[^abc]	not a or b or c	
[a-q]	letter between a and q	
[A-Q]	upper case letter between A and Q	
[0-7]	digit between 0 and 7	
Pattern modifiers		
i	case insensitive	
Other helpers		
.*	swallows text between 2 words	
\s+	guarantees minimum of 1 whitespace between 2 words	
\s*	guarantees 0 or more whitespace between 2 words	
^\s*	beginning of line with zero or more whitespace	
\s+.*	swallows all text and white space between 2 words	
\d+	guarantees minimum of 1 number between 2 words	
<\w>	identical to <[a-zA-Z0-(_]>	

Regular Expressions

Description	Regular Expression			
([a-zA-Z0-9]+)	Letters, numbers, hyphens			
Find the line beginning with **`sshd`**. Then, using a colon `:` as delimiter, check that the value four ":" over is equal to 99999.	^sshd:[^:]*:[^:]*:[^:]*:99999:			
Verify that **`PASS_MAX_DAYS`** exists starting in position **`1`** and a value after it is ⇐ 90.	^\s*PASS_MAX_DAYS\s+([0-9]	[1-8][0-9]	90)	
Verify that **`ROOTPW`** (in any case) exists on an uncommented line.	/[^#]*ROOTPW/i			
Verify that line in file starts with size and the value after is ⇐ 4096k.	^\s*size\s+(409[0-6]	40[0-8][0-9]	[123][09]{3}	\d{1,3})k
Find line with string **`restrict 127.0.0.1`** that starts in position `1 to ensure it is not commented out.	^\s*restrict\s+127\.0\.0\.1			
Find an uncommented line that contains **`/home`**. There will be additional text before the desired string.	[^#]*\/home			

Examples

Reportable Fields in Infrastructure Automation

Infrastructure Automation provides a set of out of the box reports covering a variety of areas. These fields are collected by Infrastructure Automation from the different parts of the infrastructure. Most of the fields are named directly as the vendor would name them. However, there are some fields that Infrastructure Automation calculates given this data. Note that this list may vary by Provider and may change as new Providers are added to Infrastructure Automation. Also, note that the value returned by each reportable field below is in megabytes (MB).

Reportable Field
Memory - Aggregate Used for Child VMs for Collected Intervals 30 Day Avg

Images

Chargeback

The Chargeback dashboard includes the utilization, reporting, and chargeback data from the Infrastructure Automation – Infrastructure Management component.

You can use the dashboard to view and manage chargeback cost. The chargeback feature provides the way to calculate monetary virtual machine charges based on owner or company tag. Access the Chargeback dashboard by browsing to the menu, click **Manage costs > Chargeback**

- Tag Categories and Tags
- Chargeback Rates
- Chargeback Assignments
- Chargeback Reports

Tags

With Infrastructure Management, you can create your own set of tags and tag categories. You can use tags to create a customized, searchable index for your resources. After you create these values, you can apply them to your resources.

Company Tag Categories and Tags

Infrastructure Management provides two types of tags. Company tags and System tags.

Company tags that you see under **My Company Tags** for a resource.

1. Create company tags from the console by browsing to the menu, click **Automate infrastructure > Infrastructure management**
2. Click **Settings**, then click **Application Settings**.
3. Select the region: **Region** and click the **Tags** tab.
4. Select the **My Company Tags** tab.

A selection of company tags is provided to you by default as samples. Tags can be deleted if you don't need them, but are not re-created by Infrastructure Management.

System tags are assigned automatically by Infrastructure Management.

For more information, see Tags.

Chargeback Rates

Infrastructure Management provides a default set of rates for calculating chargeback costs.

You can configure chargeback rates for various resources by selecting either Compute or Storage in the Rates tab. Compute sets chargeback rates for CPU, disk I/O, fixed compute cost, memory, and network I/O items. Storage sets chargeback rates for fixed storage costs and disk storage.

Chargeback costs are computed by using a set formula based on hourly cost per unit and hourly usage.

Chargeback can be calculated in many currencies.

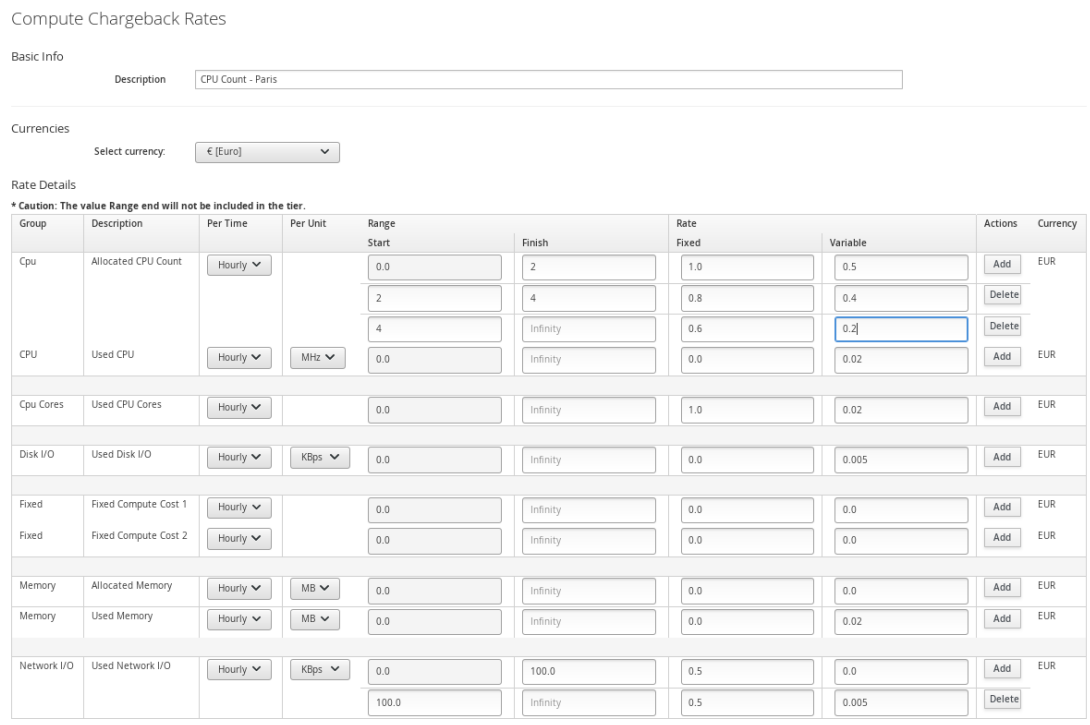
Chargeback rates can be assigned at a single rate or by tiers, where rates are assigned in ranges that depend on the level of usage.

Creating Chargeback Rates

Infrastructure Management provides the capability to create your own set of computing and storage costs to use for billing.

Chargeback can be calculated at one fixed rate, or by a combination of fixed and variable rates per tier. Fixed rates are charged once per unit of time. The variable rate is calculated by the level of usage that is multiplied by the number of resources that are used in a unit of time.

Adding a Chargeback Rate



The following example shows a scenario to create a new chargeback rate for allocated CPU usage in Euro per week measured by the following tiers, calculating both fixed and variable costs:

- Tier 1: 0-2 CPU = 1 Euro fixed + 0.5 Euro variable
- Tier 2: 2-4 CPU = 0.8 Euro fixed + 0.4 Euro variable
- Tier 3: 4 CPU or more = 0.6 Euro fixed + 0.2 Euro variable

To configure this rate:

1. Browse to the menu, click **Manage costs > Chargeback**.
2. Click the **Rates** tab, then click **New rate**. The Infrastructure Management is launched in a new browser tab.

   Note: You can also navigate to Chargeback rates from the Infrastructure Management tab if it is already launched by selecting, **Overview** > **Chargeback** > **Rates**. Select **Configuration** > **Add a new Chargeback Rate**.
3. Enter a **Description** for the chargeback rate.
4. Confirm that the **Type** is set to **Compute**.
5. Select the currency for the new rate. For example, **Euro**.
6. In **Rate Details**, select the time, and complete the range and rates for each tier. Optionally, a single chargeback rate can be configured by using only one tier. For this example, in **Allocated CPU Count**, configure:
    1. For tier 1, set:
        1. In **Per Time**, select **Hourly**.
        2. In **Range**, specify the CPU range: **Start** remains as `0.0` and **Finish** is `2`.
        3. In **Rate**, specify `1` for the **Fixed** rate, and `0.5` for the **Variable** rate.
        4. Click **Add** under **Actions** to create a new, blank **Allocated CPU Count** line for tier 2.
    2. For tier 2, set:
        1. In the new line in **Range**, specify the CPU range: **Start** is `2` and **Finish** is `4`.
        2. In **Rate**, specify `0.8` for the **Fixed** rate, and `0.4` for the **Variable** rate.
        3. Click **Add** under **Actions** to create another new, blank **Allocated CPU Count** line for tier 3.
    3. For tier 3, set:
        1. In the new line in **Range**, specify the CPU range: **Start** is `4` and leave **Finish** as `Infinity`.
        2. In **Rate**, specify `0.6` for the **Fixed** rate, and `0.2` for **Variable**.

Tiered chargeback

7. Click **Add** to save the chargeback rate.

The rate can now be assigned.

For more information, see Chargeback Rates.

Chargeback assignments

Compute rates can be assigned to

- The enterprise
- Selected clusters
- Selected providers
- Tagged VMs and instances
- Tenants

Storage rates can be assigned to

- The enterprise
- Selected datastores
- Tagged datastores
- Tenants

Infrastructure Management provides you with the capability to assign chargeback rates by choosing from **Compute** and **Storage**. You can assign either a custom chargeback rate, or a default rate for Compute, Storage, or Container Images.

Note: The **Default Container Image Rate** can be useful when applied to a container provider with multiple images, where only some of the images have a chargeback rate assigned. The images without a custom rate use the default rate.

1. Browse to the menu, click **Manage costs > Chargeback**.
2. Click the **Assignments** tab, then click **Create assignments**. The Infrastructure Management component is called.
3. From the **Chargeback Assignments** menu, click **Compute** or **Storage**.

Configuring Chargeback for Compute

Use **Compute** to assign a compute chargeback rate. You can assign chargeback rates to **The Enterprise**, **Selected Providers**, **Selected Clusters**, **Tagged VMs and Instances**, **Tagged Configured Systems**, **Tagged Images**, **Labeled Images**, or **Tenants**.

1. From the **Selections** area, choose each item to set, select the chargeback rate to use. The options that are displayed vary based on the type you select.
2. For **Tagged VMs and Instances** and **Tagged Images** select a **Tag Category**.
3. Click **Save**.

Configuring Chargeback for Storage

Use **Storage** to assign a storage chargeback rate. You can assign chargeback rates to **The Enterprise**, **Selected Datastores**, **Tagged Datastores**, or **Tenants**.

1. From the **Selections** area, choose each item to set, select the chargeback rate to use. The options that are displayed vary based on the type you select.
2. For **Tagged Datastores**, select a **Tag Category**.
3. Click **Save**.

The rate is assigned. The next time that you generate a chargeback report, these values will be used.

Note: When you view chargeback, you see a rate for a virtual machine for the number of the CPUs. The chargeback for this parameter is calculated based on when the virtual machine is running. If the virtual machine isn't running, then it is not charged for CPU allocation.

For more information, see Assigning Chargeback Rates.

Chargeback Reports

Prerequisites for running chargeback reports

1. Enable Capacity & Utilization Collection and Metric Workers
    1. Browse to the menu, click **Automate infrastructure > Infrastructure management**.
    2. Click **Settings**, then click **Application Settings**.
    3. Click **Settings > Current Region**, then click the **C & U Collection** tab.
    4. Metrics data is needed to generate chargeback reports. It is required to enable collecting metrics data. You can select individual cluster(s), datastore(s) or select all clusters and datastores.
    5. Click **Save**.
2. Set Server Roles
    1. Browse to the menu, click **Automate infrastructure > Infrastructure management**.
    2. Click **Settings**, then click **Application Settings**.
    3. Click **Settings > Current Region**, then in the tree select **Zones > Current Zone > Current Server**.
    4. In the **Server Control** section turn on the required server roles to get metric data for chargeback reports:
        - Capacity & Utilization Coordinator
        - Capacity & Utilization Data Collector
        - Capacity & Utilization Data Processor
3. Set Assignments
    1. See Chargeback Assignments
    2. Assign rates to a specific scope of resources (The Enterprise, Selected Providers,...). All resources (VMs,...) have an assigned rate when you select **The Enterprise** (for Compute and Storage) in the **Assigned To** selection box.
4. Set Chargeback Filters on chargeback reports

    Filters on chargeback reports must match resources to see any results on the report result. Setting of the filters affects the scope of resources taken into account for chargeback report generation. You can display all resources (VMs,...) on the report result by setting **Show Costs by** to **tenant** and **Tenant** to **My Company** in the **Chargeback Filter** section. When creating reports, click the **Filter** tab to set filters for the data displayed in the report.

Chargeback Reports can be generated based on:

- Allocation
- Utilization

Creating a Chargeback Report

Infrastructure Management provides you with the capability to create chargeback reports to monitor costs.

Note: When you create a chargeback report, the **Total Cost** is the complete cost for the chosen workload over the selected time frame. Total costs are calculated by adding the calculated costs for the amount that is used and the amount that is allocated for the time frame. When you add cost-related columns to display on your report, be sure to select all rate assigned fields to present a comprehensive accounting of total costs.

1. Browse to the menu, click **Manage costs > Chargeback**.
2. Select the **Reports** tab, then click **Create reports** or **New report**.

    The Infrastructure Management is launched in a new browser tab.
3. From the Infrastructure Management, select the **Overview** > **Reports**.
4. Click **Reports** accordion, then select **Configuration** and click **Add a new Report**.
5. On the **Columns** tab, complete the **Basic Report Info** area.
    - Type a unique name in **Menu Name** for how you want the report to be named in the menu list.
    - Type the **Title** to display on the report.
6. Add fields in the **Configure Report Columns** area.
    - From the **Base the report on** list, select **Chargeback for Vms**, **Chargeback for Configured Systems**, **Containers**, or any other object.

- Select the fields to include in the report from the **Available Fields** list, then click **Move selected fields down**. Also, you can select any tags that you created and assigned.
- Change the order of the fields in the report by clicking **Move up selected fields** or **Move down selected fields**.

7. Click the **Formatting** tab to set the size of paper for a PDF and column header format.
   - From the **PDF Output** area, select the page size from the **Page Size** list.
   - From **Specify Column Headers and Formats**, type the text to display for each field. For each numeric field, you can also set the numeric format.
8. Click the **Filter** tab to set filters for the data displayed in the report.
   - From **Chargeback Filters**, select how you want the costs to show, the tag category, the tags, and how you want the items to be grouped. **Note:** You can select multiple tags.
   - From **Chargeback Interval**, select the time interval. You must have a full interval worth of data to select an option other than **Partial** in the **Daily Ending With** list.
9. Click the **Preview** tab, and then **Load** to see how the report appears.
10. When you're satisfied with the report, click **Add** to create the new report.

The new report is created. To make the report accessible from the **Report** menu, you must add it to a report menu.

For more information, see Creating a Chargeback Report.

Running Reports

Generating a Single Report

1. Browse to the menu, click **Manage costs > Chargeback**.
2. Select the **Reports** tab, and then click the report name in the **Reports** section.
3. Click **Run report** to generate the report.

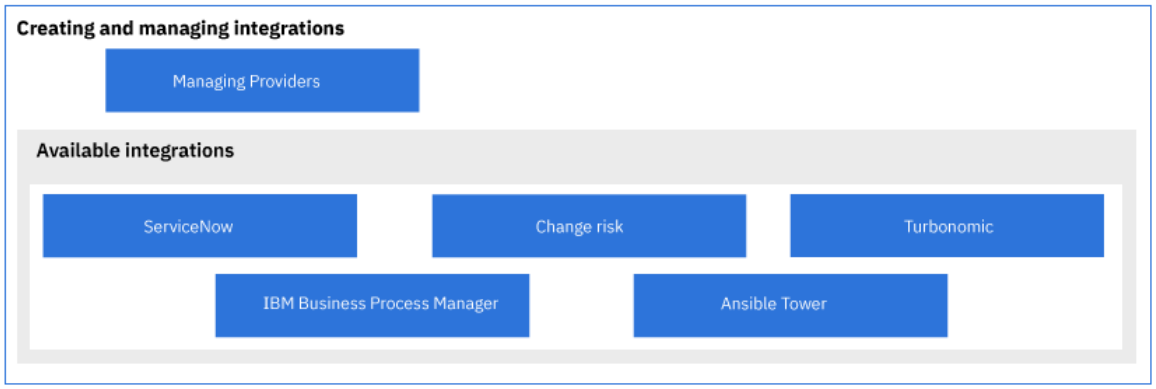
Infrastructure Management uses interactive report generation so that reports are placed on a queue. A visual indicator of the reports status is shown. All reports are automatically saved so that they can be downloaded and analyzed later.

Viewing Reports

Once you have run a report, you can view it at any time after the report has been generated.

1. Browse to the menu, click **Manage costs > Chargeback**.
2. Select the **Reports** tab, and then click the report name in the **Reports** section.
3. From the **Saved Reports**, click the report **Last run** entry under the **Saved Reports** to view the report details.

Note: From the report details you can click the column headings to sort the details by value.



Exporting Reports

1. Browse to the menu, click **Manage costs > Chargeback**.
2. Select the **Reports** tab, and then click the report name in the **Reports** section.
3. From the **Saved Reports**, click the report **Last run** entry under the **Saved Reports** to view the report details.
4. Click **Export Report** and select **Download as Text** or **Download as CSV**.

Managing integrations

Learn more about the available integrations for Infrastructure Automation.

To learn more about managing integrations for Infrastructure Automation, click a subject within the following image to view the related available documentation (or click the subject from list that follows the image):

- Managing Providers
- ServiceNow integration
- Change risk integration
- Turbonomic integration
- IBM Business Process Manager integration
- Ansible Tower integration

- Managing Providers
- Infrastructure Providers
- Refreshing Providers
- Tagging Multiple Providers
- Viewing a Provider
- Removing a Provider
- Viewing the Provider Timeline
- Viewing Hosts and Clusters
- Viewing Virtual Machines and Templates
- Configuration Management Providers
- Automation Management Providers
  - Embedded Workflows
    - Embedded Workflows UI
    - Adding an Embedded Workflows Repository
    - Viewing the List of Workflows in a Repository
    - Refreshing Repositories
    - Adding Credentials
      - Credential Types
        - SCM
    - Authoring a workflow
      - Running an Embedded Workflow on Appliances
      - Running an Embedded Workflow on the OpenShift Container Platform (OCP)
      - Example: Provisioning Workflow
      - Credentials
    - Viewing workflow details
    - Creating a Service Dialog using an Embedded Workflow
    - Creating Service Catalog Items using an Embedded Workflow
  - Ansible
    - Enabling the Embedded Ansible Server Role
    - Verifying the Embedded Ansible Worker State
    - Adding a Playbook Repository
    - Refreshing Repositories
- Credentials
  - Adding Credentials
  - Credential Types
    - Machine
    - Network
    - SCM
    - Amazon
    - Azure
    - OpenStack
    - Red Hat Virtualization
    - VMware
- Tagging Ansible Playbooks, Repositories, and Credentials
  - Adding Tags to Ansible Playbooks
  - Adding Tags to Ansible Repositories
  - Adding Tags to Ansible Credentials
- Optimizing Ansible Playbooks for Infrastructure Automation

    - Installing Roles on an Embedded Ansible Appliance
    - Ansible Service Linking
        - Example: Linking a virtual machine to a service
        - Modifying the Automate Workspace Using the manageiq-automate Role.
            - Role Variables
            - Example Playbook
    - Callbacks in Multiple Appliance Environments
        - Ansible Tower
            - Working with an Ansible Tower Provider
            - Adding an Ansible Tower Provider
            - Refreshing an Ansible Tower Provider
            - Viewing Ansible Tower Providers and Inventory
            - Viewing Ansible Tower Configured Systems
            - Executing an Ansible Tower Job or Workflow Template from a Service Catalog
            - Executing an Ansible Tower Job Using a Custom Automate Button
    - Embedded Terraform (OpenTofu)
    - Importing OpenTofu image on an appliance
    - Usage of Embedded Terraform (OpenTofu)
        - Enabling the Embedded Terraform Server Role
        - Verifying the Embedded Terraform worker state
        - Adding a Template Repository
        - Refreshing Repositories
        - Credentials
            - Adding Credentials
            - Credential Types
                - SCM
                - Amazon
                - Azure
                - Google Compute Engine
                - IBM Cloud Classic Infrastructure
                - OpenStack
                - VMware
        - Running a Terraform Template from a Service Catalog
            - Create a catalog
            - Create a Terraform Service Catalog item
            - Run the Terraform Template:

Managing Providers

Infrastructure Automation can manage a variety of external environments, which are known as providers and managers. A provider or manager is any system that Infrastructure Automation integrates with for the purpose of collecting data and performing operations.

In Infrastructure Automation, a *provider* is an external virtualization, cloud, or containers environment that manages multiple virtual machines or instances residing on multiple hosts. One example is Red Hat Virtualization, a platform that manages multiple hosts and virtual machines.

In Infrastructure Automation, a *manager* is an external management environment that manages more than one type of resource. One example of a manager is OpenStack, which manages infrastructure, cloud, network, and storage resources.

This guide covers working with providers and managers in Infrastructure Automation, which include:

- Infrastructure providers
- Configuration management providers
- Automation management providers
- Cloud providers
- Physical infrastructure providers
- Networking management providers
- Container providers
- Storage managers

For information on working with the resources that are contained by a provider or manager, see Managing Infrastructure and Inventory.

Infrastructure Providers

In Infrastructure Automation, an infrastructure provider is a virtual infrastructure environment that you can add to a Infrastructure Automation appliance to manage and interact with the resources in that environment. This chapter describes the different types of infrastructure providers that you can add to Infrastructure Automation, and how to manage them. Infrastructure providers can be either discovered automatically by Infrastructure Automation, or added individually.

The web interface uses virtual thumbnails to represent infrastructure providers. Each thumbnail contains four quadrants by default, which display basic information about each provider:

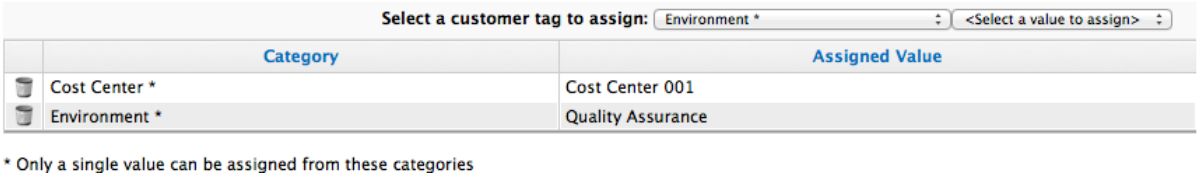
1. Number of hosts
2. Management system software
3. Currently unused
4. Authentication status

Icon	Description
	Validated: Valid authentication credentials have been added.
	Invalid: Authentication credentials are invalid.
	Unknown: Authentication status is unknown or no credentials have been entered.

For information on managing specific infrastructure providers see the following.

- Red Hat Virtualization Providers
- OpenStack Infrastructure Providers
- VMware vCenter Providers
- IBM Power HMC
- OpenShift Virtualization (KubeVirt)

Refreshing Providers



Refresh a provider to find other resources related to it. Use **Refresh** after initial discovery to get the latest data about the provider and the virtual machines it can access. Ensure the provider has credentials to do this. If the providers were added using **Discovery**, add credentials using (**Edit Selected Infrastructure Provider**).

1. Browse to menu: **Compute > Infrastructure > Providers**.
2. Select the providers to refresh.
3. Click **Configuration**, and then (**Refresh Relationships and Power States**).
4. Click **OK**.

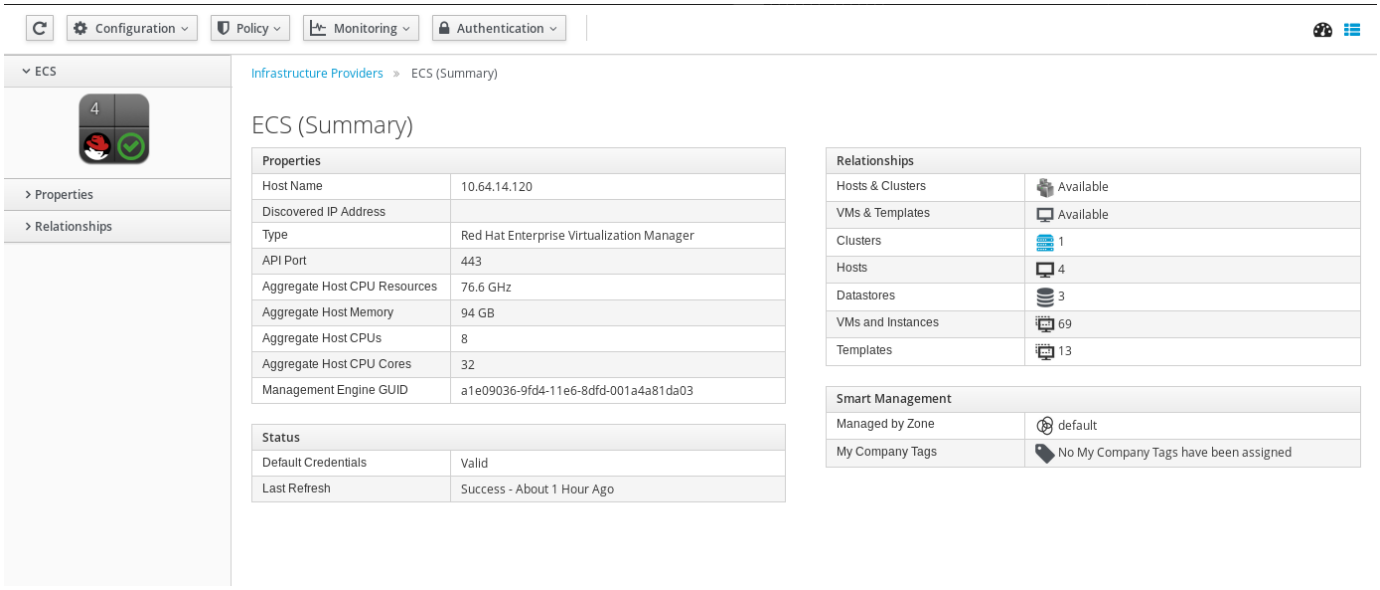
Tagging Multiple Providers

Apply tags to all providers to categorize them together at the same time.

1. Navigate to **Infrastructure > Providers**.
2. Check the providers to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. In the **Tag Assignment** area, select a customer tag to assign from the first list, then select a value to assign from the second list.

* Only a single value can be assigned from these categories

5. Select more tags as required; click (**Save**).

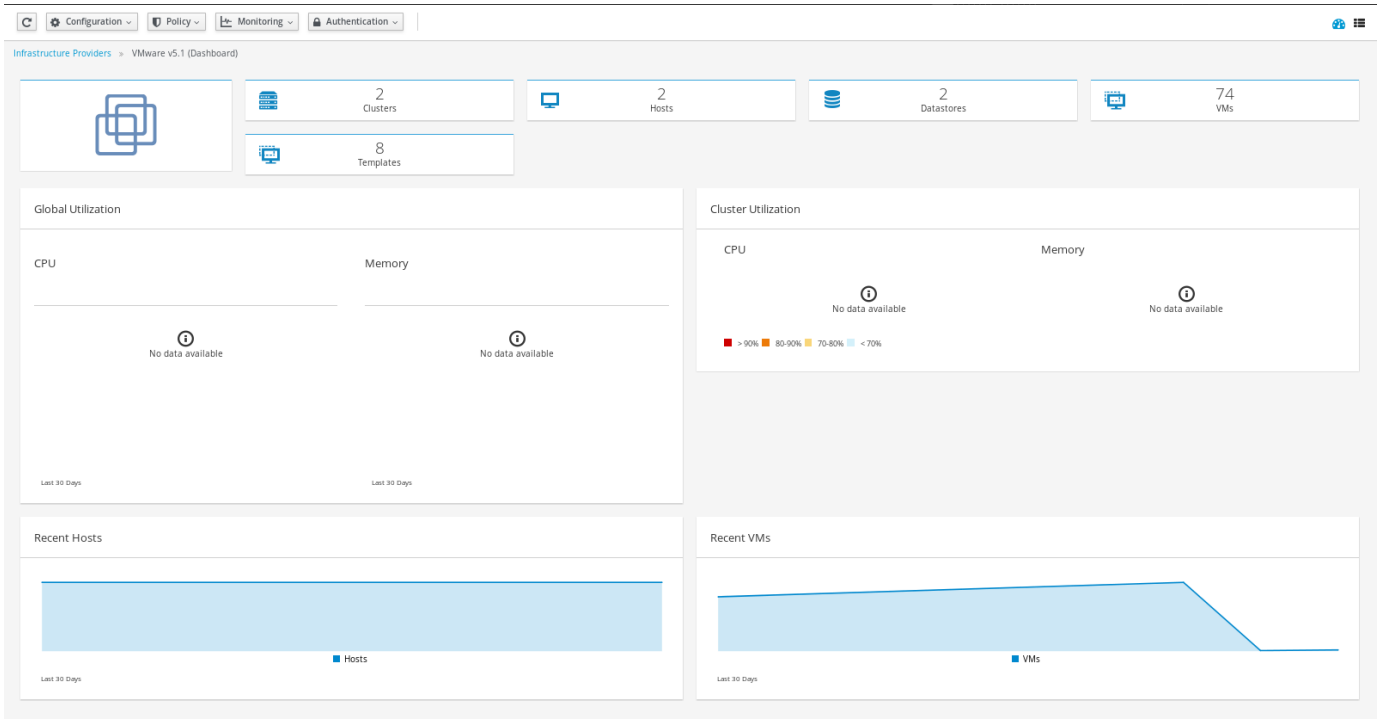


Viewing a Provider

From a list of providers, you can review a specific provider by clicking on it. This displays various options to access provider information.

There are two methods of viewing an infrastructure provider's details: the summary screen (default) and the dashboard screen. Use the summary and dashboard buttons to toggle between views.

Both the summary and dashboard screens contain a taskbar with **Reload**, **Configuration**, **Policy**, **Monitoring**, and **Authentication** buttons to manage the selected provider.



Provider Summary Screen.

The provider summary screen displays information about the provider in table format.

- Provider accordion: Displays details about the provider's **Properties** and **Relationships** on the sidebar. Click to expand these lists.
- Provider summary: Displays a provider's **Properties**, **Status**, **Relationships**, and **Smart Management**. Click on an item in the **Relationships** table to see more information about that entity.

Provider Dashboard Screen.

From the dashboard, you can view:

- Number of clusters, hosts, virtual machines, templates, datastores, resource pools, and other entities on the provider. Click on an entity to see more information about that item.
- Aggregate utilization for CPU, memory, and storage
- Network I/O statistics
- Trends for hosts and virtual machines discovered

To view the dashboard:

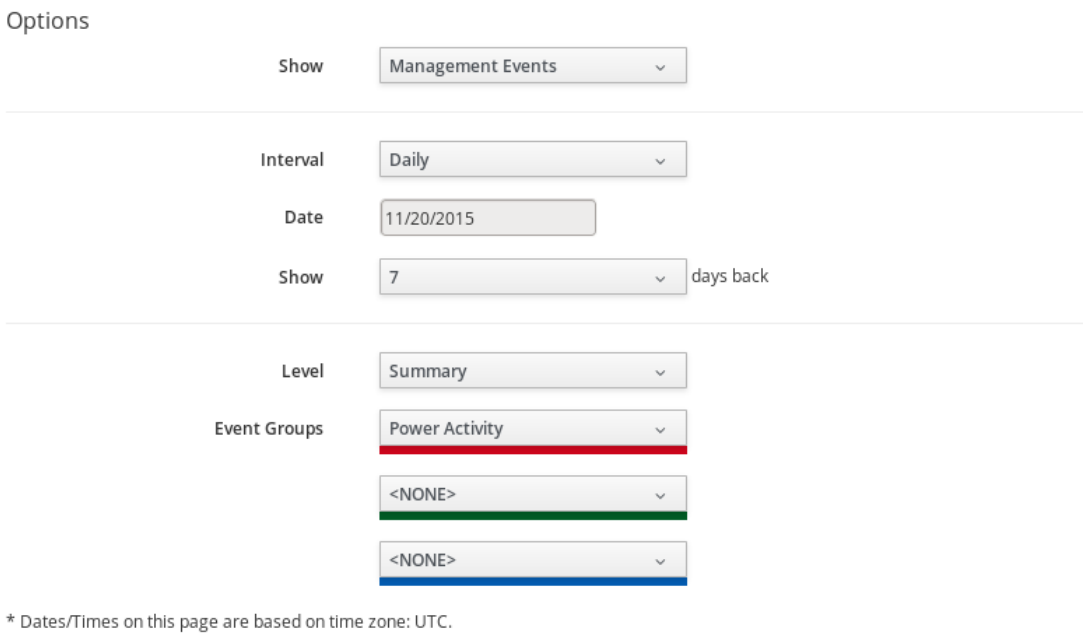
1. Browse to menu: **Compute > Infrastructure > Providers**.
2. Click the infrastructure provider to view.

3. To access the dashboard view, click (**Dashboard view**).

To return to the summary view, click (**Summary view**).

Removing a Provider

If a provider has been decommissioned or requires some troubleshooting, it might require deletion from the VMDB.



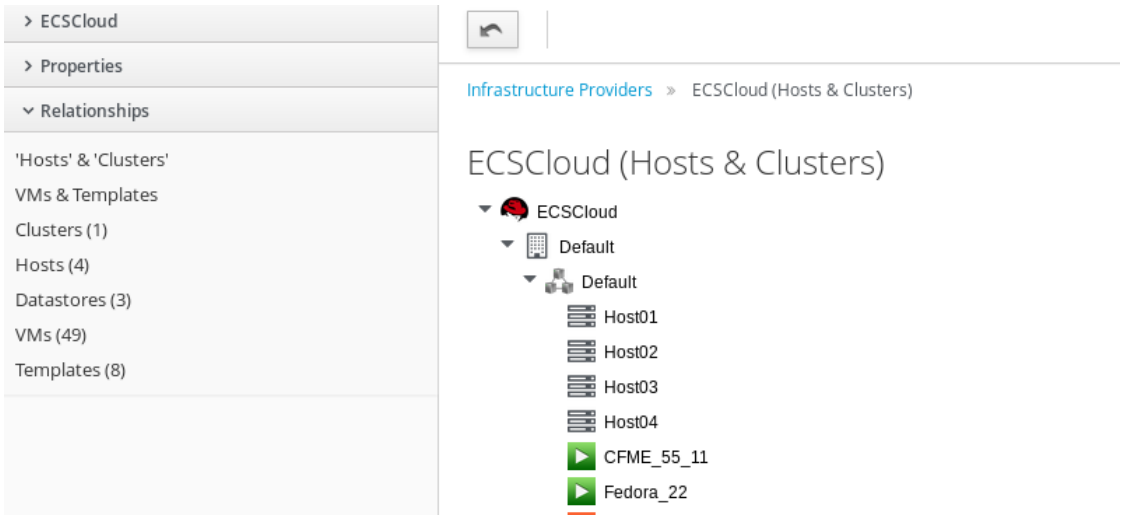
Deleting a provider removes the account information from Infrastructure Automation console. You will no longer be able to view any associated history including chargeback reports generated for the deleted provider. Additionally, if Infrastructure Automation is the database of record, deleting providers would become a major problem for the other systems relying on it for accurate and consistent billing information. Review all the dependencies carefully before deleting a provider.

1. Navigate to **Compute > Infrastructure > Providers**.
2. Select the check box for the provider to delete.
3. Click (**Configuration**), then (**Remove Infrastructure Providers from the VMDB**).
4. Click (**OK**).

Viewing the Provider Timeline

View the timeline of events for the virtual machines registered to a provider.

1. Navigate to **Compute > Infrastructure > Providers**.
2. Click a provider.
3. Click (**Monitoring**), and then (**Timelines**)from the taskbar, or from the provider accordion, click **Properties > Timeline**.
4. From **Options**, customize the period of time to display and the types of events to see.



- Use **Show** to select regular Management Events or Policy Events.
- Use the **Interval** dropdown to select hourly or daily data points.
- Use **Date** to type the date for the timeline to display.
- If you select to view a daily timeline, use **Show** to set how many days back to go. The maximum history is 31 days.
- The three **Event Groups** lists allow you to select different groups of events to display. Each has its own color.
- From the **Level** list, select a **Summary** event, or a **Detail** list of events. For example, the detail level of a **Power On** event might include the power on request, the starting event, and the actual **Power On** event. If you select **Summary**, only the Power On event displays in the timeline.

Viewing Hosts and Clusters

Access a tree view of the hosts and clusters for a provider from the **Provider Summary**.

1. Navigate to **Compute > Infrastructure > Providers**.
2. Click the provider to view the hosts and clusters.
3. Click on the **Relationships** accordion, then click **Hosts & Clusters**.

Viewing Virtual Machines and Templates

Access a tree view of the virtual machines and templates for a provider from the **Provider Summary**.

1. Navigate to **Compute > Infrastructure > Providers**.
2. Click the provider to view the virtual machines and templates.
3. From accordion menu, click **Relationships**, then click **VMs & Templates**.

Configuration Management Providers

In Infrastructure Automation, a configuration management provider is a systems management product that you can add to a Infrastructure Automation appliance to manage the lifecycle of your resources. Configuration management providers are useful for uniformly applying changes and updates across providers, and for recording and reporting status and change activity. They can also help eliminate the confusion and error brought about by the existence of different providers.

This chapter describes the different types of configuration management providers available to Infrastructure Automation, and how to manage them. Configuration management providers must be added individually to Infrastructure Automation.

- IBM Terraform provider
- Red Hat Satellite 6

Automation Management Providers

In Infrastructure Automation, an automation management provider is a management tool that integrates with Infrastructure Automation to simplify automation operations for your resources. The following chapter describes the automation management providers that you can use with Infrastructure Automation, and how to work with them.

Infrastructure Automation provides automation management through the following features:

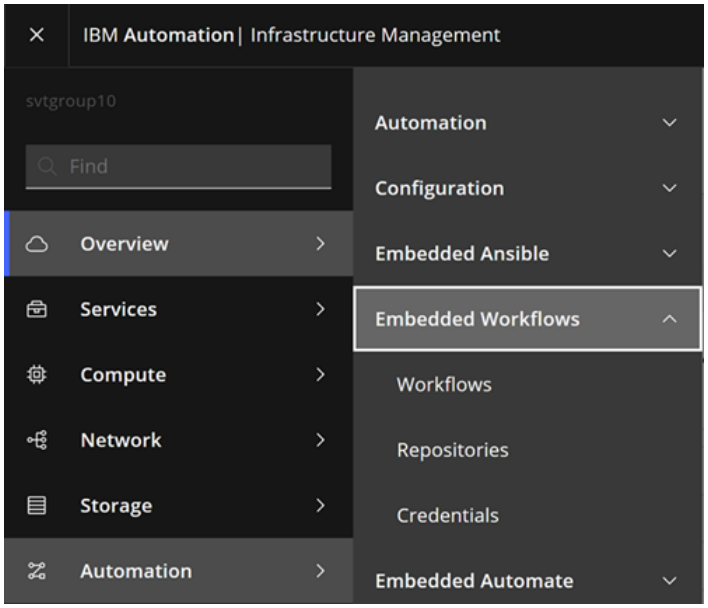
Automate enables real-time, bidirectional process integration. This embedded automate feature provides you with a method to implement adaptive automation for management events and administrative or operational activities.

Embedded Workflows provide the capability to simplify service catalog creation and improve the overall service catalog experience through a step-based automation system. Workflows can run docker containers to accomplish a task that the user requires as part of the state machine. Workflows are imported from Git repository content into Infrastructure Automation where they are made available for users to run. *Embedded Workflows* are an alternative to the *Embedded*

Automate capability for authoring and running automation. With *Embedded Workflows*, you can continue to use the *Embedded Automate* feature for service catalog creation and management.

Ansible integration delivers out-of-the-box support for backing service, alert, and policy actions by using Ansible playbooks. Sync your existing playbook repositories with Infrastructure Automation, add credentials to access providers, and create service catalog items for actions ranging from creating and retiring VMs, updating security software, or adding more disks when space runs low.

Ansible Tower is a management tool that is integrated with Infrastructure Automation, designed to help automate infrastructure operations utlizizing existing Ansible Tower providers in your inventory. Infrastructure Automation allows you to execute Ansible Tower jobs by using service catalogs and Automate. Using Ansible Tower, you can schedule Ansible playbook runs and monitor current and historical results, allowing for troubleshooting or identification of issues before they occur.



Embedded Workflows

Embedded Workflows provide the capability to simplify service catalog creation and improve the overall service catalog experience through a step-based automation system. Workflows can run docker containers to accomplish a task that the user requires as part of the state machine. Workflows are imported from Git repository content into Infrastructure Automation where they are made available for users to run.

Embedded Workflows are an alternative to the *Embedded Automate* capability for authoring and running automation. With *Embedded Workflows*, you can continue to use the *Embedded Automate* feature for service catalog creation and management.

Embedded Workflows UI

For the *Embedded Workflows* feature, the following pages are available in the UI, which you can use to access and work with workflows. To view these pages, go to **Automation** > **Embedded Workflows** and select the page.

- **Workflows**

  This UI page includes a summary of the available workflows. You can use different views to review the workflows:

  - Text view, which is the raw representation (JSON or YAML) of the Amazon State Languages (ASL) code.
  - Graph view, which shows a visual representation of the workflow structure.

- **Repositories**

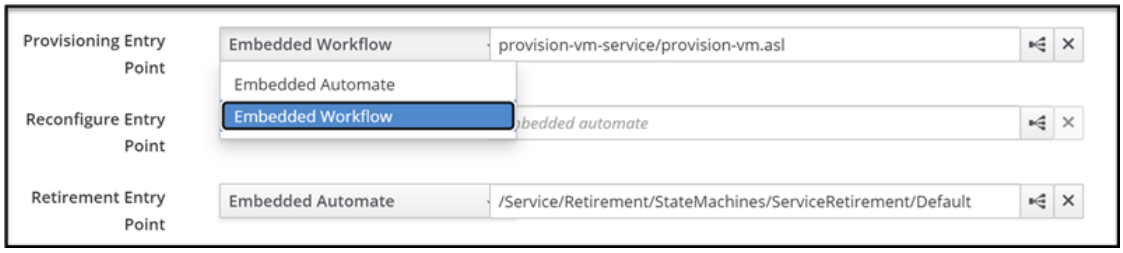
  This page lists, and provides a summary of, the added embedded workflow repositories. From this page, you can add, update, and remove repositories. When a repository is added and synchronized, any workflows that are found in the repository can be viewed on the **Workflows** UI page.

- **Credentials**

  Credentials are used by Infrastructure Automation for any authentication that is required when running embedded workflows, and when importing workflows from a version control system.

  This page lists, and provides a summary of, the credentials for accessing and using embedded workflows. From this page, you can add, update, and delete credentials.

In addition to the *Embedded Workflows* UI, **Embedded Workflows** can also be used in Service Dialogs for dynamic dialog fields and with Service Catalog Items for provisioning, reconfiguration, and retirement entrypoints.

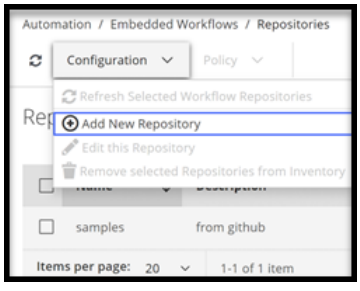


- Service Dialog

  When creating a service dialog, fields that are dynamic include the option for using **Embedded Workflows** or **Embedded Automate**.

- Service Catalog Items

  The provisioning, reconfigure, and retirement entry points include the option for using **Embedded Workflows** or **Embedded Automate**. You can set the point field to the workflow that you want to use for any, or all, of the three service entry points.

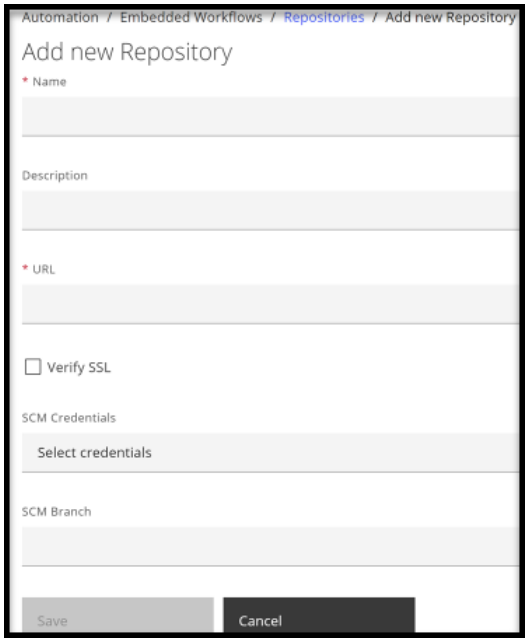


Adding an Embedded Workflows Repository

As a starting point to begin using workflows, you must first add a repository that includes your workflows.

To add a repository, complete the following steps:

1. Click **Automation** > **Embedded Workflows** > **Repositories** > **Configuration** > **Add New Repository**.



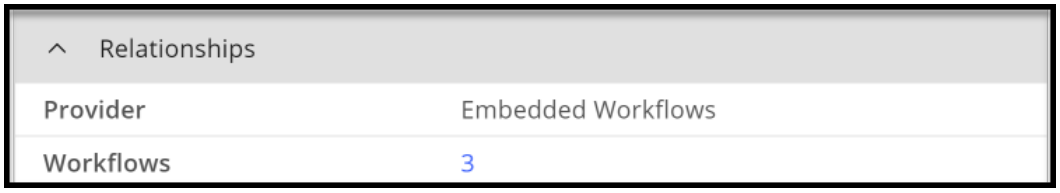
2. Enter the repository name in the **Name** field.
3. Add a description for the repository in the **Description** field.
4. Enter a Git repository URL for the repository in the **URL** field. The Git repository URL does not need to be a GitHub repository.

5. If you are adding a repository that requires authentication then add an SCM (Source Control Management) credential for accessing the repository. Select that credential for this repository from the **SCM Credentials** dropdown menu. These credentials are used in different ways within embedded workflows.

   Source Control credentials have several attributes that can be configured:

   - **Username**: The username to use in conjunction with the source control system.
   - **Password**: The password to use in conjunction with the source control system.
   - **Private key passphrase**: If the SSH private key used is protected by a passphrase, you can configure a key passphrase for the private key.
   - **Private Key**: Copy or drag and drop the actual SSH Private Key to be used to authenticate the user to the source control system by using SSH.
6. Provide a branch name in the **SCM Branch** field for the branch that you want to pull.
7. Click **Save**. Upon saving, the repository is imported and scanned for any included workflows (any Amazon States Language `.asl` files).

8. Confirm that the synchronization with your repository is successful by viewing the list of workflows that are detected for the repository.



To view the added repositories, return to the **Automation** > **Embedded Workflows** > **Repositories** page. The list of repositories is displayed. To view a summary of details for a repository, click the repository to open the *Summary* page for that repository.

If you need to edit a repository, select the repository from the list of repositories. Then, click **Configuration** > **Edit this Repository**. After you complete your edits, click **Save**.

If you need to delete a repository, select the repository from the list of repositories. Then, click **Configuration** > **Remove this Repository from Inventory**.

Viewing the List of Workflows in a Repository

When your repository is added, the repository shows in the *Repositories* list. You can now click the entry for the repository to open it so that you can view the imported workflows. If any workflows are found, click the corresponding number to view the list of workflows.

Alternatively, click **Automation** > **Embedded Workflows**. Then, click **Workflows** to see the list of workflows across all repositories.

Refreshing Repositories

Infrastructure Automation allows you to refresh a targeted repository or all repositories in your inventory to ensure that your workflows are current.

Refresh a targeted repository:

1. Browse to the menu: **Automation** > **Embedded Workflows** > **Repositories**.
2. Click a repository.
3. Click **Configuration**, then (**Refresh this Repository**).

Alternately, you can refresh some or all repositories from the list view:

1. Browse to the menu: **Automation** > **Embedded Workflows** > **Repositories**.

2. Check those repositories to refresh. Click **Check All** to select all repositories.
3. Click **Configuration**, then (**Refresh Selected Workflow Repositories**).

Adding Credentials

Credentials are used by Infrastructure Automation for any authentication that is required when running embedded workflows, or when importing workflows from a version control system.

Infrastructure Automation can store credentials that are used by embedded workflows. Credentials that are saved in Infrastructure Automation are mapped to values in the `Credentials` field of your Workflow and are made available to the container with a workflow when the workflow runs.

1. Browse to the menu: **Automation** > **Embedded Workflows** > **Credentials**.
2. Click **Configuration**, then (**Add New Credential**).
3. Provide a **Name** for the credential.
4. Select the **Credential Type**. More fields appear depending on the type chosen.
5. Click **Add**.

To view the added credentials, return to the **Automation** > **Embedded Workflows** > **Credentials** page. The list of credentials is displayed. To view a summary of details for a credential, click the credential to open the *Summary* page for that credential.

If you need to edit a credential, select the credential from the list of credentials. Then, click **Configuration** > **Edit this Credential**. After you complete your edits, click **Save**.

If you need to delete a credential, select the credential from the list of credentials. Then, click **Configuration** > **Remove selected Credentials from Inventory**.

Credential Types

Each credential type that is used by Infrastructure Automation for embedded workflows is detailed in the following sections.

SCM

SCM (source control Management) credentials are used with Projects to clone and update local source code Git repositories. Source Control credentials have several attributes that can be configured:

- **Username**: The username to use in conjunction with the source control system.
- **Password**: The password to use in conjunction with the source control system.
- **Private key passphrase**: If the SSH private key used is protected by a passphrase, you can configure a key passphrase for the private key.
- **Private Key**: Copy or drag-and-drop the actual SSH Private Key to be used to authenticate the user to the source control system by using SSH.

Authoring a workflow

You can configure workflows for use in the following areas during service catalog creation:

- **Dynamic dialog fields** - You (or your users) can attach workflows to a field so that the field becomes populated or refreshed with the results from the running of the workflow.
- **Service Entry Points** - You (or your users) can set and use workflows for provisioning, reconfiguring, and retiring services.

You can create and use embedded workflows as needed to not only change parts of the provisioning process, but also to automate other operational tasks.

Workflows must be authored in Amazon State Languages (ASL) format. As part of authoring a workflow, you (or your users) can build container images that are able to perform any tasks that are required in any language that you like. You can use these images during Task states in your workflows.

1. Define the code for the workflow. If your workflow requires the use of any credentials or parameters to be specified, ensure that they are passed in the code.

   Within the workflow code, you need to specify the states that your workflow requires, including any next steps. For `Task` type steps in the workflow, a docker container is called. The container defines what happens for that Task state. For example, a docker container can run to clone a template. If your states require parameters or credentials, you can specify them in your state definitions.

   The workflow code must be in the Amazon States Language (ASL) format and follow its supported specifications. For more information about Amazon States Language and its specification, see Amazon States Language Guide.

   Note: The current implementation of the Amazon States Language does not support **Map** and **Parallel** states.

2. Build the docker containers that are required for the workflow.

   When you have the code for your task resource written, you need to bundle it into a docker image. You can bundle the code by creating a standard Dockerfile and building the image (https://docs.docker.com/engine/reference/commandline/build/). Then, you can push the image to a registry, which makes the image available to be used by Infrastructure Automation. When you have pushed your images to an image registry, you can add the registry to Infrastructure Automation.

Pull secrets for containers are used differently between appliances and the OpenShift Container Platform (OCP). These differences are outlined in the following sections.

Running an Embedded Workflow on Appliances

- On appliances, **podman** is used to execute the container so use podman login as the **manageiq** user.

  ```
  # su manageiq
  $ podman login docker.io
  Username:
  Password:
  Login Succeeded!
  ```

  If you use the –root flag in the podman pull, images are pulled to a local directory '/var/www/miq/vmdb/data/containers/storage' as in the example

  ```
    podman pull <repository>/<image>:<tag>  --root /var/www/miq/vmdb/data/containers/storage
  ```

  It is worth noting that the default /home/manageiq partition has insufficient space to store large images.

  You can use any repository to store your images, for example you can use docker.io access token so that the token does not expire.

- Provide an image pull secret to a podified Kubernetes container, and then add it to a service account

  In order to pull an image from a private registry you have to provide an **ImagePullSecret** to your containers, see Pull an Image from a Private Registry. Infrastructure Automation uses a service account called ibm-infra-management-application-default to run containers for your workflows. You can add an **ImagePullSecret** to this service account by following Add Image Pull Secrets to a service account.

Running an Embedded Workflow on the OpenShift Container Platform (OCP)

If the user is running an embedded workflow on OCP, and is using a docker repository requiring a custom pull secret for their container images, the following steps need to be carried out.

1. Create a pull secret for the repository in question in the same namespace as Infrastructure Automation, for example:

   ```
   oc create secret docker-registry <pull-secret-name> --docker-server=<docker-server> --docker-username=<docker-username> --docker-password=<docker-password>
   ```

2. Add this pull secret to the ibm-infra-management-application-default, for example:

   ```
   oc secret link ibm-infra-management-application-default <pull-secret-name> --for=pull
   ```

Example: Provisioning Workflow

```
{
  "Comment": "Provision a VMware VM.",
  "StartAt": "CloneTemplate",
  "States": {
    "CloneTemplate": {
      "Type": "Task",
      "Resource": "docker://docker.io/manageiq/workflows-examples-clone-template:latest",
      "Next": "CheckTaskComplete",
      "Credentials": {

      }
    },

    "FailState": {
      "Type": "Fail",
      "Error": "FailStateError",
      "Cause": "No Matches!"
    },

    "SuccessState": {
      "Type": "Succeed"
    }
  }
}
```

Credentials

Infrastructure Automation provides a mechanism for securely passing credentials to your running workflows. Credentials should never be set statically in your workflow definition.

Long lived credentials like usernames and passwords should be defined as Mapped Credentials as described in **`Adding Credentials`**.

Short lived credentials such as bearer tokens which are obtained while the workflow is running can be set as state output and stored securely in the Credentials field for further states. This can be accomplished by using **`ResultPath`** with a path starting with **`$.Credentials`**. This will set the output of the state in the **`Credentials`** payload.

For an example lets say we have a State which takes a username and password and outputs a bearer token to be used later on:

```
"Login": {
  "Type": "Task",
  "Resource": "docker://login:latest",
  "Credentials": {
    "username.$": "$.username",
    "password.$": "$.password"
  },
  "ResultPath": "$.Credentials",
  "Next": "NextState"
}
```

If the output of the docker image is **`{"bearer_token":"abcd"}`** then we will be able to use this in the next state like so:

```
"NextState": {
  "Type": "Task",
  "Resource": "docker://do-something:latest",
  "Credentials": {
    "token.$": "$.bearer_token"
  }
}
```

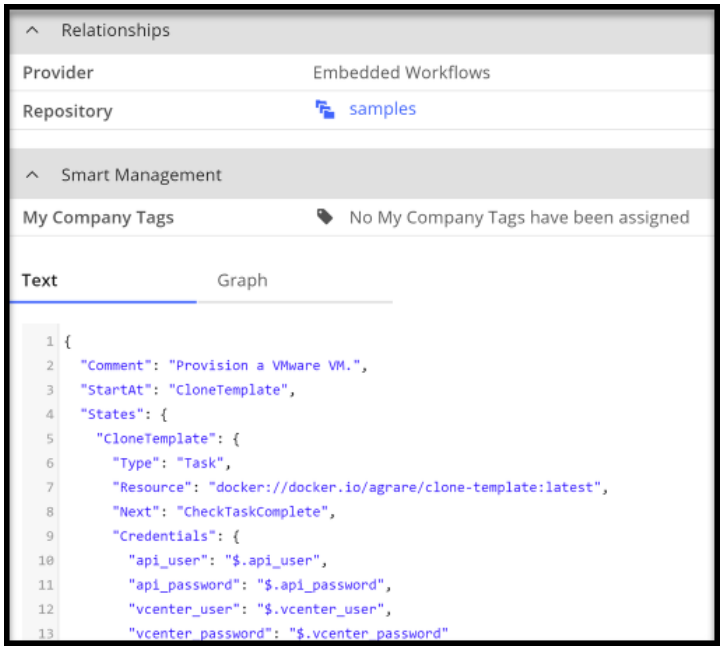
All of the normal Input/Output processing still applies so if you need to manipulate the output you can use **`ResultSelector`**. Say for example our login docker image outputs the token as **`{"result":"abcd"}`** but we want to store it as **`"bearer_token"`**. We can use **`ResultSelector`** to change this:

```
"Login": {
  "Type": "Task",
  "Resource": "docker://login:latest",
  "Credentials": {
    "username.$": "$.username",
    "password.$": "$.password"
  },
  "ResultSelector": {
    "bearer_token.$": "$.result"
  },
  "ResultPath": "$.Credentials",
  "Next": "NextState"
}
```

We can also store the result in a parent node for organization:

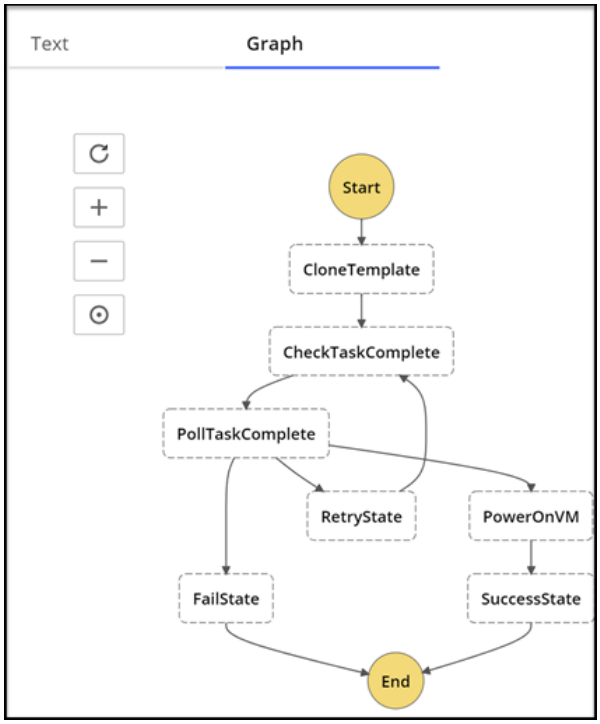
```
"Login": {
  "Type": "Task",
  "Resource": "docker://login:latest",
  "Credentials": {
    "username.$": "$.username",
    "password.$": "$.password"
  },
  "ResultPath": "$.Credentials.VMware",
  "Next": "NextState"
}
```

And then access it like:



```
"NextState": {
  "Type": "Task",
  "Resource": "docker://do-something:latest",
  "Credentials": {
    "token.$": "$.VMware.bearer_token"
  }
}
```

If you have a mapped credential and your state overwrites its, a new non-mapped entry will be created and the original mapped credential will be left intact.



Viewing workflow details

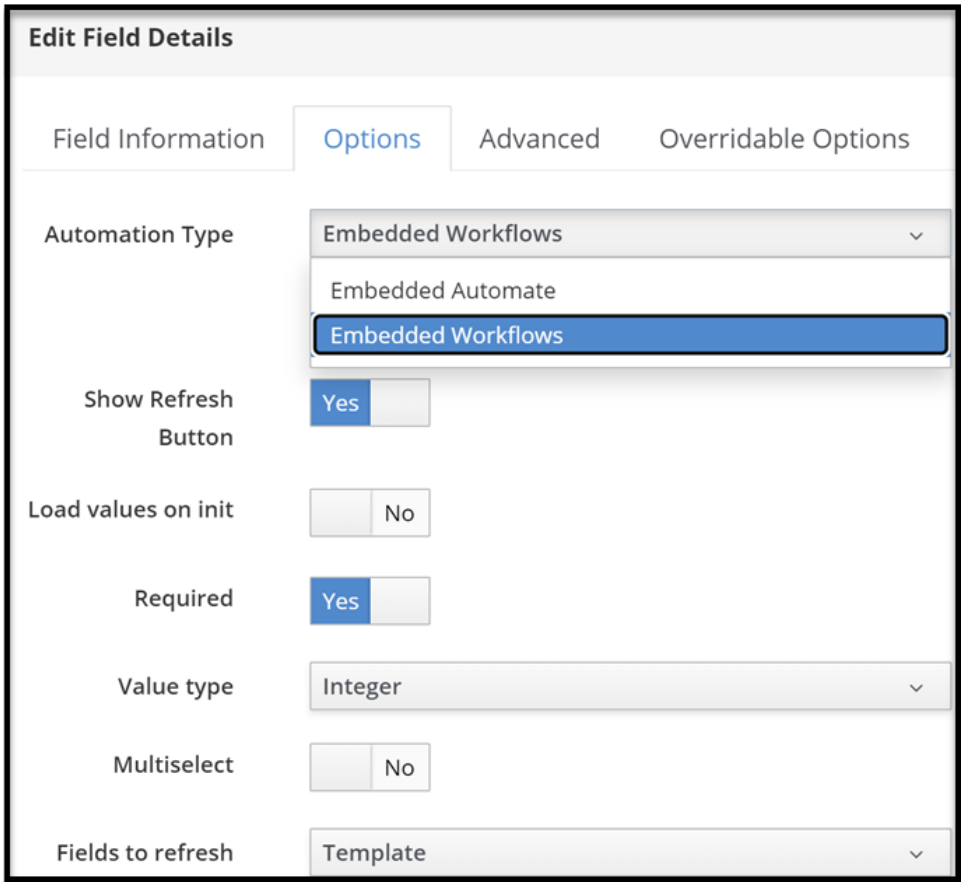
Once a workflow is imported, you can view the details, such as to verify the payload. To view the details for a workflow:

1. Go to the menu: **Automation** > **Embedded Workflows**. Then, click **Workflows** to see the workflows list.
2. Click a workflow. The default *Text* view of the workflow opens where you see the code content.

Alternatively, click the **Graph** tab to see a graph of the same data.

3. If your workflow has credential fields, create a workflow credential for each of the fields. For more information about creating a credential, see Adding Credentials.
4. Map any workflow credentials to the workflow.
    1. Go to the menu: **Automation** > **Embedded Workflows**. Then, click **Workflows** to see the workflows list.
    2. Select the workflow that includes the credentials that you need to map.
    3. Click **Configuration** > **Map Credentials to this Workflow**.

        The table that displays on the *Map Credentials* page displays all the current mappings for the selected workflow. Verify that the list of credential identifiers includes all of the identifiers that are in the workflow payload.
    4. Use the drop-down fields to map one or more credentials for the workflow. Verify that the table is updated with the correct information.
    5. Click **Save**.



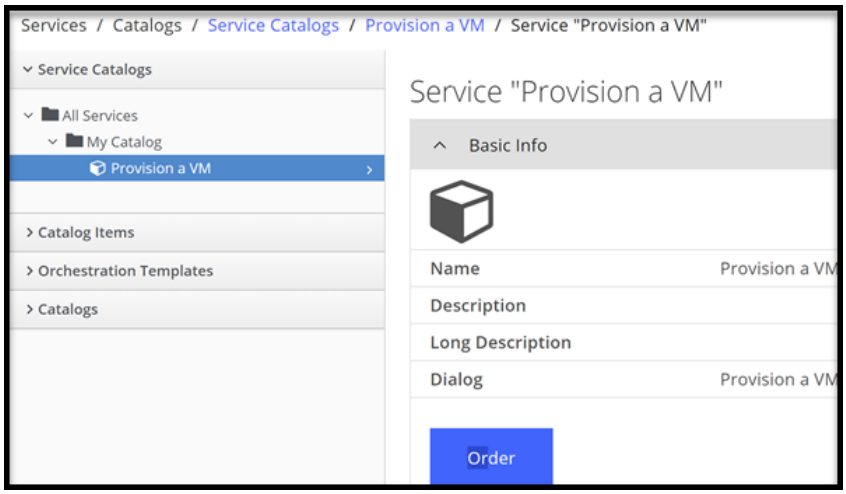
Creating a Service Dialog using an Embedded Workflow

Fields that are *Dynamic* offer the choice of *Embedded Workflows* in addition to the original *Embedded Automate*.

Dialogs are the part of Infrastructure Automation that you interface with when you order services.

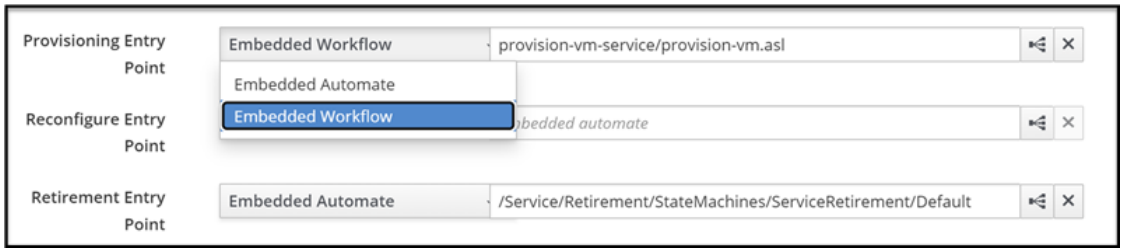
1. To open a service dialog, click **Automation** > **Embedded Automate** > **Customization**.
2. From the *Service Dialog* section, review the list of created dialogs. Click one of the dialogs to view the details.
3. Click **Edit the dialog**. You can edit the *Name*, *Provider*, and *Template*.

    When you select to edit any of the dropdown settings, you can see a *dynamic* option. Toggle to **On** to make sure it is enabled.
4. Click the **Options** tab. You can now select between *Embedded Automate* and *Embedded Workflows* in the Automation field.



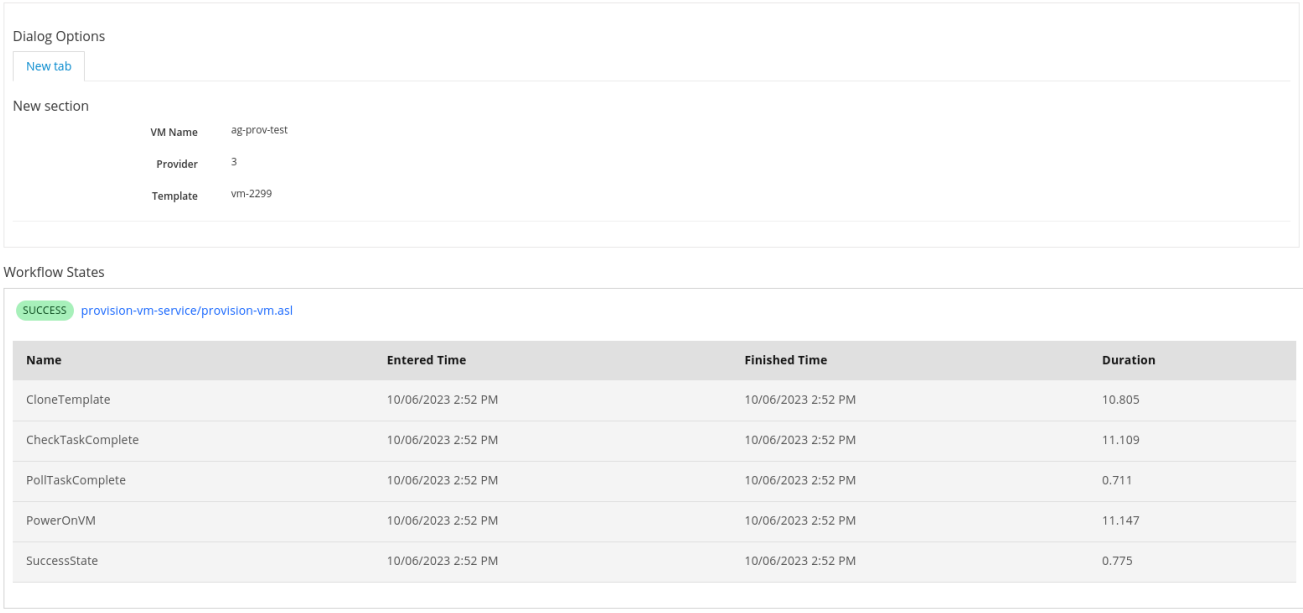
If you choose **Embedded Workflows**, you can select the workflow to run. Complete the remaining fields and click **Save** when you complete the form. You can chain dialog fields together by using **Fields to refresh**, which lets one dialog field trigger the run of another when there are interdependencies. When you *order* a service catalog, any dynamic dialogs that are backed by embedded workflows run in the background to populate the dialogs.

Creating Service Catalog Items using an Embedded Workflow



You can create a generic service catalog item that uses an embedded workflow. To use previously set up workflows and to view a service catalog item, you need to *order* the item. Complete the following steps to order a service catalog item that uses embedded workflows:

1. Click **Services** > **Catalogs**.
2. The *Service Catalogs* section opens and you see the existing Service Catalogs. If you want to order one, click it and then **Order**.



Complete the fields for your specified dialog. Then, click **Submit**.

3. If you want to know more about the item first or to edit it, click the **Catalogs** section, and then click that item that is created. Click **Configuration** > **Edit this item**.

4. When you complete all your edits, click **Save**.
5. Confirm that you can order the service catalog item and that it runs the workflows to drive the dynamic dialog dropdown.

   The list of services and requests is shown when the catalog item is submitted. Clicking the request shows the execution status, including any embedded workflows.

Ansible

Ansible integrates with Infrastructure Automation to provide automation solutions, using playbooks, for Service, Policy and Alert actions. Ansible playbooks consist of series of *plays* or tasks that define automation across a set of hosts, which is known as the inventory.

Ranging from simple to complex tasks, Ansible playbooks can support cloud management:

- **Services** - allow a playbook to back a Infrastructure Automation service catalog item.
- **Control Actions** - Infrastructure Automation policies can execute playbooks as actions based on events from providers.
- **Control Alerts** - set a playbook to launch prompted by a Infrastructure Automation alert.

Ansible is built into Infrastructure Automation so there is nothing to install. The basic workflow when using Ansible in Infrastructure Automation is as follows:

1. Enable the **Embedded Ansible** server role.
2. Add a source control repository that contains your playbooks.
3. Establish credentials with your inventory.
4. Back your services, alerts, and policies using available playbooks.

Enabling the Embedded Ansible Server Role

In Infrastructure Automation, the **Embedded Ansible** role is disabled by default. Enable this server role to utilize Ansible Automation Inside.

Note: Configure your Infrastructure Automation appliance network identity (hostname/IP address) before enabling the Embedded Ansible server role. Restart the **`evmserverd`** service on the appliance with the enabled Embedded Ansible server role after making any changes to the hostname or IP address.

1. Browse to the settings menu, then **Configuration > Settings**.
2. Select the desired server under **Zones**.
3. Set the **Server Role** for **Embedded Ansible** to **On**.

Verifying the Embedded Ansible Worker State

Verify that the Embedded Ansible worker has started to utilize its features.

1. Browse to the settings menu, then **Configuration > Diagnostics** and click on the desired server.
2. Click on the **Roles by Servers** tab.

A table of all workers and current status will appear from which you can confirm the state of your embedded Ansible worker.

Adding a Playbook Repository

Add a repository so that Infrastructure Automation can discover and make available your playbooks.

1. Browse to menu: **Automation > Ansible > Repositories**.
2. Click **Configuration**, then (**Add New Repository**).
3. Provide a Repository Name in the **Name** field.
4. Add a description for the repository in the **Description** field.
5. Add a **URL** or IP Address for the repository.
6. Select the appropriate **SCM Credentials** from the drop-down menu.
7. Provide a branch name in the **SCM Branch** field.
8. Click **Save**.

Once you have synced a repository, its playbooks will become available to Infrastructure Automation.

Refreshing Repositories

Infrastructure Automation allows you to refresh a targeted playbook repository or all repositories in your inventory to ensure your playbooks are current.

Refresh a targeted repository:

1. Browse to menu: **Automation > Ansible > Repositories**.
2. Click on a repository.
3. Click **Configuration**, then (**Refresh this Repository**).

Alternately, you can refresh some or all repositories from the list view:

1. Browse to menu: **Automation > Ansible > Repositories**.
2. Check those repositories to refresh. Click **Check All** to select all repositories.
3. Click **Configuration**, then (**Refresh Selected Ansible Repositories**).

Credentials

Credentials are utilized by Infrastructure Automation for authentication when running Ansible playbooks against machines, synchronizing with inventory sources, and importing project content from a version control system.

Adding Credentials

Infrastructure Automation can store credentials used by playbooks. Credentials saved in Infrastructure Automation are matched and executed with a playbook when run.

1. Browse to menu: **Automation > Ansible > Credentials**.
2. Click **Configuration**, then (**Add New Credential**).
3. Provide a **Name** for the credential.
4. Select the **Credential Type**. Additional fields will appear depending on the type chosen.
   - **Vault Password**: Ansible Vault credentials have only the **Vault Password** attribute that may be configured. For more information on Ansible Vault, see Using Vault in playbooks.
5. Click **Add**.

Credential Types

Each credential type used by Infrastructure Automation is detailed in the following sections.

Machine

Machine credentials enable Infrastructure Automation to invoke Ansible on hosts under your management. Just like using Ansible on the command line, you can specify the SSH username, optionally provide a password, an SSH key, or a key password. They define SSH and user-level privilege escalation access for playbooks, and are used when running playbooks on a remote host.

- **Username**: The username to be used for SSH authentication.
- **Password**: The actual password to be used for SSH authentication.
- **SSH Private Key**: Copy or drag-and-drop the SSH private key for the machine credential.
- **Private Key Passphrase**: If the SSH Private Key used is protected by a password, you can configure a Key Password for the private key.
- **Privilege Escalation**: Specifies the type of escalation privilege to assign to specific users. Options include **sudo**, **su**, **pbrun**, **pfexec**.
- **Privilege Escalation Username**: Enter the username to use with escalation privileges on the remote system.
- **Privilege Escalation Password**: Enter the actual password to be used to authenticate the user via the selected privilege escalation type on the remote system.

Network

Network credentials are used by Ansible networking modules to connect to and manage networking devices.

Network credentials have several attributes that may be configured:

- **Username**: The username to use in conjunction with the network device.
- **Password**: The password to use in conjunction with the network device.
- **Authorize**: Select this from the Options field to add an Authorize password which signs the RSA key with a password.
- **Authorize password**: If **Authorize** is checked, enter a password in the **Authorize Password** field.
- **SSH Key**: Copy or drag-and-drop the actual SSH Private Key to be used to authenticate the user to the network via SSH.
- **Private key passphrase**: The actual passphrase for the private key to be used to authenticate the user to the network via SSH.

SCM

SCM (source control) credentials are used with Projects to clone and update local source code repositories from a remote revision control system such as Git, Subversion, or Mercurial.

Source Control credentials have several attributes that may be configured:

- **Username**: The username to use in conjunction with the source control system.
- **Password**: The password to use in conjunction with the source control system.
- **Private key passphrase**: If the SSH private key used is protected by a passphrase, you may configure a key passphrase for the private key.
- **Private Key**: Copy or drag-and-drop the actual SSH Private Key to be used to authenticate the user to the source control system via SSH.

Amazon

Selecting this credential type enables synchronization of cloud inventory with Amazon Web Services.

- **Access Key**: User credentials that allow for programmatic calls to Amazon Web Services.
- **Secret Key**: The secret key that corresponds to the user access key.
- **STS Token**: Token generated by Amazon Web Services Security Token Service.

Azure

Selecting this credential type enables synchronization of cloud inventory with Microsoft Azure.

Microsoft Azure credentials have several attributes to configure:

- **Username**: The username to use to connect to the Microsoft Azure account.
- **Password**: The password to use to connect to the Microsoft Azure account.
- **Subscription ID**: The Subscription UUID for the Microsoft Azure account.
- **Tenant ID**: The Tenant ID for the Microsoft Azure account.
- **Client Secret**: The Client Secret for the Microsoft Azure account.
- **Client ID**: The Client ID for the Microsoft Azure account.

OpenStack

Selecting this credential type enables synchronization of cloud inventory with Red Hat OpenStack Platform.

OpenStack credentials have several attributes that may be configured:

- **Username**: The username to use to connect to OpenStack.
- **Password (API Key)**: The password or API key to use to connect to OpenStack.
- **Host (Authentication URL)**: The host to be used for authentication.
- **Project (Tenant Name)**: The Tenant name or Tenant ID used for OpenStack. This value is usually the same as the username.
- **Domain name**: The FQDN to be used to connect to OpenStack.

Red Hat Virtualization

Selecting this credential type enables synchronization of cloud inventory with Red Hat Virtualization.

Red Hat Virtualization credentials have several attributes that may be configured:

- **Username**: The username to use to connect to Red Hat Virtualization.
- **Password**: The password to use to connect to Red Hat Virtualization.
- **Host (Authentication URL)**: The host to be used for authentication.

  Important: Enter in **Host** the Red Hat Virtualization provider URL, followed by the path `/ovirt_engine/api`. Example: `https://your.rhv.com/ovirt_engine/api`

  For more information on the Ansible Roles that are available for Red Hat Virtualization, see Ansible Roles.

VMware

Selecting this credential type enables synchronization of inventory with VMware vCenter.

Important: If both Infrastructure Automation and a VMware provider are located in the same IPv6-only network, use a DNS-resolvable hostname for the VMware provider in the **vCenter Host** field when adding credentials.

VMware credentials have several attributes that may be configured:

- **Username**: The username to use to connect to vCenter.
- **Password**: The password to use to connect to vCenter.
- **vCenter Host**: The vCenter hostname or IP address to connect to.

Note: If the VMware guest tools are not running on the instance, VMware inventory sync may not return an IP address for that instance.

Tagging Ansible Playbooks, Repositories, and Credentials

Apply tags to Ansible playbooks, repositories, and credentials to categorize them. Tagging enables administrators to limit users to view those Ansible elements that have been enabled for that set of user permissions.

Adding Tags to Ansible Playbooks

1. Navigate to **Automate > Ansible > Playbooks**.
2. Select the checkboxes for the Ansible playbooks to tag.
3. Click **Policy**, and then (**Edit Tags**).
4. Select a customer tag to assign from the first list.
5. Select a value to assign from the value list.
6. Click **Save**.

Adding Tags to Ansible Repositories

1. Navigate to **Automate > Ansible > Repositories**.
2. Select the checkboxes for the Ansible repositories to tag.
3. Click **Policy**, and then (**Edit Tags**).
4. Select a customer tag to assign from the first list.
5. Select a value to assign from the value list.
6. Click **Save**.

Adding Tags to Ansible Credentials

1. Navigate to **Automate > Ansible > credentials**.
2. Select the checkboxes for the Ansible credentials to tag.
3. Click **Policy**, and then  (**Edit Tags**).
4. Select a customer tag to assign from the first list.
5. Select a value to assign from the value list.
6. Click **Save**.

Optimizing Ansible Playbooks for Infrastructure Automation

Ansible is a simple model-driven configuration management, multi-node deployment, and remote-task execution system. When designing playbooks for use with Infrastructure Automation it is helpful to utilize solutions within the playbook itself to ensure optimal implementation of playbook-backed services or automated processes.

This section is intended to complement the existing documentation on Ansible playbooks and guide administrators through optimizing playbooks for use with Infrastructure Automation.

Installing Roles on an Embedded Ansible Appliance

Roles are ways of automatically loading certain variable files, tasks, and handlers based on a known file structure. Grouping content by roles also allows for easy sharing of roles with other users. Install roles on a Infrastructure Automation appliance with the Embedded Ansible server role activated to optimize playbooks.

When using this role in a playbook on a Infrastructure Automation appliance, add an empty **`roles`** directory at the root of the playbook. In the **`roles`** directory, include a **`requirements.yml`** file with the following contents:

```
---
- src: <ansible-galaxy-role>
```

Infrastructure Automation automatically installs the role once it sees the **`requirements.yml`** file in the playbook.

Ansible Service Linking

Infrastructure Automation provides a module allowing inventoried resources such as virtual machines created using Ansible playbooks to link back to the services used to generate them. During service ordering of a playbook the **`add_provider_vms`** module will allow the playbook to connect back to the worker appliance and identify the provider resources it was responsible for generating. Once linked, the newly generated resources are available to Infrastructure Automation's life cycle management features.

Linking VMs back to the service that created it requires implementing the following tasks in the playbook used for provisioning:

1. Create a resource and register it.
2. Link the service using the **`add_provider_vms`** method to the newly created resource.

Example: Linking a virtual machine to a service

In the following playbook task examples, a virtual machine is deployed to Amazon EC2 and linked back to the service. Examples are provided for linking the resource to its service by both an *href slug* and as an object.

Note:

- This example utilizes the `syncrou.manageiq-vmdb` role. This role allows Infrastructure Automation users to modify and/or change VMDB objects using an Ansible playbook. For information on implementing and utilizing roles when writing Ansible playbooks for Infrastructure Automation, see Installing Ansible Roles.
- For more information on Ansible Galaxy and roles, see the Ansible Galaxy documentation.
- Note the provider ID in order to successfully link to the service.

1. Create and register the resource.

```
- name: Create Ec2 Instance
  ec2:
    key_name: ""
    instance_tags: {Name: ""}
    group_id: ""
    instance_type: ""
    region: ""
    image: ""
    wait: yes
    count: 1
    vpc_subnet_id: ""
    assign_public_ip: yes
  register: ec2
```

2. Call the **`add_provider_vms`** method as an action to link to the service via an *href slug* or an object.

```
- name: Service Linking via an href slug
  manageiq_vmdb:
    href: "href_slug::services/80"
    action: add_provider_vms
    data:
      uid_ems:
        - ""
      provider:
        id: 24

- name: Service Linking via an object
  manageiq_vmdb:
    vmdb: ""
    action: add_provider_vms
    data:
      uid_ems:
        - ""
      provider:
        id: 24
```

Modifying the Automate Workspace Using the `manageiq-automate` Role.

The **`manageiq-automate`** role allows users of Infrastructure Automation Automate to modify and add to the automate workspace via an Ansible playbook.

Note: When using this role in a playbook on a Infrastructure Automation appliance with Embedded Ansible activated, add an empty **`roles`** directory at the root of the playbook. In the **`roles`** directory, include a **`requirements.yml`** file with the following contents:

```
---
- src: syncrou.manageiq-automate
```

Infrastructure Automation will automatically install the role once it sees the **`requirements.yml`** file in the playbook.

Role Variables

The **`manageiq_automate`** role employs the following variables when implemented in a playbook run on a Infrastructure Automation appliance. Variables are defined in **`defaults/main.yml`** and **`vars/main.yml`**.

`auto_commit`: By default is set to **`True`**. If set to False it does not auto commit back to Infrastructure Automation each call to a **`set_`** method in the **`manageiq_automate`** module.

`manageiq_validate_certs`: By default is set to **`True`**. If passed in with **`extra_vars`** or assigned in the playbook variables then the lookup allows self-signed certificates to be used when using SSL REST API connection URLs.

Example Playbook

The following example utilizes the **`manageiq-automate`** role. Using variable substitution, playbook tasks retrieve method parameters which are then used to modify object attributes. A final task uses the **`set_retry`** module to update the retry interval.

```
- name: Siphon Method Parameters into an object
  hosts: localhost
  connection: local
  vars:
  - auto_commit: True
  - object: root
  - interval: 600

  gather_facts: False
  roles:
  - syncrou.manageiq-automate

  tasks:
    - name: "Get the list of Method Parameters"
      manageiq_automate:
        workspace: ""
        get_method_parameters: yes
      register: method_params

    - name: "Set attributes"
      manageiq_automate:
        workspace: ""
        set_attributes:
          object: ""
          attributes: ""

    - name: Set Retry
      manageiq_automate:
        workspace: ""
        set_retry:
          interval: ""
```

Callbacks in Multiple Appliance Environments

In a Infrastructure Automation multiple appliance environment, enable the Embedded Ansible server role on a dedicated Infrastructure Automation appliance. Add **`store_session:sql`** to Ansible playbooks to ensure successful callbacks to Infrastructure Automation appliances in a multiple appliance environment.

Ansible Tower

Ansible Tower is a management tool integrated with Infrastructure Automation, designed to help automate infrastructure operations. Infrastructure Automation allows you to execute Ansible Tower jobs or workflows using service catalogs and Automate. No custom configuration or Ruby scripting is needed in Infrastructure Automation, as configuration is done in Ansible Tower using playbooks.

You can use the large library of existing Ansible playbooks as Infrastructure Automation state machines to automate tasks such as deployments, backups, package updates, and maintenance in your Infrastructure Automation environment. This can be particularly useful for quickly applying changes across large environments with many virtual machines or instances.

Using Ansible Tower, you can schedule Ansible playbook runs and monitor current and historical results, allowing for troubleshooting or identification of issues before they occur.

Infrastructure Automation supports Ansible Tower API v2 provider integration.

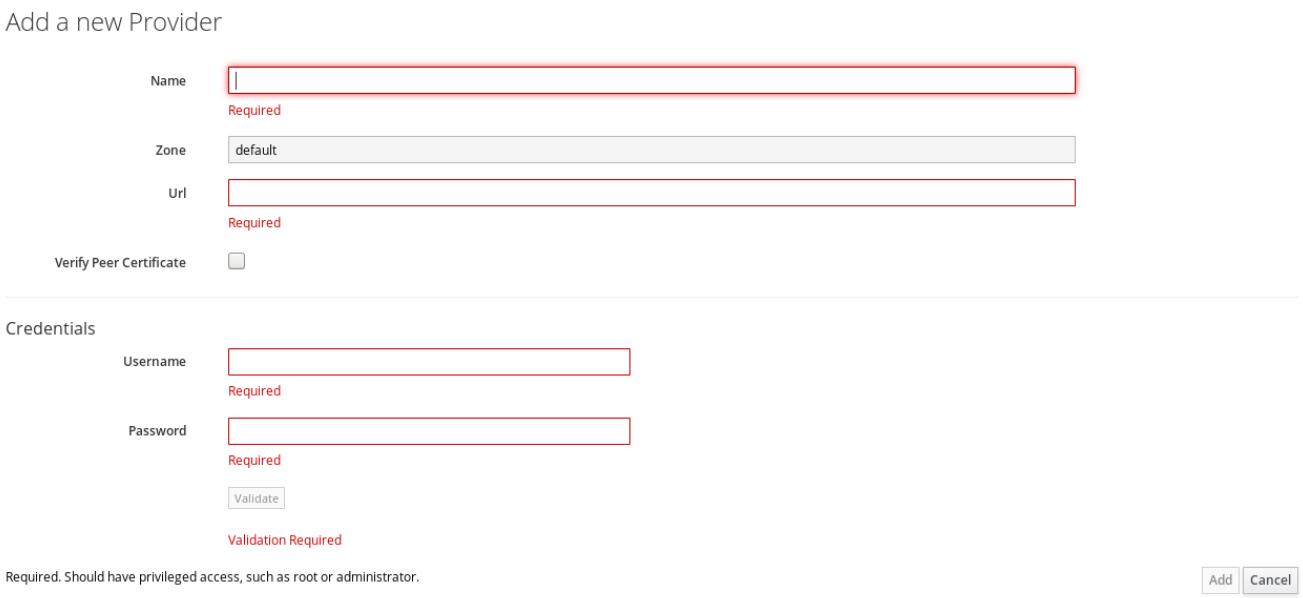
Working with an Ansible Tower Provider

The basic workflow when using Infrastructure Automation with an Ansible Tower provider is as follows:

1. Create an Ansible playbook which performs a specific task.
2. A new Ansible Tower job template is created from the playbook (or workflow template created from disparate jobs), which is then retrieved by Infrastructure Automation.
3. From the Ansible Tower job or workflow template, create a new catalog item in Infrastructure Automation, optionally with a service dialog that allows the user to enter parameters if needed.
4. The user orders the service from the Infrastructure Automation user interface, and fills out any additional arguments (for example, limiting the task to run on a specific set of virtual machines).
5. The job or workflow executes.

Notes:

- For more information about Ansible playbooks, see the Ansible playbook documentation.
- For more information about worklows, see Workflows in the Ansible Tower *User Guide*.



Adding an Ansible Tower Provider

To access your Ansible Tower inventory from Infrastructure Automation, you must add Ansible Tower as a provider.

Notes:

- Ensure **ENABLE HTTP BASIC AUTH** is set to **On** in the Ansible Tower configuration settings before adding the provider. See Tower Configuration in the Ansible Tower *Administration Guide*.
- A trailing slash is **not** required at the end of the Ansible Tower provider URL. Adding the trailing slash to the provider URL may result in a validation error.

1. Browse to menu: **Automation > Ansible Tower > Explorer** and click on the **Providers** accordion tab.
2. Under **Configuration**, click **Add a new Provider**.
3. In the **Add a new Provider** area:

1. Enter a **Name** for the new provider.

2. Add a **Zone** for the provider.
3. Enter the **URL** location or IP address to the Ansible Tower server. Add a trailing slash to the end of the Ansible Tower provider URL.
4. Select the **Verify Peer Certificate** checkbox if desired.
5. In the **Credentials** area, provide the **Username** and **Password**, and **Confirm Password**.
6. Click **Validate** to verify credentials.
7. Click **Add**.

After adding the Ansible Tower provider, refresh its relationships and power states in order to view the current inventory.

Refreshing an Ansible Tower Provider

Refresh relationships of all items related to an existing Ansible Tower configuration management provider including inventory, hosts, virtual machines, and clusters.

You can refresh inventory from Infrastructure Automation, or by enabling the **Update on Launch** option for inventory groups in Ansible Tower. The **Update on Launch** option allows Ansible Tower to automatically update inventory using a dynamic inventory script before launching an Ansible Tower job from a playbook. For more information, see the Ansible Tower documentation.

Important: It can take a long time to retrieve information from providers containing many virtual machines or instances. The Ansible Tower dynamic inventory script can be modified to limit updates to specific items and reduce refresh time.

To refresh an Ansible Tower provider's inventory in Infrastructure Automation:

1. Browse to menu: **Automation > Ansible Tower > Explorer** and click the **Providers** accordion tab.
2. Select the checkboxes for the Ansible Tower providers to refresh under **All Ansible Tower Providers**.
3. Click **Configuration**, and then (**Refresh Relationships and Power States**).
4. Click **OK**.

Infrastructure Automation then queries the Ansible Tower API and obtains an inventory of all available hosts, job, and workflow templates.

Viewing Ansible Tower Providers and Inventory

Infrastructure Automation automatically updates its inventory from Ansible Tower. This includes system groups (known as Inventories in Ansible Tower), basic information about individual systems, and available Ansible Tower job or workflow templates to be executed from the service catalog or Automate.

Note: To view and access Ansible Tower inventories and job or workflow templates in Infrastructure Automation, you must first create them in Ansible Tower.

To view a list of Ansible Tower providers and inventory:

1. Browse to menu: **Automation > Ansible Tower > Explorer**.
2. select the **Providers** accordion menu to display a list of **All Ansible Tower Providers**.
3. Select your Ansible Tower provider to expand and list the inventory groups on that Ansible Tower system. The inventory groups can be expanded to view the systems contained within each group, as well as configuration details for these systems.

Similarly, all discovered job and workflow templates are accessed under the provider by expanding the menu: **Automation > Ansible Tower > Explorer** and click the **Templates** accordion menu.

Viewing Ansible Tower Configured Systems

To view the systems in your Ansible Tower inventory:

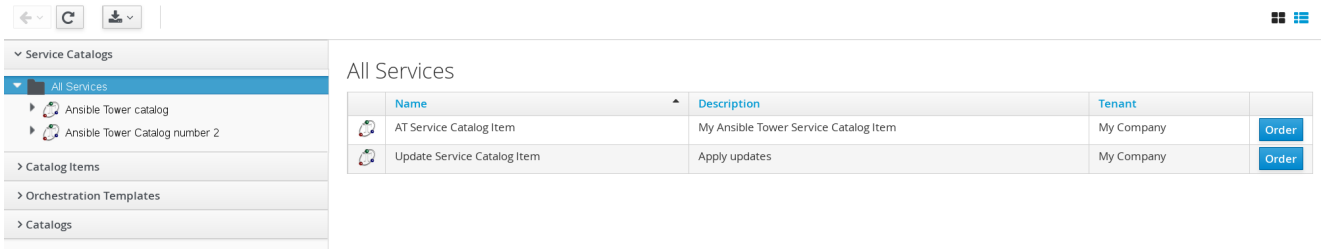
1. Browse to menu: **Automation > Ansible Tower > Explorer** and click **Configured Systems**.
2. Under **All Ansible Tower Configured Systems**, select **Ansible Tower Configured Systems** to display a list.

Executing an Ansible Tower Job or Workflow Template from a Service Catalog

You can execute an Ansible Tower playbook from Infrastructure Automation by creating a service catalog item from an Ansible Tower job or workflow template.

Important: You must first create the job or workflow template in Ansible Tower. The job or workflow templates are automatically discovered by Infrastructure Automation when refreshing your Ansible Tower provider's inventory.

First, create a catalog:



1. Browse to menu: **Services > Catalogs** and click **Catalog Items**.
2. Click **Configuration**, then (**Add a New Catalog**)
3. Enter a **Name** and **Description** for the catalog.
4. Click **Add**.

Then, create an Ansible Tower service catalog item:

1. Browse to menu: **Automation > Ansible Tower > Explorer**, then click the **Templates** according menu.
2. Click **Ansible Tower Templates** and select an Ansible Tower job or workflow template.
3. Click **Configuration**, then (**Create Service Dialog from this Template**).
4. Enter a **Service Dialog Name** (for example, *ansible_tower_job*)and click **Save**.
5. Browse to menu: **Services > Catalogs** and click **Catalog Items**.
6. Click **Configuration**, then (**Add a New Catalog Item**) to create a new catalog item with the following details, at minimum:
   - For **Catalog Item type**, select **Ansible Tower**.
   - Enter a **Name** for the service catalog item.
   - Select **Display in Catalog**.
   - In **Catalog**, select the catalog you created previously.
   - In **Dialog**, select the service dialog you created previously (in this example, *ansible_tower_job*). To ask the user to enter extra information when running the task, **Service Dialog** must be selected. A dialog is required if **Display in Catalog** is chosen.
   - In **Provider**, select your Ansible Tower provider. This brings up the **Ansible Tower Template** option and configures the **Provisioning Entry Point State Machine** automatically.
   - Add configuration information for **Reconfigure Entry Point** and **Retirement Entry Point** as applicable.
   - Select your desired **Ansible Tower Template** from the list. Generally, this is the Ansible Tower job or workflow template previously used to create the service dialog.
7. Click **Add**. The catalog item you created will appear in the **All Service Catalog Items** list.

To execute the Ansible Tower job:

1. Browse to menu: **Service > Catalogs** and click on **Service Catalogs** then click **Ansible Tower catalog**.

2. Click **Order** for the catalog item.
3. Enter any variables requested and click **Submit**.

Infrastructure Automation takes you to the **Requests** queue page and show the status of the job.

The service item's details can be viewed in menu: **Services > My Services** in Infrastructure Automation.

Note: Instead of running a single job at a time, multiple service catalog items can also be grouped together as a catalog bundle to create one deployment with multiple job templates. For more information, see Catalogs and Services.

Executing an Ansible Tower Job Using a Custom Automate Button

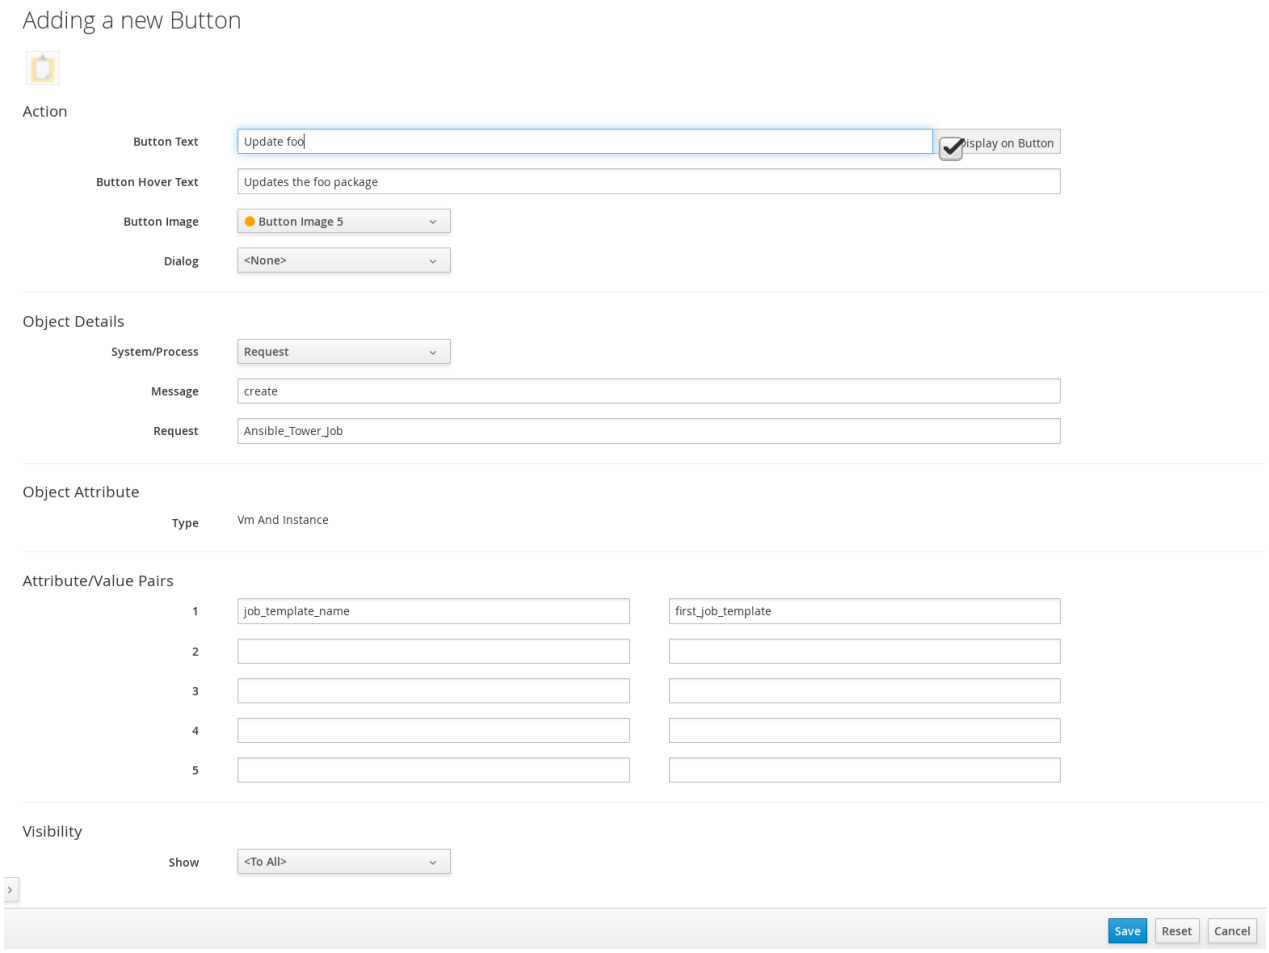
Infrastructure Automation can execute Ansible Tower jobs on virtual machines or instances using custom buttons in Automate.

Ansible Tower jobs can either be noncustomizable, which do not require any extra configuration from the user, or alternatively, they can allow the user to specify a parameter (for example, a package name to install). In Ansible Tower jobs containing a dialog, Infrastructure Automation accepts additional information from the user and adds it to the appropriate API call in Automate, and then sends it into Ansible Tower.

Prerequisites.

Before creating an Automate button to execute an Ansible Tower job, the following must be configured:

- An Ansible playbook in Ansible Tower. See the Ansible Tower documentation for instructions.
- Ansible Tower must be able to reach virtual machines or instances deployed by Infrastructure Automation at the IP level.
- The virtual machine template must have the Ansible Tower environment's public SSH key injected. For cloud instances, `cloud-init` can be used and the public SSH key can be passed without rebuilding the image.
- Any dynamic inventory scripts used must be configured to return the virtual machine names exactly as they are stored in Infrastructure Automation, without the UUID appended.

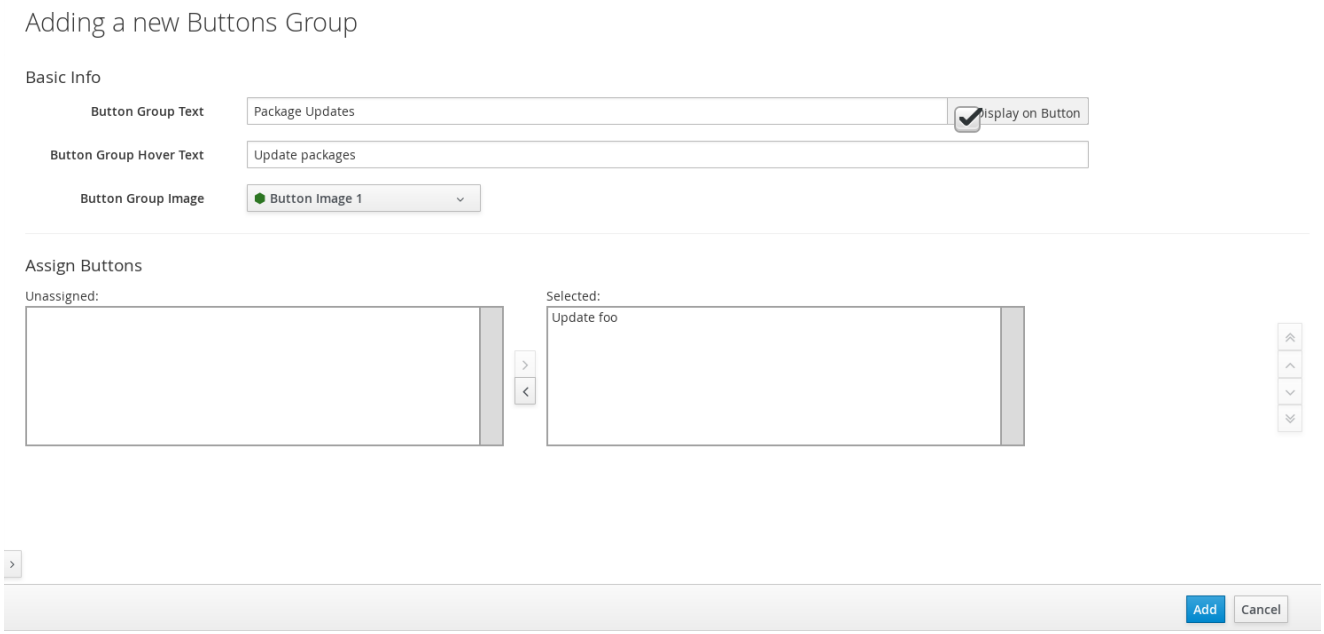


Executing an Ansible Tower Job using a Custom Automate Button.

To configure a custom button to execute an Ansible Tower job on a virtual machine or instance, first create the button:

1. Browse to menu: **Automation > Automate > Customization**.
2. Click the **Buttons** accordion menu.
3. Click menu: **VM and Instance > Unassigned Buttons**. This configures the button to run on virtual machines or instances.
4. Click **Configuration**, then click (**Add a new Button**).
    1. In the **Adding a new Button** screen, configure the **Action** parameters as desired. **Dialog** can be left blank if the playbook does not require extra variables. To ask the user to enter extra information when running the task, **Service Dialog** must be selected.
    2. Configure **Object Details** fields with the following request details:

- For **System/Process**, select **Request**.
- For **Message**, enter **create**.
- For **Request**, enter **Ansible_Tower_Job**.

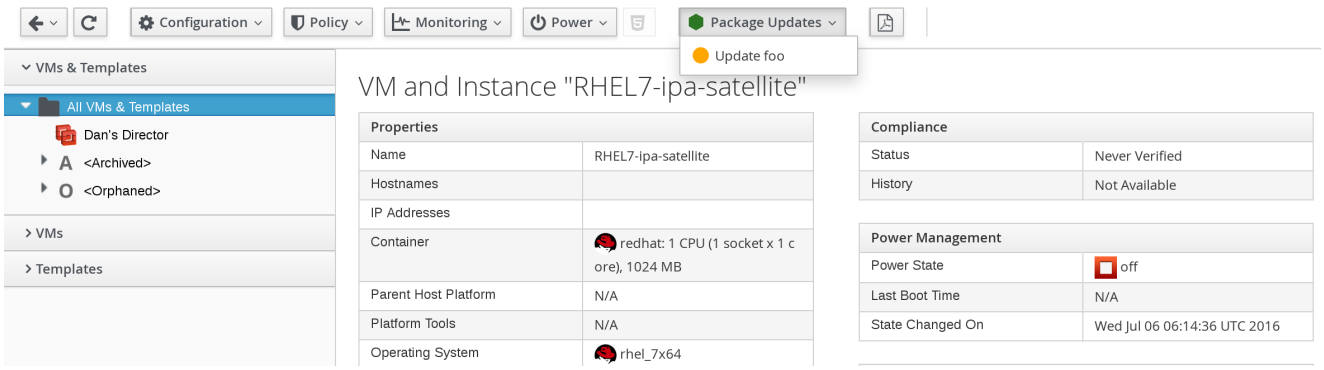


1. Configure **Attribute/Value Pairs** with the following parameters:
- **job_template_name** is the Ansible Tower job template name to associate with the button. The **job_template_name** field is mandatory; other parameters are provided by the Tower job dialog.
- Configure **Visibility** to all users, or limit visibility by role as desired.

1. Click **Add**.

If you do not have an existing button group to assign the new button to, create a new button group:

1. From menu: **Automation > Automate > Customization**, browse to menu: **Buttons** and click **VM and Instance > Add a new Button Group**, and configure the following:
    1. Configure **Basic Info** as desired. For example, name the button group `VM Actions`.
    2. In **Assign Buttons**, select the button you just created from the **Unassigned** list and click to assign it to **Selected**.



1. Click **Add**.

To assign the button to an existing button group:

1. Browse to menu: **Buttons > VM and Instance > VM Actions > Edit this Button Group**.
2. In **Assign Buttons**, select the button you just created from the **Unassigned** list and click to assign it to **Selected**.
3. Click **Add**.

To use the button to run an Ansible Tower job on a virtual machine:

1. Browse to menu: **Compute > Infrastructure > Virtual Machines**.
2. Select the virtual machine to run the Ansible Tower job template on.
3. Click the **VM Actions** button to show the button you created, and click the button from the list to run the Ansible Tower job template.

4. Click **Submit** to execute the job.

Infrastructure Automation then confirms the job has been executed.

If you selected a service dialog to run when creating the button, Infrastructure Automation will then prompt you to enter variables to complete the task. After entering your desired parameters, Infrastructure Automation takes you to the **Requests** page.

The service item's details can be viewed in menu: **Services > My Services** in Infrastructure Automation.

Embedded Terraform (OpenTofu)

OpenTofu is an open source infrastructure as code tool, which can be used to build, change, and version the infrastructure. You can use OpenTofu to define infrastructure resources in human-readable configuration files that you can use to version, reuse, and share.

OpenTofu is built into Infrastructure Automation so you do not need to install any additional components.

If you want to use the Embedded Terraform feature in Infrastructure Automation that is deployed as a virtual machine appliance, then you need to manually import the Terraform image on an appliance:

Importing OpenTofu image on an appliance

Note: Follow this section if you have Infrastructure Automation that is deployed as a virtual appliance. These steps are not applicable to a containerized deployment (podified) of Infrastructure Automation.

Use the following command to import the OpenTofu image on your appliance server.

```
runuser --login manageiq --command 'podman --root=/var/www/miq/vmdb/data/containers/storage pull
cp.icr.io/cp/cp4waiops/infra-mgmt-opentofu-runner:v4.6.0-20240612.1413-5b98dbde8'
```

Where **`OpenTofu_image`** is the name of your OpenTofu image.

You also need to set the docker image name in advanced settings before enabling the server role. Navigate to the **Settings** > **Application Settings** in Infrastructure Automation UI and set the value for **`workers/worker_base/opentofu_worker/container_image`** field.

An example value of this field is **`container_image: cp.icr.io/cp/cp4waiops/infra-mgmt-opentofu-runner:v4.6.0-20240612.1413-5b98dbde8`**.

Usage of Embedded Terraform (OpenTofu)

The following sections show the usage of Embedded Terraform in Infrastructure Automation. The following sections apply to Infrastructure Automation that is deployed as a containerized deployment (podified) and Infrastructure Automation that is deployed as a virtual machine appliance:

1. Enable the Embedded Terraform server role.
2. Add a source control repository that contains your templates.
3. Add credentials to access the repository.
4. Create a Service Catalog item with the desired Terraform template.

Enabling the Embedded Terraform Server Role

In Infrastructure Automation, the Embedded Terraform server role is disabled by default. Enable this server role to use Embedded Terraform (OpenTofu).

To enable the Embedded Terraform Server Role, use the following steps:

1. Browse to the settings menu, and click **Configuration** > **Application Settings**.
2. Select the desired server under **Zones**.
3. Set the **Server Role** for **Embedded Terraform** to **`On`**.

Verifying the Embedded Terraform worker state

Verify that the Embedded Terraform worker is started to use its features:

1. Browse to the settings menu, then click **Configuration** > **Application Settings**.
2. Click **Diagnostics** and click the server that you want to choose.
3. Click **Roles by Servers** tab.

A table of all workers and their status appears from which you can confirm the state of your Embedded Terraform worker.

Adding a Template Repository

To enable Infrastructure Automation to discover and use your Terraform templates, add a repository to store and manage your templates.

If your repository requires credentials for access, then you need to create SCM credentials. For more information about how to create SCM credentials, see SCM credentials.

Use the following steps to add a repository:

1. Browse to the menu and click **Automation > Embedded Terraform > Repositories**.
2. Click **Configuration**, then ⊕ (**Add New Repository**).
3. Provide a Repository Name in the **Name** field.
4. Add a description for the repository in the **Description** field.
5. Add a **URL** and an optional port for the repository.
6. Select the appropriate **SCM Credentials** from the drop-down menu.
7. Provide a branch name in the **SCM Branch** field. This field is optional and default value is set to **`master`** branch.
8. Click **Save**.

When you save the repository, the Terraform templates are synced, and are available to Infrastructure Automation.

Refreshing Repositories

You can use Infrastructure Automation to refresh specific Terraform repositories or all repositories in your inventory to make sure that your templates are up to date.

Use the following steps to refresh a specific repository:

1. Browse to the menu and click **Automation > Embedded Terraform > Repositories**.
2. Click a repository.

3. Click **Configuration**, then (**Refresh this Repository**).

Alternately, you can refresh some or all of the repositories from the list view:

1. Browse to the menu and click **Automation > Embedded Terraform > Repositories**.
2. Select the repositories that you want to refresh. Click **Check All** to select all repositories.
3. Click **Configuration**, then (**Refresh Selected Ansible Repositories**).

Credentials

Use the following sections to learn more about credentials that are associated with Infrastructure Automation and Embedded Terraform:

Adding Credentials

Credentials are used by Infrastructure Automation for authentication when you connect to cloud providers for infrastructure deployment.

1. Browse to the menu and click **Automation > Embedded Terraform > Credentials**.
2. Click **Configuration**, then (**Add New Credential**).
3. Provide a **Name** for the credential.
4. Select the **Credential Type**. Additional fields might appear depending on the credential type that you chose.
5. Click **Add**.

Credential Types

Each credential type that is used by Infrastructure Automation for the Embedded Terraform is listed in the following sections:

SCM

SCM (source control) credentials are used with projects to clone and update the local source code repositories from a remote revision control system such as Git, Subversion, or Mercurial.

Source Control credentials contain multiple attributes, which you need to configure:

- **Username**: The username for source control system.
- **Password**: The password for source control system.
- **Private key passphrase**: If the SSH private key used is protected by a passphrase, you might need to configure a key passphrase for the private key.
- **Private Key**: Copy or drag-and-drop the actual SSH private key, which is used to authenticate the user to the source control system by using SSH.

Amazon

If you select this credential type, it enables connection between Infrastructure Automation and Amazon Web Services.

Amazon Web Services credentials contain multiple attributes, which you need to configure:

- **Access Key**: User credentials that allow for programmatic calls to Amazon Web Services.
- **Secret Key**: The secret key that corresponds to the user access key.
- **STS Token**: Token generated by Amazon Web Services Security Token Service.
- **AWS region**: Multiple, physically separated and isolated Availability Zones that are connected with low latency, high throughput, and highly redundant networking.

Azure

If you select this credential type, it enables connection between Infrastructure Automation and Microsoft Azure.

Microsoft Azure credentials contain multiple attributes, which you need to configure:

- **Subscription ID**: The Subscription UUID for the Microsoft Azure account.
- **Tenant ID**: The Tenant ID for the Microsoft Azure account.
- **Client Secret**: The Client Secret for the Microsoft Azure account.
- **Client ID**: The Client ID for the Microsoft Azure account.

Google Compute Engine

If you select this credential type, it enables connection between Infrastructure Automation and Google Compute Engine.

Google Compute Engine credentials contain multiple attributes, which you need to configure:

- **Service Account Email Address**: The Service Account email address to connect to the Google Compute Engine.

- **RSA Private Key**: Contents of the PEM file associated with the service account email.
- **Project**: The Google Compute Engine assigned identification. This field is constructed as two words followed by a three-digit number, such as `squeamish-ossifrage-123`.
- **Google Cloud Region**: The default region for the resources. If another region is specified on the resource, it takes precedence.

IBM Cloud Classic Infrastructure

If you select this credential type, it enables connection between Infrastructure Automation and IBM Cloud Classic Infrastructure.

IBM Cloud Classic Infrastructure credentials contain multiple attributes, which you need to configure:

- **IBM Cloud Classic Infrastructure User Name**: The username for IBM Cloud Classic Infrastructure.
- **IBM Cloud Classic Infrastructure API Key**: The API key for IBM Cloud Classic Infrastructure.

OpenStack

If you select this credential type, it enables connection between Infrastructure Automation and OpenStack.

OpenStack credentials contain multiple attributes, which you might need to configure:

- **Username**: The username to connect to OpenStack.
- **Password (API Key)**: The password or API key to connect to OpenStack.
- **Host (Authentication URL)**: The host to be used for authentication.
- **Project (Tenant Name)**: The Tenant name or Tenant ID to connect to OpenStack. This value is usually the same as the username.
- **Domain name**: The Fully qualified domain name (FQDN) to connect to OpenStack.

VMware

If you select this credential type, it enables connection between Infrastructure Automation and VMware vCenter.

Important: If both Infrastructure Automation and a VMware provider are located in the same IPv6-only network, then use a DNS-resolvable hostname for the VMware provider in the **vCenter Host** field when you add the credentials.

VMware credentials contain multiple attributes, which you might need to configure:

- **Username**: The username to connect to vCenter.
- **Password**: The password to connect to vCenter.
- **vCenter Host**: The vCenter hostname or IP address to connect to.

Running a Terraform Template from a Service Catalog

You can run a Terraform Template from Infrastructure Automation by creating a Service Catalog item from a Terraform template.

Use the following listed steps in each section to run the Terraform Template from a Service Catalog:

1. Create a catalog
2. Create a Terraform Service Catalog item
3. Run the Terraform template

Create a catalog

Use the following steps to create a catalog:

1. In the navigation bar, click **Services** > **Catalogs**.
2. Click **Catalogs**.
3. Click **Configuration**, then click **Add a New Catalog**.
4. Enter a **Name** and **Description** for the catalog.
5. Click **Add**.

Create a Terraform Service Catalog item

Use the following steps to create a Terraform Service Catalog item:

1. In the navigation bar click **Automation** > **Embedded Automate** > **Customization**, then click **Service Dialog**.
2. Click **Configuration** > **Create Service Dialog**.
3. Enter a **Service Dialog Name** and add the required fields for the Terraform template.
4. Click **Save**.
5. In the navigation bar, click **Services** > **Catalogs** > **Catalog Items**.
6. Click **Configuration** > **Add a New Catalog Item** to create a new catalog item with the following details at minimum:

- For **Catalog Item type**, select **Terraform Template**.
- Enter a **Name** for the service catalog item.
- Select **Display** in **Catalog**.
- In Catalog, select the catalog that you created previously.
- In Provisioning, select the repository that you previously added and select the Terraform template that you want to deploy.
- In Provisioning, select the **Cloud Type** and then select the **credential** to connect to the cloud.
- In Provisioning, select the **Service Dialog** that you created previously. If you want to enter additional information when you run the task, **Service Dialog** must be selected. A dialog is required if **Display in Catalog** is chosen.

7. Click **Save**.

The catalog item that you created appears in the *All Service Catalog Items* list.

Run the Terraform Template:

Use the following steps to run the Terraform Template.

1. In the navigation bar, click **Service** > **Catalogs** > **Service Catalogs** > **created catalog**.
2. Click **Order** for the catalog item.
3. Enter any variables that are requested and click **Submit**.

Infrastructure Automation takes you to the *Requests queue* page and displays the status of the job.

The service item details can be viewed when you navigate to **Services** > **My Services in Infrastructure Automation**.

Cloud Providers

In Infrastructure Automation, a cloud provider is a cloud computing environment that you can add to a Infrastructure Automation appliance to manage and interact with the resources in that environment. This chapter describes the different types of cloud providers that you can add to Infrastructure Automation, and how to manage them. Most cloud providers are added individually to Infrastructure Automation. Additionally, Amazon EC2 and Azure cloud providers can be discovered automatically by Infrastructure Automation.

The web interface uses virtual thumbnails to represent cloud providers. Each thumbnail contains four quadrants by default, which display basic information about each provider:

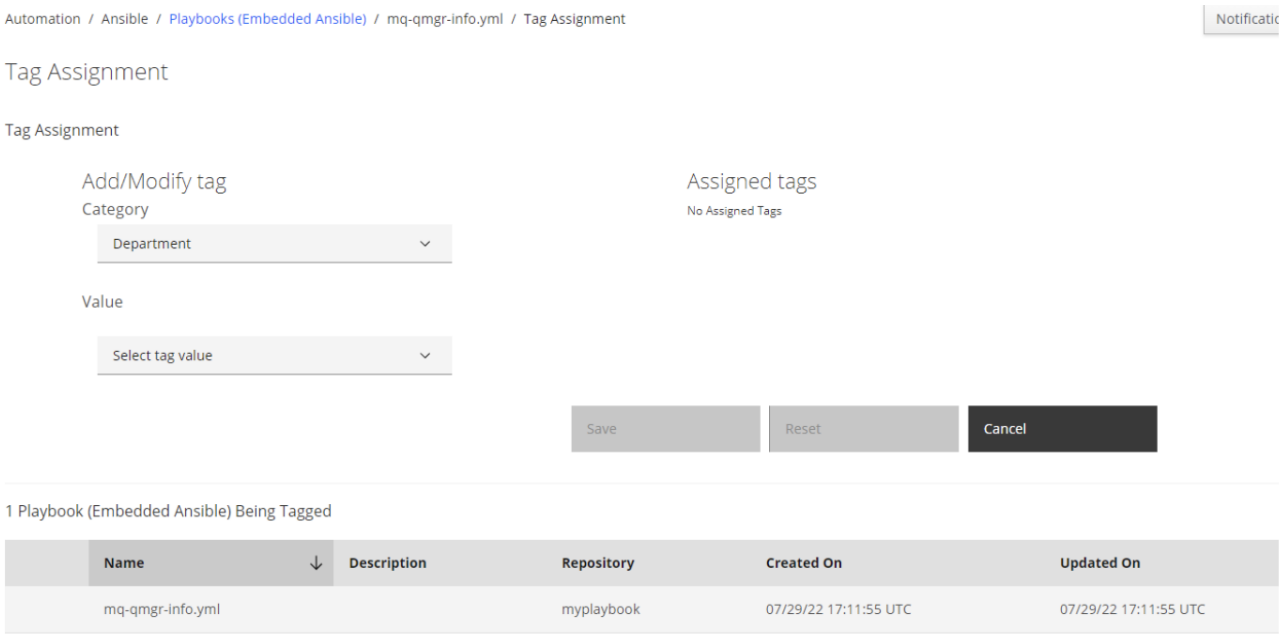
1. Number of instances
2. Management system software
3. Number of images
4. Authentication status

Icon	Description
	Validated: Valid authentication credentials have been added.
	Invalid: Authentication credentials are invalid.
	Unknown: Authentication status is unknown or no credentials have been entered.

Provider authentication status

Refreshing Cloud Providers

Refresh a cloud provider to find other resources related to it. Ensure the chosen cloud providers have the correct credentials before refreshing.



1. Browse to menu: **Compute > Clouds > Providers**.
2. Select the checkboxes for the cloud providers to refresh.
3. Click **Configuration**, and then (**Refresh Relationships and Power States**).

4. Click **OK**.

Tagging Cloud Providers

Apply tags to all cloud providers to categorize them together at the same time.

1. Navigate to **Compute > Clouds > Providers**.
2. Select the checkboxes for the Cloud Providers to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. Select a customer tag to assign from the first list.

5. Select a value to assign from the second list.
6. Click **Save**.

Removing Cloud Providers

A cloud provider might require removal from the VMDB if it is no longer in use.

1. Browse to menu: **Compute > Clouds > Providers**.
2. Check the cloud providers to remove.
3. Click **Configuration**, and then (**Remove Cloud Providers from the VMDB**).
4. Click **OK**.

Editing a Cloud Provider

Edit information about a provider such as the name, IP address, and login credentials.

Note:

The **Type** value is unchangeable.

To use a different cloud provider, create a new one.

1. Browse to menu: **Compute > Clouds > Providers**.
2. Click the cloud provider to edit.

3. Click **Configuration**, and then **(Edit Selected Cloud Provider)**.
4. Edit the **Basic Information**. This varies depending on the **Type** of provider.
5. Fill out the **Credentials** by typing in a **Username**, **Password**, and a verification of this password (**Confirm Password**).
    - If selecting **Amazon EC2**, generate an **Access Key** in the **Security Credentials** of your Amazon AWS account. The **Access Key ID** acts as your **User ID**, and your **Secret Access Key** acts as your **Password**.
    - If selecting **OpenStack**, use the `Keystone User ID` and `Password` for your login credentials.
6. If editing an OpenStack provider, use the **AMQP** subtab to provide credentials required for the Advanced Message Queuing Protocol service on your OpenStack Nova component.
7. Click **Validate** and wait for notification of successful validation.
8. Click **Save**.

Viewing a Cloud Provider's Timeline

View the timeline of events for instances registered to a cloud provider.

1. Navigate to **Compute > Clouds > Providers**.
2. Click the desired cloud provider for viewing the timeline.
3. Click (**Monitoring**), and then (**Timelines**).
4. From **Options**, customize the period of time to display and the types of events to see.
    - Use **Show** to select regular Management Events or Policy Events.
    - Use the **Type** list to select hourly or daily data points.
    - Use **Date** to type the date for the timeline to display.
    - If you select to view a daily timeline, use **Show** to set how many days back to go. The maximum history is 31 days.
    - The three **Event Groups** list allow you to select different groups of events to display. Each has its own color.
    - From the **Level** list, select a **Summary** event, or a **Detail** list of events.

- Azure Providers
- Amazon EC2 Providers
- Google Compute Engine Providers
- IBM Cloud VPC Provider
- IBM Power Systems Virtual Servers Providers
- IBM PowerVC Providers
- OpenStack Providers
- Oracle Cloud Providers

Physical Infrastructure Providers

In Infrastructure Automation, a physical infrastructure provider is a management console used to manage physical inventory such as physical servers, chassis, racks, and physical networking/storage devices.

ManageIQ supports the following types of physical infrastructure providers:

- Lenovo XClarity
- Redfish

Image Import Workflows

IBM PowerVC to IBM Power Systems Virtual Server

The image import functionality allows you to easily move an image from your on-prem PowerVC environment to an off-prem Power Systems Virtual Server environment using Infrastructure Automation web interface. The enablement of the workflow in Infrastructure Automation requires you to perform certain preparations that are described in detail below.

Preparing Infrastructure Automation hosting server (required once):

The following commands are to be run on a server (or in a corresponding docker container) that is dedicated to hosting your Infrastructure Automation instance.

1. Install **`ansible-runner`** application using the installation instructions. The application must be available in the the command line of the user under which the Infrastructure Automation web-server is running.

Preparing IBM PowerVC Server (required once):

The following commands are to be run on a PowerVC server that is dedicated to supporting the image import workflow.

1. Make sure that the minimal IBM PowerVC version you are using is 1.4.4.
2. Install **`python3.X`**, **`pip3`**, **`virtualenv`** applications as well as the **`libselinux-python3`** library. You can achieve this by issuing the following command as a "root" user:

   ```
   yum install -y python3 python-pip3 python-virtualenv libselinux-python3 gcc
   ```

   The standard **`python3.X`** installation will be used in order to run auxiliary scripts, which will upload PowerVC disk images (in Open Virtualization Format) to the IBM Cloud Object Storage. The **`pip3`** is required in order to install Cloud Object Storage Python SDK and auxiliary packages for proper functioning of the import workflow. The role of **`virtualenv`** will be to isolate python package installations that are relevant only to the image import workflow from the Python system packages. The **`libselinux-python3`** library is needed for the proper functioning of Ansible's **`copy`** module, which will be used for the copying of auxiliary data between the Infrastructure Automation hosting site and the PowerVC server. Presence of **`gcc`** is needed as a dependency of one of the Python packages (**`pycryptodome`**) that will be installed on later steps.
3. Prepare enough local storage for holding transient PowerVC disk images that will be transported into Power Systems Virtual Server and deleted from a local storage upon workflow completion. A typical PowerVC image file size can be many GBs. As an example, a RHEL 8.3 disk image can be of 20GB size or more. You would therefore require more space in your local storage than the mentioned disk image size in order to support the import workflow. You would also need enough space to hold Python virtual environment described in the next steps. Its size however will be no more than 100MB. Additionally, import session will place auxiliary files into the sessions directory during the workflow execution but their collective size will not exceed 5MB. In summary, if you're attempting to import an image whose size is 'G' Gigabytes, then having 'G+1' Gigabytes of free space in that directory would be sufficient.
4. Create an empty sessions directory **`/home/sessions`** which will have to be located on the local storage with sufficient space as described in the previous step. In addition, make sure that already existing **`/var/opt/ibm/powervc/imgstaging`** directory also has at least G+1 Gigabytes of free storage as described in previous paragraph since IBM PowerVC internally uses it as a temporary staging area during export of images to the local filesystem.

   ```
   mkdir /home/sessions
   ```
5. The image import workflow will use Ansible via SSH from the Infrastructure Automation server in order to execute commands on the PowerVC server. At this point you need to choose a system user that will be made available to Infrastructure Automation instance for connection to the PowerVC server via SSH. Make sure the user has a read/write access to the **`/home/sessions`** directory. The user must also be able to execute **`powervc-image`** application through the command line. In general, a good security practice would be to permit user only as much as it is required to run the import workflow. We will assume that all further commands in this section are executed using this existing or newly created system user:

   ```
   su - your_user
   ```
6. Create a separate virtual Python environment:

   ```
   virtualenv --system-site-packages /home/sessions/venv
   ```

   This environment will hold Python packages that are relevant only to the image import workflow and as such will not be available system-wide. Conversely, the **`--system-site-packages`** will indicate to the application that the existing Python system packages are to be made available to the virtual environment.
7. Installing packages in the environment requires one to first activate the environment after which all the Python package installations via **`pip3`** will become environment relative only. Therefore, activate the newly created Python environment:

   ```
   source /home/sessions/venv/bin/activate
   ```
8. Install Python packages inside the virtual environment using:

   ```
   pip3 install pathlib pycryptodome ibm-cos-sdk
   ```

   The **`pathlib`** is used for handling file paths. The **`pycryptodome`** is required for encrypting/decrypting IBM Cloud connection credentials and the **`ibm-cos-sdk`** represents the IBM Cloud Object Storage Python SDK.
9. Upon completing the Python package installations above you should exit the virtual environment by running:

   ```
   deactivate
   ```
10. Make sure to have a valid PowerVC connection/resource file under **`/opt/ibm/powervc/powervcrc`** (or at your custom location) containing similar definitions (the values below represent an example and not a suggestion for usage).

    ```
    export OS_IDENTITY_API_VERSION=3
    export OS_AUTH_URL=https://host:5000/v3/
    export OS_CACERT=/etc/pki/tls/certs/powervc.crt
    export OS_REGION_NAME=RegionOne
    export OS_PROJECT_DOMAIN_NAME=Default
    export OS_PROJECT_NAME=ibm-default
    export OS_TENANT_NAME=$OS_PROJECT_NAME
    export OS_USER_DOMAIN_NAME=Default
    export OS_USERNAME=root
    ```

```
export OS_PASSWORD=password
export OS_COMPUTE_API_VERSION=2.46
export OS_NETWORK_API_VERSION=2.0
export OS_IMAGE_API_VERSION=2
export OS_VOLUME_API_VERSION=2
```

11. The last step is to test the exporting of PowerVC disk image to the local filesystem. Firstly, execute:

    ```
    source /opt/ibm/powervc/powervcrc
    ```

    This will acquire all the environmental variables required for issuing commands to the corresponding PowerVC instance. Now run the following command:

    ```
    powervc-image list
    ```

    The output should be similar to the one below:

    ```
    +----------+--------------------------------------+--------+---------+------+-------------+--------------+-----------
    +------------+
    | Name     | ID                                   | Status | Volumes | Size | Description | Architecture | OS Distro
    | Exportable |
    +----------+--------------------------------------+--------+---------+------+-------------+--------------+-----------
    +------------+
    | test-IMG | XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX | active | 1       | 20   |             | ppc64        | rhel
    | True       |
    +----------+--------------------------------------+--------+---------+------+-------------+--------------+-----------
    +------------+
    ```

    Note the name of the image you would like to export, which will be **`test-IMG`** in our example. Next export the image of your choice:

    ```
    powervc-image export -i test-IMG -p /home/sessions/image.ova
    ```

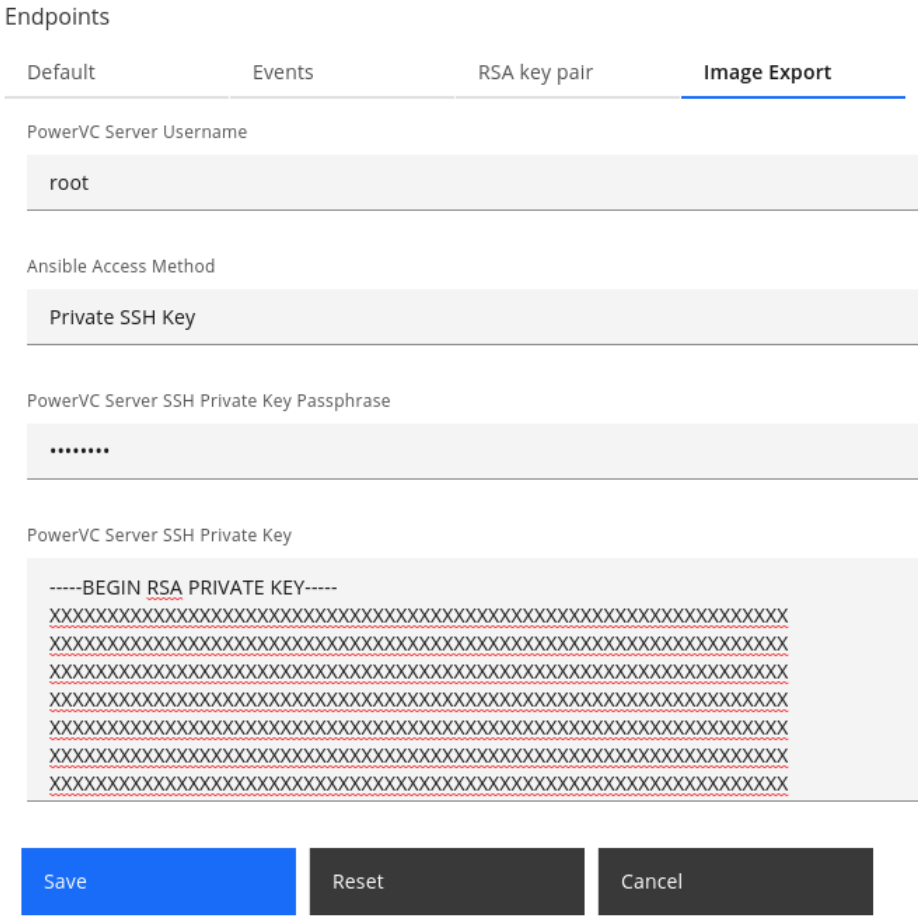
    It is a time-consuming operation with the runtime taking several minutes to complete depending on the size of exported image. Once the operation completes you should be able to find the exported image under **`/home/sessions/image.ova`**. At this stage you can remove the exported image thus concluding the test:

    ```
    rm /home/sessions/image.ova
    ```

Add a Cloud Object Storage provider in Infrastructure Automation:

1. See the corresponding instructions here.
2. Create a bucket in your Cloud Object Storage that will hold the transient OVA image files.

Make sure to choose the region for the bucket that **corresponds** to the region that you have specified when registering the Cloud Object Storage provider.

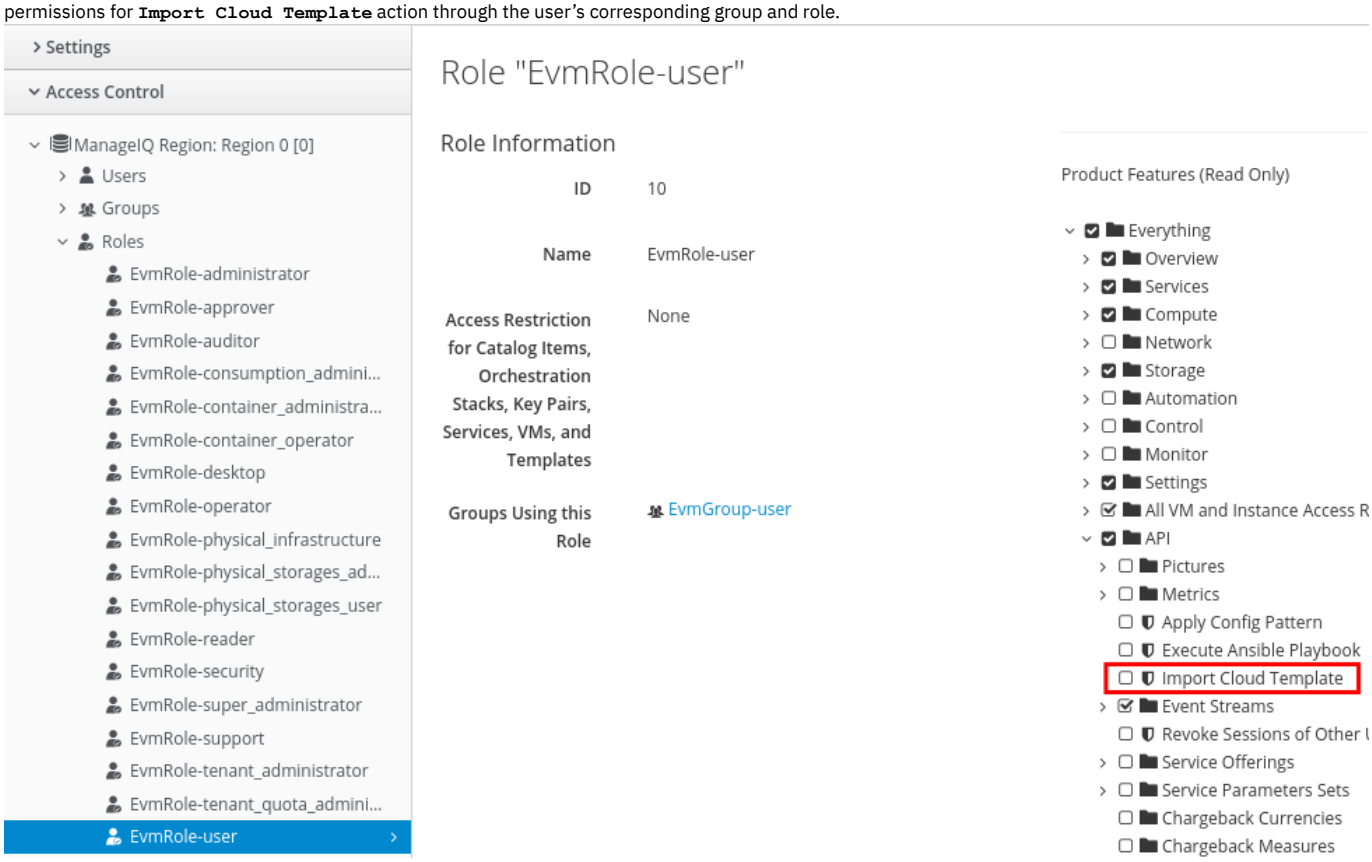


NOTE: The “root” user as well as the workflow dedicated user of the PowerVC server from step 5 would both be able to decrypt the Cloud Object Storage’s credentials during the execution of the import workflow and therefore make sure to take this into consideration in your security setup.

Add an IBM Power Systems Virtual Server provider in Infrastructure Automation:

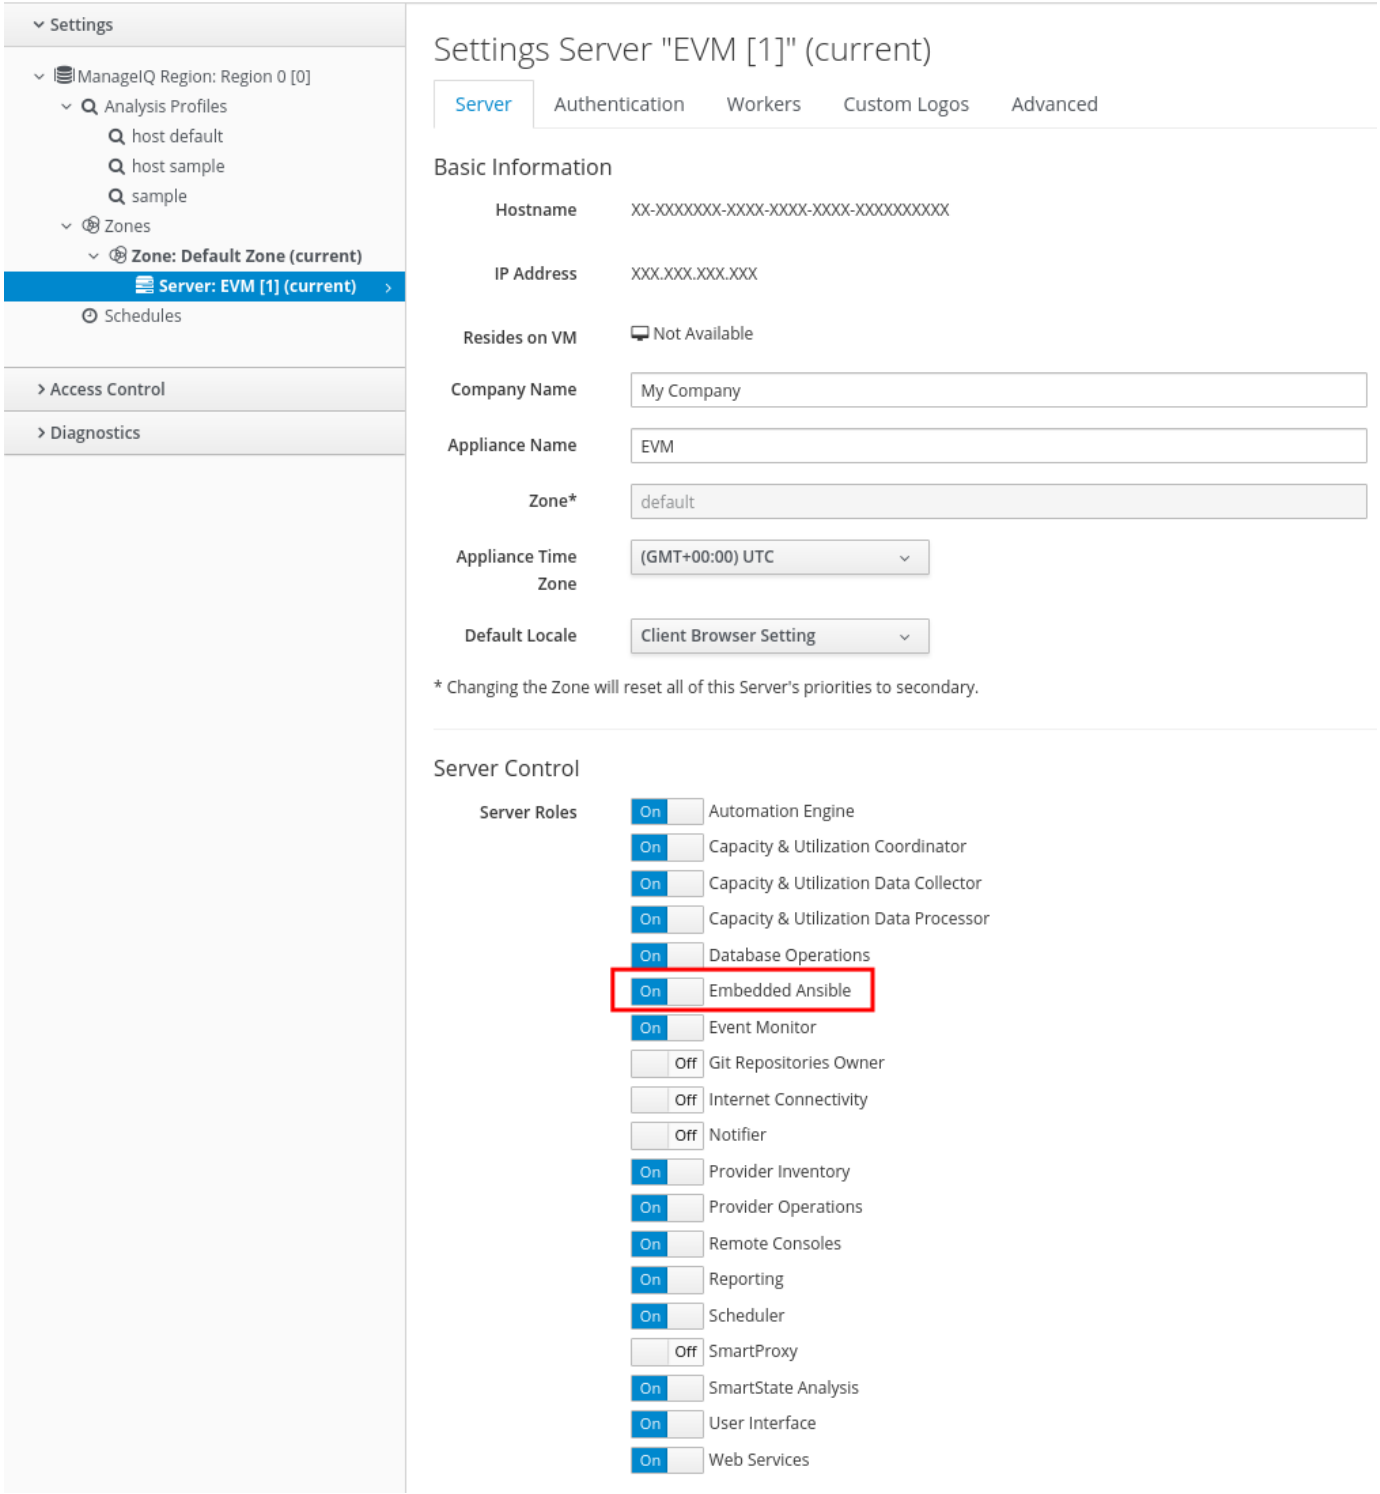
1. See the corresponding instructions here.

Add an IBM PowerVC provider in Infrastructure Automation:



1. See the corresponding instructions here.
2. Specify the image import related parameters on the PowerVC registration form.
   - Enter the SSH username for access to the PowerVC server. It corresponds to the user on your PowerVC server that is dedicated to running image import related commands via Ansible as described in 5.
   - Enter the private key and the private key passphrase (if present).

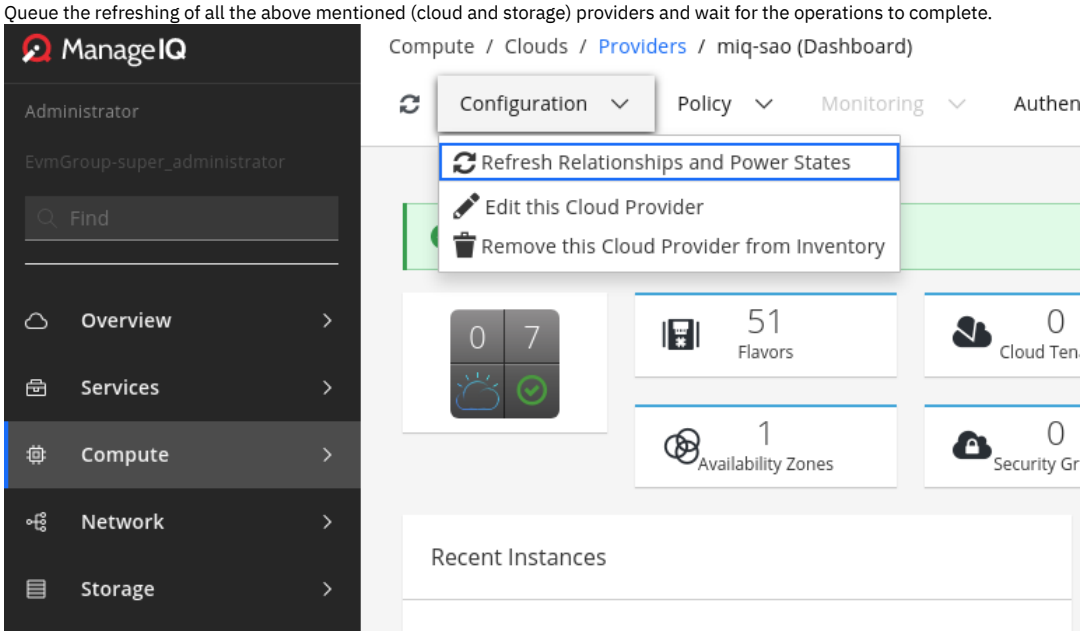
Grant Image Import Permissions in Infrastructure Automation:



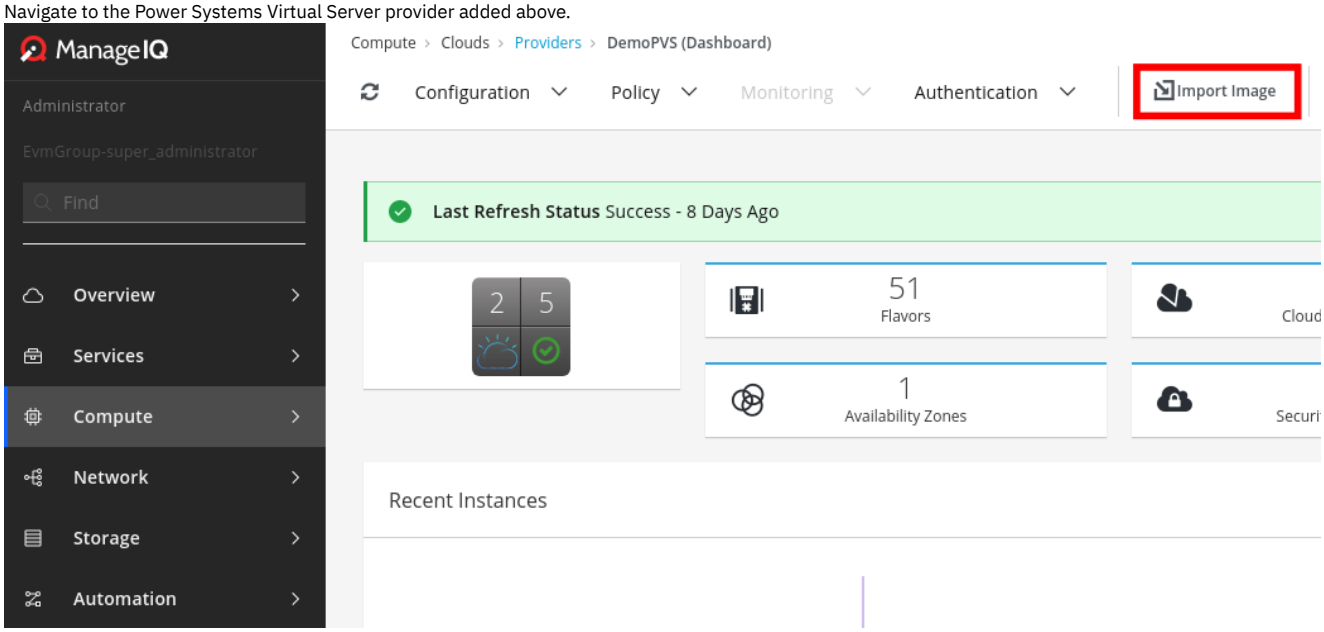
User performing image import needs a corresponding permission in Infrastructure Automation in order to perform this operation. For granting permissions, log-in through an administrative account and navigate to **`Settings -> Application Settings -> Access Control`**. Make sure the user of your choice has

permissions for **`Import Cloud Template`** action through the user's corresponding group and role.

Enable Embedded Ansible in Infrastructure Automation:



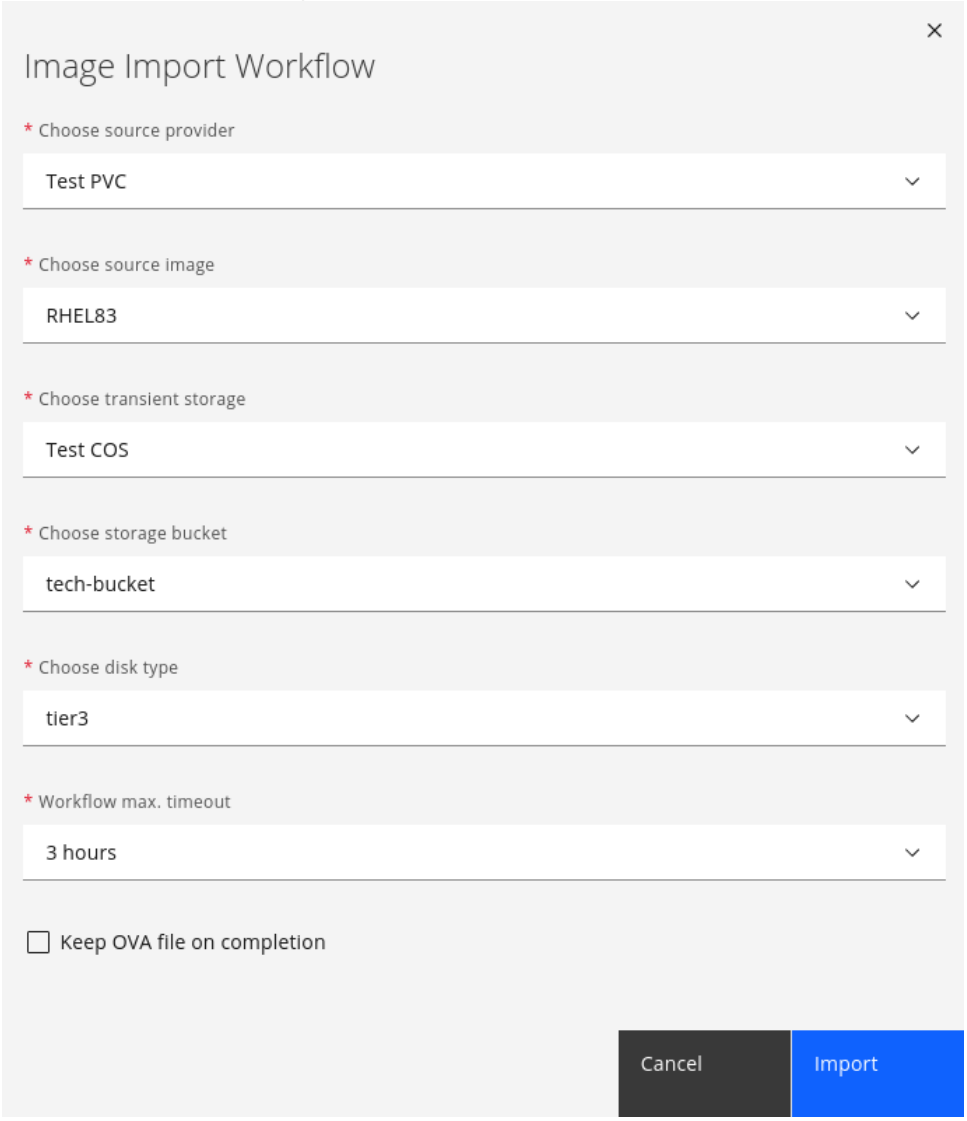
Currently the workflow event is queued as Embedded Ansible playbook upon request submission and as such the corresponding functionality has to be enabled in Infrastructure Automation by navigating to: **`Settings -> Application Settings -> Settings`**



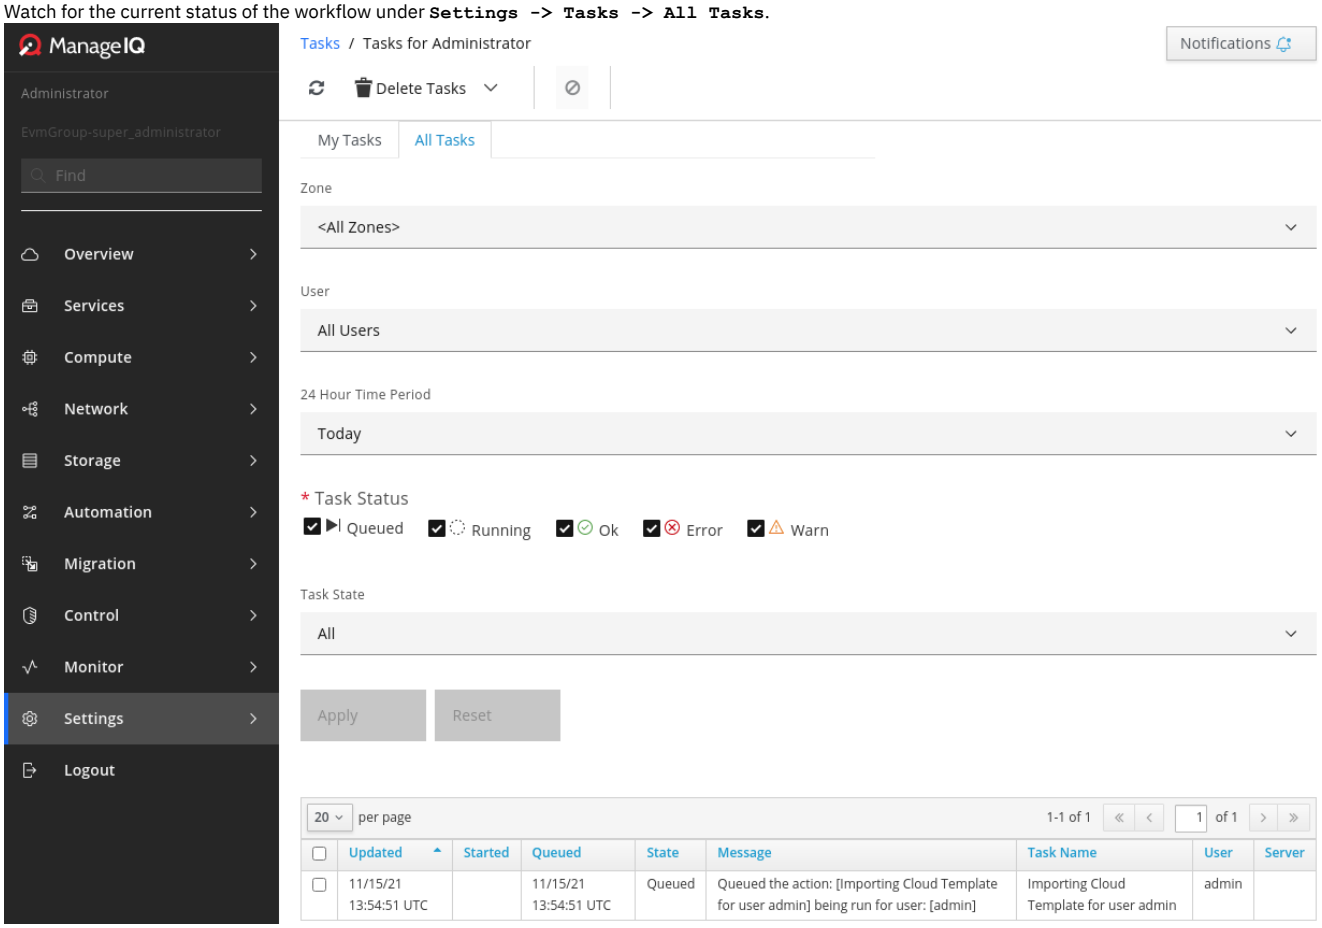
Start the workflow

The workflow operates by exporting the image as an OVA file onto a PowerVC local storage, uploading it to the Cloud Object Storage bucket and then transferring it into Power Systems Virtual Server image registry. In order to initiate the workflow:

1. Queue the refreshing of all the above mentioned (cloud and storage) providers and wait for the operations to complete.



2. Navigate to the Power Systems Virtual Server provider added above.



3. Click on the **`Import Image`** button after which an import form will appear.
4. Choose the PowerVC provider added above as a source provider.
5. Choose the image you would like to import.
6. Choose the Cloud Object Storage provider added above.
7. Choose the transient bucket created above.
8. Choose target disk type for the image being imported.
9. Choose the timeout value for your request (default is 3 hours).
10. Check the corresponding box if you wish to keep the OVA file in the cloud bucket upon workflow completion.

11. Click on the **`Import`** button initiating the workflow.

12. The workflow can take an hour or more depending on the image size, bucket location, Power Systems Virtual Server and PowerVC internal load.

13. Watch for the current status of the workflow under **`Settings -> Tasks -> All Tasks`**.

14. Initiate the refreshing of the Power Systems Virtual Server provider upon workflow completion and wait for the newly imported image to appear.

Troubleshooting

- If the Infrastructure Automation UI shows no detailed error description then make sure to check the latest logs with **`journalctl -t evm`** or **`oc logs`** on a server or pod that hosts your Infrastructure Automation instance.
- If **`Infrastructure Automation`** server is terminated during the workflow execution then certain residual objects will have to be removed manually. These are potentially the session directory on the PowerVC server under **`/home/sessions`**, the already uploaded OVA image file in the Cloud Object Storage bucket or its parts as explained here (see **`Abort incomplete multipart uploads`**).
- Currently only one import workflow for a given PowerVC <–> Power Systems Virtual Server pair is allowed. Any newly submitted import workflow, where at least one of the instances in the pair is involved with some other import workflow request, will be queued until the latter completes. You would need to cancel such already executing workflow in order to force immediate execution of the newly submitted one.

Network Managers

In Infrastructure Automation, a network manager is an inventory of networking entities on existing cloud and infrastructure providers managed by your Infrastructure Automation appliance.

This provider type exposes software-defined networking (SDN) providers including *OpenStack Network (Neutron)*, *Azure Network*, and *Amazon EC2 Network*, which enables software-defined networking inventory collection. The OpenStack Network provider collects inventory of floating IPs from OpenStack so that IPs can be allocated without querying OpenStack database every time. Also, it refreshes all Neutron data from both OpenStack and OpenStack Infrastructure, and extracts the Neutron logic to a shared place. Note that management via the network providers configuration is currently disabled.

This chapter describes the different types of network managers available to Infrastructure Automation, and how to manage them. Network managers are discovered automatically by Infrastructure Automation from other connected providers.

Adding or Viewing Network Providers

Note:

All supported network providers—OpenStack Network, Azure Network, and Amazon EC2 Network, are added or removed automatically upon adding or removing the respective cloud provider.

Viewing network providers:

1. Browse to menu: **Networks > Providers** to see a list of all network providers, along with information such as *Name*, *Type*, *EVM Zone*, *Number of Instances*, *Subnets*, and *Region*.
2. Click on a provider from the list to view its summary screen.

Network providers summary:

The summary screen includes tables containing information on *Properties*, *Status*, *Relationships*, *Overview*, and *Smart Management*. Click on rows in the *Relationship* and *Overview* tables to see detailed information for individual entities.

Accordion tabs in the sidebar provide access to **Properties** and **Relationships** details.

Click on **Reload**, **Configuration**, **Policy**, and **Monitoring** actions in the taskbar to manage the selected provider.

Note:

Alternatively, click on a cloud provider to see the cloud provider details and its relationships such as Network Manager, Tenants, Instances among others. In Relationships, click Network Manager to see information about the network provider, and its relationship with the cloud provider, on the summary page.

Refreshing Network Providers

Refresh a network provider to find other resources related to it. Ensure the selected network providers have the correct credentials before refreshing.

1. Browse to menu: **Networks > Providers**.
2. Select the network providers to refresh.
3. Click **Configuration**, and then (**Refresh Relationships and Power States**).
4. Click **OK**.

Tagging Network Providers

Apply tags to network providers to categorize them together at the same time.

1. Navigate to **Networks > Providers**.
2. Select the network providers to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. **Select a customer tag to assign** from the first list.
5. Select a value to assign from the second list.
6. Click **Save**.

Removing Network Providers

Although network providers are added or removed automatically upon adding or removing the respective cloud provider, you can manually remove a network provider if it is no longer in use. This will remove the network provider from the VMDB and any relationship with the cloud provider.

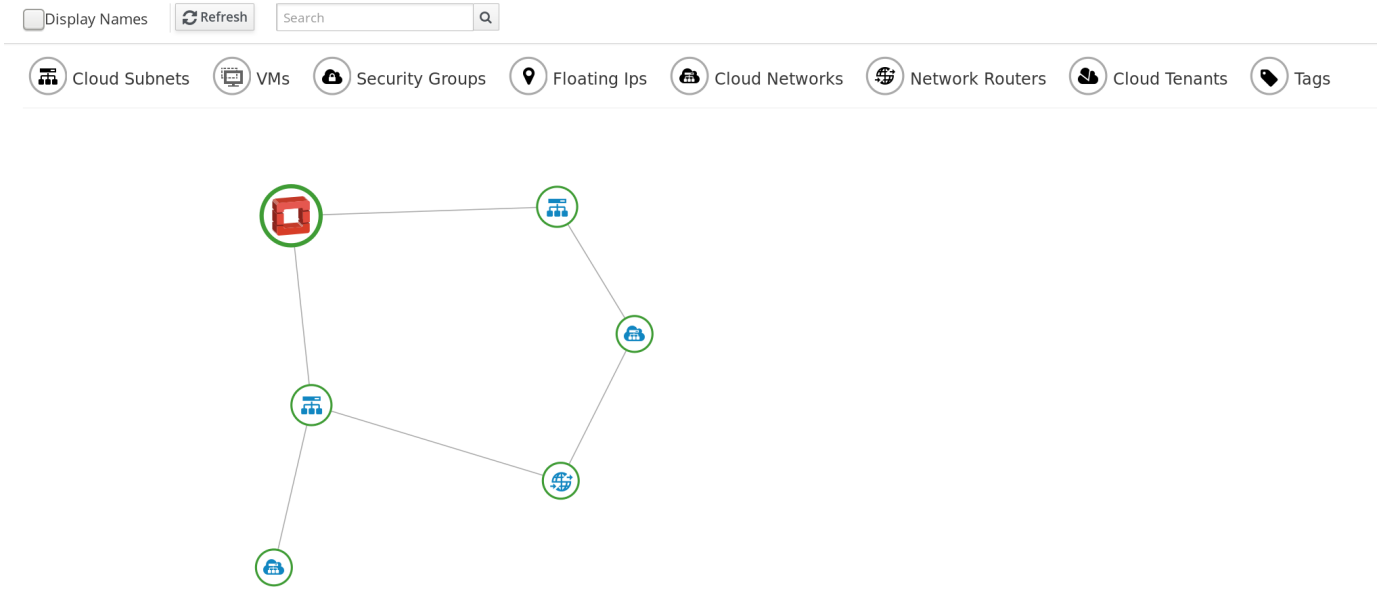
1. Browse to menu: **Networks > Providers**.
2. Click the network provider to remove.
3. Click **Configuration**, and then (**Remove this Network Provider from the VMDB**).
4. Click **OK**.

Viewing a Network Provider's Timeline

View the timeline of events for instances registered to a network provider.

1. Navigate to **Networks > Providers**.
2. Click the network provider you want to monitor the timeline for.

3. Click (**Monitoring**), and then (**Timelines**).
4. From **Options**, select the event type and interval, and customize the period of time to display and the types of events to see.
    - Select *Management Events* or *Policy Events* from the **Show** list.
    - Select an **Interval** between *Hourly* and *Daily*.
    - Select **Date**.
    - If you selected *Daily* for **Interval**, set the number of days in the past to see the event timeline for. The maximum is *31 days back*.
    - Select **Summary** or **Detail** for **Level**.
    - Select the required **Event Groups** from the lists you want to monitor the timeline for.



You can also assign policy profiles to network providers, or remove them. The method for doing so is similar to that of any normal policy profile.

Using the Topology Widget for Network Providers

The **Topology** widget is an interactive topology graph, showing the status and relationships between the different entities of the network providers that Infrastructure Automation has access to.

The topology graph includes cloud subnets, virtual machines, security groups, floating IP addresses, cloud networks, network routers, cloud tenants, and tags within the overall network provider environment.

Each entity in the graph displays a color indication of its status: green indicates an active entity, while red indicates inactivity or an issue.

1. Browse to menu: **Networks > Topology**.
2. Click the desired network provider for viewing the provider summary.

Alternatively, you can open the topology widget from the provider summary page by clicking **Topology** under **Overview**.

- Hovering over any individual graph element will display a summary of details for the individual element.
- Double-click an entity in the graph to browse to its summary page.
- Drag elements to reposition the graph.
- Click the symbols in the legend at the top of the graph to show or hide entities.
- Click the **Display Names** checkbox to show or hide entity names.
- Click **Refresh** to refresh the display of the network provider entities.
- Enter a search term in the **Search** box to locate an entity by full or partial name.

Containers Providers

A containers provider is a service that manages container resources, that can be added to the Infrastructure Automation appliance.

Infrastructure Automation can connect to OpenShift Container Platform containers providers and manage them similarly to infrastructure and cloud providers. This allows you to gain control over different aspects of your containers environment and answer questions such as:

- How many containers exist in my environment?
- Does a specific node have enough resources?
- How many distinct images are used?
- Which image registries are used?

When Infrastructure Automation connects to a container's environment, it collects information on different areas of the environment:

- Entities such as pods, nodes, or services.
- Basic relationships between the entities, for example: Which services are serving which pods?
- Advanced insight into relationships, for example: Which two different containers are using the same image?
- Additional information, such as events, projects, routes, and metrics.

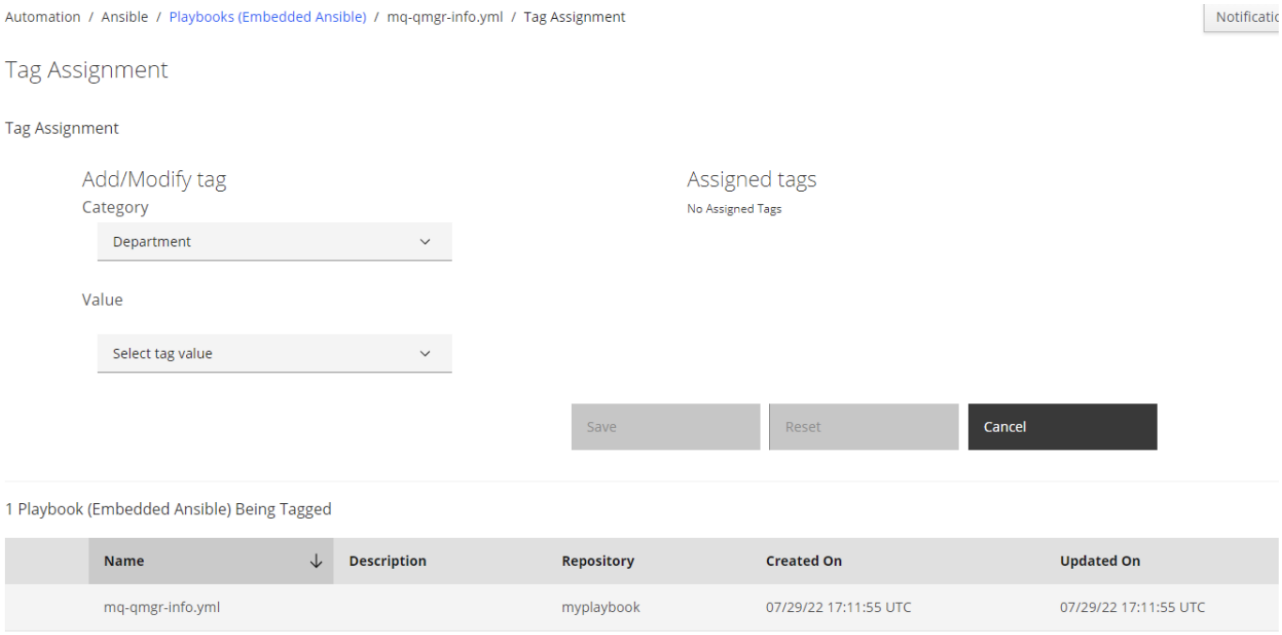
You can manage policies for containers entities by adding tags. All containers entities except volumes can be tagged.

Note:

This chapter provides details on managing containers providers. For details on working with the resources within a container environment, see Container Entities in *Managing Infrastructure and Inventory*.

The Infrastructure Automation user interface uses virtual thumbnails to represent containers providers. Each thumbnail contains four quadrants by default, which display basic information about each provider:

1. Number of nodes
2. Container provider software
3. Power state
4. Authentication status



Icon	Description
	Validated: Valid authentication credentials have been added.
	Invalid: Authentication credentials are invalid.
	Unknown: Authentication status is unknown or no credentials have been entered.

Containers provider authentication status

Tagging Containers Providers

Apply tags to all containers providers to categorize them together at the same time.

1. Navigate to **Compute > Containers > Providers**.
2. Select the checkboxes for the containers providers to tag.
3. Click (**Policy**), and then (**Edit Tags**).
4. Select a tag to assign from the drop-down menu.

5. Select a value to assign.
6. Click **Save**.

Removing Containers Providers

You may want to remove a containers provider from the VMDB if the provider is no longer in use.

1. Browse to menu: **Compute > Containers > Providers**.
2. Select the checkboxes for the containers providers to remove.
3. Click **Configuration**, and then (**Remove Containers Providers from Inventory**).
4. Click **OK**.

Editing a Containers Provider

Edit information about a provider such as the name, hostname, IP address or port, and credentials as required. If you have just upgraded your Infrastructure Automation environment from an older version, edit the provider to specify the authentication method the provider uses to connect to Infrastructure Automation.

1. Browse to menu: **Compute > Containers > Providers**.
2. Click the containers provider to edit.
3. Click **Configuration**, and then (**Edit Selected Containers Provider**).
4. Edit the **Name** if required.

   Note:

   The **Type** value is unchangeable.
5. Under **Endpoints** in the **Default** tab, edit the following as required:
   1. Select a **Security Protocol** method to specify how to authenticate the provider:
      - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.
      - **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.

        Note:

        You can obtain your OpenShift Container Platform provider's CA certificate for all endpoints (default, metrics, alerts) from `/etc/origin/master/ca.crt`. Paste the output (a block of text starting with `-----BEGIN CERTIFICATE-----`) into the **Trusted CA**

Certificates field.

- **SSL without validation**: Authenticate the provider insecurely (not recommended).

2. Enter the **Hostname** (or IPv4 or IPv6 address) of the provider.

   Important:

   The **Hostname** must use a unique fully qualified domain name.

3. Enter the **API Port** of the provider. The default port is **8443**.
4. Enter a token for your provider in the **Token** box.

   Note:

   To obtain a token for your provider, run the **oc get secret** command on your provider; see Obtaining an OpenShift Container Platform Management Token.

   For example:

   # oc get secret –namespace management-infra management-admin-token-8ixxs –template='' | base64 –decode

5. Click **Validate** to confirm that Infrastructure Automation can connect to the OpenShift Container Platform provider.

6. Under **Endpoints** in the **Metrics** tab, configure the following for gathering capacity and utilization metrics for Prometheus based on the selection:

   1. Select a **Security Protocol** method to specify how to authenticate the provider:

      - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.
      - **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.
      - **SSL without validation**: Authenticate the provider insecurely using SSL. (Not recommended)

   2. Enter the **Hostname** (or IPv4 or IPv6 address) of the provider.
   3. Enter the **API Port** if your provider uses a non-standard port for access. The default port is **443**.
   4. Click **Validate** to confirm that Infrastructure Automation can connect to the endpoint.

7. Under **Endpoints** in the **Alerts** tab, configure the following for Prometheus alerting from the cluster.

   - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.
   - **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.
   - **SSL without validation**: Authenticate the provider insecurely using SSL. (Not recommended)
     - Enter the **Hostname** (or IPv4 or IPv6 address) of the provider.
     - Enter the **API Port** if your provider uses a non-standard port for access. The default port is **443**.
     - Click **Validate** to confirm that Infrastructure Automation can connect to the endpoint.

8. Click **Save**.

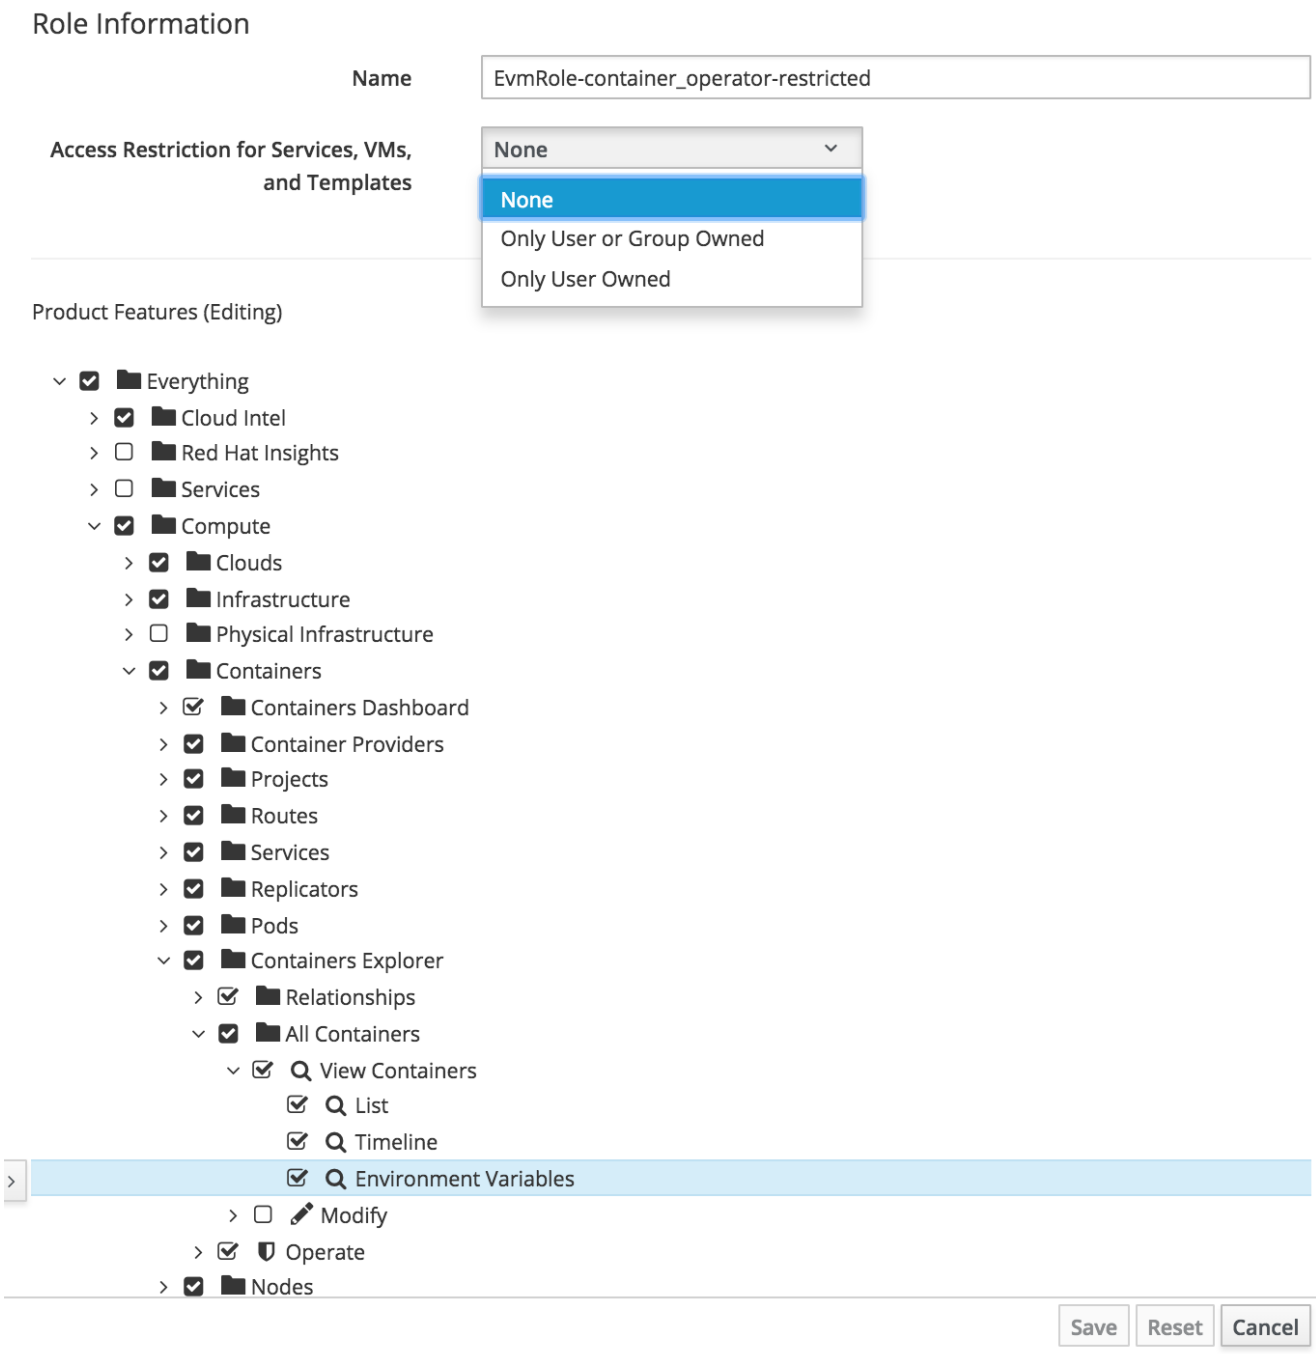
Hiding Environment Variables for Containers Providers

You can restrict users from viewing container provider environment variables by configuring user roles.

This is useful as the environment variables panel can expose sensitive information, such as passwords, that you may not want certain users to view.

Note:

The default user roles in Infrastructure Automation are read-only. To customize a role's settings, create a new role or a copy of an existing role.



You can view role information and the product features the role can access (marked by a checkmark) by clicking on any role in **Access Control**. Expand the categories under **Product Features** to see further detail.

To configure user access to container environment variables:

1. Click (**Configuration**).
2. Click the **Access Control** accordion, then click **Roles**.
3. Select a existing custom role from the **Access Control Roles** list, and click (**Configuration**), then (**Edit the selected Role**).

Alternatively, to create a new custom role, select a role from the **Access Control Roles** list, and click (**Configuration**), then (**Copy this Role to a new Role**).

4. Edit the name for the role if desired.
5. For **Access Restriction for Services, VMs, and Templates**, select if you want to limit users with this role to only see resources owned by the user or their group, owned by the user, or all resources (**None**).
6. Expand the **Product Features (Editing)** tree options to show **Everything > Compute > Containers > Containers Explorer > All Containers > View Containers**.
7. Clear the **Environment Variables** checkbox to restrict the user role from viewing container environment variables.

8. Click **Save**.

For more information about user roles, see Roles in *General Configuration*.

Viewing a Containers Provider's Timeline

View the timeline of events for instances registered to a containers provider.

1. Navigate to **Compute > Containers > Providers**.
2. Click the desired containers provider for viewing the timeline.
3. Click  (**Monitoring**), and then  (**Timelines**).
4. From **Options**, customize the period of time to display and the types of events to see.
    - Use **Show** to select regular Management Events or Policy Events.
    - Use the **Interval** dropdown to select hourly or daily data points.
    - Use **Date** to type the date for the timeline to display.
    - If you select to view a daily timeline, use **Show** to set how many days back to go. The maximum history is 31 days.
    - From the **Level** dropdown, select a **Summary** event, or a **Detail** list of events.
    - The three **Event Groups** dropdowns allow you to select different groups of events to display. Each has its own color.

Click on an item for more detailed information.

- Azure Kubernetes Providers
- Red Hat OpenShift Providers
- IBM Cloud Kubernetes Service Providers
- Oracle Kubernetes Engine Providers
- VMware Tanzu Providers

Storage Managers

In Infrastructure Automation, a storage manager is a service providing storage resources that you can manage from a Infrastructure Automation appliance. This chapter describes the different types of storage managers used by Infrastructure Automation, and how they are added to Infrastructure Automation.

There are three types of storage managers currently available to Infrastructure Automation:

- Amazon Elastic Block Store Managers
- OpenStack Block Storage Managers
- OpenStack Object Storage Managers
- IBM Cloud Object Storage Managers

Appendix

Using a Self-Signed CA Certificate

Adding a self-signed Certificate Authority (CA) certificate for SSL authentication requires more configuration on OpenStack Platform and Microsoft System Center Virtual Machine Manager (SCVMM) providers.

Note: This procedure is not required for OpenShift Container Platform, or Red Hat Virtualization, which have the option to select **SSL trusting custom CA** as a **Security Protocol** in the user interface. These steps are needed only for providers without this option in the user interface.

Before adding the provider, configure the following:

1. Copy your provider's CA certificate in PEM format to **`/etc/pki/ca-trust/source/anchors/`** on your Infrastructure Automation appliance.
2. Update the trust settings on the appliance:

    ```
    # update-ca-trust
    ```

3. Restart the EVM processes on the server:

    ```
    # rake evm:restart
    ```

The CA certificate is added to the appliance, and you can add the provider to Infrastructure Automation.

- Overview
- Configuring ServiceNow Connection
- Managing Record Attributes
    - Create and Update (_patch) Record
        - Attribute
    - Get and Delete Record

    - Get All Records
- Use Cases
    - Provisioning a Virtual Machine from a Template
    - Virtual Machine Retirement
    - Virtual Machine Reconfiguration (VMware Only)

Overview

Infrastructure Automation integration with ServiceNow enables authentication with an existing ServiceNow database and **add/amend** items in the ServiceNow database during state machine processing, such as the virtual machine provisioning state machine. Note that information in this guide assumes you have credentials and access to a ServiceNow database instance.

The following new namespace and class delivers support for the management of **ServiceNow Configuration Management Database** (CMDB) records using **ServiceNow's RESTful** web service.

`/Integration/ServiceNow/CMDB`

You can manage records in the **CMDB_CI_SERVER** table, including `create`, `update`, and/or `delete`. The following methods are included:

Method	Action
create	Create record in specified ServiceNow table.
delete	Delete record in specified ServiceNow table.
get	Get record from specified ServiceNow table and list its attributes.
get_all	Get all records in ServiceNow and list attributes.
update	Get specified record, update required attributes and post updated record.
update_patch	Post required attributes to specified record.

Note:

Configuration item (CI) and record are used interchangeably and refer to items in a ServiceNow database table.

Configuring ServiceNow Connection

Configure the connection to the ServiceNow database by specifying the credentials in the **CMDB schema** or instances within.

The following methods are included:

snow_server	ServiceNow database IP address or resolvable hostname.
snow_user	ServiceNow user account with the necessary permissions.
snow_password	Associated user account password.

The table name cannot be changed unless there is a specific requirement to manage records elsewhere. Entries in this table appear in the **Configuration > Base Items > Servers** menu in the ServiceNow web user interface.

table_name	ServiceNow cmdb_ci_server database table.

Managing Record Attributes

You can specify any attribute via the **URI** or **CMDB** class instance. If neither exists, the value is determined from the Infrastructure Automation **VM** or **miq_provision** objects.

The attributes can be reduced or extended as required by amending the Ruby methods.

Note:

Some attributes are not free-text (variable) fields, that is, they must be specific values. For example, the `vendor` value must already exist in the ServiceNow Vendor table beforehand.

Create and Update (_patch) Record

You can use the following attributes when creating and/or updating a record.

Attribute

Attribute	Value
virtual	Boolean true or false, set to true.
name VMs	Virtual infrastructure name.
short_description	Infrastructure Automation virtual machine GUID.
host_name	The virtual machine's operating system hostname.
cpu_count	The virtual machine's CPU count.
ram	The virtual machine's memory.
vendor	The virtual machine's hardware vendor (provider).

sys_id [1]	ServiceNow record unique system ID.

Get and Delete Record

You can use the following attribute for getting or deleting a record.

Attribute	Value
sys_id	ServiceNow record unique system ID.

Get All Records

There are no attributes required to get all records. This method gets all records in the specified **ServiceNow table** and writes their attributes to `automation.log`.

1. sys_id attribute is not required during `create`. Its value is returned from the `create` request and the Infrastructure Automation object custom attribute **servicenow_sys_id** is created and updated.

Use Cases

The following examples show how ServiceNow can be integrated with automation workflows.

Provisioning a Virtual Machine from a Template

The Cloud and Infrastructure **Provision VM from Template** State Machines contain **RegisterCMDB** and **ActivateCMDB** states.

To create a new ServiceNow record during virtual machine provisioning, amend the **ActiveCMDB** state to call the `create` method, for example:

`/Integration/ServiceNow/CMDB/create`

ActivateCMDB	/Integration/ServiceNow/CMDB/create

Virtual Machine Retirement

The Cloud and Infrastructure default **Retirement** State Machines contain the **DeactivateCMDB** state.

To update a virtual machine's ServiceNow record during virtual machine retirement, amend the **DeactivateCMDB** state to call the `update_patch` method, for example:

`Integration/ServiceNow/CMDB/update_patch?description=VM%20${/#vm.guid}%20retired%20from%20{productname_short}`

DeactivateCMDB	/Integration/ServiceNow /CMDB/update_patch?description=VM%20${/#vm.guid}%20retired%20from%20CloudForms

Virtual Machine Reconfiguration (VMware Only)

Create a new **System Event** instance to update the ServiceNow record after a virtual machine reconfiguration request has been approved and completed.

Create a new **/System/Event/ReconfigVM_Task_Complete** instance with a relationship value:

`/Integration/ServiceNow/CMDB/update_patch`

rel1	/Integration/ServiceNow/CMDB/update_patch

Change risk integration for Infrastructure Automation

You can enable an integration for Infrastructure Automation to gain the advantage of change risk assessments. With this integration, your IT operators can use data from ServiceNow to assess the risk of a code deployment based on prior incidents, estimate the chances of a successful update, identify risks, build logs, apply security policies and more.

The Change Risk module ingests un-structured data from ServiceNow, and analyzes the data to look for similar tickets and to understand how incidents and failures might have occurred. The module can then provide an assessment of the overall risk of suggested changes. With an integration with ServiceNow for change risk, Infrastructure Automation allows for the automation of the delivery of infrastructure services which integrates with ServiceNow. Since Infrastructure Automation is an end-to-end infrastructure provisioning and management capability, Infrastructure Automation can complete ongoing checks against configurations after infrastructure is provisioned to ensure systems are running as prescribed and adhere to system-wide compliance policies. Through the integration, updates can be made to the ServiceNow CMDB or to create change requests.

With the integration in place, the following flow demonstrates the possible interactions between Infrastructure Automation and the Change Risk components of IBM Cloud Pak for AIOps and ServiceNow:

Scenario: A change is proposed to add additional disk space to a virtual machine.

Interaction Flow:

1. The Operator invokes a day-2 operation in Infrastructure Automation to change the server configuration to create and attach the new disk.
2. The day-2 operation creates a Change Request ticket in ServiceNow, populating it with details on the requested change (virtual machine ID, new disk size, and more).
3. The Change Risk component monitors the ServiceNow tickets. Using a pre-trained model to analyzing similar tickets, IBM Cloud Pak for AIOps can classify the change as a high or low risk change and add a confidence level of the prediction onto the ServiceNow ticket.
4. The ServiceNow operator approves the change request based on the confidence level, and marks it ready for implementation.
5. The day-2 operation in Infrastructure Automation waits for the ServiceNow Change Request to be approved before proceeding.
6. After observing the change in the state of the ServiceNow Change Request, Infrastructure Automation carries out the provisioning change to add the disk to the virtual machine.
7. After completing the provisioning action, Infrastructure Automation updates the ServiceNow Change Request to mark it as complete. The request can be reviewed and closed by a ServiceNow operator.
8. Infrastructure Automation policies are applied against the configuration and alerts are raised if server configuration isn't in compliance. Both server VM parameters as well as application middleware packages can be checked for compliance against defined policies.

For more information abouth the steps to configure the AI algorithm to determine change risk, see Configuring change risk.

Turbonomic connection

You can enable a cloud connection between Infrastructure Automation and Turbonomic to integrate the systems. You can use Turbonomic for capacity planning to help identify usage patterns, trends and the optimization of application resource usage to help you reduce waste and control costs while meeting application service level agreements (SLA). Turbonomic also provides insights and recommended actions based on multiple sources of data. With this integration, Turbonomic delivers insights directly to the Infrastructure Automation service management so that your DevOps personnel can act on the insights when needed.

With an integration set up between Infrastructure Automation and Turbonomic, you can take advantage of the following capabilities:

- You can use Turbonomic to monitor your cloud environment. This includes monitoring infrastructure provisioned through Infrastructure Automation.
- Infrastructure Automation can run multiple workflow steps by using Terraform and Ansible, which can include steps to update ServiceNow, issue notifications, and configuring the application inside the virtual machine (VM).
- Infrastructure Automation can run steps for the workflow, such as to resize the VMs and update the ServiceNow configuration management database (CMDB) as dictated by the parameters of the action recommended by Turbonomic.
- Turbonomic can monitor and identify VMs that can be resized to save resources while keeping the application SLA.
- Turbonomic can associate the VM to the Infrastructure Automation service that provisioned it by using ingested tags from the provisioned infrastructure.
- Turbonomic can invoke Infrastructure Automation REST API to resize the VM in a particular service instance by using a custom action script that is registered to Turbonomic and defined in a policy specific to the service.
- Turbonomic can view the updated VM, measure the performance, and ensure that the application SLA is being met with the changed configuration.

For Infrastructure Automation to access your Turbonomic environment, you must provide the value of the following Turbonomic cloud connection parameters to enable the integration:

- **Turbonomic server URL** - The authentication URL, which is used for the identification purposes. Use the format `http://<IP_ADDRESS>`.
- **User Name** - The user name for logging into the Turbonomic server.
- **Password** - The password for the provided user name.

For more information about these values and how to configure them, see Target Configuration.

Enabling or disabling IBM Business Process Manager

Post the installation of Managed services, you can enable or disable Business Process Manager from the IBM Cloud Pak for AIOps.

Procedure

Complete these steps from your OpenShift console.

1. Click **Operators** > **Installed Operators**.
2. Select `cp4aiops` namespace from the **Project** drop-down list.
3. Select the operator `IBM Management Infrastructure managed services`.
4. Select the tab Managed services.
5. Edit the Managed services instance by selecting **Edit ManageService** from the overflow menu.
6. Search `camBpmProvider` in YAML and change the following values:
   - Change `replicaCount` to 1.
   - Edit `bpmEndpoint` with the BPM endpoint value.
   - Edit `bpmUserName` with the user name value.
   - Edit `bpmUserPwd` with the password.

     These are the sample values for BPM provider:

```
camBpmProvider:
  bpmEndpoint: 'https://9.9.9.9:9443/'
  bpmUserName: 'admin'
  bpmUserPwd: 'passw0rd'
  replicaCount: 1
```

7. Save the YAML file.

Note: The supported version of IBM Business Process Manager is 8.5.7.

Enabling or disabling Ansible Integration

Post the installation of Managed services, you can enable or disable Ansible integration from the IBM Cloud Pak for AIOps.

Procedure

Complete these steps from your OpenShift console.

1. Click **Operators** > **Installed Operators**.
2. Select `cp4aiops` namespace from the **Project** drop-down list.
3. Select the operator `IBM Management Infrastructure managed services`.
4. Select the tab Managed services `.
5. Edit the Managed services instance by selecting **Edit ManageService** from the overflow menu.
6. Search `camAnsibleProvider` in YAML and change the `replicaCount` to 1.
7. Save the YAML file.

Creating IBM Infrastructure Management integrations

You can send event data from Infrastructure Management to IBM Cloud Pak for AIOps through an Infrastructure Management integration.

- Before you begin
- Creating Infrastructure Management integrations
- Editing Infrastructure Management integrations
- Deleting Infrastructure Management integrations

Before you begin

Before you configure an Infrastructure Management integration, ensure that the following prerequisites are met:

- You have a working Infrastructure Management cluster. Infrastructure Management must be installed on an Red Hat OpenShift Container Platform cluster. The integration cannot be created for an Infrastructure Management appliance that is running on a virtual machine (VM).
- Event syndication and inventory syndication is enabled within Infrastructure Management.

  For information on how to enable event and inventory syndication, see *Enabling Events and Inventory Syndication* within the topic General Configuration.

Note: Infrastructure Management and Cloud Pak for AIOps can be located in the same cluster or in different clusters.

Creating Infrastructure Management integrations

To create an Infrastructure Management integration, complete the following steps:

1. Log in to the IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the **Integrations** page, click **Add integration**.
4. From the list of available integrations, find and click the Infrastructure Management tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Select the **Events** and **Topology** type from the **Category** list.
5. On the side panel, review the information and when ready to continue, click **Get started**.

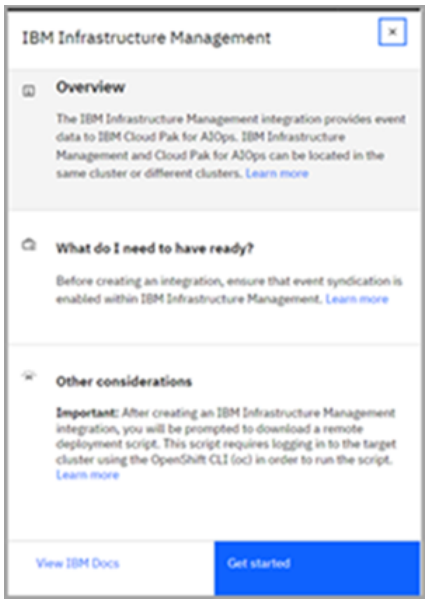


Figure. Add Infrastructure Management integration - get started

6. On the Add integration page, define the general integration details:

   Name: The display name for the integration.

   Description (optional): An optional description for the integration.

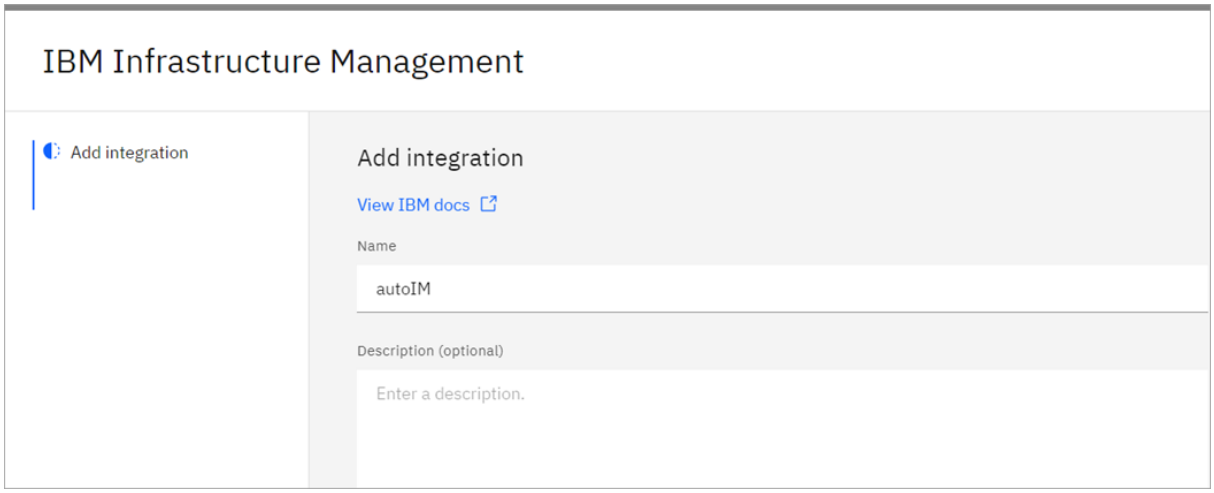

Figure. Add Infrastructure Management integration

7. Click **Done**.

   Important: After creating the integration, you are prompted to copy or download a boostrap command for running a remote deployment script. The script is generated when you create the integration in IBM Cloud Pak for AIOps. This script is required for establish the integration from Infrastructure Management to IBM Cloud Pak for AIOps.

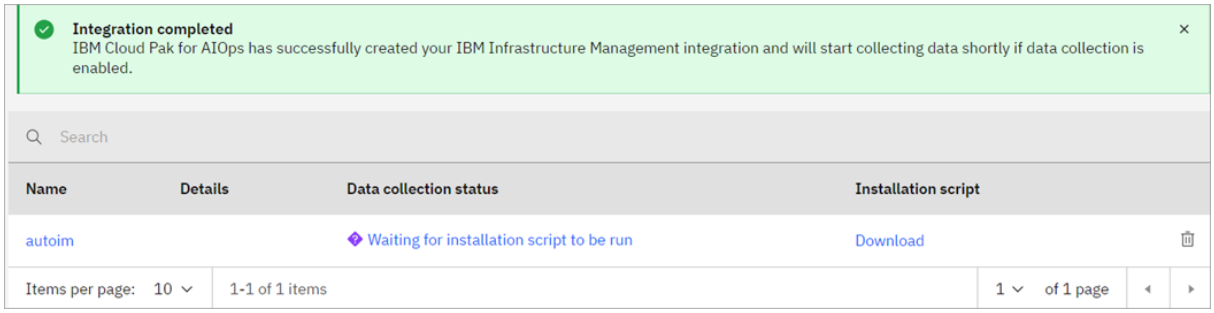

Figure. Add Infrastructure Management integration - completed

8. Copy or download the bootstrap command for the deployment script.

   You can click the **Copy to clipboard** button to copy the command, or click **Download as shell script** to download the command as a `bootstrap.sh` file.

   Note: If you do not obtain the command now, you can copy or download the command later by completing the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Infrastructure Management** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the IBM Infrastructure Management page, click the **Download** link in the **Remote deployment script** column for the integration.
5. Either copy or download the bootstrap command for the deployment script.

9. Run the remote deployment script on your Infrastructure Management cluster.
    1. Get the OpenShift CLI `oc login` command from the cluster where Infrastructure Management is installed.
    2. From a command line, log in to the Infrastructure Management cluster with the `oc login` command.
    3. Switch to the project (namespace) where Infrastructure Management is installed.
    4. Run the deployment script as a `sh` (script file), such as the downloadable `bootstap.sh` file.

Editing Infrastructure Management integrations

After you create a integration, you can edit the integration to update the name or description. Complete the following steps to edit the integration:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Infrastructure Management** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the IBM Infrastructure Management page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required.
6. Click **Save** when you are done editing.

Deleting Infrastructure Management integrations

If you no longer need your IBM Infrastructure Management integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

To delete a integration, you need to complete the following steps for IBM Cloud Pak for AIOps. Then, you need to complete steps on your Infrastructure Management to remove the integration deployment. The deployment on the cluster is not removed when you delete the integration in the IBM Cloud Pak for AIOps console for IBM Cloud Pak for AIOps.

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Infrastructure Management** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the IBM Infrastructure Management integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**. Your integration is deleted.
6. Delete the integration deployment on your Infrastructure Management cluster. To delete the deployment, you must manually run OpenShift CLI (`oc`) commands against the cluster.
    1. From a command line, use the `oc login` command to log in to your Infrastructure Management cluster.
    2. Switch to the project (namespace) where Infrastructure Management is installed.

       ```
       oc project <project>
       ```

       Where `<project>` is the project (namespace) where Infrastructure Management is installed.
    3. Delete the `grpc-bridge-secret` secret.

       ```
       oc delete secret grpc-bridge-secret
       ```
    4. Delete the integration deployment

       ```
       oc delete deploy aiops-connector
       ```

       The deployment is now deleted from your Infrastructure Management cluster.

Migrating infrastructure data to Infrastructure Automation

You can migrate infrastructure data, such as services data and appliances, to Infrastructure Automation from other products and services, such as IBM Cloud Pak for Multicloud Management, IBM Cloud Private, and IBM Red Hat CloudForms.

- Migrating IBM Cloud Private Managed services
- Upgrading IBM Red Hat CloudForms and IBM Cloud Pak for Multicloud Management appliances

Migrating IBM Cloud Private Managed services to Infrastructure Automation

This topic describes the process of migrating Managed services from IBM Cloud Private to Infrastructure Automation.

Most of the Managed services pods are stateless, except MongoDB pod. The MongoDB pod stores state in external volumes, that is, persistent volumes. You must do the migration for the following resources:

- Logs

  The logs from different MongoDB pods in IBM Cloud Private are stored in persistent volumes, but in Infrastructure Automation, the pods don't use persistent volumes to store logs. The Infrastructure Automation uses **`system.out`** as default logging mechanism. It is recommended to use an external log aggregator like Kibana for the IBM Cloud Private customers.

- Terraform binaries

  In IBM Cloud Private, the custom terraform binaries are stored in persistent volumes whereas in Infrastructure Automation, the custom terraform binaries are stored in MongoDB. If in case, you have a custom terraform binaries or want to use binary version's that is not shipped anymore as part of the Infrastructure Automation release, then you can upload using Terraform file APIs.

- MongoDB

  The MongoDB pod contains IBM Cloud Private state. This state needs to be backed up and restored in Infrastructure Automation. For more information, see Backing up MongoDB in IBM Cloud Private and Restoring MongoDB.

Backing up MongoDB in IBM Cloud Private

1. Stop the running pods by setting the replica count to 0 and ensure that nothing is written to the MongoDB pod or scale down the MongoDB pod to 0.
2. Start the MongoDB pod and set replica of MongoDB pod count to 1.
3. Switch to the service namespace.

   ```
   kubectl config set-context $(kubectl config current-context) --namespace=services
   ```

4. Create a new MongoDB pod using the **`mongopod.yaml`** file and ensure to use the same labels as other pods.

   ```
   kind: Pod
   apiVersion: v1
   metadata:
     name: cam-mongo-backup
     labels:
       app.kubernetes.io/instance: cam
       app.kubernetes.io/managed-by: Helm
       app.kubernetes.io/name: cam-manageservice
       certmanager.k8s.io/time-restarted: 2022-2-23.1227
       helm.sh/chart: manageservice-4.2.0
       name: cam-mongo-backup
       release: cam
     annotations:
       openshift.io/scc: anyuid
   spec:
     containers:
       - name: backup-mongo
         image: mongo:4.0.16
   ```

   Note: Get the mongo version of the targeted cluster by executing inside the mongo pod and running **`mongo --version`**. Use the same tag of mongo image while creating the backup mongo pod.

   Run **`kubectl apply -f mongopod.yaml`** to create the **`cam-mongo-backup`** pod and wait for the pod to get started.

   If you encounter with an error message like **`no matching repositories in ClusterImagePolicy`** while applying the **`kubectl`**, then edit the cluster policy and add image policy for the MongoDB pod as following:

   ```
   kubectl  edit ClusterImagePolicy image-policy

   -name:docker.io/mongo:*
   ```

5. Get the IP address of MongoDB pod.

   ```
   MONGO_IP=$(kubectl get -n management-infrastructure-management svc/cam-mongo --no-headers | awk '{print $3}')
   ```

6. Get password to connect to the MongoDB pod.

   ```
   MONGO_PASSWORD=$(kubectl get -n management-infrastructure-management secret cam-secure-values-secret -o yaml | grep
   mongoDbPassword: | awk '{print $2}' | base64 --decode)
   ```

7. Get the username and port by describing **cam-mongo** pod.

   ```
   kubectl describe pod cam-mongo
   ```

8. Execute the **mongodump** from **cam-mongo-backup** pod to create a zip file.

   ```
   kubectl -it exec cam-mongo-backup -- bash -c "mongodump --ssl --sslAllowInvalidCertificates --uri
   mongodb://MONGODB_USERNAME:$MONGO_PASSWORD@$MONGO_IP:27017/cam?ssl=true --archive=/tmp/mongo_backup.gz --gzip"
   ```

   Note: Verify whether the tar file is present at **/tmp** location in the pod.

9. Run the following command to copy the back up archive to your local set up, for example, the **/tmp/dbbackup** directory

   ```
   kubectl cp cam-mongo-backup:/tmp/mongo_backup.gz /tmp/dbbackup
   ```

10. Delete **cam-mongo-backup** pod.

    ```
    kubectl delete pod cam-mongo-backup
    ```

11. Restore the replica count for the pods that you scaled down in a previous step.

Restoring MongoDB in Infrastructure Automation

The MongoDB contains Managed services state and to restore this state, do the following.

1. Stop the running pods by setting the replica count to 0 and ensure that nothing is written to the MongoDB pod or scale down the MongoDB pod to 0.
2. Start the MongoDB pod and set replica of MongoDB pod count to 1.
3. Switch to the **cp4aiops** namespace.

   ```
   oc project cp4aiops
   ```

4. Create a new MongoDB pod using the **mongopod.yaml** file and ensure to use the same labels as other pods:

   ```
   kind: Pod
   apiVersion: v1
   metadata:
     name: cam-mongo-backup
     labels:
       app.kubernetes.io/instance: cam
       app.kubernetes.io/managed-by: Helm
       app.kubernetes.io/name: cam-manageservice
       certmanager.k8s.io/time-restarted: 2022-2-23.1227
       helm.sh/chart: manageservice-4.2.0
       name: cam-mongo-backup
       release: cam
     annotations:
       openshift.io/scc: anyuid
   spec:
     containers:
       - name: backup-mongo
         image: mongo:4.0.16
   ```

   Note: Get the mongo version of the targeted cluster by executing inside the mongo pod and running **mongo --version**. Use the same tag of mongo image while creating the backup mongo pod.

   Run **oc apply -f mongopod.yaml** to create the **cam-mongo-backup** pod and wait for the pod to get started.

5. Copy the desired back up archive to restore into the **cam-mongo-backup** container.

   ```
   oc rsync /tmp/dbbackup/ cam-mongo-backup:/tmp/
   ```

6. Get the IP address of MongoDB pod.

   ```
   MONGO_IP=$(kubectl get -n cp4aiops svc/cam-mongo --no-headers | awk '{print $3}')
   ```

7. Get password to connect to the MongoDB pod.

   ```
   MONGO_PASSWORD=$(kubectl get -n cp4aiops secret cam-secure-values-secret -o yaml | grep mongoDbPassword: | awk
   '{print $2}' | base64 --decode)
   ```

8. Get the username and port by describing **cam-mongo pod**.

   ```
   oc describe pod cam-momgo
   ```

9. Restore the data by running the following command:

   ```
   oc -it exec cam-mongo-backup -- bash -c "mongorestore --ssl --sslAllowInvalidCertificates --uri
   mongodb://camuser:$MONGO_PASSWORD@$MONGO_IP:27017/cam?ssl=true --archive=/tmp/mongo_backup.gz --gzip --drop"
   ```

10. Delete **cam-mongo-backup** pod.

    ```
    oc delete pod cam-mongo-backup
    ```

11. Restore the replica count for the pods that you scaled down in a previous step.
12. For the services that are not Globally accessible, you need to create the namespaces if they do not already exist. Create the namespaces in the cluster where you are restoring data so that the services can be accessed.

Migrating IBM Red Hat CloudForms and IBM Cloud Pak for Multicloud Management appliances to Infrastructure Automation

This topic describes the process of doing a full appliance replacement upgrade when a new release of Infrastructure Automation – Infrastructure Management is available.

The following migration paths are supported:

- IBM Cloud Pak for Multicloud Management 2.3.x - Infrastructure Management to IBM Cloud Pak for AIOps 4.6.0 - Infrastructure Automation
- IBM Red Hat CloudForms 4.7 through 5.0 to IBM Cloud Pak for AIOps 4.6.0 - Infrastructure Automation

Ordering migrations

You must complete all migrations of the databases before you configure replication and high availability. The reason is because you deploy new appliances for migrating to Infrastructure Management.

Important: Do not run **evmserverd** if a database is in a partially migrated state.

Modifying the PostgreSQL configuration

This procedure modifies the strategy that is used for updating the PostgreSQL configuration. Previously, changes were made directly to the **postgresql.conf** file in the data directory. After you update the new configuration, changes will be made by editing a separate file in the **/etc/manageiq/postgresql.conf.d** directory. This modification allows future PostgreSQL configuration changes to be made more easily.

Note: The **01_miq_overrides.conf** file in the **/etc/manageiq/postgresql.conf.d** directory is reserved for application overrides and is re-created on application updates. **Important:** This file must not be edited. More files are read by the PostgreSQL server process according to the documentation here: PostgreSQL - Managing Configuration File Contents

1. Back up the **postgresql.conf** file so that you have any configuration changes:

   ```
   cp $APPLIANCE_PG_DATA/postgresql.conf <file_location>
   ```

2. Copy the updated **postgresql.conf** file to the **pg_data** directory:

   ```
   cp $APPLIANCE_SOURCE_DIRECTORY/TEMPLATE/var/opt/rh/rh-postgresql95/lib/pgsql/data/postgresql.conf
   $APPLIANCE_PG_DATA/postgresql.conf
   ```

3. Optional: If you updated the **postgresql.conf** file before this procedure, create a new **02_user_overrides.conf** file, and add any modifications that you have from the original **postgresql.conf** file. Example layout of the **02_user_overrides.conf** file:

   ```
   #--------------------------------------------
   # WRITE AHEAD LOG
   #--------------------------------------------

   wal_level = 'logical'
   wal_log_hints = on
   wal_buffers = 16MB
   min_wal_size = 1GB
   max_wal_size = 2GB
   checkpoint_completion_target = 0.9
   ```

   After the **02_user_overrides.conf** file is modified and saved, restart the postgresql service:

   ```
   systemctl restart $APPLIANCE_PG_SERVICE
   ```

All **postgresql.conf** customizations are now made to files in the **/etc/manageiq/postgresql.conf.d** directory due to the following **include_dir** line in the default configuration. The settings in these new files override ones in the **postgresql.conf** file.

```
include_dir = '/etc/manageiq/postgresql.conf.d`
```

Migrating to the Infrastructure Management appliance

Overview

This procedure describes the process of migrating to the Infrastructure Management appliance. This procedure does not necessarily include migration of all possible customer modifications, so it is recommended that you fully test any modifications before you migrate your environment.

Important:

- Read through all of the steps in this procedure before you begin the migration process.
- Infrastructure Management appliances require 12 GB memory. However, before you migrate your appliances, adjust resources in your environment to avoid performance issues.

You can classify the migration into three groups of appliances:

- VMDB appliance - An appliance with running workers that also hosts its own database that other appliances can also connect to.
- Non-VMDB appliance - An appliance with running workers that does not host a database. The appliance is connected to an external database.

- Dedicated database appliance - A Infrastructure Management appliance or non-Infrastructure Management virtual machine with no running workers on it: the appliance contains only a database for other appliances to connect to.

Migration workflow summary

In summary, the migration process follows this workflow:

1. Prepare appliances:

   Note: This step applies only for a multi-region Infrastructure Management environment. Remove all the subscriptions from the global region before you migrate the global database since the subscriptions must be dropped and re-created.

2. Back up the database of your appliance.
3. Migrate appliances:
   1. Provision new appliances to replace each appliance.
   2. On the database and nondatabase appliances, copy the GUID file from the version of the same appliance to the same location.
   3. On the database and nondatabase appliances, use the appliance console menu to stop the evmserverd service, manually remove the pre-configured database and key, and fetch the v2_key from an appliance.
   4. Copy the appliance database backup file and restore the database on each VMDB and dedicated database appliance.
   5. Load the new version of the pglogical library on the VMDB and dedicated database appliances.

      Note: This step applies only for a multi-region Infrastructure Management environment.

   6. Migrate the VMDB appliance databases and update the Automate Model.
   7. Restart **`evmserverd`** on the VMDB appliances.
4. Configure replication after the migration process is complete and appliances are running again.

Backing up current appliances

These steps do not affect the operations of your appliance infrastructure. However, they help ensure that you are able to roll back if required and replicate the network settings.

1. Find the size of the databases by using the following command. Then, ensure that your volume has enough space for the backup file.

   ```
   psql -d vmdb_production -c "SELECT pg_size_pretty(pg_database_size('vmdb_production'));"
   ```

2. If it's a multi-region environment, ensure you removed all subscriptions from the global database appliance.
3. Stop the **`evmserverd`** process.

   ```
   systemctl stop evmserverd
   ```

4. Back up the databases of your appliances in the root directory. Take a snapshot if possible.

   ```
   pg_dumpall -c --if-exists | gzip > vmdb.pg.gz
   ```

   Notes:

   - This command creates a compressed text-based backup. **`pg_dumpall`** is a utility for writing out ("dumping") all PostgreSQL databases of a cluster into one script file. For more information, see pg_dumpall.
   - When you run a **`pg_dumpall`**, the **`pg_replication_slots`** is not copied over causing the slots to become inactive. Also, the size of the global database appliance is reduced allowing for quicker backup and restore.
   - Even a compressed database backup can be large so consider storing it on a file system with adequate space such as /var/tmp. Review your file system available space by using the df command.
   - You must also provide backup for configuration files such as **`/var/www/miq/vmdb/certs/v2_key`**, **`/var/www/miq/vmdb/config/database.yml`**, and **`/var/www/miq/vmdb/GUID`**.
5. Back up the following files and take note of the appliance that each file comes from. These files are used to replace the old appliances in the database and for disaster recovery.

   - /var/www/miq/vmdb/GUID
6. During the upgrade, the iptables configuration file **`/etc/sysconfig/iptables`** is removed. If you changed the iptables configuration from the default, run the **`iptables --list -n`** command to see the current configuration. Run the following command to back up the iptables configuration:

   ```
   iptables-save > /etc/iptables.conf
   ```

   You can restore your iptables configuration file with the following command:

   ```
   iptables-restore < /etc/iptables.conf
   ```

   You can also add this command to **`/etc/rc.local`** to reload the rules at every restart.

Steps to follow on newly deployed Infrastructure Management 4.6.0 Appliances

Complete the following steps on your appliances as specified to migrate to Infrastructure Management.

Note: Some steps are run on certain appliances. Ensure you wait for each command to finish before you move to the next step.

1. Provision and start the new appliances.
2. On the VMDB and non-VMDB appliances, run the following commands as the root user:
    1. Copy the GUID file from the appliance.

        ```
        scp root@$IP_of_old_appliance:/var/www/miq/vmdb/GUID /var/www/miq/vmdb/
        ```

        Notes:

        - Complete these steps on VMDB appliances first. The non-VMDB appliances don't have a database to connect to if they're done first.
        - Complete this step only if you want to keep the same appliance/miq_servers records in the database and inherit that appliance's existing settings. If you plan on deploying new appliances with new IP addresses and hostname and not inherit the settings, you might prefer creating new records by not copying the GUID.
    2. Stop the evmserverd process.

        ```
        systemctl stop evmserverd
        ```

    3. Remove the previously generated encryption key.

        ```
        rm /var/www/miq/vmdb/certs/v2_key
        ```

    4. Copy the default database configuration file, ovewriting the previously generated one that used the deleted encryption key.

        ```
        scp root@<IP_of_old_appliance>:/var/www/miq/vmdb/config/database.yml /var/www/miq/vmdb/config/database.yml
        ```

    5. Drop the previously generated database.

        ```
        dropdb vmdb_production
        ```

    6. For VMDB appliances, configure the application, fetch the key from remote system, and Reset Configured Database.
    7. For VMDB appliances, select the same region number and database password as the old installation. You can find the region number that is used for an installation that is listed as **Database/Region:** in the `appliance_console` summary information.
    8. For non-VMDB appliances, configure the application by using the join region in external database option. Note as part of the database configuration step, fetch the `v2_key` from the appliances.
    9. Allow the appliance to start.
3. On the new VMDB and new dedicated database appliances:
    1. Stop the evmserverd process.

        ```
        systemctl stop evmserverd
        ```

    2. Drop the default database.

        ```
        dropdb vmdb_production
        ```

    3. Copy the database dump from the appliance. Update the following location to reflect the source file location of the database dump and copy it to a location with enough available space.

        ```
        scp root@$IP_of_old_appliance:/var/tmp/vmdb.pg.gz /var/tmp
        ```

    4. Decompress and restore the database dump backup file.

        ```
        gunzip < vmdb.pg.gz | psql postgres
        ```

    5. Change to the vmdb directory.

        ```
        cd /var/www/miq/vmdb/
        ```

    6. Run the command appropriate to your environment to migrate everything in the database to work with the latest configuration. If you run into an error, contact IBM Support.

        ```
        rake db:migrate
        ```

4. Update the Automate Model to the latest version. This resets the ManageIQ and IBM domains (base domains) to a new and upgraded version. In a single (stand-alone database) or replicated environment, run this command on each VMDB appliance.

    ```
    rake evm:automate:reset
    ```

5. Start the evmserverd process. In a single (stand-alone database) or replicated environment, run this command on each VMDB appliance:

    ```
    systemctl start evmserverd
    ```

The migration process is now complete. Once appliances are running again, you can configure database replication in your environment. For more information, see Configuring Database Replication and Centralized Administration in the General Configuration guide.

Infrastructure Automation backup and restore

Learn how to back up and restore IBM Cloud Pak® for AIOps Infrastructure Automation, such as for recovering from a disaster like a complete data center outage.

- Overview
- Planning
- Backup process
- Restore process
- Components

Overview

Infrastructure Automation backup and restore is based on the storage and database backup of critical datastores, cluster resources, and component data and settings. With the backup and restore feature, you can recover your services to a previous point in time backup to recover from data corruption, system failures, or user errors.

You can also use the backup and restore feature as a means of copying data from one cluster to another, or from one environment into another, such as for disaster recovery purposes.

If you are using backup data to restore environments on a new cluster in another data center, your recovery time objective (RTO) and recovery point objective (RPO) must be sufficient for this usage.

Infrastructure Automation uses the *OpenShift APIs for Data Protection* (OADP) and the open source tool Velero to backup data to object storage. In the case of a failure, the APIs and Velero are used to restore data from the backups.

For more information about these tools, see:

- OpenShift APIs for Data Protection (OADP) features
- Velero documentation

Planning for backup and restore

When you are planning your Infrastructure Automation backup and restore strategy, consider what hardware requirements are needed for backing up your environment:

- You need to install the backup and restore tools in the Red Hat OpenShift Container Platform cluster. These tools include the OpenShift APIs for Data Protection (OADP), Velero, and Restic. You need to configure the OpenShift APIs and Velero with the appropriate object storage for storing your backups. This object storage must support RWX (read-write-execute) mode.
- You can backup both smaller starter and larger production sized cluster deployments.
- You can use backed up data to restore data to the existing cluster where the data was backed up, or to a new cluster.
- A restored cluster should have the same size and high availability level as the original cluster.
- Data is copied and stored in object Storage as part of the backup process. During a restoration, the same data is fetched and restored.

Notes:

- The backup and restore processes can take time. Using a backup to restore data or configurations is most useful when your recover time objective (RTO) and recovery point objectives (RPO) are met.
- As your data grows, the size of your backup storage might need to grow.
- A backup and restore of Red Hat OpenShift Container Platform or ETCD is not completed as part of the Infrastructure Automation backup and restore feature.
- Configure the duration between your backups to be less than your RPO. By default, the RPO is 12 hours, which requires backups to run once every 12 hours. The default RTO is 4 hours.
- Custom configuration settings for the Infrastructure Automation - Managed services component, such as Ansible replica count, extra variables, might not be backed up and restored. If you need this data and resources to be included in restored clusters, you need to directly add the data or resources to the restored cluster.
- If you upgrade your deployment, you must setup back and restore again. For more information, see Upgrading Infrastructure Automation backup and restore artifacts.

Backup process

The IBM Cloud Pak® for AIOps backup process is capable of backing up data for both Infrastructure Automation and IBM Cloud Pak for AIOps. The backup of data is completed by backing up the datastores that include Infrastructure Automation data, and if available, IBM Cloud Pak for AIOps data. Some datastores are backed up and restored in their entirety. Other datastores are backed up and restored depending on a particular component need.

The following table shows the Infrastructure Automation datastores that are backed up:

Table: Backed up datastores

Datastores	Backup type
`IM-Postgres`	Volume backup
`CS-edbPostgres`	Data export
`CAM-mongodb`	Volume backup
`metastore`	Data export

The following table shows the Infrastructure Automation resources that are backed up:

Table: Backed up resources

Backup resource name	Resource type
`backup-metastore`	pod
`backup-postgres`	pod
`backup-cam`	pod

Backup resource name	Resource type
`zen-secrets-aes-key`	secret
`im-iminstall`	ManageIQ
`im-iminstall`	IMInstall
`ibm-infra-management-application`	secret
`postgresql`	secret
`backup-imedb`	pod

The backup process is run by `custom backup-job(s)`. When the backup job runs, pods can be scaled down to ensure consistent backups are created. The backup job calls Velero to back up Kubernetes resources and volumes. Native backup scripts are run to back up datastores. The backup job then scales up pods to match their state before the backup process began. Datastores that have a selective backup types are backed up only when the datastore is updated since the previous backup.

For more information about the backup process, see:

- Backing up Infrastructure Automation data.
- Backing up IBM Cloud Pak for AIOps data.

Restore process

To run the restore process, you first need to create a new cluster and install the required prerequisites on the cluster. The prerequisites include installing the required CLI tools, creating the storage classes, and updating the `bcdr/common/aiops-config.json` and `bcdr/restore/restore-data.json` files with the required configuration values. Then you need to configure Velero to point to the same s3 storage where the backup is located.

You then need to create the required namespaces for IBM Cloud Pak® for AIOps by running the `restore-namespace.sh` job. This script creates only the namespaces and namespace metadata, not the contents of the namespace. This namespace restore is needed because the metadata contains SELinux settings that must match the settings from the corresponding namespaces on the cluster where you took the backup.

Then, you need to complete the installation of Infrastructure Automation. With the Infrastructure Automation instance created and Velero configured, you can run the Velero restore jobs to populate the instance. When the jobs complete you need to run any other post restore tasks that you need to complete.

Note: Velero does not support the overriding of resources during the restore. The restoration of resources alread existing in the cluster are skipped. If this occurs, sync the existing resources and create only the resources that were not restored instead of creating a new resources Operator.

For more information about the restore process, see Restoring Infrastructure Automation.

Procedures for backing up and restoring Infrastructure Automation

- Installing the backup and restore tools
- Backing up Infrastructure Automation
- Restoring Infrastructure Automation
- Upgrading Infrastructure Automation backup and restore artifacts
- Backup and Restore Infrastructure management appliances

Installing the backup and restore tools

Learn how to install the tools that are required for the backup and restore of IBM Cloud Pak® for AIOps Infrastructure Automation.

You need to install the Red Hat OpenShift APIs for Data Protection (OADP). OADP provides default Velero plug-ins that are integrated with storage providers to support backup operations.

Note: The backup and restore tools for Infrastructure Automation are the same as the tools for backing up and restoring IBM Cloud Pak for AIOps. If you have the tools installed for IBM Cloud Pak for AIOps, you do not need to complete the following procedure.

Prerequisites

- Provision the object storage (S3 bucket) for storing your backups. The backup process moves backup files to an S3 bucket, which must be in an S3 compatible location, such as Amazon Web Services (AWS).
- Ensure that the following command line tools are installed on your workstation:
  - `oc`
  - `jq`
  - `git`
- Ensure that you are logged in to your Red Hat® OpenShift® Container Platform cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).

Procedure

1. Install the Velero client CLI
2. Install OpenShift API for Data Protection (OADP)
3. (Offline deployments only) Mirror the backup and restore images

1. Install the Velero client CLI

Install the Velero client CLI on the workstation that you plan to use to run the scripts for backing up and restoring the cluster.

1. Run the following command to download the Velero CLI client:

   ```
   curl -LO https://github.com/vmware-tanzu/velero/releases/download/v1.12.3/velero-v1.12.3-linux-amd64.tar.gz
   ```

2. Extract the tarball:

   ```
   tar -xzf velero-v1.12.3-linux-amd64.tar.gz
   ```

3. Move the extracted velero binary to **/usr/local/bin**:

   ```
   mv velero-v1.12.3-linux-amd64/velero /usr/local/bin/velero
   ```

4. Run the following command to verify the installation.

   ```
   velero version
   ```

   Example output:

   ```
   Client:
    Version: v1.12.3
    Git commit: 06d12dec4030703cb46b2699ca434cdabd9edbb0
   velero version
   ```

2. Install Red Hat OpenShift APIs for Data Protection (OADP)

Follow the Red Hat OpenShift documentation to install Red Hat OpenShift API for Data Protection: About installing OADP.

You must install the Red Hat OpenShift APIs for Data Protection (OADP) Operator.

1. Clone the IBM Cloud Pak for AIOps samples GitHub repository that includes the backup and restore scripts. Clone this repository by running the following command:

   ```
   git clone https://github.com/IBM/cp4waiops-samples.git
   ```

   If you have an offline (air-gapped) deployment of Infrastructure Automation, then copy the cloned scripts to your air-gapped environment.

2. Update the **install-oadp-config.json** file.

   1. Go to the directory **<Path>/bcdr/4.6.0/install** where you have the backup and recovery files downloaded. **<Path>** is the path to where you downloaded and extracted the IBM Cloud Pak for AIOps backup and restore files.

   2. Open the **install-oadp-config.json** file for editing. Configure the following settings in the file:

      - **aws_access_key_id** - Access key ID to connect to your object storage S3 bucket.
      - **aws_secret_access_key** - Secret access key to connect to your S3 bucket.
      - **bucket_name** - Name of the S3 bucket where backup data will be stored.
      - **bucket_region** - Region where the S3 bucket is deployed.
      - **namespace** - Namespace name in which you want to deploy OADP. If the namespace does not exist, it is created when you run the OADP installation script.
      - **backup_label** - Label for creating a folder structure to organize sets of backups together.

3. Change to the **install** directory where the installation script is located:

   ```
   cd <Path>/bcdr/4.6.0/install
   ```

   Where **<Path>** is the path to where you downloaded and extracted the IBM Cloud Pak for AIOps backup and restore files.

4. Run the OADP installation script:

   ```
   nohup ./install-oadp.sh > install-oadp.log &
   ```

5. Check the logs by running the following command:

   ```
   tail -f install-oadp.log
   ```

6. Export an environment variable with the Velero namespace.

   ```
   export OADP_NAMESPACE=<oadpNamespace>
   ```

   Where **<oadpNamespace>** is the namespace where OADP is installed.

7. Check the Velero pods status by running the following command:

   ```
   oc get pods -n ${OADP_NAMESPACE}
   ```

   The Velero and Restic pods should be in a running state.

8. Check the status of the **backupStorageLocation** by running the following command:

   ```
   oc get backupStorageLocation -n ${OADP_NAMESPACE}
   ```

The **backupStorageLocation** needs to be in an available status.

3. (Offline deployments only) Mirror the backup and restore image

If the deployment that you are backing up or restoring to is an offline (air-gapped) deployment, then you must copy the backup and restore image to a registry that is available to your air-gapped environment. You can do this by using either a bastion host or a portable device. For background information on offline (air-gapped) deployments, see Installing Infrastructure Automation in an air-gapped environment (offline).

Prerequisites:

- The host that you are running the mirror from must allow access to **icr.io** on port 443.
- You must have a target registry available to mirror the backup and restore image into. The target registry must adhere to the requirements in Set up a target registry.

Follow the instructions in Mirroring with a bastion host or Mirroring with a portable device.

Mirroring with a bastion host

1. Set environment variables.

```
export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
export TARGET_REGISTRY_USER=<username>
export TARGET_REGISTRY_PASSWORD=<password>
export BCDR_IMAGE=<bcdr_image>
export BCDR_UTILS_IMAGE=cp4waiops-bcdr-utils@sha256:1db594ad10da9c7049367b5dd4373e86af7e6bcb875758022e2e743c83cf486f
export IA_NAMESPACE=<ia_namespace>
```

   Where

   - **<bcdr_image>** is the name of the backup and restore image, as given in the backup helm chart **values.yaml** file, in the form **cp4waiops-bcdr@{digest}**. An example value for BCDR_IMAGE is **cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355**.
   - **<ia_namespace>** is the namespace that Infrastructure Automation is deployed in.

   If your bastion host must connect to the internet through a proxy, then also set the following environment variables:

```
export https_proxy=http://proxy-server-hostname:port
export http_proxy=http://proxy-server-hostname:port
```

2. Authenticate with the target registry.

   You do not need to authenticate with the IBM Entitled Registry, as the image that you require for backup and restore is freely available.

   You need to authenticate with the target registry to enable the **oc image mirror** command to push the image to your target registry. Log in to your target registry to generate an authentication file containing the registry credentials, and then create an environment variable that has the location of the authentication file.

   Run the following commands:

```
podman login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD}
export REGISTRY_AUTH_FILE=${XDG_RUNTIME_DIR}/containers/auth.json
```

   Note: The authentication file is usually at **${XDG_RUNTIME_DIR}/containers/auth.json**. For more information, see the Options section in the Podman documentation.

3. Mirror the image.

   Connect the bastion host to the internet and disconnect if from the air-gapped environment. Then run the following command to mirror the backup and restore image to the target registry:

```
oc image mirror icr.io/cpopen/cp4waiops/${BCDR_IMAGE} ${TARGET_REGISTRY}/cpopen/cp4waiops/${BCDR_IMAGE} -a
${REGISTRY_AUTH_FILE} --insecure
oc image mirror icr.io/cpopen/cp4waiops/${BCDR_UTILS_IMAGE} ${TARGET_REGISTRY}/cpopen/cp4waiops/${BCDR_UTILS_IMAGE} -
a ${REGISTRY_AUTH_FILE} --insecure
```

4. Create the **ImageContentSoucePolicy**.

   1. Switch to the namespace that Infrastructure Automation is deployed in.

```
oc project ${IA_NAMESPACE}
```

   2. Run the following command to create the **ImageContentSourcePolicy**.

```
cat << EOF | oc apply -f -
apiVersion: operator.openshift.io/v1alpha1
kind: ImageContentSourcePolicy
metadata:
 name: bcdr-mirrors
spec:
 repositoryDigestMirrors:
  - mirrors:
    - ${TARGET_REGISTRY}/cpopen/cp4waiops/
    source: icr.io/cpopen/cp4waiops/
EOF
```

Mirroring with a portable device

If you are using a portable storage device, then connect it to a host with access to the internet. If you are using a portable compute device, then connect it to the internet. Run the following steps.

1. Set environment variables.

   ```
   export IMAGE_PATH=<image-path>
   export BCDR_IMAGE=<bcdr_image>
   export BCDR_UTILS_IMAGE=cp4waiops-bcdr-utils@sha256:1db594ad10da9c7049367b5dd4373e86af7e6bcb875758022e2e743c83cf486f
   ```

   Where

   - `<image_path>` is the directory where you want the image to be stored.
   - `<bcdr_image>` is the name of the backup and restore image, as given in the backup helm chart `values.yaml` file, in the form `cp4waiops-bcdr@{digest}`. An example value for BCDR_IMAGE is `cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355`.

   If your device must connect to the internet through a proxy, then also set the following environment variables:

   ```
   export https_proxy=http://proxy-server-hostname:port
   export http_proxy=http://proxy-server-hostname:port
   ```

2. Mirror the images to the file system on your portable device.

   You do not need to authenticate with the IBM Entitled Registry, as the image that you require for backup and restore is freely available. Run the following command to mirror the image from the IBM Entitled Registry to the file system on your portable device.

   ```
   oc image mirror \
   icr.io/cpopen/cp4waiops/${BCDR_IMAGE} file://cpopen/cp4waiops/${BCDR_IMAGE} \
   --filter-by-os '.*' \
   --insecure \
   --skip-multiple-scopes \
   --dir "${IMAGE_PATH}" \
   --max-per-registry=1

   oc image mirror \
   icr.io/cpopen/cp4waiops/${BCDR_UTILS_IMAGE} file://cpopen/cp4waiops/${BCDR_UTILS_IMAGE} \
   --filter-by-os '.*' \
   --insecure \
   --skip-multiple-scopes \
   --dir "${IMAGE_PATH}" \
   --max-per-registry=1
   ```

3. Setup the file system in the air-gapped environment.

   1. (Portable storage device only) Copy files to the air-gapped environment

      If you are using a portable storage device, you must copy the files at $IMAGE_PATH on the portable storage device to a local compute device in the air-gapped environment that has access to the target registry. If you are using a portable compute device, then these files are already present, and you can proceed to the next step.

   2. Disconnect the device that has your file system (the portable compute device or the local compute device) from the internet and connect it to the air-gapped environment.

   3. Set environment variables on the device in the air-gapped environment that has access to the target registry.

      If you are using a portable compute device, then set the following environment variables on it. If you are using a portable storage device, then set the following environment variables on your local compute device within the air-gapped environment.

      ```
      export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
      export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
      export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
      export TARGET_REGISTRY_USER=<username>
      export TARGET_REGISTRY_PASSWORD=<password>
      export IMAGE_PATH=<image_path>
      export BCDR_IMAGE=<bcdr_image>
      export BCDR_UTILS_IMAGE=cp4waiops-bcdr-
      utils@sha256:1db594ad10da9c7049367b5dd4373e86af7e6bcb875758022e2e743c83cf486f
      export IA_NAMESPACE=<ia_namespace>
      ```

      Where

      - `<image_path>` is the directory where you want the image to be stored.
      - `<bcdr_image>` is the name of the backup and restore image, as given in the backup helm chart `values.yaml` file, in the form `cp4waiops-bcdr@{digest}`. An example value for BCDR_IMAGE is `cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355`.
      - `<ia_namespace>` is the namespace that Infrastructure Automation is deployed in.

4. Authenticate with the target registry.

   Authenticate with the target registry in the air-gapped environment that you are mirroring the image into. You need to authenticate with the target registry to enable the `oc image mirror` command to push the image to your target registry. Log in to your target registry to generate an authentication file containing the registry credentials, and then create an environment variable that has the location of the authentication file.

   ```
   podman login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD}
   export REGISTRY_AUTH_FILE=${XDG_RUNTIME_DIR}/containers/auth.json
   ```

Note: The authentication file is usually at `${XDG_RUNTIME_DIR}/containers/auth.json`. For more information, see the Options section in the Podman documentation.

5. Mirror the images to the target registry from the file system.

   Run the following commands on the device that has your file system (the portable compute device or the local compute device) to copy the image from the file system to the $TARGET_REGISTRY. Your device with the file system must be connected to both the target registry and the Red Hat® OpenShift® Container Platform cluster that you want to backup or restore Infrastructure Automation on.

   ```
   oc image mirror \
   file://cpopen/cp4waiops/${BCDR_IMAGE} ${TARGET_REGISTRY}/cpopen/cp4waiops/${BCDR_IMAGE} \
   --from-dir "${IMAGE_PATH}" \
   -a ${REGISTRY_AUTH_FILE} \
   --filter-by-os '.*' \
   --insecure  \
   --skip-multiple-scopes \
   --max-per-registry=1

   oc image mirror \
   file://cpopen/cp4waiops/${BCDR_UTILS_IMAGE} ${TARGET_REGISTRY}/cpopen/cp4waiops/${BCDR_UTILS_IMAGE} \
   --from-dir "${IMAGE_PATH}" \
   -a ${REGISTRY_AUTH_FILE} \
   --filter-by-os '.*' \
   --insecure  \
   --skip-multiple-scopes \
   --max-per-registry=1
   ```

6. Create the `ImageContentSoucePolicy`.

   1. Switch to the namespace that Infrastructure Automation is deployed in.

      ```
      oc project ${IA_NAMESPACE}
      ```

   2. Run the following command to create the `ImageContentSourcePolicy`.

      ```
      cat << EOF | oc apply -f -
      apiVersion: operator.openshift.io/v1alpha1
      kind: ImageContentSourcePolicy
      metadata:
       name: bcdr-mirrors
      spec:
       repositoryDigestMirrors:
        - mirrors:
          - ${TARGET_REGISTRY}/cpopen/cp4waiops/
          source: icr.io/cpopen/cp4waiops/
      EOF
      ```

Troubleshooting

- Red Hat OpenShift APIs for Data Protection (OADP) installation failed
- Backups are not showing after installation

Red Hat OpenShift APIs for Data Protection (OADP) installation failed

If your installation of OADP fails for any reason, delete any related files and reattempt the installation.

For example, the installation script `install-oadp.sh` might not complete successfully. If this occurs an error similar to the following message can display:

```
error: unable to recognize "STDIN": no matches for kind "DataProtectionApplication" in version
"oadp.openshift.io/v1alpha1"
```

This can occur if the network or cluster is running slow and taking too long to pull the required images. This delay causes the OADP operator to take too long to create the required custom resource.

If the preceding issue occurs, or the installation fails for another reason, run the following `oc` commands to delete any existing OADP installation files before attempting to install again.

1. Delete any cluster service versions (CSV) in the project:

   ```
   oc delete csv --all -n ${OADP_NAMESPACE}
   ```

2. Delete any subscriptions in the project:

   ```
   oc delete subscription --all -n ${OADP_NAMESPACE}
   ```

3. Delete any deployments in the project:

   ```
   oc delete deploy --all -n ${OADP_NAMESPACE}
   ```

4. Delete any daemonsets in the project:

   ```
   oc delete ds --all -n ${OADP_NAMESPACE}
   ```

5. Delete the project (namespace):

   ```
   oc delete project ${OADP_NAMESPACE}
   ```

Any existing installation is deleted and you can reattempt the installation.

Backups are not showing after installation

If your backups do not show, complete the following steps:

1. Correct the **bucket** and **prefix** property within the **backupstoragelocation** resource that is named **bcdr-s3-location**. The **bucket** and **prefix** name should match the value that is defined within the **install-oadp-config.json** file during the OADP installation.

   Run the **oc edit** command to edit the **backupstoragelocation** resource:

   ```
   oc edit backupstoragelocation bcdr-s3-location -n ${OADP_NAMESPACE}
   ```

2. Delete the Velero pod by running the following command:

   ```
   oc delete pod <pod> -n ${OADP_NAMESPACE}
   ```

   The backups should now be available.

3. Run the following command to list the backups:

   ```
   velero get backup
   ```

Backing up Infrastructure Automation data

Learn how to back up data for Infrastructure Automation components.

The backup process uses OADP for cluster object backups and volume backups. The backup script must be the same version as your deployment.

Note: If you also need to back up data for IBM Cloud Pak for AIOps components, the process and tools to use are the same. The only change that is required is when you are packaging the Helm chart. During this step you need to configure the value of the **enabledComponents** parameter to include **'"AIOPS"'** as well as **'"IA"'**. All other steps remain the same.

Prerequisites

- Ensure that you are logged in to your Red Hat OpenShift cluster with **oc login** for any steps that use the Red Hat OpenShift command-line interface (CLI).
- If they are not already installed, install the backup and restore tools. You need to install the Red Hat® OpenShift® Container Platform APIs for Data Protection (OADP) in the Red Hat OpenShift Container Platform cluster. For more information, see Installing the backup and restore tools.
- Provision S3 compliant object storage for your backups. You must have sufficient storage to backup the data that is contained in the datastores and persistent volume claims (PVCs) of the components that are backed up, as detailed in Backup process. The storage must also be accessible by any environment that a backup might need to be restored to. The backup process moves backup files to an S3 bucket, which must be in an S3 compatible location. For instance, you can use the following public or private cloud options for provisioning storage for your backups:
  - MinIO
  - Red Hat OpenShift Data Foundation object store
  - IBM Cloud Object Storage
  - AWS Cloud

  Important: Ensure that the OADP is configured to point to the same object storage (S3 bucket) that includes the backup that you plan to use.

Note: As your data grows, the capacity of your backup storage might need to grow, and you must ensure that sufficient storage for backups is provisioned to accommodate any growth in backup data.

Backup procedure

Follow these steps to backup Infrastructure Automation.

1. Prepare to backup Infrastructure Automation
2. Backup Infrastructure Automation
3. Setup on-demand backups of Infrastructure Automation

1. Prepare to backup Infrastructure Automation

1. Clone the IBM Cloud Pak for AIOps samples GitHub repository to retrieve the latest Infrastructure Automation backup and restore scripts by running the following command:

   ```
   git clone https://github.com/IBM/cp4waiops-samples.git
   ```

   If you have an offline (air-gapped) deployment of Infrastructure Automation, then copy the cloned scripts to your air-gapped environment.

2. Export the environment variables that you will need for the backup procedure.

   If you are backing up an online deployment, set the following:

   ```
   export OADP_NAMESPACE=<oadpNamespace>
   export PATH=<path>
   export IA_NAMESPACE=<ia_namespace>
   ```

   If you are backing up an offline deployment, set the following:

```
export TARGET_REGISTRY_HOST=<target_registry_host>
export TARGET_REGISTRY_PORT=<port>
export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
export TARGET_REGISTRY_USER=<username>
export TARGET_REGISTRY_PASSWORD=<password>
export EMAIL=<email>
export PATH=<path>
export OADP_NAMESPACE=<oadpNamespace>
export IA_NAMESPACE=<ia_namespace>
```

Where:

- **<target_registry_host>** is the IP address or FQDN of the target registry that holds the backup and restore images, from Offline deployments only: Mirror the backup and restore images
- **<port>** is the port_number of the target registry
- **<username>** is the username for the target registry
- **<password>** is the password for the target registry
- **<email>** is the email for the target registry
- **<path>** is the path to where you downloaded and extracted the IBM Cloud Pak for AIOps backup and restore files.
- **<oadpNamespace>** is the OADP namespace
- **<ia_namespace>** is the namespace where IBM Cloud Pak for AIOps is installed.

3. Package the Helm Chart

   1. Change to the directory where you have the backup and recovery files downloaded.

      ```
      cd ${PATH}/bcdr/4.6.0/backup
      ```

   2. Update the following parameters in the **values.yaml** file. The file is located in the **./helm** directory.

      - **repository** - Do not edit this parameter.
      - **pullPolicy** - The policy for determining when to pull the image from the image registry server. For example, to force pull the image, use the **Always** policy.
      - **schedule** - The Cron expression for the automated backup. For example, to take a backup once a day, use the **0 0 * * *** Cron expression.
      - **backupStorageLocation** - The storage location where backed up data is stored. For example, **bcdr-s3-location**.

        Use the **oc get backupstoragelocation -n ${OADP_NAMESPACE}** command to get the **backupStorageLocation** on the OpenShift cluster.
      - **backupNameSuffix** - The prefix for the backup name when the backup is created by using the job. Generally, it can be name of source cluster itself. For example, **aiops-cluster-backup-106**.
      - **aiopsNamespace** - The namespace where Infrastructure Automation is installed.
      - **csNamespace** - The namespace where IBM Cloud Pak foundational services is installed. From Infrastructure Automation v4.4.0 this is the same as the namespace where Infrastructure Automation is installed.
      - **oadpNamespace** - The namespace where OADP is installed.
      - **ttl** - The time-to-live setting for the backup. The backed up data is retained until the **ttl** value is reached (expires). For example **720h0m0s**.
      - **enabledNamespaces** The namespaces of the components that need to be backed up. You can delete any unused namespaces from the list to reduce the time that is required for the backup process. If you have installed only Infrastructure Automation, then you require the namespaces that Infrastructure Automation and IBM Cloud Pak foundational services are installed in. From Infrastructure Automation v4.4.0, the IBM Cloud Pak foundational services namespace is the same as the Infrastructure Automation namespace, but this namespace must be listed twice, as in the following example.

        ```
        enabledNamespaces:
        - '"cp4aiops"'
        - '"cp4aiops"'
        ```

      - **enabledComponents** - Required. The list of components to back up.

        The backup and restore processes support backing up and restoring both the IBM Cloud Pak for AIOps and Infrastructure Automation components. These components can be installed together or independtly. You can specify to back up both, or only one of these components. Any other value is ignored and a corresponding error message is generated.

        To specify Infrastructure Automation, set the value **'"IA"'**.

        To specify IBM Cloud Pak for AIOps, set the value **'"AIOPS"'**.

        The following configuration shows both components listed:

        ```
        enabledComponents:
        - '"IA"'
        - '"AIOPS"'
        ```

   3. Package the Helm Chart.

      ```
      helm package ./helm
      ```

2. Setup an automated backup of Infrastructure Automation

Run the following steps to trigger an automated backup.

1. Change to the **backup** directory where the script is located:

   ```
   cd ${PATH}/bcdr/4.6.0/backup
   ```

2. Deploy the backup job by running the following command:

   ```
   helm install backup-job clusterbackup-0.1.0.tgz
   ```

3. Optional - update the **schedule** parameter in the **values.yaml** file (located in the **./helm** directory). This uses a cron expression to schedule the automated backup. For example, to take a backup once a day, use the **0 0 * * *** Cron expression.

3. Setup on-demand backups of Infrastructure Automation

This step is optional. Use only when you do not want to wait untill the next scheduled backup job.

Prerequisite: The deployment of an automated backup job is a prerequisite for the on-demand job. Only after you initiate an automated backup job can you then trigger an on-demand backup.

1. Deploy the on-demand backup job by running the following command:

   ```
   oc create job --from=cronjob/backup-job on-demand-backup-job -n ${OADP_NAMESPACE}
   ```

2. Check the on-demand backup pods status by running the following command:

   ```
   oc get pods -n ${OADP_NAMESPACE}
   ```

3. Check the on-demand backup job logs by running the following command:

   ```
   oc logs -f <on-demand-backup-job-***> -n ${OADP_NAMESPACE}
   ```

4. Find and export the name of your backup.

   You can see the backup name after the on-demand backup job is complete. For example, you might see the backup name **aiops-cluster-backup-106-1622193915** in the on-demand backup job log as follows:

   ```
   Waiting for backup aiops-cluster-backup-106-1622193915 to complete
   ```

   Export the name of your backup by running the following command:

   ```
   export BACKUP_NAME=<backup_name>
   ```

   Where **<backup_name>** is the name of the backup.

5. Check the backup status by running the following command:

   ```
   velero get backup ${BACKUP_NAME} -n ${OADP_NAMESPACE}
   ```

   When the backup is finished, the status is **Completed**, such as in the following sample output:

   ```
   aiops-backup-1654171690-testfest34   Completed   2022-06-02 05:08:11 -0700 PDT   29d   bcdr-data-protection-app-1
   cp4aiops.ibm.com/backup=t
   ```

   To see more details, you can also:

   - Check the backup pods' status by running the following command:

     ```
     oc get pods -n ${OADP_NAMESPACE}
     ```

   - Check the backup job logs by running the following command:

     ```
     oc logs -f <backup-job-***>
     ```

6. Review the backup result summary that is included within the logs of the backup job.

   Note: A **backup-result-config** ConfigMap is created to include this result. To view this ConfigMap, run the following command:

   ```
   oc get cm backup-result-config -n ${IA_NAMESPACE} -o yaml
   ```

Troubleshooting

- Backup process is stuck in an *In progress* state
- Classifier and layout pods remain not ready after running a backup
- Helm install backup job command failed

Backup process is stuck in an *In progress* state

If your backups process is stuck in an *In progress* state for an unexpected duration, complete the following steps. This procedure stops the backup process so that you can try the backup again.

1. Delete the Velero pod by running the following command:

   ```
   oc delete pod <pod> -n <oadpNamespace>
   ```

   Where **<oadpNamespace>** is the namespace where OADP is installed, and **<pod>** is the name of the Velero pod.

2. Run the backup that is stuck in the *In progress* state:

   ```
   velero delete backup <backup>
   ```

   Where **<backup>** is the backup that you want to delete. The backup process should begin again.

3. Wait for the backup to complete and verify that the backup is created.

Classifier and layout pods remain not ready after running a backup

After you complete a backup, you might notice that the classifier (**aiops-ir-analytics-classifier**) and layout (**aiops-topology-layout**) pods do not change to a ready state, which can cause **AIOpsAnalyticsOrchestrator** to be stuck in an updating phase. This issue can occur after most backups. To resolve this issue, you need to either restart the pods or increase the resource limits for the pods.

- For the classifier (**aiops-ir-analytics-classifier**) pod, restart the pod.
- For the layout (**aiops-topology-layout**) pod, restart the pod. If the restart does not result in the pod becoming ready, increase the resource limits for the pod. Doubling the **cpu** and **memory** limits and request allocations for the pods can result in the pod starting and entering a ready state.

Helm install backup job command failed

When you are running the **helm install backup-job clusterbackup-0.1.0.tgz** command, you might encounter the command failing with an error that is similar to the following error:

```
Error: admission webhook "trust.hooks.securityenforcement.admission.cloud.ibm.com" denied the request:
Deny "icr.io/cpopen/cp4waiops/cp4aiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355", no
matching repositories in ClusterImagePolicy and no ImagePolicies in the "velero" namespace
```

If you encounter this error, complete the following steps to resolve the issue:

1. Uninstall the **backup-job** job by running the following command:

   ```
   helm uninstall backup-job -n ${OADP_NAMESPACE}
   ```

2. Export an environment variable for the image.

   For an online deployment:

   ```
   export REGISTRY=icr.io/cpopen/cp4waiops/cp4aiops-bcdr
   export BCDR_IMAGE=${REGISTRY}/<bcdr_image>
   ```

   For an offline deployment:

   ```
   export REGISTRY=$TARGET_REGISTRY
   export BCDR_IMAGE=${REGISTRY}/<bcdr_image>
   ```

   Where **<bcdr_image>** is the name of the backup and restore image, as given in the backup helm chart **values.yaml** file, in the form **cp4waiops-bcdr@{digest}**. An example value for BCDR_IMAGE is **icr.io/cpopen/cp4waiops/cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355**.

3. Create a **backup-image-policy.yaml** file and add the following content within the file:

   ```
   apiVersion: securityenforcement.admission.cloud.ibm.com/v1beta1
   kind: ClusterImagePolicy
   metadata:
     name: backup-image-policy
   spec:
    repositories:
     - name: ${BCDR_IMAGE}
       policy:
   ```

4. Apply the policy by running the following command:

   ```
   oc apply -f backup-image-policy.yaml
   ```

5. Deploy the backup job by running the following command:

   ```
   helm install backup-job clusterbackup-0.1.0.tgz
   ```

Restoring Infrastructure Automation data

Learn how to restore data for Infrastructure Automation components to a cluster, such as for disaster recovery.

The following procedure restores all backed up data that exists in the specified backup for Infrastructure Automation components. The steps in the following procedure restore Infrastructure Automation in a new cluster.

Before you begin

- All required storage classes must be created before you run the restore process. The storage classes must have the same name as the backup cluster.
- Custom configuration settings for the Infrastructure Automation - Managed services component, such as Ansible replica count, extra variables, might not be backed up and restored. If you need this data and resources to be included in restored clusters, you need to directly add the data or resources to the restored cluster.
- You can restore a backup only within an environment that has the same version of Infrastructure Automation as the environment where the backup was created. For example, a backup of an Infrastructure Automation 4.6.0 environment must be restored within a cluster that has Infrastructure Automation 4.6.0 installed. If you need to upgrade as well as restore data, complete the restore process before you upgrade.
- If you are also restoring IBM Cloud Pak for AIOps data, the overall procedure is mostly the same, with the following additional steps required:
  - After you install IBM Cloud Pak for AIOps on the cluster where you are restoring data, you need to install Infrastructure Automation.
  - After you restore your IBM Cloud Pak for AIOps data, you need to restore your Infrastructure Automation data.

    For more information, see Restoring IBM Cloud Pak for AIOps.

Restore procedure

Follow the steps to restore Infrastructure Automation from backup.

1. Set up your new cluster for backup and restore.
2. Prepare the backup data for restoring.
3. Restore the cluster namespaces and install Infrastructure Automation
4. Optional. Restore IBM Cloud Pak for AIOps data
5. Restore the Infrastructure Automation data

If you encounter any issues with the restore process, see Troubleshooting

1. Set up your new cluster for backup and restore

1. Install Red Hat OpenShift by using the instructions in the Red Hat OpenShift documentation.

   IBM Cloud Pak for AIOps requires OpenShift to be installed and running. You must have administrative access to your OpenShift cluster.

   Important: Ensure that the version of Red Hat OpenShift Container Platform that you install is the same as the version that was installed in the backed-up cluster.

   For information about the supported versions of OpenShift, see Supported Red Hat OpenShift Container Platform versions.

   Note: Infrastructure Automation uses the OpenShift image registry when it builds images in real time. If the OpenShift image registry is not persistent and the registry respawns, then workloads can temporarily fail until respawning is complete. A persistent OpenShift image registry is recommended to avoid this issue. For more information, see Setting up and configuring the registry in the Red Hat OpenShift Container Platform documentation.

2. Install the OpenShift command-line interface (`oc`) on your cluster's boot node and run `oc login`, using the instructions in Getting started with the Red Hat OpenShift CLI.

3. Configure storage

   The storage configuration must satisfy your sizing requirements. For more information about the storage classes that are needed for installing IBM Cloud Pak for AIOps, see Storage.

   Important: All required storage classes must be created before running the restore process. The storage classes must have the same name as the backup cluster.

4. Install the backup and restore tools

   Install the Red Hat OpenShift APIs for Data Protection (OADP) in the Red Hat OpenShift Container Platform cluster. For more information, see Installing the backup and restore tools.

   Important: Ensure that the OADP is configured to point to the same object storage (S3 bucket) that includes the backup that you plan to use.

5. Export the environment variables that you will need for the restore procedure.

   If you are restoring to an online deployment, set the following:

   ```
   export PATH=<path>
   export OADP_NAMESPACE=<oadpNamespace>
   ```

   If you are restoring to an offline deployment, set the following:

   ```
   export TARGET_REGISTRY_HOST=<target_registry_host>
   export TARGET_REGISTRY_PORT=<port>
   export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
   export TARGET_REGISTRY_USER=<username>
   export TARGET_REGISTRY_PASSWORD=<password>
   export EMAIL=<email>
   export PATH=<path>
   export OADP_NAMESPACE=<oadpNamespace>
   ```

   Where:

   - `<target_registry_host>` is the IP address or FQDN of the target registry that holds the backup and restore images, from Offline deployments only: Mirror the backup and restore images
   - `<port>` is the port_number of the target registry
   - `<username>` is the username for the target registry

- **<password>** is the password for the target registry
- **<email>** is the email for the target registry
- **<path>** is the path to where you downloaded and extracted the IBM Cloud Pak for AIOps backup and restore files.
- **<oadpNamespace>** is the OADP namespace

2. Prepare the backup data for restoring

Verify your backed up data and prepare the data for restoring.

1. Check the backup status

   Check the backup status to ensure that the backup that you want to restore in your cluster is complete. Run the following command to check the contents of the backup:

   ```
   velero describe backup <backup-name> --details
   ```

   The output should list the backed-up data for Infrastructure Automation and for IBM Cloud Pak foundational services. If you also backed up IBM Cloud Pak for AIOps data, this data (**cp4aiops/***) should also be listed.

2. Package and install the Helm Chart

   1. Change to the **restore** directory where you need to package the Helm Chart:

      ```
      cd ${PATH}/bcdr/4.6.0/restore
      ```

   2. Update the following parameters in the **values.yaml** file. The file is located in the **./helm** directory:

      - **backupName** - The name of the backup that you are restoring.
      - **aiopsNamespace** - The namespace where IBM Cloud Pak for AIOps is installed.
      - **csNamespace** - The namespace where IBM Cloud Pak foundational services is installed. In IBM Cloud Pak for AIOps v4.6.0 this is the same as the namespace where IBM Cloud Pak for AIOps is installed.
      - **oadpNamespace** - The namespace where OADP is installed.

   3. Package the Helm Chart.

      ```
      helm package ./helm
      ```

   4. Install the Helm Chart for restoring data by running the following job:

      ```
      helm install restore-job clusterrestore-0.1.0.tgz
      ```

3. Restore the cluster namespaces and install Infrastructure Automation

Since the restore job does not install Infrastructure Automation, you need to first install Infrastructure Automation before you can run the restore jobs for restoring database and component data. A restore job for restoring the cluster namespaces is available and must be run before you install Infrastructure Automation.

1. Restore the cluster namespaces

   You need to restore the projects (namespaces) of the backed-up cluster so that your new cluster includes the metadata with the SELinux settings that need to match the settings for the backup data that you plan to restore.

   These steps only restore the namespaces and namespace metadata. The commands do not restore the contents of the namespaces.

   Note: In Infrastructure Automation v4.6.0, the IBM Cloud Pak foundational services namespace is the same as the Infrastructure Automation namespace.

   1. Change to the **restore** directory where the restore script is located:

      ```
      cd ${PATH}/bcdr/4.6.0/restore
      ```

   2. Optional. Delete any existing namespace restore jobs:

      ```
      oc delete -f ns-restore-job.yaml
      ```

   3. Create a job to restore the cluster namespaces:

      ```
      oc create -f ns-restore-job.yaml
      ```

   4. Check the restore job logs by running the following command:

      ```
      oc logs -f <ns-restore-job-***>
      ```

   5. Check the velero-restore status for the namespace by running the following command:

      ```
      velero get restore <RESTORE_NAME>
      ```

      Where **<RESTORE_NAME>** is the name of the restore for namespace.

      You can view the restore name after the restore job is completed. For example, you might see the restore name **aiops-namespace-restore-20221006054710** within the restore job log as follows:

      ```
      Restore request "aiops-namespace-restore-20221006054710" submitted successfully.
      ```

      Ensure that the projects (namespaces) are restored before you proceed.

2. Optional. Install IBM Cloud Pak for AIOps

If you also need to restore IBM Cloud Pak for AIOps data, you need to install IBM Cloud Pak for AIOps before you install Infrastructure Automation. For more information, see Installing IBM Cloud Pak for AIOps.

- For more information about restoring IBM Cloud Pak for AIOps, see Restoring IBM Cloud Pak for AIOps.

Important: Ensure that the version of IBM Cloud Pak for AIOps that you are installing is the same as the version that was installed in the backed-up cluster.

3. Install Infrastructure Automation.

   For more information, see Installing Infrastructure Automation.

   Note: When you install Infrastructure Automation, the Infrastructure Automation operator and the IAConfig CR are created.

   - If you install the Managed services component, the Managed Services operator is also installed and the corresponding custom resource (CR) is automatically created.
   - If you install the Infrastructure management component, only the Infrastructure management operator is installed. The corresponding CR is not created. You do not need to create this CR as it is created during the restore process in the following steps.

   Important:

   - Ensure that the version of IBM Cloud Pak for AIOps that you are installing is the same as the version that was installed in the backed up cluster.
   - The backup includes keys and certificates from the backed-up cluster. Ensure that your new cluster is configured to support the use of these keys and certificates so that the restored data can be accessed.
   - Wait until the installation is complete and all pods in the IBM Cloud Pak for AIOps project (namespace) are running before you proceed with the following restore steps.

4. Optional. Restore the IBM Cloud Pak for AIOps data

If you are also restoring IBM Cloud Pak for AIOps data, run the commands to restore the IBM Cloud Pak for AIOps data before you restore your Infrastructure Automation data. For more information, see Restoring IBM Cloud Pak for AIOps.

5. Restore the Infrastructure Automation data

This procedure restores the data for all backed up Infrastructure Automation databases and components. Optionally, you can choose to restore only individual components. For details, see Restoring individual components.

1. Change to the **restore** directory where the restore script is located:

   ```
   cd ${PATH}/bcdr/4.6.0/restore
   ```

2. Optional. Delete any existing Infrastructure Automation restore jobs:

   ```
   oc delete -f ia-restore-job.yaml
   ```

3. Create a job to restore Infrastructure Automation:

   ```
   oc create -f ia-restore-job.yaml
   ```

4. Check the restore job logs by running the following command:

   ```
   oc logs -f <ia-restore-job-***>
   ```

5. Check the velero-restore status by running the following command:

   ```
   velero get restore <RESTORE_NAME>
   ```

   Where **<RESTORE_NAME>** is the name of the restore for Infrastructure Automation.

   You can view the restore name after the restore job is completed. For example, you might see the restore name **cam-restore-20221006054710** for the Managed services restore in the restore job log as follows:

   ```
   Restore request "cam-restore-20221006054710" submitted successfully.
   ```

   Similarly, the velero restore name for other components can display in the restore job log.

6. When the restore is completed, and all **infrastructure-management** pods are in a running started, restart the **zen-watcher** pod. Run the following command to restart the pod:

   ```
   oc delete pod -l app.kubernetes.io/component=zen-watcher -n <aiopsNamespace>
   ```

   Where **aiopsNamespace** is the namespace where IBM Cloud Pak for AIOps is installed.

Restoring individual components

If needed, you can choose to restore data for specific individual databases and components instead of for all databases and components at the same time.

1. Change to the **restore** directory where the restore script is located:

   ```
   cd ${PATH}/bcdr/4.6.0/restore
   ```

2. Copy the **ia-restore-job.yaml** file. Rename your new file **<component>-restore-job.yaml**, where **<component>** is the name of the component that you are restoring.

   For example, if you are restoring Managed services, rename the file to be **cam-restore-job.yaml**. If you are restoring Infrastructure management, rename the file to be **im-restore-job.yaml**.

3. Open the new **<component>-restore-job.yaml** file for editing. Update the **name** and **command** sections to match the values for the component that you are restoring:
   - Update the **name** of the restore job in the metadata section to be the individual component job, such as **cam-restore-job**.
   - Update the command section **command: ["/bin/bash", "restore.sh","-ia"]** to replace **-ia** with the respective argument for the component that you are restoring. For the list of component arguments, see the table that follows this procedure.
4. Create a job to restore the individual component.

   ```
   oc create -f <component>-restore-job.yaml
   ```

5. Check the restore job logs by running the following command:

   ```
   oc logs -f <cp4waiops-component-restore-job-***>
   ```

6. Check the velero-restore status by running the following command:

   ```
   velero get restore <RESTORE_NAME>
   ```

   Where **<RESTORE_NAME>** is one of the restore names for the component.

   You can view the names for the component in the restore job log when the restore job is completed. For example, the restore name for a Managed services restore can be **cam-restore-20221006054710**, which can display in an entry similar to the following example log entry:

   ```
   Restore request "cam-restore-20221006054710" submitted successfully.
   ```

Component or database arguments for restore job command configuration

Table. Component or database arguments for restore job commands

Component or Database	Argument
Cassandra	-cassandra
CouchDB	-couchdb
Elasticsearch	-es
Metastore	-metastore
Minio	-minio
Postgres	-postgres
IBM Cloud Pak foundational services	-cs
Managed services	-cam
Infrastructure management	-im

Troubleshooting

- LDAP user login is not working after a restore
- Restore process is stuck in an *In progress* state
- Helm install restore job command failed
- Restore process terminated mid-process with partial data available
- Managed services instance deployment fails due to a socket hang up
- Infrastructure management pods are not running after a restore
- Infrastructure management URL in the navigation panel points to the cluster where the backup was taken
- Troubleshooting the IBM Cloud Pak for AIOps restore

LDAP user login is not working after a restore

Follow the steps to solve the problem:

1. Log in to the console as the default admin user.
2. From the main navigation menu, click **Administer** > **Identify and access**.
3. Select the LDAP connection, and click **Edit connection**. Edit the LDAP connection with the correct information.
4. Click **Test connection**.
5. Click **Save** once the connection is success.
6. log in to the console with the LDAP user's credentials.

Restore process is stuck in an *In progress* state

If your backups remain stuck in an *In progress* state for an unexpected duration, complete the following steps. This procedure stops the backup process so that you can try the backup again.

1. Delete the Velero pod by running the following command:

   ```
   oc delete pod <pod> -n <oadpNamespace>
   ```

   Where **<oadpNamespace>** is the namespace where OADP is installed, and **<pod>** is the name of the Velero pod.

2. Delete the restore that is stuck in the *In progress* state:

   ```
   velero delete restore <restore>
   ```

   Where **<restore>** is the restore process that you want to delete. The process should begin again.

3. Wait for the process to complete and verify that the restored data is available.

Helm install restore job command failed

When you are running the **helm install restore-job clusterrestore-0.1.0.tgz** command, you might encounter the command failing with an error that is similar to the following error:

```
Error: admission webhook "trust.hooks.securityenforcement.admission.cloud.ibm.com" denied the request:
Deny "icr.io/cpopen/cp4waiops/cp4aiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355", no
matching repositories in ClusterImagePolicy and no ImagePolicies in the "velero" namespace
```

If you encounter this error, complete the following steps to resolve the issue:

1. Uninstall the **restore-job** job by running the following command:

   ```
   helm uninstall restore-job -n $OADP_NAMESPACE
   ```

2. Export an environment variable for the image.

   For an online deployment:

   ```
   export REGISTRY=icr.io/cpopen/cp4waiops/cp4aiops-bcdr
   export BCDR_IMAGE=${REGISTRY}/<bcdr_image>
   ```

   For an offline deployment:

   ```
   export REGISTRY=$TARGET_REGISTRY
   export BCDR_IMAGE=${REGISTRY}/<bcdr_image>
   ```

   Where **<bcdr_image>** is the name of the backup and restore image, as given in the backup helm chart **values.yaml** file, in the form **cp4waiops-bcdr@{digest}**. An example value for BCDR_IMAGE is **icr.io/cpopen/cp4waiops/cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355**.

3. Create a **restore-image-policy.yaml** file and add the following content within the file:

   ```
   apiVersion: securityenforcement.admission.cloud.ibm.com/v1beta1
   kind: ClusterImagePolicy
   metadata:
     name: restore-image-policy
   spec:
    repositories:
     - name: ${BCDR_IMAGE}
       policy:
   ```

4. Apply the policy by running the following command:

   ```
   oc apply -f restore-image-policy.yaml
   ```

5. Deploy the backup job by running the following command:

   ```
   helm install restore-job clusterbackup-0.1.0.tgz
   ```

Restore process terminated mid-process with partial data available

If the restore process does not complete as expected for a data store, such as if it is aborted or terminated during its run, data might not be restored correctly. This incomplete restored data neeeds to be removed before you run the restore process again. To remove the data, you need to run a post-restore cleanup script to clean up the data store.

To run a script, complete the following steps:

1. Define the following environment variable on your workstation:

   ```
   export WORKDIR="<Path>/bcdr/4.6.0/"
   ```

   Where **<Path>** is the path to where you downloaded and extracted the IBM Cloud Pak® for AIOps backup and restore files.

2. Change to the **restore** directory where the post-restore cleanup script is located:

   ```
   cd <Path>/bcdr/4.6.0/restore/<data_store>/
   ```

   Where

   - **<Path>** is the path to where you downloaded and extracted the IBM Cloud Pak® for AIOps backup and restore files.
   - **<data_store>** is the directory for the data store or custom resource that needs to be cleaned up. For example, **couchdb** is the directory for CouchDb.

3. Run the post-restore cleanup script:

   ```
   nohup ./<data-store>-post-restore.sh.sh > <data-store>-post-restore.log &
   ```

   Where **<data_store>** is the data store or custom resource that needs to be cleaned up.

4. Run the restore process for that data store or resource again.

For example, if the restore job for restoring the Cassandra data store aborted, you need to run the **cassandra-post-restore.sh** post-restore script that is stored in the **bcdr/restore/cassandra** directory to clean the data. Then, run the **cassandra-native-post-restore.sh** post-restore script.

The following table lists the cleanup script to run for each data store:

Table. Cleanup script for components

Component or Database	Cleanup script
`Cassandra`	Run first: `bcdr/4.6.0/restore/cassandra/cassandra-post-restore.sh` Then, run: `bcdr/4.6.0/restore/cassandra/cassandra-native-post-restore.sh`
`CouchDB`	`bcdr/4.6.0/restore/couchdb/couchdb-post-restore.sh`
`Elasticsearch`	`bcdr/4.6.0/restore/elasticsearch/es-post-restore.sh`
`Metastore`	`bcdr/4.6.0/restore/metastore/metastore-post-restore.sh`
`Minio`	`bcdr/4.6.0/restore/minio/minio-post-restore.sh`
`Postgres`	`bcdr/4.6.0/restore/postgres/postgres-post-restore.sh`
IBM Cloud Pak foundational services	`bcdr/4.6.0/restore/common-services/cs-post-restore.sh`
Managed services	`bcdr/4.6.0/restore/cam/cam-post-restore.sh`
Infrastructure Management	`bcdr/4.6.0/restore/infrastructure-management/im-cleanup-restore.sh`

Managed services instance deployment fails due to a socket hang up

After your restore a Managed services (`cam`) backup and Managed services is deployed, the Managed services instance can fail due to a socket hang up issue. If this issue ocurs, restart the `cam-iaas` pod:

```
oc delete pod <cam-iaas-xxxx> -n <aiopsNamespace>
```

Where `aiopsNamespace` is the namespace where IBM Cloud Pak for AIOps is installed.

Infrastructure management pods are not running after a restore

Following a restore, you can notice that the Infrastructure Management pods (prefixed with "1-") are showing as not running.

For example,

```
oc get pod |grep postgresql
postgresql-6cff46dcdc-g5cn8                                       0/1     Running     0                33m
```

This issue can occur when Postgres is not fully initialised. To resolve this issue, if the pod is not showing a ready state (`1/1`), restart the pod manually. This restart enables the Infrastructure Management pods to start.

Infrastructure management URL in the navigation panel points to the cluster where the backup was taken

Following a restore, the Infrastructure Management URL in the navigation panel points to the cluster where the backup was taken. To resolve this issue, restart the zen watcher pod on the restored cluster:

```
oc delete pod -l app.kubernetes.io/component=zen-watcher
```

Troubleshooting the IBM Cloud Pak for AIOps restore

If you are also restoring IBM Cloud Pak for AIOps data and encounter an issue with the restore process for IBM Cloud Pak for AIOps or encounter an issue with data not being available or processed after the restore, see Troubleshooting IBM Cloud Pak for AIOps restore.

Upgrading Infrastructure Automation backup and restore artifacts

Use this procedure if you want to run backup or restore on an upgraded Infrastructure Automation deployment.

If you run a backup or restore on an Infrastructure Automation deployment, the backup and restore scripts must always be the same version as your deployment. For example, if you run backup on an Infrastructure Automation v4.6.0 deployment, you must use a v4.6.0 backup script.

If you previously set up backup or restore on a deployment that you have now upgraded, then you must cleanup any existing backup or restore artifacts. If you then want to run a new backup or restore, you must get the new version of the backup or restore scripts.

Note: If you have never set up backup or restore and you want to run backup or restore, then use the instructions in Infrastructure Automation backup and restore.

Set up backup on an upgraded Infrastructure Automation deployment

Use the following steps to upgrade your backup artifacts.

1. Uninstall the backup helm chart.

   Run the following command in the namespace that `Red Hat OpenShift APIs for Data Protection` (OADP) is installed in.

   ```
   helm uninstall backup-job
   ```

2. Set up backup for Infrastructure Automation v4.6.0.

   If you need to run backup for Infrastructure Automation v4.6.0, follow the instructions in Backing up Infrastructure Automation data to set up backup.

   Important: The `cp4waiops-bcdr` image must be the same version as your Infrastructure Automation deployment. Follow these instructions to ensure that your `cp4waiops-bcdr` image is v4.6.0 for your Infrastructure Automation v4.6.0 deployment.

Set up restore on an upgraded Infrastructure Automation deployment

Use the following steps to upgrade your backup artifacts.

1. Uninstall the restore helm chart.

   Run the following command in the namespace that **Red Hat OpenShift APIs for Data Protection** (OADP) is installed in.

   ```
   helm uninstall restore-job
   ```

2. Set up restore for Infrastructure Automation v4.6.0.

   If you need to run restore for Infrastructure Automation v4.6.0, follow the instructions in Restoring Infrastructure Automation data.

   Important: The **cp4waiops-bcdr** image must be the same version as your Infrastructure Automation deployment. Follow these instructions to ensure that your **cp4waiops-bcdr** image is v4.6.0 for your Infrastructure Automation v4.6.0 deployment.

CLI tools

Optionally install the command line interface (CLI) tools **cloudctl** (deprecated) and **kubectl**.

- Installing the IBM Cloud Pak CLI (cloudctl) (deprecated)
- Installing the Kubernetes CLI (kubectl)

Install the IBM Cloud Pak® CLI (cloudctl)

You can use IBM Cloud Pak® CLI (cloudctl) to view information about your cluster, manage your cluster, and more.

After you install IBM Cloud Pak® CLI (cloudctl), you can install another supported CLI, such as the Kubernetes command line tool (kubectl).

To set up the IBM Cloud Pak® CLI, complete the following steps:

1. Get the service hostnames. Use the **management-ingress** service hostname in the command to download the installation file.

   ```
   oc get route -n <project>
   ```

   Where **<project>** is the project (namespace) that IBM Cloud Pak for AIOps is deployed in.

2. Download the installation file with the following command. Replace the **<cluster_address>** with your IBM Cloud Pak console route.

   ```
   curl -kLo cloudctl-linux-amd64-v3.2.3-1557 https://<cluster address>/api/cli/cloudctl-linux-amd64
   ```

   If you need to get the IBM Cloud Pak console route, run the following command:

   ```
   oc get route -n <project> cp-console -o jsonpath='{.spec.host}'
   ```

   Where **<project>** is the project (namespace) that IBM Cloud Pak for AIOps is deployed in.

3. Change the file to an executable file and move the file with the following command. Replace **<path_to_installer>** with the path to the directory where you downloaded the cloudctl file, and replace **<install_file>** with the downloaded file name.

   ```
   chmod 755 <path_to_installer>/<install_file>
   ```

   ```
   sudo mv <path_to_installer>/<install_file> /usr/local/bin/cloudctl
   ```

   In this example, it is moved to the **/usr/local/bin/cloudctl** directory.

4. Confirm that cloudctl is installed:

   ```
   cloudctl --help
   ```

   The cloudctl usage is displayed.

5. Log in to your cluster with the following command. Replace **<cluster_address>** with your IBM Cloud Pak console route.

   ```
   cloudctl login -a https://<cluster address> --skip-ssl-validation
   ```

   You can now use cloudctl to view information about your cluster and manage your clusters.

Installing the Kubernetes CLI (kubectl)

You can install and configure the Kubernetes command line tool (kubectl) to complete cluster administrator tasks. Some tasks require the use of both the kubectl tool and the IBM Cloud Pak® CLI (cloudctl).

Before you begin:

- Install the IBM Cloud Pak® CLI (cloudctl).
- Synchronize the clocks between your client computer and the nodes in your cluster. To synchronize your clocks, use network time protocol (NTP). For more information about setting up NTP, see the user documentation for your operating system.

To set up the kubectl CLI, complete the following steps. You can also download from Kubernetes. For more information, see Install and Set Up kubectl.

1. Get the service hostnames. Use the **management-ingress** service hostname in the command to download the installation file.

```
oc get route -n kube-system
```

2. Download the installation file with the following command. Replace the **<cluster_address>** with your IBM Cloud Pak console route.

   ```
   curl -kLo kubectl-linux-amd64-v1.13.11 https://<cluster address>/api/cli/kubectl-linux-amd64
   ```

   If you need to get the IBM Cloud Pak console route, run the following command:

   ```
   oc get route -n <project> cp-console -o jsonpath='{.spec.host}'
   ```

   Where **<project>** is the project (namespace) that IBM Cloud Pak for AIOps is deployed in.

3. Change the file to an executable file and move the file with the following command. Replace **<path_to_installer>** with the path to the directory where you downloaded the kubectl file, and replace **<install_file>** with the downloaded file name.

   ```
   chmod 755 <path_to_installer>/<install_file>
   ```

   ```
   sudo mv <path_to_installer>/<install_file> /usr/local/bin/kubectl
   ```

   In this example, it is moved to the **/usr/local/bin/kubectl** directory.

4. Confirm that kubectl is installed:

   ```
   kubectl version --client
   ```

   The kubectl information is displayed.

5. Obtain the cluster configuration details. You can obtain the cluster configuration details by using cloudctl. For more information about the cloudctl commands that you can run, see Managing your cluster with IBM Cloud Pak CLI (cloudctl).

Nonproduction features (Technology preview)

IBM Cloud Pak® for AIOps can include components and features for nonproduction use only as technology previews. As licensee of IBM Cloud Pak for AIOps, you can use these components and features only as part of your internal development and test environment for internal nonproduction use. Components and features that are available for nonproduction use are not to be relied on in a production environment.

Features available for nonproduction use:

- Installing on Linux Install a nonproduction IBM Cloud Pak for AIOps deployment directly on Linux®, without the need to install Red Hat® OpenShift® Container Platform.
- Visualizing analytics with IBM Cognos Analytics

  IBM Cloud Pak for AIOps supports an integration with IBM Cognos® Analytics. This integration provides you with additional tools to create custom dashboards and reports to visualize and analyze your IBM Cloud Pak for AIOps data. When you set up this integration, you can open IBM Cognos Analytics from the Cloud Pak for AIOps console and begin using IBM Cognos Analytics dashboards to build visualizations of your IBM Cloud Pak for AIOps data, such as alert and topology data.
- Incident (Story) prioritization from persistence analysis and golden signals extraction

  Incident prioritization uses the golden signal policy and the alert suppression policy to filter out incidents when the observed alerts contain a golden signal and are not suppressed. The policy suppresses alerts that do not need attention.
- Deploy to single ROSA cluster configured across multiple AWS Zones

  You can install IBM Cloud Pak for AIOps on Red Hat OpenShift Service on AWS (ROSA). When you are installing, you can follow any of the main installation options for installing IBM Cloud Pak® for AIOps, but for installing on Red Hat OpenShift Service on AWS, you do need to complete some additional and replacement steps. For more information, see Installing IBM Cloud Pak for AIOps on Red Hat OpenShift Service on AWS (ROSA).
- Multi-zone high availability and disaster recovery (HADR)

  Install IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HADR) for better resilience. IBM Cloud Pak for AIOps is starting to implement multi-zone availability, as provided by the Red Hat OpenShift Container Platform.

  Installing on a cluster that spans multiple availability zones improves resiliency by enabling the distribution of services across nodes in different zones in the cluster. If a zone becomes unavailable, then the remaining services in the other zones are still able to service requests, and disruption is lessened.
- New data collection functionality for Dynatrace integration

  This new Dynatrace integration allows for the collection of both metric and event data together, which is new as previously you could only collection metric data when setting up a Dynatrace integration. This new Dynatrace integration does not allow for historic data collection, and the following should be adhered to if you select to run Dynatrace in remote mode:

  1. Podman must be installed to execute the remote deployment script with a recommended minimum version of 4.4.1.
  2. Read and write access are required for the folder where the remote deployment script will be executed and the script also must have execution permissions in order to be run.
  3. No more than one remote deployment script should be executed per host.

Installing IBM Cloud Pak for AIOps on Linux

BETA The deployment of IBM Cloud Pak® for AIOps on Linux® is available only for technology preview, and is not for production usage.

You can install a nonproduction deployment of IBM Cloud Pak for AIOps directly on a Linux cluster, without the need to install Red Hat® OpenShift® Container Platform.

The deployment is a base deployment that does not have the log anomaly detection and ticket analysis capabilities enabled. You cannot change this to an extended deployment post-install. Extended deployments of IBM Cloud Pak for AIOps on Linux are not supported.

Read about planning an installation, and then select one of the installation options.

- Planning an installation - learn about the system requirements for installing IBM Cloud Pak for AIOps on a Linux cluster.
- Online installation - follow these instructions if your cluster is connected to the internet.
- Offline installation - follow these instructions if your cluster is not connected to the internet.

Planning an installation of IBM Cloud Pak for AIOps on Linux

BETA The deployment of IBM Cloud Pak® for AIOps on Linux® is available only for technology preview, and is not for production usage.

Learn about the system requirements for an installation of IBM Cloud Pak for AIOps on Linux.

- Licensing
- Hardware requirements
- Storage requirements
- Network requirements

Licensing

License usage tracking is required. The **`aiopsctl`** tool deploys the IBM Cloud Pak foundational services License Service on your Linux cluster. This background service collects and stores the license usage information for tracking license consumption and for audit purposes. For more information, see Licensing.

Hardware requirements

IBM Cloud Pak for AIOps can be installed on Red Hat® Enterprise Linux® 9 only. The hardware architecture for installing IBM Cloud Pak for AIOps must be x86_64 (amd64).

For production-sized deployments, multiple Linux nodes are required, and IBM Cloud Pak for AIOps is installed on this cluster of nodes. The control plane node coordinates the running of IBM Cloud Pak for AIOps across the other nodes, and is the entry point into the product. Worker nodes provide more compute resources to run IBM Cloud Pak for AIOps services. The cluster must be reserved for the sole use of IBM Cloud Pak for AIOps.

You must ensure that the clocks on your Linux cluster are synchronized. Each node in the cluster must have access to an NTP server to synchronize their clocks. Discrepancies between the clocks on the nodes can cause IBM Cloud Pak for AIOps to experience operational issues.

A production sized base deployment of IBM Cloud Pak for AIOps on a Linux cluster requires the following hardware:

Table 1. Minimum requirements for a production-sized deployment

Resource	
Node count	6
Total vCPU	130
Total memory (GB)	310

Processing abilities

Expand the following sections to find out about the processing abilities of a production-sized deployment of IBM Cloud Pak for AIOps.

▶ Supported resource number and throughput rates for starter and production deployments

▶ Event, alert, and incident rates

Storage requirements

You must have local storage configured for your cluster, and it must be distributed across the nodes in your cluster. IBM Cloud Pak for AIOps requires 3000 GB of persistent storage.

Important: The file system used by MinIO must be **`XFS`**, not **`ext4`**. The **`ext4`** file system has a limit on the number of inodes that can be created for each file system. If inode usage reaches 100%, the file system becomes read-only even if enough PVC space is available and MinIO is prevented from creating new files or directories. Refer to your storage provider's documentation for information about setting **`XFS`** as the file system.

Additional requirements for offline deployments

If you are installing in an air-gapped environment (offline), you must also ensure that you have adequate space to download the IBM Cloud Pak for AIOps images to the target registry in your offline environment. The IBM Cloud Pak for AIOps images total 118 GB.

IOPS requirements

The following table identifies the input/output operations per second (IOPS) per node that must be supported. Ensure that your hardware can support the expected IOPS per node. A minimum configuration of three nodes for the storage cluster is needed. Each node of the storage solution requires a minimum of one disk (SSD or high-performance storage array). The results for your storage can vary depending on your exact usage, data sets, hardware, storage solution, and more.

Table 3. IOPS requirements

Deployment size	Minimum	Recommended
Production deployment	10,000	20,000

Network requirements

The control plane node requires the following access:

Table 4. Control plane node access

Port number	Direction	Protocol	Description
80	Inbound	TCP	Application HTTP port
443	Inbound	TCP	Application HTTPS port
6443	Inbound from cluster worker nodes	Control plane server API (HTTPS)	
5001	Between cluster nodes	TCP	Distributed registry
8472	Between cluster nodes	UDP	Virtual network

Worker nodes require the following access:

Table 5. Worker node access

Port number	Direction	Protocol	Description
8472	Inbound from other cluster nodes	UDP	Virtual network
5001	Inbound from other cluster nodes	TCP	Distributed registry
6443	Outgoing to control plane node		IBM Cloud Pak for AIOps components

Firewall rules

Some Linux distributions require extra firewall rules to avoid potential conflicts or restrictions.

1. Check whether the firewall is enabled.

   ```
   systemctl status firewalld
   ```

   If the firewall is enabled, then the command output provides the status of the firewall, including any active rules. If the firewall is disabled, then the command outputs the message *No such file or directory.*

2. If the firewall is enabled, run the following commands:

   ```
   firewall-cmd --permanent --add-port=6443/tcp #apiserver
   firewall-cmd --permanent --zone=trusted --add-source=10.42.0.0/16 #pods
   firewall-cmd --permanent --zone=trusted --add-source=10.43.0.0/16 #services
   firewall-cmd --reload
   ```

3. If you are permitting the collection of usage data, then ensure that outbound traffic to https://api.segment.io is allowed. For more information, see Updating usage data collection preferences.

nm-cloud-setup service

The `nm-cloud-setup` service must not be enabled. Run the following steps on each of your nodes.

1. Check if `nm-cloud-setup.service` is enabled.

   ```
   systemctl is-enabled nm-cloud-setup.service
   ```

   If the service is enabled, the command returns `enabled`.

2. If the service is enabled, then disable it and reboot the node.

   ```
   systemctl disable nm-cloud-setup.service nm-cloud-setup.timer
   reboot
   ```

Online installation of IBM Cloud Pak for AIOps on Linux

BETA The deployment of IBM Cloud Pak® for AIOps on Linux® is available only for technology preview, and is not for production usage.

Learn about installing IBM Cloud Pak for AIOps on Linux.

Overview

You can install a large (production-sized) deployment of IBM Cloud Pak for AIOps on a Linux platform, without installing Red Hat® OpenShift® Container Platform. This deployment, although sized for production, cannot be used in production and is intended for trial and proof of concept use only.

The deployment is a base deployment that does not have the log anomaly detection and ticket analysis capabilities enabled. You cannot change to an extended deployment post-install. Extended deployments of IBM Cloud Pak for AIOps on Linux are not supported.

The deployment is configured to collect usage data. If you want to disable usage data collection, then you can do this post-install. For more information, see Updating usage data collection preferences.

Limitations

- Starter-size deployments and custom-sized deployments are not supported.
- You cannot upgrade from a deployment on Red Hat OpenShift to a deployment on Linux.
- The following features and capabilities are only available for deployments of IBM Cloud Pak for AIOps on Red Hat OpenShift, and are not available for deployments of IBM Cloud Pak for AIOps on Linux:
  - Extended deployment
  - FIPs support
  - Deployment in AllNamespace mode
  - Secure tunnel
  - Multi-zone HADR
  - Backup and restore
  - Cluster restart
  - IBM Cognos® Analytics integration

Before you begin

Ensure that you meet the following prerequisites:

- Your cluster meets the hardware and storage requirements that are detailed in Planning an installation of IBM Cloud Pak for AIOps on Linux. In particular, note the requirement that the Linux cluster is reserved for the sole use of IBM Cloud Pak for AIOps.
- You have the credentials for the root user. Root user must be used to install IBM Cloud Pak for AIOps.
- The client machine that you are running the installation from has network connectivity to the control plane node.
- The worker nodes have network connectivity to the control plane node.

Important: To uninstall a deployment of IBM Cloud Pak for AIOps on Linux, you must delete the nodes that you installed your deployment on.

Installation Procedure

The installation procedure requires you to download the **`aiopsctl`** tool, which installs IBM Cloud Pak for AIOps and its prerequisites on your cluster.

1. Retrieve your entitlement key
2. Create environment variables
3. Install the **`aiopsctl`** tool and register cluster nodes
4. Install IBM Cloud Pak for AIOps
5. Access the Cloud Pak for AIOps console

1. Retrieve your entitlement key

Obtain the IBM entitlement key that is assigned to your **`IBMid`**. The key is needed to pull the IBM Cloud Pak for AIOps images from the IBM® Entitled Registry.

1. Log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.
2. In the *Entitlement key* section, select **Copy** to copy the entitlement key to the clipboard.

2. Create environment variables

Create and then source a shell script that is named *aiops_var.sh*, which defines the environment variables that are used to provide installation parameters for your deployment. Use the following codeblock as a template, replacing the brackets **`< ... >`** with values for your environment.

```
#================================================================================================================================
=======
# IBM Cloud Pak for AIOps installation variables (Linux)
#================================================================================================================================
=======
export TARGET_USER="root"
export ACCEPT_LICENSE=<license_acceptance> # Set to --accept-license to agree to the license terms.

# --------------------------------------------------------------------------------------------------------------------------
--------
# IBM Entitled Registry
# --------------------------------------------------------------------------------------------------------------------------
--------
export IBM_ENTITLEMENT_KEY=<ibm-entitlement-key> # Set to the entitlement key retrieved in previous step.

# --------------------------------------------------------------------------------------------------------------------------
--------
# Hostnames
# `<control_plane_node>` - set to FQDN or IP address of your control plane node. For example, "control-plane.example.com"
```

```
# `<worker-n>` - the FQDN or IP address of each worker node, where n is the number of nodes. For example, "worker-
1.example.com"
# ------------------------------------------------------------------------------------------------------------------
--------
export CONTROL_PLANE_NODE="<control_plane_node>"
export WORKER_NODES=(
  "<worker-1>"
  "<worker-2>"
  "<worker-3>"
  "<worker-4>"
  "<worker-5>"
  "<worker-6>"
  "<worker-7>"
)
```

Run the following command to source your script and set the environment variables:

```
. ./aiops_var.sh
```

3. Install the `aiopsctl` tool and register cluster nodes

1. Run the following commands to install **aiopsctl** on your cluster, and then register the control plane node and worker nodes.

   ```
   AIOPSCTL_TAR="aiopsctl-linux_amd64.tar.gz"
   AIOPSCTL_INSTALL_URL="https://github.com/IBM/aiopsctl/releases/download/v4.6.0/${AIOPSCTL_TAR}"
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} curl -LO "${AIOPSCTL_INSTALL_URL}"
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} tar xf "${AIOPSCTL_TAR}"
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} mv aiopsctl /usr/local/bin/aiopsctl

   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node up ${ACCEPT_LICENSE} --role=control-plane --registry-
   token="${IBM_ENTITLEMENT_KEY}"

   K3S_TOKEN=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --token-only)
   K3S_HOST=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --server-url-only)

   for WORKER_NODE in "${WORKER_NODES[@]}"
   do
     ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} curl -LO "${AIOPSCTL_INSTALL_URL}"
     ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} tar xvf "${AIOPSCTL_TAR}"
     ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} mv aiopsctl /usr/local/bin/aiopsctl
     ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} aiopsctl cluster node up
   ${ACCEPT_LICENSE} --role=worker --server-url="${K3S_HOST}" --token="${K3S_TOKEN}" --registry-
   token="${IBM_ENTITLEMENT_KEY}"
   done
   ```

   Note: The preceding commands install the Red Hat OpenShift CLI (oc) if it is not already installed. If it is already installed, then you must ensure that it is at version 4.14 or higher.

2. Run the following command to see information about your cluster:

   ```
   aiopsctl cluster node info
   ```

   Example output:

   ```
   #  aiopsctl cluster node info
   Node Details
   Role: Control plane
   Server URL: https://test-server.acme.com:6443
   Token: ***** (Use --show-secrets to reveal token)
   ```

3. Check for network connectivity issues.

   VMWare vSphere virtual machines (VMs) with Red Hat® Enterprise Linux® can have connectivity issues. If you are not using vSphere VMs for your IBM Cloud Pak for AIOps deployment, then skip this step. Otherwise, run the following lookup command:

   ```
   nslookup kubernetes.default.svc.cluster.local 10.43.0.10
   ```

   If the lookup is successful, then proceed to the next step. If the lookup fails, then run the following command on each of your VMs to rectify connectivity problems:

   ```
   ethtool -K flannel.1 tx-checksum-ip-generic off
   ```

   For more information, see Installation on Linux fails with network connectivity errors when using `aiopsctl` to install on vSphere VMs.

4. Install IBM Cloud Pak for AIOps

Run the **aiopsctl** tool to install IBM Cloud Pak for AIOps.

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up
```

The installation takes one to two hours to complete. If the installation is unsuccessful, an error message is displayed and a nonzero exit code is returned.

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

5. Access the Cloud Pak for AIOps console

Run the following command on the control plane node to see the URL, username, and password for your IBM Cloud Pak for AIOps deployment.

```
aiopsctl server info --show-secrets
```

Example output:

```
aiopsctl server info --show-secrets

Cluster Access Details
URL:      aiops-cpd.test-server.acme.com
Username: cpadmin
Password: abcdefghijklmno
```

Note: If your cluster is running on a private network, configure your DNS to resolve the hosts for accessing the Cloud Pak for AIOps console. Add the following records to your DNS settings:

```
<your server node IP> aiops-cpd.<your fully-qualified server domain name>
<your server node IP> cp-console-aiops.<your fully-qualified server domain name>
```

What to do next

- Define integrations and applications with Defining.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.

Important: Any commands that use `oc` must be run from the control plane node.

Offline installation of IBM Cloud Pak for AIOps on Linux (bastion host)

BETA The deployment of IBM Cloud Pak® for AIOps on Linux® is available only for technology preview, and is not for production usage.

Learn about installing IBM Cloud Pak for AIOps on Linux in an offline environment with a bastion host.

Overview

If your Linux cluster does not have internet access, you can still install IBM Cloud Pak for AIOps by using an offline or air-gapped deployment. In this scenario, your air-gapped (offline) environment has a target registry, and a Linux cluster on which IBM Cloud Pak for AIOps is to be installed. The bastion host has access to the internet and to the air-gapped environment. IBM Cloud Pak for AIOps images are mirrored from the IBM Entitled Registry through the bastion server to the target registry in the offline environment. IBM Cloud Pak for AIOps can then be installed in the offline environment by using the target registry.

You can install a large (production-sized) deployment of IBM Cloud Pak for AIOps on a Linux platform, without installing Red Hat® OpenShift® Container Platform. This deployment, although sized for production, cannot be used in production and is intended for trial and proof of concept use only.

The deployment is a base deployment that does not have the log anomaly detection and ticket analysis capabilities enabled. You cannot change to an extended deployment post-install. Extended deployments of IBM Cloud Pak for AIOps on Linux are not supported.

The deployment is configured to collect usage data. If you want to disable usage data collection, then you can do this post-install. For more information, see Updating usage data collection preferences.

Limitations

- Starter-size deployments and custom-sized deployments are not supported.
- You cannot upgrade from a deployment on Red Hat OpenShift to a deployment on Linux.
- The following features and capabilities are only available for deployments of IBM Cloud Pak for AIOps on Red Hat OpenShift, and are not available for deployments of IBM Cloud Pak for AIOps on Linux:
  - Extended deployment
  - FIPs support
  - Deployment in AllNamespace mode
  - Secure tunnel
  - Multi-zone HADR
  - Backup and restore
  - Cluster restart
  - IBM Cognos® Analytics integration

Before you begin

Ensure that you meet the following prerequisites:

- Your cluster meets the hardware and storage requirements that are detailed in Planning an installation of IBM Cloud Pak for AIOps on Linux. In particular, note the requirement that the Linux cluster is reserved for the sole use of IBM Cloud Pak for AIOps.
- You have the credentials for the root user. The root user must be used to install IBM Cloud Pak for AIOps.
- The bastion host has network connectivity to the control plane node.
- The worker nodes have network connectivity to the control plane node.

Important: To uninstall a deployment of IBM Cloud Pak for AIOps on Linux, you must delete the nodes that you installed your deployment on.

Installation Procedure

The installation procedure requires you to download the `aiopsctl` tool, which installs IBM Cloud Pak for AIOps and its prerequisites on your cluster.

1. Setup the mirroring environment
2. Retrieve your entitlement key
3. Create environment variables
4. Mirror images
5. Install the `aiopsctl` tool and register cluster nodes
6. Install IBM Cloud Pak for AIOps
7. Access the Cloud Pak for AIOps console

1. Setup the mirroring environment

Prerequisites

Allow access to the following sites and ports:

Table 1. Sites and ports that must be accessible

Site	Description
• `icr.io` • `cp.icr.io` • `dd0.icr.io` • `dd2.icr.io` • `dd4.icr.io` • `dd6.icr.io`	Allow access to these hosts on port 443 to enable access to the `IBM Cloud Container Registry`, CASE OCI artifact, and IBM Cloud Pak® foundational services catalog source.
• `dd1-icr.ibm-zh.com` • `dd3-icr.ibm-zh.com` • `dd5-icr.ibm-zh.com` • `dd7-icr.ibm-zh.com`	If you are located in China, also allow access to these hosts on port 443.
`github.com`	GitHub houses CASE files, IBM Cloud Pak tools, and scripts.
`mirror.openshift.com`	for the `oc` CLI

1.1 Download documentation and scripts for offline access

Download the Cloud Pak for AIOps 4.6.0 PDF (this documentation) so that you can access it offline.

1.2 Set up a target registry

You must have a local Docker type production-grade registry available to store the IBM Cloud Pak for AIOps images in. The registry must meet the following requirements:

- supports Docker Manifest V2, schema 2 and OCI Manifests.
- supports multi-architecture images.
- is accessible from the cluster nodes.
- must serve images over HTTPS.
- allows path separators in the image name.
- you have the username and password for a user who can read from and write to the registry.
- must have 118 GB of storage to hold all the software that is to be transferred to the target registry.

If you do not already have a suitable production-grade registry available, then you must install and configure one.

1.3 Prepare a bastion host

The bastion host must meet the following requirements:

- is able to connect to the internet
- is able to connect to the air-gapped environment with access to the cluster and the target registry.
- Podman is installed for container management. For more information, see the Podman Installation Instructions.

2. Retrieve your entitlement key

Obtain the IBM entitlement key that is assigned to your **IBMid**. The key is needed to pull the IBM Cloud Pak for AIOps images from the IBM® Entitled Registry.

1. Log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.
2. In the *Entitlement key* section, select **Copy** to copy the entitlement key to the clipboard.

3. Create environment variables

Create and then source a shell script that is named *aiops_var.sh*, which defines the environment variables that are used to provide installation parameters for your deployment. Use the following codeblock as a template, replacing the brackets **< ... >** with values for your environment.

```
#================================================================================================================================
# IBM Cloud Pak for AIOps installation variables (Linux)
#================================================================================================================================
export TARGET_USER="root"
export ACCEPT_LICENSE=<license_acceptance> # Set to --accept-license to agree to the license terms.

# --------------------------------------------------------------------------------------------------------------------------------
# IBM Entitled Registry
# --------------------------------------------------------------------------------------------------------------------------------
export IBM_ENTITLEMENT_KEY=<ibm-entitlement-key> # Set to the entitlement key retrieved in previous step.

# --------------------------------------------------------------------------------------------------------------------------------
# Hostnames
# `<control_plane_node>` - set to FQDN or IP address of your control plane node. For example, "control-plane.example.com"
# `<worker-n>` - the FQDN or IP address of each worker node, where n is the number of nodes. For example, "worker-
1.example.com"
# --------------------------------------------------------------------------------------------------------------------------------
export CONTROL_PLANE_NODE="<control_plane_node>"
export WORKER_NODES=(
  "<worker-1>"
  "<worker-2>"
  "<worker-3>"
  "<worker-4>"
  "<worker-5>"
  "<worker-6>"
  "<worker-7>"
)

# --------------------------------------------------------------------------------------------------------------------------------
# Variables for offline installation
# --------------------------------------------------------------------------------------------------------------------------------
export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
export TARGET_REGISTRY_USER=<your-registry-username>
export TARGET_REGISTRY_PASSWORD=<your-registry-password>
export SKIP_TLS=false # Set to true if your target registry does not provide a signed TLS certificate
```

Run the following command to source your script and set the environment variables:

```
. ./aiops_var.sh
```

4. Mirror images

1. Connect your bastion host to the internet and disconnect it from the air-gapped environment.
2. Run the following commands to download the **aiopsctl** tool and its prerequisites.

   ```
   AIOPSCTL_TAR="aiopsctl-linux_amd64.tar.gz"
   AIOPSCTL_INSTALL_URL="https://github.com/IBM/aiopsctl/releases/download/v4.6.0/${AIOPSCTL_TAR}"
   curl -LO "${AIOPSCTL_INSTALL_URL}"
   tar xf "${AIOPSCTL_TAR}"
   mv aiopsctl /usr/local/bin/aiopsctl

   podman login cp.icr.io -u cp -p ${IBM_ENTITLEMENT_KEY}

   USE_TLS="true"
   if [ $SKIP_TLS = "true" ]; then
   USE_TLS="false"
   fi
   podman login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD} --tls-verify="${USE_TLS}"
   unset IBM_ENTITLEMENT_KEY

   aiopsctl cluster mirror-images --registry ${TARGET_REGISTRY}
   ```

   You can use the following command to monitor the mirroring process:

   ```
   tail -f /root/.aiopsctl/logs/aiopsctl.log
   ```

3. Disconnect the bastion host from the internet, and connect it to the air-gapped environment.

5. Install the `aiopsctl` tool and register cluster nodes

1. Run the following commands to install **aiopsctl** on your offline cluster, and then register the control plane node and worker nodes.

```
scp -r ~/.aiopsctl ${TARGET_USER}@${CONTROL_PLANE_NODE}:~/.aiopsctl
scp /usr/local/bin/aiopsctl ${TARGET_USER}@${CONTROL_PLANE_NODE}:/usr/local/bin/aiopsctl

if [ "$(command -v "oc")"  ]; then
  scp "$(command -v "oc")" ${TARGET_USER}@${CONTROL_PLANE_NODE}:/usr/local/bin/oc
else
  scp ~/.aiopsctl/mirror/oc ${TARGET_USER}@${CONTROL_PLANE_NODE}:/usr/local/bin/oc
fi

ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node up ${ACCEPT_LICENSE} --role=control-plane --
registry="${TARGET_REGISTRY}" --registry-user="${TARGET_REGISTRY_USER}" --registry-
token="${TARGET_REGISTRY_PASSWORD}" --offline --insecure-skip-tls-verify="${SKIP_TLS}"

# Configure kubeconfig for oc CLI
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} "mkdir -p ~/.kube && ln -s /etc/rancher/k3s/k3s.yaml ~/.kube/config"

K3S_TOKEN=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --token-only)
K3S_HOST=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --server-url-only)

for WORKER_NODE in "${WORKER_NODES[@]}"
do
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp -r ~/.aiopsctl ${TARGET_USER}@${WORKER_NODE}:~/.aiopsctl/
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp /usr/local/bin/aiopsctl
${TARGET_USER}@${WORKER_NODE}:/usr/local/bin/aiopsctl
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} aiopsctl cluster node up
${ACCEPT_LICENSE} --role=worker --server-url="${K3S_HOST}" --token="${K3S_TOKEN}" --registry="${TARGET_REGISTRY}" --
registry-user="${TARGET_REGISTRY_USER}" --registry-token="${TARGET_REGISTRY_PASSWORD}" --offline --insecure-skip-tls-
verify="${SKIP_TLS}"
done
```

Note: The preceding commands install the Red Hat OpenShift CLI (oc) if it is not already installed. If it is already installed, then you must ensure that it is at version 4.14 or higher.

2. Run the following command to see information about your cluster:

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info
```

Example output:

```
# ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info
Node Details
Role: Control plane
Server URL: https://test-server.acme.com:6443
Token: ***** (Use --show-secrets to reveal token)
```

3. Check for network connectivity issues.

VMWare vSphere virtual machines (VMs) with Red Hat® Enterprise Linux® can have connectivity issues. If you are not using vSphere VMs for your IBM Cloud Pak for AIOps deployment, then skip this step. Otherwise, run the following lookup command:

```
nslookup kubernetes.default.svc.cluster.local 10.43.0.10
```

If the lookup is successful, then proceed to the next step. If the lookup fails, then run the following command on each of your VMs to rectify connectivity problems:

```
ethtool -K flannel.1 tx-checksum-ip-generic off
```

For more information, see Installation on Linux fails with network connectivity errors when using **aiopsctl** to install on vSphere VMs.

6. Install IBM Cloud Pak for AIOps

Run the **aiopsctl** tool to install IBM Cloud Pak for AIOps.

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up
```

The installation takes one to two hours to complete. If the installation is unsuccessful, an error message is displayed and a nonzero exit code is returned.

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

7. Access the Cloud Pak for AIOps console

Run the following command on the control plane node to see the URL, username, and password for your IBM Cloud Pak for AIOps deployment.

```
aiopsctl server info --show-secrets
```

Example output:

```
aiopsctl server info --show-secrets

Cluster Access Details
URL:      aiops-cpd.test-server.acme.com
Username: cpadmin
Password: abcdefghijklmno
```

Note: If your cluster is running on a private network, configure your DNS to resolve the hosts for accessing the Cloud Pak for AIOps console. Add the following records to your DNS settings:

```
<your server node IP> aiops-cpd.<your fully-qualified server domain name>
<your server node IP> cp-console-aiops.<your fully-qualified server domain name>
```

What to do next

- Define integrations and applications with Defining.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.

Important: Any commands that use `oc` must be run from the control plane node.

APIs

IBM Cloud Pak® for AIOps offers a set of tools and APIs that you can use to predict, communicate, and resolve events before they become serious problems for your organization.

Learn how to use the tools and APIs that work with IBM Cloud Pak for AIOps in the following topics:

- Custom resource definitions
- Accessing APIs
- Integrated UI APIs
- User management (IAM) APIs
- licensing APIs
- Issue resolution API
- Probable Cause Customization API
- Change Risk API
- Metric API
- Automation (runbook) API
- Topology APIs
- Infrastructure Management API Guide
- Managed services APIs

Important: You can directly access the Swagger UI for only the Topology API and Metric API.

- For more information about accessing Metric service Swagger UI, see Accessing Metric service Swagger UI.
- For more information about accessing topology service Swagger UI, see Accessing Topology service Swagger UI.

Custom resource definitions

Use the following information to learn about the custom resource definitions (CRDs) used by IBM Cloud Pak for AIOps and Infrastructure Automation.

For more information about API conventions and definitions, see API Conventions in the Kubernetes documentation.

- IBM Cloud Pak for AIOps custom resource definitions
- Infrastructure Automation custom resource definitions

IBM Cloud Pak for AIOps custom resource definitions

Use this information to learn about the custom resource definitions (CRDs) used by IBM Cloud Pak for AIOps.

In the following table, CRDs that do not have a hyperlink must not be manually edited unless otherwise instructed, and are manipulated only by the operator.

Table 1. IBM Cloud Pak for AIOps CRDs

Kind	API version	Operator name	Description

Kind	API version	Operator name	Description
AIManagerMainProd	v1beta1	aimanager-operator	AIManagerMainProd is the Schema for the aimanagermainprods API. For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.
AIManager	v1beta1	aimanager-operator	AIManager Deploys the IBM AIOps AI Manager service components of IBM Cloud Pak for AIOps. For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.
Algorithm	v1alpha1	aimanager-operator	Algorithm is the Schema for the algorithms API
Algorithm	v1beta1	aimanager-operator	Algorithm is the Schema for the algorithms API
AIOpsEdge	v1beta1	aiopsedge-operator	AIOpsEdge is the Schema for the aiopsedges API
AIOpsKafkaTopic	v1beta1	aiopsedge-operator	AIOpsKafkaTopic is the Schema for the aiopskafkatopics API
AutomationAction	v1beta1	aiopsedge-operator	AutomationAction is the Schema for the automationactions API
BundleManifest	v1alpha1	aiopsedge-operator	BundleManifest is the Schema for the bundlemanifests API
BundleManifest	v1beta1	aiopsedge-operator	BundleManifest is the Schema for the bundlemanifests API
ConnectorComponent	v1beta1	aiopsedge-operator	ConnectorComponent is the Schema for the connectorcomponents API
ConnectorConfiguration	v1beta1	aiopsedge-operator	ConnectorConfiguration is the Schema for the connectorconfigurations API
ConnectorSchema	v1beta1	aiopsedge-operator	ConnectorSchema is the Schema for the connectorschemas API
GitApp	v1beta1	aiopsedge-operator	GitApp is the Schema for the GitApp API
MicroEdgeConfiguration	v1beta1	aiopsedge-operator	MicroEdgeConfiguration is the Schema for the microedgeconfigurations API
ASMFormation	v1beta1	asm-operator	Create a formation deployment. Documentation This product is not deployable standalone and it is part of the LICCR already accepted
ASM	v1beta1	asm-operator	(No Description)
AIOpsAnalyticsOrchestrator	v1beta1	ibm-aiops-ir-ai	AIOpsAnalyticsOrchestrator is the Schema for the aiopsanalyticsorchestrators API. This product is not deployable standalone and it is part of the LICCR already accepted
IssueResolutionCore	v1beta1	ibm-aiops-ir-core	IssueResolutionCore installs core components required for the issue resolution capabilities of IBM Cloud Pak for AIOps. This product is not deployable standalone and it is part of the LICCR already accepted.
LifecycleService	v1beta1	ibm-aiops-ir-lifecycle	LifecycleService is the Schema for the lifecycleservices API
LifecycleTrigger	v1beta1	ibm-aiops-ir-lifecycle	LifecycleTrigger is the Schema for the lifecycletriggers API
CustomSize	v1alpha1	ibm-aiops-orchestrator	CustomSize is the Schema for the customsizes API. This API is an alpha feature that has not been made generally available.
Installation	v1alpha1	ibm-aiops-orchestrator	Leverage advanced, explainable AI to resolve incidents faster, gain visibility into critical workloads, and intelligently manage key application resources. Learn More. By installing this product you accept the license terms.
Tunnel	v1	ibm-secure-tunnel-operator	Tunnel is the Schema for the tunnels API
AIModelUI	v1	ibm-watson-aiops-ui-operator	For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.
AIOpsUIExtension	v1	ibm-watson-aiops-ui-operator	AIOpsUIExtension is the Schema for the aiopsuiextensions API
AIOpsUI	v1	ibm-watson-aiops-ui-operator	For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.
AIOpsUI is the Schema for the aiopsuis API.			
BaseUI	v1	ibm-watson-aiops-ui-operator	For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.
ConnectorUI	v1	ibm-watson-aiops-ui-operator	For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.
InsightsUI	v1	ibm-watson-aiops-ui-operator	For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.

AIModelUI/v1

For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.

spec

Description: CommonSpecs - specs that are common to determining a deployment.

Type: object

Table 1. Description of AIModelUI/v1 spec

Property	Type	Description
spec	object	CommonSpecs - specs that are common to determining a deployment.
spec.configuration	object	Additional configuration for the UI deployment
spec.configuration.topologyModel	string	TopologyModel - Specify the terminology to use in CP4WAIOps when defining collections of topology resource groups. Valid values are "application" or "service". If this setting is not specified, the default value will be "application".
spec.container	object	ContainerSpec - possible configurations around containers
spec.container.containerPort	integer	(No Description)
spec.container.env	array	(No Description)
spec.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.image	object	ImageSpec - specification around how to pull an image.
spec.image.path	string	(No Description)
spec.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.image.pullSecret	string	(No Description)
spec.license	object	License - license spec determines whether a license has been accepted
spec.license.accept	boolean	License acceptance switch
spec.name	string	Name of the service being deployed
spec.replicas	integer	(No Description)
spec.size	string	(No Description)
spec.tlsSecretName	string	(No Description)
spec.version	string	Version of the csv deploying
spec.zenserviceName	string	name of the zenservice cr that is used for this deployment

status

Description: (No Description)

Type: object

Table 1. Description of AIModelUI/v1 status

Property	Type	Description
status	object	(No Description)
status.conditions	array	(No Description)
status.managedResources	array	(No Description)
status.phase	string	(No Description)
status.versions	object	(No Description)
status.versions.reconciled	string	(No Description)

AIOpsEdge/v1beta1

AIOpsEdge is the Schema for the aiopsedges API

spec

Description: AIOpsEdgeSpec defines the desired state of AIOpsEdge

Type: object

Table 1. Description of AIOpsEdge/v1beta1 spec

Property	Type	Description
spec	object	AIOpsEdgeSpec defines the desired state of AIOpsEdge
spec.certificates	object	Certificates contains information required to create and trust certificates for internal TLS communication.
spec.certificates.caConfigMapKey	string	Key in the ConfigMap identified by caConfigMapName that contains root certificates to be trusted for internal TLS.
spec.certificates.caConfigMapName	string	Name of the ConfigMap that contains root certificates to be trusted for internal TLS.
spec.certificates.issuer	string	Name of the cert-manager.io/Issuer that will be used to create TLS certificates.
spec.disableDefaultConnectors	boolean	DisableDefaultConnectors can be enabled to prevent the installation of default connectors
spec.kafka	object	The specification of the Kafka and ZooKeeper clusters, and Topic Operator.
spec.kafka.clientsCa	object	Configuration of the clients certificate authority.
spec.kafka.clientsCa.certificateExpirationPolicy	string	How should CA certificate expiration be handled when `generateCertificateAuthority=true`. The default is for a new CA certificate to be generated reusing the existing private key.
spec.kafka.clientsCa.generateCertificateAuthority	boolean	If true then Certificate Authority certificates will be generated automatically. Otherwise the user will need to provide a Secret with the CA certificate. Default is true.
spec.kafka.clientsCa.generateSecretOwnerReference	boolean	If true then the Certificate Authority certificates secrets owner reference is set to the Kafka object. Otherwise no owner reference is set so deleting the Kafka object won't delete the secrets. Default is true.
spec.kafka.clientsCa.renewalDays	integer	The number of days in the certificate renewal period. This is the number of days before the a certificate expires during which renewal actions may be performed. When `generateCertificateAuthority` is true, this will cause the generation of a new certificate. When `generateCertificateAuthority` is true, this will cause extra logging at WARN level about the pending certificate expiry. Default is 30.
spec.kafka.clientsCa.validityDays	integer	The number of days generated certificates should be valid for. The default is 365.
spec.kafka.clusterCa	object	Configuration of the cluster certificate authority.
spec.kafka.clusterCa.certificateExpirationPolicy	string	How should CA certificate expiration be handled when `generateCertificateAuthority=true`. The default is for a new CA certificate to be generated reusing the existing private key.
spec.kafka.clusterCa.generateCertificateAuthority	boolean	If true then Certificate Authority certificates will be generated automatically. Otherwise the user will need to provide a Secret with the CA certificate. Default is true.
spec.kafka.clusterCa.generateSecretOwnerReference	boolean	If true then the Certificate Authority certificates secrets owner reference is set to the Kafka object. Otherwise no owner reference is set so deleting the Kafka object won't delete the secrets. Default is true.
spec.kafka.clusterCa.renewalDays	integer	The number of days in the certificate renewal period. This is the number of days before the a certificate expires during which renewal actions may be performed. When `generateCertificateAuthority` is true, this will cause the generation of a new certificate. When `generateCertificateAuthority` is true, this will cause extra logging at WARN level about the pending certificate expiry. Default is 30.
spec.kafka.clusterCa.validityDays	integer	The number of days generated certificates should be valid for. The default is 365.
spec.kafka.cruiseControl	object	Configuration for Cruise Control deployment. Deploys a Cruise Control instance when specified.
spec.kafka.cruiseControl.brokerCapacity	object	The Cruise Control `brokerCapacity` configuration.
spec.kafka.cruiseControl.brokerCapacity.cpuUtilization	integer	Broker capacity for CPU resource utilization as a percentage (0 - 100).
spec.kafka.cruiseControl.brokerCapacity.disk	string	Broker capacity for disk in bytes, for example, 100Gi.
spec.kafka.cruiseControl.brokerCapacity.inboundNetwork	string	Broker capacity for inbound network throughput in bytes per second, for example, 10000KB/s.
spec.kafka.cruiseControl.brokerCapacity.outboundNetwork	string	Broker capacity for outbound network throughput in bytes per second, for example 10000KB/s.

Property	Type	Description
spec.kafka.cruiseControl.config	object	The Cruise Control configuration. For a full list of configuration options refer to https://github.com/linkedin/cruise-control/wiki/Configurations. Note that properties with the following prefixes cannot be set: bootstrap.servers, client.id, zookeeper., network., security., failed.brokers.zk.path,webserver.http., webserver.api.urlprefix, webserver.session.path, webserver.accesslog., two.step., request.reason.required,metric.reporter.sampler.bootstrap.servers, metric.reporter.topic, partition.metric.sample.store.topic, broker.metric.sample.store.topic,capacity.config.file, self.healing., anomaly.detection., ssl. (with the exception of: ssl.cipher.suites, ssl.protocol, ssl.enabled.protocols, webserver.http.cors.enabled,webserver.http.cors.origin, webserver.http.cors.exposeheaders).
spec.kafka.cruiseControl.image	string	The docker image for the pods.
spec.kafka.cruiseControl.jvmOptions	object	JVM Options for the Cruise Control container.
spec.kafka.cruiseControl.jvmOptions.-XX	object	A map of -XX options to the JVM.
spec.kafka.cruiseControl.jvmOptions.-Xms	string	-Xms option to to the JVM.
spec.kafka.cruiseControl.jvmOptions.-Xmx	string	-Xmx option to to the JVM.
spec.kafka.cruiseControl.jvmOptions.gcLoggingEnabled	boolean	Specifies whether the Garbage Collection logging is enabled. The default is false.
spec.kafka.cruiseControl.jvmOptions.javaSystemProperties	array	A map of additional system properties which will be passed using the `-D` option to the JVM.
spec.kafka.cruiseControl.livenessProbe	object	Pod liveness checking for the Cruise Control container.
spec.kafka.cruiseControl.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.cruiseControl.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.cruiseControl.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.cruiseControl.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.cruiseControl.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.cruiseControl.logging	object	Logging configuration (log4j1) for Cruise Control.
spec.kafka.cruiseControl.logging.loggers	object	A Map from logger name to logger level.
spec.kafka.cruiseControl.logging.name	string	The name of the `ConfigMap` from which to get the logging configuration.
spec.kafka.cruiseControl.logging.type	string	Logging type, must be either 'inline' or 'external'.
spec.kafka.cruiseControl.metrics	object	The Prometheus JMX Exporter configuration. See https://github.com/prometheus/jmx_exporter for details of the structure of this configuration.
spec.kafka.cruiseControl.metricsConfig	object	Metrics configuration.
spec.kafka.cruiseControl.metricsConfig.type	string	Metrics type. Only 'jmxPrometheusExporter' supported currently.
spec.kafka.cruiseControl.metricsConfig.valueFrom	object	ConfigMap where the Prometheus JMX Exporter configuration is stored. For details of the structure of this configuration, see the {JMXExporter}.
spec.kafka.cruiseControl.metricsConfig.valueFrom.configMapKeyRef	object	Reference to the key in the ConfigMap containing the metrics configuration.
spec.kafka.cruiseControl.metricsConfig.valueFrom.configMapKeyRef.key	string	Key corresponds to the JSON schema field "key".
spec.kafka.cruiseControl.metricsConfig.valueFrom.configMapKeyRef.name	string	Name corresponds to the JSON schema field "name".

Property	Type	Description
spec.kafka.cruiseControl.metricsConfig.valueFrom.configMapKeyRef.optional	boolean	Optional corresponds to the JSON schema field "optional".
spec.kafka.cruiseControl.readinessProbe	object	Pod readiness checking for the Cruise Control container.
spec.kafka.cruiseControl.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.cruiseControl.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.cruiseControl.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.cruiseControl.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.cruiseControl.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.cruiseControl.resources	object	CPU and memory resources to reserve for the Cruise Control container.
spec.kafka.cruiseControl.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.cruiseControl.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.cruiseControl.template	object	Template to specify how Cruise Control resources, **`Deployments`** and **`Pods`**, are generated.
spec.kafka.cruiseControl.template.apiService	object	Template for Cruise Control API **`Service`**.
spec.kafka.cruiseControl.template.apiService.metadata	object	Metadata applied to the resource.
spec.kafka.cruiseControl.template.apiService.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.cruiseControl.template.apiService.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.cruiseControl.template.cruiseControlContainer	object	Template for the Cruise Control container.
spec.kafka.cruiseControl.template.cruiseControlContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext	object	Security context for the container.
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".

Property	Type	Description
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".

Property	Type	Description
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.cruiseControl.template.cruiseControlContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.cruiseControl.template.deployment	object	Template for Cruise Control **`Deployment`**.
spec.kafka.cruiseControl.template.deployment.metadata	object	Metadata applied to the resource.
spec.kafka.cruiseControl.template.deployment.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.cruiseControl.template.deployment.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.cruiseControl.template.pod	object	Template for Cruise Control **`Pods`**.
spec.kafka.cruiseControl.template.pod.affinity	object	The pod's affinity rules.
spec.kafka.cruiseControl.template.pod.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.cruiseControl.template.pod.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.cruiseControl.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.cruiseControl.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.cruiseControl.template.pod.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".

Property	Type	Description
spec.kafka.cruiseControl.template.pod.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.cruiseControl.template.pod.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.cruiseControl.template.pod.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.cruiseControl.template.pod.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.cruiseControl.template.pod.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.cruiseControl.template.pod.hostAliases	array	The pod's HostAliases. HostAliases is an optional list of hosts and IPs that will be injected into the pod's hosts file if specified.
spec.kafka.cruiseControl.template.pod.imagePullSecrets	array	List of references to secrets in the same namespace to use for pulling any of the images used by this Pod. When the **`STRIMZI_IMAGE_PULL_SECRETS`** environment variable in Cluster Operator and the **`imagePullSecrets`** option are specified, only the **`imagePullSecrets`** variable is used and the **`STRIMZI_IMAGE_PULL_SECRETS`** variable is ignored.
spec.kafka.cruiseControl.template.pod.metadata	object	Metadata applied to the resource.
spec.kafka.cruiseControl.template.pod.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.cruiseControl.template.pod.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.cruiseControl.template.pod.priorityClassName	string	The name of the priority class used to assign priority to the pods. For more information about priority classes, see {K8sPriorityClass}.
spec.kafka.cruiseControl.template.pod.schedulerName	string	The name of the scheduler used to dispatch this **`Pod`**. If not specified, the default scheduler will be used.
spec.kafka.cruiseControl.template.pod.securityContext	object	Configures pod-level security attributes and common container settings.
spec.kafka.cruiseControl.template.pod.securityContext.fsGroup	integer	FsGroup corresponds to the JSON schema field "fsGroup".
spec.kafka.cruiseControl.template.pod.securityContext.fsGroupChangePolicy	string	FsGroupChangePolicy corresponds to the JSON schema field "fsGroupChangePolicy".
spec.kafka.cruiseControl.template.pod.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.cruiseControl.template.pod.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.cruiseControl.template.pod.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".

Property	Type	Description
spec.kafka.cruiseControl.template.pod.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.cruiseControl.template.pod.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.cruiseControl.template.pod.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.cruiseControl.template.pod.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.cruiseControl.template.pod.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.cruiseControl.template.pod.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.cruiseControl.template.pod.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.cruiseControl.template.pod.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.cruiseControl.template.pod.securityContext.supplementalGroups	array	SupplementalGroups corresponds to the JSON schema field "supplementalGroups".
spec.kafka.cruiseControl.template.pod.securityContext.sysctls	array	Sysctls corresponds to the JSON schema field "sysctls".
spec.kafka.cruiseControl.template.pod.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.cruiseControl.template.pod.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.cruiseControl.template.pod.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.cruiseControl.template.pod.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.cruiseControl.template.pod.terminationGracePeriodSeconds	integer	The grace period is the duration in seconds after the processes running in the pod are sent a termination signal, and the time when the processes are forcibly halted with a kill signal. Set this value to longer than the expected cleanup time for your process. Value must be a non-negative integer. A zero value indicates delete immediately. You might need to increase the grace period for very large Kafka clusters, so that the Kafka brokers have enough time to transfer their work to another broker before they are terminated. Defaults to 30 seconds.
spec.kafka.cruiseControl.template.pod.tolerations	array	The pod's tolerations.
spec.kafka.cruiseControl.template.pod.topologySpreadConstraints	array	The pod's topology spread constraints.

Property	Type	Description
spec.kafka.cruiseControl.template.podDisruptionBudget	object	Template for Cruise Control `PodDisruptionBudget`.
spec.kafka.cruiseControl.template.podDisruptionBudget.maxUnavailable	integer	Maximum number of unavailable pods to allow automatic Pod eviction. A Pod eviction is allowed when the `maxUnavailable` number of pods or fewer are unavailable after the eviction. Setting this value to 0 prevents all voluntary evictions, so the pods must be evicted manually. Defaults to 1.
spec.kafka.cruiseControl.template.podDisruptionBudget.metadata	object	Metadata to apply to the `PodDistruptionBugetTemplate` resource.
spec.kafka.cruiseControl.template.podDisruptionBudget.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.cruiseControl.template.podDisruptionBudget.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.cruiseControl.template.tlsSidecarContainer	object	Template for the Cruise Control TLS sidecar container.
spec.kafka.cruiseControl.template.tlsSidecarContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext	object	Security context for the container.
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".

Property	Type	Description
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.cruiseControl.template.tlsSidecarContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.cruiseControl.tlsSidecar	object	TLS sidecar configuration.
spec.kafka.cruiseControl.tlsSidecar.image	string	The docker image for the container.

Property	Type	Description
spec.kafka.cruiseControl.tlsSidecar.livenessProbe	object	Pod liveness checking.
spec.kafka.cruiseControl.tlsSidecar.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.cruiseControl.tlsSidecar.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.cruiseControl.tlsSidecar.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.cruiseControl.tlsSidecar.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.cruiseControl.tlsSidecar.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.cruiseControl.tlsSidecar.logLevel	string	The log level for the TLS sidecar. Default value is `notice`.
spec.kafka.cruiseControl.tlsSidecar.readinessProbe	object	Pod readiness checking.
spec.kafka.cruiseControl.tlsSidecar.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.cruiseControl.tlsSidecar.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.cruiseControl.tlsSidecar.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.cruiseControl.tlsSidecar.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.cruiseControl.tlsSidecar.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.cruiseControl.tlsSidecar.resources	object	CPU and memory resources to reserve.
spec.kafka.cruiseControl.tlsSidecar.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.cruiseControl.tlsSidecar.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.entityOperator	object	Configuration of the Entity Operator.
spec.kafka.entityOperator.affinity	object	The pod's affinity rules.
spec.kafka.entityOperator.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.entityOperator.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".

Property	Type	Description
spec.kafka.entityOperator.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.entityOperator.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.entityOperator.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.entityOperator.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.template	object	Template for Entity Operator resources. The template allows users to specify how is the **`Deployment`** and **`Pods`** generated.
spec.kafka.entityOperator.template.deployment	object	Template for Entity Operator **`Deployment`**.
spec.kafka.entityOperator.template.deployment.metadata	object	Metadata applied to the resource.
spec.kafka.entityOperator.template.deployment.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.entityOperator.template.deployment.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.entityOperator.template.pod	object	Template for Entity Operator **`Pods`**.
spec.kafka.entityOperator.template.pod.affinity	object	The pod's affinity rules.
spec.kafka.entityOperator.template.pod.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.entityOperator.template.pod.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".

Property	Type	Description
spec.kafka.entityOperator.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.entityOperator.template.pod.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.entityOperator.template.pod.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.template.pod.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.template.pod.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.entityOperator.template.pod.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.template.pod.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.entityOperator.template.pod.hostAliases	array	The pod's HostAliases. HostAliases is an optional list of hosts and IPs that will be injected into the pod's hosts file if specified.
spec.kafka.entityOperator.template.pod.imagePullSecrets	array	List of references to secrets in the same namespace to use for pulling any of the images used by this Pod. When the **`STRIMZI_IMAGE_PULL_SECRETS`** environment variable in Cluster Operator and the **`imagePullSecrets`** option are specified, only the **`imagePullSecrets`** variable is used and the **`STRIMZI_IMAGE_PULL_SECRETS`** variable is ignored.
spec.kafka.entityOperator.template.pod.metadata	object	Metadata applied to the resource.
spec.kafka.entityOperator.template.pod.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.entityOperator.template.pod.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.entityOperator.template.pod.priorityClassName	string	The name of the priority class used to assign priority to the pods. For more information about priority classes, see {K8sPriorityClass}.
spec.kafka.entityOperator.template.pod.schedulerName	string	The name of the scheduler used to dispatch this **`Pod`**. If not specified, the default scheduler will be used.
spec.kafka.entityOperator.template.pod.securityContext	object	Configures pod-level security attributes and common container settings.
spec.kafka.entityOperator.template.pod.securityContext.fsGroup	integer	FsGroup corresponds to the JSON schema field "fsGroup".

Property	Type	Description
spec.kafka.entityOperator.template.pod.securityContext.fsGroupChangePolicy	string	FsGroupChangePolicy corresponds to the JSON schema field "fsGroupChangePolicy".
spec.kafka.entityOperator.template.pod.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.entityOperator.template.pod.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.entityOperator.template.pod.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.entityOperator.template.pod.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.entityOperator.template.pod.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.entityOperator.template.pod.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.entityOperator.template.pod.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.entityOperator.template.pod.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.entityOperator.template.pod.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.entityOperator.template.pod.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.entityOperator.template.pod.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.entityOperator.template.pod.securityContext.supplementalGroups	array	SupplementalGroups corresponds to the JSON schema field "supplementalGroups".
spec.kafka.entityOperator.template.pod.securityContext.sysctls	array	Sysctls corresponds to the JSON schema field "sysctls".
spec.kafka.entityOperator.template.pod.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.entityOperator.template.pod.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.entityOperator.template.pod.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".

Property	Type	Description
spec.kafka.entityOperator.template.pod.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.entityOperator.template.pod.terminationGracePeriodSeconds	integer	The grace period is the duration in seconds after the processes running in the pod are sent a termination signal, and the time when the processes are forcibly halted with a kill signal. Set this value to longer than the expected cleanup time for your process. Value must be a non-negative integer. A zero value indicates delete immediately. You might need to increase the grace period for very large Kafka clusters, so that the Kafka brokers have enough time to transfer their work to another broker before they are terminated. Defaults to 30 seconds.
spec.kafka.entityOperator.template.pod.tolerations	array	The pod's tolerations.
spec.kafka.entityOperator.template.pod.topologySpreadConstraints	array	The pod's topology spread constraints.
spec.kafka.entityOperator.template.tlsSidecarContainer	object	Template for the Entity Operator TLS sidecar container.
spec.kafka.entityOperator.template.tlsSidecarContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext	object	Security context for the container.
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".

Property	Type	Description
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.entityOperator.template.tlsSidecarContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.entityOperator.template.topicOperatorContainer	object	Template for the Entity Topic Operator container.
spec.kafka.entityOperator.template.topicOperatorContainer.env	array	Environment variables which should be applied to the container.

Property	Type	Description
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext	object	Security context for the container.
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".

Property	Type	Description
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.entityOperator.template.topicOperatorContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.entityOperator.template.userOperatorContainer	object	Template for the Entity User Operator container.
spec.kafka.entityOperator.template.userOperatorContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.entityOperator.template.userOperatorContainer.securityContext	object	Security context for the container.
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".

Property	Type	Description
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".

Property	Type	Description
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.entityOperator.template.userOperatorContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.entityOperator.tlsSidecar	object	TLS sidecar configuration.
spec.kafka.entityOperator.tlsSidecar.image	string	The docker image for the container.
spec.kafka.entityOperator.tlsSidecar.livenessProbe	object	Pod liveness checking.
spec.kafka.entityOperator.tlsSidecar.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.entityOperator.tlsSidecar.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.entityOperator.tlsSidecar.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.entityOperator.tlsSidecar.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.entityOperator.tlsSidecar.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.entityOperator.tlsSidecar.logLevel	string	The log level for the TLS sidecar. Default value is **`notice`**.
spec.kafka.entityOperator.tlsSidecar.readinessProbe	object	Pod readiness checking.
spec.kafka.entityOperator.tlsSidecar.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.

Property	Type	Description
spec.kafka.entityOperator.tlsSidecar.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.entityOperator.tlsSidecar.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.entityOperator.tlsSidecar.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.entityOperator.tlsSidecar.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.entityOperator.tlsSidecar.resources	object	CPU and memory resources to reserve.
spec.kafka.entityOperator.tlsSidecar.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.entityOperator.tlsSidecar.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.entityOperator.tolerations	array	The pod's tolerations.
spec.kafka.entityOperator.topicOperator	object	Configuration of the Topic Operator.
spec.kafka.entityOperator.topicOperator.image	string	The image to use for the Topic Operator.
spec.kafka.entityOperator.topicOperator.jvmOptions	object	JVM Options for pods.
spec.kafka.entityOperator.topicOperator.jvmOptions.-XX	object	A map of -XX options to the JVM.
spec.kafka.entityOperator.topicOperator.jvmOptions.-Xms	string	-Xms option to to the JVM.
spec.kafka.entityOperator.topicOperator.jvmOptions.-Xmx	string	-Xmx option to to the JVM.
spec.kafka.entityOperator.topicOperator.jvmOptions.gcLoggingEnabled	boolean	Specifies whether the Garbage Collection logging is enabled. The default is false.
spec.kafka.entityOperator.topicOperator.jvmOptions.javaSystemProperties	array	A map of additional system properties which will be passed using the `-D` option to the JVM.
spec.kafka.entityOperator.topicOperator.livenessProbe	object	Pod liveness checking.
spec.kafka.entityOperator.topicOperator.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.entityOperator.topicOperator.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.entityOperator.topicOperator.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.entityOperator.topicOperator.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.

Property	Type	Description
spec.kafka.entityOperator.topicOperator.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.entityOperator.topicOperator.logging	object	Logging configuration.
spec.kafka.entityOperator.topicOperator.logging.loggers	object	A Map from logger name to logger level.
spec.kafka.entityOperator.topicOperator.logging.name	string	The name of the **`ConfigMap`** from which to get the logging configuration.
spec.kafka.entityOperator.topicOperator.logging.type	string	Logging type, must be either 'inline' or 'external'.
spec.kafka.entityOperator.topicOperator.readinessProbe	object	Pod readiness checking.
spec.kafka.entityOperator.topicOperator.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.entityOperator.topicOperator.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.entityOperator.topicOperator.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.entityOperator.topicOperator.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.entityOperator.topicOperator.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.entityOperator.topicOperator.reconciliationIntervalSeconds	integer	Interval between periodic reconciliations.
spec.kafka.entityOperator.topicOperator.resources	object	CPU and memory resources to reserve.
spec.kafka.entityOperator.topicOperator.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.entityOperator.topicOperator.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.entityOperator.topicOperator.topicMetadataMaxAttempts	integer	The number of attempts at getting topic metadata.
spec.kafka.entityOperator.topicOperator.watchedNamespace	string	The namespace the Topic Operator should watch.
spec.kafka.entityOperator.topicOperator.zookeeperSessionTimeoutSeconds	integer	Timeout for the ZooKeeper session.
spec.kafka.entityOperator.userOperator	object	Configuration of the User Operator.
spec.kafka.entityOperator.userOperator.image	string	The image to use for the User Operator.
spec.kafka.entityOperator.userOperator.jvmOptions	object	JVM Options for pods.

Property	Type	Description
spec.kafka.entityOperator.userOperator.jvmOptions.-XX	object	A map of -XX options to the JVM.
spec.kafka.entityOperator.userOperator.jvmOptions.-Xms	string	-Xms option to to the JVM.
spec.kafka.entityOperator.userOperator.jvmOptions.-Xmx	string	-Xmx option to to the JVM.
spec.kafka.entityOperator.userOperator.jvmOptions.gcLoggingEnabled	boolean	Specifies whether the Garbage Collection logging is enabled. The default is false.
spec.kafka.entityOperator.userOperator.jvmOptions.javaSystemProperties	array	A map of additional system properties which will be passed using the `-D` option to the JVM.
spec.kafka.entityOperator.userOperator.livenessProbe	object	Pod liveness checking.
spec.kafka.entityOperator.userOperator.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.entityOperator.userOperator.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.entityOperator.userOperator.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.entityOperator.userOperator.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.entityOperator.userOperator.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.entityOperator.userOperator.logging	object	Logging configuration.
spec.kafka.entityOperator.userOperator.logging.loggers	object	A Map from logger name to logger level.
spec.kafka.entityOperator.userOperator.logging.name	string	The name of the `ConfigMap` from which to get the logging configuration.
spec.kafka.entityOperator.userOperator.logging.type	string	Logging type, must be either 'inline' or 'external'.
spec.kafka.entityOperator.userOperator.readinessProbe	object	Pod readiness checking.
spec.kafka.entityOperator.userOperator.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.entityOperator.userOperator.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.entityOperator.userOperator.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.entityOperator.userOperator.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.

Property	Type	Description
spec.kafka.entityOperator.userOperator.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.entityOperator.userOperator.reconciliationIntervalSeconds	integer	Interval between periodic reconciliations.
spec.kafka.entityOperator.userOperator.resources	object	CPU and memory resources to reserve.
spec.kafka.entityOperator.userOperator.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.entityOperator.userOperator.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.entityOperator.userOperator.secretPrefix	string	The prefix that will be added to the KafkaUser name to be used as the Secret name.
spec.kafka.entityOperator.userOperator.watchedNamespace	string	The namespace the User Operator should watch.
spec.kafka.entityOperator.userOperator.zookeeperSessionTimeoutSeconds	integer	Timeout for the ZooKeeper session.
spec.kafka.jmxTrans	object	Configuration for JmxTrans. When the property is present a JmxTrans deployment is created for gathering JMX metrics from each Kafka broker. For more information see https://github.com/jmxtrans/jmxtrans[JmxTrans GitHub].
spec.kafka.jmxTrans.image	string	The image to use for the JmxTrans.
spec.kafka.jmxTrans.kafkaQueries	array	Queries to send to the Kafka brokers to define what data should be read from each broker. For more information on these properties see, xref:type-JmxTransQueryTemplate-reference[`JmxTransQueryTemplate` schema reference].
spec.kafka.jmxTrans.logLevel	string	Sets the logging level of the JmxTrans deployment.For more information see, https://github.com/jmxtrans/jmxtrans-agent/wiki/Troubleshooting[JmxTrans Logging Level].
spec.kafka.jmxTrans.outputDefinitions	array	Defines the output hosts that will be referenced later on. For more information on these properties see, xref:type-JmxTransOutputDefinitionTemplate-reference[`JmxTransOutputDefinitionTemplate` schema reference].
spec.kafka.jmxTrans.resources	object	CPU and memory resources to reserve.
spec.kafka.jmxTrans.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.jmxTrans.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.jmxTrans.template	object	Template for JmxTrans resources.
spec.kafka.jmxTrans.template.container	object	Template for JmxTrans container.
spec.kafka.jmxTrans.template.container.env	array	Environment variables which should be applied to the container.
spec.kafka.jmxTrans.template.container.securityContext	object	Security context for the container.
spec.kafka.jmxTrans.template.container.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.jmxTrans.template.container.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.jmxTrans.template.container.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.jmxTrans.template.container.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".

Property	Type	Description
spec.kafka.jmxTrans.template.container.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.jmxTrans.template.container.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.jmxTrans.template.container.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.jmxTrans.template.container.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.jmxTrans.template.container.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.jmxTrans.template.container.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.jmxTrans.template.container.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.jmxTrans.template.container.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.jmxTrans.template.container.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.jmxTrans.template.container.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.jmxTrans.template.container.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.jmxTrans.template.container.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.jmxTrans.template.container.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.jmxTrans.template.container.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.jmxTrans.template.container.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.jmxTrans.template.container.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.jmxTrans.template.container.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".

Property	Type	Description
spec.kafka.jmxTrans.template.container.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.jmxTrans.template.deployment	object	Template for JmxTrans **`Deployment`**.
spec.kafka.jmxTrans.template.deployment.metadata	object	Metadata applied to the resource.
spec.kafka.jmxTrans.template.deployment.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.jmxTrans.template.deployment.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.jmxTrans.template.pod	object	Template for JmxTrans **`Pods`**.
spec.kafka.jmxTrans.template.pod.affinity	object	The pod's affinity rules.
spec.kafka.jmxTrans.template.pod.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.jmxTrans.template.pod.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.jmxTrans.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.jmxTrans.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.jmxTrans.template.pod.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.jmxTrans.template.pod.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.jmxTrans.template.pod.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.jmxTrans.template.pod.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.jmxTrans.template.pod.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.jmxTrans.template.pod.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.jmxTrans.template.pod.hostAliases	array	The pod's HostAliases. HostAliases is an optional list of hosts and IPs that will be injected into the pod's hosts file if specified.

Property	Type	Description
spec.kafka.jmxTrans.template.pod.imagePullSecrets	array	List of references to secrets in the same namespace to use for pulling any of the images used by this Pod. When the **`STRIMZI_IMAGE_PULL_SECRETS`** environment variable in Cluster Operator and the **`imagePullSecrets`** option are specified, only the **`imagePullSecrets`** variable is used and the **`STRIMZI_IMAGE_PULL_SECRETS`** variable is ignored.
spec.kafka.jmxTrans.template.pod.metadata	object	Metadata applied to the resource.
spec.kafka.jmxTrans.template.pod.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.jmxTrans.template.pod.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.jmxTrans.template.pod.priorityClassName	string	The name of the priority class used to assign priority to the pods. For more information about priority classes, see {K8sPriorityClass}.
spec.kafka.jmxTrans.template.pod.schedulerName	string	The name of the scheduler used to dispatch this **`Pod`**. If not specified, the default scheduler will be used.
spec.kafka.jmxTrans.template.pod.securityContext	object	Configures pod-level security attributes and common container settings.
spec.kafka.jmxTrans.template.pod.securityContext.fsGroup	integer	FsGroup corresponds to the JSON schema field "fsGroup".
spec.kafka.jmxTrans.template.pod.securityContext.fsGroupChangePolicy	string	FsGroupChangePolicy corresponds to the JSON schema field "fsGroupChangePolicy".
spec.kafka.jmxTrans.template.pod.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.jmxTrans.template.pod.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.jmxTrans.template.pod.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.jmxTrans.template.pod.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.jmxTrans.template.pod.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.jmxTrans.template.pod.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.jmxTrans.template.pod.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.jmxTrans.template.pod.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.jmxTrans.template.pod.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.jmxTrans.template.pod.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.jmxTrans.template.pod.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".

Property	Type	Description
spec.kafka.jmxTrans.template.pod.securityContext.supplementalGroups	array	SupplementalGroups corresponds to the JSON schema field "supplementalGroups".
spec.kafka.jmxTrans.template.pod.securityContext.sysctls	array	Sysctls corresponds to the JSON schema field "sysctls".
spec.kafka.jmxTrans.template.pod.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.jmxTrans.template.pod.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.jmxTrans.template.pod.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.jmxTrans.template.pod.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.jmxTrans.template.pod.terminationGracePeriodSeconds	integer	The grace period is the duration in seconds after the processes running in the pod are sent a termination signal, and the time when the processes are forcibly halted with a kill signal. Set this value to longer than the expected cleanup time for your process. Value must be a non-negative integer. A zero value indicates delete immediately. You might need to increase the grace period for very large Kafka clusters, so that the Kafka brokers have enough time to transfer their work to another broker before they are terminated. Defaults to 30 seconds.
spec.kafka.jmxTrans.template.pod.tolerations	array	The pod's tolerations.
spec.kafka.jmxTrans.template.pod.topologySpreadConstraints	array	The pod's topology spread constraints.
spec.kafka.kafka	object	Configuration of the Kafka cluster.
spec.kafka.kafka.affinity	object	The pod's affinity rules.
spec.kafka.kafka.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.kafka.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.kafka.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.kafka.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".

Property	Type	Description
spec.kafka.kafka.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.kafka.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.authorization	object	Authorization configuration for Kafka brokers.
spec.kafka.kafka.authorization.allowOnError	boolean	Defines whether a Kafka client should be allowed or denied by default when the authorizer fails to query the Open Policy Agent, for example, when it is temporarily unavailable). Defaults to **`false`** - all actions will be denied.
spec.kafka.kafka.authorization.clientId	string	OAuth Client ID which the Kafka client can use to authenticate against the OAuth server and use the token endpoint URI.
spec.kafka.kafka.authorization.delegateToKafkaAcls	boolean	Whether authorization decision should be delegated to the 'Simple' authorizer if DENIED by Keycloak Authorization Services policies. Default value is **`false`**.
spec.kafka.kafka.authorization.disableTlsHostnameVerification	boolean	Enable or disable TLS hostname verification. Default value is **`false`**.
spec.kafka.kafka.authorization.expireAfterMs	integer	The expiration of the records kept in the local cache to avoid querying the Open Policy Agent for every request. Defines how often the cached authorization decisions are reloaded from the Open Policy Agent server. In milliseconds. Defaults to **`3600000`**.
spec.kafka.kafka.authorization.grantsRefreshPeriodSeconds	integer	The time between two consecutive grants refresh runs in seconds. The default value is 60.
spec.kafka.kafka.authorization.grantsRefreshPoolSize	integer	The number of threads to use to refresh grants for active sessions. The more threads, the more parallelism, so the sooner the job completes. However, using more threads places a heavier load on the authorization server. The default value is 5.
spec.kafka.kafka.authorization.initialCacheCapacity	integer	Initial capacity of the local cache used by the authorizer to avoid querying the Open Policy Agent for every request Defaults to **`5000`**.
spec.kafka.kafka.authorization.maximumCacheSize	integer	Maximum capacity of the local cache used by the authorizer to avoid querying the Open Policy Agent for every request. Defaults to **`50000`**.
spec.kafka.kafka.authorization.superUsers	array	List of super users. Should contain list of user principals which should get unlimited access rights.
spec.kafka.kafka.authorization.tlsTrustedCertificates	array	Trusted certificates for TLS connection to the OAuth server.
spec.kafka.kafka.authorization.tokenEndpointUri	string	Authorization server token endpoint URI.
spec.kafka.kafka.authorization.type	string	Authorization type. Currently, the supported types are **`simple`**, **`keycloak`**, and **`opa`**. **`simple`** authorization type uses Kafka's **`kafka.security.authorizer.AclAuthorizer`** class for authorization. **`keycloak`** authorization type uses Keycloak Authorization Services for authorization. **`opa`** authorization type uses Open Policy Agent based authorization.
spec.kafka.kafka.authorization.url	string	The URL used to connect to the Open Policy Agent server. The URL has to include the policy which will be queried by the authorizer. This option is required.
spec.kafka.kafka.brokerRackInitImage	string	The image of the init container used for initializing the **`broker.rack`**.
spec.kafka.kafka.config	object	Kafka broker config properties with the following prefixes cannot be set: listeners, advertised., broker., listener., host.name, port, inter.broker.listener.name, sasl., ssl., security., password., principal.builder.class, log.dir, zookeeper.connect, zookeeper.set.acl, zookeeper.ssl, zookeeper.clientCnxnSocket, authorizer., super.user, cruise.control.metrics.topic, cruise.control.metrics.reporter.bootstrap.servers (with the exception of: zookeeper.connection.timeout.ms, ssl.cipher.suites, ssl.protocol, ssl.enabled.protocols,cruise.control.metrics.topic.num.partitions, cruise.control.metrics.topic.replication.factor, cruise.control.metrics.topic.retention.ms,cruise.control.metrics.topic.auto.create.retries, cruise.control.metrics.topic.auto.create.timeout.ms,cruise.control.metrics.topic.min.insync.replicas).
spec.kafka.kafka.image	string	The docker image for the pods. The default value depends on the configured **`Kafka.spec.kafka.version`**.
spec.kafka.kafka.jmxOptions	object	JMX Options for Kafka brokers.
spec.kafka.kafka.jmxOptions.authentication	object	Authentication configuration for connecting to the Kafka JMX port.

Property	Type	Description
spec.kafka.kafka.jmxOptions.authentication.type	string	Authentication type. Currently the only supported types are `password`.`password` type creates a username and protected port with no TLS.
spec.kafka.kafka.jvmOptions	object	JVM Options for pods.
spec.kafka.kafka.jvmOptions.-XX	object	A map of -XX options to the JVM.
spec.kafka.kafka.jvmOptions.-Xms	string	-Xms option to to the JVM.
spec.kafka.kafka.jvmOptions.-Xmx	string	-Xmx option to to the JVM.
spec.kafka.kafka.jvmOptions.gcLoggingEnabled	boolean	Specifies whether the Garbage Collection logging is enabled. The default is false.
spec.kafka.kafka.jvmOptions.javaSystemProperties	array	A map of additional system properties which will be passed using the `-D` option to the JVM.
spec.kafka.kafka.listeners	array	Listeners corresponds to the JSON schema field "listeners".
spec.kafka.kafka.livenessProbe	object	Pod liveness checking.
spec.kafka.kafka.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.kafka.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.kafka.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.kafka.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.kafka.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.kafka.logging	object	Logging configuration for Kafka.
spec.kafka.kafka.logging.loggers	object	A Map from logger name to logger level.
spec.kafka.kafka.logging.name	string	The name of the `ConfigMap` from which to get the logging configuration.
spec.kafka.kafka.logging.type	string	Logging type, must be either 'inline' or 'external'.
spec.kafka.kafka.metrics	object	The Prometheus JMX Exporter configuration. See https://github.com/prometheus/jmx_exporter for details of the structure of this configuration.
spec.kafka.kafka.metricsConfig	object	Metrics configuration.
spec.kafka.kafka.metricsConfig.type	string	Metrics type. Only 'jmxPrometheusExporter' supported currently.
spec.kafka.kafka.metricsConfig.valueFrom	object	ConfigMap where the Prometheus JMX Exporter configuration is stored. For details of the structure of this configuration, see the {JMXExporter}.
spec.kafka.kafka.metricsConfig.valueFrom.configMapKeyRef	object	Reference to the key in the ConfigMap containing the metrics configuration.
spec.kafka.kafka.metricsConfig.valueFrom.configMapKeyRef.key	string	Key corresponds to the JSON schema field "key".
spec.kafka.kafka.metricsConfig.valueFrom.configMapKeyRef.name	string	Name corresponds to the JSON schema field "name".
spec.kafka.kafka.metricsConfig.valueFrom.configMapKeyRef.optional	boolean	Optional corresponds to the JSON schema field "optional".
spec.kafka.kafka.rack	object	Configuration of the `broker.rack` broker config.

Property	Type	Description
spec.kafka.kafka.rack.topologyKey	string	A key that matches labels assigned to the Kubernetes cluster nodes. The value of the label is used to set the broker's **broker.rack** config and **client.rack** in Kafka Connect.
spec.kafka.kafka.readinessProbe	object	Pod readiness checking.
spec.kafka.kafka.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.kafka.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.kafka.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.kafka.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.kafka.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.kafka.replicas	integer	The number of pods in the cluster.
spec.kafka.kafka.resources	object	CPU and memory resources to reserve.
spec.kafka.kafka.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.kafka.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.kafka.storage	object	Storage configuration (disk). Cannot be updated.
spec.kafka.kafka.storage.class	string	The storage class to use for dynamic volume allocation.
spec.kafka.kafka.storage.deleteClaim	boolean	Specifies if the persistent volume claim has to be deleted when the cluster is un-deployed.
spec.kafka.kafka.storage.id	integer	Storage identification number. It is mandatory only for storage volumes defined in a storage of type 'jbod'.
spec.kafka.kafka.storage.overrides	array	Overrides for individual brokers. The **overrides** field allows to specify a different configuration for different brokers.
spec.kafka.kafka.storage.selector	object	Specifies a specific persistent volume to use. It contains key:value pairs representing labels for selecting such a volume.
spec.kafka.kafka.storage.size	string	When type=persistent-claim, defines the size of the persistent volume claim (i.e 1Gi). Mandatory when type=persistent-claim.
spec.kafka.kafka.storage.sizeLimit	string	When type=ephemeral, defines the total amount of local storage required for this EmptyDir volume (for example 1Gi).
spec.kafka.kafka.storage.type	string	Storage type, must be either 'ephemeral', 'persistent-claim', or 'jbod'.
spec.kafka.kafka.storage.volumes	array	List of volumes as Storage objects representing the JBOD disks array.
spec.kafka.kafka.template	object	Template for Kafka cluster resources. The template allows users to specify how are the **StatefulSet**, **Pods** and **Services** generated.
spec.kafka.kafka.template.bootstrapService	object	Template for Kafka bootstrap **Service**.
spec.kafka.kafka.template.bootstrapService.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.bootstrapService.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **StatefulSets**, **Deployments**, **Pods**, and **Services**.
spec.kafka.kafka.template.bootstrapService.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **StatefulSets**, **Deployments**, **Pods**, and **Services**.
spec.kafka.kafka.template.brokersService	object	Template for Kafka broker **Service**.
spec.kafka.kafka.template.brokersService.metadata	object	Metadata applied to the resource.

Property	Type	Description
spec.kafka.kafka.template.brokersService.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.brokersService.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.clusterCaCert	object	Template for Secret with Kafka Cluster certificate public key.
spec.kafka.kafka.template.clusterCaCert.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.clusterCaCert.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.clusterCaCert.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.externalBootstrapIngress	object	Template for Kafka external bootstrap `Ingress`.
spec.kafka.kafka.template.externalBootstrapIngress.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.externalBootstrapIngress.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.externalBootstrapIngress.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.externalBootstrapRoute	object	Template for Kafka external bootstrap `Route`.
spec.kafka.kafka.template.externalBootstrapRoute.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.externalBootstrapRoute.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.externalBootstrapRoute.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.externalBootstrapService	object	Template for Kafka external bootstrap `Service`.
spec.kafka.kafka.template.externalBootstrapService.externalTrafficPolicy	string	Specifies whether the service routes external traffic to node-local or cluster-wide endpoints. `Cluster` may cause a second hop to another node and obscures the client source IP. `Local` avoids a second hop for LoadBalancer and Nodeport type services and preserves the client source IP (when supported by the infrastructure). If unspecified, Kubernetes will use `Cluster` as the default.
spec.kafka.kafka.template.externalBootstrapService.loadBalancerSourceRanges	array	A list of CIDR ranges (for example `10.0.0.0/8` or `130.211.204.1/32`) from which clients can connect to load balancer type listeners. If supported by the platform, traffic through the loadbalancer is restricted to the specified CIDR ranges. This field is applicable only for loadbalancer type services and is ignored if the cloud provider does not support the feature. For more information, see https://v1-17.docs.kubernetes.io/docs/tasks/access-application-cluster/configure-cloud-provider-firewall/.
spec.kafka.kafka.template.externalBootstrapService.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.externalBootstrapService.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.externalBootstrapService.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.

Property	Type	Description
spec.kafka.kafka.template.initContainer	object	Template for the Kafka init container.
spec.kafka.kafka.template.initContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.kafka.template.initContainer.securityContext	object	Security context for the container.
spec.kafka.kafka.template.initContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.kafka.template.initContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.kafka.template.initContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.kafka.template.initContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.kafka.template.initContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.kafka.template.initContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.kafka.template.initContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.kafka.template.initContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.kafka.template.initContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.kafka.template.initContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.kafka.template.initContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.kafka.template.initContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.kafka.template.initContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.kafka.template.initContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafka.template.initContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".

Property	Type	Description
spec.kafka.kafka.template.initContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.kafka.template.initContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.kafka.template.initContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafka.template.initContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.kafka.template.initContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.kafka.template.initContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.kafka.template.initContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.kafka.template.kafkaContainer	object	Template for the Kafka broker container.
spec.kafka.kafka.template.kafkaContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.kafka.template.kafkaContainer.securityContext	object	Security context for the container.
spec.kafka.kafka.template.kafkaContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.kafka.template.kafkaContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.kafka.template.kafkaContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.kafka.template.kafkaContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.kafka.template.kafkaContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.kafka.template.kafkaContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.kafka.template.kafkaContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.kafka.template.kafkaContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".

Property	Type	Description
spec.kafka.kafka.template.kafkaContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.kafka.template.kafkaContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.kafka.template.kafkaContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.kafka.template.kafkaContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.kafka.template.kafkaContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.kafka.template.kafkaContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafka.template.kafkaContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.kafka.template.kafkaContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.kafka.template.kafkaContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.kafka.template.kafkaContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafka.template.kafkaContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.kafka.template.kafkaContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.kafka.template.kafkaContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.kafka.template.kafkaContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.kafka.template.perPodIngress	object	Template for Kafka per-pod `Ingress` used for access from outside of Kubernetes.
spec.kafka.kafka.template.perPodIngress.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.perPodIngress.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.perPodIngress.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.

Property	Type	Description
spec.kafka.kafka.template.perPodRoute	object	Template for Kafka per-pod `Routes` used for access from outside of OpenShift.
spec.kafka.kafka.template.perPodRoute.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.perPodRoute.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.perPodRoute.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.perPodService	object	Template for Kafka per-pod `Services` used for access from outside of Kubernetes.
spec.kafka.kafka.template.perPodService.externalTrafficPolicy	string	Specifies whether the service routes external traffic to node-local or cluster-wide endpoints. `Cluster` may cause a second hop to another node and obscures the client source IP. `Local` avoids a second hop for LoadBalancer and Nodeport type services and preserves the client source IP (when supported by the infrastructure). If unspecified, Kubernetes will use `Cluster` as the default.
spec.kafka.kafka.template.perPodService.loadBalancerSourceRanges	array	A list of CIDR ranges (for example `10.0.0.0/8` or `130.211.204.1/32`) from which clients can connect to load balancer type listeners. If supported by the platform, traffic through the loadbalancer is restricted to the specified CIDR ranges. This field is applicable only for loadbalancer type services and is ignored if the cloud provider does not support the feature. For more information, see https://v1-17.docs.kubernetes.io/docs/tasks/access-application-cluster/configure-cloud-provider-firewall/.
spec.kafka.kafka.template.perPodService.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.perPodService.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.perPodService.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.persistentVolumeClaim	object	Template for all Kafka `PersistentVolumeClaims`.
spec.kafka.kafka.template.persistentVolumeClaim.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.persistentVolumeClaim.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.persistentVolumeClaim.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.pod	object	Template for Kafka `Pods`.
spec.kafka.kafka.template.pod.affinity	object	The pod's affinity rules.
spec.kafka.kafka.template.pod.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.kafka.template.pod.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".

Property	Type	Description
spec.kafka.kafka.template.pod.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.kafka.template.pod.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.template.pod.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.template.pod.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.kafka.template.pod.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.template.pod.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafka.template.pod.hostAliases	array	The pod's HostAliases. HostAliases is an optional list of hosts and IPs that will be injected into the pod's hosts file if specified.
spec.kafka.kafka.template.pod.imagePullSecrets	array	List of references to secrets in the same namespace to use for pulling any of the images used by this Pod. When the **`STRIMZI_IMAGE_PULL_SECRETS`** environment variable in Cluster Operator and the **`imagePullSecrets`** option are specified, only the **`imagePullSecrets`** variable is used and the **`STRIMZI_IMAGE_PULL_SECRETS`** variable is ignored.
spec.kafka.kafka.template.pod.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.pod.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.kafka.template.pod.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.kafka.template.pod.priorityClassName	string	The name of the priority class used to assign priority to the pods. For more information about priority classes, see {K8sPriorityClass}.
spec.kafka.kafka.template.pod.schedulerName	string	The name of the scheduler used to dispatch this **`Pod`**. If not specified, the default scheduler will be used.
spec.kafka.kafka.template.pod.securityContext	object	Configures pod-level security attributes and common container settings.
spec.kafka.kafka.template.pod.securityContext.fsGroup	integer	FsGroup corresponds to the JSON schema field "fsGroup".
spec.kafka.kafka.template.pod.securityContext.fsGroupChangePolicy	string	FsGroupChangePolicy corresponds to the JSON schema field "fsGroupChangePolicy".
spec.kafka.kafka.template.pod.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.kafka.template.pod.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.kafka.template.pod.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.kafka.template.pod.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".

Property	Type	Description
spec.kafka.kafka.template.pod.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.kafka.template.pod.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.kafka.template.pod.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafka.template.pod.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.kafka.template.pod.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.kafka.template.pod.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.kafka.template.pod.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafka.template.pod.securityContext.supplementalGroups	array	SupplementalGroups corresponds to the JSON schema field "supplementalGroups".
spec.kafka.kafka.template.pod.securityContext.sysctls	array	Sysctls corresponds to the JSON schema field "sysctls".
spec.kafka.kafka.template.pod.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.kafka.template.pod.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.kafka.template.pod.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.kafka.template.pod.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.kafka.template.pod.terminationGracePeriodSeconds	integer	The grace period is the duration in seconds after the processes running in the pod are sent a termination signal, and the time when the processes are forcibly halted with a kill signal. Set this value to longer than the expected cleanup time for your process. Value must be a non-negative integer. A zero value indicates delete immediately. You might need to increase the grace period for very large Kafka clusters, so that the Kafka brokers have enough time to transfer their work to another broker before they are terminated. Defaults to 30 seconds.
spec.kafka.kafka.template.pod.tolerations	array	The pod's tolerations.
spec.kafka.kafka.template.pod.topologySpreadConstraints	array	The pod's topology spread constraints.
spec.kafka.kafka.template.podDisruptionBudget	object	Template for Kafka **`PodDisruptionBudget`**.
spec.kafka.kafka.template.podDisruptionBudget.maxUnavailable	integer	Maximum number of unavailable pods to allow automatic Pod eviction. A Pod eviction is allowed when the **`maxUnavailable`** number of pods or fewer are unavailable after the eviction. Setting this value to 0 prevents all voluntary evictions, so the pods must be evicted manually. Defaults to 1.

Property	Type	Description
spec.kafka.kafka.template.podDisruptionBudget.metadata	object	Metadata to apply to the `PodDistruptionBugetTemplate` resource.
spec.kafka.kafka.template.podDisruptionBudget.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.podDisruptionBudget.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.statefulset	object	Template for Kafka `StatefulSet`.
spec.kafka.kafka.template.statefulset.metadata	object	Metadata applied to the resource.
spec.kafka.kafka.template.statefulset.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.statefulset.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as `StatefulSets`, `Deployments`, `Pods`, and `Services`.
spec.kafka.kafka.template.statefulset.podManagementPolicy	string	PodManagementPolicy which will be used for this StatefulSet. Valid values are `Parallel` and `OrderedReady`. Defaults to `Parallel`.
spec.kafka.kafka.template.tlsSidecarContainer	object	Template for the Kafka broker TLS sidecar container.
spec.kafka.kafka.template.tlsSidecarContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.kafka.template.tlsSidecarContainer.securityContext	object	Security context for the container.
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".

Property	Type	Description
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.kafka.template.tlsSidecarContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.kafka.tlsSidecar	object	TLS sidecar configuration.
spec.kafka.kafka.tlsSidecar.image	string	The docker image for the container.
spec.kafka.kafka.tlsSidecar.livenessProbe	object	Pod liveness checking.
spec.kafka.kafka.tlsSidecar.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.

Property	Type	Description
spec.kafka.kafka.tlsSidecar.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.kafka.tlsSidecar.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.kafka.tlsSidecar.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.kafka.tlsSidecar.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.kafka.tlsSidecar.logLevel	string	The log level for the TLS sidecar. Default value is `notice`.
spec.kafka.kafka.tlsSidecar.readinessProbe	object	Pod readiness checking.
spec.kafka.kafka.tlsSidecar.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.kafka.tlsSidecar.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.kafka.tlsSidecar.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.kafka.tlsSidecar.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.kafka.tlsSidecar.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.kafka.tlsSidecar.resources	object	CPU and memory resources to reserve.
spec.kafka.kafka.tlsSidecar.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.kafka.tlsSidecar.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.kafka.tolerations	array	The pod's tolerations.
spec.kafka.kafka.version	string	The kafka broker version. Defaults to {DefaultKafkaVersion}. Consult the user documentation to understand the process required to upgrade or downgrade the version.
spec.kafka.kafkaExporter	object	Configuration of the Kafka Exporter. Kafka Exporter can provide additional metrics, for example lag of consumer group at topic/partition.
spec.kafka.kafkaExporter.enableSaramaLogging	boolean	Enable Sarama logging, a Go client library used by the Kafka Exporter.
spec.kafka.kafkaExporter.groupRegex	string	Regular expression to specify which consumer groups to collect. Default value is `.*`.
spec.kafka.kafkaExporter.image	string	The docker image for the pods.
spec.kafka.kafkaExporter.livenessProbe	object	Pod liveness check.
spec.kafka.kafkaExporter.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.kafkaExporter.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.kafkaExporter.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.kafkaExporter.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.kafkaExporter.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.

Property	Type	Description
spec.kafka.kafkaExporter.logging	string	Only log messages with the given severity or above. Valid levels: [**debug**, **info**, **warn**, **error**, **fatal**]. Default log level is **info**.
spec.kafka.kafkaExporter.readinessProbe	object	Pod readiness check.
spec.kafka.kafkaExporter.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.kafkaExporter.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.kafkaExporter.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.kafkaExporter.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.kafkaExporter.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.kafkaExporter.resources	object	CPU and memory resources to reserve.
spec.kafka.kafkaExporter.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.kafkaExporter.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.kafkaExporter.template	object	Customization of deployment templates and pods.
spec.kafka.kafkaExporter.template.container	object	Template for the Kafka Exporter container.
spec.kafka.kafkaExporter.template.container.env	array	Environment variables which should be applied to the container.
spec.kafka.kafkaExporter.template.container.securityContext	object	Security context for the container.
spec.kafka.kafkaExporter.template.container.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.kafkaExporter.template.container.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.kafkaExporter.template.container.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.kafkaExporter.template.container.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.kafkaExporter.template.container.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.kafkaExporter.template.container.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.kafkaExporter.template.container.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.kafkaExporter.template.container.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".

Property	Type	Description
spec.kafka.kafkaExporter.template.container.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.kafkaExporter.template.container.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.kafkaExporter.template.container.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.kafkaExporter.template.container.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.kafkaExporter.template.container.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.kafkaExporter.template.container.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafkaExporter.template.container.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.kafkaExporter.template.container.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.kafkaExporter.template.container.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.kafkaExporter.template.container.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafkaExporter.template.container.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.kafkaExporter.template.container.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.kafkaExporter.template.container.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.kafkaExporter.template.container.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.kafkaExporter.template.deployment	object	Template for Kafka Exporter **`Deployment`**.
spec.kafka.kafkaExporter.template.deployment.metadata	object	Metadata applied to the resource.
spec.kafka.kafkaExporter.template.deployment.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.

Property	Type	Description
spec.kafka.kafkaExporter.template.deployment.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.kafkaExporter.template.pod	object	Template for Kafka Exporter **`Pods`**.
spec.kafka.kafkaExporter.template.pod.affinity	object	The pod's affinity rules.
spec.kafka.kafkaExporter.template.pod.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.kafkaExporter.template.pod.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafkaExporter.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafkaExporter.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.kafkaExporter.template.pod.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.kafkaExporter.template.pod.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafkaExporter.template.pod.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafkaExporter.template.pod.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.kafkaExporter.template.pod.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafkaExporter.template.pod.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.kafkaExporter.template.pod.hostAliases	array	The pod's HostAliases. HostAliases is an optional list of hosts and IPs that will be injected into the pod's hosts file if specified.
spec.kafka.kafkaExporter.template.pod.imagePullSecrets	array	List of references to secrets in the same namespace to use for pulling any of the images used by this Pod. When the **`STRIMZI_IMAGE_PULL_SECRETS`** environment variable in Cluster Operator and the **`imagePullSecrets`** option are specified, only the **`imagePullSecrets`** variable is used and the **`STRIMZI_IMAGE_PULL_SECRETS`** variable is ignored.
spec.kafka.kafkaExporter.template.pod.metadata	object	Metadata applied to the resource.

Property	Type	Description
spec.kafka.kafkaExporter.template.pod.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.kafkaExporter.template.pod.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.kafkaExporter.template.pod.priorityClassName	string	The name of the priority class used to assign priority to the pods. For more information about priority classes, see {K8sPriorityClass}.
spec.kafka.kafkaExporter.template.pod.schedulerName	string	The name of the scheduler used to dispatch this **`Pod`**. If not specified, the default scheduler will be used.
spec.kafka.kafkaExporter.template.pod.securityContext	object	Configures pod-level security attributes and common container settings.
spec.kafka.kafkaExporter.template.pod.securityContext.fsGroup	integer	FsGroup corresponds to the JSON schema field "fsGroup".
spec.kafka.kafkaExporter.template.pod.securityContext.fsGroupChangePolicy	string	FsGroupChangePolicy corresponds to the JSON schema field "fsGroupChangePolicy".
spec.kafka.kafkaExporter.template.pod.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.kafkaExporter.template.pod.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.kafkaExporter.template.pod.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.kafkaExporter.template.pod.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.kafkaExporter.template.pod.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.kafkaExporter.template.pod.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.kafkaExporter.template.pod.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.kafkaExporter.template.pod.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.kafkaExporter.template.pod.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.kafkaExporter.template.pod.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.kafkaExporter.template.pod.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".

Property	Type	Description
spec.kafka.kafkaExporter.template.pod.securityContext.supplementalGroups	array	SupplementalGroups corresponds to the JSON schema field "supplementalGroups".
spec.kafka.kafkaExporter.template.pod.securityContext.sysctls	array	Sysctls corresponds to the JSON schema field "sysctls".
spec.kafka.kafkaExporter.template.pod.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.kafkaExporter.template.pod.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.kafkaExporter.template.pod.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.kafkaExporter.template.pod.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.kafkaExporter.template.pod.terminationGracePeriodSeconds	integer	The grace period is the duration in seconds after the processes running in the pod are sent a termination signal, and the time when the processes are forcibly halted with a kill signal. Set this value to longer than the expected cleanup time for your process. Value must be a non-negative integer. A zero value indicates delete immediately. You might need to increase the grace period for very large Kafka clusters, so that the Kafka brokers have enough time to transfer their work to another broker before they are terminated. Defaults to 30 seconds.
spec.kafka.kafkaExporter.template.pod.tolerations	array	The pod's tolerations.
spec.kafka.kafkaExporter.template.pod.topologySpreadConstraints	array	The pod's topology spread constraints.
spec.kafka.kafkaExporter.template.service	object	Template for Kafka Exporter **`Service`**.
spec.kafka.kafkaExporter.template.service.metadata	object	Metadata applied to the resource.
spec.kafka.kafkaExporter.template.service.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.kafkaExporter.template.service.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.kafkaExporter.topicRegex	string	Regular expression to specify which topics to collect. Default value is **`.*`**.
spec.kafka.maintenanceTimeWindows	array	A list of time windows for maintenance tasks (that is, certificates renewal). Each time window is defined by a cron expression.
spec.kafka.topicOperator	object	Configuration of the Topic Operator.
spec.kafka.topicOperator.affinity	object	Pod affinity rules.
spec.kafka.topicOperator.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.topicOperator.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".

Property	Type	Description
spec.kafka.topicOperator.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.topicOperator.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.topicOperator.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.topicOperator.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.topicOperator.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.topicOperator.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.topicOperator.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.topicOperator.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.topicOperator.image	string	The image to use for the Topic Operator.
spec.kafka.topicOperator.jvmOptions	object	JVM Options for pods.
spec.kafka.topicOperator.jvmOptions.-XX	object	A map of -XX options to the JVM.
spec.kafka.topicOperator.jvmOptions.-Xms	string	-Xms option to to the JVM.
spec.kafka.topicOperator.jvmOptions.-Xmx	string	-Xmx option to to the JVM.
spec.kafka.topicOperator.jvmOptions.gcLoggingEnabled	boolean	Specifies whether the Garbage Collection logging is enabled. The default is false.
spec.kafka.topicOperator.jvmOptions.javaSystemProperties	array	A map of additional system properties which will be passed using the `-D` option to the JVM.
spec.kafka.topicOperator.livenessProbe	object	Pod liveness checking.
spec.kafka.topicOperator.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.topicOperator.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.topicOperator.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.topicOperator.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.

Property	Type	Description
spec.kafka.topicOperator.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.topicOperator.logging	object	Logging configuration.
spec.kafka.topicOperator.logging.loggers	object	A Map from logger name to logger level.
spec.kafka.topicOperator.logging.name	string	The name of the `ConfigMap` from which to get the logging configuration.
spec.kafka.topicOperator.logging.type	string	Logging type, must be either 'inline' or 'external'.
spec.kafka.topicOperator.readinessProbe	object	Pod readiness checking.
spec.kafka.topicOperator.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.topicOperator.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.topicOperator.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.topicOperator.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.topicOperator.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.topicOperator.reconciliationIntervalSeconds	integer	Interval between periodic reconciliations.
spec.kafka.topicOperator.resources	object	CPU and memory resources to reserve.
spec.kafka.topicOperator.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.topicOperator.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.topicOperator.tlsSidecar	object	TLS sidecar configuration.
spec.kafka.topicOperator.tlsSidecar.image	string	The docker image for the container.
spec.kafka.topicOperator.tlsSidecar.livenessProbe	object	Pod liveness checking.
spec.kafka.topicOperator.tlsSidecar.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.topicOperator.tlsSidecar.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.topicOperator.tlsSidecar.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.topicOperator.tlsSidecar.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.topicOperator.tlsSidecar.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.topicOperator.tlsSidecar.logLevel	string	The log level for the TLS sidecar. Default value is `notice`.

Property	Type	Description
spec.kafka.topicOperator.tlsSidecar.readinessProbe	object	Pod readiness checking.
spec.kafka.topicOperator.tlsSidecar.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.topicOperator.tlsSidecar.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.topicOperator.tlsSidecar.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.topicOperator.tlsSidecar.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.topicOperator.tlsSidecar.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.topicOperator.tlsSidecar.resources	object	CPU and memory resources to reserve.
spec.kafka.topicOperator.tlsSidecar.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.topicOperator.tlsSidecar.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.topicOperator.topicMetadataMaxAttempts	integer	The number of attempts at getting topic metadata.
spec.kafka.topicOperator.watchedNamespace	string	The namespace the Topic Operator should watch.
spec.kafka.topicOperator.zookeeperSessionTimeoutSeconds	integer	Timeout for the ZooKeeper session.
spec.kafka.zookeeper	object	Configuration of the ZooKeeper cluster.
spec.kafka.zookeeper.affinity	object	The pod's affinity rules.
spec.kafka.zookeeper.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.zookeeper.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.zookeeper.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.zookeeper.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".

Property	Type	Description
spec.kafka.zookeeper.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.zookeeper.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.config	object	The ZooKeeper broker config. Properties with the following prefixes cannot be set: server., dataDir, dataLogDir, clientPort, authProvider, quorum.auth, requireClientAuthScheme, snapshot.trust.empty, standaloneEnabled, reconfigEnabled, 4lw.commands.whitelist, secureClientPort, ssl., serverCnxnFactory, sslQuorum (with the exception of: ssl.protocol, ssl.quorum.protocol, ssl.enabledProtocols, ssl.quorum.enabledProtocols, ssl.ciphersuites, ssl.quorum.ciphersuites, ssl.hostnameVerification, ssl.quorum.hostnameVerification).
spec.kafka.zookeeper.image	string	The docker image for the pods.
spec.kafka.zookeeper.jvmOptions	object	JVM Options for pods.
spec.kafka.zookeeper.jvmOptions.-XX	object	A map of -XX options to the JVM.
spec.kafka.zookeeper.jvmOptions.-Xms	string	-Xms option to to the JVM.
spec.kafka.zookeeper.jvmOptions.-Xmx	string	-Xmx option to to the JVM.
spec.kafka.zookeeper.jvmOptions.gcLoggingEnabled	boolean	Specifies whether the Garbage Collection logging is enabled. The default is false.
spec.kafka.zookeeper.jvmOptions.javaSystemProperties	array	A map of additional system properties which will be passed using the `-D` option to the JVM.
spec.kafka.zookeeper.livenessProbe	object	Pod liveness checking.
spec.kafka.zookeeper.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.zookeeper.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.zookeeper.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.zookeeper.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.zookeeper.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.zookeeper.logging	object	Logging configuration for ZooKeeper.
spec.kafka.zookeeper.logging.loggers	object	A Map from logger name to logger level.
spec.kafka.zookeeper.logging.name	string	The name of the `ConfigMap` from which to get the logging configuration.
spec.kafka.zookeeper.logging.type	string	Logging type, must be either 'inline' or 'external'.
spec.kafka.zookeeper.metrics	object	The Prometheus JMX Exporter configuration. See https://github.com/prometheus/jmx_exporter for details of the structure of this configuration.
spec.kafka.zookeeper.metricsConfig	object	Metrics configuration.
spec.kafka.zookeeper.metricsConfig.type	string	Metrics type. Only 'jmxPrometheusExporter' supported currently.

Property	Type	Description
spec.kafka.zookeeper.metricsConfig.valueFrom	object	ConfigMap where the Prometheus JMX Exporter configuration is stored. For details of the structure of this configuration, see the {JMXExporter}.
spec.kafka.zookeeper.metricsConfig.valueFrom.configMapKeyRef	object	Reference to the key in the ConfigMap containing the metrics configuration.
spec.kafka.zookeeper.metricsConfig.valueFrom.configMapKeyRef.key	string	Key corresponds to the JSON schema field "key".
spec.kafka.zookeeper.metricsConfig.valueFrom.configMapKeyRef.name	string	Name corresponds to the JSON schema field "name".
spec.kafka.zookeeper.metricsConfig.valueFrom.configMapKeyRef.optional	boolean	Optional corresponds to the JSON schema field "optional".
spec.kafka.zookeeper.readinessProbe	object	Pod readiness checking.
spec.kafka.zookeeper.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.zookeeper.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.zookeeper.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.zookeeper.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.zookeeper.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.zookeeper.replicas	integer	The number of pods in the cluster.
spec.kafka.zookeeper.resources	object	CPU and memory resources to reserve.
spec.kafka.zookeeper.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.zookeeper.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.zookeeper.storage	object	Storage configuration (disk). Cannot be updated.
spec.kafka.zookeeper.storage.class	string	The storage class to use for dynamic volume allocation.
spec.kafka.zookeeper.storage.deleteClaim	boolean	Specifies if the persistent volume claim has to be deleted when the cluster is un-deployed.
spec.kafka.zookeeper.storage.id	integer	Storage identification number. It is mandatory only for storage volumes defined in a storage of type 'jbod'.
spec.kafka.zookeeper.storage.overrides	array	Overrides for individual brokers. The **`overrides`** field allows to specify a different configuration for different brokers.
spec.kafka.zookeeper.storage.selector	object	Specifies a specific persistent volume to use. It contains key:value pairs representing labels for selecting such a volume.
spec.kafka.zookeeper.storage.size	string	When type=persistent-claim, defines the size of the persistent volume claim (i.e 1Gi). Mandatory when type=persistent-claim.
spec.kafka.zookeeper.storage.sizeLimit	string	When type=ephemeral, defines the total amount of local storage required for this EmptyDir volume (for example 1Gi).
spec.kafka.zookeeper.storage.type	string	Storage type, must be either 'ephemeral' or 'persistent-claim'.
spec.kafka.zookeeper.template	object	Template for ZooKeeper cluster resources. The template allows users to specify how are the **`StatefulSet`**, **`Pods`** and **`Services`** generated.
spec.kafka.zookeeper.template.clientService	object	Template for ZooKeeper client **`Service`**.
spec.kafka.zookeeper.template.clientService.metadata	object	Metadata applied to the resource.

Property	Type	Description
spec.kafka.zookeeper.template.clientService.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.clientService.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.nodesService	object	Template for ZooKeeper nodes **`Service`**.
spec.kafka.zookeeper.template.nodesService.metadata	object	Metadata applied to the resource.
spec.kafka.zookeeper.template.nodesService.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.nodesService.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.persistentVolumeClaim	object	Template for all ZooKeeper **`PersistentVolumeClaims`**.
spec.kafka.zookeeper.template.persistentVolumeClaim.metadata	object	Metadata applied to the resource.
spec.kafka.zookeeper.template.persistentVolumeClaim.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.persistentVolumeClaim.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.pod	object	Template for ZooKeeper **`Pods`**.
spec.kafka.zookeeper.template.pod.affinity	object	The pod's affinity rules.
spec.kafka.zookeeper.template.pod.affinity.nodeAffinity	object	NodeAffinity corresponds to the JSON schema field "nodeAffinity".
spec.kafka.zookeeper.template.pod.affinity.nodeAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution	object	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.template.pod.affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms	array	NodeSelectorTerms corresponds to the JSON schema field "nodeSelectorTerms".
spec.kafka.zookeeper.template.pod.affinity.podAffinity	object	PodAffinity corresponds to the JSON schema field "podAffinity".
spec.kafka.zookeeper.template.pod.affinity.podAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".

Property	Type	Description
spec.kafka.zookeeper.template.pod.affinity.podAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.template.pod.affinity.podAntiAffinity	object	PodAntiAffinity corresponds to the JSON schema field "podAntiAffinity".
spec.kafka.zookeeper.template.pod.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution	array	PreferredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "preferredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.template.pod.affinity.podAntiAffinity.requiredDuringSchedulingIgnoredDuringExecution	array	RequiredDuringSchedulingIgnoredDuringExecution corresponds to the JSON schema field "requiredDuringSchedulingIgnoredDuringExecution".
spec.kafka.zookeeper.template.pod.hostAliases	array	The pod's HostAliases. HostAliases is an optional list of hosts and IPs that will be injected into the pod's hosts file if specified.
spec.kafka.zookeeper.template.pod.imagePullSecrets	array	List of references to secrets in the same namespace to use for pulling any of the images used by this Pod. When the **`STRIMZI_IMAGE_PULL_SECRETS`** environment variable in Cluster Operator and the **`imagePullSecrets`** option are specified, only the **`imagePullSecrets`** variable is used and the **`STRIMZI_IMAGE_PULL_SECRETS`** variable is ignored.
spec.kafka.zookeeper.template.pod.metadata	object	Metadata applied to the resource.
spec.kafka.zookeeper.template.pod.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.pod.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.pod.priorityClassName	string	The name of the priority class used to assign priority to the pods. For more information about priority classes, see {K8sPriorityClass}.
spec.kafka.zookeeper.template.pod.schedulerName	string	The name of the scheduler used to dispatch this **`Pod`**. If not specified, the default scheduler will be used.
spec.kafka.zookeeper.template.pod.securityContext	object	Configures pod-level security attributes and common container settings.
spec.kafka.zookeeper.template.pod.securityContext.fsGroup	integer	FsGroup corresponds to the JSON schema field "fsGroup".
spec.kafka.zookeeper.template.pod.securityContext.fsGroupChangePolicy	string	FsGroupChangePolicy corresponds to the JSON schema field "fsGroupChangePolicy".
spec.kafka.zookeeper.template.pod.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.zookeeper.template.pod.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.zookeeper.template.pod.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.zookeeper.template.pod.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.zookeeper.template.pod.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".

Property	Type	Description
spec.kafka.zookeeper.template.pod.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.zookeeper.template.pod.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.zookeeper.template.pod.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.zookeeper.template.pod.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.zookeeper.template.pod.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.zookeeper.template.pod.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.zookeeper.template.pod.securityContext.supplementalGroups	array	SupplementalGroups corresponds to the JSON schema field "supplementalGroups".
spec.kafka.zookeeper.template.pod.securityContext.sysctls	array	Sysctls corresponds to the JSON schema field "sysctls".
spec.kafka.zookeeper.template.pod.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.zookeeper.template.pod.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.zookeeper.template.pod.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.zookeeper.template.pod.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.zookeeper.template.pod.terminationGracePeriodSeconds	integer	The grace period is the duration in seconds after the processes running in the pod are sent a termination signal, and the time when the processes are forcibly halted with a kill signal. Set this value to longer than the expected cleanup time for your process. Value must be a non-negative integer. A zero value indicates delete immediately. You might need to increase the grace period for very large Kafka clusters, so that the Kafka brokers have enough time to transfer their work to another broker before they are terminated. Defaults to 30 seconds.
spec.kafka.zookeeper.template.pod.tolerations	array	The pod's tolerations.
spec.kafka.zookeeper.template.pod.topologySpreadConstraints	array	The pod's topology spread constraints.
spec.kafka.zookeeper.template.podDisruptionBudget	object	Template for ZooKeeper **`PodDisruptionBudget`**.
spec.kafka.zookeeper.template.podDisruptionBudget.maxUnavailable	integer	Maximum number of unavailable pods to allow automatic Pod eviction. A Pod eviction is allowed when the **`maxUnavailable`** number of pods or fewer are unavailable after the eviction. Setting this value to 0 prevents all voluntary evictions, so the pods must be evicted manually. Defaults to 1.
spec.kafka.zookeeper.template.podDisruptionBudget.metadata	object	Metadata to apply to the **`PodDistruptionBugetTemplate`** resource.

Property	Type	Description
spec.kafka.zookeeper.template.podDisruptionBudget.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.podDisruptionBudget.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.statefulset	object	Template for ZooKeeper **`StatefulSet`**.
spec.kafka.zookeeper.template.statefulset.metadata	object	Metadata applied to the resource.
spec.kafka.zookeeper.template.statefulset.metadata.annotations	object	Annotations added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.statefulset.metadata.labels	object	Labels added to the resource template. Can be applied to different resources such as **`StatefulSets`**, **`Deployments`**, **`Pods`**, and **`Services`**.
spec.kafka.zookeeper.template.statefulset.podManagementPolicy	string	PodManagementPolicy which will be used for this StatefulSet. Valid values are **`Parallel`** and **`OrderedReady`**. Defaults to **`Parallel`**.
spec.kafka.zookeeper.template.tlsSidecarContainer	object	Template for the Zookeeper server TLS sidecar container. The TLS sidecar is not used anymore and this option will be ignored.
spec.kafka.zookeeper.template.tlsSidecarContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext	object	Security context for the container.
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".

Property	Type	Description
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.zookeeper.template.tlsSidecarContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.zookeeper.template.zookeeperContainer	object	Template for the ZooKeeper container.

Property	Type	Description
spec.kafka.zookeeper.template.zookeeperContainer.env	array	Environment variables which should be applied to the container.
spec.kafka.zookeeper.template.zookeeperContainer.securityContext	object	Security context for the container.
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.allowPrivilegeEscalation	boolean	AllowPrivilegeEscalation corresponds to the JSON schema field "allowPrivilegeEscalation".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.capabilities	object	Capabilities corresponds to the JSON schema field "capabilities".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.capabilities.add	array	Add corresponds to the JSON schema field "add".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.capabilities.drop	array	Drop corresponds to the JSON schema field "drop".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.privileged	boolean	Privileged corresponds to the JSON schema field "privileged".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.procMount	string	ProcMount corresponds to the JSON schema field "procMount".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.readOnlyRootFilesystem	boolean	ReadOnlyRootFilesystem corresponds to the JSON schema field "readOnlyRootFilesystem".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.runAsGroup	integer	RunAsGroup corresponds to the JSON schema field "runAsGroup".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.runAsNonRoot	boolean	RunAsNonRoot corresponds to the JSON schema field "runAsNonRoot".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.runAsUser	integer	RunAsUser corresponds to the JSON schema field "runAsUser".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.seLinuxOptions	object	SeLinuxOptions corresponds to the JSON schema field "seLinuxOptions".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.seLinuxOptions.level	string	Level corresponds to the JSON schema field "level".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.seLinuxOptions.role	string	Role corresponds to the JSON schema field "role".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.seLinuxOptions.type	string	Type corresponds to the JSON schema field "type".

Property	Type	Description
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.seLinuxOptions.user	string	User corresponds to the JSON schema field "user".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.seccompProfile	object	SeccompProfile corresponds to the JSON schema field "seccompProfile".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.seccompProfile.localhostProfile	string	LocalhostProfile corresponds to the JSON schema field "localhostProfile".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.seccompProfile.type	string	Type corresponds to the JSON schema field "type".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.windowsOptions	object	WindowsOptions corresponds to the JSON schema field "windowsOptions".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.windowsOptions.gmsaCredentialSpec	string	GmsaCredentialSpec corresponds to the JSON schema field "gmsaCredentialSpec".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.windowsOptions.gmsaCredentialSpecName	string	GmsaCredentialSpecName corresponds to the JSON schema field "gmsaCredentialSpecName".
spec.kafka.zookeeper.template.zookeeperContainer.securityContext.windowsOptions.runAsUserName	string	RunAsUserName corresponds to the JSON schema field "runAsUserName".
spec.kafka.zookeeper.tlsSidecar	object	TLS sidecar configuration. The TLS sidecar is not used anymore and this option will be ignored.
spec.kafka.zookeeper.tlsSidecar.image	string	The docker image for the container.
spec.kafka.zookeeper.tlsSidecar.livenessProbe	object	Pod liveness checking.
spec.kafka.zookeeper.tlsSidecar.livenessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.zookeeper.tlsSidecar.livenessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.zookeeper.tlsSidecar.livenessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.zookeeper.tlsSidecar.livenessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.zookeeper.tlsSidecar.livenessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.zookeeper.tlsSidecar.logLevel	string	The log level for the TLS sidecar. Default value is **`notice`**.
spec.kafka.zookeeper.tlsSidecar.readinessProbe	object	Pod readiness checking.

Property	Type	Description
spec.kafka.zookeeper.tlsSidecar.readinessProbe.failureThreshold	integer	Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.
spec.kafka.zookeeper.tlsSidecar.readinessProbe.initialDelaySeconds	integer	The initial delay before first the health is first checked. Default to 15 seconds. Minimum value is 0.
spec.kafka.zookeeper.tlsSidecar.readinessProbe.periodSeconds	integer	How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.
spec.kafka.zookeeper.tlsSidecar.readinessProbe.successThreshold	integer	Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness. Minimum value is 1.
spec.kafka.zookeeper.tlsSidecar.readinessProbe.timeoutSeconds	integer	The timeout for each attempted health check. Default to 5 seconds. Minimum value is 1.
spec.kafka.zookeeper.tlsSidecar.resources	object	CPU and memory resources to reserve.
spec.kafka.zookeeper.tlsSidecar.resources.limits	object	Limits corresponds to the JSON schema field "limits".
spec.kafka.zookeeper.tlsSidecar.resources.requests	object	Requests corresponds to the JSON schema field "requests".
spec.kafka.zookeeper.tolerations	array	The pod's tolerations.
spec.kafkaAccessSecret	string	KafkaAccessSecret when set will configure the application to use the provided kafka credentials instead of deploying its own.
spec.license	object	LicenseAccept is used to accept the license agreement
spec.license.accept	boolean	(No Description)
spec.postgres	object	Postgres property
spec.postgres.accessSecret	string	Access secret name that contains the Postgres service name and port, username, password, and CA certificate.
spec.size	string	(No Description)
spec.storageClass	string	StorageClass is the storage class used for PVCs. If not set it will fall back to the cluster default when available.

status

Description: CommonStatus that can be used with StatusUpdater

Type: object

Table 1. Description of AIOpsEdge/v1beta1 status

Property	Type	Description
status	object	CommonStatus that can be used with StatusUpdater
status.conditions	array	(No Description)
status.observedGeneration	integer	(No Description)
status.phase	string	(No Description)
status.resources	object	Resources contained in status

Type: object

Table 1. Description of AIOpsUI/v1 spec

Property	Type	Description
spec	object	(No Description)

Property	Type	Description
spec.configuration	object	Additional configuration for the UI deployment
spec.configuration.topologyModel	string	TopologyModel - Specify the terminology to use in CP4WAIOps when defining collections of topology resource groups. Valid values are "application" or "service". If this setting is not specified, the default value will be "application".
spec.container	object	ContainerSpec - possible configurations around containers
spec.container.applicationUiApi	object	(No Description)
spec.container.applicationUiApi.container	object	ContainerSpec - possible configurations around containers
spec.container.applicationUiApi.container.containerPort	integer	(No Description)
spec.container.applicationUiApi.container.env	array	(No Description)
spec.container.applicationUiApi.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.applicationUiApi.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.applicationUiApi.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.applicationUiApi.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.applicationUiApi.image	object	ImageSpec - specification around how to pull an image.
spec.container.applicationUiApi.image.path	string	(No Description)
spec.container.applicationUiApi.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.container.applicationUiApi.image.pullSecret	string	(No Description)
spec.container.applicationUiApi.tlsSecretName	string	(No Description)
spec.container.containerPort	integer	(No Description)
spec.container.env	array	(No Description)
spec.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiApi	object	(No Description)
spec.container.uiApi.container	object	ContainerSpec - possible configurations around containers
spec.container.uiApi.container.containerPort	integer	(No Description)
spec.container.uiApi.container.env	array	(No Description)
spec.container.uiApi.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.uiApi.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.uiApi.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiApi.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/

Property	Type	Description
spec.container.uiApi.image	object	ImageSpec - specification around how to pull an image.
spec.container.uiApi.image.path	string	(No Description)
spec.container.uiApi.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.container.uiApi.image.pullSecret	string	(No Description)
spec.container.uiApi.tlsSecretName	string	(No Description)
spec.container.uiBundleApi	object	(No Description)
spec.container.uiBundleApi.container	object	ContainerSpec - possible configurations around containers
spec.container.uiBundleApi.container.containerPort	integer	(No Description)
spec.container.uiBundleApi.container.env	array	(No Description)
spec.container.uiBundleApi.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.uiBundleApi.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.uiBundleApi.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiBundleApi.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiBundleApi.image	object	ImageSpec - specification around how to pull an image.
spec.container.uiBundleApi.image.path	string	(No Description)
spec.container.uiBundleApi.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.container.uiBundleApi.image.pullSecret	string	(No Description)
spec.container.uiBundleApi.tlsSecretName	string	(No Description)
spec.container.uiContent	object	(No Description)
spec.container.uiContent.container	object	ContainerSpec - possible configurations around containers
spec.container.uiContent.container.containerPort	integer	(No Description)
spec.container.uiContent.container.env	array	(No Description)
spec.container.uiContent.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.uiContent.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims,that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.uiContent.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiContent.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiContent.image	object	ImageSpec - specification around how to pull an image.
spec.container.uiContent.image.path	string	(No Description)
spec.container.uiContent.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.container.uiContent.image.pullSecret	string	(No Description)

Property	Type	Description
spec.container.uiContent.tlsSecretName	string	(No Description)
spec.container.uiServer	object	(No Description)
spec.container.uiServer.container	object	ContainerSpec - possible configurations around containers
spec.container.uiServer.container.containerPort	integer	(No Description)
spec.container.uiServer.container.env	array	(No Description)
spec.container.uiServer.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.uiServer.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container.This is an alpha field and requires enabling the DynamicResourceAllocation feature gate.This field is immutable. It can only be set for containers.
spec.container.uiServer.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiServer.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiServer.image	object	ImageSpec - specification around how to pull an image.
spec.container.uiServer.image.path	string	(No Description)
spec.container.uiServer.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.container.uiServer.image.pullSecret	string	(No Description)
spec.container.uiServer.tlsSecretName	string	(No Description)
spec.elasticSearch	object	Contact details for ElasticSearch
spec.elasticSearch.bindingSecret	string	Data store binding secret
spec.image	object	ImageSpec - specification around how to pull an image.
spec.image.path	string	(No Description)
spec.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.image.pullSecret	string	(No Description)
spec.license	object	License - license spec determines whether a license has been accepted
spec.license.accept	boolean	License acceptance switch
spec.name	string	Name of the service being deployed
spec.redis	object	Name of the service being deployed
spec.redis.bindingSecret	string	Data store binding secret
spec.replicas	integer	(No Description)
spec.size	string	(No Description)
spec.tlsSecretName	string	(No Description)
spec.version	string	Version of the csv deploying
spec.zenserviceName	string	name of the zenservice cr that is used for this deployment

status

Description: (No Description)

Type: object

Table 1. Description of AIOpsUI/v1 status

Property	Type	Description
status	object	(No Description)
status.conditions	array	(No Description)
status.managedResources	array	(No Description)
status.phase	string	(No Description)
status.versions	object	(No Description)
status.versions.reconciled	string	(No Description)

AIOpsUIExtension/v1

AIOpsUIExtension is the Schema for the aiopsuiextensions API

spec

Description: AIOpsUIExtensionSpec defines the desired state of AIOpsUIExtension

Type: object

Table 1. Description of AIOpsUIExtension/v1 spec

Property	Type	Description
spec	object	AIOpsUIExtensionSpec defines the desired state of AIOpsUIExtension
spec.menuRoutes	(No Type)	MenuRoutes contains menu configurations, that will be mapped to the formats required by Zen and Akora.
spec.routes	(No Type)	Routes contains page configuration and bundle configurations.

status

Description: (No Description)

Type: object

Table 1. Description of AIOpsUIExtension/v1 status

Property	Type	Description
status	object	(No Description)
status.conditions	array	(No Description)
status.managedResources	array	(No Description)
status.phase	string	(No Description)
status.versions	object	(No Description)
status.versions.reconciled	string	(No Description)

AIManager/v1beta1

AIManager Deploys the IBM AIOps AI Manager service components of IBM Cloud Pak for AIOps. For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.

spec

Description: AIManagerSpec defines the desired state of AIManager

Type: object

Table 1. Description of AIManager/v1beta1 spec

Property	Type	Description
spec	object	AIManagerSpec defines the desired state of AIManager
spec.aimanagerValues	object	Plumbing Values Override (hidden)
spec.cartridge	object	Cartridge Name
spec.cartridge.name	string	Cartridge Name
spec.certificates	object	Certificates contains information required to create and trust certificates for internal TLS communication.
spec.certificates.caConfigMapKey	string	Key in the ConfigMap identified by caConfigMapName that contains root certificates to be trusted for internal TLS.
spec.certificates.caConfigMapName	string	Name of the ConfigMap that contains root certificates to be trusted for internal TLS.
spec.certificates.issuer	string	Name of the cert-manager.io/Issuer that will be used to create TLS certificates.
spec.chatOpsDisabled	boolean	ChatOpsDisabled (hidden)
spec.chatopsAuthentication	object	ChatopsAuthentication (hidden)
spec.chatopsAuthentication.configmapName	string	(No Description)
spec.chatopsAuthentication.secretName	string	(No Description)
spec.debug	object	Debug Options (hidden)
spec.debug.devPullSecrets	array	(No Description)
spec.debug.disableAIManager	boolean	(No Description)
spec.debug.disableElastic	boolean	(No Description)
spec.debug.disableKafka	boolean	(No Description)

Property	Type	Description
spec.debug.disableModeltrain	boolean	Note: this element is no longer used and should be removed in the next major version of this API
spec.debug.disableZen	boolean	(No Description)
spec.debug.enableCustomSCC	boolean	(No Description)
spec.debug.useDockerIOForKafka	boolean	(No Description)
spec.directFlink	boolean	(No Description)
spec.elasticsearch	object	Elastic Search
spec.elasticsearch.elasticSuperuserSecretName	string	ElasticUserSecretName
spec.elasticsearch.elasticUserSecretName	string	ElasticUserSecretName
spec.eventProcessor	object	Event Processor
spec.eventProcessor.name	string	Event Processor Name
spec.existingPullSecret	object	Existing Pull Secret
spec.existingPullSecret.name	string	Secret Name
spec.flink	object	Flink
spec.flink.secretName	string	Flink Secret Name
spec.integratorProxy	object	Integrator Proxy Config Properties
spec.integratorProxy.enabled	boolean	A proxy outgoing Chatops routes through.
spec.integratorProxy.proxyRoute	string	(No Description)
spec.kafka	object	Kafka
spec.kafka.secretName	string	Kafka Secret Name
spec.license	object	Please accept the licenses to allow for installation
spec.license.accept	boolean	I have read and accept the license: https://ibm.biz/cp4aiops-460-license
spec.logAnomaly	object	LogAnomalyDetectorConfig (hidden)
spec.logAnomaly.limits	object	(No Description)
spec.logAnomaly.limits.cpu	string	(No Description)
spec.logAnomaly.limits.memory	string	(No Description)
spec.logAnomaly.replicas	integer	(No Description)
spec.logAnomaly.requests	object	(No Description)
spec.logAnomaly.requests.cpu	string	(No Description)
spec.logAnomaly.requests.memory	string	(No Description)
spec.logAnomaly.serverPools	integer	(No Description)
spec.logAnomalyDisabled	boolean	LogAnomalyDisabled (hidden)
spec.minio	object	Minio Properties
spec.minio.customSizing	object	MinioCustomResources (hidden)
spec.minio.customSizing.limits	object	(No Description)
spec.minio.customSizing.limits.cpu	string	(No Description)
spec.minio.customSizing.limits.memory	string	(No Description)
spec.minio.customSizing.replicas	integer	(No Description)
spec.minio.customSizing.requests	object	(No Description)
spec.minio.customSizing.requests.cpu	string	(No Description)
spec.minio.customSizing.requests.memory	string	(No Description)
spec.minio.customSizing.serverPools	integer	(No Description)
spec.minio.storage	object	The Minio storage options
spec.minio.storage.storageClassName	string	The StorageClassName
spec.minio.storage.storageSize	string	The Size of Storage (format example "100Gi")
spec.modelTrain	object	Model Train Properties
spec.modelTrain.maxLearners	integer	Maximum number of training to run at once
spec.modelTrain.pollInterval	integer	Poll Interval for the Queue
spec.modelTrain.sizeLimit	integer	Size Limit for the Queue
spec.postgresDB	object	Postgres Database Instance Properties
spec.postgresDB.edbSecretName	string	EDB Postgresql Database Connection Secret Name
spec.postgresDB.secretName	string	Postgresql Database Connection Secret Name
spec.redis	object	Redis
spec.redis.bindingSecretName	string	Redis Binding Secret Name
spec.repo	string	The private registry to pull images from instead of cp.icr.io. Leave blank if a private registry is not used. All images must be pushed to repo via mirroring.
spec.size	string	Preconfigured HA Sizing Options
spec.storage	object	The storage options
spec.storage.enabled	boolean	Enable Storage

Property	Type	Description
spec.storage.storageClassName	string	The StorageClassName
spec.ticketAnalysisDisabled	boolean	TicketAnalysisDisabled (hidden)
spec.version	string	Version
spec.zen	object	The Zen options
spec.zen.deploy	boolean	Flag to deploy our own cpd in the same namespace as aimanager
spec.zen.ignoreReady	boolean	Flag to deploy zen customization even if not in ready state
spec.zen.instanceId	string	ID of Zen Service Instance
spec.zen.serviceInstanceName	string	Name of the ZenService Instance object
spec.zen.serviceNamespace	string	Namespace of the ZenService Instance
spec.zen.storage	object	The Zen storage options
spec.zen.storage.storageClassNam e	string	The StorageClassName

status

Description: AIManagerStatus defines the observed state of AIManager

Type: object

Table 1. Description of AIManager/v1beta1 status

Property	Type	Description
status	object	AIManagerStatus defines the observed state of AIManager
status.message	string	Status information from AIManager
status.phase	string	Current phase of AIManager.
status.versions	object	Information on versions for AI Manager
status.versions.available	object	Available properties
status.versions.available.versions	array	Possible available versions for AI Manager
status.versions.reconciled	string	Current version of the reconciled instance

Algorithm/v1alpha1

Algorithm is the Schema for the algorithms API

spec

Description: AlgorithmSpec defines the desired state of Algorithm

Type: object

Table 1. Description of Algorithm/v1alpha1 spec

Property	Type	Description
spec	object	AlgorithmSpec defines the desired state of Algorithm
spec.description	string	(No Description)
spec.enabled	boolean	(No Description)
spec.manifestBase64	string	(No Description)
spec.name	string	(No Description)
spec.registered	boolean	(No Description)
spec.runtime	string	(No Description)
spec.usedStatus	array	(No Description)
spec.version	string	(No Description)

status

Description: AlgorithmStatus defines the observed state of Algorithm

Type: object

Table 1. Description of Algorithm/v1alpha1 status

Property	Type	Description
status	object	AlgorithmStatus defines the observed state of Algorithm

Algorithm/v1beta1

Algorithm is the Schema for the algorithms API

spec

Description: AlgorithmSpec defines the desired state of Algorithm

Type: object

Table 1. Description of Algorithm/v1beta1 spec

Property	Type	Description
spec	object	AlgorithmSpec defines the desired state of Algorithm
spec.description	string	(No Description)
spec.enabled	boolean	(No Description)
spec.manifestBase64	string	(No Description)
spec.name	string	(No Description)
spec.registered	boolean	(No Description)
spec.runtime	string	(No Description)
spec.usedStatus	array	(No Description)
spec.version	string	(No Description)

status

Description: AlgorithmStatus defines the observed state of Algorithm

Type: object

Table 1. Description of Algorithm/v1beta1 status

Property	Type	Description
status	object	AlgorithmStatus defines the observed state of Algorithm

ASM/v1beta1

spec

Description: ASMSpec defines the desired state of ASM

Type: object

Table 1. Description of ASM/v1beta1 spec

Property	Type	Description
spec	object	ASMSpec defines the desired state of ASM
spec.advanced	object	Advanced image properties
spec.advanced.imagePullPolicy	string	The default pull policy is IfNotPresent, which causes the Kubelet to skip pulling an image that already exists.
spec.advanced.imagePullRepository	string	Docker registry that all component images are pulled from
spec.asm	object	Topology components
spec.asm.aaionap	boolean	Do you want to deploy AAI ONAP Service
spec.asm.almObserver	boolean	Do you want to deploy ALM Observer
spec.asm.ansibleawxObserver	boolean	Do you want to deploy Ansible AWX Observer
spec.asm.appDisco	object	Application Discovery properties
spec.asm.appDisco.caCertProperty	string	Cert Property
spec.asm.appDisco.caCertSecret	string	Cert Secret
spec.asm.appDisco.caKeyProperty	string	Key Property
spec.asm.appDisco.certSecret	string	DB2 Certificate Secret
spec.asm.appDisco.dbsecret	string	DB2 secret
spec.asm.appDisco.dburl	string	DB2 host to connect
spec.asm.appDisco.enabled	boolean	Enable Application Discovery and Application Discovery Observer
spec.asm.appDisco.scaleDS	integer	(No Description)
spec.asm.appDisco.scaleSSS	integer	(No Description)
spec.asm.appDisco.secure	boolean	Secure DB connection
spec.asm.appDisco.tlsSecret	string	(No Description)
spec.asm.appdynamicsObserver	boolean	Do you want to deploy AppDynamics Observer
spec.asm.awsObserver	boolean	Do you want to deploy AWS Observer
spec.asm.azureObserver	boolean	Do you want to deploy Microsoft Azure Observer
spec.asm.bigcloudfabricObserver	boolean	Do you want to deploy BigCloud Fabric Observer

Property	Type	Description
spec.asm.bigfixinventoryObserver	boolean	Do you want to deploy BigFix Inventory Observer
spec.asm.cienablueplanetObserver	boolean	Do you want to deploy Ciena Blue Planet Observer
spec.asm.ciscoaciObserver	boolean	Do you want to deploy Cisco ACI Observer
spec.asm.contrailObserver	boolean	Do you want to deploy Juniper Contrail Observer
spec.asm.datadogObserver	boolean	Do you want to deploy Datadog Observer
spec.asm.dnsObserver	boolean	Do you want to deploy DNS Observer
spec.asm.dockerObserver	boolean	Do you want to deploy Docker Observer
spec.asm.dynatraceObserver	boolean	Do you want to deploy Dynatrace Observer
spec.asm.fileObserver	boolean	Do you want to deploy File Observer
spec.asm.gitlabObserver	boolean	Do you want to deploy GitLab Observer
spec.asm.googlecloudObserver	boolean	Do you want to deploy Google Cloud Platform Observer
spec.asm.hpnfvdObserver	boolean	Do you want to deploy HPNFVD Observer
spec.asm.iafCartridgeRequirementsName	string	IAF CartridgeRequirements Instance Name for connection to IAF ElasticSearch
spec.asm.iafElasticBindingSecret	string	IAF ElasticSearch Binding Secret for connection to IAF ElasticSearch
spec.asm.iafKafkaBindingSecret	string	IAF Kafka Binding Secret for connection to IAF Kafka
spec.asm.ibmcloudObserver	boolean	Do you want to deploy IBM Cloud Observer (default = false)
spec.asm.itnmObserver	boolean	Do you want to deploy ITNM Observer
spec.asm.jenkinsObserver	boolean	Do you want to deploy Jenkins Observer
spec.asm.junipercsoObserver	boolean	Do you want to deploy Juniper Networks CSO Observer
spec.asm.kubernetesObserver	boolean	Do you want to deploy Kubernetes Observer (default = true)?
spec.asm.netDisco	boolean	Do you want to deploy Network Discovery and Network Discovery Observer
spec.asm.newrelicObserver	boolean	Do you want to deploy New Relic Observer
spec.asm.openstackObserver	boolean	Do you want to deploy OpenStack Observer
spec.asm.rancherObserver	boolean	Do you want to deploy Rancher Observer
spec.asm.restObserver	boolean	Do you want to deploy REST Observer
spec.asm.sdconapObserver	boolean	Do you want to deploy SDC ONAP Observer
spec.asm.servicenowObserver	boolean	Do you want to deploy ServiceNow Observer
spec.asm.sevoneObserver	boolean	Do you want to deploy SevOne Observer
spec.asm.taddmObserver	boolean	Do you want to deploy TADDM Observer
spec.asm.userServiceUrl	string	CEM User Service Url connection
spec.asm.viptelaObserver	boolean	Do you want to deploy Viptela Observer
spec.asm.vmvcenterObserver	boolean	Do you want to deploy VMware VCenter Observer
spec.asm.vmwarensxObserver	boolean	Do you want to deploy VMware NSX Observer
spec.asm.zabbixObserver	boolean	Do you want to deploy Zabbix Observer
spec.clusterDomain	string	Use the fully qualified domain name (FQDN) to specify the cluster domain: apps. ...com
spec.deploymentType	string	Deployment type (small or large)
spec.entitlementSecret	string	Entitlment secret to pull images
spec.helmValuesASM	object	(Not shown within UI)
spec.ingress	object	Vanilla Kube (Not shown within UI)
spec.ingress.port	string	(No Description)
spec.ingress.prefixWithReleaseName	boolean	(No Description)
spec.ingress.tlsSecret	string	(No Description)
spec.license	object	License properties
spec.license.accept	boolean	If you have purchased IBM Cloud Pak for AIOps, you must read and accept this license: https://ibm.biz/cp4aiops-460-license.
spec.persistence	object	Persistence properties
spec.persistence.enabled	boolean	Enable persistence storage
spec.persistence.storageClass	string	Storage Class
spec.persistence.storageSizeCassandraBackup	string	Storage Size Cassandra Backup
spec.persistence.storageSizeCassandraData	string	Storage Size Cassandra Data
spec.persistence.storageSizeElastic	string	Storage Size Elasticsearch
spec.persistence.storageSizeFileObserver	string	Storage size File Observer .
spec.persistence.storageSizeKafka	string	Storage Size Kafka
spec.persistence.storageSizeSdconapObserver	string	Storage Size SDCONAP Observer
spec.persistence.storageSizeZookeeper	string	Storage Size Zookeeper
spec.version	string	Version
spec.zen	object	The Zen Parameters
spec.zen.deploy	boolean	Flag to deploy our own cpd in the same namespace as aimanager
spec.zen.ignoreReady	boolean	Flag to deploy zen customization even if not in ready state

Property	Type	Description
spec.zen.instanceId	string	ID of Zen Service Instance
spec.zen.serviceInstanceName	string	Name of the ZenService Instance object
spec.zen.serviceNamespace	string	Namespace of the ZenService Instance
spec.zen.storage	object	The Zen storage options
spec.zen.storage.storageClassName	string	The StorageClassName

status

Description: (No Description)

Type: object

Table 1. Description of ASM/v1beta1 status

Property	Type	Description
status	object	(No Description)
status.conditions	array	(No Description)
status.managedResources	array	Resources managed by Netcool Agile Service Manager
status.message	string	(No Description)
status.phase	string	Current phase of installed full Cloud deployment.
status.versions	object	Information on versions for Agile Service Manager
status.versions.available	object	(No Description)
status.versions.available.versions	array	Possible available versions for Agile Service Manager
status.versions.reconciled	string	Current version of the reconciled instance

BaseUI/v1

For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.

spec

Description: (No Description)

Type: object

Table 1. Description of BaseUI/v1 spec

Property	Type	Description
spec	object	(No Description)
spec.bedrockVersion	string	(No Description)
spec.certificates	object	Certificates contains information required to create and trust certificates for internal TLS communication.
spec.certificates.caConfigMapKey	string	Key in the ConfigMap identified by caConfigMapName that contains root certificates to be trusted for internal TLS.
spec.certificates.caConfigMapName	string	Name of the ConfigMap that contains root certificates to be trusted for internal TLS.
spec.certificates.issuer	string	Name of the cert-manager.io/Issuer that will be used to create TLS certificates.
spec.configuration	object	Additional configuration for the UI deployment
spec.configuration.topologyModel	string	TopologyModel - Specify the terminology to use in CP4WAIOps when defining collections of topology resource groups. Valid values are "application" or "service". If this setting is not specified, the default value will be "application".
spec.container	object	ContainerSpec - possible configurations around containers
spec.container.containerPort	integer	(No Description)
spec.container.env	array	(No Description)
spec.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/

Property	Type	Description
spec.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.image	object	ImageSpec - specification around how to pull an image.
spec.image.path	string	(No Description)
spec.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.image.pullSecret	string	(No Description)
spec.license	object	License - license spec determines whether a license has been accepted
spec.license.accept	boolean	License acceptance switch
spec.modules	object	Modules is a list of module settings for the operator. This value will be default for 4.6.x and will eventually be required.
spec.modules.logs	object	(No Description)
spec.modules.logs.enabled	boolean	Enabled toggles the module as enabled or disabled, by default modules are enabled
spec.name	string	Name of the service being deployed
spec.replicas	integer	(No Description)
spec.size	string	(No Description)
spec.tlsSecretName	string	(No Description)
spec.version	string	Version of the csv deploying
spec.zenserviceName	string	name of the zenservice cr that is used for this deployment

status

Description: (No Description)

Type: object

Table 1. Description of BaseUI/v1 status

Property	Type	Description
status	object	(No Description)
status.conditions	array	(No Description)
status.managedResources	array	(No Description)
status.phase	string	(No Description)
status.versions	object	(No Description)
status.versions.reconciled	string	(No Description)

BundleManifest/v1alpha1

BundleManifest is the Schema for the bundlemanifests API

spec

Description: BundleManifestSpec defines the desired state of BundleManifest

Type: object

Table 1. Description of BundleManifest/v1alpha1 spec

Property	Type	Description
spec	object	BundleManifestSpec defines the desired state of BundleManifest
spec.instanced	object	GitAppSpec defines the desired state of GitApp
spec.instanced.authSecret	object	AuthSecret is the name of the secret containing credentials for Basic-Auth in the username and password keys
spec.instanced.authSecret.name	string	Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names TODO: Add other useful fields. apiVersion, kind, uid?
spec.instanced.branch	string	Branch to checkout
spec.instanced.certSecret	object	CertSecret is the name of the secret containing the ca.crt needed to access the repo if the origin uses a self-signed certificate
spec.instanced.certSecret.name	string	Name of the referent. More info: https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names TODO: Add other useful fields. apiVersion, kind, uid?
spec.instanced.components	array	(No Description)

Property	Type	Description

ConnectorUI/v1

For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.

spec

Description: CommonSpecs - specs that are common to determining a deployment.

Type: object

Table 1. Description of ConnectorUI/v1 spec

Property	Type	Description
spec	object	CommonSpecs - specs that are common to determining a deployment.
spec.configuration	object	Additional configuration for the UI deployment
spec.configuration.topologyModel	string	TopologyModel - Specify the terminology to use in CP4WAIOps when defining collections of topology resource groups. Valid values are "application" or "service". If this setting is not specified, the default value will be "application".
spec.container	object	ContainerSpec - possible configurations around containers
spec.container.containerPort	integer	(No Description)
spec.container.env	array	(No Description)
spec.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.image	object	ImageSpec - specification around how to pull an image.
spec.image.path	string	(No Description)
spec.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.image.pullSecret	string	(No Description)
spec.license	object	License - license spec determines whether a license has been accepted
spec.license.accept	boolean	License acceptance switch
spec.name	string	Name of the service being deployed
spec.replicas	integer	(No Description)
spec.size	string	(No Description)
spec.tlsSecretName	string	(No Description)
spec.version	string	Version of the csv deploying

Property	Type	Description
spec.zenserviceName	string	name of the zenservice cr that is used for this deployment

status

Description: (No Description)

Type: object

Table 1. Description of ConnectorUI/v1 status

Property	Type	Description

status.phase	string	(No Description)
status.versions	object	(No Description)
status.versions.reconciled	string	(No Description)

InsightsUI/v1

For documentation regarding install parameters, see IBM Documentation. By installing this product you accept the license terms.

spec

Description: (No Description)

Type: object

Table 1. Description of InsightsUI/v1 spec

Property	Type	Description
spec	object	(No Description)
spec.asm	object	Contact details for ASM
spec.asm.bindingSecret	string	Data store binding secret
spec.configuration	object	Additional configuration for the UI deployment
spec.configuration.topologyModel	string	TopologyModel - Specify the terminology to use in CP4WAIOps when defining collections of topology resource groups. Valid values are "application" or "service". If this setting is not specified, the default value will be "application".
spec.container	object	ContainerSpec - possible configurations around containers
spec.container.containerPort	integer	(No Description)
spec.container.datarouter	object	(No Description)
spec.container.datarouter.containerPort	integer	(No Description)
spec.container.datarouter.env	array	(No Description)
spec.container.datarouter.image	object	ImageSpec - specification around how to pull an image.
spec.container.datarouter.image.path	string	(No Description)
spec.container.datarouter.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.container.datarouter.image.pullSecret	string	(No Description)
spec.container.datarouter.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.datarouter.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.

Property	Type	Description
spec.container.datarouter.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.datarouter.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.datarouter.tlsSecretName	string	(No Description)
spec.container.env	array	(No Description)
spec.container.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.ui	object	(No Description)
spec.container.ui.containerPort	integer	(No Description)
spec.container.ui.env	array	(No Description)
spec.container.ui.image	object	ImageSpec - specification around how to pull an image.
spec.container.ui.image.path	string	(No Description)
spec.container.ui.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.container.ui.image.pullSecret	string	(No Description)
spec.container.ui.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.ui.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.ui.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.ui.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.ui.tlsSecretName	string	(No Description)
spec.container.uiApi	object	(No Description)
spec.container.uiApi.containerPort	integer	(No Description)
spec.container.uiApi.env	array	(No Description)
spec.container.uiApi.image	object	ImageSpec - specification around how to pull an image.
spec.container.uiApi.image.path	string	(No Description)
spec.container.uiApi.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.container.uiApi.image.pullSecret	string	(No Description)
spec.container.uiApi.resources	object	ResourceRequirements describes the compute resource requirements.
spec.container.uiApi.resources.claims	array	Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container. This is an alpha field and requires enabling the DynamicResourceAllocation feature gate. This field is immutable. It can only be set for containers.
spec.container.uiApi.resources.limits	object	Limits describes the maximum amount of compute resources allowed. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/

Property	Type	Description
spec.container.uiApi.resources.requests	object	Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/
spec.container.uiApi.tlsSecretName	string	(No Description)
spec.demodatasets	array	(No Description)
spec.elasticSearch	object	Contact details for ElasticSearch
spec.elasticSearch.bindingSecret	string	Data store binding secret
spec.image	object	ImageSpec - specification around how to pull an image.
spec.image.path	string	(No Description)
spec.image.pullPolicy	string	PullPolicy describes a policy for if/when to pull a container image
spec.image.pullSecret	string	(No Description)
spec.kafka	object	Contact details for Kafka
spec.kafka.bindingSecret	string	Data store binding secret
spec.license	object	License - license spec determines whether a license has been accepted
spec.license.accept	boolean	License acceptance switch
spec.name	string	Name of the service being deployed
spec.postgres	object	Contact details for postgres
spec.postgres.bindingSecret	string	Data store binding secret
spec.replicas	integer	(No Description)
spec.size	string	(No Description)
spec.tlsSecretName	string	(No Description)
spec.version	string	Version of the csv deploying
spec.zenserviceName	string	name of the zenservice cr that is used for this deployment

Installation/v1alpha1

Leverage advanced, explainable AI to resolve incidents faster, gain visibility into critical workloads, and intelligently manage key application resources. Learn More.
By installing this product you accept the license terms.

spec

Description: For detailed information about the following settings, see the IBM Documentation at https://ibm.biz/cp4aiops_460_install

Type: object

Table 1. Description of Installation/v1alpha1 spec

Property	Type	Description
spec	object	For detailed information about the following settings, see the IBM Documentation at https://ibm.biz/cp4aiops_460_install

Property	Type	Description
spec.automationFoundation	object	AutomationFoundation contains parameters that can be used to customize how the IBM Automation Foundation objects are configured.
spec.automationFoundation.automationBase	string	AutomationBase is the name of the IBM Automation Foundation "AutomationBase" CR instance that the Cloud Pak should use. If a name is not specified, and no "AutomationBase" instances exist in the namespace, the Cloud Pak will attempt to provision one.
spec.automationFoundation.automationUIConfig	string	AutomationUIConfig is the name of the IBM Automation Foundation "AutomationUIConfig" CR instance that the Cloud Pak should use. If a name is not specified, and no "AutomationUIConfig" instances exist in the namespace, the Cloud Pak will attempt to provision one.
spec.automationFoundation.enabled	boolean	The Enabled flag controls whether the Cloud Pak will register with IBM Automation Foundation. The default value is `true`. When the flag is set to `false`, the Cloud Pak will not create any Automation Foundation objects, including those referenced in other parts of the AutomationFoundation spec.
spec.enableConnectionModule	boolean	Use the Secure Tunnel to safely connect to remote data sources.
spec.imagePullSecret	string	Select the image pull secret to use for the Cloud Pak. If no secret is selected, the global pull secret will be used.
spec.installPlanApproval	string	Approval is the user approval policy for an InstallPlan. It must be one of "Automatic" or "Manual".
spec.license	object	License acceptance is required to create resources.
spec.license.accept	boolean	I accept the product license after reading it at https://ibm.biz/cp4aiops-460-license
spec.pakModules	array	Pak Modules are modular pieces that may be enabled for deployment
spec.proxyServer	string	If the target cluster is air-gapped, specify the address and port number of an HTTP proxy that will provide access to the Slack or MS Teams service used for ChatOps, for example, proxy.company.com:8080.
spec.resourceOverrides	string	Specify the name of a configmap that finely tunes the capabilities and capacity of an installation.
spec.size	string	Select a size to determine the amount of virtual resources requested and the level of high availability support.
spec.storageClass	string	Select a file storage class that supports ReadWriteMany access mode.
spec.storageClassLargeBlock	string	Select a storage class with a large block size (for example, 64k).
spec.topologyModel	string	Specify the terminology to use when defining collections of resource groups. You can select application or service.

status

Description: InstallationStatus defines the observed state of Installation

Type: object

Infrastructure Automation custom resource definitions

Use this information to learn about the custom resource definitions (CRDs) used by Infrastructure Automation.

In the following table, CRDs that do not have a hyperlink must not be manually edited unless otherwise instructed, and are manipulated only by the operator.

Table 1. Infrastructure Automation CRDs

Kind	API version	Operator name	Description
IAConfig	v1alpha1	ibm-infrastructure-automation-operator	Build, deploy, and manage VMs and Kubernetes clusters. Enable self-service orchestration of resources across clouds. Learn More.
ManageService	v1alpha1	ibm-management-cam-install	ManageService is the Schema for the manageservices API
ManageIQ	v1alpha1	ibm-management-im-install	ManageIQ is the Schema for the manageiqs API
IMInstall	v1alpha1	ibm-management-im-install	IMInstall is the Schema for the iminstalls API

IAConfig/v1alpha1

Build, deploy, and manage VMs and Kubernetes clusters. Enable self-service orchestration of resources across clouds. Learn More.

spec

Description: IAConfigSpec defines the desired state of IAConfig

Type: object

Table 1. Description of IAConfig/v1alpha1 spec

Property	Type	Description
spec	object	IAConfigSpec defines the desired state of IAConfig
spec.imagePullSecret	string	Select a secret to serve as the ImagePullSecret
spec.infraAutoComposableComponents	array	Enable Infrastructure management (im) and/or Manage services (cam).
spec.license	object	License acceptance is required to create resources.
spec.license.accept	boolean	I accept the product license after reading it at https://ibm.biz/cp4aiops-460-license
spec.skipAutomationBaseStatus	boolean	This field is reserved for support person to use.
spec.skipAutomationUiConfigStatus	boolean	This field is reserved for support person to use.
spec.storageClass	string	Select a storage class that supports ReadWriteMany access mode.
spec.storageClassLargeBlock	string	Select a storage class with a large block size (for example, 64k).

Important: The following fields are deprecated and should not be used in Infrastructure Automation 4.6.0:

- skipAutomationBaseStatus
- skipAutomationUiConfigStatus

status

Description: IAConfigStatus defines the observed state of IAConfig

Type: object

Table 2. Description of IAConfig/v1alpha1 status

Property	Type	Description
status	object	IAConfigStatus defines the observed state of IAConfig
status.failureMessage	string	INSERT ADDITIONAL STATUS FIELD - define observed state of cluster Important: Run "make" to regenerate code after modifying this file
status.phase	string	InstallationPhase describes the phase of the overall Installation
status.storageclass	string	(No Description)
status.storageclasslargeblock	string	(No Description)
status.version	string	(No Description)

ManageService/v1alpha1

ManageService is the Schema for the manageservices API.

spec

Description: ManageServiceSpec defines the desired state of ManageService.

Type: object

Table 1. Description of IAManageService spec

Property	Type	Description	Default

Property	Type	Description	Default
camAPI	object	Configuration for Cloud Automation Manager API microservices	`{"camComposerApi":{"resources":{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}},"camComposerUi":{"resources":{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}},"camIaas":{"resources":{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}},"camMongo":{"resources":{"limits":{"cpu":"500m","memory":"4Gi"},"requests":{"cpu":"100m","memory":"2Gi"}}},"camOrchestration":{"resources":{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}},"camPortalUi":{"resources":{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}},"camProviderTerraformApi":{"resources":{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}},"terraformSSHDir":{"terraformSSHDirSecret":""}},"camSecret":{"secretName":"cam-api-secret"},"camServiceLibraryUi":{"resources":{"limits":{"cpu":"300m","memory":"512Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}},"camServiceLibraryUiAPi":{"resources":{"limits":{"cpu":"100m","memory":"512Mi"},"requests":{"cpu":"50m","memory":"256Mi"}}},"camTenantApi":{"resources":{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}},"camUiBasic":{"resources":{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}},"certificate":{"certName":"cert"},"replicaCount":1}`
camAPI.replicaCount	int	Number of replicas for cam microservices	`1`
camController.replicaCount	int	Number of replicas for Controller	`1`
camLoggingPolicies	object	Configuration for the logging level used with Cloud Automation Manager microservices	`{"logLevel":"info"}`
camLoggingPolicies.logLevel	string	Log Level for logging	`"info"`
camMongoPV	object	MongoDB Persistant Storage	`{"name":"cam-mongo-pv","persistence":{"accessMode":"ReadWriteOnce","enabled":true,"existingClaimName":"","size":"15Gi","storageClassName":"","useDynamicProvisioning":false}}`
camMongoPV.persistence.accessMode	string	Access Mode for Storage	`"ReadWriteOnce"`
camMongoPV.persistence.enabled	bool	Enable persistance	`true`
camMongoPV.persistence.existingClaimName	string	Specify the name of the Existing Claim to be used by your application, empty string means don't use an existClaim	`""`
camMongoPV.persistence.size	string	MongoDB PVC size (in Gi)	`"15Gi"`
camMongoPV.persistence.storageClassName	string	Specify the name of the StorageClass empty string means don't use a StorageClass	`""`
camMongoPV.persistence.useDynamicProvisioning	bool	useDynamicProvisioning for persistence	`false`
camProviderTerraform	object	Configuration for Cloud Automation Manager Provider Terraform	`{"isolateRuntime":false,"replicaCount":1,"runtime":{"replicaCount":0},"terraformSSHDir":{"terraformSSHDirSecret":""}}`

Property	Type	Description	Default
camProviderTerraform.isolateRuntime	bool	Select to enable isolation mode for Provider Terraform runtime. In this mode, the runtime runs in separate pods and have read only access to the cam-terraform-pv.	`false`
camProviderTerraform.replicaCount	int	Number of replicas for camProviderTerraformApi	`1`
camProviderTerraform.runtime	object	Configuration for Cloud Automation Manager Provider Terraform runtime	`{"replicaCount":0}`
camProviderTerraform.runtime.replicaCount	int	Number of replicas for Provider Terraform Runtime. This value is only applicable when camProviderTerraform.isolateRuntime is enabled	`0`
camProviderTerraform.terraformSSHDir	object	Cloud Automation Manager Provider Terraform SSH Directory	`{"terraformSSHDirSecret":""}`
camProviderTerraform.terraformSSHDir.terraformSSHDirSecret	string	Secret name for Cloud Automation Manager Provider Terraform SSH Directory Contents	`""`
camProxy	object	CAM Proxy configuration	`{"customNginxSSLCertificate":{"customNginxSSLCertName":""},"limits":{"cpu":"500m","memory":"1500Mi"},"replicaCount":1,"requests":{"cpu":"100m","memory":"256Mi"},"resources":null}`
camProxy.customNginxSSLCertificate.customNginxSSLCertName	string	Nginx SSL Custom Certificate Secret Name	`""`
camProxy.limits.cpu	string	The CPU limit	`"500m"`
camProxy.limits.memory	string	The memory limit	`"1500Mi"`
camProxy.replicaCount	int	Number of replicas for Proxy	`1`
camProxy.requests.cpu	string	The requested CPU	`"100m"`
camProxy.requests.memory	string	The requested memory	`"256Mi"`
camUI	object	UI Configuration	`{"camUISecret":{"secretName":"cam-ui-secret","sessionKey":"opsConsole.sid","sessionTTL":"43200"},"replicaCount":1}`
camUI.camUISecret	object	User Interface Secret	`{"secretName":"cam-ui-secret","sessionKey":"opsConsole.sid","sessionTTL":"43200"}`
camUI.camUISecret.secretName	string	User interface Secret Name	`"cam-ui-secret"`
camUI.camUISecret.sessionKey	string	Session Key	`"opsConsole.sid"`

Property	Type	Description	Default
camUI.camUISecret.sessionTTL	string	Session timeout in seconds	`"43200"`
camUI.replicaCount	int	Number of replicas for UI	`1`
database	object	Optionally use an external MongoDB	`{"bundled":true}`
database.bundled	bool	Use internal MongoDB. Set to false for external. For more information, see Using an external MongoDB in the IBM Knowledge Center	`true`
license	object	License acceptance	`{"accept":true}`
license.accept	bool	Accept the license to use the product"	`true`
proxy	object	Configuration for a proxy used with Cloud Automation Manager. Supply details in the secure values secret.	`{"useProxy":false}`
proxy.useProxy	bool	Select to use a proxy with CAM and fill out the fields in the Secure Values secret (see the Knowledge Center install instructions for more details)	`false`
resources	object	Amount of memory and CPU to assign to Cloud Automation Manager microservices	`{"limits":{"cpu":"500m","memory":"1500Mi"},"requests":{"cpu":"100m","memory":"256Mi"}}`
resources.limits.cpu	string	The memory limit	`"500m"`
resources.limits.memory	string	The CPU limit	`"1500Mi"`
resources.requests.cpu	string	The requested CPU	`"100m"`
resources.requests.memory	string	The requested memory	`"256Mi"`
roks	bool	Select to indicate it is Red Hat OpenShift on IBM Cloud System	`false`
roksRegion	string	Red Hat OpenShift on IBM Cloud Storage Region selection	`""`
roksZone	string	Red Hat OpenShift on IBM Cloud Storage Zone selection	`""`

IMInstall/v1alpha1

IMInstall is the Schema for the iminstalls API

spec

Description: IMInstallSpec defines the desired state of IMInstall

Type: object

Table 1. Description of IMInstall/v1alpha1 spec

Property	Type	Description
spec	object	IMInstallSpec defines the desired state of IMInstall
spec.appAnnotations	object	Optional Annotations to apply to the Httpd, Kafka, Memcached, Orchestrator and PostgresQL Pods
spec.appName	string	Application name used for deployed objects (default: iminstall)
spec.applicationDomain	string	Domain name for the external route. Used for external authentication configuration
spec.applicationImage	string	Image string used for the infrastructure management application deployment. By default it is based on the olm.relatedImage.application annotation
spec.backupLabelName	string	This label will be applied to essential resources that need to be backed up (default: manageiq.org/backup)
spec.baseWorkerImage	string	Image string used for the base worker deployments By default this is determined by the orchestrator pod
spec.databaseRegion	string	Database region number (default: 0)
spec.databaseSecret	string	Secret containing the database access information, content generated if not provided (default: postgresql-secrets)
spec.databaseVolumeCapacity	string	Database volume size (default: 50Gi)
spec.deployMessagingService	boolean	Deprecated: Flag to indicate if Kafka and Zookeeper should be deployed (default: false)
spec.enableApplicationLocalLogin	boolean	Flag to allow logging into the application without SSO (default: false)
spec.enableSSO	boolean	Flag to enable SSO in the application (default: false)
spec.enforceWorkerResourceConstraints	boolean	Flag to trigger worker resource constraint enforcement (default: true)
spec.httpdAuthConfig	string	Secret containing the httpd configuration files Mutually exclusive with the OIDCClientSecret and OIDCProviderURL if using openid-connect
spec.httpdAuthenticationType	string	Type of httpd authentication (default: internal) Options: internal, external, active-directory, saml, openid-connect Note: external, active-directory, and saml require an httpd container with elevated privileges
spec.httpdCpuLimit	string	Httpd deployment CPU limit (default: 1000m)
spec.httpdCpuRequest	string	Httpd deployment CPU request (default: 50m)
spec.httpdImage	string	Image string used for the httpd deployment (default: os.Getenv("HTTPD_IMAGE"))
spec.httpdImageNamespace	string	Image namespace used for the httpd deployment (default: docker-na-public.artifactory.swg-devops.com/hyc-cp4mcm-team-docker-local/infra-mgmt) Note: the exact image will be determined by the authentication method selected
spec.httpdImageTag	string	Image tag used for the httpd deployment (default: 2-el9)
spec.httpdMemoryLimit	string	Httpd deployment memory limit (default: 200Mi)
spec.httpdMemoryRequest	string	Httpd deployment memory request (default: 100Mi)
spec.imagePullSecret	string	Secret containing the image registry authentication information needed for the manageiq images
spec.initialAdminGroupName	string	Group name to create with the super admin role. This can be used to seed a group when using external authentication
spec.internalCertificatesSecret	string	Secret containing all of the necessary certificates to secure communication between pods (default: internal-certificates-secret)
spec.kafkaCpuRequest	string	Kafka deployment CPU request (default: 250m)
spec.kafkaCpulimit	string	Kafka deployment CPU limit (default: 250m)
spec.kafkaImage	string	Image string used for the kafka deployment (default: os.Getenv("KAFKA_IMAGE"))
spec.kafkaImageName	string	Image used for the kafka deployment (default: docker.io/bitnami/kafka)
spec.kafkaImageTag	string	Image tag used for the kafka deployment (default: latest)

Property	Type	Description
spec.kafkaMemoryLimit	string	Kafka deployment memory limit (default: 1024Mi)
spec.kafkaMemoryRequest	string	Kafka deployment memory request (default: 256Mi)
spec.kafkaSecret	string	Secret containing the kafka access information, content generated if not provided (default: kafka-secrets)
spec.kafkaVolumeCapacity	string	Kafka volume size (default: 1Gi)
spec.license	object	Opt-in license acceptance is required to create resources
spec.license.accept	boolean	Accept is an opt-in license acceptance required to deploy resources
spec.memcachedCpuLimit	string	Memcached deployment CPU limit (default: 1000m)
spec.memcachedCpuRequest	string	Memcached deployment CPU request (default: 50m)
spec.memcachedImage	string	Image string used for the memcached deployment (default: :)
spec.memcachedImageName	string	Image used for the memcached deployment (default: manageiq/memcached)
spec.memcachedImageTag	string	Image tag used for the memcached deployment (default: 1-el9)
spec.memcachedMaxConnection	string	Memcached max simultaneous connections (default: 1024)
spec.memcachedMaxMemory	string	Memcached item memory in megabytes (default: 64)
spec.memcachedMemoryLimit	string	Memcached deployment memory limit (default: 200Mi)
spec.memcachedMemoryRequest	string	Memcached deployment memory request (default: 100Mi)
spec.memcachedSlabPageSize	string	Memcached max item size (default: 1m, min: 1k, max: 1024m)
spec.migrationsRan	array	A list of CR data migrations that have been run
spec.oidcAuthIntrospectionURL	string	URL for OIDC authentication introspection Only used with the openid-connect authentication type. If not specified, the operator will attempt to fetch its value from the "introspection_endpoint" field in the Provider metadata at the OIDCProviderURL provided.
spec.oidcCaCertSecret	string	Secret containing the trusted CA certificate file(s) for the OIDC server. Only used with the openid-connect authentication type
spec.oidcClientSecret	string	Secret name containing the OIDC client id and secret Only used with the openid-connect authentication type
spec.oidcProviderURL	string	URL for the OIDC provider Only used with the openid-connect authentication type
spec.orchestratorCpuLimit	string	Orchestrator deployment CPU limit (default: 1000m)
spec.orchestratorCpuRequest	string	Orchestrator deployment CPU request (default: 200m)
spec.orchestratorImage	string	Image string used for the orchestrator deployment (default: / :)
spec.orchestratorImageName	string	Image name used for the orchestrator deployment (default: infra-mgmt-orchestrator)
spec.orchestratorImageNamespace	string	Image namespace used for the orchestrator and worker deployments (default: manageiq)
spec.orchestratorImageTag	string	Image tag used for the orchestrator and worker deployments (default: latest-18.y)
spec.orchestratorInitialDelay	string	Number of seconds to wait before starting the orchestrator liveness check (default: 2400)
spec.orchestratorMemoryLimit	string	Orchestrator deployment memory limit (default: 2048Mi)
spec.orchestratorMemoryRequest	string	Orchestrator deployment memory request (default: 1024Mi)
spec.postgresqlCpuLimit	string	PostgreSQL deployment CPU limit (default: 10000m)
spec.postgresqlCpuRequest	string	PostgreSQL deployment CPU request (default: 500m)
spec.postgresqlImage	string	Image string used for the postgresql deployment (default: :)
spec.postgresqlImageName	string	Image used for the postgresql deployment (Default: docker.io/manageiq/postgresql)
spec.postgresqlImageTag	string	Image tag used for the postgresql deployment (Default: 13-el9)
spec.postgresqlMaxConnections	string	PostgreSQL maximum connection setting (default: 1000)

Property	Type	Description
spec.postgresqlMemoryLimit	string	PostgreSQL deployment memory limit (default: 8192Mi)
spec.postgresqlMemoryRequest	string	PostgreSQL deployment memory request (default: 2048Mi)
spec.postgresqlSharedBuffers	string	PostgreSQL shared buffers setting (default: 1GB)
spec.serverGuid	string	Server GUID (default: auto-generated)
spec.storageClassName	string	StorageClass name that will be used by manageiq data stores
spec.tlsSecret	string	Secret containing the tls cert and key for the ingress, content generated if not provided (default: tls-secret)
spec.uiWorkerImage	string	Image string used for the UI worker deployments By default this is determined by the orchestrator pod
spec.opentofuRunnerImage	string	Image string used for the Opentofu runner deployments By default this is determined by the orchestrator pod
spec.webserverWorkerImage	string	Image string used for the webserver worker deployments By default this is determined by the orchestrator pod
spec.zookeeperCpuRequest	string	Zookeeper deployment CPU request (default: 250m)
spec.zookeeperCpulimit	string	Zookeeper deployment CPU limit (default: 250m)
spec.zookeeperImage	string	Image string used for the zookeeper deployment (default: :)
spec.zookeeperImageName	string	Image used for the zookeeper deployment (default: docker.io/bitnami/zookeeper)
spec.zookeeperImageTag	string	Image tag used for the zookeeper deployment (default: latest)
spec.zookeeperMemoryLimit	string	Zookeeper deployment memory limit (default: 256Mi)
spec.zookeeperMemoryRequest	string	Zookeeper deployment memory request (default: 256Mi)
spec.zookeeperVolumeCapacity	string	Zookeeper volume size (default: 1Gi)

status

Description: IMInstallStatus defines the observed state of IMInstall

Type: object

Table 1. Description of IMInstall/v1alpha1 status

Property	Type	Description
status	object	IMInstallStatus defines the observed state of IMInstall

Accessing APIs

You can access and use IBM Cloud Pak® for AIOps APIs after you obtain an access token for authentication.

About this task

To use any IBM Cloud Pak for AIOps API, you must first authenticate your credentials by including an access token in your API calls. This token is required because a password-based authentication approach is not supported for API calls with IBM Cloud Pak for AIOps, for instance, you cannot call an LDAP server to directly authenticate passwords.

The token that is generated is scoped to your user profile and the permissions that you are assigned when the access token is generated. With your access token, you can use API to access everything that you would typically be able to access when you log in to the IBM Cloud Pak for AIOps console.

To get a Platform UI access token, first you must have either an Identity and Access Management (IAM) access token or an API key that is authenticated by your user credentials. Then, you can use the IAM access token or API key to obtain your Platform UI access token. This Platform UI access token must be included in the authorization header of your calls to IBM Cloud Pak for AIOps API:

To create your token, complete either of the following procedures based on your preferred method:

- Get access token by using your API key
- Get access token by using your username and password
- Get authentication by using Platform UI API Key

Important: You can directly access the Swagger UI for only the Topology API and Metric API.

- For more information about accessing Metric service Swagger UI, see Accessing Metric service Swagger UI.

- For more information about accessing topology service Swagger UI, see Accessing Topology service Swagger UI.

Get access token by using your API key

1. Generate your platform API key:

    1. Log in to the IBM Cloud Pak for AIOps console to authenticate your user credentials.

       For more information, such as for how to obtain the URL route for accessing the Cloud Pak for AIOps console, see Accessing the Cloud Pak for AIOps console.

    2. From the toolbar, click your avatar.

    3. Click **Profile and settings**.

    4. Click **API key** > **Generate new key**.

    5. Click **Generate**.

    6. Click **Copy** and save your key somewhere safe. You cannot recover this key if you lose it.

    If you lose your API key, repeat the preceding steps to generate a new API key. Your old API key becomes invalid, and any applications or scripts cannot authenticate to the platform until you provide your new API key. For more information, see Generating API keys for authentication.

2. Get your Platform UI access token by running the following cURL command:

```
curl -k -X POST \
  https://<hostname>/icp4d-api/v1/authorize \
  -H 'Content-Type: application/json' \
  -d '{
    "username": "<username>",
    "api_key": "<API_key>"
  }'
```

    - `<hostname>` - The IBM Cloud Pak platform (`cpd`) route hostname.
    - `<username>` - Your username.
    - `<API_key>` - The API key that you generated in the previous step.

    The API response can resemble the following sample:

```
{
    "_messageCode_": "200",
    "message": "Success",
    "token": "<encoded-token-string>"
}
```

    - `<encoded-token-string>` - Your Platform UI access token.

Get access token by using your username and password

1. Get your Identity and Access Management (IAM) access token with the following cURL command:

```
curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" \
-d "grant_type=password&username=<username>&password=<password>&scope=openid" \
https://<cluster_address>/idprovider/v1/auth/identitytoken
```

    Where:

    - `<username>` - Your username.
    - `<password>` - Your password.
    - `<cluster_address>` - The IBM Cloud Pak for AIOps console route. For more information about how to get this Cloud Pak for AIOps console route, see Accessing the Cloud Pak for AIOps console.

    The command returns an `access_token`, `refresh_token`, and `id_token`, as shown in the following example:

```
{"access_token":
"eb837eaf32459b711945a9d2259880119056e805ff0d2f36421cc171f94e58fef349f0005d217e36889b62271d9f00fc7cb5b1fe5a86546d9dee

51ef843ee5d98e5bbafaeb4096301853fa5fdc876275defd3ecabd0eb656c7cd2441e523e0c5468a1f261fb44"
```

2. Get your Platform UI access token by running the following cURL command:

```
curl -k X GET 'https://<hostname>/v1/preauth/validateAuth' \
-H 'username: admin' \
-H 'iam-token: <iam-token>'
```

- `<hostname>` - The IBM Cloud Pak platform (`cpd`) route hostname.
- `<username>` - Your username.
- `<iam-token>` - The IAM access token that you obtained from the response in the previous step.

The API response can resemble the following sample:

```
{
    "_messageCode_": "200",
    "message": "Success",
    "token": "<encoded-token-string>"
}
```

- `<encoded-token-string>` - Your Platform UI access token.

Get authentication by using Platform UI API Key

1. Generate your platform API (Zen) key:
    1. Log in to the IBM Cloud Pak for AIOps console to authenticate your user credentials.

       For more information, such as for how to obtain the URL route for accessing the Cloud Pak for AIOps console, see Accessing the Cloud Pak for AIOps console.

    2. From the toolbar, click your avatar.
    3. Click **Profile and settings**.
    4. Click **API key** > **Generate new key**.
    5. Click **Generate**.
    6. Click **Copy** and save your key somewhere safe. You cannot recover this key if you lose it.

    If you lose your API key, repeat the preceding steps to generate a new API key. Your old API key becomes invalid, and any applications or scripts cannot authenticate to the platform until you provide your new API key. For more information, see Generating API keys for authentication.

2. Generate a base64 format of your Platform UI API Key:

```
ZENAPIKEY=$(echo "<username>:<API_key>" | base64 -w 0)
```

- `<username>` - Your username.
- `<API_key>` - The API key that you generated in the previous step.

3. The output is an encoded value. See the following example.

```
YWRtaW46MUFKblRIYngxNFJUVnBoR0FTdW0wcDJEOFl6UXFyVllmU2tmeW5qYgo=
```

This encoded (base64 format) Platform UI API Key is used as the value for `<ZenApiKey>`.

4. Construct your Authorization header with the Platform UI API Key.

```
--header "Authorization: ZenApiKey <ZenApiKey>"
```

- `<ZenApiKey>` - The Platform UI API key that you get in the previous step.

5. Run the following cURL command:

```
curl "https://<Endpoint URL>" --header 'Content-Type: application/json' --header "Authorization: ZenApiKey
<ZenApiKey>" --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --insecure
```

- `<Endpoint URL>` - The Endpoint URL as specified on the API page of the service that you want to use, for example, you can find the Endpoint URL for metrics here.

Next steps

Access IBM Cloud Pak for AIOps API with your Platform UI authentication token or API keys. Include the Platform UI access token in the authorization header of your API calls.

For more information on the available API and related Swagger documentation, see APIs.

Generating API keys for authentication

With an API key, you can automatically authenticate to the platform or to a specific instance of a service from a script or application. Your API keys are associated with your credentials and are specific to you. With API keys, you can authenticate without entering your username and password.

You can generate:

- A platform API key

Your platform API key enables scripts and applications to access everything that you would typically be able to access when you log in to the console.

Before you begin

Before you generate an API key, consider the following factors:

What level of access is required?

As a security best practice, it is recommended that you give the least amount of access necessary to the script or application. For example, if a script needs to interact only with a specific service instance, generate an API key for that service instance.

Important: Be sure to store your API keys somewhere safe. If you lose an API key, you'll need to create a new key and update any scripts or applications where the key is used.

Platform API key

With a platform API key, you can access everything that you would typically be able to access when you log in to the console.

To generate a platform API key:

1. Log in to the console.
2. From the toolbar, click your avatar.
3. Click **Profile and settings**.
4. Click **API key** > **Generate new key**.
5. Click **Generate**.
6. Click **Copy** and save your key somewhere safe. You cannot recover this key if you lose it.

If you lose your API key, repeat the preceding steps to generate a new API key. Your old API key becomes invalid, and any applications or scripts cannot authenticate to the platform until you provide your new API key.

If you believe that your API key is compromised:

1. Log in to the console.
2. From the toolbar, click your avatar.
3. Click **Profile and settings**.
4. Click **API key** > **Revoke current key**.
5. Click **Revoke**.

Any applications or scripts that use the key won't be able to authenticate to the platform.

Platform UI APIs

Learn more about the Platform UI APIs that are available for you to use to manage users and the personalization of the console.

User management APIs

Create and manage users and access to the console with the user management API.

Custom cards API

Create custom cards to display information on the console home page with the Custom cards REST API.

Creating custom home page cards with API

Create custom cards to display information on the console home page with the Custom cards REST API.

For example, if you want to show disk usage as a percentage of available disk space, you can add a custom card to the home page that displays the data in a donut or bar chart.

You can use the Custom cards REST API to complete the following tasks:

- Generate an authorization token
- Get a list of custom cards

- Create or replace a custom card
- Edit a custom card
- Delete a custom card

You cannot use the Custom cards API to replace, edit, or delete existing cards that are added by default.

Sample custom cards

You can start with a template to create each of the custom cards that are shown in the following image. Review the template types for a description of the templates that are used.

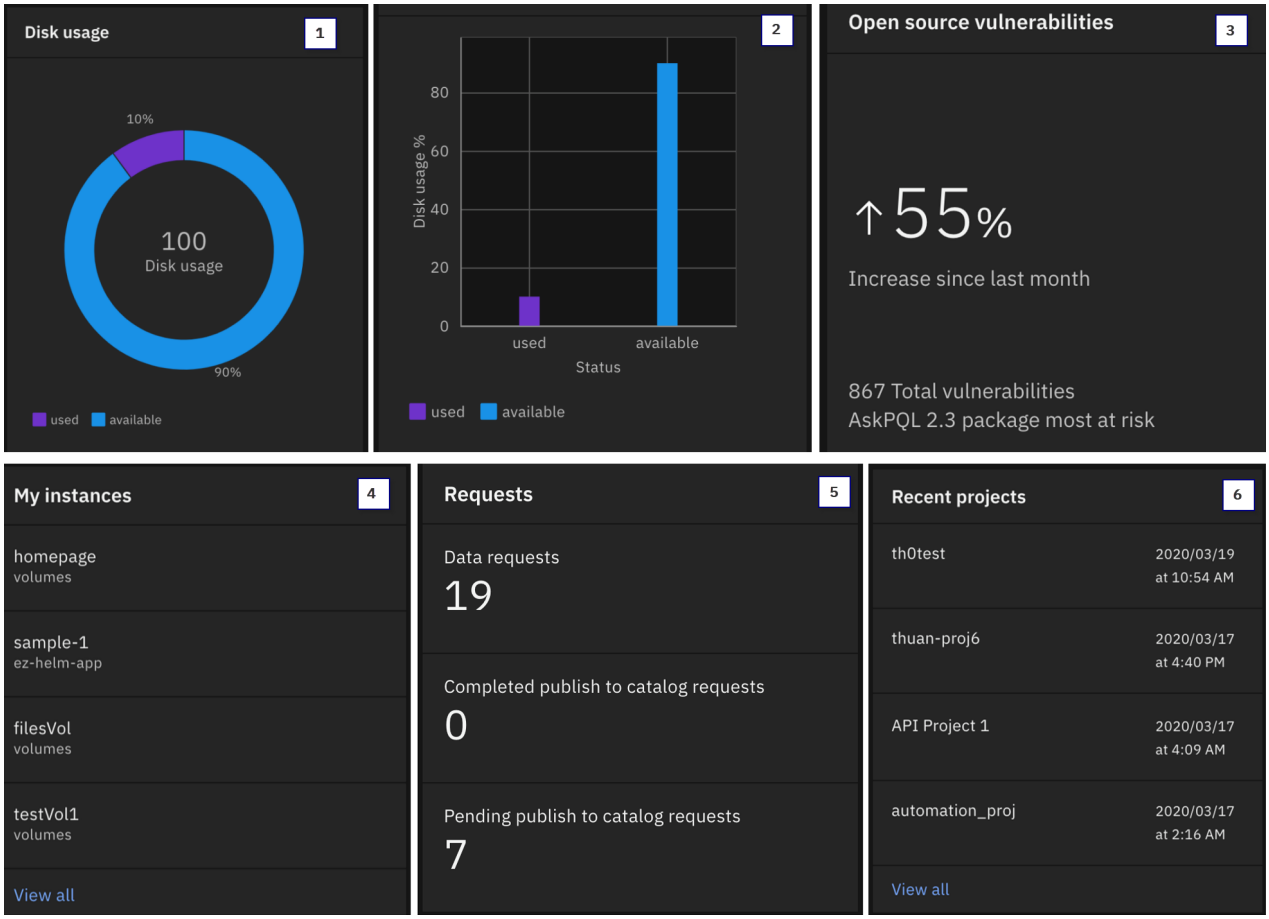

Figure 1. Custom cards types

Template types:

1. The **donut** template illustrates an array of values as percentages in a donut chart.
2. The **bar** template creates a two-dimensional bar graph.
3. The **big_number** template highlights significant data.
4. The **text_list** displays a list of text strings.
5. The **number_list** displays a list of numeric values and associated text.
6. The **list** displays a list of navigation links. The list can contain headers and associated clickable links.

For the JSON payload that describes these custom cards, see the sample command in Create or replace a custom card.

Generate an authorization token

To use the Custom cards REST API, you must first authenticate. Use the token that you get in the response as a token in subsequent API calls.

1. Get an Identity Management (IM) access token:

```
curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" \
-d "grant_type=password&username=<username>&password=<password>&scope=openid" \
https://<cluster_address>/idprovider/v1/auth/identitytoken
```

   - **<username>** is your username.
   - **<password>** is your password.
   - **<cluster_address>** is the IBM Cloud Pak console route. You can get the IBM Cloud Pak console route by running the following command:

```
oc get route -n <your-foundational-services-namespace> cp-console -o jsonpath='{.spec.host}'
```

   Following is a sample output:

`cp-console.apps.mycluster.mydomain.com`

Based on the example output, your console URL would be `https://cp-console.apps.mycluster.mydomain.com`.

The username and password are defined in the `config.yaml` file.

2. Use the IM access token to call the Platform UI token API:

```
curl -k X GET 'https://<master_node_hostname>/v1/preauth/validateAuth' \
-H 'username: admin' \
-H 'iam-token: <iam-token>'
```

- `<master_node_hostname>` the hostname for the master node.
- `<iam-token>` is the IM token that you obtained from the response in the previous step.

Get a list of custom cards

Retrieves the properties for the custom cards that you can update.

Curl

```
GET /zen-data/v1/custom_cards
```

Sample command

```
curl -kiv -X GET \
  https://my-deployment-url/zen-data/v1/custom_cards \
  -H 'Authorization: Bearer authorization-token' \
  -H 'Content-Type: application/json'
```

Sample response

In the following code block, the body of the response is replaced with `...`.

```
"_messageCode_": "success",
    "message": "Successfully retrieved custom cards",
    "requestObj": {
      ...
}
```

Create or replace a custom card

Creates a custom card or replaces an existing custom card.

You must include the card definition as a JSON string in the HTTP request body. The definition specifies the structure and the content of the card.

Table 1. Card parameters

Parameter	Type	Description
`key`	`String`	The name of the card that you want to create or replace. The string must be unique. If a custom card with the specified key does not exist, the custom card is created, otherwise the existing custom card is replaced.
`data`	`object`	Provides data to the card. You must provide either a `data_url` object or a `data` object. The `data` object is an object that populates data in the card. The properties of the object must match the type of template defined. The expected structure for each `template_type` parameter is in following examples.
`data_url`	`endpoint`	Provides data to the card. You must provide either a `data_url` object or a `data` object. The `data_url` object is an endpoint that is called to populate data in the card. The response that is sent by the endpoint matches the type of template defined. The expected response structure for each `template_type` parameter is shown in the following examples.
`description`	`String`	Helps users understand the purpose of the card. The string must be 200 characters or less.
`drilldown_url` (Optional)	`String`	Defines the URL that the user navigates to when they click **View details**. If this parameter is not defined, the card does not display a **View details** link.
`order`	`integer`	Defines the position of the card. The value must be in the range 1 - 50.
`permissions`	`array`	Specifies the permissions that a user needs to see the card. The array must have at least one permission. If the array has no `permissions` parameter, the card is shown to everyone.
`refresh_rate` (Optional)	`Integer`	The interval in seconds at which the content is refreshed by the source.
`template_type`	`enumerated_type`	Defines the display type of the card. The `template\_type` parameter must be one of the following values: - `donut` - `bar` - `big_number` - `text_list` - `number_list` - `list`
`title`	`String`	The display name for the card. The string must be 40 characters or less.
`window_open_target` (Optional)	`string`	Specifies the target attribute or the name of the window. The following values are supported: - Empty or not provided - the URL gets loaded on the current page by default. - `_blank` - URL is loaded into a new window or tab every time. - `name` - The name of the window where the URL is loaded. The name does not specify the title of the new window.

Use the following examples to understand the `data` object.

bar_data

```
"data": {
        "bar_data": {
              x_axis_label: 'Packages',
              y_axis_label: 'Projects',
                "data_array": [
                  {
                        "group": "Qty",
                        "value": 65000
                    },
                    {
                        "group": "More",
                        "value": 29123
                    },
                    {
                        "group": "Sold",
                        "value": 35213
                    },
                    {
                        "group": "Restocking",
                        "value": 51213
                    },
                    {
                        "group": "Misc",
                        "value": 16932
                    }
                ]
        }
}
```

big_number_data

```
"data": {
       "big_number_data": {
              prefix: 'ArrowUp32',
              metric: '1.6',
              suffix: '%',
              sub_text: 'Since last month',
              footer_1: '867 Total vulnerabilities',
              footer_2: 'AskPQL 2.3 package most at risk'
       }
}
```

donut_data

```
"data": {
              "donut_data": {
                "center_label": "Disk usage",
                "data_array": [
                  {
                    "group": "2V2N 9KYPM version 1",
                    "value": 20000
                  },
                  {
                    "group": "L22I P66EP L22I P66EP L22I P66EP",
                    "value": 65000
                  },
                  {
                    "group": "JQAI 2M4L1",
                    "value": 75000
                  },
                  {
                    "group": "J9DZ F37AP",
                    "value": 1200
                  },
                  {
                    "group": "YEL48 Q6XK YEL48",
                    "value": 10000
                  },
                  {
                    "group": "Misc",
                    "value": 25000
                  }
                ]
              }
            }
```

list_data

```
"data": {
       list_data: {

                },
                {
                        'project_name': 'Project X Final version 2',
                        'last_updated_time': 'Yesterday 12:45 AM',
                        'nav_url': ' /projects/49753ad5-dcf5-4f94-913f-tuv
                }
                ]
        }
}
```

number_list_data

```
"data": {
        "number_list_data": {
                rows: [
                {
                        drilldown_url: '/zen/#/openSource/packages',
                        label: 'Total approved packages',
                        value: '3'
                },
                {
                        label: 'Total licenses',
                        value: '2345'
                },
                {
                        label: 'Total user interactions',
                        value: '25K'
                }
                ]
        }
}
```

text_list_data

```
"data": {
        "text_list_data": {
                rows: [
                {
                        drilldown_url: '/zen/#/openSource/packages',
                        label: 'Data virtualization',
                        sub_text: 'dv'
                },
                {
                        label: 'Watson assistant',
                        sub_text: 'assistant'
                },
                {
                        label: 'Watson openscale',
                        sub_text: 'aios'
                }
                ]
        }
}
```

Use the following examples to understand the **data_url** object. The format of the expected response that is provided in the **data_url** from the endpoint for each card type is shown in the following examples.

donut

```
{
      "center_label": "Disk usage",
      "data_array": [
         {
            "group": "2V2N 9KYPM version 1",
            "value": 20000
         },
         {
            "group": "L22I P66EP L22I P66EP L22I P66EP",
            "value": 65000
         },
         {
            "group": "JQAI 2M4L1",
            "value": 75000
         },
         {
```

```
            "group": "J9DZ F37AP",
            "value": 1200
         },
         {
            "group": "YEL48 Q6XK YEL48",
            "value": 10000
         },
         {
            "group": "Misc",
            "value": 25000
         }
      ]
}
```

bar

```
{
      "x_axis_label": "Packages",
      "y_axis_label": "Projects",
      "data_array": [
         {
            "group": "Australia",
            "value": 250
         },

                "big_number_data": {
                    "metric": "55",
                    "sub_text": "Increase since last month",
                    "prefix": "ArrowUp32",
                    "suffix": "%",
                    "footer_1": "867 Total vulnerabilities",
                    "footer_2": "AskPQL 2.3 package most at risk"
                }
            }
        }
    ],
    "message": "PUT custom card succeeded"
}
```

Edit a custom card

Edit the information that is displayed on an existing card.

You can edit the following content:

- `data`
- `data\_url`
- `description`
- `drilldown\_url`
- `order`
- `permissions`
- `template\_type`
- `title`

To edit a custom card, use the rules that are specified in Create or replace a custom card.

Curl

```
PATCH /zen-data/v1/custom_cards/{key}
```

Path parameters

Table 2. Path parameters - patch

Parameter	Type	Description
key	`String`	The name of the card that you want to update.

Sample command

This command updates the title of a custom card called `disk_usage_donut`.

```
curl -kiv -X PATCH \
  https://my-deployment-url/zen-data/v1/custom_cards/disk_usage_donut \

  -H 'Authorization: Bearer authorization-token' \
  -d '{

  "title": "Disk usage"
}'
```

Sample response

```
{
    "_messageCode_": "success",
    "data": [
        {
            "id": "1",
            "name": "homepage_card_disk_usage",
            "title": "Disk usage",
            "description": "",
            "drilldown_url": "/zen/#/v1/diskUsage",
            "order": 2,
            "template_type": "donut",
            "data_url": "/zen-data/v1/homepage/diskUsage",
            "empty_state": {},
            "source_url": "",
            "refresh_rate": 0,
            "data": null
        }
    ],
    "message": "Successfully edited custom card"
}
```

Delete a custom card

Deletes an existing card with the specified key.

Curl

```
DELETE /zen-data/v1/custom_cards/{key}
```

Path parameters

Table 3. Path parameters - delete

Parameter	Type	Description
key	`String`	The name of the custom card that you want to delete.

Sample command

This command deletes the `os_vulnerabilities` card.

```
curl -kiv -X DELETE \
  https://my-deployment-url/zen-data/v1/custom_cards/os_vulnerabilities \
  -H 'Authorization: Bearer authorization-token'
```

Sample response

```
{
    "_messageCode_": "success",
    "message": "Successfully deleted custom card"
}
```

IM APIs

Identity management (IM) APIs.

- OIDC Registration APIs
- Identity Provider V3 APIs

Preparing to run API commands

Before you run API commands, retrieve the authentication token and download the CA certificate for your cluster.

Procedure

1. Set the project to the namespace where you deployed foundational services.

   ```
   oc project <your-foundational-services-namespace>
   ```

2. Retrieve the authentication tokens. You can run curl commands.

   ```
   curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8"  -d
   "grant_type=password&username=`oc get secret platform-auth-idp-credentials -o json | jq -r .data.admin_username|
   base64 -d`&password=`oc get secret platform-auth-idp-credentials -o json | jq -r .data.admin_password | base64 -
   d`&scope=openid" https://`oc get routes cp-console -o jsonpath='{.spec.host}'`/idprovider/v1/auth/identitytoken | jq
   ```

   The command returns an **access_token**, **refresh_token**, and **id_token**, as shown in the following example:

   ```
   {"access_token":"eb837eaf32459b711945a9d2259880119056e805ff0d2f36421cc171f94e58fef349f0005d217e36889b62271d9f00fc7cb5

   r5QUZJ0b0DytKuY5HxpswpIFaO9U8JlYAFoOZ18eO_CzERHRQ_Ii1ePmagGAk-eLJjmCNqY1zynfpEUuKlWUR5rVGHGzSbGA8J4CLvg"
   ```

3. Store the authentication token in a variable. You can access IBM Cloud Pak® for AIOps APIs by specifying an authentication token in the request header. Run the following command, where **<ID token>** is the displayed ID token:

   ```
   export ID_TOKEN=<ID token>
   ```

4. Store the access token in a variable. Include the full contents of the access token, including the Bearer value. For example, from the access token in the Curl command output in step 1, you must include the token value from **"eb837e** to **1fb44"**. You can access IBM Cloud Pak for AIOps user management APIs by specifying the access token in the request header. Run the following command, where **<Access token>** is the following displayed access token:

   ```
   export ACCESS_TOKEN=<Access token>
   ```

5. Obtain a copy of the CA certificate for your cluster. If you can access the boot node, the CA certificate file is **/<installation_directory>/cluster/cfc-certs/root-ca/ca.crt**.

OIDC Registration APIs

APIs to manage authentication.

Base path: **https://<cluster_address>/idprovider/v1/auth/**

Note: The **/idauth** route is removed and not supported for client registration.

Client Registration API

Following is the curl command to register the API:

```
curl -i -k -X POST --header "Authorization: Bearer $ACCESS_TOKEN" \ --header "Content-Type: application/json" \ --data
"@platform-oidc-registration.json" \
https://<cluster_address>/idprovider/v1/auth/registration
```

You can also use the access token in the body:

```
curl -i -k -X POST -d "access_token=$ACCESS_TOKEN" \
https://<cluster_address>/idprovider/v1/auth/registration
```

The contents of the platform-oidc-regisration.json file are in the following example:

```
{
    "token_endpoint_auth_method": "client_secret_basic",
    "client_id": <WLP_CLIENT_ID>,
    "client_secret": <WLP_CLIENT_SECRET>,
    "scope": "openid profile email",
    "grant_types": ["authorization_code", "client_credentials", "implicit",
           "refresh_token", "urn:ietf:params:oauth:grant-type:jwt-bearer"],
    "response_types": ["code", "token", "id_token token"],
    "application_type": "web",
    "subject_type": "public",
    "post_logout_redirect_uris": ["https://<ICP_PROXY_IP>:<PORT_WHERE_SERVICE_RUNS>"],
    "preauthorized_scope": "openid profile email general",
    "introspect_tokens": true,
    "trusted_uri_prefixes": ["https://<ICP_ENDPOINT>:8443", "https://<ICP_PROXY_IP>"],
    "redirect_uris": ["https://<ICP_PROXY_IP>:<PORT_WHERE_SERVICE_RUNS>/auth/liberty/callback"],
}
```

The **WLP_CLIENT_ID** and **WLP_CLIENT_SECRET** must be generated by the user who is trying to register the client and the values must be unique.

Note: Calling **/Userinfo** does not work for the tokens with **grant_type** as **client_credentials**. Use **/instrospect** endpoints instead.

Delete the client ID

1. Export these variables:

   ```
   export CLIENT_ID=<client_id>
   ```

2. Run the curl command to delete the ID.

   ```
   curl -i -k -X DELETE --header "Authorization: Bearer $ACCESS_TOKEN"\
   https://icp-cluster-ip:8443/idprovider/v1/auth/registration/$CLIENT_ID
   ```

Call the authorization endpoint to display the login page

Get access token by using cpclient_credentials

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster Port

Path

/idprovider/v1/auth/token

Command

POST

Command output format

application/json

Following is the curl command:

```
curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" \
-d "grant_type=cpclient_credentials&client_id=<client_ID>&client_secret=<client_secret>&scope=openid" \
https://<cluster_address>/idprovider/v1/auth/token --insecure
```

The sample response resembles the following code:

```
{
  "access_token":
"3b17b831c5f21e46c64718d26fe415ce2fc2f5482121ab8f213a28db8f3838c6a6cda5e3a9a8d38be359cb3c8351655e7fac2af40a805fb42e701d0ad

Get information about a user

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster Port

Path

/idprovider/v1/auth/userInfo

Command

POST

Command output format

application/json

For information about **$ACCESS_TOKEN**, see Preparing to run API commands.

The sample curl command resembles the following code:

```
curl -k -X POST --header "Authorization: Bearer $ACCESS_TOKEN" \
https://<cluster_address>/idprovider/v1/auth/userInfo
```

You can also use the access token in the body:

```
curl -k -X POST -d "access_token=$ACCESS_TOKEN" \
https://<cluster_address>/idprovider/v1/auth/userInfo
```

The response resembles the following code:

```
{
  "sub":"admin",
  "iss":"https://mycluster.icp:9443/idprovider/v1/auth"
}
```

Call introspect endpoint

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster Port

Path

/idprovider/v1/auth/introspect

Command

GET

Command output format

application/json

1. Export these variables. To get the values, see Client Registration API.

```
export TOKEN=<your access token here>
export CLIENT_ID=<client_id here>
export CLIENT_SECRET=<client_secret here>
```

2. Get the Basic authorization header by using the following command:

```
BASIC_AUTH_HEADER=`echo -n "$CLIENT_ID:$CLIENT_SECRET" | base64 -w 0`
```

3. Run the curl command to call the endpoint.

```
curl -H "Authorization: Basic $BASIC_AUTH_HEADER" -d "token=$TOKEN"
https://<cluster_address>/idprovider/v1/auth/introspect
```

The response resembles the following code:

```
{
  "sub": "admin",
  "grant_type": "resource_owner",
  "realmName": "customRealm",
  "scope": "openid",
  "uniqueSecurityName": "admin",
  "iss": "https://127.0.0.1:9443/idprovider/v1/auth",
  "active": true,
  "exp": 1529358338,
  "token_type": "Bearer",
  "iat": 1529315138,
  "
```

Revoke access token or refresh token

Identity Provider APIs

Use Identity Provider (IdP) V3 APIs to register IdP connection and configuration.

If you are configuring SSO (single sign-on), you must use the IdP V3 APIs.

See the following notes:

- You can get the hostname from the route available in your foundational services namespace. To get the host details, see Getting the host details.
- The **`Administrator`** IM role is allowed to access the IdP V3 APIs.

IdP V3 APIs

You can register the following providers and connections by using the IdP V3 APIs:

- OIDC provider For more information, see Registering OIDC clients by using IdP V3.
- SAML provider For more information, see Registering SAML clients by using IdP V3. To configure SAML, use IBM Cloud Pak for AIOps UI. For more information, see Configuring single sign-on using IBM Cloud Pak for AIOps UI.
- LDAP For more information, see Configuring LDAP connection by using IdP V3.

OIDC clients

Currently, only the following platforms are verified to register OIDC by using IdP V3 APIs.

Note: Service providers might change the links that are listed here. If any links is broken, check the service provider website for the new location.

- IBM Security Verify
  - **Note:** In the IBM Security Verify application, whenever you map attributes, enable the **Send all known user attributes in the ID token** option. And, do not use spaces in IBM Security Verify groups.
- Google Cloud Platform
- Microsoft
- Okta

Before you begin, register yourself in your service provider application. During registration, use the following URLs:

- For application URL, use the cp-console URL.
- For redirect URL, use **`https://<cp-console-url>/ibm/api/social-login/redirect/<name of the oidc>`**.

After you register, you get a unique client ID, client secret, and **`discovery_url`** endpoint.

Note: The curl commands that are used in the following sections contain different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3.

- Registering the OIDC clients
- Deleting the registration of the client
- Getting the list of registered OIDC clients
- Updating the OIDC clients

Registering OIDC clients

API details - register OIDC clients - POST

            "family_name": "family_name",
            "sub": "uid",
            "email": "email"
        }
    }
}'
```

Sample response - update client

```
{
    "status": "success",
    "message": "{NpiV6qBhsSDEjKRvJDQLl} is Updated."
}
```

Sample error message - update client

```
400 "error": "Document not found"
401 "error": "Insufficient user permission for role :Viewer"
200: Ok Response
```

SAML clients

You can register the SAML IdP by the following methods:

- SAML with SCIM dependency registration
- SAML registration without any dependency
- SAML with LDAP dependency registration

Note: You can configure only one SAML registration at an instance. The UID generated on the POST request is **`defaultSP`**. For **`idp_metadata`**, you need to provide the base64-encoded value of the generated IdP metadata **`xml`** file.

Get the base64-encoded value by using the following command:

```
cat idp-metadata-xml | base64
```

Note: The maximum accepted size of the metadata file is **`2 MB`**. If the size of the metadata file is more than 2 MB, an error message is displayed during the SAML registration.

SAML with SCIM dependency registration

You can register IdP V3 with the following platforms:

- IdP V3 registration with IBM Security Verify
- IdP V3 registration with Okta

Note: The curl commands that are used in the following sections contain different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3.

Note: By using the POST call, you can get the unique identifier (UID) as a successful response. The UID is required for the further operations or tasks. You can also get the list of UIDs of registered IdPs by using the Getting the list of registered OIDC clients by query API.

IdP V3 registration with IBM Security Verify

The following example shows IdP V3 registration with IBM Security Verify that supports SCIM-enabled IdP with SAML. Hence, the **`token_attribute_mappings`** and **`scim_attribute_mappings`** can be different for the respective IdPs.

200 OK Response
```

IdP V3 registration with Okta

The following example shows IdP V3 registration with Okta.

API details - registration with Okta - POST

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/

Command

POST

Command output format

application/json

Table 1. Command parameters

Mapping	Description
`token_attribute_mappings`	A custom mapping that you can provide based on the SAML attribute mapping that is configured at Okta. You must modify the values, not the key, based on the Okta SAML attribute configuration. For more information about attributes, see step 9 in Configure CloudPak as SAML service provider (SP) at OKTA and Okta doc for SAML attributes.
`scim_attribute_mappings`	Provide the mapping attributes as shown in the curl command for OKTA registration as SAML IdP. The defined mapping is used to filter query, and to create attributes and responses to be sent.
`redirect_url`	Only applicable for the IdP **"type": "okta"**. Must be an array. The `redirect_url` is used to create the OIDC client registration for the OKTA instance. For a non-IBM OIN app, the `redirect_uri` can be one of the following URIs based on the environment (a standard org, an EMEA org, or an Okta Preview org): https://system-admin.okta.com/admin/app/cpc/${appName}/oauth/callback https://system-admin.okta-emea.com/admin/app/cpc/${appName}/oauth/callback https://system-admin.oktapreview.com/admin/app/cpc/${appName}/oauth/callback **Note:** Replace the `${appName}` with the variable name for your application instance. If you don't know the variable name for application instance, you can find it as part of the App embed link from the browser by opening the embed link, or you can also check the **Name** attribute for the application at the `/Apps API` endpoint. For example, if the URL embedded link is https://dev-68798908-admin.okta.com/admin/app/dev-68798908_iamsaml_3/instance/0oa6vnyhkm86B4xha5d7/#tab-general, the **${appName}** is **dev-68798908_iamsaml_3** and so the redirect_uri is https://system-admin.okta.com/admin/app/cpc/dev-68798908_iamsaml_3/oauth/callback. For more information, see Okta documentation.

Sample curl command - registration with Okta

```
curl --location --request POST 'https://cpconsoleroute/idprovider/v3/auth/idsource' \
--header 'Authorization: Bearer $accessToken' \
--header 'Content-Type: application/json' \
--data-raw '{
            "name": "OKTASAML",
            "description": "OKTASAML",
            "protocol": "saml",
            "type": "okta",
            "idp_config": {
                "token_attribute_mappings": {
                    "sub": "uid",
                    "given_name": "firstName",
                    "family_name": "lastName",
                    "groups": "groups",
                    "email": "emailAddress",
                    "first_name": "firstName",
                    "last_name": "lastName"
                },
                "idp_metadata": "Base64-encoded-metadata"
            },
            "jit": false,

                            {
                                "value": "emails",
                                "type": "home"
                            }
                        ],
                        "id": "id",
                        "userName": "userName"
                    },
                    "group": {
                        "principalName": "displayName",
                        "id": "displayName"
                    }
```

```
                }
            }
        }'
```

Sample response - registration with Okta

```
{
    "status": "success",
    "message": "Identity provider {oktasaml} is successfully registered with unique identifier : defaultSP, oktaclient
created with clientId: yx3a5pwtdrmn0sf8ockyf97dg55lswo7 , client secret: okta-oidcclient-secret"
}
```

Sample error message - registration with Okta

```
401 "error": "Insufficient user permission for role : rolename"
400 "error": "schema error:schema validation error followed by error"
400 "error": "duplicate : Idp with protocol=saml is already created"
500 "error": "Other errors"
200 OK Response
```

SAML registration without any dependency

API details - registration without any dependency - POST

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/

Command

POST

Command output format

application/json

See the following notes:

- You can find the SAML attribute and claim names from the IdP administration. Specify the SAML attributes and claim names as the values in the **token_attribute_mappings** attributes.
- You can also provide an optional attribute named **uniqueSecurityName** in **token_attribute_mappings** payload to map the IdP attributes. By default, the **uniqueSecurityName** attribute is mapped to the **Subject** in the response of **userinfo** or **introspect** endpoint.

Sample curl command for SAML registration with w3id SAML provider

```
curl -k -X POST 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
  "name": "w3id-sample-saml",
  "description": "w3id-sample-saml-test",
  "protocol": "saml",
  "type": "default",
  "idp_config": {
    "token_attribute_mappings": {
      "sub": "uid",
      "given_name": "firstName",
      "family_name": "lastName",
      "groups": "blueGroups",
      "email": "emailAddress"
    },
    "idp_metadata": "<base64-encoded-idp-xml>"
  },
```

```
  "jit": true
}'
```

Sample response - registration with w3id SAML provider

```
{
    "status": "success",
    "message": "Identity provider {w3id-sample-saml} is successfully registered with unique identifier defaultSP"
}
```

Sample error message - registration with w3id SAML provider

```
401 "error": "Insufficient user permission for role : rolename"
400 "error": "schema error:schema validation error followed by error"
400 "error": "duplicate : Idp with protocol=saml is already created"
500 "error": "Other errors"
200 OK Response
```

SAML with LDAP dependency registration

The following example is provided for IBM W3 SAML provider and with dependency of an IBM Tivoli Directory Server LDAP. The **token_attribute_mappings** might change based on the SAML provider.

API details - SAML with LDAP dependency registration - POST

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/

Command

POST

Command output format

application/json

Note: When LDAP is configured, the response for **userinfo** or **introspect** endpoints are directly collected from liberty. Therefore, the attributes that are provided in the **token_attribute_mappings** payload are not available in the response of the **userinfo** or **introspect** endpoints.

Sample curl command - SAML with LDAP dependency registration

```
curl -k -X POST 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
  "name": "saml-test",
  "description": "saml bluepages with ldap",
  "protocol": "saml",
  "type": "default",
  "idp_config": {
    "token_attribute_mappings": {
      "sub": "uid",
      "given_name": "firstName",
      "family_name": "lastName",
      "groups": "blueGroups",
      "email": "email"
    },
    "idp_metadata": "<base64-encoded-idp-xml>"
  },
  "ldap_config": {
    "ldap_id": "<existing_ldap_id>"
  },
  "jit": false
}'
```

Sample response - SAML with LDAP dependency registration

```
{
    "status": "success",
    "message": "Identity provider {saml-test} is successfully registered with unique identifier defaultSP"
}
```

Sample error message - SAML with LDAP dependency registration

```
401 "error": "Insufficient user permission for role : rolename"
400 "error": "schema error:schema validation error followed by error"
400 "error": "duplicate : Idp with protocol=saml is already created"
500 "error": "Other errors"
200 OK Response
```

Getting SAML registration by UID

You can get the IdP registration by the following ways:

- By name
- By list
- By query

Getting IdP V3 registration by name

The following example shows how to get the details of IdP V3 registration by name:

API details - registration by UID - GET

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/defaultSP

Command

GET

Command output format

application/json

Note: The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3.

Sample curl command - registration by UID

```
curl -k -X GET 'https://cp-console.apps.mycluster.mydomain.com/idprovider/v3/auth/idsource/defaultSP' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Sample response - registration by UID

```
{
    "name": "w3id-sample-saml",
    "description": "w3id-sample-saml-test",
    "protocol": "saml",
    "type": "default",
    "idp_config": {
        "token_attribute_mappings": {
            "sub": "uid",
            "given_name": "firstName",
            "family_name": "lastName",
            "groups": "blueGroups",
            "email": "emailAddress"
        },
        "idp_metadata": "<base64-encoded-idp-xml>"
    },
```

```
    "jit": true,
    "uid": "defaultSP"
}
```

Sample error message - registration by UID

```
401 "error": "Insufficient user permission for role : rolename"
404 "error": "Cannot find {defaultSP}
500 "error": "Other errors"
200 OK Response
```

Getting the list of IdP V3 registration

The following example shows how to get the list of IdP V3 registration:

Note: This API returns all registered IdPs of SAML or OIDC clients through IdP V3 API.

API details - list of IdP V3 registration - GET

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource

Command

GET

Command output format

application/json

Note: The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3.

Sample curl command - IdP V3 registration

```
curl -k -X GET 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Sample response - IdP V3 registration

```
{
    "idp": [
        {
            "name": "w3id-sample-saml",
            "description": "w3id-sample-saml-test",
            "protocol": "saml",
            "type": "default",
            "idp_config": {
                "token_attribute_mappings": {
                    "sub": "uid",
                    "given_name": "firstName",
                    "family_name": "lastName",
                    "groups": "blueGroups",
                    "email": "emailAddress"
                },
                "idp_metadata": "<base64-encoded-idp-xml>"
            },
            "jit": true,
            "uid": "defaultSP"
        }
    ]
}
```

Sample error message - IdP V3 registration

```
401 "error": "Insufficient user permission for role : rolename"
500 "error": "Other errors"
200 OK Response
```

Getting SAML registration by query

The following example shows how to get the IdP V3 registration by query:

API details - SAML registration by query - GET

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/:UID

Command

GET

Command output format

application/json

Note: The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3.

Sample curl command - SAML registration by query

```
curl -k -X GET 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource?protocol=saml'
\
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Sample response - SAML registration by query

```
{
    "idp": [
        {
            "name": "w3id-sample-saml",
            "description": "w3id-sample-saml-test",
            "protocol": "saml",
            "type": "default",
            "idp_config": {
                "token_attribute_mappings": {
                    "sub": "uid",
                    "given_name": "firstName",
                    "family_name": "lastName",
                    "groups": "blueGroups",
                    "email": "emailAddress"
                },
                "idp_metadata": "<base64-encoded-idp-xml>"
            },
            "jit": true,
            "uid": "defaultSP"
        }
    ]
}
```

Sample error message - SAML registration by query

```
401 "error": "Insufficient user permission for role : rolename"
500 "error": "Other errors"
200 OK Response
```

Updating SAML registration

To update the SAML registration, you require the IdP UID. To get the IdP UID, see Get the list of IdP V3 registration. Alternatively, you can use the UID as **defaultSP** because only one SAML registration at an instance is supported for now.

The following example shows how to update the IdP registration:

API details - Update SAML registration - PUT

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/:UID

Command

PUT

Command output format

application/json

Note: The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3.

Sample curl command - Update SAML registration

```
curl -k -X PUT 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/defaultSP' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
' {
  "name": "w3id-sample-saml",
  "description": "this is plain saml testing",
  "protocol": "saml",
  "type": "default",
  "idp_config": {
    "token_attribute_mappings": {
      "sub": "uid",
      "given_name": "firstName",
      "family_name": "lastName",
      "groups": "blueGroups",
      "email": "emailAddress"
    },
    "idp_metadata": "<base64-encoded-idp-xml>"
  },
  "jit": true
}'
```

Sample response - Update SAML registration

```
{
    "status": "success",
    "message": "{defaultSP} is Updated."
}
```

Sample error message - Update SAML registration

```
401 "error": "Insufficient user permission for role : rolename"
400 "error": "schema validation error:followed by error"
500 "error": "Other errors"
200 OK Response
```

Deleting SAML registration

To delete the SAML registration, you require the IdP UID. To get the IdP UID, see Get the list of IdP V3 registration. Alternatively, you can use the UID as **defaultSP** because only one SAML registration at an instance is supported for now.

The following example shows how to delete the IdP registration:

API details - Delete SAML registration - DELETE

API version
1.0.0
API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/:UID

Command

DELETE

Command output format

application/json

Note: The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3.

Sample curl command - Delete SAML registration

```
curl -k -X DELETE 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/defaultSP' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Sample response - Delete SAML registration

```
{
    "status": "success",
    "message": "{defaultSP} is deleted"
}
```

Sample error message - Delete SAML registration

```
400 "error": "Insufficient user permission for role : rolename"
404 "error": "Document not found"
500 "error": "Other errors"
202 OK Response
```

SAML metadata download by using IdP V3

You can export the SAML metadata by using IdP V3 API.

Details of downloading SAML metadata by using IdP V3 API.

Downloading the SAML metadata by using IdP V3 API

The following example shows how to export SAML metadata by using the **samlmetadata** API:

API details - download SAML metadata - GET

API version
1.0.0
API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

```
/idprovider/v3/auth/idsource/
```

Command

```
GET
```

Command output format

```
application/xml
```

Sample curl command - download SAML metadata

```
curl -k -v -X GET 'https://<cluster_address>/idprovider/v3/auth/idsource/<SERVICE_PROVIDER_ID>' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Example command - download SAML metadata

```
curl -k -v -X GET 'https://cp-console.apps.cp.fyre.ibm.com/idprovider/v3/auth/idsource/defaultSP' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Note: If you choose to download SAML metadata API, the response code shows `200 OK` status with SAML metadata sample.

Sample response - download SAML metadata

```

```

Configuring LDAP connection by using IdP V3 API

IMPORTANT: Creating and deleting an LDAP connection simultaneously can cause misconfiguration at the backend. Therefore, avoid creating and deleting the LDAP connection simultaneously.

Before you begin: Ensure that you are informed about the other LDAP configuration parameters that are used in the Identity Provider V3 APIs. For more information, see LDAP authentication, LDAP filters and Default LDAP filters by LDAP type. The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3 and Schema elements for LDAP connection.

Validating LDAP configuration while creating the LDAP connection using IdP V3 API

The following example shows how to validate the LDAP connection while creating an LDAP connection by using IdP V3 API:

API details - validate LDAP connection while creating - POST

API version
1.0.0
API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/ldap/validateConnection

Command

POST

Command output format

application/json

See the following notes:

- If you are setting up multiple LDAP connections, you must individually connect to each directory.
- In the curl command, you must use a base64-encoded password in the **"LDAP_BINDPASSWORD"** parameter. To encode the password, use the following command:

  ```
  echo -n <password> | base64
  ```

  Following is an example output:

  ```
  UGFzc3cwcmQ=
  ```

Sample curl command for validating LDAP configuration while creating an LDAP connection

```
curl -k -X POST 'https://cp-
console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/ldap/validateConnection' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
    "name": "openLDAP",
    "idp_config": {
        "ldap_url": "ldap://9.35.210.15:389",
        "ldap_basedn": "dc=ibm,dc=com",
        "ldap_binddn": "cn=admin,dc=ibm,dc=com",
        "ldap_bindpassword": "HNJat5opcqR="
    }
}'
```

Sample response - validate LDAP connection while creating

```
{"status":"success","result":"Successfully validated LDAP configuration."}%
```

Validating LDAP configuration while updating the LDAP connection by using IdP V3 API

The following example shows how to validate the LDAP connection while you update an LDAP connection by using IdP V3 API:

API details - validate LDAP connection while updating - POST

API version
1.0.0
API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/ldap/validateConnection

Command

POST

Command output format

application/json

See the following notes:

- The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3 and Schema elements for LDAP connection.
- In the curl command, you must use a base64-encoded password in the **"LDAP_BINDPASSWORD"** parameter. To encode the password, use the following command:

  ```
  echo -n <password> | base64
  ```

  Example output:

  ```
  UGFzc3cwcmQ=
  ```

Sample curl command for validating LDAP configuration while you update an LDAP connection

```
curl -k -X POST 'https://cp-
console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/ldap/validateConnection' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
    "name": "openLDAP",
    "idp_config": {
        "ldap_url": "ldap://9.35.210.15:389",
        "ldap_basedn": "dc=ibm,dc=com",
        "ldap_binddn": "cn=admin,dc=ibm,dc=com"
    }
}'
```

Sample response - validate LDAP connection while updating

```
{"status":"success","result":"Successfully validated LDAP configuration."}%
```

Registering an LDAP connection by using IdP V3 API

See the following notes:

- The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3 and Schema elements for LDAP connection.
- In the curl command, you must use a base64-encoded password in the **"LDAP_BINDPASSWORD"** parameter. To encode the password, use the following command:

  ```
  echo -n <password> | base64
  ```

  Example output:

  ```
  UGFzc3cwcmQ=
  ```

The following example shows how to register an LDAP connection by using IdP V3 API:

API details - register an LDAP connection - POST

API version
1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/

Command

POST

Command output format

application/json

The following sample curl command is for creating a custom LDAP connection. Replace the **"type"** parameter value with your LDAP type. For more information about the supported LDAP types, see Configuring LDAP connection.

You must also replace the parameter values in the **"idp_config"** section based on your LDAP type. For more information about the parameter values for each LDAP type, see Default LDAP filters by LDAP type.

Sample curl command for creating a custom LDAP connection

```
curl -k -X POST 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
  "name": "openldap",
  "description": "",
  "protocol": "ldap",
  "type": "Custom",
  "idp_config": {
        "ldap_id": "openldap",
        "ldap_realm": "REALM",
        "ldap_url": "ldap://9.30.253.13:389",
        "ldap_basedn": "dc=ibm,dc=com",
        "ldap_binddn": "cn=admin,dc=ibm,dc=com",
        "ldap_bindpassword": "UGFzc3cwcmQ=",
        "ldap_type": "Custom",
        "ldap_ignorecase": "false",
        "ldap_userfilter": "(&(uid=%v)(objectclass=person))",
        "ldap_useridmap": "*:uid",
        "ldap_groupfilter": "(&(cn=%v)(objectclass=groupOfUniqueNames))",
        "ldap_groupidmap": "*:cn",
        "ldap_groupmemberidmap": "groupOfUniqueNames:uniqueMember",
        "ldap_nestedsearch": "false",
        "ldap_pagingsearch": "false"
        }
}'
```

Getting information about all LDAP connections

The following example shows how to get the list of all the registered LDAP directories:

API details - information about all LDAP connections - GET

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource?protocol=ldap

Command

GET

Command output format

application/json

Note: The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3 and Schema elements for LDAP connection.

Sample curl command to get the list of registered LDAP connections

```
curl -k -X GET 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/?protocol=ldap' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Sample response - information about all LDAP connections

```
{"id":"8967e54c-7f6f-4755-a944-
cf4d2a4b8a64","LDAP_ID":"openldap","LDAP_REALM":"REALM","LDAP_HOST":"corp.abc.com","LDAP_PORT":"389","LDAP_IGNORECASE":"fa
lse","LDAP_BASEDN":"dc=ibm,dc=com","LDAP_BINDDN":"cn=admin,dc=ibm,dc=com","LDAP_TYPE":"Custom","LDAP_USERFILTER":"(&
(uid=%v)(objectclass=person))","LDAP_GROUPFILTER":"(&(cn=%v)
(objectclass=groupOfUniqueNames))","LDAP_USERIDMAP":"*:uid","LDAP_GROUPIDMAP":"*:cn","LDAP_GROUPMEMBERIDMAP":"groupOfUniqu
eNames:uniquemember","LDAP_URL":"ldap://corp.abc.com:389","LDAP_PROTOCOL":"ldap"}
```

Getting information about LDAP connection by using UID

The following example shows how to get the registered LDAP directory by UID:

API details - LDAP information by UID - GET

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/:UID

Command

GET

Command output format

application/json

Note: The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3 and Schema elements for LDAP connection.

Sample curl command to get the list of registered LDAP connections by UID

```
curl -k -X GET 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/:UID' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Sample response - LDAP information by UID

```
{"id":"8967e54c-7f6f-4755-a944-
cf4d2a4b8a64","LDAP_ID":"openldap","LDAP_REALM":"REALM","LDAP_HOST":"corp.abc.com","LDAP_PORT":"389","LDAP_IGNORECASE":"fa
lse","LDAP_BASEDN":"dc=ibm,dc=com","LDAP_BINDDN":"cn=admin,dc=ibm,dc=com","LDAP_TYPE":"Custom","LDAP_USERFILTER":"(&
(uid=%v)(objectclass=person))","LDAP_GROUPFILTER":"(&(cn=%v)
(objectclass=groupOfUniqueNames))","LDAP_USERIDMAP":"*:uid","LDAP_GROUPIDMAP":"*:cn","LDAP_GROUPMEMBERIDMAP":"groupOfUniqu
eNames:uniquemember","LDAP_URL":"ldap://corp.abc.com:389","LDAP_PROTOCOL":"ldap"}
```

Updating an LDAP connection by using IdP V3 API

See the following notes:

- Use **UID** to update the LDAP connection. To get the UID, see Getting information about LDAP connection by using UID.
- The curl command contains different schema elements. To understand the use of these schema elements, see Different schema elements for IdP V3 and Schema elements for LDAP connection.
- In the curl command, you must use a base64-encoded password in the **"LDAP_BINDPASSWORD"** parameter. To encode the password, use the following command:

  ```
  echo -n <password> | base64
  ```

The following is an example output:

```
UGFzc3cwcmQ=
```

The following example shows how to update an LDAP connection by using IdP V3 API:

API details - update an LDAP connection - PUT

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/:UID

Command

PUT

Command output format

application/json

Sample curl command to update an LDAP connection

```
curl -k -X PUT 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/8967e54c-7f6f-4755-
a944-cf4d2a4b8a64' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
  "name": "openldap",
  "description": "",
  "protocol": "ldap",
  "type": "Custom",
  "idp_config": {
        "ldap_id": "openldap",
        "ldap_realm": "REALM",
        "ldap_url": "ldap://9.35.210.15:389",
        "ldap_host": "9.35.210.15",
        "ldap_port": "389",
        "ldap_protocol": "ldap",
        "ldap_basedn": "dc=ibm,dc=com",
        "ldap_binddn": "cn=admin,dc=ibm,dc=com",
        "ldap_bindpassword": "UGFzc3cwcmQ=",
        "ldap_type": "Custom",
        "ldap_ignorecase": "false",
        "ldap_userfilter": "(&(uid=%v)(objectclass=person))",
        "ldap_useridmap": "*:uid",
        "ldap_groupfilter": "(&(cn=%v)(objectclass=groupOfUniqueNames))",
        "ldap_groupidmap": "*:cn",
        "ldap_groupmemberidmap": "groupOfUniqueNames:uniqueMember",
        "ldap_nestedsearch": "false",
        "ldap_pagingsearch": "false"
        }
}'
```

Sample response - update an LDAP connection

```
{"status":"success","message":"{8967e54c-7f6f-4755-a944-cf4d2a4b8a64} is Updated."}
```

Deleting an LDAP connection by using IdP V3 API

The following example shows how to delete an LDAP connection by using IdP V3 API:

API details - delete an LDAP connection - DELETE

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/:UID

Command

DELETE

Command output format

application/json

Note: To get the UID, see Getting information about LDAP connection by using UID.

Sample curl command to delete an LDAP connection

```
curl -k -X DELETE 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/8967e54c-7f6f-4755-a944-cf4d2a4b8a64' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

Sample response - delete an LDAP connection

```
{"status":"success","message":"{8967e54c-7f6f-4755-a944-cf4d2a4b8a64} is deleted"}
```

Disabling OpenShift authentication by using IdP V3 API

The following example shows how to disable Red Hat OpenShift authentication by using IdP V3 API:

API details - disable OpenShift authentication - PUT

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster address

Port number

Cluster port

Path

idprovider/v3/auth/idsource/osauth

Command

PUT

Command output format

application/json

Sample curl command to disable Red Hat OpenShift authentication

```
curl -k -X PUT 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/osauth' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
    "uid": "osauth",
    "description": "OpenShift Authentication enablement",
    "enabled": "false",
    "idp_config": {
        "ROKS_URL": "https://oauth-openshift.apps.cp3custom.cp.fyre.ibm.com",
```

```
        "ROKS_USER_PREFIX": ""
    },
    "name": "OpenShift",
    "protocol": "oauth",
    "type": "OpenShiftAuthentication"
}'
```

Sample response - disable OpenShift authentication

```
{
    "status": "success",
    "message": "{osauth} is Updated."
}
```

Getting the host details

1. Install OC client and connect to the Red Hat® OpenShift® Container Platform cluster. By default, Red Hat® OpenShift® Container Platform is enabled automatically once you install foundational services.
2. Get the hostname from the route available in the namespace where the foundational services is installed.

   ```
   oc get route -n <your-foundational services-namespace> cp-console -o jsonpath='{.spec.host}' && echo
   ```

   Sample output:

   ```
   cp-console.apps.mycluster.mydomain.com
   ```

Different schema elements for IdP V3 APIs

See the following mandatory fields and their description:

- `name`: Name of the IdP that you want to register.
- `description`: Short description of the registration.
- `protocol`: Type of protocol. Currently, OIDC, SAML, and LDAP are the only supported protocols.
- `type`: Type of configured LDAP, OIDC, or SAML IdP. For example, Google, Microsoft, IBM ISV, and Okta for OIDC; `isv` and `default` for SAML.
- `idp_config`: Contains the following subfields:
  - OIDC has the following fields:
    - `discovery_url`: A well-known endpoint by OIDC provider.
    - `client_id`: A client ID that is provided by the registered application in the IdP.
    - `client_secret`: A client secret that is provided by the registered application in the IdP.
  - SAML has the following fields:
    - `idp_metadata`: A base64-encoded value of IdP metadata XML file. The maximum accepted size of the metadata file is `2 MB`. If the size of the metadata file is more than 2 MB, an error message is displayed during the SAML registration.
    - `token_attribute_mappings`: Used to map the token attributes with the IdP user attributes You need to replace only the `values_to_be_mapped` based on your IDP configuration at the backend.
      - Sample mapping:

        ```
        "token_attribute_mappings": {
                "groups": "values_to_be_mapped",
                "given_name": "values_to_be_mapped",
                "family_name": "values_to_be_mapped",
                "sub": "values_to_be_mapped",
                "email": "values_to_be_mapped"
                }
        ```

        The mapped values are case-sensitive.

Schema elements for SAML with SCIM dependency

See the following schema elements:

- `scim_config`: Used to provide SCIM configuration and SCIM attribute mapping information.
  - `grant_type` - Identifies the token generation flow. The `client_credentials` value is used to issue the tokens to access the SCIM APIs.
  - `token_url` - Token endpoint of IdP. It is used to request the token.
  - `client_id` - Used for the client credentials flow.
  - `client_secret` - Used for the client credentials flow.

Example schema

```
"scim_config": {
  "scim_base_path": "https://bedrock-iam.verify.ibm.com/v2.0/",
  "grant_type": "client_credentials",
  "token_url": "https://bedrock-iam.verify.ibm.com/v1.0/endpoint/default/token",
  "client_id": "Your_isv_client_id",
```

```
  "client_secret": "Your_isv_client_secret",
  "scim_attribute_mappings": {
    "user": {
      "principalName": "userName",
      "givenName": "name.givenName",
      "middleName": "name.middleName",
      "familyName": "name.familyName",
      "formatted": "name.formatted"
    },
    "group": {
      "principalName": "displayName",
      "created": "meta.created",
      "lastModified": "meta.lastModified"
    }
  }
}
```

Schema elements for SAML with LDAP dependency

ldap_config is used to provide LDAP dependency information. See the following example:

```
"ldap_config":
{
  "ldap_id": "existing-ldap-connection-name"
}
```

Schema elements for LDAP connection

To know more about LDAP parameters that are used in Identity Provider APIs, see LDAP authentication, LDAP filters, and Default LDAP filters by LDAP type.

- **LDAP_PAGINGSEARCH**: If the **LDAP_PAGINGSEARCH** parameter is set as **"false"**, it indicates that the pagination option is disabled. Set this parameter to **"true"** to enable the pagination option.
- **LDAP_PAGING_SIZE**: It is a numeric field that defines the page size of the LDAP type. You can set the number as per your requirement. It is an optional field. If you do not provide the value to the **LDAP_PAGING_SIZE** parameter, the default page size of the LDAP server is considered as a request in the API query.

  For example, when the LDAP type is Microsoft Active Directory and you do not provide the **LDAP_PAGING_SIZE** value in the API, then 1000 (default page size) value is considered as a request in the API. Also, the **LDAP_PAGING_SIZE** value must not exceed the default server-side page limit or the maximum configured value for the respective LDAP type.

SAML metadata export by using samlmetadata API

Export SAML metadata by using the **samlmetadata** API.

The following example shows how to export SAML metadata by using the **samlmetadata** API:

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster Master Host

Port number

Cluster Master API Port

Path

/idprovider/v3/saml/metadata/

Command

GET

Command output format

application/xml

The sample curl command resembles the following code:

```
curl -k -v -X GET 'https://<cluster_address>/idprovider/v3/saml/metadata/<SERVICE_PROVIDER_ID>' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

See the following example. **Note:** As of now, **defaultSP** is the only supported service provider metadata for the **samlmetadata** API.

```
curl -k -v -X GET 'https://cp-console.apps.cp.fyre.ibm.com/idprovider/v3/saml/metadata/defaultSP' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

The response resembles the following code:

Note: If you choose to download SAML metadata API, the response code shows `200 OK` status with SAML metadata sample.

```
200 OK

Issue resolution API

The issue resolution API allows for the interaction with alerts, incidents and related artifacts.

Note: The API reference (Swagger) document for the issue resolution API is not interactive and is published for your understanding of the different APIs and schemas available. For more information about how to access these APIs, review the following commands and procedure.

Endpoint URLs

Issue resolution events API

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/issue-resolution/v1/events/
```

Issue resolution alerts API

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/issue-resolution/v1/alerts/
```

Issue resolution incidents API

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/issue-resolution/v1/incidents
```

Authentication

The API uses Platform UI (Zen) authentication, so you either need a JWT token or ZenApiKey to be authenticated. The token or key is used to determine whether a user or service ID has access when you use the API.

Accessing the API with cURL

1. Log in to your cluster and authenticate your admin user credentials for running API commands:
    1. Adjust the project (namespace) for your system:

        ```
        NAMESPACE=cp4aiops
        ```

    2. Get the route for loading your metric data and set it as an environment variable by running the following command:

        ```
        ROUTE=$(oc -n $NAMESPACE get route | grep ibm-nginx-svc | awk '{print $2}')
        ```

    3. Get the admin username and set it as an environment variable by running the following command

        ```
        USER=$(oc -n $NAMESPACE get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_username}' | base64 -d)
        ```

    4. Get the password for your admin username and set it as an environment variable by running the following command:

        ```
        PASS=$(oc -n $NAMESPACE get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_password}' | base64 -d)
        ```

    Note: Two methods of authentication are available:

    - JWT Bearer Token

        This token is temporary and lasts about 4 hours.

    - Platform UI (ZenApiKey) API key

        This key remains until deleted.

    For more information about API authentication, see Accessing APIs

2. Set your authentication.
    - If you are using the Platform UI (ZenApiKey) API key option, encode your admin username and API key with Base64 encoding:

        ```
        ZENAPIKEY=$(echo "<username>:<API_key>" | base64 -w 0); echo $ZENAPIKEY
        ```

    - If you are using the JWT Bearer Token option, set the token as an environment variable. The following command uses variables that are set in the previous step:

        ```
        TOKEN=$(curl -k -X POST https://$ROUTE/icp4d-api/v1/authorize -H "Content-Type: application/json" -d "{\"username\": \"$USER\",\"password\": \"$PASS\"}" 2>/dev/null|awk -F'"' '{print $(NF-1)}')
        ```

3. Run a command to access the API. For example, the following command uses cURL to access the issue resolution alerts API to load alert data:
    - By using the route and the Platform UI (ZenApiKey) API key option:

        ```
        curl -k -v -X POST "https://${ROUTE}/aiops/api/issue-resolution/v1/alerts/" --header "Content-Type: application/json" --header "Authorization: ZenApiKey ${ZENAPIKEY}" --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --data @<FILEPATH/FILE>.json
        ```

        Where **<FILEPATH/FILE>** is the full path to the JSON file that includes your sample alert data to load.

    - By using the route and the JWT Bearer Token option:

        ```
        curl -k -v -X POST "https://${ROUTE}/aiops/api/issue-resolution/v1/alerts/" --header "Content-Type: application/json" --header "Authorization: Bearer ${TOKEN}" --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --data @<FILEPATH/FILE>.json
        ```

        Where **<FILEPATH/FILE>** is the full path to the JSON file that includes your sample alert data to load.

Enabling access to the Probable cause customization APIs

The Probable cause API ranks the alerts in an incident. This API uses a classifier that uses Natural Language Processing (NLP) to determine the meaning of an alert and calculates the topology path between alerts to create a ranking for each applicable alert.

Probable cause can be computed by the following two approaches:

- Word based approach is very useful when the environment does not have topological data. This approach works in partnership with the topological probable causes when the topological data is available. Word based approach allows the users to define keywords that are given an importance score. If a word is in the summary field, the alert is given that score (the sum of all words).
- With the severity based approach, the higher severity alert is assigned a larger score. A higher severity alert does not always mean that an alert is a root cause. Higher severity alert generally gives more context to the operator about the impact. These alerts within a large group is important so that an operator can get

context quickly.

You can use the Probable cause API to customize the analytics for probable cause, and add edge configurations when new custom edge types are added to IBM Cloud Pak for AIOps.

Note: If the topological data includes a user-defined edge, then the probable cause API does not understand the relationships in the topology. You can see improved results when an edge type is added to the system.

The Probable cause customization APIs are exposed by default, but to access them you must generate the token first. The API uses the IBM Cloud Pak Platform UI authentication, so you need a JWT (JSON Web Token) to be authenticated. The token is used to determine whether a user or service ID has access when they use the API.

Probable Cause Customization APIs

1. Log in to the cluster.
2. Set ROUTE to **cpd** route.

   For example:

   ```
   ROUTE=$(oc get route cpd -n cp4aiops --no-headers | awk '{print $2}')
   ```

3. Use the admin-user-details secret to set PASS.

   ```
   PASS=$(oc get secret admin-user-details -o jsonpath='{.data.initial_admin_password}' -n cp4aiops | base64 -d)
   ```

4. Create the TOKEN.

   ```
   TOKEN=$(curl -s -k -X POST https://$ROUTE/icp4d-api/v1/authorize -H 'Content-Type: application/json' -d '{"username": "admin","password": <PASS>}' | jq .token | sed 's/"//g')
   ```

   Where **PASS** is the password obtained in the preceding step.

Example of accessing the APIs

You can now access the APIs, for example:

`/customisation/edge_type`

Use a GET request **/customisation/edge_type** to get the list of edges in the system.

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}" https://$ROUTE/aiops/api/issue-resolution/mime/v1/customisation/edge_type -H "accept: application/json" -H "X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255"
```

The label and edge names are the same as those added in the topological resource group. Some edges have different weight due to directorial. Overall, an **indegree** edge has a higher weight than an **outdegree** edge.

Note: If the system encounters an **unknown** edge type, then it uses the average of weight in the edge label group.

The following example shows a response(200) for the GET request:

```
{
"edge_type_list": [
   {
      "edge": "string",
      "label": "AGGREGATION",
      "outdegree": 0,
      "indegree": 0
   }
]
}
```

Use a POST request **/customisation/edge_type** to overwrite the complete list of edge types.

```
curl -k -X POST -H "Content-Type: application/json" -H "Authorization: Bearer ${TOKEN}" https://$ROUTE/aiops/api/issue-resolution/mime/v1/customisation/edge_type -H "X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255" -d '{"edge_type_list":[{ "edge": "newEdgeName", "label": "association", "outdegree": 20,"indegree": 5}]}'
```

The following example shows a response(200) for the POST request:

```
{"Result":"Success"}
```

After the path score is calculated, the summary is classified in one of the following 8 categories.

Table 1. Label and Weight relationship for classification of summary

Label	Weight
errorrate	1.4
exception	1.2
information	1
latency	2

Label	Weight
saturation	2.2
stateChange	1.8
traffic	2.4
unknown	-1

In order to modify the label weight, use the API **`/customisation/label_weight`**.

`/customisation/label_weight`

Use a POST request **`/customisation/label_weight`** to add or update label weight. The request body is an array of label weight objects.

```
curl -k -X POST -H "Content-Type: application/json" -H "Authorization: Bearer ${TOKEN}" https://$ROUTE/aiops/api/issue-resolution/mime/v1/customisation/label_weight -H "X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255" -d '{"label_weight_list":[{"label":"association","weight":1.2}]}'
```

The following example shows a response(200) for the POST request:

```
{"Result":"Success"}
```

Note: Before removing a label from the list, remove all of the training examples from the classifier. The classifier looks at the word in the summary and attempts to put the alert in the in the appropriate category.

`/customisation/words`

Use a GET request **`/customisation/words`** to get the list of words in alert summary that is used by probable cause for the specified tenant ID. If the GET request is successfull(200 response), the response includes an array of **`words`** for the alert.

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}" https://$ROUTE/aiops/api/issue-resolution/mime/v1/customisation/words -H "accept: application/json" -H "X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255"
```

The following example shows a response(200) for the GET request:

```
{
   "words":[
      {
         "word":"error",
         "caseSenstive":false,
         "weight":100
      },
      {
         "word":"ECC",
         "caseSenstive":true,
         "weight":10
      }
   ]
}
```

If both words "error" and "ECC" are found in same alert summary then the weight(score) is added. For example, if **`error`** has a weight of 100 and **`ECC`** has a weight of 10, then the total word score is 110. The higher the score, the more likely that this alert is a root cause.

Use a POST request **`/customisation/words`** to update(replace) the words in the system. The request body is the JSON array of words for probable cause.

```
curl -k -X POST --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}" -H "Content-Type: application/json" https://$ROUTE/aiops/api/issue-resolution/mime/v1/customisation/words -H "accept: application/json" -H "X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255" -d '{"words":[{"word":"error","caseSenstive": false, "weight":100}, {"word":"ECC","caseSenstive": true, "weight":10}]}'
```

The following example shows a response(200) for the POST request:

```
{"Result":"Success"}
```

`/customisation/severity`

Use a GET request **`customisation/severity`** to get the list of severities that is used by probable cause for the specified tenant ID. Based on the severity of the alert, the weight is added to the word score. Refer to the following table for more details:

Table 2. Severity and Weight relationship

Severity	Weight
1	10
2	20
3	30
4	40
5	50
6	60

If the word score is 110(Error and ECC from previous example) and the severity of the alert is critical(which is 6), then 60 is added to the score, resulting in a word score of 170.

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}" https://$ROUTE/aiops/api/issue-resolution/mime/v1/customisation/severity -H "accept: application/json" -H "X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255"
```

The following example shows a response(200) for the GET request:

```
{
   "severities":[
      {
         "severity":2,
         "weight":20
      }
   ]
}
```

Use a POST request **/customisation/severity** to update(replace) the probable cause to use the array of severities. The request body is JSON array of severities which will overwrite the current array of severities.

The following example shows a response(200) for the POST request:

```
{"Result":"Success"}
```

Use a DELETE request **/customisation/severity** to delete all the severities for the specified tenant ID.

The following example shows a response(200) for the DELETE request:

```
{"Result":"Success"}
```

/customisation/scoring/config

Use a GET request **customisation/scoring/config** to get the scoring configuration parameters for the specified tenant ID. If the API request is successfull(200 response), the response includes a list of the scoring configuration attributes that are turned on or off.

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}" https://$ROUTE/aiops/api/issue-resolution/mime/v1/customisation/scoring/config -H "accept: application/json" -H "X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255"
```

The following example shows a response(200) for the GET request:

```
{
"pathCaculationEnabled": true,
"wordEnabled": true,
"severityEnabled": true,
"causeScoreEnabled": true,
"itnmproccessing": true,
"itnmCausesWeight": 110,
"firstBoost" : true,
"firstBoostWeight" : 100,
}
```

Use a POST request **customisation/scoring/config** to alter the scoring configuration parameters for the specified tenant ID.

The following example shows a response(200) for the POST request:

```
{"Result":"Success"}
```

For more information about probable cause ranking and probable cause determination, see Probable cause ranking

Next steps

For more information about probable cause, see Probable cause in ChatOps.

For more information about the available APIs and related Swagger documentation, see the additional topics under APIs. For example, for more on access tokens, see Accessing APIs.

IBM Cloud Pak for AIOps Change Risk REST API

This documentation is for the IBM Cloud Pak for AIOps Change Risk REST API

Version: 1.0.0

Endpoint Root URL

Change Risk REST API root URL is as follows:

```
https://cpd-{CLUSTER_NAMESPACE}.apps.{CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/ai-manager/change-risk/v1
```

/change_requests/risk_assessment

POST

Description

Get the risk assessment by providing a change request ticket information.

Parameters

- include_explanation : true or false for turning on/off explanation. Explanation is included by default.

Responses

Code	Description
200	Response
400	Bad request
404	Not found
500	Internal server error
504	Internal processing timeout
default	unexpected error

Example

The sample curl command resembles the following code:

```
CLUSTER_URL=https://cpd-cp4waiops.apps.mycluster.mydomain.myco.com/aiops/api/ai-manager/change-risk/v1
curl -X POST $CLUSTER_URL/change_requests/risk_assessment?include_explanation=true \
-H "Authorization: Bearer $ACCESS_TOKEN" \
-H 'Content-Type: application/json' \
--data '{
   "number":"CHG0775062",
   "sys_domain":"crn:v1:bluemix:public::mil01::::",
   "business_service":"Network",
   "short_description":"is DATACENTER 2020-05-17 08:29:00 UTC",
   "description":"description text field",
   "justification":"none",
   "backout_plan":".",
   "impact":"No",
   "reason":"Replace server due to hardware issue.",
   "state":"Closed",
   "type":"softlayer",
   "sys_created_by":"SoftLayer Jira.SA",
   "assigned_to":"name@email.com",
   "close_code":"successful",
   "close_notes":"Change was completed successfully"
}'
```

The preceding data field must validate against a change record schema. The response will look similar to the following:

```
{
   "id":"77f3f724727811eb9e81c8e0eb1474cb",
   "prediction_text":"Prior ticket data insights classify this as a high risk change.",
   "prediction_confidence":0.979616,
   "explanation":{
      "words":{
         "test":0.1,
         "run":0.073,
         "pod":0.059,
         "node":0.056,
         "error":0.041,
         "release":0.036,
         "remove":0.027,
         "backout":0.025,
         "fail":0.023,
         "plan":0.017,
         "utc":0.017,
         "system":0.013,
         "previous":0.012
      },
      "relevant_change_tickets":[
         {
            "number":"CHG0675192",
            "sys_domain":"crn:v1:bluemix:public::mil01::::",
            "business_service":"Network",
            "short_description":"is DATACENTER 2020-05-17 08:29:00 UTC",
            "description":"description text field",
            "justification":"none",
            "backout_plan":".",
            "impact":"No",
            "reason":"Replace server due to hardware issue.",
            "state":"Closed",
            "type":"softlayer",
            "sys_created_by":"SoftLayer Jira.SA",
            "assigned_to":"name@email.com",
            "close_code":"successful",
            "close_notes":"Change was completed successfully"
            "induced_incidents":[
               {
                  "description":"description text",
                  "number":"INC2468135",
                  "severity":"1 - High"
               }
            ]
         }
      ],
      "ticket_relevance_level":{
```

```
         "CHG0675192":10.0
      },
      "ticket_similarity_level":{
         "CHG0675192":1.0
      }
   }
}
```

/feedback/types/risk_assessment

POST

Description

Provide feedback for the corresponding change risk assessment

Responses

Code	Description
200	Response
400	Bad request
404	Not found
500	Internal server error
default	unexpected error

/feedback/types/risk_assessment_explanation

Metric REST API

The Metric API allows for the posting of metric data for anomaly detection and forecasting.

Note: The API reference (Swagger) document for the metric API is not interactive and is published for your understanding of the different APIs and schemas available. For more information about how to access these APIs, review the following commands and procedure.

Endpoint URLs

Metric Ingestion API

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/app/metric-api/v1/metrics
```

Metric Retrieval API

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/app/metric-api/v1/metrics
```

Metric Forecasting API

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/app/metric-api/v1/forecast
```

Authentication

The API uses Platform UI (Zen) authentication, so you either need a JWT token or ZenApiKey to be authenticated. The token or key is used to determine whether a user or service ID has access when you use the API.

Error handling

Metric Ingestion API error handling

Table. Metric ingestion API error codes

HTTP Error Code	Description	Recovery
`200`	Success	Success.
`400`	Bad Request	Invalid value in JSON.
`403`	Forbidden	The supplied authentication is not authorized to access '{namespace}'.
`500`	Internal Server Error	An error occurred processing your request.

Metric Retrieval API error handling

Table. Metric retrieval API error codes

HTTP Error Code	Description	Recovery
`200`	Success	Success.
`400`	Bad Request	Invalid parameters.
`403`	Forbidden	The supplied authentication is not authorized to access '{namespace}'.
`500`	Internal Server Error	An error occurred processing your request.

Metric Forecasting API error handling

Table. Metric forecasting API error codes

HTTP Error Code	Description	Recovery
`200`	Success	Success.
`204`	No Content	Success, no data is found for provided attributes.
`400`	Bad Request	Invalid value in JSON.
`401`	Unauthorized	You are not authorized to make this request.
`403`	Forbidden	The supplied authentication is not authorized to access '{namespace}'.
`500`	Internal Server Error	An error occurred processing your request.

Ingest data

To inject data for metric analysis, you need to first log in to your cluster and authenticate for using APIs:

1. Log in to your cluster and authenticate your admin user credentials for running API commands:
    1. Adjust the project (namespace) for your system:

```
NAMESPACE=cp4aiops
```

2. Get the route for loading your metric data and set it as an environment variable by running the following command:

   ```
   ROUTE=$(oc -n $NAMESPACE get route | grep ibm-nginx-svc | awk '{print $2}')
   ```

3. Get the admin username and set it as an environment variable by running the following command

   ```
   USER=$(oc -n $NAMESPACE get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_username}' | base64 -d)
   ```

4. Get the password for your admin username and set it as an environment variable by running the following command:

   ```
   PASS=$(oc -n $NAMESPACE get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_password}' | base64 -d)
   ```

Note: Two methods of authentication are available:

- JWT Bearer Token

  This token is temporary and lasts about 4 hours.

- Platform UI (ZenApiKey) API key

  This key remains until deleted.

For more information about API authentication, see Accessing APIs

2. Set your authentication.

   - If you are using the Platform UI (ZenApiKey) API key option, encode your admin username and API key with Base64 encoding:

     ```
     ZENAPIKEY=$(echo "<username>:<API_key>" | base64 -w 0); echo $ZENAPIKEY
     ```

   - If you are using the JWT Bearer Token option, set the token as an environment variable. The following command uses variables that are set in the previous step:

     ```
     TOKEN=$(curl -k -X POST https://$ROUTE/icp4d-api/v1/authorize -H 'Content-Type: application/json' -d "{\"username\": \"$USER\",\"password\": \"$PASS\"}" 2>/dev/null|awk -F'"' '{print $(NF-1)}')
     ```

3. Run a command to load the training data file. As an example, the following command uses cURL to access the API.

   - By using the route and the Platform UI (ZenApiKey) API key option:

     ```
     curl -k -v -X POST "https://${ROUTE}/aiops/api/app/metric-api/v1/metrics" --header 'Content-Type: application/json' --header "Authorization: ZenApiKey ${ZENAPIKEY}" --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --data @<FILEPATH/FILE>.json
     ```

     Where **<FILEPATH/FILE>** is the full path to the JSON file that includes your training data to load.

   - By using the route and the JWT Bearer Token option:

     ```
     curl -k -v -X POST "https://${ROUTE}/aiops/api/app/metric-api/v1/metrics" --header 'Content-Type: application/json' --header "Authorization: Bearer ${TOKEN}" --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --data @<FILEPATH/FILE>.json
     ```

4. To ensure that data is injected, run a command to return data with the API. As an example, the following command uses cURL to access the API.

   - By using the route and the Platform UI (ZenApiKey) API key option:

     ```
     curl -v "https://${ROUTE}/aiops/api/app/metric-api/v1/metrics?resource=MyApp&group=Latency&metric=calls.sum" --header "Authorization: ZenApiKey ${ZENAPIKEY}" --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --insecure
     ```

   - By using the route and the JWT Bearer Token option:

     ```
     curl -v "https://${ROUTE}/aiops/api/app/metric-api/v1/metrics?resource=MyApp&group=Latency&metric=calls.sum" --header "Authorization: Bearer ${TOKEN}" --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --insecure
     ```

JSON schema for metrics data

JSON Payload:

```
{
    "groups": [
        {
            "timestamp": <timestamp>,
            "resourceID": "<resource ID>",
            "metrics": {
                "<kpi-1>": <value-1>,
                "<kpi-2>": <value-2>,
                ...
                "<kpi-n>": <value-n>
            },
            "attributes": {
                "group": "<metric namespace>",
                "node": "<top-level resource>"
            }
        }
```

```
    ]
}
```

- `timestamp` - The epoch time in milliseconds (13 digits) or ISO-8601.
- `resourceID` - The resource that is being measured.
- `metrics` - A map of metric name to metric value.
- `attributes` - Anything that helps provide context to the user.
- `group` - Field that you can use to namespace a metric. For example, "customer1". Therefore, group helps distinguish metrics names.
- `node` - The top-level resource.

Example JSON Payload:

```
{
    "groups": [
        {
            "timestamp": "1642516320000",
            "resourceID": "MyApp",
            "metrics": {
              "calls.sum": 476.0,
              "latency.mean": 1.6722689
            },
            "attributes": {
              "group": "Latency",
              "node": "MyApp"
            }
        }
    ]
}
```

Note: The `attributes.group`, `resourceID`, and the `metrics` (for example, `metrics.access-denied`) fields, along with the `tenantID` (part of the header in the HTTP request) make up the unique identifier for a KPI. Therefore, as part of the metric anomaly processing and detection, any data points with different values for these fields are considered as different metrics. For example, consider the following two data points:

```
{
  "groups": [
    {
      "timestamp": 1634846130000,
      "resourceID": "10.10.10.2",
      "metrics": {
        "access-denied": 14977
      },
      "attributes": {
        "group": "Org1",
        "node": "firewall-1"
      }
    },
    {
      "timestamp": 1634846130000,
      "resourceID": "10.10.10.2",
      "metrics": {
        "access-denied": 379
      },
      "attributes": {
        "group": "Org2",
        "node": "firewall-1"
      }
    }
  ]
}
```

These two data points have the same `timestamp` value (`1634846130000`) and `resourceID` value (`10.10.10.2`), but have two different group attribute names (`Org1` and `Org2`). This difference causes the data points to be treated as different metrics.

The JSON metric field for correlating a metric anomaly with an element in a resource group depends on the data source for the corresponding topology data. For example, for topology data that is ingested through an Instana connection, the following matching rule is used for correlation: `${name}:::${uniqueId}`. As another example, for topology data that is ingested through a file observer job, the `resourceID` field is used as the identifier for topology correlation.

Unpegging, accumulator and counter attributes: For metrics that count upwards only from when the system starts, the analytics wants to work on the delta values rather than the raw values.

- To identify which metrics are pegs, accumulators, or counters in metric anomaly detection, set an attribute per metric group, for example: `"accumulators":"TotalConnections,SuccessfulLoginCount"`
- Alternatively, you can set the attribute to `ALL` to apply to all metrics, for example: `"accumulators":"ALL"`

Aggregation attributes: Average is the default aggregation type, except for accumulators, where sum is the default.

- To identify which metrics are to be aggregated with sum in metric anomaly detection, set an attribute per metric group, for example: `"sumAggregator":"newConnections,Logins"`
- Alternatively, you can set the attribute to `ALL` to apply to all metrics, for example: `"sumAggregator":"ALL"`

Introduction

Runbook Automation is responsible for the management of runbooks and runbook instances. Runbooks are structured operational procedures which can be created, changed, and executed. They might include several types of automation and run manual, semi-automated, or fully-automated. Runbook instances are the execution records of Runbooks. They contain the status and details of one specific execution and can be changed to step through an execution and finish it. Additionally other administrative functions are presented in the API, including configuration management. To send API calls, create an API key in the application and find detailed API documentation inside the Swagger document.

Endpoint URLs

Runbook API

It is used to manage runbooks.

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/story-manager/rba/v1/runbooks
```

Runbook instance API

It is used to manage runbook executions.

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/story-manager/rba/v1/runbookinstances
```

Configuration API

It is used to manage Runbook Automation configuration.

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/story-manager/rba/v1/configuration
```

Tag API

It is used to retrieve runbook tags.

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/story-manager/rba/v1/tags
```

Usage Statistics API

It is used to retrieve Runbook Automation usage statistics.

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/story-manager/rba/v1/statistics/runbookinstances
```

Status API

It is used to retrieve the status of the Runbook Automation deployment.

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/story-manager/rba/v1/status
```

User API

It is used to retrieve a list of all users who have a given role.

```
cpd-aiops.apps.{OC_CLUSTER_NAME}.{CLUSTER_DOMAIN_PREFIX}.{CLUSTER_TERMINAL_DOMAIN}/aiops/api/story-manager/rba/v1/users
```

Authentication

The API uses Zen authentication which requires a JWT token to be authenticated. The token is used to determine whether a user or service ID has access when they use the API.

Error handling

The Runbook Automation API returns one of the following HTTP responses for every API call.

HTTP Error Code	Description	Recovery
200	Success	The call was successful. See the output for the requested data.
204	No Content	Action completed successfully, no data is returned by the server.
400	Bad Request	The input was invalid. Read the error message and adjust your input before trying again.
401	Unauthorized	The request was not authorized. Make sure your API key is valid and the user and password are entered correctly.
403	Forbidden	The supplied authentication is not authorized to access the given API.
500	Internal Server Error	An internal error happened. A correlationId is provided. Include this ID in any request towards IBM support.

Application and topology APIs

IBM Cloud Pak® for AIOps offers a set of tools and APIs that you can use to predict, communicate, and resolve events before they become serious problems for your organization.

To learn more about how topologies are displayed in the UI, review the topology viewer documentation. For more information, see Topology viewer.

API authentication

For more information on how to authenticate to use APIs, see Accessing APIs.

Access to URL routes

For more information on how to access the URL routes for the topology Swagger documentation, see Enabling access to URL routes.

Access the topology service Swagger through port forwarding

- Accessing topology Swagger

Swagger documentation

Review the following Swagger documentation to use Topology APIs for configure File Observer and Rest Observer jobs.

- Topology File Observer API
- Topology Rest Observer API

To learn more about how to use these jobs, such as for including custom data in topologies, see:

- Configuring REST Observer jobs
- Configuring File Observer jobs

Troubleshooting: Swagger UI not responding during high-volume query

When querying for resources using **`GET /resources`**, the Swagger UI may become unresponsive if there are in excess of a thousand results.

- **Cause:** This is a Swagger limitation.
- **Workaround:** None. Avoid high-volume Swagger queries.

API reference documentation

To learn more about using the topology APIs, including terminology and properties, see Topology API reference.

Accessing Topology service Swagger UI

You can access the Topology service Swagger using port forwarding.

Before you begin

You need to be an administrator with **`oc client`** access in order to **`get`** secrets, services, and to enable port-forwarding in the ASM namespace.

About this task

A simple way to access the Topology service Swagger is to use the **`oc port-forward`** command. You can then access Swagger on your local browser through **`localhost`**. **Note:** Port forwarding will be enabled temporarily only. When there is no traffic, it will automatically be closed.

- To log on, use **`oc login`**
- To obtain the service name, use **`oc get service`**
- To enable port forwarding, use **`oc port-forward service/aiops-topology-topology 8080`**

Enable port forwarding

See the following steps as an example.

1. Log on using the **`oc login`** command.
2. Find the secret storing the credentials for Swagger using the **`oc get secret | grep topology-asm-credentials`** command.

   System output:

   ```
   aiops-topology-asm-credentials                                    Opaque                                2      3h54m
   ```

3. Find the topology service secret using the **`oc get service | grep topology-topology`** command.

   System output:

   ```
   aiops-topology-topology                                  ClusterIP   1.2.3.4    <none>        8080/TCP,8081/TCP
   3h49m
   ```

4. Enable port forwarding using the **`oc port-forward service/aiops-topology-topology 8080`** command.

System output:

```
Forwarding from 127.0.0.1:8080 -> 8080
Forwarding from [::1]:8080 -> 8080
```

Note: If the port is not accessed for a while, the connection is closed:

```
Forwarding from [::1]:8080 -> 8080
E0622 07:57:52.101053   25681 portforward.go:233] lost connection to pod
```

5. Now access the topology service swagger api in a browser on the same host as the one the oc commands were run on, at the following URL `https://localhost:8080/1.0/topology/swagger`

6. Authorise using the credentials from the secret obtained in step 3.

Enabling access to URL routes for topology observer APIs

To access the URL routes for the topology Swagger documentation, you need to update the IBM ASM Operator configuration.

About this task

The URL to access an observer API consists of **{HOST}/{PATH}** and the Swagger UI URL consists of **{HOST}/{PATH}/swagger**.

Procedure

Complete the following configuration to expose all observers for both **full** and **listen** jobs.

1. Run the following command to edit the ASM operator configuration:

   ```
   oc edit asm aiops-topology
   ```

2. Search for the string `helmValuesASM:` within the `spec` section of the operator custom resource. Add `global.enableAllRoutes: true` to the list of values to enable the routes. The following example, shows this setting:

   ```
   spec:
     helmValuesASM:
       global.enableAllRoutes: true
   ```

3. Save your changes and wait for the ASM operator to reload.

4. Use the `oc get route | grep` command to view the route details for an observer API to check whether the topology routes are enabled:

   ```
   oc get route | grep topology
   ```

   Output:

   ```
   aiops-topology-topology-cp4aiops.apps.aiops.xxxxxx.xxxxxx.com /1.0/topology/
   ```

Examples

Example: View AppDynamics observer route details

The following example uses the AppDynamics observer:

```
oc get route | grep appdynamics
```

Output:

```
NAME                                    HOST/PORT
PATH                              SERVICES                                    PORT    TERMINATION          WILDCARD
aiops-topology-appdynamics-observer       aiops-topology-appdynamics-observer-aiops.apps.myibm.com       /1.0/appdynamics-
observer       aiops-topology-appdynamics-observer       9148    reencrypt/Redirect   None
```

Example: cURL command to the AppDynamic Observer (or job) endpoint

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}" https://aiops-topology-appdynamics-
observer-aiops.apps.myibm.com/1.0/appdynamics-observer/jobs --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255'
{"_items":[],"_limit":100}
```

Note: To obtain your access token, see Accessing APIs.

Example Swagger UI URL: `https://aiops-topology-appdynamics-observer-aiops.apps.myibm.com/1.0/appdynamics-observer/swagger`

Next steps

For more information on the available API and related Swagger documentation, see the additional topics under APIs.

Topology API reference

The following topics explain the common terminology, properties, types, and more for the available topology APIs.

Terminology

In addition to the following terms, ensure that you are familiar with the important terms that are defined within the Glossary.

resource: A resource is a node in an interconnected topology, sometimes also referred to as a vertex, or simply a node. It can be anything in a user-specific topology that is designated as such, for example a hardware or virtual device, a location, a user, or an application.

edge: An edge is a relationship between resources, also simply referred to as the 'link' between resources. Edges have a label, which allocates them to a family of edges with specific behavior. It also governs how they are displayed in the UI, and an edgeType, which defines the relationship in real terms.

tenant: A tenant is represented by a globally unique identifier, its tenant ID. The default tenant ID is: cfd95b7e-3bc7-4006-a4a8-a73a79c71255

provider: A provider is usually a single data source within the scope of a tenant. The provider is a namespace for the resource's uniqueId. That uniqueId property is unique only within the scope of a provider.

status: Status is a property of one or more resources, and a single resource can have different types of status.

Each status can be in one of three states:

- open
- clear
- closed

The severity can be one of the following ratings:

- clear
- information
- indeterminate
- warning
- minor
- major
- critical

The status of a resource is derived from events, or if the resource is retrieved through the status service. It can also be supplied when resources are posted to the topology service.

Reference documentation

Properties

The Topology Service has two categories of properties, generic and user. Generic properties have fixed data types, while user-defined properties do not.

Edge labels

The topology service defines a family of labels for the edges it supports.

Edge types

All edges created in the Topology Service should define an edge **type**. The following section lists the edge types that are associated with each of the public-facing edge labels. If none of the default edge types suffice, you can create custom edge types.

Entity types

Use the Topology Service to group together resources of the same type using the **`entityTypes`** property, and identify them in the UI by their icon. Usually a resource has only a single entity type but as the property is a *Set*, it is possible for a resource to have more than one entity type. A number of pre-defined entity types are supplied. In addition, you can create more entity types as required.

Status (and state)

Resources have specific statuses, and in turn each status has a state of open, clear or closed.

Timestamps

Both vertex and edge graph elements can have multiple timestamps, as are documented here.

Topology examples

You can review examples that describe best-practice guidelines to provide you with practical information, such as implementation examples and code samples, that you can use to get started.

Properties

The topology API has two categories of properties, generic and user. Generic properties have fixed data types, while user-defined properties do not.

- Some properties have special semantics, as described in **Generic properties**.
- The pre-defined properties are listed in the **Pre-defined properties** table.
- You can add any property as required, as described in **User properties**.

Generic properties

Generic properties are few and constrained to a fixed data type. They can also be subdivided into those which are read/write and those which are read-only.

- **`uniqueId`**

  The uniqueId is the string that is used to match resources from the same provider. It could be, for example, a UUID by which the provider can look up its own local data store for information about that device.

  If you send the same resource with the same uniqueId and the same provider more than once, it will be treated as the same resource.

  The provider is a project (namespace) for the resource's uniqueId. That uniqueId property is unique only within the scope of a provider.

- **`matchTokens`**

  These tokens are used to store strings, which are significant to that resource, and might match it to events.

- **`name`**

  This string does not have to be unique, and it should be short and memorable.

- **`tags`**

  Tags can be used to search for resources in the topology view, and to group resources. For more information on configuring tag rules and tag-based templates, see the following sections:

  - Defining rules
  - Group templates

- **`entityTypes`**

  These are defined as a set, though with usually only a single member, of one or more types this resource represents.

  For more information on entityTypes, see the Entity types topic.

Predefined properties

Table. Predefined properties

Name	Type	Cardinality	Alias	Read-only	Indexed
age	integer	single		no	y
aliasIds	ID	set	_aliasIds	yes	n
beginTime	long	single	_startedAt	yes	y
changeTime	long	single	_modifiedAt	yes	n
createTime	long	single	_createdAt	yes	y
deleteTime	long	single		yes	n
description	string	single		no	y
edgeTenantId	ID	single	_edgeTenantId	yes	n
edgeType	string	single	_edgeType	yes	n
endTime	long	single	_deletedAt	yes	y
entityTypes	string	set		no	y
eventId	string	single		yes	n
eventManager	string	single		yes	n
expireTime	long	single	_expiredAt	yes	n
geolocation	GeoLocation	single		no	n
hasState	string	single		yes	n
icon	string	single		no	n
id	long	single		yes	n
keyIndexName	string	single		yes	n
label	string	single		yes	n
matchTokens	string	set		no	y
name	string	single		no	y
observedTime	long	single	_observedAt	yes	n
operation	string	single		yes	n
partOfExternal	Boolean	single		yes	n
prevBeginTime	long	single		yes	y
providerId	ID	single		yes	n
providerName	string	single		yes	n
reconciliationTokens	string	set		yes	n
referenceId	ID	single		yes	y

Name	Type	Cardinality	Alias	Read-only	Indexed
referenceNo	long	single		yes	n
serializedHashMap	HashMap	single		yes	n
severity	string	single		no	n
speed	long	single		no	y
statusType	string	single		yes	n
tags	string	set		no	y
tenantIds	ID	set	_tenantIds	yes	y
uniqueId	string	single		no	y
uuid	ID	single	_id	yes	y
version	string	single		no	y
vertexType	string	single		yes	y

User properties

User-defined properties are free-form, and are not constrained by any data type. You can add new user properties as needed.

You can define any custom properties, such as, **`ipAddress`**.

Note: All user-defined properties such as **`ipAddress`**s are not in the generic set, and are stored as a serialized **`blob`** data type instead. The implication of this serialized data type storage convention is that these properties cannot be filtered, as they are incompatible with the **`_filter`** query parameter used in the REST API.

JSON record depicting both types of properties

The following picture depicts how the properties in a JSON record from an Observer can be split into both generic and user properties.

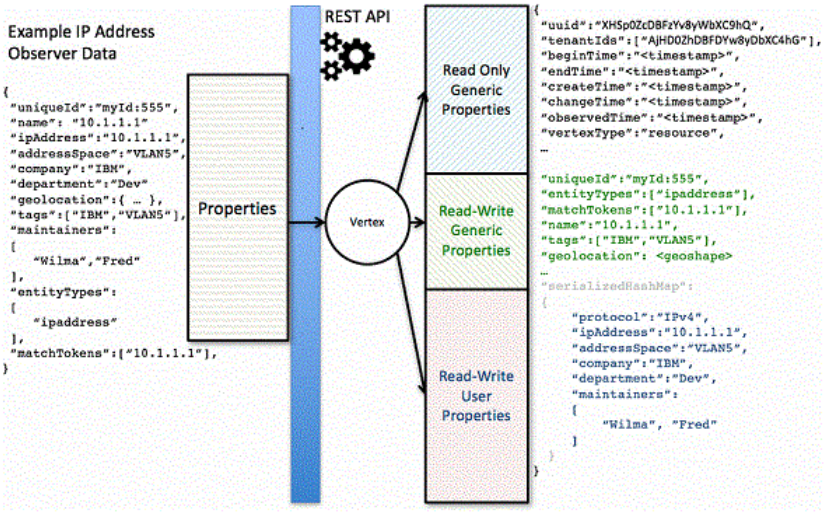

Figure. JSON record properties

Edge labels

The topology service defines a family of labels for the edges it supports.

Note: Most interactions with edges in the topology are with edge *types* rather than edge *labels*. These types can be conceptualized as instances of the edge label classes, and are documented separately. For more information, see Edge types.

- **`aggregation`**

  A relationship where the target vertex can exist independently of the source, but is needed for the source to function.

  A 'parent-child' relationship where the parent (source) is aggregating the children (target).

  The type of aggregation is determined by the value of the edge type.

  Use this edge label to represent a resource in the UI that is composed of various elements, for example a book **`contains`** words.

  - The direction is always from parent to child.
  - Children can have multiple parents.

  For more information on the types that associated with this label, see Edge types.

- **`association`**

A ‘weak’ relationship where both source and target vertex can exist independently and each does not require the other to function.

The specific type of association is determined by the edge type.

Use this edge label to represent a general relationship between vertices in the UI, for example a person **has** a house.

The label itself has no direction, but a direction could be implied by the edge **type** used.

For more information on the types that associated with this label, see Edge types.

- **composition**

  A ‘part-whole’ relationship where the child (source) is a part of the parent (target).

  Use when you need to create a short-cut from a node to its root, bypassing fine-grained relationships, for example a component is **partOf** a device.

  - The direction is always child to parent.
  - Children cannot have multiple parents.
  - Composition relationships are hidden from the element-to-element view. They are used to construct the element-to-host view.
  - **partOf** is the only edge type you can use for the 'composition' label, and is reserved for its exclusive use.
- **dataFlow**

  A dataFlow label represents a data flow between a pair of vertices.

  The specific type of data flow is qualified by properties on the edge type.

  Use this label when you need to represent any form of data flow in the UI, for example a person emailing another person.

  The label itself has no direction, but a direction can be implied from the edge type used.

  For more information on the types that associated with this label, see Edge types.

- **dependency**

  A 'strong' relationship where the source depends on the target and cannot operate independently of it, and is not integral to it.

  The specific type of dependency is determined by the edgeType.

  Use this label when you need to represent the dependency of one resource on another in the UI, for example an application dependsOn a database.

  The direction is always from the dependent resource to the independent resource.

  For more information on the types that associated with this label, see Edge types.

Edge types

All edges created in the topology should have an edge **type** defined. Review the following lists of the types that are associated with each edge label. If none of the default types suffice, you can create your own custom types.

Edge **types** can be thought of as being instances of the edge **label** classes. Most interactions with edges in the topology are with *types* rather than *labels*.

Edge types for labels

Types for the aggregation label

Edge type	Description	Example
contains	The source resource is considered to contain the target resource	Slot **contains** a card
federates	The source resource is a federation of the target resources	Database **federates** nodes
members	The source resource has the target resources as its members	Subnet **members** are IP addresses

Types for the association label

Edge type	Description	Example
aliasOf	Depicts that one resource is an alias of another; potentially from different providers	FQDN1 is an **alias** of FQDN2
assignedTo	When one resource is assigned to another	The alarm is **assingedTo** an operator
attachedTo	When one resource is attached to another	The plug is **attachedTo** to the cable
classifies	When one resource is used to classify another	The government **classifies** the document
configures	When one resource configures or provides configuration for another resource	The file **configures** the application
deployedTo	Describes when one resource is deployed to another resource	The application was **deployedTo** the server
exposes	When one resource exposes another	The application **exposes** the interface
has	Generalized relationship when one resource possesses, owns, or has another resource	Host **has** component
implements	When one resource implements another	The class **implements** the interface
locatedAt	When one resource is physically located in or at another resource's location	Host is **locatedAt** data center
manages	When one resource manages another	The boss **manages** the employee
monitors	When one resource monitors another	The application **monitors** the host

Edge type	Description	Example
movedTo	When one resource moves to a new and different resource	The service has **`movedTo`** the host
origin	Indicates the origin of a Vertex	Device's **`origin`** is a vendor
owns	Indicates ownership of one resource by another resource	The user **`owns`** the server
rates	Can be used when one resource rates another	The manager **`rates`** the employee
resolvesTo	When one resource resolves to another	The hostname **`resolvesTo`** an address
realizes	When one resource realizes another	The hypervisor **`realizes`** the virtual machine
segregates	When one resource segregates another	The firewall **`segregates`** the network
uses	When one resource takes, employs or deploys another resource as a means of achieving something	Application **`uses`** this disk

Types for the dataFlow label

Edge type	Description	Example
accessedVia	One resource is accessed through another, typically remote.	Server is **`accessedVia`** a FQDN
bindsTo	A network layering relationship such that the source runs on top of the target.	Logical interface **`bindsTo`** a physical port
communicatesWith	A relationship whereby one resource communicates with another	The sensor **`communicatesWith`** an application
connectedTo	A relationship whereby one resource is connected to another	The laptop is **`connectedTo`** the switch
downlinkTo	One resource is down-linked to another	The controller has a **`downlinkTo`** the sensor
reachableVia	A resource is reachable through another resource	The network is **`reachableVia`** the gateway
receives	A resource receives data from another	The Mail server **`receives`** an email
routes	A relationship whereby one resource routes data for another	The device **`routes`** the data
routesVia	A relationship whereby data from one resource routes through another	The traffic **`routesVia`** the device
loadBalances	One resource which balances load for others	The load balancer **`loadBalances`** to servers
resolved	When one resource resolved something for another	DNS server **`resolved`** IP address
resolves	Represents that one resource uses another to resolve it	FQDN **`resolves`** to the address
sends	A resource sends some data to another	The application **`sends`** an SMS message
traverses	Describes when one resource traverses another	The message **`traverses`** the network
uplinkTo	One resource is up-linked to another	The sensor has an **`uplinkTo`** the controller

Types for the dependency label

Edge type	Description	Example
dependsOn	A generic dependency between resources	One application **`dependsOn`** another
runsOn	A resource runs on (and therefore depends on) another resource	The service **`runsOn`** the host

Custom edge types

If no default edge types suitably represents a relationship, you can define a custom edge type through the **`https://localhost:8080/1.0/topology/types/edge`** POST API.

Important: A custom edge type needs to be created **before** the observation job passes any edges with the type to the topology service.

- **`edgeType`**

  Required. The edgeType name, which must be unique and **cannot** match the edgeType name of a default edgeType, unless the edgeLabel also matches the corresponding default edge type's edgeLabel parameter.

  Restriction: A scenario where both edgeType and edgeLabel match the fields of a default edge type is equivalent to manually creating a default edge type, which is not necessary as default edge types are created implicitly by the topology when needed.

- **`edgeLabel`**

  Required. The edgeLabel of the custom edgeType, which must have one of the following labels:

  - dataFlow
  - dependency
  - association
  - aggregation
- **`description`**

  Optional, but recommended. This should be a meaningful description of the type of relationship this edge type represents.

Example

```
curl -k -X POST --header 'Content-Type: application/json' --header 'Accept: application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' -d '{
  "edgeType": "connectedTo",
  "edgeLabel": "dataFlow",
  "description": "Default relationship between two devices that exchange data"
}' 'https://localhost:8080/1.0/topology/types/edge'
```

Entity types

The Topology Service allows you to group resources of the same type that uses the **`entityTypes`** property, and identify them in the UI by their icon.

Usually a resource has only a single entity type, but, as the property is a *Set*, it is possible for a resource to have more than one entity type. Pre-defined associations of icons to specific entityTypes are listed in the following sections. You can create additional entity types as required.

- An entityType is defined by defining a resource with that type in the entityTypes list field.
- You can associate icons with named types in the Topology Viewer.
- You can add custom icons.

Predefined entity types

An entity type is used to map the resource vertex to an icon.

Notes:

- An administrator user can create more custom resource or entity types as required. Any observer may add new types.
- The topology service API only returns the resource or entity types in use.

To assign an entityType

1. Select a resource with the provided entityType in the Topology Viewer.
2. Select the topology tools (the **cog** icon), then navigate to the resource types.
3. Find the type to be edited, and select the icon to assign it. You can find an icon either by name from the dropdown list, or by using the **View all icons** option (the **eye** icon).

Entity type icons

The following table lists these entity types with links to their icons, if defined:

Table. Entity type icons

Entity type	Icon
aircond	
alarm	
application	
backplane	
bridge
