Status (and state)

Resources have specific statuses, and in turn each status has a state of open, clear, or closed.

Status

A single status can affect multiple resources, and a single resource can have multiple different statuses. For example, a single *link down* event can generate the status for both the interface resource and the host resource, or, a single host might have *CPU* or *disk usage* status in addition to any *link down* status.

Resource status can be viewed in the Topology Viewer. An 'open' event is one with a severity other than 'clear'.

Important: When modeling resources, you must consider Status assignment from events.

Tip: The Topology Service stores the event **Severity**, and nodes in the UI are colored based on severity, which always has one of the following definitions:

- clear
- indeterminate
- information
- warning
- minor
- major
- critical

Look at the severity icons in the topology viewer reference topic Severity icons table.

Status assignment

The status of a single resource can be supplied, alongside other resource properties, when creating or updating a resource. Alternatively, an event can generate the status of one or more resources.

Remember: A status **always** has one of the following three states:

- **`Open`**

  Always has a severity other than 'clear' to indicate an active issue that can require your attention.

- **`Clear`**

  Working as expected. Also has a severity of 'clear'.

- **`Closed`**

  No longer active or relevant, a deleted event. Also has a severity of 'clear'.

Status assignment from events

The status service receives events and tries to find matching resources in the topology service. A resource with no match tokens defined will not have events matched to it, but if found, the status of those resources is set from the event data. The default fields of the alert used to look up resource matchTokens are *resource.sourceId* and *resource.name*. The assigned status depends on the following event data:

- **`matchTokens`**

  This property must be used to list any data that can identify (match) the resource.

  Each field may be globally unique, or may be unique within the scope of a composition. In other words, a resource modeled as a composition relationship, such as **`partOf`**, can be distinguished from other children within the composition using these fields.

  For example, either a globally unique and fully qualified domain name or IP address, or a locally unique interface name (that is, local within the scope of the host), can be used to identify the resource.

- **`partOf`** composition relationship

  The status service uses composition relationships to match fields that are unique only within the scope of a parent.

  For example, an IP address can be used to find a main node, and an interface name can be used to identify an interface within that main node.

- **Note:** If two different resources have the same **`matchTokens`** value, an event cannot be assigned to them unless they have been merged to become members of the same composite, **or** they have a parent-child **`partOf`** relationship.

Access scope

The scoping functions allows for preferential matching of IBM Cloud Pak for AIOps alerts. If similar resources and alerts in your environment exist in multiple different scopes, you can tag them with scope-specific information to allow a unique match to be made.

Such a scenario can occur (for example) under the following conditions:

- The same applications are running in test, staging and production environments.
- The same deployments are running in multiple namespaces in a single Kubernetes cluster.
- The same components are running in cloned Openstack projects.
- The same private IPs exist in multiple routing domains.

If an alert matches duplicate resources, a (case-insensitive) match of the alert scope against the resource scope is attempted.

Resource scope: Resources have an *accessScopeTokens* list property containing the following information:

- The provider of the resource, as defined by the observer job
- Optional additional scope supplied in the observer job's *Access Scope* CSV string parameter
- Scope explicitly added by some observers, such as the Kubernetes observer's *data_center* and *namespace* job parameters

Alert scope: The alert fields to use for scope are configurable.

- You can use the **AIOPS_SCOPING_FIELDS** variable defaults (*accessScope*, scopeId, *location*, *cluster*) to deuplicate resources when there are multiple matches on matchTokens.
- The values of these fields are compared with the resource property *accessScopeTokens* , with preferential matching based on case-insensitive comparison.

Troubleshooting alert lookup failures:

1. Check for a unique resource match at `GET /resources?_filter=matchTokens:{alertFieldToLookup}`
2. If the alert is older than the resource, it might not have existed when the alert processing looked it up.

Timestamps

Both vertex and edge graph elements can have multiple timestamps.

The following formats apply across all Topology APIs when specifying timestamps:

- Millisecond Epoch

  Example:

  ```
  date "+%s%3N"
  1655991641000
  ```

- RFC-3339 / ISO-8601

  Format:

  ```
  YYYY-MM-DDThh:mm:ss.sssZ
  ```

  Example:

  ```
  date --universal "+%FT%T.%3NZ"
  2022-06-23T13:40:41.000Z
  ```

- **`beginTime`** - The beginTime timestamp records the beginning of a period of time for which the resource was valid, with endTime marking the end of that period.

  Tip: A resource can have multiple begin times in its historic record, and gaps can happen in that record if the resource was offline for periods.

  - All resources and historic resources that are representations of the same thing have a distinct beginTime
  - Resource beginTime together with endTime is used in historic graph traversals, that is, when the _at parameter is supplied. The period during which a resource is valid is defined as:

    ```
    atTime >= beginTime && atTime < endTime
    ```

  - A vertex or edge, which has the beginTime equal to the endTime, can be used to store audit information, such as the provider which deleted a resource. However, because it takes up zero time it does not form part of the history and is ignored by the preceding equation.

- **`prevBeginTime`** - If history exists for a resource, then this property is set to the beginTime of the most recent historical resource.
- **`changeTime`** - The changeTime timestamp records when the properties of the element last changed. The value can be less than the observedTime, which is updated on a POST or PUT even if no property values have changed.
- **`createTime`** - The createTime timestamp records when the element was first created in the topology service.
  - Historical resources do not store createTime, as it is shared with the anchor.
  - createTime is needed when looking for something older than 30 days – that is, when there is no beginTime this old because the historical resources have timed out.
- **`endTime`** - The endTime timestamp records when the element was deleted.
  - All resources and historic resources that are representations of the same thing have a distinct endTime.
  - Resource endTime is used in historic graph traversals, that is, when the _at parameter is supplied.
  - For current resources, endTime is LONG _MAX. This is sometimes hidden through the REST API.
- **`observedTime`** - The observedTime timestamp records when the element was last observed, that is, when data was last input to the topology service for the element.

Topology examples

The following examples describe best-practice guidelines to provide you with practical information, such as implementation examples and code samples, that you can use to get started.

Restriction: The examples provided here must be amended and adjusted to suit your own implementation.

Virtual machine example

One of the most important goals of IBM Cloud Pak® for AIOps is to support the assurance and provisioning of modern IT, network, and storage environments. These environments all make extensive use of increasingly nested virtualization technologies that need to be modeled. The following example introduces such an IT Virtualization scenario, and describes an OpenStack response that provides a solution.

Physical device example

The following example of an IBM Tivoli Network Manager environment accessed through IBM Cloud Pak for AIOps provides insights into any environment that uses physical network devices.

Virtual machine example

One of the most important goals of IBM Cloud Pak® for AIOps is to support the assurance and provisioning of modern IT, network, and storage environments. These environments all make extensive use of increasingly nested virtualization technologies that need to be modeled. The following recipe introduces such an IT Virtualization scenario, and describes an OpenStack response that provides a solution.

IT Virtualization

The IBM Cloud Pak for AIOps model of a nested virtualization scenario can extend the traditional types of models provided by other solutions.

This model can represent a multi-domain view of the world that links IT, network, storage, applications, and services. In addition, it can incorporate concepts such as OpenStack's Heat Orchestration and Slack collaboration relative to traditional IT resources.

Some of the benefits of this approach are:

- To provide extra context

  Increasingly, teams are more multi-disciplined and no longer operate in informational or functional silos. For example, network teams may include IT Virtualization specialists.

  Such teams need access to more context when needed, to be able to answer some of their business-critical questions, such as:

  - What storage volume is a VM attached to?
  - Which orchestration step realized a network port?
  - Who collaborated with whom for a particular incident?
  - Which applications and services are supported by a network subnet?
  - Which VM instances were shut down as part of a scale-in activity 1 hour ago?
  - What is the impact of removing a Hypervisor from the environment?
  - Which fixed IP addresses have a floating IP address that has been bound to in the last week?
- To provide a data-rich base

  Added value services can be bolted onto a base system, provided the information exists, and the system has an architecture that allows for rapid extension.

  For example, when building analytics on the topology data, the availability of information such as seasonality can provide extra insights.

  The following diagram depicts the nested layers of virtualization, including networking, between these layers and technologies such as Docker and LXC or LXD.

  Note: The services that are exposed can be applications or appear to be traditionally physical services such as network routers, switches, firewalls, and load balancers (a key goal of NFV).

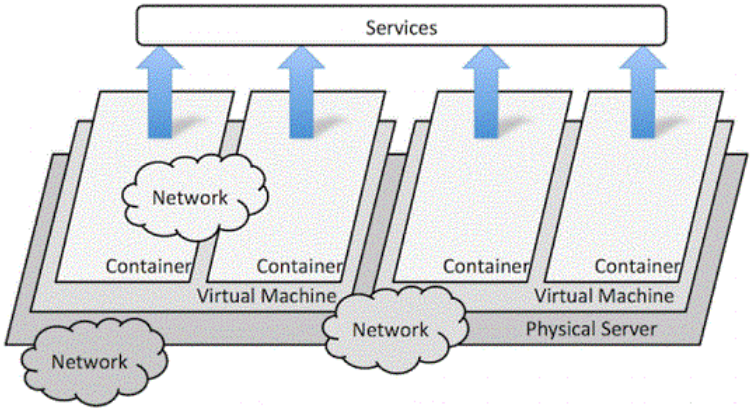

Figure. Physical services

OpenStack

OpenStack is a free and open source platform for cloud computing, typically deployed as an IaaS (Infrastructure-as-a-Service) capability. The software platform consists of interrelated components that control diverse, multi-vendor hardware pools of processing, storage, and network resources throughout and between data centers.

OpenStack provides a number of projects, and related services and APIs, that are summarized here, as they speak directly to the need to have a multi-domain view of the environment. For more information, see the OpenStack project navigator

OpenStack **core services** include the following services:

- Nova

  Compute manages the lifecycle of compute instances in an OpenStack environment.

- Neutron

  Networking enables network connectivity as a service for other OpenStack services.

- Swift

  Object Storage stores and retrieves arbitrarily unstructured data through a REST API.

- Cinder

  Block Storage provides persistent storage to running instances.

- Keystone

  Identity provides authentication and authorization services to OpenStack services and a service catalog.

- Glance

  Image Service stores and retrieves virtual machine disk images for use by Nova.

OpenStack **optional services** include the following services:

- Horizon

  dashboarding

- Ceilometer

  telemetry

- Heat

  orchestration

- Sahara

  Platform Symphony MapReduce

- Designate

  DNS

- Barbican

  Key Management

IBM Cloud Pak for AIOps provides an Observer that makes extensive use of OpenStack's core and Heat APIs to build an end-to-end (or multi-domain) model.

IT Virtualization OpenStack scenario

The following example of an OpenStack environment accessed through IBM Cloud Pak for AIOps provides insights into any environment consisting of, for example, a combination of physical services and storage combined with virtualization from VMware (or similar).

IT Virtualization OpenStack scenario

The following example of an OpenStack environment provides insights into any environment consisting of, for example, a combination of physical services and storage combined with virtualization from VMware, or similar virtualization providing infrastructure.

IT virtualization

The following figure depicts a Hypervisor running a VM (LB Server) that is assigned to a tenant, has classification data and a number of network interfaces. Each network interface has a MAC address, one or more IP addresses (v4 or v6) and each IP address is considered to be part of an IP subnet. It is also related to orchestration data from Heat that helps identify how the instance was created.

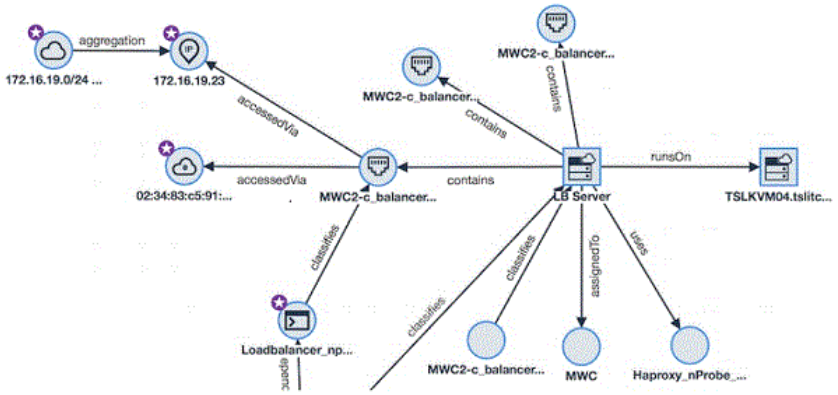

Figure. Example multi-domain topology

Property use guidance

Although the topology service is flexible, you should use the following guidelines when setting property values to ensure that elements are appropriately represented:

- Set **`entityType`** to one of the pre-defined entity types with an associated icon where possible.
- Set **`name`** and **`description`** to values that are easy to read or remember wherever possible.
- Use the default generic properties to represent generally applicable characteristics of an element and to provide a basic degree of labeling and filtering. For a list of generic properties, see the following topic: Properties

Model patterns - Part one

Stepping through each of the sections of the example of a multi-domain topology helps to identify reusable patterns.

In the following figure, the Hypervisor 'TSLKVM04' is running a VM 'LB Server'.

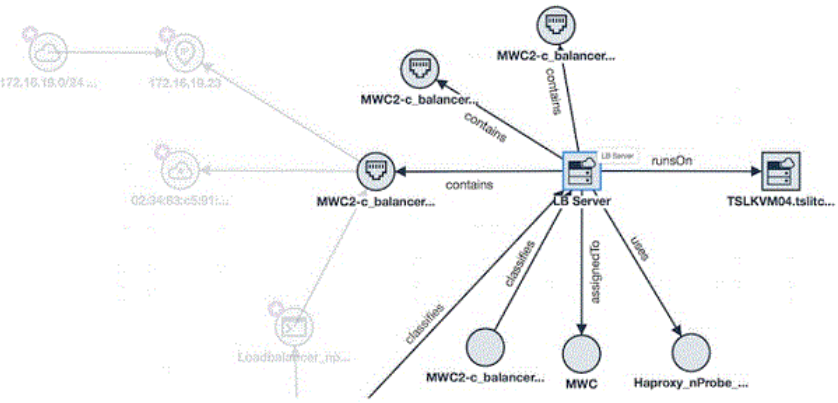

Figure. Figure of Hypervisor

The LB Server in this image is:

- Assigned to the 'MWC' tenant
- Contains three network interfaces
- Uses the Haproxy _nProbe image (OpenStack image)
- Is classified as an MWC2-c _balancer (OpenStack flavor)

This means that the following pattern can be identified:

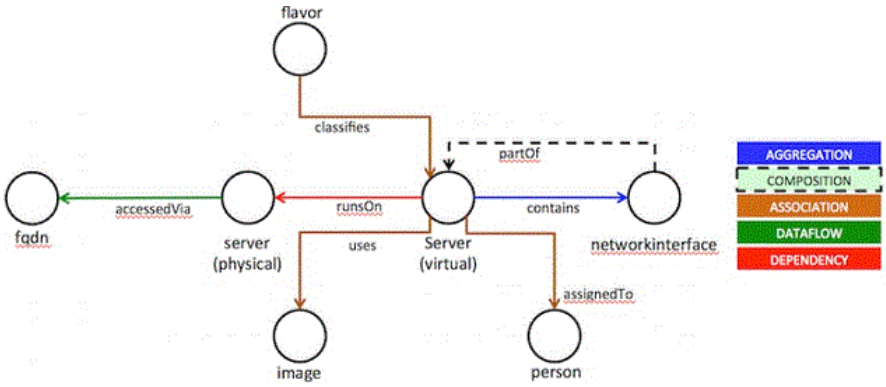

Figure. Pattern

Usage tips:

- The associations shown for flavor, image and person are optional.
- Network interfaces and other components of the device must be associated with it through a partOf relationship. The exception is if an IP or MAC address is known independently of any device, for example flow data would expose those but the device would be unknown.
- The FQDN (hostname, short or full DNS name) is associated directly with the server in this case as nothing else is known about the Hypervisor.

  Note: This is **not** shown in the topology fragment.
- The **`partOf`** composition is not shown by the topology GUI, but must be created where the relationship between a component and a device is known. This is in addition to relationships such as **`contains`**, which the IBM Cloud Pak for AIOps console will show.

Hypervisor example JSON

```
{
    "_executionTime": 3,
    "createTime": 1501741671066,
    "name": "TSLKVM04",
    "uniqueId": "CYooventry_DC1:MWC/ComputeHost/TSLKVM04",
    "observedTime": 1501776262368,
    "_startedAt": "2017-08-03T06:27:51.066Z",
    "entityTypes": [
        "server"
    ],
    "beginTime": 1501741671066,
    "_id": "KNN6TCGhKyM4MCI6jooGWg",
    "_observedAt": "2017-08-03T16:04:22.368Z",
    "_modifiedAt": "2017-08-03T06:27:51.066Z",
    "_createdAt": "2017-08-03T06:27:51.066Z",
    "changeTime": 1501741671066,
    "matchTokens": [
        "Coventry_DC1:MWC/ComputeHost/TSLKVM04",
        "TSLKVM04"
    ]
}
```

Note: Many of the properties starting with _ are internal (such as timestamps). Also:

- The **`uniqueId`** is a composite of a number of fields: data center, tenant, className and name of the Hypervisor because the ID is a highly ambiguous integer.
- The **`name`** is the name of the instance from OpenStack.
- The **`entityType`** is set to 'server' to ensure correct classification and icon use.

Virtual machine example JSON

```
{

        "1e35c68a-86b0-445f-9741-e581121a0577",
        "LB server"
    ]
}
```

Note: Many of the properties starting with _ are internal (such as timestamps). Also:

- The **`uniqueId`** in this case is the UUID of the instance from OpenStack.
- The **`name`** is the name of the instance from OpenStack.

- The `entityType` is set to 'server' and 'vm' to ensure correct classification and icon use.
- The `isVirtual` Boolean is set to true.

Network interface example JSON

```
{
    "_executionTime": 3,
    "isAdminStateUp": true,
    "createTime": 1501741717674,
    "name": "aab47c85-3110-401a-8bad-960b7c4bcd7b",
    "uniqueId": "aab47c85-3110-401a-8bad-960b7c4bcd7b",
    "observedTime": 1501741718855,
    "_startedAt": "2017-08-03T06:28:38.855Z",
    "entityTypes": [
        "networkinterface"
    ],
    "beginTime": 1501741718855,
    "isPortSecurityEnabled": true,
    "_id": "kkKpDH6yLn7cmNVXOddImg",
    "_observedAt": "2017-08-03T06:28:38.855Z",
    "_modifiedAt": "2017-08-03T06:28:38.855Z",
    "_createdAt": "2017-08-03T06:28:37.674Z",
    "changeTime": 1501741718855,
    "matchTokens": [
        "aab47c85-3110-401a-8bad-960b7c4bcd7b"
    ]
}
```

Note: As with the LB Server data, many of the properties are internal. Also:

- The `uniqueId` in this case is the UUID of the instance from OpenStack.
- The `name` is the name of the instance from OpenStack.
- The `entityType` is set to `networkinterface` to ensure correct classification and icon use.
- The type of the interface (such as `ifType` from IBM Tivoli Network Manager) is unknown.

Model patterns - Part two

Note: Each section of the example of the multi-domain topology identifies the reusable patterns.

In the following figure, the LB Server VM contains a network interface.

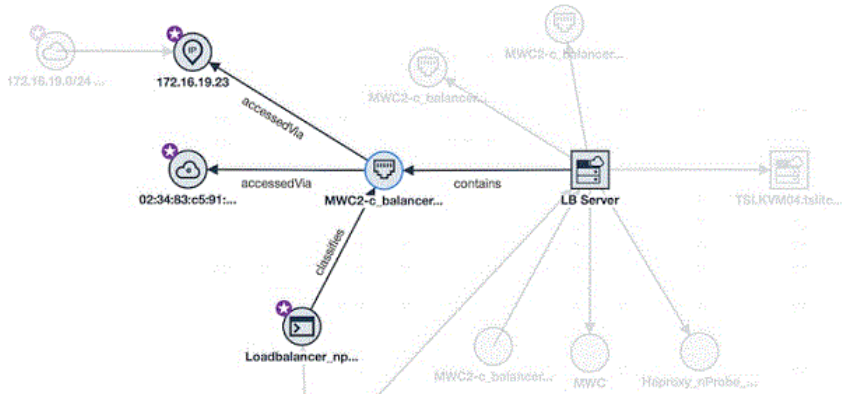

Figure. LB Server VM

The network interface in this image is:

- Accessed through an IP address and a MAC address
- Classified by a Heat orchestration resource

This means that the following pattern can be identified:

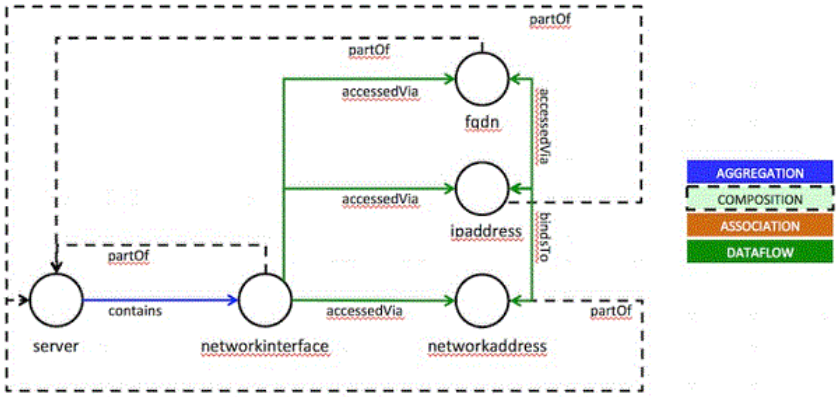

Figure. Pattern

Usage Tips:

- The Heat orchestration element and relationship is optional. Such things can be added if known to provide extra context.
- The network interface must be contained by and **`partOf`** the device. **`Contains`** is more fine-grained and may reference intermediate cards (for example) within the containment hierarchy of the device, such as

  `json device--contains-->card--->contains--->port`

- If an IP address, FQDN or MAC address is known to be related to a specific device, then they must be associated with the device through a **`partOf`** relationship *in addition* to the **`accessedVia`** relationship.
- If an IP address, FQDN, or MAC address is known independently of a device, then no **`partOf`** relationship from them is necessary.
- If an IP address is known to resolve to an FQDN, then relationships between them should be created to depict that one resolves to another and one accesses another (**`accessedVia`** shown in the example).

IP address example JSON

```
{
    "_executionTime": 3,
    "createTime": 1501741717656,
    "name": "172.24.4.5",
    "uniqueId": "172.24.4.5",
    "ipNumber": 2887255045,
    "addressSpace": "Coventry_DC1:MWC",
    "observedTime": 1501741731565,
    "_startedAt": "2017-08-03T06:28:51.565Z",
    "entityTypes": [
        "ipaddress"
    ],
    "beginTime": 1501741731565,
    "version": "IPv4",
    "_id": "jPLc72DU-UvPeTQE_7YdPQ",
    "_observedAt": "2017-08-03T06:28:51.565Z",
    "_modifiedAt": "2017-08-03T06:28:51.565Z",
    "_createdAt": "2017-08-03T06:28:37.656Z",
    "changeTime": 1501741731565,
    "matchTokens": [
        "172.24.4.5",
        "IPv4:2887255045"
    ]
}
```

Note:

- The **`uniqueId`** is the IP address itself. This is an RFC1918 IP address and so it **must** be qualified with an address space to disambiguate it from other instances of the same IP address. Similar precautions should be used with MAC addresses, which can be ambiguous.
- The **`protocol`** reflects whether the IP address is an IPv4 or IPv6 address.
- The **`ipNumber`** is a numeric representation of the IPv4 or IPv6 address. A Java BigInteger has the precision to represent IPv6 addresses.

Model patterns - Part three

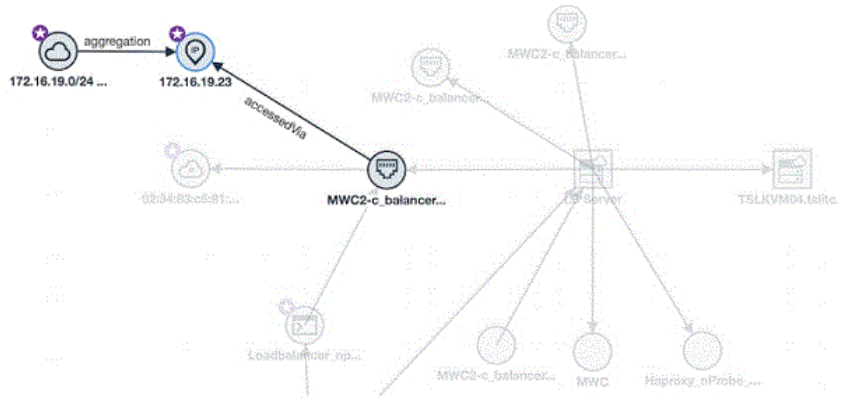

Figure. Multi-domain topology

This means that the following pattern can be identified:

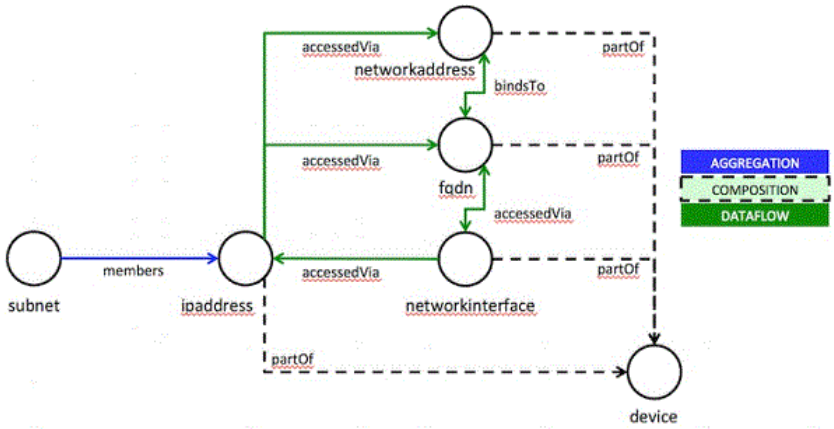

Figure. Pattern

Usage Tips:

- The IP subnet should aggregate any IP addresses known to be in it.
- Elements accessed through an IP should be related to it, such as a network interface, service, or process.
- If an FQDN is known to resolve to an IP address (and vice-versa), then they should be related.
- If a MAC address is known to bind to an IP address and vice-versa, they should be related.
- If an IP address, MAC address, or FQDN is known to relate to a device, they should be considered **`partOf`** it; otherwise, they are independent.

IP subnet example JSON

```

      "_observedAt": "2017-08-04T09:24:40.418Z",
      "_createdAt": "2017-08-04T09:24:40.418Z",
      "beginTime": 1501838680418,
      "_startedAt": "2017-08-04T09:24:40.418Z",
      "observedTime": 1501838680418
    },
  ],
  "_executionTime": 11,
```

```
  "_modifiedAt": "2017-08-04T09:24:40.356Z",
  "isDhcpEnabled": false,
  "dnsNames": "None Available",
  "_observedAt": "2017-08-04T09:24:40.356Z",
  "gatewayIp": "172.24.4.1",
  "_startedAt": "2017-08-04T09:24:40.356Z",
  "observedTime": 1501838680356,
  "changeTime": 1501838680356,
  "ipVersion": "V4",
  "createTime": 1501838680356,
  "_createdAt": "2017-08-04T09:24:40.356Z",
  "cidr": "172.24.4.0/24",
  "networkId": "3e2b5d07-653a-4fc8-8224-45801d9d113f",
  "beginTime": 1501838680356,
  "allocationPools": "172.24.4.2-to-172.24.4.254"
}
```

Notes:

- The **uniqueId** in this case is the UUID of the subnet from OpenStack.
- The **name** in this case is set to CIDR notation plus the ID of the subnet.
- The **entityType** is set to subnet to ensure appropriate classification and icon usage.
- Some example relationships are shown: For example, an IP address that is part of the subnet is visible, and the subnet's use of an allocation pool is also depicted.

Physical device recipe

The following example of an IBM Tivoli Network Manager environment accessed through IBM Cloud Pak® for AIOps provides insights into any environment that uses physical network devices.

Network physical devices

The following figure depicts two physical devices, 172.20.1.104 and 172.20.1.1, which are connected to each other.

Server 172.20.1.1 has 3 Gigabit Ethernet ports on the same card, one of which has a subinterface with an **ifName** of 'ge-1/1/3.0'. That subinterface shares the MAC address as its physical parent and has two IPv6 addresses and one IPv4 address associated with it.

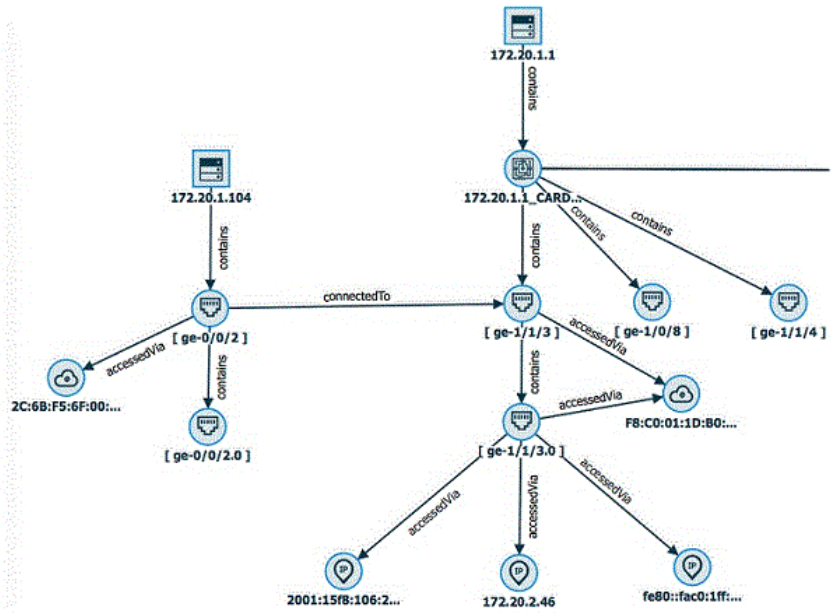

Figure. Figure that shows devices

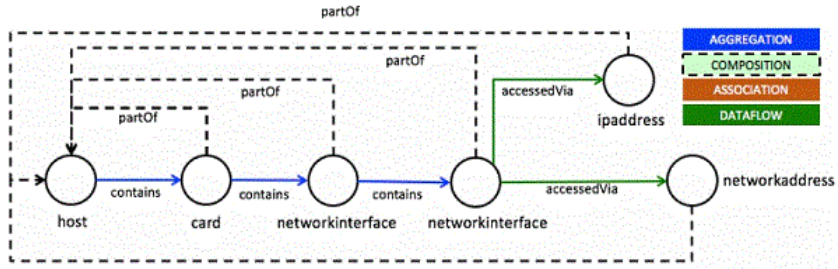
Outline pattern

The topology service has an edge type of **partOf**, which is a member of the composition edge label family. For more information, see Edge labels.

The following image illustrates how this relationship is used to tie the card, interfaces, and network addresses to the hosting device.



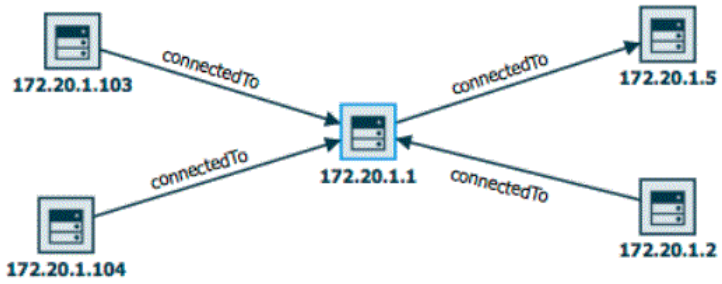


Figure. Relationships to hosting device

The **partOf** relationship is not shown as an explicit edge in the topology UI. However, it is used to determine which resources should be hidden in the host-to-host view, which in the context of this scenario would show just the hosts 172.20.1.104 and 172.20.1.1. It would also show the **connectedTo** edge between them, as depicted in the following part of the image.

{: caption="Figure. Figure that shows **partOf** relationship" caption-side="bottom"}

Host example JSON

The following JSON extract is an example of the properties that you might choose to include when creating a host vertex. The properties that start with an underscore character are aliases for some of the read-only generic properties. They also include a few read/write generic properties, such as **name** and **uniqueId**. However, most of the properties in this example are free from 'User' properties.

```
{

  "accessProtocol": "IPv4"
}
```

Note: Some of the generic properties in this example are:

- The **uniqueId** in this case is a string, which uniquely identifies this resource to IBM Tivoli Network Manager.
- The **name** is the name of the host and will be used in the UI.
- The **entityType** is set to 'host'.

- The `matchTokens` contains the FQDN name of the host.

Network interface example JSON

```

}
```

Note: Some of the generic properties in this example are the following:

- The `uniqueId` in this case is a string, which uniquely identifies this resource to IBM Tivoli Network Manager.
- The `name` is the name of the host and will be used in the UI.
- The `entityType` is set to `networkinterface`.
- The `matchTokens` contains both the `ifName` and a string denoting the `ifIndex` in the `ifEntry` table.

Infrastructure Management API Documentation

In this guide you will find a detailed overview of REST API, reference material, appendices, and examples. The guides provide information on how to integrate Infrastructure Automation – Infrastructure Management with external applications. It details the specification of the Infrastructure Management REST API, which is implemented as standard REST HTTP requests and responses of content type JSON.

- API Overview
- API Reference
- API Appendices
- API Examples
- Prerequisites

Infrastructure Management API Overview

In this guide you will find a detailed overview of Infrastructure Automation – Infrastructure Management REST API.

- REST API Authorization
- Password Updates
- CRUD
- HTTP Basics
- JSON Specification
- Query Specification
- Bulk Querying
- Collection Filtering
- Pagination

Prerequisites for Infrastructure Management APIs

Infrastructure Management can be installed as either a VM aplliance or as a containerized deployment. To issue API calls to the Infrastructure Management that is installed as a containerized deployment, obtain the authorization token and the URL hostname as described below.

Set the values for the following variables:

Variable	Description
IM_USER	IM_USER is the user you want to use. You can use either the default admin user or any user in the user group that you have configured in the im-iminstall CR. See https://ibm.biz/IM_containerized_pod.
IM_PASSWORD	Set the user password variable.
CP_CONSOLE_HOSTNAME	Set the CP console hostname with the command `oc -n <IA_installation_namespace> get routes cp-console -o=jsonpath='{.spec.host}'`.

Where **<IA_installation_namespace>** is the namespace that Infrastructure Automation is installed in.

1. Run the command to get the bearer token for the user

   ```
   export IM_BEARER_TOKEN=$(curl -ks -X POST  -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8"  -d
   "grant_type=password&username=${IM_USER}&password=${IM_PASSWORD}&scope=openid"
   https://${CP_CONSOLE_HOSTNAME}/idprovider/v1/auth/identitytoken|jq -r .access_token)
   ```

2. Run the command to get the URL hostname,

   export IM_HOSTNAME=$(oc -n cp4aiops get route | grep inframgmt | awk '{print $2}')

3. After the variables IM_BEARER_TOKEN and IM_HOSTNAME are defined, use them to issue the API calls. A curl command should be in this format,

```
curl  -H "Authorization: Bearer ${IM_BEARER_TOKEN}" \
     ..........................  \
     "https://${IM_HOSTNAME}/api/......"
```

For example, to issue a GET request to the Infrastructure Management that is installed as a containerized deployment, specify,

```
curl  -H "Authorization: Bearer ${IM_BEARER_TOKEN}" \
     -k -i -X GET -H "Accept: application/json"   \
     "https://${IM_HOSTNAME}/api/providers"
```

Note: To issue API calls to the Infrastructure Management that is installed as a VM appliance, follow the instructions in the subsequent sections in Infrastructure Management API Guide. To issue API calls to the Infrastructure Management that is installed as a containerized deployment, replace the HTTP authorization header and the URL segment (http://localhost:3000) with those described above.

- REST API Authorization
  - Specifying Authorization Group
  - Specifying an Invalid Authorization Group

REST API Authorization

When authenticating to the appliance, the current group of the authenticated user will be used for determining the authorization of what the user can see and do using the REST API. While this is acceptable when users only belong to a single group, this falls short when users are authenticating using their External Authentication credentials (IPA, LDAP or AD) where they may belong to multiple groups.

Specifying Authorization Group

This section describes how to specify an authorization group for the user. The mechanism described here is honored for both methods of authentication:

- Basic Authentication
- Token based Authentication

The user's group is to be specified in the new HTTP Header:

```
X-MIQ-Group
```

and is to contain the user's group name.

Example request using Basic Authentication:

```
$ curl --user username:password
       -i -X GET -H "Accept: application/json"
       -H "X-MIQ-Group: auditors"
       http://localhost:3000/api/vms
```

Example request using Token based Authentication:

```
$ curl -i -X GET -H "Accept: application/json"
      -H "X-Auth-Token: 93d98fd44cc5a401ff385ba87b21fd13"
      -H "X-MIQ-Group: auditors"
      http://localhost:3000/api/vms
```

The validated users's group will be in effect for the duration of the REST API request. Multiple requests can be made as a particular user but with different authorization groups concurrently.

Specifying an Invalid Authorization Group

In case an invalid authorization group is specified, a 401 Unauthorized is returned:

```
HTTP/1.1 401 Unauthorized
X-Frame-Options: SAMEORIGIN
...

{
  "error" : {
    "kind" : "unauthorized",
    "message" : "Invalid Authorization Group <invalid_group_name> specified",
    "klass" : "ApiController::AuthenticationError"
  }
}
```

- Password Updates

Password Updates

When the appliance is configured for Database authentication, users can update their passwords via the REST API.

Note that if an authenticated REST API user is entitled to edit users, they can edit other users' passwords, e.g. admin account.

Passwords can be updated via the **edit** post action on the user's resource as follows:

```
POST /api/users/:id

{
  "action" : "edit",
  "resource" : { "password" : "<new_password>" }
}
```

So for updating one's password, the */api/users/:id* being updated must be the authenticated REST API user's object.

- CRUD Request Examples
  - Show a collection of Resources
  - Return a single Resource
  - Create a Resource
  - Update a Resource
  - Delete a Resource

CRUD Request Examples

The following examples show the basic CRUD operations (Create, Read, Update, Delete) using the REST API.

For Authentication, we are showing here basic authentication via the *–user admin:smartvm* credentials argument. For multiple API calls it is recommended to access the REST API via token based authentication, please refer the the Authentication Page for details.

Show a collection of Resources

Get a collection of services: **GET /api/services**

```
curl --user admin:smartvm
     -i -X GET -H "Accept: application/json"
     http://localhost:3000/api/services
```

Return a single Resource

Return a single service: **GET /api/services/:id**

```
curl --user admin:smartvm
     -i -X GET -H "Accept: application/json"
     http://localhost:3000/api/services/1
```

Create a Resource

Create a new provider: **POST /api/providers**

```
curl --user admin:smartvm
     -i -X POST -H "Accept: application/json"
     -d '{
           "type"      : "ManageIQ::Providers::Redhat::InfraManager",
           "name"      : "RHEVM Provider",
           "hostname"  : "rhevm.local.com",
           "ipaddress" : "192.168.5.1",
           "credentials" : {
             "userid"   : "admin",
             "password" : "12345"
           }
     }'
     http://localhost:3000/api/providers
```

Update a Resource

Update the name of a service: **PUT /api/services/:id**

```
curl --user admin:smartvm
      -i -X PUT -H "Accept: application/json"
      -d '{ "name" : "updated service name" }'
      http://localhost:3000/api/services/1
```

Delete a Resource

Delete a service: **DELETE /api/services/:id**

```
curl --user admin:smartvm
      -i -X DELETE -H "Accept: application/json"
      http://localhost:3000/api/services/1
```

HTTP Basics

- REST Entry Point
  - Entry Point Details
- Supported Content Types
- URL Paths
- Methods and related URLs
- Updating resources
- Return Codes

REST API Entry Point

The REST API is made available via the /api URL prefix. It can be accessed on the Appliance server directly via HTTP using the default port as follows:

```
http://localhost:3000/api
```

Or external to the Appliance as follows:

```
https://<applianceHost_fqdn>/api
```

Response:

```
{
  "name" : "API",
  "description" : "REST API",
  "version" : "2.3.0",
  "versions" : [
    {
      "name" : "2.3.0",
      "href" : "http://localhost:3000/api/v2.3.0"
    }
  ],
  ...
  "collections" : [
    ...
    {
      "name" : "providers",
      "href" : "http://localhost:3000/api/providers",
      "description" : "Providers"
    },
    ...
    {
      "name" : "vms",
      "href" : "http://localhost:3000/api/vms",
      "description" : "Virtual Machines"
    },
    ...
  ]
}
```

- Version is the Current API version, accessible via either of the following:

- /api/
- /api/v2.0.0/
- Versions lists current and any earlier API versions that are still exposed via their respective entry points:
- /api/v**Version**/

Entry Point Details

An authenticated request of the entry point:

```
GET /api
```

returns the following structure:

```
{
  "name": "API",
  "description": "REST API",
  "version": "2.3.0",
  "versions": [
    {
      "name": "2.3.0",
      "href": "http://localhost:3000/api/v2.3.0"
    }
  ],
  "settings": {
  },
  "identity": {
    "userid": "admin",
    "name": "Administrator",
    "user_href": "http://localhost:3000/api/users/1",
    "group": "EvmGroup-super_administrator",
    "group_href": "http://localhost:3000/api/groups/2",
    "role": "EvmRole-super_administrator",
    "role_href": "http://localhost:3000/api/roles/1",
    "tenant": "My Company",
    "groups": [
      "EvmGroup-super_administrator"
    ]
  },
  "server_info": {
    "version": "master",
    "build": "20161104133757_01d7244",
    "appliance": "EVM"
  },
  "product_info": {
    "name": "ManageIQ",
    "name_full": "ManageIQ",
    "copyright": "Copyright (c) 2014-present ManageIQ Authors.",
    "support_website": "http://www.manageiq.org",
    "support_website_text": "ManageIQ.org"
  },
  "collections": [
    {
      "name": "actions",
      "href": "http://localhost:3000/api/actions",
      "description": "Actions"
    },
    ...
    {
      "name": "vms",
      "href": "http://localhost:3000/api/vms",
      "description": "Virtual Machines"
    },
    {
      "name": "zones",
      "href": "http://localhost:3000/api/zones",
      "description": "Zones"
    }
  ]
}
```

Where **settings** and **identity** are specific to the authenticated user.

Supported Content Types

Requests:

```
Accept: application/json
```

Responses:

```
Content-Type: application/json
```

URL Paths

The recommended convention for URLs is to use alternate collection / resource path segments, relative to the API entry point as described in the following example:

URL	Description
/api	The REST API entry point
/api/v**Version**	The REST entry point for a specific version of the REST API
/api/:collection	A top-level collection
/api/:collection/:id	A specific resource of that collection
/api/:collection/:id/:subcollection	Sub-collection under the specific resource

Methods and related URLs

The basic HTTP Methods used for the API are GET, POST, PUT, PATCH, OPTIONS and DELETE.

URL	Semantic
GET /api/:collection	Return all resources of the collection
GET /api/:collection/:id	Return the specific resource
POST /api/:collection	Create a resource in the collection
POST /api/:collection/:id	Perform an Action on a resource in the collection
PUT /api/:collection/:id	Update a specific resource
PATCH /api/:collection/:id	Update a specific resource
OPTIONS /api/:collection	Return metadata about the collection Please refer to Collection Metadata for details
DELETE /api/:collection/:id	Delete a specific resource

There :collection represent specific Appliance entities like services, hosts, vms, etc.

Updating resources

As shown in the above table, there are a couple of way to update attributes in a resource. These are:

- Update a resource via the PUT HTTP Method
- Update a resource via a POST Method with an *edit* action.
- Update a resource via the PATCH HTTP Method

While the PUT is the common method, the PATCH mechanism gives better control on which attribute to edit, add as well as remove which is not available with the other two methods.

Modifying Resource attributes

```
PUT /api/services/42

{
  "name" : "The new Service name",
  "description" : "A Description for the new Service"
}

POST /api/services/42

{
  "action" : "edit",
  "resource" : {
    "name" : "A new Service name",
    "description" : "A Description for the new Service"
  }
}

PATCH /api/services/42

[
  { "action": "edit", "path": "name", "value": "A new Service name" },
  { "action": "add", "path": "description", "value": "A Description for the new Service" },
  { "action": "remove", "path": "display" }
]
```

Return Codes

- Success
- Client Errors
- Server Errors

Success

- **200 OK** - The request has succeeded without errors, this code should be returned for example when retrieving a collection or a single resource.

- **201 Created** - The request has been fulfilled and resulted in a **new resource being created**. The resource is available before this status code is returned. The response includes the HTTP body of the newly created resource.
- **202 Accepted** - The request has been accepted for processing, but the processing has not been completed. Like, resource is not fully available yet. This status code is usually returned when the resource creation happens asynchronously. In this case the HTTP response includes a pointer to *monitor* or a *job* where the client can query to get the current status of the request and the estimate on when the request will be actually fulfilled.
- **204 No Content** - The server has fulfilled the request but does not need to return an entity-body, and might want to return updated meta information. This HTTP response is commonly used for the DELETE requests, as the resource that was deleted does not exists anymore.

Client Errors

- **400 Bad Request** - The request could not be understood by the server due to malformed syntax. The client SHOULD NOT repeat the request without modifications. In REST API this status code should be returned to client when the client use the wrong combination of attributes, like expanding the non-existing collection, or using the pagination parameter incorrectly. Another use-case could be creating or performing actions on the resource, when the wrong JSON serialization of the resource or action is used.
- **401 Unauthorized** - The request requires user authentication. The response MUST include a *Authenticate* header field containing a challenge applicable to the requested resource. If the request include *Authenticate* header, then this HTTP status code might indicate that the current user is **not authorized** to perform given action or to access given resource.
- **403 Forbidden** - The server understood the request, but is refusing to fulfill it. Authorization will not help in this case. This HTTP status code might indicate that the action performed is not supported for this resource or collection.
- **404 Not Found** - In this case, the server has not found anything that matches with the URL.
- **415 Unsupported Media Type** - The server is refusing to service the request because the entity of the request is in a format not supported by the requested resource for the requested method. This error must be returned, when the client is explicitly asking for format other than JSON (application/json).

Server Errors

- **500 Internal Server Error** - The server encountered an unexpected condition which prevented it from fulfilling the request. This error code must be used when an exception is raised in the application and the exception has nothing to do with the client request.

JSON Specification

General Conventions

The API uses JSON throughout; the Content-Type for all requests and responses is **application/json**.

As is general practice with REST, clients should not make assumptions about the server's URL space. Clients are expected to discover all URL's by navigating the API. To keep this document readable, we still mention specific URL's, generally in the form of an absolute path. Clients should not use these, or assume that the actual URL structure follows these examples, and instead use discovered URL's. Any client should start its discovery with the API entry point, here denoted with **/api**.

- Basic Types
- Common Attributes and Actions
  - Attributes
- Actions
- Collections
- Action Specification
- Collection Actions
- Resource Actions
- Action Responses

Basic types

The following are basic data types and type combinators that are used throughout:

Name	Explanation	Example serialization

Name	Explanation	Example serialization
Integer	Integer value	{ “memsize” : 2048 }
String	JSON string	{ “state” : “running” }
URL	Absolute URL	{ “href” : “http://SERVER/vms/1/start” }
Timestamp	Timestamp in ISO8601 format	{ “created” : “2013-12-05T08:15:30Z” }
Array[T]	Array where each entry has type T	{ “vms” : [{ “id” : “1” }, { “id” : “2” }] }
Ref[T]	A reference to a T, used to model relations, the T is a valid Resource identifier	{ “vm” : { “href” : URL } }
Collection	Array[T] where T represents a Ref[T], this might allow actions to be executed on all members as a single unit	{ “vms” : { “count” : 2, “resources” : [{ “href” : URL}, { “href” : URL }], “actions” : [] }
Struct	A structure with sub-attributes	“power_state”: {“state” : “ON”, “last_boot_time” : “2013-05-29T15:28Z”, “state_change_time” : “2013-05-29T15:28Z”}

Common Attributes and Actions

The following describes attributes and actions that are shared by all resources and collections defined in this API.

Attributes

Attribute	Type	Description
id	String	A string identifier for the referenced resource
href	Ref(self)	A unique self reference
name	String	A human name of the resource

```
{
  "id" : "10",
  "href" : "http://localhost:3000/api/vms/10",
  "name" : "first_vm"
}
```

Actions

Action	HTTP method	Description
create	POST	Create new resource in the collection
edit	PUT/PATCH/POST	Edit attributes in resource
delete	DELETE	Delete resource

Note:

About permissions and security:

Advertising of the common actions depends purely on the role and permissions of that the current API user does have for the particular resource.

Collections

Resources can be grouped into collections. Each collection is homogeneous so that it contains only one type of resource, and is unordered. Resources can also exist outside any collection. In this case, we refer to these resources as singleton resources. Collections are themselves resources as well.

Collections can exist globally, at the top level of an API, but can also be contained inside a single resource. In the latter case, we refer to these collections as sub-collections. Sub-collections are usually used to express some kind of “contained in” relationship

Collections are serialized in JSON in the following way:

```
{
  "name" : String,
  "count": Integer,
  "subcount": Integer,
  "resources": [ ... ],
  "actions": [ ... ]
}
```

Where the **name** attribute is the collection name. The **count** attribute in a collection always denotes the total number of items in the collection, not the number of items returned. **subcount** attribute in a collection depicts the number of items returned. Then the **resources** attribute is an Array[T] where T might be a list of references to the T or, if expanded a list of resources with all attributes. The **actions** then contains an Array of actions that can be performed against the collection resources.

Action Specification

The representation of each resource will only contain an action and its URL if the current user is presently allowed to perform that action against that resource. Actions will be contained in the **actions** attribute of a resource; that attribute contains an array of action definition, where each action definition has a rel, method and a href attribute.

- **name** attribute contains the action name
- **method** attribute states the HTTP method that must be used in a client HTTP request in order to perform the given action (eg. GET, POST, PUT, DELETE)
- **href** attribute contains the absolute URL that the HTTP request should be performed against
- **form** an optional attribute that references a JSON document which describes the resource attributes that can be provided in the message body when performing this action. This description will indicate which of those attributes are mandatory and which are optional.

Collection actions

The actions performed against a collection of resources are in most cases batch operations against multiple resources. The action request must include an HTTP body with the action name and the list of resource representations that the action will be performed against.

The resource representation might include the resource attributes as they can change the way how the action is actually performed. In the example below, the first service is retired immediately, versus the second being retired at a later date with a retirement warning of 3 days.

Sample JSON request body for collection action:

```
POST /api/services

{
  "action": "request_retire",
  "resources" : [
    { "href" : "http://localhost:3000/api/services/101" },
    { "href" : "http://localhost:3000/api/services/102",
      "date" : "10/30/2015",
      "warn" : 3
    }
  ]
}
```

Actions in collection:

```
{
  "name" : String,
  "count": Integer,
  "resources": [ ... ],
  "actions": [
    {
      "name"   : "start",
      "method" : "post",
      "href"   : URL
    },
    {
      "name"   : "stop",
      "method" : "post",
      "href"   : URL
    },
    {
      "name"   : "suspend",
      "method" : "post",
      "href"   : URL
    },
    {
      "name"    : "edit",
      "method" : "post",
      "href"   : URL
    },
    {
      "name"    : "delete",
      "method" : "post",
      "href"   : URL
    },
    {
      "name"   : "delete",
      "method" : "delete",
      "href"   : URL
    }
  ]
}
```

Resource actions

An action performed against a given resource is always described in the body of the HTTP request. The HTTP body could contain a list of resource attributes that dictate how the state of the receiving resource is to be changed once the action is performed. At minimum the JSON document in the message body must contain the name of the action to be performed.

In cases where no attributes are required to perform an action the HTTP body will contain an empty JSON document, in which case default values will be assigned to the corresponding attributes.

Sample JSON request body for resource action:

```
POST /api/services/101

{
  "action"   : "request_retire",
  "resource" : { "date" : "10/30/2015", "warn" : 5 }
}

POST /api/vms/321

{
  "action"   : "start",
  "resource" : {}
}
```

or Simply:

```
{
  "action"   : "start"
}
```

Actions in a resource:

```
{
  "id"     : String,
  "href"   : Ref(self),
  "name"   : "resource human name",
  "actions" : [
    {
      "name"   : "edit",
      "method" : "post",
      "href"   : URL
    }
  ]
}
```

Action Responses

When performing actions on resources, there are two types of responses that one is to expect.

1. For actions that operate on the resource itself like a *create* or *edit*, the response is usually the updated resource. This includes creation of Provision or Automate requests where the created /api/provision_requests and /api/automation_requests gets returned.
2. For others like a *start* or *stop* action, the response includes an action result for each targetted resource. An action result has the following construct in the response:

```
{
  "results" : [
    {
      "success" : true | false,
      "message" : String,
      "href" : Ref[resource],
      "result" : Struct,
      "task_id" : Id,
      "task_href" : Ref[task]
    },
    ...
  ]
}
```

results being an array of action results as one or more resources could be targeted in a request.

NOTE:

- success and message are always there.
- result is optional and would exist when an action results in data, i.e. policy resolve.
- href is populated for the resource being targeted by the action
- task_id and task_href are optional. They are defined when actions are run asynchronously and a task is created, i.e. http://localhost:3000/api/tasks/:id which can be monitored for action completion.

Other action specific attributes could also be returned in the the action result.

For tagging actions:

```
{
  "tag_category" : String,
  "tag_name" : String,
  "tag_href" : Ref[tags]
}
```

When executing actions on subcollections, like *policies*, *policy_profiles* and *service_templates*, the following is also provided in the action result:

```
{
  "<subcollection>_id" : Id,
  "<subcollection>_href" : Ref[subcollection]
}
```

- Query Specification
  - Control Attributes
  - Filtering
  - Expanding Collection
  - Virtual Attributes and Relationships

Query Specification

This specification identifies the controls available when querying collections.

The controls are specified in the GET URL as attribute value pairs as follows:

```
GET /api/:collection?attr1=val1&attr2=val2&...
```

Control Attributes

Category	Attribute	Semantics
Pagination		
	offset	0-based offset of first item to return
	limit	number of items to return. If 0 is specified then the remaining items are returned
	Please refer to Pagination for details on default pagination and pagination links provided by the API	
Scope		
	filter[]	One or more filters to search on. See Filtering below.
	attributes=atr1,atr2,...	Which attributes in addition to id and href to return. If not specified or *all* (default is attributes=*all*), then all attributes are returned
	expand=resources	To expand the resources returned in the collection and not just the href. See Expanding Collection below
Sorting		
	sort_by=atr1,atr2,...	By which attribute(s) to sort the result by. SQL friendly virtual attributes are also supported.
	sort_order=asc or desc	Order of the sort
	sort_options=ignore_case	Option for case insensitive sort

- The **count** attribute in a collection always denotes the total number of items in the collection, not the number of items returned.
- The **subcount** attribute in a collection denotes the number of items from the collection that were returned. For example, as a result of a paged request.

Filtering

GET requests against collections support the following query parameters to enable filtering:

- **filter**: The filter to use for querying the collection, i.e. filter[]=name='myservice%'.

```
GET /api/:collection?filter[]=name='myservice%'
```

For more information on filter[] please reference the Filtering page

Expanding Collection

While in the JSON serialization example the description says that the resource might be a list of references to these resource, using the **expand** parameter they can be expanded to return a full JSON serialization of the resource instead:

GET */api/vms*

```
{
  "name" : "vms",
  "count" : 2,
  "subcount" : 2,
  "resources" : [
    { "href" : "http://localhost:3000/api/vms/1" },
    { "href" : "http://localhost:3000/api/vms/2" }
  ],
  "actions" : []
}
```

GET */api/vms?expand=resources*

```
{
  "name" : "vms",
  "count" : 2,
  "subcount" : 2,
  "resources" : [
    {
      "id" : "1",
      "href" : "http://localhost:3000/api/vms/1",
      "name" : "My First VM",
      ...
    },
    {
      "id" : "2",
      "href" : "http://localhost:3000/api/vms/2",
      "name" : "My Second VM",
      ...
    }
  ],
  "actions" : []
}
```

Virtual Attributes and Relationships

When querying resources, virtual attributes (not database columns) as well as relationships can be queried via the attributes parameter.

For example, while accounts and software are defined subcollections of vms

```
GET /api/vms/166?expand=software&attributes=ipaddresses,lans,storage
```

```
{
  "href": "http://localhost:3000/api/vms/166",
  "id": "166",
  "vendor": "vmware",
  "name": "Dev Nightly Appl",
  "location": "Nightly Appl 201.vmx",
  "host_id": "4",
  "created_on": "2014-11-20T19:37:28Z",
  "updated_on": "2015-03-07T04:32:33Z",
  "storage_id": "12",
  "guid": "a9409862-70ec-11e4-90c6-b8e85646e742",
  "uid_ems": "422f50c6-2ba6-1059-338d-423cc3daf5b4",
  "tools_status": "toolsNotRunning",
  "standby_action": "checkpoint",
  "power_state": "off",
  "state_changed_on": "2014-11-20T19:37:28Z",
  "connection_state": "connected",
  "memory_reserve": 0,
  "memory_reserve_expand": false,
  "memory_limit": -1,
  "memory_shares": 40960,
  "memory_shares_level": "normal",
  "raw_power_state": "poweredOff",
  ...
  "ipaddresses": [
    "192.168.100.1"
  ],
  "lans": [
    {
      "id": "8",
      "switch_id": "6",
      "name": "VM Network",
      "tag": "0",
      "created_on": "2014-11-20T19:37:23Z",
      "updated_on": "2014-11-20T19:37:23Z",
      "uid_ems": "VM Network",
      "computed_allow_promiscuous": false,
      "computed_forged_transmits": true,
      "computed_mac_changes": true
    }
  ],
  "storage": {
    "id": "12",
    "name": "StarM1-Dev",
    "store_type": "VMFS",
    "total_space": 2134061875200,
    "free_space": 385020329984,
    "created_on": "2014-11-20T19:37:22Z",
    "updated_on": "2015-03-09T13:36:05Z",
    "multiplehostaccess": 0,
    "location": "4e43dd32-c6b7543a-32bf-0010187f038c",
    "uncommitted": 845539212800,
    "ems_ref_obj": "--- !ruby/string:VimString\nstr: datastore-15624\nxsiType: :ManagedObjectReference\nvimType:
:Datastore\n",
    "directory_hierarchy_supported": true,
    "thin_provisioning_supported": true,
    "raw_disk_mappings_supported": true,
    "master": false,
    "ems_ref": "datastore-15624"
  }
  "software": [
    {
      "href": "http://localhost:3000/api/vms/320/software/1",
      "id": "1",
      "name": "OpenOffice",
      "vendor": "OpenOffice.org",
      "vm_or_template_id": "166"
    }
  ]
}
```

As another example, one can query good details on hosts:

```
GET /api/hosts/8?attributes=custom_attributes,ext_management_system,resource_pools,storages,vms,hardware
```

of course, one needs to be careful with queries like these as list of vms for a host could be quite large.

Virtual attributes can also be queried from one-to-one relationships via the dot notation as follows:

```
GET /api/hosts/8?attributes=ext_management_system.id,ext_management_system.guid,ext_management_system.name
```

```
{
  "href": "http://localhost:3000/api/hosts/8",
  "id": "8",
  "name": "test1.sample.com",
  "hostname": "test1.sample.com",
  "ipaddress": "test1.sample.com",
  "vmm_vendor": "vmware",
  "vmm_version": "5.0.0",
  "vmm_product": "ESXi",
  "vmm_buildnumber": "515841",
```

```
  ...
  "ext_management_system": {
    "name": "vcenter50",
    "guid": "e84e8c58-bdbd-11e4-8983-b8e85646e742",
    "id": "6"
  }
}
```

With attributes, database attributes, virtual attributes, and relationships can be specified together as in the following example:

```
GET /api/vms/166?attributes=name,raw_power_state,ipaddresses,storage.name
```

```
{
  "href": "http://localhost:3000/api/vms/166",
  "id": "166",
  "name": "Dev Nightly Appl",
  "raw_power_state": "poweredOff",
  "ipaddresses": [
    "192.168.253.1"
  ],
  "storage": {
    "name": "StarM1-Dev"
  }
}
```

This is helpful when specific information is needed out of resources and helps with response time when querying large number of resources as in the following example:

```
GET /api/vms?limit=1000&offset=1000&expand=resources&
    attributes=name,raw_power_state,ipaddresses,storage.name
```

- Bulk Querying

Bulk Querying

While the capability to fetch an individual resource via /api/:collection/:id is available, fetching multiple resources via a filtered search is possible but has limitation on GET url limits and is cumbersome on the filtering syntax.

The Bulk Queries provides this capability by implementing a *query* POST action on the primary collections.

```
POST /api/vms
```

```
{
  "action" : "query",
  "resources" : [
    { "guid" : "...." },
    { "guid" : "...." },
    ...
  ]
}
```

The *query* interface is flexible in that it allows resources to be specified by different relevant attributes. These include:

Identifying Attributes
href
id
guid (*if applicable*)

Some other attributes can also be used as identifying attributes as shown in the following table:

Collection	Optional Identifying Attributes
/api/groups	description
/api/roles	name
/api/tags	name
/api/users	name, userid

As with regular GETs, queries return expanded resources, but also support other query parameters as in the following example:

```
POST /api/vms?attributes=name,raw_power_state
```

```
{
  "action" : "query",
  "resources" : [
    { "id" : 10 },
    { "id" : 20 },
    { "id" : 23 },
    { "id" : 28 },
    { "id" : 30 }
  ]
}
```

Sample response:

```
{
  "results": [
    {
      "href": "http://localhost:3000/api/vms/10",
      "id": "10",
```

```
      "name": "test_vm_1",
      "raw_power_state": "down"
    },
    {
      "href": "http://localhost:3000/api/vms/20",
      "id": "20",
      "name": "demo_server_A",
      "raw_power_state": "down"
    },
    {
      "href": "http://localhost:3000/api/vms/23",
      "id": "23",
      "name": "demo_server_B",
      "raw_power_state": "down"
    },
    {
      "href": "http://localhost:3000/api/vms/28",
      "id": "28",
      "name": "aab_dev_vm",
      "raw_power_state": "up"
    },
    {
      "href": "http://localhost:3000/api/vms/30",
      "id": "30",
      "name": "ipa_dev",
      "raw_power_state": "down"
    }
  ]
}
```

- Collection Filtering

Collection Filtering

When querying collections, filters can be specified by providing one or more filter[]=... parameter.

```
GET /api/:collection?filter[]=...&filter[]=...&filter[]=...
```

Syntax for a filter is as follows:

```
filter[]=attribute op value
```

By default, filters are logically *anded* together, for a logical or, prefix the attribute with *or* as follows:

```
filter[]=or attribute op value
```

Where op supports the following operators:

Operator	Description	Operands
=	Equality	Numeric or string. For String, supports % or * as wildcard NULL or nil can also be specified instead of quoted string
!=	Inequality	
<	Less Than	Numeric
<=	Less Than or Equal	Numeric
>=	Greater Than or Equal	Numeric
>	Greater Than	Numeric

When strings, value to be quoted in single or double quotes. When datetimes, only strict comparison operators are supported.

Example Query of VMs named sample*, created_on > 2019-09-01, and return name and vendor

```
GET /api/vms?expand=resources&attributes=name,vendor&filter[]=created_on>2019-09-01&filter[]=name='sample%'
```

Example Query looking for services that are retired but have an unspecified service_id

```
GET /api/services?expand=resources&attributes=retired&filter[]=service_id=nil&filter[]=retired=true
```

Example Query of VMs with power_state of on or off:

```
GET /api/vms?expand=resources&filter[]=power_state=[on,off]
```

Alternately, you can use the following more verbose syntax using OR:

```
GET /api/vms?expand=resources&filter[]=power_state=off&filter[]=or%20power_state=on
```

Example Query of VMs with more than 4 CPU sockets or more than 16,000 MB of RAM (OR):

```
GET /api/vms?expand=resources&filter[]=num_cpu>4&filter[]=or%20ram_size>16000
```

Example Query of VMs without a specific value (attribute negation):

```
GET /api/vms?expand=resources&filter[]=power_state!=unknown
```

Example Query of VMs where a field is NOT NULL (vms that are either retired or not):

```
GET /api/vms?expand=resources&filter[]=retired!=nil
GET /api/vms?expand=resources&filter[]=retired!=NULL
```

```
GET /api/vms?expand=resources&filter[]=retired!=null
```

Example Query of VMs using a boolean:

```
GET /api/vms?expand=resources&filter[]=retired=true
```

Example Query of VMs created before a specific time:

```
GET /api/vms?expand=resources&filter[]=created_on<2023-01-01
```

Attributes specified via the filter[] parameter can include virtual attributes, including one level association of the virtual attribute as follows:

The HTTP **OPTIONS** request can be used on a collection to display all of the collection specific metadata, including the available virtual attributes. For more information please refer to the Collection Metadata page.

```
GET /api/vms?attributes=name,vendor,hardware&filter[]=vendor='vmware'&filter[]=hardware.memory_mb>=8192
```

Here filtering on the virtual attribute *hardware* including the one level association *memory_mb* off hardware.

- Pagination
  - About max_results_per_page

Pagination

Pagination is enabled by default. When querying collections and the *limit* query parameter is not specified, only 1000 resources are returned by default. This is driven by the new advanced setting:

```
:api:
  :max_results_per_page: 1000
```

Example GET with offset and limit specified.

```
GET /api/vms?offset=2&limit=2&sort_by=name&expand=resources
```

```
{
  "name"      : "vms",
  "count"     : 7,
  "subcount"  : 2,
  "pages"     : 4,
  "resources" : [
    {
      "href"    : "http://localhost:3000/api/vms/7254",
      "id"      :  "7254",
      "vendor" : "vmware",
      "name"    : "test-vm1",
      ...
    },
    {
      "href"    : "http://localhost:3000/api/vms/7257",
      "id"      : "7257",
      "vendor" : "vmware",
      "name"    : "test-vm2",
      ...
    }
  ],
 "actions" : [
    ...
  ],
 "links" : {
   "self"     : "http://localhost:3000/api/vms?offset=2&limit=2&sort_by=name&expand=resources",
   "next"     : "http://localhost:3000/api/vms?offset=4&limit=2&sort_by=name&expand=resources",
   "previous" : "http://localhost:3000/api/vms?offset=0&limit=2&sort_by=name&expand=resources",
   "first"    : "http://localhost:3000/api/vms?offset=0&limit=2&sort_by=name&expand=resources",
   "last"     : "http://localhost:3000/api/vms?offset=6&limit=2&sort_by=name&expand=resources"
 }
}
```

With pagination enabled by default, collection queries now return the following:

- “pages” metadata which is the total number of pages for the *limit* specified (or the default 1000).
- “links” metadata section which includes the necessary URL’s for fetching the current page, next and previous pages, as well as the first and last pages.

Notes:

- When the page being returned is the first page (i.e. offset = 0), the *previous* link is not returned.
- When the page being returned is the last page, the *next* page link is not returned.
- For small result sets where *limit* is less than max_results_per_page, the *limit* will be honored.
- For large result sets where the *limit* is greater than max_results_per_page, *limit* will be ignored and the result will be limited to the first max_results_per_page resources.

About max_results_per_page

If the default value for max_results_per_page does not meet your needs, it can be changed using the Advanced Settings feature in the UI. However, it is *NOT* recommended to set it to some arbitrarily large number in an effort to circumvent the pagination feature. The pagination feature is designed to prevent excessive

load on the API workers, which is easy to do with large collections such as metric rollups and event streams that may have millions of records.

Infrastructure Management API Reference

In this guide you will find a detailed reference for the Infrastructure Automation – Infrastructure Management REST API.

- Primary Collections

- Collections

Collections

The following tables shows the currently available primary collections accessible via:

```
GET /api/:collection
```

Where :collection is one of the following:

Collection	Description
actions	Actions
alert_definition_profiles	Alert Definition Profiles
alert_definitions	Alert Definitions
alerts	Alerts

Collection	Description
auth_key_pairs	Auth Key Pairs
authentications	Authentications
automate	Automate Model
automate_classes	Automate Classes
automate_domains	Automate Domains
automate_workspaces	Automate Workspaces
automation_requests	Automation Requests
availability_zones	Availability Zones
categories	Categories
chargebacks	Chargebacks
cloud_networks	Cloud Networks
cloud_object_store_containers	Cloud Object Store Containers
cloud_subnets	Cloud Subnets
cloud_templates	Cloud Templates
cloud_tenants	Cloud Tenants
cloud_volume_types	Cloud Volume Types
cloud_volumes	Cloud Volumes
clusters	Clusters
conditions	Conditions
configuration_profiles	Configuration Profiles
configuration_script_payloads	Configuration Script Payloads
configuration_script_sources	Configuration Script Source
configuration_scripts	Configuration Scripts
configured_systems	Configured Systems
container_groups	Container Groups
container_images	Container Images
container_nodes	Container Nodes
container_projects	Container Projects
container_templates	Container Templates
container_volumes	Container Volumes
containers	Containers
conversion_hosts	Conversion Hosts
currencies	Currencies
custom_button_sets	Custom Button Sets
custom_buttons	Custom Buttons
customization_scripts	Customization Scripts
customization_templates	Customization Templates
data_stores	Datastores
enterprises	Enterprises
event_streams	Event Streams
events	Events
features	Product Features
firmware_registries	Firmware Registries
firmwares	Firmwares
flavors	Flavors
floating_ips	Floating IPs
generic_object_definitions	Generic Object Definitions
generic_objects	Generic Objects
groups	Groups
guest_devices	Guest Devices
hosts	Hosts
instances	Instances
lans	Lans
load_balancers	Load Balancers
measures	Measures
metric_rollups	Metric Rollups
network_routers	Network Routers
notifications	User’s past notifications
orchestration_stacks	Orchestration Stacks
orchestration_templates	Orchestration Template
physical_chassis	Physical Chassis
physical_racks	Physical Racks
physical_servers	Physical Servers
physical_storages	Physical Storages

Collection	Description
physical_switches	Physical Switches
pictures	Pictures
policies	Policies
policy_actions	Actions
policy_profiles	Policy Profiles
providers	Providers
provision_dialogs	Provisioning Dialogs
provision_requests	Provision Requests
pxe_images	PXE Images
pxe_menus	PXE Menus
pxe_servers	PXE Servers
rates	Chargeback Rates
regions	Regions
reports	Reports
request_tasks	Request Tasks
requests	Requests
resource_pools	Resource Pools
results	Report Results
roles	Roles
search_filters	Search Filters
security_groups	Security Groups
servers	EVM Servers
service_catalogs	Service Catalogs
service_dialogs	Service Dialogs
service_offerings	Service Offerings
service_orders	Service Orders
service_parameters_sets	Service Parameters Sets
service_requests	Service Requests
service_templates	Service Templates
services	Services
settings	Settings
switches	Switches
tags	Tags
tasks	Tasks
templates	Templates
tenant_groups	Tenant Groups
tenants	Tenants
transformation_mappings	Transformation Mappings
users	Users
vms	Virtual Machines
widgets	Miq Widgets
zones	Zones

- Actions
  - Querying Actions
  - Creating Actions
  - Editing Actions
  - Deleting Actions

Actions

Management of actions is provided via the following collection:

`/api/actions`

Full CRUD actions on resources is available:

- Querying Actions
- Creating Actions
- Editing Actions
- Deleting Actions

Querying Actions

Querying all actions in the system is simply:

```
GET /api/actions
```

Getting details on a specific Action:

```
GET /api/actions/:id
```

Creating Actions

Actions can be created via a POST to the actions collection or via the **create** action signature which also allows creation of multiple actions in a single request.

```
POST /api/actions
```

```
{
  "name" : "sample_action",
  "description" : "Sample Action",
  "action_type" : "custom_automation",
  "options" : {
    "ae_message" : "message",
    "ae_request" : "request",
    "ae_hash" : { "sample_key" : "sample_value" }
  }
}
```

or creating multiple actions:

```
{
  "action" : "create",
  "resources" : [
    { "name" : "action_1", "description" : "Action 1", ... },
    { "name" : "action_2", "description" : "Action 2", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating actions.

Editing Actions

```
POST /api/actions/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "description" : "Updated Description"
  }
}
```

or editing multiple actions:

```
POST /api/actions
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/actions/101",
      "description" : "Updated Description 1"
    },
    {
      "href" : "http://localhost:3000/api/actions/102",
      "description" : "Updated Description 2"
    },
    ...
  ]
}
```

Deleting Actions

Actions can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/actions/101
```

```
{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/actions/101
```

Deleting multiple actions can be done as follows:

```
POST /api/actions
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/actions/101" },
    { "href" : "http://localhost:3000/api/actions/102" },
```

```
    ...
  ]
}
```

- Alert Management
  - Querying Alerts
  - Querying Alert Actions
  - Creating Alert Actions
  - Querying Alert Definitions
  - Creating Alert Definitions
  - Editing Alert Definitions
  - Deleting Alert Definitions

Alert Management

Management of alerts, alert actions and alert definitions is provided via the following collections and subcollections:

```
/api/alerts
/api/alerts/:id/alert_actions

/api/alert_definitions
```

Queries of alerts:

- Querying Alerts

Queries and creation of alert actions:

- Querying Alert Actions
- Creating Alert Actions

Full CRUD actions on alert definitions:

- Querying Alert Definitions
- Creating Alert Definitions
- Editing Alert Definitions
- Deleting Alert Definitions

Querying Alerts

Querying all alerts in the system is simply:

```
GET /api/alerts
```

Getting details on a specific alert:

```
GET /api/alerts/:id
```

Querying Alert Actions

Querying all alert actions of a specific alert is done via the subcollection as follows:

```
GET /api/alerts/:alert_id/alert_actions
```

Querying an alert action of a specific alert is done via the subcollection resource as follows:

```
GET /api/alerts/:alert_id/alert_actions/:alert_action_id
```

Creating Alert Actions

Creating an alert action for a specific alert can be done by the following POST:

```
POST /api/alerts/:alert_id/alert_actions
```

```
{
  "action_type" : "custom_automation",
  "comment" : "Comment about the Alert Action"
}
```

Querying Alert Definitions

Querying all alert definitions in the system is simply:

```
GET /api/alert_definitions
```

Getting details on a specific alert definition:

```
GET /api/alert_definitions/:id
```

Creating Alert Definitions

Alert definitions can be created via a POST to the alert definitions collection or via the **create** action signature which also allows creation of multiple alert definitions in a single request.

```
POST /api/alert_definitions

{
  "description" : "Test Alert Definition",
  "db" : "ContainerNode",
  "expression" : { "eval_method" : "dwh_generic", "mode" : "internal", "options" : {} },
  "options"    : { "notifications" : { "delay_next_evaluation" : 600, "evm_event" : {} } },
  "enabled"    : true
}
```

or creating multiple alert definitions:

```
{
  "action" : "create",
  "resources" : [
    { "description" : "Sample Alert Definition 1", ... },
    { "description" : "Sample Alert Definition 2", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating alert definitions.

Editing Alert Definitions

```
POST /api/alert_definitions/:id

{
  "action" : "edit",
  "resource" : {
    "options" : { "notifications" : { "delay_next_evaluation" : 1200, "evm:event" : {} } }
  }
}
```

or editing multiple alert definitions:

```
POST /api/alert_definitions

{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/alert_definitions/101",
      "options" : { "notifications" : { "delay_next_evaluation" : 1200, "evm:event" : {} } }
    },
    {
      "href" : "http://localhost:3000/api/alert_definitions/102",
      "options" : { "notifications" : { "delay_next_evaluation" : 1200, "evm:event" : {} } }
    },
    ...
  ]
}
```

Deleting Alert Definitions

Alert definitions can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/alert_definitions/101

{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/alert_definitions/101
```

Deleting multiple alert definitions can be done as follows:

```
POST /api/alert_definitions

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/alert_definitions/101" },
    { "href" : "http://localhost:3000/api/alert_definitions/102" },
    ...
  ]
}
```

- Authentications
  - Querying Authentications
  - Creating Authentications
  - Editing Authentications
  - Refreshing Authentications

- Deleting Authentications

Authentications

Management of authentications is provided via the following collection:

```
/api/authentications
```

Full CRUD actions on authentications is available:

- Querying Authentications
- Creating Authentications
- Editing Authentications
- Refreshing Authentications
- Deleting Authentications

Querying Authentications

Querying all authentications in the system is simply:

```
GET /api/authentications
```

Getting details on a specific authentication:

```
GET /api/authentications/:id
```

One can also query authentications of a configuration script payload's manager as follows:

```
GET /api/configuration_script_payloads/:id/authentications
```

Or getting details on a specific authentication:

```
GET /api/configuration_script_payloads/:id/authentications/:authentication_id
```

Creating Authentications

Authentications can be created via a POST to the authentications collection or via the **create** action signature which also allows creation of multiple authentications in a single request.

```
POST /api/authentications
```

```
{
  "description" : "Authentication Description",
  "name" : "SomeCredentials",
  "related" : {},
  "type" : "ManageIQ::Providers::AnsibleTower::AutomationManager::Credential",
  "manager_resource" : { "href" : "http://localhost:3000/api/providers/7" }
}
```

or creating multiple authentications:

```
{
  "action" : "create",
  "resources" : [
    { "description" : "System Credentials", "name" : "SystemCreds", ... },
    { "description" : "Admin Credentials",  "name" : "AdminCreds", ... },
    ...
  ]
}
```

Optionally, authentications can be created for a provider of a specific configuration script payload, thus eliminating the need of specifying a provider.

```
POST /api/configuration_script_payloads/:id/authentications
```

```
{
  "description" : "Authentication Description",
  "name" : "SomeCredentials",
  "related" : {},
  "type" : "ManageIQ::Providers::AnsibleTower::AutomationManager::Credential"
}
```

Also supporting bulk creates:

```
{
  "action" : "create",
  "resources" : [
    { "description" : "System Credentials", "name" : "SystemCreds", ... },
    { "description" : "Admin Credentials",  "name" : "AdminCreds", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating authentications.

Editing Authentications

```
POST /api/authentications/:id

{
  "action" : "edit",
  "resource" : {
    "name" : "UpdatedCredentials"
  }
}
```

or editing multiple authentications:

```
POST /api/authentications

{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/authentications/101",
      "description" : "Updated Sample Credentials 1",
      "name" : "UpdatedCredentials1"
    },
    {
      "href" : "http://localhost:3000/api/authentications/102",
      "description" : "Updated Sample Credentials 2",
      "name" : "UpdatedCredentials2"
    },
    ...
  ]
}
```

Refreshing Authentications

Authentications can be refreshed by posting a **refresh** action to a single resource or to multiple resources in bulk by targeting the collection.

```
POST /api/authentications/:id

{
  "action" : "refresh"
}
```

or refreshing multiple authentications:

```
POST /api/authentications

{
  "action" : "refresh",
  "resources" : [
    { "id" : "51" },
    { "id" : "52" }
  ]
}
```

Example:

```
POST /api/authentications/51

{
  "action" : "refresh"
}
```

Response:

```
{
  "success" : true,
  "message" : "Refreshing Authentication id:51 name:'SampleCredentials'",
  "task_id" : "8",
  "task_href" : "http://localhost:3000/api/tasks/8",
  "tasks" : [
    {
      "id" : "8",
      "href" : "http://localhost:3000/api/tasks/8"
    }
  ]
}
```

Deleting Authentications

Authentications can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/authentications/101

{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/authentications/101
```

Deleting multiple authentications can be done as follows:

```
POST /api/authentications
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/authentications/101" },
    { "href" : "http://localhost:3000/api/authentications/102" },
    ...
  ]
}
```

- Automate
  - Usage
  - Querying Domains
  - Querying By Fully Qualified Name
  - Querying First Level Children Nodes
  - Querying Subtree
  - Querying State Machines Subtree

Automate

Querying the Automate model is provided via the following entrypoint:

```
/api/automate
```

- Usage
- Querying Domains
- Querying By Fully Qualified Name
- Querying First Level Children Nodes
- Querying Subtree
- Querying State Machines Subtree

Usage

Querying the Automate Model via /api/automate allows queries of:

- top level Automate Domains
- any object in the Automate Model
- arbitrary depth via the **depth** parameter

depth value	data returned
0	Just node itself
1	Node itself plus its first level children nodes
#	Node itself plus # levels of children nodes
-1	Node itself plus the whole subtree underneath it

- Automate model object tree to include state machine endpoints via the **search_options** parameter with value **state_machines**

Example queries:

```
GET /api/automate
GET /api/automate/manageiq
GET /api/automate/manageiq?depth=2
GET /api/automate/manageiq?depth=-1&search_options=state_machines
```

Querying Domains

Querying the Automate Domains can be done via GET on the /api/automate entrypoint as follows:

```
GET /api/automate
```

```
{
  "name": "automate",
  "subcount": 4,
  "resources": [
    {
      "fqname": "/ManageIQ",
      "domain_fqname": "/",
      "klass": "MiqAeDomain",
      "id": "2352",
      "name": "ManageIQ",
      "created_on": "2016-10-31T14:58:09Z",
      "updated_on": "2016-10-31T14:58:09Z",
      "description": "Base domain",
      "updated_by": "system",
      "priority": 0,
```

```
      "enabled": true,
      "tenant_id": "1",
      "source": "system"
    },
    ...
  ]
}
```

Note:

The fqname is always returned by this query

If desired a sub-set of attributes can be asked via as follows:

```
GET /api/automate?attributes=name,source
```

```
{
  "name": "automate",
  "subcount": 4,
  "resources": [
    {
      "fqname": "/ManageIQ",
      "name": "ManageIQ",
      "source" : "system"
    },
    ...
  ]
}
```

Querying By Fully Qualified Name

Querying any object in the Automate Model by its fully qualified name as follows:

Note:

The fqname in the query is *not* case sensitive

```
GET /api/automate/manageiq
```

```
{
  "name": "automate",
  "subcount": 1,
  "resources": [
    {
      "fqname": "/ManageIQ",
      "domain_fqname": "/",
      "klass": "MiqAeDomain",
      "id": "2352",
      "name": "ManageIQ",
      "created_on": "2016-10-31T14:58:09Z",
      "updated_on": "2016-10-31T14:58:09Z",
      "description": "Base domain",
      "updated_by": "system",
      "priority": 0,
      "enabled": true,
      "tenant_id": "1",
      "source": "system"
    }
  ]
}
```

Another example showing fetching an automate class object:

```
GET /api/automate/manageiq/system/request
```

```
{
  "name": "automate",
  "subcount": 1,
  "resources": [
    {
      "fqname": "/ManageIQ/System/Request",
      "domain_fqname": "/System/Request",
      "klass": "MiqAeClass",
      "id": "75",
      "description": "Automation Requests",
      "name": "Request",
      "created_on": "2015-12-09T20:56:44Z",
      "updated_on": "2015-12-09T20:56:44Z",
      "namespace_id": "41",
      "updated_by": "system"
    }
  ]
}
```

Automate model nodes returned include both:

- **fqname**: the fully qualified name of the node which is rooted at /.
    - i.e. /ManageIQ/System/Request
- **domain_fqname**: the fully qualified name of the node rooted at the domain, which is **fqname** without the Domain prefix

- i.e. /System/Request

Querying First Level Children Nodes

When specifying a depth of 1, the Automate model node and its first level children nodes are returned.

In this example, we are asking for the /ManageIQ Domain and its direct children nodes.

```
GET /api/automate/manageiq?depth=1&attributes=domain_fqname,klass
```

```
{
  "name": "automate",
  "subcount": 9,
  "resources": [
    {
      "fqname": "/ManageIQ",
      "domain_fqname": "/",
      "klass": "MiqAeDomain"
    },
    {
      "fqname": "/ManageIQ/System",
      "domain_fqname": "/System",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/Service",
      "domain_fqname": "/Service",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/Infrastructure",
      "domain_fqname": "/Infrastructure",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/GenericObject",
      "domain_fqname": "/GenericObject",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/Deployment",
      "domain_fqname": "/Deployment",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/Control",
      "domain_fqname": "/Control",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/ConfigurationManagement",
      "domain_fqname": "/ConfigurationManagement",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/Cloud",
      "domain_fqname": "/Cloud",
      "klass": "MiqAeNamespace"
    }
  ]
}
```

Querying Subtree

When specifying a depth of -1, the Automate model node and all of the nodes underneath it are returned.

```
GET /api/automate/manageiq?depth=-1&attributes=klass
```

```
{
  "name": "automate",
  "subcount": 935,
  "resources": [
    {
      "fqname": "/ManageIQ",
      "klass": "MiqAeDomain"
    },
    {
      "fqname": "/ManageIQ/System",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/System/Event",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/System/Event/RequestEvent",
      "klass": "MiqAeNamespace"
    },
    ...
  ]
}
```

Querying State Machines Subtree

In this example, we are querying the ManageIQ Automate Domain model tree but only asking for branches that include state machine nodes.

```
GET /api/automate/manageiq?depth=-1&attributes=domain_fqname,klass&search_options=state_machines
```

```
{
  "name": "automate",
  "subcount": 104,
  "resources": [
    {
      "fqname": "/ManageIQ",
      "domain_fqname": "/",
      "klass": "MiqAeDomain"
    },
    {
      "fqname": "/ManageIQ/System",
      "domain_fqname": "/System",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/System/CommonMethods",
      "domain_fqname": "/System/CommonMethods",
      "klass": "MiqAeNamespace"
    },
    {
      "fqname": "/ManageIQ/System/CommonMethods/QuotaStateMachine",
      "domain_fqname": "/System/CommonMethods/QuotaStateMachine",
      "klass": "MiqAeClass"
    },
    {
      "fqname": "/ManageIQ/System/CommonMethods/QuotaStateMachine/quota",
      "domain_fqname": "/System/CommonMethods/QuotaStateMachine/quota",
      "klass": "MiqAeInstance"
    },
    ...
  ]
}
```

- Automate Domains
  - Querying Domains
  - Accessing Domains
  - Refresh From Source

Automate Domains

Querying the Automate Domains and triggering actions on domains is provided via the following entrypoint:

```
/api/automate_domains
```

- Querying Domains
- Accessing Domains
- Refresh From Source

Querying Domains

Querying the Automate Domains can be done via GET on the /api/automate_domains entrypoint and can be queried like any other collection:

```
GET /api/automate_domains
```

```
{
  "name": "automate_domains",
  "count": 9,
  "subcount": 9,
  "resources": [
    {
      "href": "http://localhost:3000/api/automate_domains/2352"
    },
    {
      "href": "http://localhost:3000/api/automate_domains/2347"
    },
    ...
  ],
  "actions": [
    {
      "name": "query",
      "method": "post",
      "href": "http://localhost:3000/api/automate_domains"
    },
    {
      "name": "refresh_from_source",
      "method": "post",
      "href": "http://localhost:3000/api/automate_domains"
    }
  ]
}
```

Accessing Domains

Accessing individual domains can be done via their numeric id or their name (*case sensitive*) as follows:

```
GET /api/automate_domains/2352
```

```
GET /api/automate_domains/ManageIQ
```

Refresh From Source

When Automate domains are imported from external sources, i.e. Git, the *refresh_from_source* will re-fetch the Automate domain from external source and refresh the automate domain. This will refetch the Domain from the same reference, i.e. branch or tag and name.

```
POST /api/automate_domains/SampleDomain
```

```
{
  "action": "refresh_from_source"
}
```

All refresh_from_source actions are done asynchronously and the related Task id and href are returned as follows:

```
{
  "success": true,
  "message": "Refreshing Automate Domain id:2347 name:'SampleDomain' from git repository",
  "task_id": "61",
  "task_href": "http://localhost:3000/api/tasks/61",
  "href": "http://localhost:3000/api/automate_domains/SampleDomain"
}
```

If the Domain needs to be refreshed from a different branch or tag and name, the following can be passed in with the *refresh_from_source* action:

```
{
  "action": "refresh_from_source",
  "resource" : {
    "ref_type" : "branch" | "tag",
    "ref" : "other_branch_or_tag_name"
  }
}
```

- Automation Requests
  - Creating Requests
  - Editing Requests
  - Approving or Denying Requests
    - Approving a Request
    - Denying a Request
  - Monitoring Requests
    - Response:
  - Editing Request Tasks

Automation Requests

Automation requests are made available via the following entrypoint:

```
/api/automation_requests
```

- Creating Requests
- Editing Requests
- Approving or Denying Requests
- Monitoring Requests
- Editing Request Tasks

Creating Requests

Either by specifying a *create* action or by posting the automation request directly to **/api/automation_requests**.

As an example:

```
{
  "uri_parts" : {
    "namespace" : "System",
    "class"     : "Request",
    "instance"  : "InspectME",
    "message"   : "create"
  },
  "parameters" : {
    "var1" : "value 1",
    "var2" : "value 2",
    "minimum_memory" : 2048
  },
  "requester" : {
    "auto_approve" : true
```

```
  }
}
```

Editing Requests

Updating requests can be performed by posting an *edit* action as follows:

```
POST /api/automation_requests/11

{
  "action" : "edit",
  "resource" : {
    "options" : {
      "attrs" : {
        "var1" : "updated value1",
        "var2" : "updated value2",
        "minimum_memory" : 4096
      }
    }
  }
}
```

Response:

```
{
  "href": "http://localhost:3000/api/automation_requests/11",
  "id": "11",
  "options": {
    "message": "create",
    "namespace": "System",
    "class_name": "Request",
    "instance_name": "InspectME",
    "user_id": "1",
    "attrs": {
      "var1" : "updated value1",
      "var2" : "updated value2",
      "minimum_memory" : 4096
    }
  },
  "tenant_id": "1",
  "approval_state": "approved",
  "status": "Ok",
  "request_type": "automation",
  "description": "Automation Task",
  "type": "AutomationRequest",
  "created_on": "2018-01-08T13:48:00Z",
  "updated_on": "2018-01-08T13:56:15Z",
  "requester_id": "1",
  "requester_name": "Administrator",
  "request_state": "pending",
  "message": "Automation Request - Request Created",
  "userid": "admin",
  "process": true
}
```

Approving or Denying Requests

If an automation request is not auto approved, it can be approved or denied via the actions *approve* and *deny* on the automation request resource.

Approving a Request

```
POST /api/automation_requests/:id

{
  "action" : "approve",
  "reason" : "reason for approval"
}
```

Denying a Request

```
POST /api/automation_requests/:id

{
  "action" : "deny",
  "reason" : "reason for denial"
}
```

Monitoring Requests

Once an automation request is created, the response will be the queryable automation request itself, i.e. **/api/automation_request/:id**

Response:

```
{
  "results": [
    {
      "id": "10",
      "description": "Automation Task",
      "approval_state": "approved",
```

```
      "type": "AutomationRequest",
      "created_on": "2015-04-14T18:12:12Z",
      "updated_on": "2015-04-14T18:12:12Z",
      "requester_id": "1",
      "requester_name": "Administrator",
      "request_type": "automation",
      "request_state": "pending",
      "status": "Ok",
      "options": {
        "message": "create",
        "namespace": "System",
        "class_name": "Request",
        "instance_name": "InspectME",
        "user_id": "1",
        "attrs": {
          "var1": "value 1",
          "var2": "value 2",
          "minimum_memory": 2048,
          "userid": "admin"
        }
      },
      "userid": "admin"
    }
  ]
}
```

In the above example, the request could be queried periodically until the **request_state** reaches the **finished** state.

Note:

The request tasks of an automation request can also be queried by expanding the request_tasks subcollection as follows:

```
GET /api/automation_requests/:id?expand=request_tasks
```

or by fetching them directly as follows:

```
GET /api/automation_requests/:id/request_tasks?expand=resources
```

Editing Request Tasks

Request tasks for Automation Requests can be updated as follows:

```
POST /api/automation_requests/:id/request_tasks/:request_task_id
```

```
{
  "action" : "edit",
  "resource" : {
    "options" : {
      "request_param_a" : "value_a",
      "request_param_b" : "value_b"
    }
  }
}
```

Automate Workspaces

Management of Automate Workspaces is provided with the following collection:

```
/api/automate_workspaces
```

- Querying Automate Workspaces
- Editing Automate Workspaces
- Encrypting Automate Workspace Passwords
- Decrypting Automate Workspace Passwords

Querying Automate Workspaces

It is not allowed to query the automate workspace collection, only individual automate workspaces can be fetched by guid.

```
GET /api/automate_workspaces/:guid
```

Example GET Request and Response:

Request:

```
GET /api/automate_workspaces/430a66a0-b564-4341-b9b2-85d6f467f26f
```

Response:

```
{
  "href": "http://localhost:3000/api/automate_workspaces/430a66a0-b564-4341-b9b2-85d6f467f26f",
  "id": "2",
  "guid": "430a66a0-b564-4341-b9b2-85d6f467f26f",
  "user_id": "1",
  "tenant_id": "1",
  "input": {
    "objects": {
      "root": {
        "var1": "a",
        "var2": "b"
      }
    },
    "method_parameters": {
      "arg1": "first_argument"
    }
  },
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "http://localhost:3000/api/automate_workspaces/430a66a0-b564-4341-b9b2-85d6f467f26f"
    },
    {
      "name": "encrypt",
      "method": "post",
      "href": "http://localhost:3000/api/automate_workspaces/430a66a0-b564-4341-b9b2-85d6f467f26f"
    },
    {
      "name": "decrypt",
      "method": "post",
      "href": "http://localhost:3000/api/automate_workspaces/430a66a0-b564-4341-b9b2-85d6f467f26f"
    }
  ]
}
```

Editing Automate Workspaces

Updating Automate Workspaces can be done via the *edit* action as follows:

```
POST /api/automate_workspaces/:guid
```

```
{
  "action" : "edit",
  "resource" : {
    "objects" : {
      "root" : {
        "var3" : "c"
      }
    }
  }
}
```

Encrypting Automate Workspace Passwords

Encrypting passwords in the automate workspace can be done as follows:

Request:

```
POST /api/automate_workspaces/:guid
```

```
{
  "action" : "encrypt",
  "resource" : {
    "object" : "method_parameters",
    "attribute" : "arg2",
    "value" : "unencrypted_password"
  }
}
```

Response:

```
{
  "href": "http://localhost:3000/api/automate_workspaces/430a66a0-b564-4341-b9b2-85d6f467f26f",
  "id": "2",
  "guid": "430a66a0-b564-4341-b9b2-85d6f467f26f",
  "user_id": "1",
  "tenant_id": "1",
  "input": {
    "objects": {
```

```
      "root": {
        "var1": "a",
        "var2": "b"
      }
    },
    "method_parameters": {
      "arg1": "first_argument",
      "arg2": "password::********"
    }
  }
}
```

Decrypting Automate Workspace Passwords

Encrypted passwords in the automate workspace can be decrypted individually as follows:

Request:

```
POST /api/automate_workspaces/:guid
```

```
{
  "action" : "decrypt",
  "resource" : {
    "object" : "method_parameters",
    "attribute" : "arg2"
  }
}
```

Response:

```
{
  "object" : "method_parameters",
  "attribtue" : "arg2",
  "value" : "unencrypted_password"
}
```

Categories & Tags

Management of Categories and Tags is provided via the following collections:

```
/api/categories
```

```
/api/tags
```

Full CRUD actions on both cateogries and tags are made available.

- Querying Categories
- Querying Tags
- Creating Categories
- Creating Tags
- Editing Categories & Tags
- Deleting Categories & Tags

Querying Categories

Querying all categories in the system is simply:

```
GET /api/categories
```

Or getting attributes of interest like *name*, *description* or *ns* for the namespace:

```
GET /api/categories?expand=resources&attributes=ns,name,description
```

Querying Tags

Querying all tags in the system is simply:

```
GET /api/tags
```

Querying tags of a specific category is done as follows:

```
GET /api/categories/:id/tags
```

Example Query for Location Category:

Request:

```
GET /api/categories/1
```

Response:

```
{
  "href": "http://localhost:3000/api/categories/1",
  "id": "1",
  "description": "Location",
  "read_only": false,
  "syntax": "string",
  "single_value": true,
  "example_text": "The geographic location of the resource, such as New York, Chicago, or London.",
  "tag_id": "4",
  "parent_id": "0",
  "show": true,
  "default": true,
  "name": "location",
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "http://localhost:3000/api/categories/1"
    },
    {
      "name": "delete",
      "method": "post",
      "href": "http://localhost:3000/api/categories/1"
    },
    {
      "name": "delete",
      "method": "delete",
      "href": "http://localhost:3000/api/categories/1"
    }
  ]
}
```

Querying all tags of the Location category:

Request:

```
GET /api/categories/1/tags?expand=resources&attributes=name
```

Response:

```
{
  "name": "tags",
  "count": 1389,
  "subcount": 4,
  "resources": [
    {
      "href": "http://localhost:3000/api/categories/1/tags/8",
      "id": "8",
      "name": "/managed/location/paris"
    },
    {
      "href": "http://localhost:3000/api/categories/1/tags/7",
      "id": "7",
      "name": "/managed/location/london"
    },
    {
      "href": "http://localhost:3000/api/categories/1/tags/6",
      "id": "6",
      "name": "/managed/location/chicago"
    },
    {
      "href": "http://localhost:3000/api/categories/1/tags/5",
      "id": "5",
      "name": "/managed/location/ny"
    }
  ],
  "actions": [
    {
      "name": "create",
      "method": "post",
```

```
      "href": "http://localhost:3000/api/categories/1/tags"
    },
    {
      "name": "delete",
      "method": "post",
      "href": "http://localhost:3000/api/categories/1/tags"
    }
  ]
}
```

For additional details on tags, the **category** and **classification** attributes can be queried on tags as follows:

```
GET /api/tags/5?attributes=category,classification
```

Additionally, a compound attribute called **categorization** is provided to return key information from both **category** and **classification** of tags as follows:

```
GET /api/tags/5?attributes=categorization
```

```
{
  "href": "http://localhost:3000/api/tags/5",
  "id": "5",
  "name": "/managed/location/ny",
  "categorization": {
    "name": "ny",
    "description": "New York",
    "category": {
      "name": "location",
      "description": "Location"
    },
    "display_name": "Location: New York"
  }
}
```

Creating Categories

Creating Categories can be done by posting the Category JSON to the categories collection directly, or via the **create** action signature as follows:

```
POST /api/categories
```

```
{
  "name" : "test",
  "description" : "Test Category"
}
```

or via the **create** action:

```
{
  "action" : "create",
  "resource" : {
    "name" : "test",
    "description" : "Test Category"
  }
}
```

Response:

```
{
  "results": [
    {
      "id": "1430",
      "description": "Test Category",
      "read_only": false,
      "syntax": "string",
      "single_value": false,
      "tag_id": "1439",
      "parent_id": "0",
      "show": true
    }
  ]
}
```

Attributes which can also be specified when creating categories include:

example_text
show
single_value
syntax

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Categories.

Creating Tags

New tags for a category can be created either as a tag collection post or via a tag subcollection **create** action to a specific category.

```
POST /api/tags
```

```
{
  "name" : "test_tag",
  "description" : "Test Tag",
  "category" : { "href" : "http://localhost:3000/api/categories/1430" }
}
```

The **category** above can identify a category by specifying either one of the **href**, **id** or **name** attributes.

Tags can optionally be created via the **create** action on the tags subcollection of a category as follows:

```
POST /api/categories/1430/tags

{
  "action" : "create",
  "resource" : {
    "name" : "test_tag",
    "description" : "Test Tag"
  }
}
```

or simply:

```
POST /api/categories/1430/tags

{
  "name" : "test_tag",
  "description" : "Test Tag"
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Tags.

Editing Categories & Tags

Editing Categories and Tags can be done via the **edit** action:

Example editing a category:

```
POST /api/categories/1430

{
  "action" : "edit",
  "resource" : {
    "description" : "Updated Category Description"
  }
}
```

Example editing a tag:

```
POST /api/tags/1441

{
  "action" : "edit",
  "resource" : {
    "name" : "updated_test_tag"
  }
}
```

Deleting Categories & Tags

Deleting Categories and Tags can be done via either the **delete** post action or the DELETE HTTP method.

```
POST /api/categories/1430

{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/categories/1430
```

Deleting associated tag example:

```
POST /api/tags/1441

{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/tags/1441
```

One can also delete the tag when accessed via the subcollection

Request:

```
POST /api/categories/1430/tags
```

```
{
  "action" : "delete",
  "resources" : [
    { "id" : "1441" },
    { "id" : "1442" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "tags id: 1441 deleting"
    },
    {
      "success": true,
      "message": "tags id: 1442 deleting"
    }
  ]
}
```

Tags to be deleted can be specified via the **href**, **id** or **name** attribute.

- Create Chargebacks (top-level rate entity)
- Assign Chargeback Rate
- Run Chargeback Report
- Results of Chargeback Report

Chargebacks, Rates & Assignments

Queries of Chargebacks and Management of Rates is provided via the following collections:

`/api/chargebacks`

`/api/rates`

- Querying Chargebacks
- Creating Chargeback Rates
- Updating Chargeback Rates
- Deleting Chargeback Rates
- Querying Assigned Chargeback Rates
- Assign action for Chargeback Rates
- Unassign action for Chargeback Rates
- Example of Chargeback Flow

Querying Chargebacks

Querying all chargebacks in the system is simply:

```
GET /api/chargebacks
```

or Query a specific chargeback, for example:

```
GET /api/chargebacks/1
```

```
{
  "href": "http://localhost:3000/api/chargebacks/1",
  "id": "1",
  "guid": "b47a0ef0-4335-11df-aba8-001d09066d98",
  "description": "Default",
  "rate_type": "Compute",
  "created_on": "2014-11-20T19:10:03Z",
  "updated_on": "2014-11-20T19:10:03Z",
  "default": true
}
```

Optionally, one can query the rates details for a chargeback as follows:

```
GET /api/chargebacks/:id/rates
```

Example getting additional rates details(attributes)

Request:

```
GET /api/chargebacks/1/rates?expand=resources&attributes=description,metric,group,source,friendly_rate
```

Response:

```
{
  "name": "rates",
  "count": 10,
  "subcount": 8,
  "resources": [
    {
      "href": "http://localhost:3000/api/chargebacks/1/rates/8",
      "id": "8",
      "description": "Fixed Compute Cost 2",
      "group": "fixed",
      "source": "compute_2",
      "friendly_rate": "0.0 Hourly"
    },
    {
      "href": "http://localhost:3000/api/chargebacks/1/rates/7",
      "id": "7",
      "description": "Fixed Compute Cost 1",
      "group": "fixed",
      "source": "compute_1",
      "friendly_rate": "1.0 Hourly"
    },
    {
      "href": "http://localhost:3000/api/chargebacks/1/rates/6",
```

```
      "id": "6",
      "description": "Used Disk I/O in KBps",
      "group": "disk_io",
      "metric": "disk_usage_rate_average",
      "source": "used",
      "friendly_rate": "Hourly @ 0.0 + 1.0 per Kbps from 0.0 to Infinity"
    },
    {
      "href": "http://localhost:3000/api/chargebacks/1/rates/5",
      "id": "5",
      "description": "Used Network I/O in KBps",
      "group": "net_io",
      "metric": "net_usage_rate_average",
      "source": "used",
      "friendly_rate": "Hourly @ 0.0 + 0.0 per Kbps from 0.0 to Infinity"
    },
    {
      "href": "http://localhost:3000/api/chargebacks/1/rates/4",
      "id": "4",
      "description": "Allocated Memory in MB",
      "group": "memory",
      "metric": "derived_memory_available",
      "source": "allocated",
      "friendly_rate": "Hourly @ 0.0 + 1.0 per Megabytes from 0.0 to Infinity"
    },
    {
      "href": "http://localhost:3000/api/chargebacks/1/rates/3",
      "id": "3",
      "description": "Used Memory in MB",
      "group": "memory",
      "metric": "derived_memory_used",
      "source": "used",
      "friendly_rate": "Hourly @ 0.0 + 0.0 per Megabytes from 0.0 to Infinity"
    },
    {
      "href": "http://localhost:3000/api/chargebacks/1/rates/2",
      "id": "2",
      "description": "Allocated CPU Count",
      "group": "cpu",
      "metric": "derived_vm_numvcpus",
      "source": "allocated",
      "friendly_rate": "Hourly @ 0.0 + 1.0 per Cpu from 0.0 to Infinity"
    },
    {
      "href": "http://localhost:3000/api/chargebacks/1/rates/1",
      "id": "1",
      "description": "Used CPU in MHz",
      "group": "cpu",
      "metric": "cpu_usagemhz_rate_average",
      "source": "used",
      "friendly_rate": "Hourly @ 0.0 + 0.0 per Megahertz from 0.0 to Infinity"
    }
  ]
}
```

Example getting additional of rates details(relations)

Request:

```
GET /api/rates?
expand=resources&attributes=chargeback_rate,detail_measure,detail_currency,chargeable_field,chargeback_tiers
```

Response:

```
{
    "name": "rates",
    "count": 138,
    "subcount": 138,
    "pages": 1,
    "resources": [
        {
            "href": "http://localhost:3090/api/rates/544",
            "id": "544",
            "enabled": true,
            "description": "Allocated CPU Count",
            "group": "cpu",
            "source": null,

Creating Chargeback Rates

Creating a Chargeback Rate is done by posting a new resource or *create* action to the rates collection.

Example follows:

Request:

```
POST /api/rates
```

```
{
  "per_time" : "daily",
  "chargeback_rate_id" : "1",
  "chargeable_field_id" : "1",
  "description": "My CPU allocation rate",
  "group" : "cpu",
  "per_unit" : "megahertz",
  "source" : "allocated",
  "chargeback_tiers": [
       {
          "start": 0.0,
          "finish": "infinity",
          "fixed_rate": 2.0,
          "variable_rate": 0.0
        }
   ]
}
```

Response:

```
{
    "results": [
        {
            "href": "http://localhost:3090/api/rates/1866",
            "id": "1866",
            "enabled": true,
            "description": "My CPU allocation rate",
            "group": "cpu",
            "source": "allocated",
            "metric": null,
            "per_time": "daily",
            "per_unit": "megahertz",
            "friendly_rate": "Daily @ 2.0 + 0.0 per MHz from 0.0 to Infinity",
            "chargeback_rate_id": "1",
            "created_on": "2020-05-28T13:28:15Z",
            "updated_on": "2020-05-28T13:28:15Z",
            "chargeback_rate_detail_measure_id": null,
            "chargeback_rate_detail_currency_id": null,
            "chargeable_field_id": "1",
            "sub_metric": null
        }
    ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Chargeback Rates.

Updating Chargeback Rates

Updating rates can be done by posting **edit** actions on the rates resource.

Request:

```
POST /api/rates/16
```

```
{
  "action" : "edit",
  "resource" : { "description" : "Allocated NICs", "per_time": "hourly" }
}
```

Response:

```
{
    "href": "http://localhost:3090/api/rates/16",
    "id": "16",
    "description": "Allocated NICs",
    "per_time": "hourly",
    "chargeback_rate_id": "1",
    "chargeable_field_id": "3",
    "enabled": true,
    "group": "net_io",
    "source": null,
    "metric": null,
    "per_unit": "cpu",
    "friendly_rate": "Hourly @ 2.0 + 0.0 per Cpu from 0.0 to Infinity",
    "created_on": "2020-04-23T15:00:29Z",
    "updated_on": "2020-05-28T13:24:33Z",
    "chargeback_rate_detail_measure_id": "1",
    "chargeback_rate_detail_currency_id": "5",
    "sub_metric": null
}
```

Deleting Chargeback Rates

Deleting Chargeback Rates can be done via either the **delete** post action or the DELETE HTTP method.

Request:

```
POST /api/rates/16
```

```
{
  "action" : "delete"
}
```

Response:

```
{
  "success": true,
  "message": "rates id: 16 deleting",
  "href": "http://localhost:3000/api/rates/16"
}
```

or simply:

```
DELETE /api/rates/16
```

Querying Assigned Chargeback Rates

Assigned chargeback rates on single rate:

```
GET /api/chargebacks/16?attributes=assigned_to
```

Response:

```
{
    "href": "http://localhost:3090/api/chargebacks/2",
    "id": "2",
    "guid": "7d7aaf20-5214-11df-a888-001d09066d98",
    "description": "Default",
    "rate_type": "Storage",
    "created_on": "2019-08-07T16:48:04Z",
    "updated_on": "2020-04-20T13:27:07Z",
    "default": true,
    "assigned_to": [
        {
            "tag": {
                "href": "http://localhost:3090/api/tags/48",
                "name": "finance",
                "category": "department"
            }
        },
        {
            "tag": {
                "href": "http://localhost:3090/api/tags/26",
                "name": "test",
                "category": "environment"
            }
        }
    ]
}
```

Assigned chargeback rates on collection:

```
GET /api/chargebacks?expand=resources&attributes=assigned_to
```

Response:

```
{
    "name": "chargebacks",
    "count": 10,
    "subcount": 2,
    "subquery_count": 2,
    "pages": 1,
    "resources": [
        {
            "href": "http://localhost:3090/api/chargebacks/1",
            "id": "1",
            "guid": "b47a0ef0-4335-11df-aba8-001d09066d98",

                        "type": "ManageIQ::Providers::Vmware::InfraManager::Storage"
                        ...
                    }
                }
            ]
        }
    ]
}
```

Assign action for Chargeback Rates

Assignments could be done for two rate types: “Compute” and “Storage”. There are few assignments type under each rates type:

“Compute” Rate Type

- Enterprise
- Selected Providers

- Selected Clusters
- Tagged VMs and Instances
- Tagged Container Images
- Labeled Container Images
- Tenants

“Storage” Rate Type

- Enterprise
- Selected Datastores
- Tagged Datastores
- Tenants

Example (chargebacks collection) - assign storage to chargeback rate with id 2 :

```
{
    "action" : "assign",
    "assignments" : [
        {
            "chargeback":
            {
                "id" : 2
            },
            "resource":
            {
                "href": "http://localhost:3090/api/data_stores/12"
            }
        }
    ]
}
```

Response:

```
{
    "success": true,
    "message": "Rates assigned successfully",
    "result": [
        {
            "chargeback": {
                "href": "http://localhost:3090/api/chargebacks/2",
                "description": "Default"
            },
            "resource": {
                "href": "http://localhost:3090/api/data_stores/12",
                "name": "EXPORT"
            }
        }
    ]
}
```

Basic Template for single chargeback request

```
POST /api/chargebacks/<chargeback_id>
```

```
{
    "action" : "assign",
    "assignments" : [
        {
            <resource>
        }
    ]
}
```

Basic Template for chargebacks collection request

```
POST /api/chargebacks
```

```
{
    "action" : "assign",
    "assignments" : [
        {
            "chargeback":
            {
                <chargeback>
            },
            <resource>
        }
    ]
}
```

<chargeback> is same for all types of assignments. For **<chargeback>** can be used **href** or **id**:

- `{"href": "http://localhost:3090/api/chargebacks/1"}`
- `{"id": "1"}`

<resource> can be different across types of assignments - formats are described in next section.

Enterprise

<resource>:

```
"href": "http://localhost:3090/api/enterprises/1"
```

POST /api/chargebacks

```
{
    "action" : "assign",
    "assignments" : [
        {
            "chargeback":
            {
                "id" : 2
            },
            "resource":
            {
                "href": "http://localhost:3090/api/enterprises/1"
            }
        }
    ]
}
```

Response

```
{
    "success": true,
    "message": "Rates assigned successfully",
    "result": [
        {
            "chargeback": {
                "href": "http://localhost:3090/api/chargebacks/2",
                "description": "Default"
            },
            "resource": {
                "href": "http://localhost:3090/api/enterprises/1",
                "name": "Enterprise"
            }
        }
    ]
}
```

Selected Providers

<resource>:

```
"href": "http://localhost:3090/api/enterprises/1"
```

Selected Clusters

<resource>:

```
"href": "http://localhost:3090/api/clusters/1"
```

Tagged VMs and Instances

Identification can be done by tag's name and tag's category, by **id** or by **href**.

assignment_prefix is string which partly determines type of assignment. In this case for "VMs and Instances" value for **assignment_prefix** is **vm**.

<resource>:

```
- "tag": {
            "category" : "department",
            "name" : "finance",
            "assignment_prefix": "vm"
         }
- "tag": {
            "id" : 28,
            "assignment_prefix": "vm"
         }
- "tag": {
            "href" : 'http://localhost:3090/api/tags/28,
            "assignment_prefix": "vm"
         }
```

Request

POST /api/chargebacks

```
{
  "action" : "assign",
  "assignments" : [
   {
```

```
      "chargeback": { "id" : 1},
      "tag": { "category" : "department", "name" : "finance", "assignment_prefix": "vm" }
    },
    {
      "chargeback": { "id" : 1},
      "tag": { "id" : 2}
    },
    {
      "chargeback": { "id" : 3},
      "tag": { "href" : "http://localhost:3090/api/tags/28", "assignment_prefix": "vm" }
    }
  ]
}
```

Tagged Container Images

Identification can be done by tag's name and tag's category, by **id** or by **href**.

assignment_prefix is string which partly determines type of assignment. - In this case for "Container Images" value for **assignment_prefix** is **container_image**

<resource>:

```
"tag":
{
    "category" : "department",
    "name" : "finance",
    "assignment_prefix": "container_image"
}
```

or

```
"tag":
{
    "id" : 28,
    "assignment_prefix": "container_image"
}
```

or

```
"tag":
{
    "href" : 'http://localhost:3090/api/tags/28,
    "assignment_prefix": "container_image"
}
```

Request

```
POST /api/chargebacks
```

```
{
  "action" : "assign",
  "assignments" : [
   {
      "chargeback": { "id" : 1},
      "tag": { "category" : "department", "name" : "finance", "assignment_prefix": "vm" }
    },
    {
      "chargeback": { "id" : 1},
      "tag": { "id" : 2}
    },
    {
      "chargeback": { "id" : 3},
      "tag": { "href" : "http://localhost:3090/api/tags/28", "assignment_prefix": "vm" }
    }
  ]
}
```

Labeled Container Images

<resource>:

```
"href": "http://localhost:3090/api/container_images/934/custom_attributes/30331"
```

This resource represents custom attributes on container images, so called "labels".

Request

```
POST /api/chargebacks
```

```
{
  "action" : "assign",
    "assignments" :
    [
      {
        "chargeback": { "id" : 1},
        "resource": { "href": "http://localhost:3090/api/container_images/934/custom_attributes/30331" }
      },
      {
        "chargeback": { "id" : 1},
        "resource": { "href": "http://localhost:3090/api/container_images/934/custom_attributes/30324" }
```

```
      }
    ]
}
```

Tenants

<resource>:

```
"href": "http://localhost:3090/api/tenants/1"
```

Example

Request

```
POST /api/chargebacks
```

```
{
    "action" : "assign",
    "assignments" : [
        {
            "chargeback": {
                "id" : 2
            },
            "resource": {
                "href": "http://localhost:3090/api/tenants/1"
            }
        },
        {
            "chargeback": {
                "id" : 2
            },
            "resource": {
                "href": "http://localhost:3090/api/tenants/2"
            }
        }
    ]
}
```

Response

```
{
    "success": true,
    "message": "Rates assigned successfully",
    "result": [
        {
            "chargeback": {
                "href": "http://localhost:3090/api/chargebacks/2",
                "description": "Default"
            },
            "resource": {
                "href": "http://localhost:3090/api/tenants/1",
                "name": "My Company"
            }
        },
        {
            "chargeback": {
                "href": "http://localhost:3090/api/chargebacks/2",
                "description": "Default"
            },
            "resource": {
                "href": "http://localhost:3090/api/tenants/2",
                "name": "OpenStack Cloud Provider OpenStack"
            }
        }
    ]
}
```

Enterprise

<resource>:

```
"resource" :
{
    href": "http://localhost:3090/api/enterprises/1"
}
```

Request

```
POST /api/chargebacks
```

```
{
    "action" : "assign",
    "assignments" : [
        {
            "chargeback":
            {
                "id" : 2
            },
            "resource":
            {
                "href": "http://localhost:3090/api/enterprises/1"
```

```
            }
        }
    ]
}
```

Selected Datastores

<resource>:

```
"resource":
{
    "href": "http://localhost:3090/api/enterprises/1"
}
```

Example

Request

```
POST /api/chargebacks
```

```
{
    "action" : "assign",
    "assignments" : [
        {
            "chargeback" :
            {
                "id" : 2
            },
            "resource" :
            {
                "href" : "/api/data_stores/1"
            }
        }
    ]
}
```

Response

```
{
    "success": true,
    "message": "Rates assigned successfully",
    "result": [
        {
            "chargeback": {
                "href": "http://localhost:3090/api/chargebacks/2",
                "description": "Default"
            },
            "resource": {
                "href": "http://localhost:3090/api/data_stores/1",
                "name": "Shared-NFS"
            }
        }
    ]
}
```

Tagged Datastores

<resource>:

```
"tag":
{
    "href": "http://localhost:3090/api/tags/26",
    "assignment_prefix": "storage"
}
```

or

```
"tag":
{
    "category" : "department",
    "name" : "finance",
    "assignment_prefix": "storage"
}
```

or

```
"tag":
{
    "id" : "26",
    "assignment_prefix": "storage"
}
```

Example

Request

```
POST /api/chargebacks
```

```
{
    "action" : "assign",
    "assignments" : [
```

```
        {
            "tag": {
                "category" : "department",
                "name" : "finance",
                "assignment_prefix": "storage"
            }
        }
    ]
}
```

Response

```
{
    "success": true,
    "message": "Rates assigned successfully",
    "result": [
        {
            "chargeback": {
                "href": "http://localhost:3090/api/chargebacks/2",
                "description": "Default"
            },
            "tag": {
                "href": "http://localhost:3090/api/tags/48",
                "name": "finance",
                "category": "department",
                "assignment_prefix": "storage"
            }
        }
    ]
}
```

Tenants

<resource>:

```
"href": "http://localhost:3090/api/tenants/1"
```

Request

POST /api/chargebacks

```
{
    "action" : "assign",
    "assignments" : [
        {
            "chargeback": {
                "id" : 2
            },
            "resource": {
                "href": "http://localhost:3090/api/tenants/1"
            }
        },
        {
            "chargeback": {
                "id" : 2
            },
            "resource": {
                "href": "http://localhost:3090/api/tenants/2"
            }
        }
    ]
}
```

Response

```
{
    "success": true,
    "message": "Rates assigned successfully",
    "result": [
        {
            "chargeback": {
                "href": "http://localhost:3090/api/chargebacks/2",
                "description": "Default"
            },
            "resource": {
                "href": "http://localhost:3090/api/tenants/1",
                "name": "My Company"
            }
        },
        {
            "chargeback": {
                "href": "http://localhost:3090/api/chargebacks/2",
                "description": "Default"
            },
            "resource": {
                "href": "http://localhost:3090/api/tenants/2",
                "name": "OpenStack Cloud Provider OpenStack"
            }
        }
    ]
}
```

Unassign action for Chargeback Rates

Unassign action has same signature as assign action and action is ‘unassign’.

Example

Request

POST

```
{
  "action" : "unassign",
  "assignments" : [
     {
       "chargeback": { "id" : 3},
       "tag": { "category" : "prov_max_retirement_days", "name" : "30", "assignment_prefix": "vm" }
     }
  ]
}
```

Example of Chargeback Flow

- Create Chargeback Report
- Create Chargeback Rates
- Assign Chargeback Rates
- Run Chargeback Report
- Results of Chargeback Report

Create Chargeback Report

`POST api/reports`

```
{
  "action" : "import",
  "resource" : {
    "report" : {
        "rpt_group"   : "Custom",
        "rpt_type"    : "Custom",
        "menu_name"   : "Chargeback Flow Example",
        "col_order"   : ["vm_name", "display_range", ..],
        "cols"        : ["start_date", "display_range", "vm_name", ..],
        "headers"     : ["VM Name", "Date Range", ..],
        "title"       : "Chargeback Flow Example",
        "db"          : "ChargebackVm",
        "group"       : "y",
        "sortby"      : ["vm_name", "start_date"],
        "template_type" : "report",
        "order"         : "Ascending",
        "db_options" : {
            "rpt_type" : "ChargebackVm",
            "options"  : {
               <report_options>
            }
        }
    },
    "options" : { "save" : true }
  }
}
```

Attribute `"report"` contains JSON with report definition which can be obtained by exporting a chargeback report.

- `db` is type of report for chargeback purposes. Possible values are `ChargebackVm`, `ChargebackContainerProject`, `ChargebackContainerImage`.

Chargeback Report Options

Chargeback Report Options are present on index `options` in request json. There are also some options about filtering and grouping which are described in this section. Default attributes are described first and then there is explanation of attributes according to chargeback type of report(attribute `db`).

Example Request with `options`

`POST /api/chargebacks`

```
"db_options" : {
        "rpt_type" : "ChargebackVm",
        "options"  : {
            "interval" : "monthly",
            "interval_size" : 12,
            "end_interval_offset" : 1,
            "tenant_id" : "1",
            "method_for_allocated_metrics" : "max",
            "include_metrics:" : true,
            "cumulative_rate_calculation" : false,
            "groupby" : "date",
            "groupby_tag" : null,
```

```
            "groupby_label" : null
        }
}
...,
```

- **method_for_allocated_metrics** - **max** or **avg**
- **include_metrics** - **true** or **false** - enable/disable whether to include metrics data, when disable it uses current values of metric data or charged resources
- **cumulative_rate_calculation** - **true** or **false** enable/disable cumulative calculation for tagged resources
- **interval** is which time detail is used for the report. Possible values are **monthly, weekly, daily**

Metric data for chargeback report are taken from this interval:

`<Time.now-interval_size, Time.now-end_interval_offset>`

- **interval_size, end_interval_offset** - attributes in **options**. there is used unit according to interval parameter, for example: when interval is “daily” then **interval_size=3** and **end_interval_offset=2** mean that generated report will be based on metrics starting 3 days ago to 1 day ago.

Request

```
POST /api/chargebacks

"report" : {
    "db_options" : {
        "options" : {
            ...
        }
    },
    ...
}
```

Filtering according to resource

This is part of json used in request below.

Each section lists possible options to filter according to resource’s type. There are used **ids** for identification each type of resource and and those **ids** are used in attributes according to type of resources. Name of attributes can be find in following sections. Attributes are located in json for request(example with tenant) on indexes **report**,
db_options and options:

Request

```
POST /api/chargebacks

"report" : {
    "db_options" : {
        "options" : {
            "tenant_id" : 1,
            ...
        }
    },
    ...
}
```

Chargeback for VMs (db=ChargebackVm)

tenant_id - Tenant id

or

owner - **userid** of user which owns VMs.

Request

```
POST /api/chargebacks

"report" : {
    "db_options" : {
        "options" : {
            "owner" : "admin",
            ...
        }
    },
    ...
}
```

or

tag - tag_path of tag

Request

```
POST /api/chargebacks

"report" : {
```

```
    "db_options" : {
        "options" : {
            "tag" : "/managed/prov_max_cpu/2",
            ...
        }
    },
    ...
}
```

Chargeback for Projects (db=ChargebackContainerProject)

tag - tag_path of tag

Request

```
POST /api/chargebacks

"report" : {
    "db_options" : {
        "options" : {
            "tag" : "/managed/prov_max_cpu/2",
            ...
        }
    },
    ...
}
```

or

provider_id - “all” or Openshift Provider id

entity_id - “all” or Container Project id

```
"report" : {
    "db_options" : {
        "options" : {
            "provider_id" : "41",
            "entity_id" : "21",
            ...
        }
    },
    ...
}
```

Chargeback for Container Images (db=ChargebackContainerImage)

provider_id - “all” or Openshift Provider id

entity_id - “all” or Container Image id

Request

```
POST /api/chargebacks

"report" : {
    "db_options" : {
        "options" : {
            "provider_id" : "all",
            "entity_id" : "all",
            ...
        }
    }
}
```

Grouping Report Options

Chargeback for VMs (db=ChargebackVm)

groupby - specifies a grouping option

Possible values for **groupby**:

date - grouping by date and Vms

date-only - grouping only by date

tenant - grouping by tenants

tag - name of tag category - attribute **groupby_tag** needs to be also specified. Values for **groupby_tag** are names of tag category which can be retrieved in **resources**

```
GET
/api/categories?expand=resources&attributes=name
```

Chargeback for Projects (db=ChargebackContainerProject)

groupby - specifies a grouping option

Possible values for **groupby**:

date - grouping by date and container projects

date-only - grouping only by date

project - grouping by container projects

tag - - name of tag category - attribute **groupby_tag** needs to be also specified. Values for **groupby_tag** are names of tag category which can be retrieved in **resources**

```
GET
/api/categories?expand=resources&attributes=name
```

Chargeback for Container Images (db=ChargebackContainerImage)

groupby - specifies a grouping option

Possible values for **groupby**:

date - grouping by date and containers

date-only - grouping only by date

project - grouping by container images

label - grouping by container labels and when this value is set - attribute **groupby_tag** needs to be also specified. Values for **groupby_tag** are names of labels which can be retrieved by **api/container_images/:id/custom_attributes** endpoint (attribute=name) for single container image.

Example request

```
GET
/api/container_images/934/custom_attributes?expand=resources&attributes=name&filter[]=section=docker_labels
```

Response

```
{
    "name": "custom_attributes",
    "count": 2041860,
    "subcount": 11,
    "subquery_count": 11,
    "pages": 1,
    "resources": [
        {
            "href": "http://localhost:3090/api/container_images/934/custom_attributes/30322",
            "name": "build-date",
            "id": "30322"
        },
        {
            "href": "http://localhost:3090/api/container_images/934/custom_attributes/30324",
            "name": "architecture",
            "id": "30324"
        }
    ],
    ...
}
```

Example of request to create chargeback report

Request

```
POST /api/chargebacks
```

```
{
  "action" : "import",
  "resource" : {
    "report" : {
        "rpt_group"  : "Custom",
        "rpt_type"   : "Custom",

        }
    ]
}
```

Create Chargeback Rates

Chargeback rate is complex structure. Create chargeback rate requires two endpoints: **`/api/chargebacks`** and **`/api/rates`**. Endpoint **`/api/chargebacks`** manage top level rate entity which aggregate other relations like rate details(**`api/rates`**), currencies(**`api/currencies`**), measures(**`api/measures`**), chargeable_fields(**`api/chargeable_fields`**) and chargeback tiers. This entity is also used to assigning rates to any resource.

Create Chargebacks (top-level rate entity)

Request

```
POST /api/chargebacks

{
  "guid" : "daily",
  "description" : "1",
  "rate_type" : "Compute"
}
```

Response

```
{
    "results": [
        {
            "href": "http://localhost:3090/api/chargebacks/14",
            "id": "14",
            "guid": "daily",
            "description": "1",
            "rate_type": "Compute",
            "created_on": "2020-05-26T12:15:51Z",
            "updated_on": "2020-05-26T12:15:51Z",
            "default": false
        }
    ]
}
```

Now we need to create rate details(**`api/rates`**) which includes chargebable_fields, currenies, measures and tiers. It is also important assign rate details to chargeback top level entity by **`chargeback_rate`** attribute.

Request

```
POST /api/rates

{
  "per_time" : "daily",
  "chargeback_rate" : {"href": "http://localhost:3090/api/chargebacks/14"},
  "chargeable_field_id" : "1",
  "description": "My CPU allocation rate",
  "group" : "cpu",
  "per_unit" : "megahertz",
  "source" : "allocated",
  "chargeback_rate_detail_measure_id": 1,
  "detail_currency" : {"id": 5},
  "detail_measure" : {"href": "http://localhost:3090/api/measures/3"},
  "chargeable_field" : {"href": "http://localhost:3090/api/chargeable_fields/3"},
  "chargeback_tiers" : [
    {
      "start": 0.0,
      "finish":1,
      "fixed_rate": 2.0,
      "variable_rate": 0.0
    },
    {
      "start": 1,
      "finish": "infinity",
      "fixed_rate": 2.0,
      "variable_rate": 0.0
    }
  ]
}
```

Response

```
{
    "results": [
        {
            "href": "http://localhost:3090/api/rates/1862",
            "id": "1862",
```

```
            "enabled": true,
            "description": "My CPU allocation rate",
            "group": "cpu",
            "source": "allocated",
            "metric": null,
            "per_time": "daily",
            "per_unit": "megahertz",
            "friendly_rate": "Daily @ 2.0 + 0.0 per Megahertz from 0.0 to 1.0\nDaily @ 2.0 + 0.0 per Megahertz from 1.0 to
Infinity",
            "chargeback_rate_id": "14",
            "created_on": "2020-05-26T12:36:32Z",
            "updated_on": "2020-05-26T12:36:32Z",
            "chargeback_rate_detail_measure_id": "3",
            "chargeback_rate_detail_currency_id": "5",
            "chargeable_field_id": "3",
            "sub_metric": null
        }
    ]
}
```

Assign Chargeback Rate

There are examples in those sections:

- Querying Assigned Chargeback Rates
- Assign action for Chargeback Rates
- Unassign action for Chargeback Rates

Run Chargeback Report

Please refer to Run Report section for details on how to run chargeback report. Running report requires report id or report href:

Report id or report href can be obtained by chargeback report creation or by listing chargeback reports:

Request

```
GET /api/reports?expand=resources&attributes=db&filter[]=db='ChargebackVm'&filter[]=or db='ChargebackContainer%'
```

Response

```
{
    "name": "reports",
    "count": 519,
    "subcount": 47,
    "subquery_count": 47,
    "pages": 1,
    "resources": [
        {
            "href": "http://localhost:3090/api/reports/157",
            "db": "ChargebackContainerImage",
            "id": "157"
        },
        {
            "href": "http://localhost:3090/api/reports/152",
            "db": "ChargebackVm",
            "id": "152"
        },
...
}
```

Results of Chargeback Report

There is request which list of report result.

Allowed parameters:

hash_attribute=value - enables hash sorting and pagination for value column

sort_by - column from **MiqReportResult#report#col_order**

sort_order - **asc** or **desc**

limit - count of records for one page

offset - result will start form **<offset>**. record

filter_column - chosen column for filtering

filter_string - this string value is used for filtering on **<filter_column>**, record of report result will be returned in API when **<filter_string>** is contained in value of **<filter_column>** .

There is possibility to filter according to more columns. We need to add other filter parameters with suffix **_X** where **X** is number (**..&filter_column_1=name&filter_string_1=TIE&filter_column_2=hostname&filter_string_2=test**)

Request

```
GET /api/results/23039?hash_attribute=result_set&sort_by=&sort_order=&limit=20&offset=0&filter_string=windemo
```

Response

```
{
    "href": "http://localhost:3090/api/results/23039",
    "id": "23039",
    "name": "Chargeback - Demo",
    ...,
    "result_set": [

```

- Cloud Volumes
  - Querying Cloud Volumes
  - Deleting Cloud Volumes

Cloud Volumes

Management of Cloud Volumes is provided via the following collection:

`/api/cloud_volumes`

The following actions are available on cloud_volumes:

- Querying Cloud Volumes
- Deleting Cloud Volumes

Querying Cloud Volumes

Querying all cloud volumes in the system is simply:

`GET /api/cloud_volumes`

And getting details of a specific Cloud Volume is as follows:

```
GET /api/cloud_volumes/:id
```

Deleting Cloud Volumes

Cloud Volumes can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/cloud_volumes/101
```

```
{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/cloud_volumes/101
```

Deleting multiple Cloud Volumes can be done as follows:

```
POST /api/cloud_volumes
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/cloud_volumes/101" },
    { "href" : "http://localhost:3000/api/cloud_volumes/102" },
    ...
  ]
}
```

- Conditions
  - Querying Conditions
  - Creating Conditions
  - Editing Conditions
  - Deleting Conditions

Conditions

Management of conditions is provided via the following collection:

```
/api/conditions
```

Full CRUD actions on conditions is available:

- Querying Conditions
- Creating Conditions
- Editing Conditions
- Deleting Conditions

Querying Conditions

Querying all conditions in the system is simply:

```
GET /api/conditions
```

Getting details on a specific Condition:

```
GET /api/conditions/:id
```

Creating Conditions

Conditions can be created via a POST to the conditions collection or via the **create** action signature which also allows creation of multiple conditions in a single request.

```
POST /api/conditions
```

```
{
  "name" : "sample_condition",
  "description" : "Sample Condition",
  "expression" : { "=" : { "field" : "ExtManagementSystem.container_images-architecture", "value" : "dsa" } },
  "towhat" : "ExtManagementSystem",
  "modifier" : "allow"
}
```

or creating multiple conditions:

```
{
  "action" : "create",
  "resources" : [
    { "name" : "condition_1", "description" : "Condition 1", ... },
    { "name" : "condition_2", "description" : "Condition 2", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating conditions.

Editing Conditions

```
POST /api/conditions/:id

{
  "action" : "edit",
  "resource" : {
    "description" : "Updated Condition Description"
  }
}
```

or editing multiple conditions:

```
POST /api/conditions

{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/conditions/101",
      "description" : "Updated Condition Description 1"
    },
    {
      "href" : "http://localhost:3000/api/conditions/102",
      "description" : "Updated Condition Description 2"
    },
    ...
  ]
}
```

Deleting Conditions

Conditions can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/conditions/101

{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/conditions/101
```

Deleting multiple conditions can be done as follows:

```
POST /api/conditions

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/conditions/101" },
    { "href" : "http://localhost:3000/api/conditions/102" },
    ...
  ]
}
```

- Configuration Script Payloads
  - Querying Configuration Script Payloads
  - Editing configuration script payloads
  - Updating configuration script payloads
  - Patch method:
  - Querying Configuration Script Payload Authentication
  - Creating Configuration Script Payload Authentication

Configuration Script Payloads

Management of configuration script payloads is provided through the following collection:

```
/api/configuration_script_payloads
```

The following actions on configuration script payloads are available:

- Querying Configuration Script Payloads
- Editing Configuration Script Payloads
- Updating Configuration Script Payloads
- Querying Configuration Script Payload Authentication
- Creating Configuration Script Payload Authentication

Querying Configuration Script Payloads

Query all configuration script payloads in the system:

```
GET /api/configuration_script_payloads
```

Example response:

```
{
  "name": "configuration_script_payloads",
  "count": 2,
  "subcount": 2,
  "pages": 1,
  "resources": [
    {
      "href": "http://localhost:3000/api/configuration_script_payloads/1"
    },
    {
      "href": "http://localhost:3000/api/configuration_script_payloads/1"
    }
  ],
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "http://localhost:3000/api/configuration_script_payloads"
    }
  ],
  "links": {
    "self": "http://localhost:3000/api/configuration_script_payloads?offset=0",
    "first": "http://localhost:3000/api/configuration_script_payloads?offset=0",
    "last": "http://localhost:3000/api/configuration_script_payloads?offset=0"
  }
}
```

Query the details on a specific configuration script payload:

```
GET /api/configuration_script_payloads/:id
```

Example response:

```
{
  "href": "http://localhost:3000/api/configuration_script_payloads/1",
  "id": "1",
  "manager_id": "2",
  "manager_ref": null,
  "name": "provision-vm-service/list-providers.asl",
  "description": null,
  "variables": null,
  "created_at": "2023-11-08T17:43:30Z",
  "updated_at": "2023-11-08T17:46:03Z",
  "survey_spec": null,
  "inventory_root_group_id": null,
  "type": "ManageIQ::Providers::Workflows::AutomationManager::Workflow",
  "parent_id": null,
  "configuration_script_source_id": "11",
  "run_by_userid": null,
  "payload": "{\n  \"Comment\": \"List Providers.\",\n  \"StartAt\": \"ListProviders\",\n  \"States\": {\n
\"ListProviders\": {\n      \"Type\": \"Task\",\n      \"Resource\": \"docker://docker.io/agrare/list-
providers:latest\",\n      \"End\": true,\n      \"Credentials\": {\n        \"api_user.$\": \"$.api_user\",\n
\"api_password.$\": \"$.api_password\",\n        \"api_token.$\": \"$.api_token\",\n        \"api_bearer_token.$\":
\"$.api_bearer_token\"\n      },\n      \"Parameters\": {\n        \"API_URL.$\": \"$$.Execution._manageiq_api_url\",\n
\"VERIFY_SSL.$\": \"$.dialog.dialog_verify_ssl\",\n\n        \"PROVIDER_TYPE\":
\"ManageIQ::Providers::Vmware::InfraManager\"\n      }\n    }\n  }\n}\n",
  "payload_type": "json",
  "credentials": null,
  "context": null,
  "output": null,
  "status": null,
  "miq_task_id": null,
  "payload_valid": true,
  "payload_error": null,
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "http://localhost:3000/api/configuration_script_payloads/1"
    },
    {
      "name": "edit",
      "method": "patch",
      "href": "http://localhost:3000/api/configuration_script_payloads/1"
    },
    {
      "name": "edit",
      "method": "put",
      "href": "http://localhost:3000/api/configuration_script_payloads/1"
    }
  ]
}
```

Editing configuration script payloads

Configuration script payloads can be edited by using a POST to the configuration script payloads collection:

```
POST /api/configuration_script_payloads
```

POST /api/configuration_script_payloads

```
{
  "action": "edit",
  "resources": [
    {"id": 1, "description": "A Helpful Description"}
  ]
}
```

Example response:

```
{
  "results": [
    {
      "href": "http://localhost:3000/api/configuration_script_payloads/1",
      "description": "A Helpful Description",
      "credentials": {
        "api_user.$": {
          "credential_ref": "manageiq_api",
          "credential_field": "userid"
        },
        "api_password.$": {
          "credential_ref": "manageiq_api",
          "credential_field": "password"
        }
      },
      "id": "1",
      "manager_id": "2",
      "manager_ref": null,
      "name": "provision-vm-service/list-providers.asl",
      "variables": null,
      "created_at": "2023-11-08T17:43:30Z",
      "updated_at": "2023-11-15T20:14:28Z",
      "survey_spec": null,
      "inventory_root_group_id": null,
      "type": "ManageIQ::Providers::Workflows::AutomationManager::Workflow",
      "parent_id": null,
      "configuration_script_source_id": "2",
      "run_by_userid": null,
      "payload": "{\n  \"Comment\": \"List Providers.\",\n  \"StartAt\": \"ListProviders\",\n  \"States\": {\n
\"ListProviders\": {\n      \"Type\": \"Task\",\n      \"Resource\": \"docker://docker.io/agrare/list-
providers:latest\",\n      \"End\": true,\n      \"Credentials\": {\n        \"api_user.$\": \"$.api_user\",\n
\"api_password.$\": \"$.api_password\",\n        \"api_token.$\": \"$.api_token\",\n        \"api_bearer_token.$\":
\"$.api_bearer_token\"\n      },\n      \"Parameters\": {\n        \"API_URL.$\": \"$$.Execution._manageiq_api_url\",\n
\"VERIFY_SSL.$\": \"$.dialog.dialog_verify_ssl\",\n\n        \"PROVIDER_TYPE\":
\"ManageIQ::Providers::Vmware::InfraManager\"\n      }\n    }\n  }\n}\n",
      "payload_type": "json",
      "context": null,
      "output": null,
      "status": null,
      "miq_task_id": null,
      "payload_valid": true,
      "payload_error": null
    }
  ]
}
```

For instance, configuration script payloads can be edited to map credentials:

```
POST /api/configuration_script_payloads
```

```
{
  "action": "edit",
  "resources": [
    {
      "id": 1,
      "credentials": [
        {"my-cred-user": {"credential_ref": "my-credential", "credential_field": "userid"}},
        {"my-cred-password": {"credential_ref": "my-credential", "credential_field": "password"}}
      ]
    }
  ]
}
```

Updating configuration script payloads

Configuration script payloads can be updated by using a PUT method or PATCH method.

PUT method:

```
PUT /api/configuration_script_payloads/:id
```

Example request:

```
PUT /api/configuration_script_payloads/1 {"description": "A Helpful Description"}
```

Response:

```
{
  "results": [
    {
      "href": "http://localhost:3000/api/configuration_script_payloads/1",
      "description": "A Helpful Description",
      "credentials": {
        "api_user.$": {
          "credential_ref": "manageiq_api",
          "credential_field": "userid"
        },
        "api_password.$": {
          "credential_ref": "manageiq_api",
          "credential_field": "password"
        }
      },
      "id": "1",
      "manager_id": "2",
      "manager_ref": null,
      "name": "provision-vm-service/list-providers.asl",
      "variables": null,
      "created_at": "2023-11-08T17:43:30Z",
      "updated_at": "2023-11-15T20:14:28Z",
      "survey_spec": null,
      "inventory_root_group_id": null,
      "type": "ManageIQ::Providers::Workflows::AutomationManager::Workflow",
      "parent_id": null,
      "configuration_script_source_id": "2",
      "run_by_userid": null,
      "payload": "{\n  \"Comment\": \"List Providers.\",\n  \"StartAt\": \"ListProviders\",\n  \"States\": {\n
\"ListProviders\": {\n      \"Type\": \"Task\",\n      \"Resource\": \"docker://docker.io/agrare/list-
providers:latest\",\n      \"End\": true,\n      \"Credentials\": {\n        \"api_user.$\": \"$.api_user\",\n
\"api_password.$\": \"$.api_password\",\n        \"api_token.$\": \"$.api_token\",\n        \"api_bearer_token.$\":
\"$.api_bearer_token\"\n      },\n      \"Parameters\": {\n        \"API_URL.$\": \"$$.Execution._manageiq_api_url\",\n
\"VERIFY_SSL.$\": \"$.dialog.dialog_verify_ssl\",\n\n        \"PROVIDER_TYPE\":
\"ManageIQ::Providers::Vmware::InfraManager\"\n      }\n    }\n  }\n}\n",
      "payload_type": "json",
      "context": null,
      "output": null,
      "status": null,
      "miq_task_id": null,
      "payload_valid": true,
      "payload_error": null
    }
  ]
}
```

Patch method:

```
PATCH /api/configuration_script_payloads/:id
```

Example request:

```
PATCH /api/configuration_script_payloads/1 {"description": "A Helpful Description"}
```

Response:

```
{
  "results": [
    {
      "href": "http://localhost:3000/api/configuration_script_payloads/1",
      "description": "A Helpful Description",
      "credentials": {
        "api_user.$": {
          "credential_ref": "manageiq_api",
          "credential_field": "userid"
        },
        "api_password.$": {
          "credential_ref": "manageiq_api",
          "credential_field": "password"
        }
      },
      "id": "1",
      "manager_id": "2",
      "manager_ref": null,
      "name": "provision-vm-service/list-providers.asl",
      "variables": null,
      "created_at": "2023-11-08T17:43:30Z",
      "updated_at": "2023-11-15T20:14:28Z",
      "survey_spec": null,
      "inventory_root_group_id": null,
      "type": "ManageIQ::Providers::Workflows::AutomationManager::Workflow",
      "parent_id": null,
      "configuration_script_source_id": "2",
      "run_by_userid": null,
      "payload": "{\n  \"Comment\": \"List Providers.\",\n  \"StartAt\": \"ListProviders\",\n  \"States\": {\n
\"ListProviders\": {\n      \"Type\": \"Task\",\n      \"Resource\": \"docker://docker.io/agrare/list-
providers:latest\",\n      \"End\": true,\n      \"Credentials\": {\n        \"api_user.$\": \"$.api_user\",\n
\"api_password.$\": \"$.api_password\",\n        \"api_token.$\": \"$.api_token\",\n        \"api_bearer_token.$\":
\"$.api_bearer_token\"\n      },\n      \"Parameters\": {\n        \"API_URL.$\": \"$$.Execution._manageiq_api_url\",\n
\"VERIFY_SSL.$\": \"$.dialog.dialog_verify_ssl\",\n\n        \"PROVIDER_TYPE\":
\"ManageIQ::Providers::Vmware::InfraManager\"\n      }\n    }\n  }\n}\n",
```

```
      "payload_type": "json",
      "context": null,
      "output": null,
      "status": null,
      "miq_task_id": null,
      "payload_valid": true,
      "payload_error": null
    }
  ]
}
```

Querying Configuration Script Payload Authentication

Query the authentication credentials for a specific configuration script payload:

```
GET /api/configuration_script_payloads/:id/authentications
```

Example response:

```
{
  "name": "authentications",
  "count": 7,
  "subcount": 1,
  "pages": 1,
  "resources": [
    {
      "href": "http://localhost:3000/api/configuration_script_payloads/2/authentications/3"
    }
  ],
  "actions": [
    {
      "name": "create",
      "method": "post",
      "href": "http://localhost:3000/api/configuration_script_payloads/2/authentications"
    }
  ],
  "links": {
    "self": "http://localhost:3000/api/configuration_script_payloads/2/authentications?offset=0",
    "first": "http://localhost:3000/api/configuration_script_payloads/2/authentications?offset=0",
    "last": "http://localhost:3000/api/configuration_script_payloads/2/authentications?offset=0"
  }
}
```

Get the details on a specific authentication credential for a configuration script payload:

```
GET /api/configuration_script_payloads/:id/authentications/:id
```

Example response:

```
{
  "href": "http://localhost:3000/api/configuration_script_payloads/2/authentications/3",
  "id": "3",
  "name": "manageiq_api",
  "authtype": null,
  "userid": "admin",
  "password": null,
  "resource_id": "25",
  "resource_type": "ExtManagementSystem",
  "created_on": "2023-11-15T19:59:23Z",
  "updated_on": "2023-11-15T19:59:23Z",
  "last_valid_on": null,
  "last_invalid_on": null,
  "credentials_changed_on": null,
  "status": null,
  "status_details": null,
  "type": "ManageIQ::Providers::Workflows::AutomationManager::WorkflowCredential",
  "auth_key": null,
  "fingerprint": null,
  "service_account": null,
  "public_key": null,
  "manager_ref": "3",
  "options": null,
  "evm_owner_id": null,
  "miq_group_id": "1",
  "tenant_id": "1",
  "become_username": null,
  "become_password": null,
  "auth_key_password": null,
  "ems_ref": "manageiq_api",
  "become_method": null
}
```

Creating Configuration Script Payload Authentication

Authentication credentials for a configuration script payload can be created by using a POST to the configuration script payload collection:

```
POST /api/configuration_script_payloads/:id/authentications
```

```
{
  "action": "create",
  "description": "Description",
```

```
  "name": "my credential",
  "type": "ManageIQ::Providers::AnsibleTower::AutomationManager::Credential"
}
```

- Configuration Script Sources
  - Querying Configuration Script Sources
  - Creating Configuration Script Sources
  - Editing Configuration Script Sources
  - Refreshing Configuration Script Sources
  - Request:
  - Response:
  - Deleting Configuration Script Sources

Configuration Script Sources

Management of configuration script sources is provided via the following collection:

```
/api/configuration_script_sources
```

Full CRUD actions on configuration script sources is available:

- Querying Configuration Script Sources
- Creating Configuration Script Sources
- Editing Configuration Script Sources
- Refreshing Configuration Script Sources
- Deleting Configuration Script Sources

Querying Configuration Script Sources

Querying all configuration script sources in the system is simply:

```
GET /api/configuration_script_sources
```

Getting details on a specific configuration script source:

```
GET /api/configuration_script_sources/:id
```

Querying configuration script payloads of a particular configuration script source:

```
GET /api/configuration_script_sources/:id/configuration_script_payloads?expand=resources
```

Querying the configuration script payloads of a particular configuration script source that belong to a specific region:

```
GET /api/configuration_script_sources/:id/configuration_script_payloads?expand=resources&filter[]=region_number=10
```

Creating Configuration Script Sources

Configuration script sources can be created via a POST to the configuration script sources collection or via the **create** action signature which also allows creation of multiple configuration script sources in a single request.

```
POST /api/configuration_script_sources
```

```
{
  "name" : "My Project",
  "description" : "My Project's Description",
  "manager_resource" : { "href" : "http://localhost:3000/api/providers/7" },
  "related" : {}
}
```

or creating multiple configuration script sources:

```
{
  "action" : "create",
  "resources" : [
    { "name" : "My First Project", "description" : "My First Project Description", ... },
    { "name" : "My Second Project", "description" : "My Second Project Description", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating configuration script sources.

Editing Configuration Script Sources

```
POST /api/configuration_script_sources/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "description" : "Updated Project Description"
```

```
  }
}
```

or editing multiple configuration script sources:

```
POST /api/configuration_script_sources

{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/configuration_script_sources/101",
      "description" : "Updated Project Description 1"
    },
    {
      "href" : "http://localhost:3000/api/configuration_script_sources/102",
      "description" : "Updated Project Description 2"
    },
    ...
  ]
}
```

Refreshing Configuration Script Sources

Configuration script sources can be refreshed by posting a **refresh** action to a single resource or to multiple resources in bulk by targeting the collection.

```
POST /api/configuration_script_sources/:id

{
  "action" : "refresh"
}
```

or refreshing multiple configuration script sources:

```
POST /api/configuration_script_sources

{
  "action" : "refresh",
  "resources" : [
    { "id" : "101" },
    { "id" : "102" }
  ]
}
```

Example:

Request:

```
POST /api/configuration_script_sources/101

{
  "action" : "refresh"
}
```

Response:

```
{
  "success" : true,
  "message" : "Refreshing ConfigurationScriptSource id:101 name:'Test Configuration Script Source'",
  "task_id" : "7",
  "task_href" : "http://localhost:3000/api/tasks/7",
  "tasks" : [
    {
      "id" : "7",
      "href" : "http://localhost:3000/api/tasks/7"
    }
  ]
}
```

Deleting Configuration Script Sources

Configuration script sources can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/configuration_script_sources/101

{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/configuration_script_sources/101
```

Deleting multiple configuration script sources can be done as follows:

```
POST /api/configuration_script_sources

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/configuration_script_sources/101" },
```

```
    { "href" : "http://localhost:3000/api/configuration_script_sources/102" },
    ...
  ]
}
```

- Custom Actions
  - Request:
  - Response:
    - Request:
    - Response:

Custom Actions

With button groups and custom buttons defined on records, the REST API provides visibility to custom actions that represent the custom buttons for the related resources. The custom actions are not returned when querying collections, they are only available when fetching an individual resource, e.g. /api/:collection/:id

This is made available with the *custom_actions* and *custom_action_buttons* virtual attributes on resources for the following collections:

/api/cloud_tenants
/api/cloud_volumes
/api/clusters
/api/container_nodes
/api/data_stores
/api/generic_objects
/api/hosts
/api/providers
/api/templates
/api/vms

- *custom_actions* return the custom buttons as laid out in the UI on the resource. The information returned includes any Resource Actions and related Dialogs for the custom button.
- *custom_action_buttons* return the array of custom buttons without the custom button groups hierarchy or details on related dialogs.

Fetching custom actions and custom action buttons for a resource:

```
GET /api/:collection/:id?attributes=custom_actions,custom_action_buttons
```

Example VM with custom buttons:

Request:

```
GET /api/vms/173?attributes=custom_actions,custom_action_buttons
```

Response:

```
{
  "href": "https://172.16.30.129/api/vms/173",
  "id": "173",
  "vendor": "vmware",
  "name": "aab-ldap",
  "location": "aab-ldap/aab-ldap.vmx",
  "host_id": "4",
  "created_on": "2018-01-09T20:23:37Z",

      "visibility": {
        "roles": [
          "_ALL_"
        ]
      }
    }
  ],
  "actions": [
    ...
  ]
}
```

When custom action buttons are defined on a VM, the returned VM resource is extended with custom actions which can be triggered via a POST action.

The action name to trigger the action is the lower-cased name of the custom button.

As an example, here's a VM without custom buttons so all actions returned are the common ones defined by the system:

```
{
  "href": "https://172.16.30.129/api/vms/172",
  "id": "172",
  "vendor": "vmware",
  "name": "aab-idp",
  "location": "aab-idp/aab-idp.vmx",
  "host_id": "4",
  "created_on": "2018-01-09T19:23:37Z",
  "updated_on": "2018-01-09T19:23:37Z",
  "storage_id": "8",
  ...
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    {
      "name": "add_event",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    ...
    {
      "name": "set_miq_server",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    {
      "name": "scan",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    {
```

```
      "name": "delete",
      "method": "delete",
      "href": "https://172.16.30.129/api/vms/173"
    }
  ]
}
```

Here is an example of a VM with the additional custom buttons *analyze* and *ping* defined:

```
{
  "href": "https://172.16.30.129/api/vms/173",
  "id": "173",
  "vendor": "vmware",
  "name": "aab-ldap",
  "location": "aab-ldap/aab-ldap.vmx",
  "host_id": "4",
  "created_on": "2018-01-09T20:23:37Z",
  "updated_on": "2018-01-09T20:23:37Z",
  "storage_id": "8",
  "guid": "dee6d969-7c69-44b6-bcd3-3b14f21702c5",
  "ems_id": "1",
  "uid_ems": "420c8f0d-4a8f-0b6d-fc3a-0c3cfab7b33f",
  "tools_status": "toolsNotRunning",
  "standby_action": "checkpoint",
  "power_state": "off",
  ...
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    {
      "name": "add_event",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    ...
    {
      "name": "set_miq_server",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    {
      "name": "scan",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    {
      "name": "delete",
      "method": "delete",
      "href": "https://172.16.30.129/api/vms/173"
    },
    {
      "name": "analyze",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    },
    {
      "name": "ping",
      "method": "post",
      "href": "https://172.16.30.129/api/vms/173"
    }
  ]
}
```

Here, the *analyze* and *ping* are custom buttons for the VM and are returned after the common actions.

For example, to request the *analyze* custom action shown above, this is simply a POST action as follows:

Request:

```
POST /api/vms/173

{
  "action" : "analyze"
}
```

Response:

Responses from custom actions are the normal action responses from the REST API:

```
{
  "success": true,
  "message": "Invoked custom action analyze for VM id: 173",
  "href": "http://localhost:3000/api/vms/173"
}
```

  - Querying Custom Attributes

- Specifying Attribute Actions
- Custom Attribute Actions
- Adding Custom Attributes
- Editing Custom Attributes
- Deleting Custom Attributes

Custom Attributes

Custom Attributes can be managed for several types of resources. This is done via the custom_attributes sub-collection as follows:

Resource Type	Custom Attribute Subcollection
Virtual Machines	/api/vms/:id/custom_attributes
Cloud Instances	/api/instances/:id/custom_attributes
Providers	/api/providers/:id/custom_attributes
Services	/api/services/:id/custom_attributes

- Querying Custom Attributes
- Specifying Custom Attributes
- Custom Attribute Actions
- Adding Custom Attributes
- Editing Custom Attributes
- Deleting Custom Attributes

Querying Custom Attributes

Custom attributes of a resource can be asked for by expanding the subcollection as follows:

```
GET /api/vms/:id?expand=custom_attributes
GET /api/instances/:id?expand=custom_attributes
GET /api/providers/:id?expand=custom_attributes
GET /api/services/:id?expand=custom_attributes
```

Optionally, just the custom attributes of a resource can be queried:

```
GET /api/vms/:id/custom_attributes
GET /api/instances/:id/custom_attributes
GET /api/providers/:id/custom_attributes
GET /api/services/:id/custom_attributes
```

Specifying Attribute Actions

Custom attributes are specified as follows:

```
{
  "name" : "...",
  "value" : "...",
  "field_type" : "...",
  "source" : "...",
  "section" : "...",
}
```

For adding custom attributes, **name** field is required.

field_type, **source** and **section** are optional.

There is no default value for **field_type**. Allowed values for **field_type** are **DateTime**, **Date** and **Time**.

Default value for **source** is **EVM**. If **source** is set to **VC**, the custom attribute field will be updated on the provider.

Default value for **section** is **metadata**. Allowed values for **section** include **metadata** and **cluster_settings**.

For editing a custom attribute, specify the custom attribute either by **name**:

```
{
  "name" : "...",
  "value" : "..."
}
```

Or by **href**:

```
{
  "href" : "http://localhost:3000/api/vms/:id/custom_attributes/:id",
  "value" : "..."
}
```

Custom Attribute Actions

Action	Description
add	Adding Custom Attributes to a Resource

Action	Description
edit	Editing Custom Attributes of a Resource
delete	Deleting Custom Attributes from a Resource

Adding Custom Attributes

Adding custom attributes to a Resource:

```
POST /api/vms/:id/custom_attributes
POST /api/instances/:id/custom_attributes
POST /api/providers/:id/custom_attributes
POST /api/services/:id/custom_attributes

{
  "action" : "add",
  "resources" : [
    { ... },
    { ... },
    ...
  ]
}
```

For example, adding two custom attributes:

```
{
  "action" : "add",
  "resources" : [
    { "name" : "ca1", "value" : "value 1" },
    { "name" : "ca2", "value" : "value 2" }
  ]
}
```

Editing Custom Attributes

Editing custom attributes of a Resource:

```
POST /api/vms/:id/custom_attributes
POST /api/instances/:id/custom_attributes
POST /api/providers/:id/custom_attributes
POST /api/services/:id/custom_attributes

{
  "action" : "edit",
  "resources" : [
    { ... },
    { ... },
    ...
  ]
}
```

For example:

```
{
  "action" : "edit",
  "resources" : [
    { "name" : "ca_name1", "value" : "updated custom attribute value 1" },
    { "name" : "ca_name2", "value" : "updated custom attribute value 2" }
  ]
}
```

Deleting Custom Attributes

Deleting custom attributes of a Resource:

```
POST /api/vms/:id/custom_attributes
POST /api/instances/:id/custom_attributes
POST /api/providers/:id/custom_attributes
POST /api/services/:id/custom_attributes

{
  "action" : "delete",
  "resources" : [
    { ... },
    { ... },
    ...
  ]
}
```

In the following example, a request to delete custom attributes of a VM by name and by href:

```
{
  "action" : "delete",
  "resources" : [
    { "name" : "ca_name1" },
    { "href" : "http://localhost:3000/api/vms/:id/custom_attributes/:id" }
  ]
}
```

Custom attributes can be deleted via a *delete* action as follows:

```
POST /api/vms/:id/custom_attributes/:ca_id
POST /api/instances/:id/custom_attributes/:ca_id
POST /api/providers/:id/custom_attributes/:ca_id
POST /api/services/:id/custom_attributes/:ca_id
```

```
{
  "action" : "delete"
}
```

They can also be deleted via the DELETE method:

```
DELETE /api/vms/:id/custom_attributes/:ca_id
DELETE /api/instances/:id/custom_attributes/:ca_id
DELETE /api/providers/:id/custom_attributes/:ca_id
DELETE /api/services/:id/custom_attributes/:ca_id
```

    - Querying Custom Buttons
    - Creating Custom Buttons
    - Editing Custom Buttons
    - Deleting Custom Buttons

Custom Button Management

Management of Custom Buttons is provided with the following collections:

```
/api/custom_button_sets
/api/custom_buttons
```

- Managing Custom Button Sets
  - Querying Custom Button Sets
  - Creating Custom Button Sets
  - Editing Custom Button Sets
  - Deleting Custom Button Sets
- Managing Custom Buttons
  - Querying Custom Buttons
  - Creating Custom Buttons
  - Editing Custom Buttons
  - Deleting Custom Buttons

Managing Custom Button Sets

Querying Custom Button Sets

Querying all available Custom Button Sets:

```
GET /api/custom_button_sets
```

Getting details on a specific Custom Button Set:

```
GET /api/custom_button_sets/:id
```

Creating Custom Button Sets

Custom Button Sets can be created as follows:

```
POST /api/custom_button_sets
```

```
{
  "name"        : "Generic Object Custom Button Group",
  "description" : "Generic Object Custom Button Group Description",
  "set_data"    : {
    "button_icon"      : "ff ff-view-expanded",
    "button_color"     : "#4727ff",
    "display"          : true,
    "applies_to_class" : "GenericObjectDefinition",
    "applies_to_id"    : "50"
  }
}
```

Editing Custom Button Sets

Updating Custom Button Sets can be done via the *edit* action as follows:

```
POST /api/custom_button_sets/:id

{
  "action" : "edit",
  "resource" : {
    "name" : "Updated Custom Button Group",
    "description" : "Updated Custom Button Group Description",
    "set_data" : {
      "button_icon" : "ff ff-closed"
    }
  }
}
```

Custom Button Sets can also be updated in bulk:

```
POST /api/custom_button_sets

{
  "action" : "edit",
  "resources" : [
    { "id" : "11", "set_data" : { "button_icon" : "ff ff-closed" } },
    { "id" : "12", "set_data" : { "button_icon" : "ff ff-closed" } },
    { "id" : "13", "set_data" : { "button_icon" : "ff ff-closed" } }
  ]
}
```

Custom button sets can also be updated with the PUT method as follows:

```
PUT /api/custom_button_sets/:id

{
  "name" : "Updated Custom Button Group",
  "description" : "Updated Custom Button Group Description",
  "set_data" : {
    "button_icon" : "ff ff-closed"
  }
}
```

Deleting Custom Button Sets

Custom Button Sets can be deleted via the *delete* action as follows:

```
POST /api/custom_button_sets/:id

{
  "action" : "delete"
}
```

and in bulk as follows:

```
POST /api/custom_button_sets

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/custom_button_sets/21" },
    { "href" : "http://localhost:3000/api/custom_button_sets/22" },
    { "id" : "23" }
  ]
}
```

A single Custom Button Set can also be deleted with the DELETE method as follows:

```
DELETE /api/custom_button_sets/:id
```

Managing Custom Buttons

Querying Custom Buttons

Querying all available Custom Buttons:

```
GET /api/custom_buttons
```

Getting details on a specific Custom Button:

```
GET /api/custom_buttons/:id
```

Creating Custom Buttons

Custom Buttons can be created as follows:

```
POST /api/custom_buttons

{
  "name"             : "Generic Object Custom Button",
  "description"      : "Generic Object Custom Button Description",
```

```
  "applies_to_class" : "GenericObjectDefinition",
  "options"          : {
    "button_icon"    : "ff ff-view-expanded",
    "button_color"   : "#4727ff",
    "display"        : true
  },
  "resource_action"  : {
    "ae_namespace"   : "SYSTEM",
    "ae_class"       : "PROCESS",
    "dialog_id"      : "1"
  },
  "visibility"       : {
    "roles"          : ["_ALL_"]
  }
}
```

Editing Custom Buttons

Updating Custom Buttons can be done via the *edit* action as follows:

```
POST /api/custom_buttons/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "name" : "Updated Custom Button",
    "description" : "Updated Custom Button Description",
    "resource_action" : {
      "ae_namespace"  : "SYSTEM2"
    }
  }
}
```

Custom Buttons can also be updated in Bulk as follows:

```
POST /api/custom_buttons
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/custom_buttons/31",
      "options" :  { "display" : false }
    },
    {
      "href" : "http://localhost:3000/api/custom_buttons/32",
      "options" :  { "display" : false }
    },
    {
      "id"   : "33",
      "options" :  { "display" : false }
    }
  ]
}
```

Deleting Custom Buttons

Custom Buttons can be deleted via the *delete* action as follows:

```
POST /api/custom_buttons/:id
```

```
{
  "action" : "delete"
}
```

Multiple Custom Buttons can also be deleted in a single request as follows:

```
POST /api/custom_buttons
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/custom_buttons/21" },
    { "id" : "22" },
    { "id" : "23" }
  ]
}
```

Single Custom Buttons can also be deleted with the DELETE method as follows:

```
DELETE /api/custom_buttons/:id
```

- Event Streams
  - Filtering by event type
  - Filtering by timestamp
  - Filtering by target type
  - Filtering by target type and id

Event Streams

Querying of Event Streams is made available via the following collection:

```
/api/event_streams
```

Event Streams can be queried as follows:

```
GET /api/event_streams
```

An individual Event Stream can also be fetched as follows:

```
GET /api/event_streams/:id
```

Relevant filter[] parameters when Event Streams are queried:

Parameter	Examples
event_type	event_type=vm_start, event_type=vm_stop
timestamp	timestamp>2017-01-03, timestamp<2017-12-31
target_type	target_type=VmOrTemplate
target_id	target_id=11

Filtering by event type

```
GET /api/event_streams?filter[]=event_type=vm_start
```

Filtering by timestamp

```
GET /api/event_streams?filter[]=timestamp>2017-01-03
                      &filter[]=timestamp<2017-01-10
```

Filtering by target type

```
GET /api/event_streams?filter[]=target_type=VmOrTemplate
```

Filtering by target type and id

```
GET /api/event_streams?filter[]=target_type=VmOrTemplate
                      &filter[]=target_id=21
```

- Flavor Management
  - Querying Flavors
  - Managing Flavors
  - Create Flavors
  - Delete Flavors

Flavor Management

Management of Flavors is available via the following endpoint:

```
/api/flavors
```

Querying Flavors

Querying all available Flavors:

```
GET /api/flavors
```

Getting details on a specific Flavor:

```
GET /api/flavors/:id
```

Querying the Flavors for a specific Provider:

```
GET /api/providers/:id/flavors
```

Getting details on a specific Flavor of a Provider:

```
GET /api/providers/:id/flavors/:flavor_id
```

Managing Flavors

The following actions are available on Flavors of Providers:

Action	Description
create	Create Flavors
delete	Delete Flavors

Create Flavors

Flavors can be created directly for a Provider as follows:

```
POST /api/providers/:id/flavors
```

```
{
  "name" : "base-system",
  "cpu_cores" : 2,
  "memory" :  4096000000,
  "root_disk_size" : 16384000000
}
```

Delete Flavors

Flavors of a Provider can be deleted via the *delete* action:

```
POST /api/providers/:id/flavors/:flavor_id
```

```
{
  "action" : "delete"
}
```

Multiple Flavors can also be deleted in a single request as follows:

```
POST /api/providers/:id/flavors
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/flavors/6" },
    { "id" : "7" }
  ]
}
```

Single Flavors can also be deleted with the DELETE HTTP method as follows:

```
DELETE /api/providers/:id/flavors/:flavor_id
```

    - Calling Generic Object Methods
    - Deleting Generic Objects

Generic Object Management

Management of Generic Objects is provided with the following collections:

```
/api/generic_object_definitions
/api/generic_objects
```

- Managing Generic Object Definitions
  - Querying Generic Object Definitions
  - Creating Generic Object Definitions
  - Editing Generic Object Definitions
  - Deleting Generic Object Definitions
- Managing Generic Objects
  - Querying Generic Objects
  - Creating Generic Objects
  - Editing Generic Objects
  - Calling Generic Object Methods
  - Deleting Generic Objects

Generic Object Definitions

Querying Generic Object Definitions

Querying all available Generic Object Definitions:

```
GET /api/generic_object_definitions
```

Getting details on a specific Generic Object Definition:

```
GET /api/generic_object_definitions/:id
```

Getting details on a specific Generic Object Definition by name:

```
GET /api/generic_object_definitions/:name
```

Querying all the Generic Objects defined for a specific Generic Object Definition:

```
GET /api/generic_object_definitions/:id/generic_objects
```

Getting a specific Generic Object defined for a Generic Object Definition:

```
GET /api/generic_object_definitions/:id/generic_objects/:generic_object_id
```

Fetching the vms associations for a specific Generic Object:

```
GET /api/generic_object_definitions/:id/generic_objects/:generic_object_id?associations=vms
```

Creating Generic Object Definitions

Generic Object Definitions can be created as follows:

```
POST /api/generic_object_definitions
```

```
{
  "name"        : "LoadBalancer",
  "description" : "LoadBalancer description",
  "properties"  : {
    "attributes"  : {
      "address"      : "string",
      "last_restart" : "datetime"
    },
    "associations" : {
      "vms"      : "Vm",
      "services" : "Service"
    },
    "methods" : [
      "add_vm",
      "remove_vm"
    ]
  },
  "picture"     : {
    "extension" : "png",
    "content"   : "iVBORw0KGgoAAAANSUhEUgAAAAEAAAABCAYAAAAfFcSJAAAABGdBTUEAALGP"\
      "C/xhBQAAACBjSFJNAAB6JgAAgIQAAPoAAACA6AAAdTAAAOpgAAA6mAAAF3Cc"\
      "ulE8AAAACXBIWXMAAAsTAAALEwEAmpwYAAABWWlUWHRYTUw6Y29tLmFkb2J1"\
      "LnhtcAAAAAAAPHg6eG1wbWV0YSB4bWxuczp4PSJhZG9iZTpuczptZXRhLyIg"\
      "eDp4bXB0az0iWE1QIENvcmUgNS40LjAiPgogICA8cmRmOlJERiB4bWxuczpy"\
      "ZGY9Imh0dHA6Ly93d3cudzMub3JnLzE5OTkvMDIvMjItcmRmLXN5bnRheC1u"\
      "cyMiPgogICAgICA8cmRmOkRlc2NyaXB0aW9uIHJkZjphYm91dD0iIgogICAg"\
      "ICAgICB4bWxuczp0aWZmPSJodHRwOi8vbnMuYWRvYmUuY29tL3RpZmYv"\
      "MS4wLyI+CiAgICAgICAgICAgIDx0aWZmOk9yaWVudGF0aW9uPjE8L3RpZmY6T3Jp"\
      "ZW50YXRpb24+CiAgICAgICAgICAgIDwvcmRmOkRlc2NyaXB0aW9uPgogICA8L3JkZjpS"\
      "REY+CjwveDp4bXBtZXRhPgpMwidZAAAADUlEQVQIHWNgYGCwBQAAQgA+3N0+"\
      "xQAAAABJRU5ErkJggg=="
  }
}
```

Example of creating a Generic Object Definition with a picture reference:

```
{
  "name"        : "LoadBalancer",
  "description" : "LoadBalancer description",
  "properties"  : {
    "attributes"  : {
      "address"      : "string",
      "last_restart" : "datetime"
    },
    "associations" : {
      "vms"      : "Vm",
      "services" : "Service"
    },
    "methods" : [
      "add_vm",
      "remove_vm"
    ]
  },
  "picture"     : {
    "href" : "http://localhost:3000/api/pictures/11"
```

```
  }
}
```

Note: picture references can be by *href* or *id*.

Editing Generic Object Definitions

Updating Generic Object Definitions can be done via the *edit* action as follows:

```
POST /api/generic_object_definitions/:id
```

or by name:

```
POST /api/generic_object_definitions/:name
```

```
{
  "action" : "edit",
  "resource" : {
    "description" : "Latest LoadBalancer Description"
  }
}
```

Generic object definitions can also be updated with the PUT method as follows:

```
PUT /api/generic_object_definitions/:id
```

```
{
  "name" : "New LoadBalancer Name",
  "description" : "New LoadBalancer Description"
}
```

Pictures can be removed from Generic Object Definitions by sending in an empty picture reference via any of the edit methods, for example:

```
POST /api/generic_object_definitions/:name
```

```
{
  "action" : "edit",
  "resource" : {
    "picture" : {}
  }
}
```

Generic Object Definitions can be edited by href, id or name in bulk as in the following example:

```
POST /api/generic_object_definitions
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "name" : "Load Balancer",
      "resource" : {
        "name" : "Enhanced Load Balancer",
        "description" : "Description for Enhanced Load Balancer",
        "picture" : { "id" : "16" }
      }
    },
    {
      "href" : "http://localhost:3000/api/generic_object_definitions/12",
      "resource" : {
        "name" : "NetworkScanner",
        "description" : "Description for Network Scanner"
      }
    },
    {
      "id" : "13",
      "resource" : {
        "name" : "NetworkFirewall",
        "description" : "Description for Network Firewall"
      }
    }
  ]
}
```

Editing Generic Object Definitions can also be done by using one of the following actions for updating *attributes*, *methods* and *associations*:

- add_attributes
- remove_attributes
- add_methods
- remove_methods
- add_associations
- remove_associations

Add Attributes

```
POST /api/generic_object_definitions/:id

{
  "action" : "add_attributes",
  "resource" : {
    "attributes" : {
      "optional_attribute1" : "string",
      "optional_attribute2" : "boolean"
    }
  }
}
```

Remove Attributes

```
POST /api/generic_object_definitions/:id

{
  "action" : "remove_attributes",
  "resource" : {
    "attributes" : {
      "unused_attribute9" : "string"
    }
  }
}
```

Add Methods

```
POST /api/generic_object_definitions/:id

{
  "action" : "add_methods",
  "resource" : {
    "methods" : [ "go_method1", "go_method2" ]
  }
}
```

Remove Methods

```
POST /api/generic_object_definitions/:id

{
  "action" : "remove_methods",
  "resource" : {
    "methods" : [ "go_method3" ]
  }
}
```

Add Associations

```
POST /api/generic_object_definitions/:id

{
  "action" : "add_associations",
  "resource" : {
    "associations" : {
      "az" : "AvailabilityZone",
      "chargeback" : "ChargebackVm"
    }
  }
}
```

Remove Associations

```
POST /api/generic_object_definitions/:id

{
  "action" : "remove_associations",
  "resource" : {
    "associations" : {
      "chargeback" : "ChargebackVm"
    }
  }
}
```

Deleting Generic Object Definitions

Generic Object Definitions can be deleted via the *delete* action as follows:

```
POST /api/generic_object_definitions/:id
```

or by name:

```
POST /api/generic_object_definitions/:name

{
  "action" : "delete"
}
```

Multiple Generic Object Definitions can also be deleted in a single request as follows:

```
POST /api/generic_object_definitions
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/generic_object_definitions/11" },
    { "id" : "12" }
  ]
}
```

Single Generic Object Definitions can also be deleted with the DELETE method as follows:

```
DELETE /api/generic_object_definitions/:id
```

or by name:

```
DELETE /api/generic_object_definitions/:name
```

Generic Objects

Querying Generic Objects

Querying all available Generic Objects:

```
GET /api/generic_objects
```

Getting details on a specific Generic Object:

```
GET /api/generic_objects/:id
```

Querying all the Generic Objects defined for a specific Service:

```
GET /api/services/:id/generic_objects
```

Querying Generic Objects and related picture and image_href for a specific Service:

Request:

```
GET /api/services/:id?expand=generic_objects&attributes=generic_objects.picture
```

Response:

```
{
  "href" : "http://localhost:3000/api/services/645",
  "id" : "645",
  "name" : "Test Azure Service",
  "description" : "Azure",
  "guid" : "6ce8f6c2-7f93-4a7e-b618-da9acab470ac",
  "options": {  },
  "display": false,
  "created_at" : "2017-08-07T16:52:46Z",
  "updated_at" : "2017-08-07T16:52:46Z",
  "miq_group_id" : "1",
  "retired": false,
  "tenant_id" : "1",
  "initiator" : "user",
  "generic_objects": [
    {
      "href" : "http://localhost:3000/api/services/645/generic_objects/1",
      "id" : "1",
      "name" : "generic_object_1",
      "generic_object_definition_id" : "1",
      "created_at" : "2017-08-15T17:35:08Z",
      "updated_at" : "2017-09-07T12:05:14Z",
      "properties": {
         "vms" : [ 615 ],
         "start" : true
      },
      "picture" : {
        "href" : "http://localhost:3000/api/picture/1",
        "id" : "1",
        "resource_id" : "1",
        "resource_type" : "GenericObjectDefinition",
        "image_href" : "http://localhost:3000/pictures/1.png",
        "extension" : "png"
      }
    }
  ],
  "actions" : {
    ...
  }
}
```

Creating Generic Objects

Generic Objects can be created as follows:

```
POST /api/generic_objects
```

```
{
  "generic_object_definition" : { "href" : "http://localhost:3000/api/generic_object_definitions/11" },
  "name" : "go1_name",
  "uid" : "optional_uid",
  "property_attributes" : {
    "widget" : "widget value",
    "supports_feature_a" : false
  },
  "associations" : {
    "vms" : [
      { "href" : "http://localhost:3000/api/vms/11" },
      { "id" : "12 }
    ]
  }
}
```

Generic Objects can also be directly created for a specific Generic Object Definition type as follows:

```
POST /api/generic_object_definitions/:id/generic_objects
```

```
{
  "name" : "go1_name",
  "uid" : "optional_uid",
  "property_attributes" : {
    "widget" : "widget value",
    "supports_feature_a" : false
  },
  "associations" : {
    "vms" : [
      { "href" : "http://localhost:3000/api/vms/11" },
      { "id" : "12 }
    ]
  }
}
```

In which case, the generic_object_definition reference is not needed.

Editing Generic Objects

Updating Generic Objects can be done via the *edit* action as follows:

```
POST /api/generic_objects/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "name" : "updated_name",
    "property_attributes" : {
      "widget" : "updated_widget"
    }
  }
}
```

Calling Generic Object Methods

When generic objects have methods defined in their definitions, those methods are exposed with the generic objects as actions.

The following example shows a generic object with two methods *method_a* and *method_b*:

```
GET /api/generic_objects/101
```

```
{
  "href" : "http://localhost:3000/api/generic_objects/101",
  "id"   : "101",
  "name" : "sample_object",
  "generic_object_definition_id" : "5",
  "property_attributes" : {
    "widget" : "a sample widget",
    "object_flag" : true
  },
  "actions" : [
    {
      "name" : "edit",
      "method" : "post",
      "href" : "http://localhost:3000/api/generic_objects/101"
    },
    {
      "name" : "delete",
      "method" : "post",
      "href" : "http://localhost:3000/api/generic_objects/101"
    },
    {
      "name" : "delete",
      "method" : "delete",
      "href" : "http://localhost:3000/api/generic_objects/101"
    },
    {
      "name" : "method_a",
      "method" : "post",
      "href" : "http://localhost:3000/api/generic_objects/101"
```

```
    },
    {
      "name" : "method_b",
      "method" : "post",
      "href" : "http://localhost:3000/api/generic_objects/101"
    }
  ]
}
```

With the above sample generic object, the custom methods can be invoked like any other action as follows:

```
POST /api/generic_objects/101
```

```
{
  "action" : "method_a",
  "resource" : {
    "attr1" : "value 1",
    "attr2" : "value 2"
  }
}
```

Deleting Generic Objects

Generic Objects can be deleted via the *delete* action as follows:

```
POST /api/generic_objects/:id
```

```
{
  "action" : "delete"
}
```

Multiple Generic Objects can also be deleted in a single request as follows:

```
POST /api/generic_objects
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/generic_objects/21" },
    { "id" : "22" },
    { "id" : "23" }
  ]
}
```

Single Generic Objects can also be deleted with the DELETE method as follows:

```
DELETE /api/generic_objects/:id
```

- Group Management
  - Querying Groups
  - Creating Groups
  - Editing Groups
  - Deleting Groups

Group Management

Management of User Groups is provided via the following collection:

```
/api/groups
```

Full CRUD actions on groups is available:

- Querying Groups
- Creating Groups
- Editing Groups
- Deleting Groups

Querying Groups

Querying all groups in the system:

```
GET /api/groups
```

Getting details on a specific group:

```
GET /api/groups/:id
```

Creating Groups

Groups can be created via a POST to the groups collection or via the **create** action signature which also allows creation of multiple groups in a single request.

```
POST /api/groups
```

```
{
  "description" : "sample_group",
```

```
  "role" : { "id" : "2" },
  "tenant" : { "href" : "http://localhost:3000/api/tenants/1" },
  "filters" : {
    "belongsto" : [ "/managed/area/1", "/managed/area/2" ],
    "managed" : [[ "/managed/infra/1", "/managed/infra/2" ]]
  }
}
```

Note:

role can be specified via **name**, **href**, or **id**

tenant can be specified via **href** or **id**

or creating multiple groups:

```
{
  "action" : "create",
  "resources" : [
    { "description" : "sample_group1", ... },
    { "description" : "sample_group2", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Groups.

Editing Groups

```
POST /api/groups/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "description" : "updated_sample_group",
    "filters" : {
      "belongsto" : [ "/managed/area/1", "/managed/area/2", "/managed/area/3" ],
      "managed" : [[ "/managed/infra/1", "/managed/infra/2"], ["/managed/other/3"]]
    }
  }
}
```

or editing multiple groups:

```
POST /api/groups
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/groups/101",
      "description" : "updated_sample_group1"
    },
    {
      "href" : "http://localhost:3000/api/groups/102",
      "description" : "updated_sample_group2"
    },
    ...
  ]
}
```

Deleting Groups

groups can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/groups/101
```

```
{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/groups/101
```

Deleting multiple groups can be done as follows:

```
POST /api/groups
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/groups/101" },
    { "href" : "http://localhost:3000/api/groups/102" },
    ...
  ]
}
```

- Host Management

- Querying Hosts
- Editing a Host

Host Management

Management of Hosts adds support of the following actions:

Action	Description
edit	Edit a Host

- Querying Hosts
- Editing a Host

Querying Hosts

Hosts are queried via the primary collection URL:

```
/api/hosts
```

Editing a Host

Currently, only the host password can be edited via the API. All other edit requests will be rejected.

The host password is provided by a *credentials* hash similar to the signature supported for providers.

```
POST /api/hosts/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "credentials" : {
      "password" : "updated_password"
    }
  }
}
```

When not specified, the authentication type used for the password is *default*:

```
POST /api/hosts/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "credentials" : {
      "auth_type" : "default",
      "password" : "updated_password"
    }
  }
}
```

Password for multiple hosts can also be updated with a single request as follows:

```
POST /api/hosts
```

```
{
  "action" : "edit",
  "resources" : [
    { "id" : "101", "credentials" : { "password" : "updated_password" } },
    { "id" : "102", "credentials" : { "password" : "updated_password" } },
    { "id" : "103", "credentials" : { "password" : "updated_password" } },
    ...
  ]
}
```

Note:

host can be referenced by **href** or **id**

- Instance Management
  - Targeting Instances
  - Querying Instances
    - Load Balancers
  - Starting an Instance
  - Stopping an Instance
  - Suspending an Instance
  - Pausing an Instance
  - Terminating an Instance
  - Shelving an Instance
  - Rebooting Guest in an Instance
  - Resetting an Instance

Instance Management

Management of instances adds support for the following actions:

Action	Description
start	Starts an Instance
stop	Stops an Instance
suspend	Suspending an Instance
pause	Pausing an Instance
reboot_guest	Rebooting Guest in an Instance
reset	Resetting an Instance
shelve	Shelving an Instance
terminate	Terminating an Instance

- Starting an Instance
- Stopping an Instance
- Suspending an Instance
- Pausing an Instance
- Rebooting Guest in an Instance
- Resetting an Instance
- Shelving an Instance
- Terminating an Instance

Targeting Instances

These actions can be triggered on individual instance resources:

```
/api/instances/:id
```

As simply as POSTing the following action to an instance.

```
{
  "action" : "start"
}
```

Requests can also be made on multiple instances by targeting the primary collection:

```
/api/instances
```

```
{
  "action" : "start",
  "resources" : [
    { "href" : "http://localhost:3000/api/instances/101" },
    { "href" : "http://localhost:3000/api/instances/102" },
    ...
  ]
}
```

Querying Instances

Instances are queried via the primary collection URL:

```
/api/instances
```

Filtering, sorting and paging as mentioned on the Querying page.

Load Balancers

Load Balancers of an instance can be queried via the load_balancers subcollection as follows:

Query all Load Balancers of an instance:

```
GET /api/instances/:id/load_balancers
```

Query a specific Load Balancer of an instance:

```
GET /api/instances/:id/load_balancers/:load_balancer_id
```

Or expanding the Load Balancers for the specific instance as follows:

```
GET /api/instances/:id?expand=load_balancers
```

Starting an Instance

```
{
  "action" : "start"
```

```
}
```

Stopping an Instance

```
{
  "action" : "stop"
}
```

Suspending an Instance

```
{
  "action" : "suspend"
}
```

Pausing an Instance

```
{
  "action" : "pause"
}
```

Terminating an Instance

```
{
  "action" : "terminate"
}
```

Shelving an Instance

```
{
  "action" : "shelve"
}
```

Rebooting Guest in an Instance

```
{
  "action" : "reboot-guest"
}
```

Resetting an Instance

```
{
  "action" : "reset"
}
```

- Metric Rollups
  - Getting 60 Daily Metric Rollups
  - Getting Hourly Metric Rollups for a range of Dates
  - Getting Hourly Metric Rollups for a Service
  - Getting 30 Daily Metric Rollups for a Vm

Metric Rollups

Querying of Metric Rollups is made available via the following collection:

`/api/metric_rollups`

Supported query parameters:

Parameter	Examples
resource_type	VmOrTemplate, Service or any resource type that supports Metric Rollups
resource_ids[]	id1
resource_ids[]	id2
resource_ids[]	...
capture_interval	hourly, daily
start_date	2018-01-10, 2018-01-10T11:20:00Z
end_date	2018-01-17, 2017-12-31T23:59:00Z

Getting 60 Daily Metric Rollups

```
GET /api/metric_rollups?resource_type=VmOrTemplate
                       &resource_ids[]=101
                       &resource_ids[]=102
                       &resource_ids[]=103
                       &capture_interval=daily
                       &start_date='2017-10-01'
                       &limit=60
```

Getting Hourly Metric Rollups for a range of Dates

```
GET /api/metric_rollups?resource_type=Service
                       &resource_ids[]=55
                       &resource_ids[]=56
```

```
                        &capture_interval=hourly
                        &start_date='2017-11-15'
                        &end_date='2017-11-18'
```

Metric rollups can also be obtained for a specific resource as a subcollection:

```
/api/vms/:id/metric_rollups
```

```
/api/services/:id/metric_rollups
```

Getting Hourly Metric Rollups for a Service

```
GET /api/services/57/metric_rollups?capture_interval=hourly&start_date='2017-06-15'
```

Getting 30 Daily Metric Rollups for a Vm

```
GET /api/vms/104/metric_rollups?capture_interval=daily&start_date='2017-01-01'&limit=30
```

- Network Routers
  - Querying Network Routers
  - Deleting Network Routers
    - Request:
    - Response:

Network Routers

Management of Network Routers is provided via the following collection:

```
/api/network_routers
```

The following actions are available on Network Routers:

- Querying Network Routers
- Deleting Network Routers

Querying Network Routers

Querying all Network Routers in the system is simply:

```
GET /api/network_routers
```

Getting details on a specific Network Router:

```
GET /api/network_routers/:id
```

Deleting Network Routers

Network Routers can be deleted via either the **delete** POST action or via the DELETE HTTP method.

Request:

```
POST /api/network_routers/101
```

```
{
  "action" : "delete"
}
```

Response:

```
{
  "success" : true,
  "message" : "Deleting Networking Router id:101 name: 'test_network_router'",
  "task_id" : "33",
  "task_href" : "http://localhost:3000/api/tasks/33"
}
```

or simply:

```
DELETE /api/network_routers/101
```

Deleting multiple Network Routers can be done as follows:

```
POST /api/network_routers
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/network_routers/101" },
    { "href" : "http://localhost:3000/api/network_routers/102" },
    ...
  ]
}
```

- Notifications Support
- Querying Notifications

- Marking Notifications as Seen
  - Deleting Notifications

Notifications Support

Support for Notifications to the authenticated user is provided via the following collection:

`/api/notifications`

- Querying Notifications
- Marking Notifications as Seen
- Deleting Notifications

Querying Notifications

The following fetches the current notifications for the authenticated user:

```
GET /api/notifications
```

```
{
  "name": "notifications",
  "count": 3,
  "subcount": 3,
  "resources": [
    {
      "href": "http://localhost:3000/api/notifications/44"
    },
    {
      "href": "http://localhost:3000/api/notifications/45"
    },
    {
      "href": "http://localhost:3000/api/notifications/46"
    }
  ],
  "actions": [
    {
      "name": "mark_as_seen",
      "method": "post",
      "href": "http://localhost:3000/api/notifications"
    },
    {
      "name": "delete",
      "method": "post",
      "href": "http://localhost:3000/api/notifications"
    }
  ]
}
```

Or fetching additional details on the notifications as follows:

```
GET /api/notifications?expand=resources&attributes=details
```

```
{
  "name": "notifications",
  "count": 3,
  "subcount": 3,
  "resources": [
    {
      "href": "http://localhost:3000/api/notifications/44",
      "id": "44",
      "user_id": "1",
      "seen": false,
      "details": {
        "level": "info",
        "created_at": "2016-11-03T17:23:29Z",
        "text": "Vm [aab-test] was powered on",
        "bindings": {
          "initiator": {
            "link": {
              "id": "1",
              "model": "User"
            },
            "text": "Administrator"
          }
        },
        "seen": false
      },
      "actions": [
        {
          "name": "mark_as_seen",
          "method": "post",
          "href": "http://localhost:3000/api/notifications/44"
        },
        {
          "name": "delete",
          "method": "post",
```

```
        "href": "http://localhost:3000/api/notifications/44"
      },
      {
        "name": "delete",
        "method": "delete",
        "href": "http://localhost:3000/api/notifications/44"
      }
    ]
  },
  {
    "href": "http://localhost:3000/api/notifications/45",
    "id": "45",
    "notification_id": "22",
    "user_id": "1",
    "seen": true,
    "details": {
      "level": "info",
      "created_at": "2016-11-03T17:23:29Z",
      "text": "Vm [aab-test2] was powered on",
      "bindings": {
        "initiator": {
          "link": {
            "id": "1",
            "model": "User"
          },
          "text": "Administrator"
        }
      },
      "seen": true
    },
    "actions": [
      {
        "name": "mark_as_seen",
        "method": "post",
        "href": "http://localhost:3000/api/notifications/45"
      },
      {
        "name": "delete",
        "method": "post",
        "href": "http://localhost:3000/api/notifications/45"
      },
      {
        "name": "delete",
        "method": "delete",
        "href": "http://localhost:3000/api/notifications/45"
      }
    ]
  },
  {
    "href": "http://localhost:3000/api/notifications/46",
    "id": "46",
    "notification_id": "23",
    "user_id": "1",
    "seen": false,
    "details": {
      "level": "info",
      "created_at": "2016-11-03T17:23:54Z",
      "text": "Vm [aab-dev] was powered off",
      "bindings": {
        "initiator": {
          "link": {
            "id": "1",
            "model": "User"
          },
          "text": "Administrator"
        }
      },
      "seen": false
    },
    "actions": [
      {
        "name": "mark_as_seen",
        "method": "post",
        "href": "http://localhost:3000/api/notifications/46"
      },
      {
        "name": "delete",
        "method": "post",
        "href": "http://localhost:3000/api/notifications/46"
      },
      {
        "name": "delete",
        "method": "delete",
        "href": "http://localhost:3000/api/notifications/46"
      }
    ]
  }
],
"actions": [
  {
    "name": "mark_as_seen",
```

```
      "method": "post",
      "href": "http://localhost:3000/api/notifications"
    },
    {
      "name": "delete",
      "method": "post",
      "href": "http://localhost:3000/api/notifications"
    }
  ]
}
```

Marking Notifications as Seen

Marking Notifications as seen for the authenticated user is done via the **mark_as_seen** action as follows:

```
POST /api/notifications/:id

{
  "action" : "mark_as_seen"
}
```

Or, marking several notifications as seen in a single call as follows:

```
POST /api/notifications

{
  "action" : "mark_as_seen",
  "resources" : [
    { "href" : "http://localhost:3000/api/notifications/44" },
    { "href" : "http://localhost:3000/api/notifications/45" },
    ...
  ]
}
```

Deleting Notifications

Deleting a notification is available via the **delete** action or DELETE on the individual notification as follows:

```
POST /api/notifications/:id

{
  "action" : "delete"
}
```

Or simply:

```
DELETE /api/notifications/:id
```

Also, deleting multiple notifications is available via the **delete** action on the collection passing in references to the different notifications:

```
POST /api/notifications

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/notifications/44" },
    { "href" : "http://localhost:3000/api/notifications/45" },
    ...
  ]
}
```

- Orchestration Support
  - Orchestration Templates ===
  - Querying Orchestration Templates
  - Creating Orchestration Templates
  - Editing Orchestration Templates
  - Copying Orchestration Templates
  - Deleting Orchestration Templates

Orchestration Support

Support for orchestration is provided by the following:

- Orchestration Templates

Orchestration Templates ===

Management of orchestration templates is provided with the following collection:

```
/api/orchestration_templates
```

Full CRUD actions on orchestration templates is available:

- Querying Orchestration Templates
- Creating Orchestration Templates

- Editing Orchestration Templates
- Copying Orchestration Templates
- Deleting Orchestration Templates

Querying Orchestration Templates

Querying all orchestration templates in the system:

```
GET /api/orchestration_templates
```

Getting details on a specific orchestration template:

```
GET /api/orchestration_templates/:id
```

Creating Orchestration Templates

Orchestration templates can be created via a POST to the orchestration templates collection or via the **create** action signature which also allows creation of multiple orchestration templates in a single request.

```
POST /api/orchestration_templates
```

```
{
  "name" : "azure-single-vm-from-user-image",
  "type" : "OrchestrationTemplateAzure",
  "description" : "Create a single VM from a user image",
  "content" : " ... ",
  "orderable" : true,
  ...
}
```

or creating multiple orchestration templates:

```
{
  "action" : "create",
  "resources" : [
    { "description" : "sample_orchestration_template1", ... },
    { "description" : "sample_orchestration_template2", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating orchestration templates.

Editing Orchestration Templates

```
POST /api/orchestration_templates/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "description" : "updated_sample_orchestration_template",
  }
}
```

or editing multiple orchestration templates:

```
POST /api/orchestration_templates
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/orchestration_templates/101",
      "description" : "updated_sample_orchestration_template1"
    },
    {
      "href" : "http://localhost:3000/api/orchestration_templates/102",
      "description" : "updated_sample_orchestration_template2"
    },
    ...
  ]
}
```

Copying Orchestration Templates

This capability allows orchestration templates to be copied onto new orchestration templates with updated content via the *copy* action as follows:

```
POST /api/orchestration_templates/:id
```

```
{
  "action" : "copy",
  "resource" : {
    "content" : "{ 'Description' : 'Copied Test Content' }"
  }
}
```

or copying multiple orchestration templates:

```
POST /api/orchestration_templates
```

```
{
  "action" : "copy",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/orchestration_templates/101",
      "content" : "{ 'Description' : 'Copied Test Content 1' }"
    },
    {
      "href" : "http://localhost:3000/api/orchestration_templates/102",
      "content" : "{ 'Description' : 'Copied Test Content 2' }"
    },
    ...
  ]
}
```

Deleting Orchestration Templates

Orchestration templates can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/orchestration_templates/101
```

```
{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/orchestration_templates/101
```

Deleting multiple orchestration templates can be done as follows:

```
POST /api/orchestration_templates
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/orchestration_templates/101" },
    { "href" : "http://localhost:3000/api/orchestration_templates/102" },
    ...
  ]
}
```

- Physical Server Management
  - Querying Physical Servers
  - Managing Physical Servers
  - Powering On a Physical Server
  - Powering Off a Physical Server

  - Turn Off the Identify LED

Physical Server Management

Management of Physical Servers is available via the following endpoint:

```
/api/physical_servers
```

Querying Physical Servers

Querying all physical servers in the system is simply:

```
GET /api/physical_servers
```

Getting details on a specific Physical Server:

```
GET /api/physical_servers/:id
```

Managing Physical Servers

The following actions are available on Physical Servers:

Action	Description
power_on	Power On
power_off	Power Off

Action	Description
power_off_now	Power Off Now
refresh_now	Refresh
restart	Restart
restart_now	Restart Now
restart_to_sys_setup	Restart to System Setup
restart_mgmt_controller	Restart Management Controller
blink_loc_led	Blink the Identify LED
turn_on_loc_led	Turn On the Identify LED
turn_off_loc_led	Turn Off the Identify LED

Powering On a Physical Server

```
{
  "action" : "power_on"
}
```

Powering Off a Physical Server

```
{
  "action" : "power_off"
}
```

Powering Off Now a Physical Server

```
{
  "action" : "power_off_now"
}
```

Refresh a Physical Server

```
{
  "action" : "refresh"
}
```

Restart a Physical Server

```
{
  "action" : "restart"
}
```

Restart Now a Physical Server

```
{
  "action" : "restart_now"
}
```

Restart a Physical Server to System Setup

```
{
  "action" : "restart_to_sys_setup"
}
```

Restart Management Controller

```
{
  "action" : "restart_mgmt_controller"
}
```

Blink the Identify LED

```
{
  "action" : "blink_loc_led"
}
```

Turn On the Identify LED

```
{
  "action" : "turn_on_loc_led"
}
```

Turn Off the Identify LED

```
{
  "action" : "turn_off_loc_led"
}
```

- Picture Management
  - Creating a Picture
  - Querying Pictures

Picture Management

Management of Pictures adds support of the following actions:

- Creating a Picture
- Querying Pictures

Creating a Picture

```
POST /api/pictures
```

```
{
  "extension": "<extension of image>",
  "content": "<base 64 encoded image here>"
}
```

Supported extensions include:

Extension
jpg
png
svg

Querying Pictures

Querying pictures like any other collection:

```
GET /api/pictures?expand=resources
```

```
{
  "name": "pictures",
  "count": 5,
  "subcount": 5,
  "resources": [
    {
      "href": "http://localhost:3000/api/pictures/1",
      "id": "1",
      "image_href" : "http://localhost:3000/pictures/1.jpg",
      "extension" : "jpg"
    },
    ...
    {
      "href": "http://localhost:3000/api/pictures/4",
      "id": "4",
      "image_href" : "http://localhost:3000/pictures/4.png",
      "extension" : "png",
      "resource_id": "1",
      "resource_type": "ServiceTemplate"
    },
    {
      "href": "http://localhost:3000/api/pictures/5",
      "id": "5",
      "image_href" : "http://localhost:3000/pictures/5.jpg",
      "extension" : "jpg"
    }
  ],
  "actions": [
    {
      "name": "create",
      "method": "post",
      "href": "http://localhost:3000/api/pictures"
    }
  ]
}
```

This query does not return the pictures themselves, simply metadata about the pictures.

Actually fetching the particular picture is done by getting the image by its image_href.

```
GET /api/pictures/4
```

```
{
  "href": "http://localhost:3000/api/pictures/4",
  "id": "4",
  "resource_id": "1",
  "resource_type": "ServiceTemplate",
  "image_href": "http://localhost:3000/pictures/4.jpg"
}
```

In which case the image can simply be downloaded with a GET:

```
GET http://localhost:3000/pictures/4.jpg
```

For fetching information about pictures pertaining to services, see the section Querying Pictures for details.

- Policy Management
  - Querying Policies

Policy Management

Management of policies and policy profiles is provided in the following forms:

- Querying of policies via the primary collection:

`/api/policies`

- Querying of policy profiles via the primary collection:

`/api/policy_profiles`

- Assigning and Unassigning policies to resources via the policies subcollection of a resource

`/api/:collection/:id/policies`

and posting **assign** or **unassign** actions to the policies subcollection.

- Assigning and Unassigning policy profiles to resources via the policy_profiles subcollection of a resource

`/api/:collection/:id/policy_profiles`

and posting **assign** or **unassign** actions to the policy_profiles subcollection.

Querying Policies

Querying all policies in the system is simply:

```
GET /api/policies
```

```
{
  "name": "policies",
  "count": 20,
  "subcount": 20,
  "resources": [
    {
      "href": "http://localhost:3000/api/policies/7"
    },
    {
      "href": "http://localhost:3000/api/policies/8"
    },
    ...
  ]
}
```

And expanding the policies, providing additional details:

```
GET /api/policies?expand=resources
```

```
{
  "name": "policies",
  "count": 3,
  "subcount": 3,
  "resources": [
    {
      "href": "http://localhost:3000/api/policies/7",
      "id": "7",
      "name": "b1fd23bc-acc4-11e4-abc7-b8e85646e742",
      "description": "test_control_policy",
      "created_on": "2015-02-04T23:22:32Z",
      "updated_on": "2015-04-09T13:20:58Z",
      "towhat": "Vm",
      "guid": "b1fd23bc-acc4-11e4-abc7-b8e85646e742",
      "created_by": "admin",
      "updated_by": "admin",
      "active": true,
      "mode": "control"
    },
    {
      "href": "http://localhost:3000/api/policies/8",
      "id": "8",
      "name": "68bfaade-ad3d-11e4-8d4e-b8e85646e742",
      "description": "server_type_control_policy",
      "created_on": "2015-02-05T13:46:39Z",
      "updated_on": "2015-04-09T13:20:58Z",
      "towhat": "Vm",
      "guid": "68bfaade-ad3d-11e4-8d4e-b8e85646e742",
      "created_by": "admin",
      "updated_by": "admin",
      "active": true,
      "mode": "control"
    },
    ...
  ]
}
```

Querying Policies of a Resource

To find out which policies are assigned to a resource, the policies subcollection can be expanded for that particular resource as follows:

```
GET /api/vms/320?expand=policies
```

This will provide the resources as well as the related policies

```
{
  "href": "http://localhost:3000/api/vms/320",
  "id": "320",
  "vendor": "vmware",
  "name": "aab-vm1",
  "description": "this is a test",
  "raw_power_state": "poweredOn",
  ...
  "policies": [
    {
      "href": "http://localhost:3000/api/vms/320/policies/7",
      "id": "7",
      "name": "b1fd23bc-acc4-11e4-abc7-b8e85646e742",
      "description": "test_control_policy",
      "created_on": "2015-02-04T23:22:32Z",
      "updated_on": "2015-04-09T13:20:58Z",
      "towhat": "Vm",
      "guid": "b1fd23bc-acc4-11e4-abc7-b8e85646e742",
      "created_by": "admin",
      "updated_by": "admin",
      "active": true,
      "mode": "control"
    }
  ]
}
```

One can also simply query the policies of a resource by the subcollection as follows:

```
GET /api/vms/320/policies
```

```
{
  "name": "policies",
  "count": 3,
  "subcount": 1,
  "resources": [
    {
      "href": "http://localhost:3000/api/vms/320/policies/7"
    }
  ],
  "actions": [
    ...
  ]
}
```

Finding the policies that are part of a policy profile is queried the same as regular resources

```
GET /api/policy_profiles/:id?expand=policies
```

or just the policies themselves as follows:

```
GET /api/policy_profiles/:id/policies
```

Creating Policies

Policies can be created via a POST to the policies collection or via the **create** action signature which also allows creation of multiple policies in a single request.

```
POST /api/policies
```

```
{
  "name" : "sample_policy",
  "description" : "Sample Policy",
  "mode" : "compliance",
  "towhat" : "ManageIQ::Providers::Redhat::InfraManager",
  "condition_ids" : [11, 12],
  "policy_contents" : [
    {
      "event_id" : 201,
      "actions" : [
        {
          "action_id" : 3001,
          "opts" : { "qualifier" : "failure" }
        }
      ]
    }
  ]
}
```

or creating multiple policies:

```
{
  "action" : "create",
  "resources" : [
    { "name" : "sample_policy_1", "description" : "Sample Policy 1", ... },
    { "name" : "sample_policy_2", "description" : "Sample Policy 2", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating policies.

Editing Policies

```
POST /api/policies/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "description" : "Updated Policy Description"
  }
}
```

or editing multiple policies:

```
POST /api/policies
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/policies/101",
      "description" : "Updated Policy Description 1"
    },
    {
      "href" : "http://localhost:3000/api/policies/102",
      "description" : "Updated Policy Description 2"
    },
    ...
  ]
}
```

Deleting Policies

Policies can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/policies/101
```

```
{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/policies/101
```

Deleting multiple policies can be done as follows:

```
POST /api/policies

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/policies/101" },
    { "href" : "http://localhost:3000/api/policies/102" },
    ...
  ]
}
```

Policy and Policy Profiles Actions

For managing policies and policy profiles on resource three available actions are available. These are:

Action	Description
assign	Assign a policy or policy profile to the resource
unassign	Unassign a policy or policy profile from the resource
resolve	Resolves a resource policy or policy profile

Resource Policy Management

Policy management on resources can be done by POSTing **assign** and **unassign** actions to the policies or policy_profiles subcollection of resources. Policy management is available on the following primary collections:

Collection
/api/clusters
/api/hosts
/api/policy_profiles
/api/providers
/api/resource_pools
/api/templates
/api/vms

Policy specification

Policies and policy profiles can be specified using one of the following forms:

By href:

```
{
  "href" : "http://localhost:3000/api/policies/:id"
}

{
  "href" : "http://localhost:3000/api/policy_profiles/:id"
}
```

Or by policy Guid:

```
{
  "guid" : "b1fd23bc-acc4-11e4-abc7-b8e85646e742"
}
```

Assigning policies to a resource

Assigning policies or policy_profiles to resources is done by posting an **assign** action against the policies or policy_profiles subcollection of a resource.

```
POST /api/vms/320/policies

{
  "action" : "assign",
  "resource" : { "href" : "http://localhost:3000/api/policies/7" }
}
```

or multiple policies:

```
{
  "action" : "assign",
  "resource" : [
    { "href" : "http://localhost:3000/api/policies/7" },
    { "href" : "http://localhost:3000/api/policies/10" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Assigning Policy: id:'7' description:'test_control_policy' guid:'b1fd23bc-acc4-11e4-abc7-b8e85646e742'",
```

```
      "href": "http://localhost:3000/api/vms/320",
      "policy_id": "7",
      "policy_href": "http://localhost:3000/api/policies/7"
    }
  ]
}
```

Unassigning policies from a resource

Unassign policies or policy_profiles to resources is done by posting an **unassign** action against the policies or policy_profiles subcollection of a resource.

```
POST /api/vms/320/policies

{
  "action" : "unassign",
  "resource" : { "href" : "http://localhost:3000/api/policies/7" }
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Unassigning Policy: id:'7' description:'test_control_policy' guid:'b1fd23bc-acc4-11e4-abc7-
b8e85646e742'",
      "href": "http://localhost:3000/api/vms/320",
      "policy_id": "7",
      "policy_href": "http://localhost:3000/api/policies/7"
    }
  ]
}
```

Resolving Policies of a Resource

Resolving a resource policy by targeting the subcollection resource directly as follows:

```
POST /api/vms/320/policies/7

{
  "action" : "resolve"
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Resolving Policy: id:'7' description:'test_control_policy' guid:'b1fd23bc-acc4-11e4-abc7-b8e85646e742'",
      "result": [
        {
          "id": "7",
          "name": "b1fd23bc-acc4-11e4-abc7-b8e85646e742",
          "description": "test_control_policy",
          "created_on": "2015-02-04T23:22:32Z",
          "updated_on": "2015-04-09T13:20:58Z",
          "towhat": "Vm",
          "guid": "b1fd23bc-acc4-11e4-abc7-b8e85646e742",
          "created_by": "admin",
          "updated_by": "admin",
          "active": true,
          "mode": "control",
          "result": "allow",
          "conditions": [

          ],
          "actions": [

          ]
        }
      ],
      "href": "http://localhost:3000/api/vms/320",
      "policy_id": "7",
      "policy_href": "http://localhost:3000/api/policies/7"
    }
  ]
}
```

Resolving Policy Profiles of a Resource

Resolving a resource policy profile by targeting the subcollection resource directly as follows:

```
POST /api/vms/320/policy_profiles/34

{
  "action" : "resolve"
}
```

Response:

```
{
  "success": true,
  "message": "Resolving Policy Profile: id:'34' description:'Control Policies' guid:'f39b25e2-ad3e-11e4-8d4e-
b8e85646e742'",
  "result": [
    {
      "id": "34",
      "name": "f39b25e2-ad3e-11e4-8d4e-b8e85646e742",
      "description": "Control Policies",
      "set_type": "MiqPolicySet",
      "created_on": "2015-02-05T13:57:41Z",
      "updated_on": "2015-02-26T13:42:43Z",
      "guid": "f39b25e2-ad3e-11e4-8d4e-b8e85646e742",
      "mode": "control",
      "result": "allow",
      "policies": [
        {
          "id": "7",
          "name": "b1fd23bc-acc4-11e4-abc7-b8e85646e742",
          "description": "test_control_policy",
          "created_on": "2015-02-04T23:22:32Z",
          "updated_on": "2015-04-09T13:20:58Z",
          "towhat": "Vm",
          "guid": "b1fd23bc-acc4-11e4-abc7-b8e85646e742",
          "created_by": "admin",
          "updated_by": "admin",
          "active": true,
          "mode": "control",
          "result": "allow",
          "conditions": [

          ],
          "actions": [

          ]
        },
        {
          "id": "8",
          "name": "68bfaade-ad3d-11e4-8d4e-b8e85646e742",

- Policy Conditions
  - Response:
- Policy Events
  - Response:

Policy Collections

Primary Policy and Policy Profile collections:

`/api/policies`

`/api/policy_profiles`

With Policy Profiles being sets of Policies with the ability to query policies of a specific policy profile via:

`GET /api/policy_profiles/:id?expand=policies`

Or just the subcollection:

`GET /api/policy_profiles/:id/policies`

- Policy Actions
- Policy Conditions
- Policy Events

Policy Actions

Policy actions can be queried as a primary collection or as a subcollection of policies as follows:

`GET /api/policy_actions`

`GET /api/policies/:id?expand=policy_actions`

or simply the subcollection:

`GET /api/policies/:id/policy_actions`

In this example, we're expanding all policy actions

`GET /api/policy_actions?expand=resources`

Response:

```
{
  "name": "policy_actions",
  "count": 33,
  "subcount": 33,
  "resources": [
    {
      "href": "http://localhost:3000/api/policy_actions/1",
      "id": "1",
      "name": "audit",
      "description": "Generate Audit Event",
      "created_on": "2014-11-20T19:10:05Z",
      "updated_on": "2014-11-20T19:10:05Z",
      "guid": "d619567a-70e8-11e4-a5b4-b8e85646e742",
      "action_type": "default",
      "options": {
      }
    },
    {
      "href": "http://localhost:3000/api/policy_actions/2",
      "id": "2",
      "name": "log",
      "description": "Generate log message",
      "created_on": "2014-11-20T19:10:05Z",
      "updated_on": "2014-11-20T19:10:05Z",
      "guid": "d61c3be2-70e8-11e4-a5b4-b8e85646e742",
      "action_type": "default",
      "options": {
      }
    },
    {
      "href": "http://localhost:3000/api/policy_actions/3",
      "id": "3",
      "name": "evm_event",
      "description": "Show EVM Event on Timeline",
      "created_on": "2014-11-20T19:10:05Z",
      "updated_on": "2014-11-20T19:10:05Z",
      "guid": "d61cb05e-70e8-11e4-a5b4-b8e85646e742",
      "action_type": "default",
      "options": {
      }
    },
    {
      "href": "http://localhost:3000/api/policy_actions/4",
      "id": "4",
      "name": "script",
      "description": "Execute an external script",
      "created_on": "2014-11-20T19:10:05Z",
      "updated_on": "2014-11-20T19:10:05Z",
      "guid": "d61d225a-70e8-11e4-a5b4-b8e85646e742",
      "action_type": "default",
      "options": {
      }
    },
    ...
  ]
}
```

Policy Conditions

Policy conditions can be queried as a primary collection or as a subcollection of policies as follows:

```
GET /api/conditions
```

```
GET /api/policies/:id?expand=conditions
```

or simply the subcollection:

```
GET /api/policies/:id/conditions
```

In this example, we're expanding the conditions of a policy:

```
GET /api/policies/10?expand=conditions
```

Response:

```
{
  "href": "http://localhost:3000/api/policies/10",
  "id": "10",
  "name": "85dd1f68-ae53-11e4-9c45-b8e85646e742",
  "description": "web_server_policy",
  "created_on": "2015-02-06T22:57:27Z",
  "updated_on": "2015-04-09T13:20:58Z",
  "towhat": "Vm",
  "guid": "85dd1f68-ae53-11e4-9c45-b8e85646e742",
  "created_by": "admin",
  "updated_by": "admin",
  "active": true,
  "mode": "control",
  "conditions": [
    {
      "href": "http://localhost:3000/api/policies/10/conditions/1",
      "id": "1",
      "name": "fe75d0bc-860f-11e4-b12d-b8e85646e742",
      "description": "Memory For Web Server",
      "modifier": "allow",
      "expression": {
        "exp": {
          ">=": {
            "field": "Vm-num_cpu",
            "value": "2"
          }
        },
        "context_type": null
      },
      "towhat": "Vm",
      "created_on": "2014-12-17T17:13:17Z",
      "updated_on": "2015-02-08T15:16:16Z",
      "guid": "fe75d0bc-860f-11e4-b12d-b8e85646e742"
    }
  ]
}
```

Policy Events

Policy events can be queried as a primary collection or as a subcollection of policies as follows:

```
GET /api/events
```

```
GET /api/policies/:id?expand=events
```

or simply the subcollection:

```
GET /api/policies/:id/events
```

In this example, we're expanding all policy events

```
GET /api/events?expand=resources
```

Response:

```
{
  "name": "events",
  "count": 121,
  "subcount": 121,
  "resources": [
    {
      "href": "http://localhost:3000/api/events/1",
      "id": "1",
      "name": "evm_server_start",
      "description": "EVM Server Start",
      "created_on": "2014-11-20T19:10:11Z",
      "updated_on": "2014-11-20T19:10:11Z",
      "guid": "d9edd528-70e8-11e4-a5b4-b8e85646e742",
      "event_type": "Default"
    },
    {
      "href": "http://localhost:3000/api/events/2",
      "id": "2",
      "name": "evm_server_stop",
      "description": "EVM Server Stop",
```

```
      "created_on": "2014-11-20T19:10:11Z",
      "updated_on": "2014-11-20T19:10:11Z",
      "guid": "d9f44c00-70e8-11e4-a5b4-b8e85646e742",
      "event_type": "Default"
    },
    {
      "href": "http://localhost:3000/api/events/3",
      "id": "3",
      "name": "evm_server_not_responding",
      "description": "EVM Server Not Responding",
      "created_on": "2014-11-20T19:10:11Z",
      "updated_on": "2014-11-20T19:10:11Z",
      "guid": "d9f5dcaa-70e8-11e4-a5b4-b8e85646e742",
      "event_type": "Default"
    },
    ...
  ]
}
```

Provider Support

Provider management including CRUD operations as well as the **refresh** action is available via the REST API. Management of providers is through:

```
/api/providers
```

- Querying Providers
- Creating Providers
- Specifying Credentials
- Specifying Connection Configurations
- Editing Providers
- Deleting Providers
- Refresh Providers
- Import Vm to Provider
- Foreman Support
- Provider Examples

Querying Providers

Providers can be queried as follows:

```
GET /api/providers
```

A specific provider can also be queried by its id:

```
GET /api/providers/:id
```

Foreman type providers can be queried by specifying the provider_class as follows:

```
GET /api/providers?provider_class=provider
```

Cloud Networks

The Cloud Networks of a provider can be queried by asking for the *cloud_networks* subcollection as follows:

```
GET /api/providers/:id/cloud_networks
```

```
GET /api/providers/:id/cloud_networks/:cloud_network_id
```

Or expanding the Cloud Networks in addition to the provider as follows:

```
GET /api/providers/:id?expand=cloud_networks
```

Cloud Subnets

The Cloud Subnets of a provider can be queried by asking for the *cloud_subnets* subcollection as follows:

```
GET /api/providers/:id/cloud_subnets
```

```
GET /api/providers/:id/cloud_subnets/:cloud_subnet_id
```

Or expanding the Cloud Subnets in addition to the provider as follows:

```
GET /api/providers/:id?expand=cloud_subnets
```

Load Balancers

Load Balancers of providers can be queried via the load_balancers subcollection as follows:

Query all Load Balancers of a provider:

```
GET /api/providers/:id/load_balancers
```

Query a specific Load Balancer of a provider:

```
GET /api/providers/:id/load_balancers/:load_balancer_id
```

Or expanding the Load Balancers for the specific provider as follows:

```
GET /api/providers/:id?expand=load_balancers
```

Virtual Machines

Virtual Machines of providers can be queried via the vms subcollection as follows:

Query all VMs of a provider:

```
GET /api/providers/:id/vms
```

Query a specific VM of a provider:

```
GET /api/providers/:id/vms/:vm_id
```

Or expanding the VMs for the specific provider as follows:

```
GET /api/providers/:id?expand=vms
```

Query specific VMs of a provider and get their name and vendor attributes:

```
GET /api/providers/:id/vms?filter[]=name='test*'&attributes=name,vendor&expand=resources
```

Creating Providers

Creating a provider is done via the **create** action as follows:

```
POST /api/providers
```

```
{
  "action" : "create",
  "resource" : {
    # New Provider JSON
  }
}
```

And like other **create** actions, the new provider data can simply be posted to the /api/providers URL.

```
POST /api/providers
```

```
{
  # New Provider JSON
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating providers.

For example, creating a VMware type provider:

```
POST /api/providers
```

```
{
  "name" : "vCenter 5",
  "type" : "ManageIQ::Providers::Vmware::InfraManager",
  "hostname" : "my_vcenter_50",
  "ipaddress" : "192.168.150.1",
  "zone" :  { "href" : "http://localhost:3000/api/zone/1" },
  "credentials" :  {
    "userid" : "vcenter_admin",
    "password" : "vcenter_password"
  }
}
```

If zone is not specified, the Default zone will be used.

The **type** attribute specifies the supported provider class names which include:

ManageIQ::Providers::Amazon::CloudManager
ManageIQ::Providers::Azure::CloudManager
ManageIQ::Providers::Kubernetes::ContainerManager
ManageIQ::Providers::Microsoft::InfraManager
ManageIQ::Providers::Openshift::ContainerManager
ManageIQ::Providers::Openstack::CloudManager
ManageIQ::Providers::Openstack::InfraManager
ManageIQ::Providers::Lenovo::PhysicalInfraManager
ManageIQ::Providers::Redhat::InfraManager
ManageIQ::Providers::Vmware::CloudManager
ManageIQ::Providers::Vmware::InfraManager

Note:

Please note that the provider **type** classes have changed in the appliance from earlier releases (*v2.0.0* of the API). Please refer to the Provider Types page for a mapping from the old to the new types.

Specifying Credentials

When creating or updating providers, the credentials can be specified as a a single default set, or a compound set where additional credentials are necessary, for example AMPQ for OpenStack or Metrics for RHEVM.

Single default credentials set:

```
{
  "name" : "vCenter 50",
  "type" : "ManageIQ::Providers::Vmware::InfraManager",
  ...
  "credentials" :  {
    "userid" : "vc_admin",
    "password" : "vc_password"
  }
}
```

Compound credentials set:

```
{
  "name" : "RHEVM",
  "type" : " ManageIQ::Providers::Redhat::InfraManager",
  ...
  "credentials" : [
     {
       "userid"    : "default_userid",
       "password"  : "default_password"
     },
     {
       "userid"    : "metrics_userid",
       "password"  : "metrics_password",
       "auth_type" : "metrics"
     }
  ]
}
```

Specifying Connection Configurations

When creating or updating providers, connection configurations can be set. Connection configurations can be used to specify resources such as an **amqp** event provider for OpenStack, adding Prometheus metrics, or an authentication token.

Prometheus metrics:

```
{
  "name": "Openshift Provider",
  "type": "ManageIQ::Providers::Openshift::ContainerManager",
  ...
  "connection_configurations": [
    {
      "endpoint": {
        "role"                : "prometheus",
        "hostname"            : "prometheus_host",
        "port"                : "443",
        "security_protocol"   : "ssl-without-validation",
        "certificate_authority" : "-----BEGIN CERTIFICATE-----",
        "verify_ssl": 0
      },
      "authentication": {
        "role"     :  "prometheus",
        "auth_key" :  "prometheus_auth_key"
      }
    }
  ]
}
```

Amqp event provider:

```
{
  "name": "Openstack Provider",
  "type": "ManageIQ::Providers::Openstack::CloudManager",
  ...
  "connection_configurations": [
    {
      "endpoint": {
        "role"              : "amqp",
        "hostname"          : "amqphost.com",
        "port"              : "5672",
        "security_protocol" : "non-ssl"
      },
      "authentication": {
        "userid"   : "amqp_userid",
        "password" : "amqp_password",
        "role"     : "amqp"
      }
    }
  ]
}
```

Ceilometer event provider:

```
{
  "name"              : "Openstack Provider",
  "type"              : "ManageIQ::Providers::Openstack::CloudManager",
  "hostname"          : "ceilometerhost.com",
  "ipaddress"         : "192.168.150.1",
  "security_protocol" : "ssl",
  ...
  "connection_configurations": {
      "userid"   :  "userid",
      "password" :  "password"
  },
  "connection_configurations": [
      "endpoint" : {
        "role"   : "ceilometer"
      }
    }
  ]
}
```

Editing Providers

Editing provider is available via the **edit** action with the **resource** specifying the attributes to update for that provider.

```
POST /api/providers/:id
```

```
{
  "action" : "edit" ,
  "resource" : {
    "hostname" : "new_vcenter_50",
    "ipaddress" : "192.168.150.2"
  }
}
```

Note:

type is a restricted attribute and cannot be edited.

Deleting Providers

Deleting a provider is done via the delete method:

```
DELETE /api/providers/:id
```

or via the **delete** action as follows:

```
POST /api/providers/:id
```

```
{
  "action" : "delete"
}
```

or by href:

```
POST /api/providers
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/providers/:id" }
  ]
}
```

Refresh Providers

Performing a refresh of providers is done via the **refresh** action.

```
POST /api/providers/:id

{
  "action" : "refresh"
}
```

You can also refresh multiple providers:

```
POST /api/providers

{
  "action" : "refresh",
  "resources" : [
    { "href" : "http://localhost:3000/api/providers/:id" },
    { "href" : "http://localhost:3000/api/providers/:id" }
  ]
}
```

Import Vm to Provider

Importing a VM into a provider is supported via the *import_vm* action.

This is currently supported for importing a Vm from a VMware vCenter provider into a Red Hat Virtualization provider.

```
POST /api/providers/:id

{
  "action" : "import_vm"
  "resource" : {
    "source" : { "href" : "http://localhost:3000/api/vms/11" },
    "target" : {
      "name"       : "new_vm_name",
      "cluster"    : { "href" : "http://localhost:3000/api/clusters/201" },
      "data_store" : { "href" : "http://localhost:3000/api/data_stores/301" },
      "sparse"     : true
    }
  }
}
```

Foreman Support

Management of Foreman providers is provided as a seperate class of providers. This is still accessed via the **/api/providers** entry point, but enabled by a new parameter:

```
  GET|POST|DELETE /api/providers?provider_class=provider
```

The **provider_class** parameter is supported with **/api/provider** for all CRUD operations including the **refresh** action.

An example of creating a Foreman provider:

```
POST /api/providers?provider_class=provider

{
  "type"      : "ManageIQ::Providers::Foreman::Provider",
  "name"      : "new_foreman_111",
  "url"       : "100.200.300.111",
  "credentials" : {
    "userid"   : "foreman_admin",
    "password" : "foreman_password"
  }
}
```

When creating providers with provider_class as *provider*, the **type** attribute specifies the supported provider class names which include:

ManageIQ::Providers::AnsibleTower::Provider
ManageIQ::Providers::Foreman::Provider
ManageIQ::Providers::Openstack::Provider

Note:

When managing providers of *provider* provider_class, Tagging and Policy management does not currently apply. So requests including the tags, policies and policy_profiles subcollections will be rejected.

Provider Examples

Below you will find example requests for creating various providers.

Ansible Tower Automation Manager:

```
{
  "type": "ManageIQ::Providers::AnsibleTower::AutomationManager",
  "name": "API test",
  "api_version": "3.1.2",
  "provider_id": 10000000000012,
  "credentials": {
    "userid": "userid",
    "password": "password"
  }
}
```

AWS:

```
{
  "type": "ManageIQ::Providers::Amazon::CloudManager",
  "provider_region": "us-east-1",
  "name": "Amazon Example",
  "credentials": {
    "userid": "<access key id>",
    "password": "<secret access key>"
  }
}
```

Azure:

```
{
  "type": "ManageIQ::Providers::Azure::CloudManager",
  "name": "Azure Example",
  "provider_region": "eastus",
  "uid_ems": "<tenant_id>",
  "subscription": "<subscription_id>",
  "credentials": {
    "userid": "<client id>",
    "password": "<client key>"
  }
}
```

Kubernetes Container Manager:

```
{
  "type": "ManageIQ::Providers::Kubernetes::ContainerManager",
  "name": "Kubernetes Test",
  "connection_configurations": [
    {
      "endpoint": {
        "hostname": "00.0.00.00",
        "port": "6443",
        "security_protocol": "ssl"
      },
      "authentication": {
        "authtype": "bearer",
        "auth_key": "<token_here>"
      }
    }
  ]
}
```

Microsoft System Center VMM (SCVMM):

```
{
  "type": "ManageIQ::Providers::Microsoft::InfraManager",
  "name": "SCVMM API example",
  "api_version": "2.1.0",
  "connection_configurations": [
    {
      "endpoint": {
        "hostname": "00.0.00.00",
        "port": "443",
        "security_protocol": "ssl"
      },
      "authentication": {
        "username": "username",
        "password": "password"
      }
    }
  ]
}
```

OpenShift Container Manager:

```
{
   "name":"ocp-example",
   "port":8443,
   "type":"ManageIQ::Providers::Openshift::ContainerManager",
   "hostname":"ocp.example.com",
   "connection_configurations":[
      {
         "endpoint":{
            "role":"default",
            "security_protocol":"ssl-without-validation",
            "verify_ssl":0
         },
         "authentication":{
            "authtype":"bearer",
            "type":"AuthToken",
            "auth_key":"<auth key>"
         }
      }
   ]
}
```

OpenStack Cloud Manager:

```
{
  "type": "ManageIQ::Providers::Openstack::CloudManager",
  "name": "API Example",
  "api_version": "v2",
  "connection_configurations": [
    {
      "endpoint": {
        "role": "default",
        "hostname": "00.0.00.001",
        "port": "5000",
        "security_protocol": "non-ssl"
      },
      "authentication": {
        "type": "ManageIQ::Providers::Openstack::CloudManager::AuthKeyPair",
        "fingerprint": "fingerprint"
      }
    }
  ]
}
```

OpenStack Infra Manager:

```
{
  "type": "ManageIQ::Providers::Openstack::InfraManager",
  "name": "OSP API example",
  "api_version": "v2",
  "connection_configurations": [
    {
      "endpoint": {
        "hostname": "00.0.00.00",
        "port": "5000",
        "security_protocol": "non-ssl"
      },
      "authentications": {
        "username": "username",
        "password": "password"
      }
    }
  ]
}
```

Red Hat Virtualization Manager:

```
{
  "type": "ManageIQ::Providers::Redhat::InfraManager",
  "name": "Sample Rhevm",
  "port": 5000,
  "hostname": "sample_rhevm.provider.com",
  "ipaddress": "100.200.300.4",
  "security_protocol": "kerberos",
  "certificate_authority": "----BEGIN CERTIFICATE----...",
  "credentials": {
    "userid": "uname",
    "password": "password"
  }
}
```

VMware Infra Manager:

```
{
  "type": "ManageIQ::Providers::Vmware::InfraManager",
  "name": "Sample VMWare provider",
  "hostname": "sample_vmware.provider.com",
  "ipaddress": "100.200.300.1",
  "credentials": {
    "userid": "uname",
    "password": "pword"
  }
}
```

VMware Cloud Manager:

```
{
  "type": "ManageIQ::Providers::Vmware::CloudManager",
  "api_version": "9.0",
  "name": "Api Test",
  "connection_configurations": [
    {
      "endpoint": {
        "port": "443",
        "hostname": "00.0.00.000"
      },
      "authentication": {
        "username": "username",
        "password": "pword"
      }
    }
  ]
}
```

- Provision Requests

  - Response:
- Editing Request Tasks

Provision Requests

Provisioning requests are made available via the following entrypoint.

`/api/provision_requests`

- Creating Requests
- Editing Requests
- Approving or Denying Requests
- Monitoring Requests
- Editing Request Tasks

Creating Requests

Either by specifying a *create* action or by posting the request directly to **/api/provision_requests**.

As an example:

```
{
  "version" : "1.1",
  "template_fields" : {
    "guid" : "afe6e8a0-89fd-11e3-b6ac-b8e85646e742"
  },
  "vm_fields" : {
    "number_of_cpus" : 1,
    "vm_name" : "aab_test_vm1",
    "vm_memory" : "1024",
    "vlan" : "nic1"
  },
  "requester" : {
    "user_name" : "jdoe",
    "owner_first_name" : "John",
    "owner_last_name" : "Doe",
    "owner_email" : "jdoe@sample.com",
    "auto_approve" : true
  },
  "tags" : {
    "network_location" : "Internal",
    "cc" : "001"
  },
  "additional_values" : {
    "request_id" : "1001"
  },
  "ems_custom_attributes" : { },
  "miq_custom_attributes" : { }
}
```

Provision Requests Attribute Groups

Attribute Group	Type	Description
version	string	Interface version. Defaults to 1.1
template_fields	hash	Fields used to find template virtual machine. Provide any or all fields. Supply a guid or ems_guid to protect against matching same-named templates on different Providers within the appliance. Supported fields are: name=[VM Template Name] Example: template_1 guid=[guid value from vms resource] ems_guid=[uid_ems value from vms resource]
vm_fields	hash	Allows for the setting of properties on the Catalog, Hardware, Network, Customize, and Schedule tabs in the Provisioning dialog
requester	hash	Allows for the setting of properties on the Requester tab in the Provisioning dialog
tags	hash	Tags to apply to newly created VM Example: network_location=Internal cc=001
additional_values	hash	Additional values are name-value pairs stored with a provision request, but not used by the core provisioning code. These values are usually referenced from automate methods for custom processing Example: Store a request_id from an external system so the system can be notified during the provisioning process

Attribute Group	Type	Description
ems_custom_attributes	hash	Custom attributes applied to the virtual machine through the Provider as part of provisioning
miq_custom_attributes	hash	Custom attributes applied to the virtual machine and stored in the database as part of provisioning

Editing Requests

Updating provision requests can be performed by posting an *edit* action as follows:

```
POST /api/provision_requests/11
```

```
{
  "action" : "edit",
  "resource" : {
    "options" : {
      "custom_var1" : "custom value1"
    }
  }
}
```

Response:

```
{
  "href": "http://localhost:3000/api/provision_requests/11",
  "id": "11",
  "description": "Provision from [template1] to [###]",
  "approval_state": "pending_approval",
  "type": "MiqProvisionRequest",
  "created_on": "2015-04-14T17:36:30Z",
  "updated_on": "2015-04-14T18:32:30Z",
  "requester_id": "88913",
  "requester_name": "API User",
  "request_type": "template",
  "request_state": "pending",
  "message": "VM Provisioning - Request Created",
  "status": "Ok"
  "options": {
    "use_pre_dialog": false,
    "request_type": "template",
    "miq_request_dialog_name": "miq_provision_dialogs",
    "src_vm_id": [
      109996,
      "template1"
    ],
    "src_vm_nics": [],
    "src_vm_lans": [],
    "src_ems_id": [
      59136,
      "ems_0000000000002"
    ],
    "placement_auto": [
      true,
      1
    ],
    "vm_tags": [],
    "ws_values": {
    },
    "ws_ems_custom_attributes": {
    },
    "ws_miq_custom_attributes": {
    },
    "tags": {
    }
    "userid": "admin",
    "source_id": "109996",
    "source_type": "VmOrTemplate",
    "custom_var1" : "custom value1"
  }
}
```

Approving or Denying Requests

If a provision is not auto approved, it can be approved or denied via the actions *approve* and *deny* on the provision request resource.

Approving a Request

```
POST /api/provision_requests/:id
```

```
{
  "action" : "approve",
  "reason" : "reason for approval"
}
```

Denying a Request

```
POST /api/provision_requests/:id
```

```
{
  "action" : "deny",
  "reason" : "reason for denial"
}
```

Monitoring Requests

Once a provision request is created, the response result will include the queryable provision request itself, i.e. **/api/provision_requests/:id**

Response:

```
{
  "results": [
    {
      "id": "3068",
      "description": "Provision from [template1] to [###]",
      "approval_state": "pending_approval",
      "type": "MiqProvisionRequest",
      "created_on": "2015-04-14T17:36:30Z",
      "updated_on": "2015-04-14T17:36:30Z",
      "requester_id": "88913",
      "requester_name": "API User",
      "request_type": "template",
      "request_state": "pending",
      "message": "VM Provisioning - Request Created",
      "status": "Ok"
      "options": {
        "use_pre_dialog": false,
        "request_type": "template",
        "miq_request_dialog_name": "miq_provision_dialogs",
        "src_vm_id": [
          109996,
          "template1"
        ],
        "src_vm_nics": [],
        "src_vm_lans": [],
        "src_ems_id": [
          59136,
          "ems_0000000000002"
        ],
        "placement_auto": [
          true,
          1
        ],
        "vm_tags": [],
        "ws_values": {
        },
        "ws_ems_custom_attributes": {
        },
        "ws_miq_custom_attributes": {
        },
        "tags": {
        }
      },
      "userid": "admin",
      "source_id": "109996",
      "source_type": "VmOrTemplate"
    }
  ]
}
```

In the above example, the request could be queried periodically until the **request_state** reaches the **finished** state. Specifically,

```
GET /api/provision_requests/3068
```

Note:

The requests tasks of a provisioning request can also be queried by expanding the request_tasks subcollection as follows:

```
GET /api/provision_requests/:id?expand=request_tasks
```

or by fetching them directly as follows:

```
GET /api/provision_requests/:id/request_tasks?expand=resources
```

Editing Request Tasks

Request tasks for Provision Requests can be updated as follows:

```
POST /api/provision_requests/:id/request_tasks/:request_task_id
```

```
{
  "action" : "edit",
  "resource" : {
    "options" : {
      "request_param_a" : "value_a",
      "request_param_b" : "value_b"
    }
  }
}
```

For a list of attributes available for the provision request attribute groups please refer to the Provision Request Supported Attributes in the appendices section.

- Request Support

    - Denying a Request
  - Request Types

Request Support

Support for Requests in the API is provided and implemented by specific request types as listed here:

API Collection	Request Type
/api/automation_requests	Automation Requests
/api/provision_requests	Provision Requests
/api/service_requests	Service Requests

A lower level support for creating and updating requests is also provided by the following:

`/api/requests`

- Creating Requests
- Querying Requests
- Editing Requests
- Approving or Denying Requests
- Request Types

Creating Requests

Either by specifying a *create* action or by posting the request directly to **/api/requests**.

As an example:

```
POST /api/requests

{
  "options" : {
    "request_type" : "service_reconfigure",
    "src_id" : "4",
    "service_param1" : "updated_value1",
    "service_param2" : "updated_value2"
  },
  "requester" : {
    "user_name" : "admin"
  },
  "auto_approve" : true | false
}
```

Response:

```
{
  "results": [
    {
      "id": "97",
      "description": "Service Reconfigure for: svc4",
      "approval_state": "pending_approval",
      "type": "ServiceReconfigureRequest",
      "created_on": "2016-11-10T21:39:08Z",
      "updated_on": "2016-11-10T21:39:08Z",
      "requester_id": "1",
      "requester_name": "Administrator",
      "request_type": "service_reconfigure",
      "request_state": "pending",
      "message": "Service Reconfigure - Request Created",
      "status": "Ok",
      "options": {
        "request_type": "service_reconfigure",
        "src_id": "4",
        "service_param1": "updated_value1",
        "service_param2": "updated_value2"
      },
      "userid": "admin",
      "source_id": "4",
      "source_type": "Service",
      "tenant_id": "1",
      "process": true
    }
  ]
}
```

Querying Requests

Once a request is created, the response result as shown above will include the id of request itself.

In the above example, the request could be queried periodically until the **request_state** reaches the **finished** state.

```
GET /api/requests/97
```

NOTE: The requests tasks of a request can also be queried by expanding the request_tasks subcollection:

```
GET /api/requests/:id?expand=request_tasks
```

Editing Requests

Updating requests is provided by specifying an *edit* action as follows:

```
POST /api/requests/97

{
  "action" : "edit",
  "resource" : {
    "options" : {
      "service_param1" : "new_updated_value1",
      "service_param2" : "new_updated_value2"
    },
    "requester" : {
      "user_name" : "admin"
    }
  }
}
```

Response:

```
{
  "href": "http://localhost:3000/api/requests/97",
  "id": "97",
  "options": {
    "request_type": "service_reconfigure",
    "src_id": "4",
    "service_param1": "new_updated_value1",
    "service_param2": "new_updated_value2"
  },
  "description": "Service Reconfigure for: svc3",
  "approval_state": "pending_approval",
  "type": "ServiceReconfigureRequest",
  "created_on": "2016-11-10T21:39:08Z",
  "updated_on": "2016-11-10T22:11:03Z",
  "requester_id": "1",
  "requester_name": "Administrator",
  "request_type": "service_reconfigure",
  "request_state": "pending",
  "message": "Service Reconfigure - Request Created",
  "status": "Ok",
  "userid": "admin",
  "source_id": "4",
  "source_type": "Service",
  "tenant_id": "1",
  "process": true
}
```

Approving or Denying Requests

If a request is not auto approved, it can be approved or denied via the actions *approve* and *deny* on the request resource.

Approving a Request

```
POST /api/requests/:id

{
  "action" : "approve",
  "reason" : "reason for approval"
}
```

Denying a Request

```
POST /api/requests/:id

{
  "action" : "deny",
  "reason" : "reason for denial"
}
```

Request Types

The details for creating each type of request using the lower level API, including validation of *request_type* and necessary options is driven by the model.

The basic structure for creating the request is as follows:

```
{
  "options" : {
    "request_type" : "...",
    ...
  },
  "requester" : {
    "user_name" : "..."
  },
  "auto_approve" : true | false
}
```

The list of supported *request_type* values as of this writing is shown here below:

request_type	Description
automation	Automation
clone_to_service	Service Provision
clone_to_template	VM Publish
clone_to_vm	VM Clone
host_pxe_install	Host Provision
provision_via_foreman	Foreman Provision
service_reconfigure	Service Reconfigure
template	VM Provision
vm_migrate	VM Migrate
vm_reconfigure	VM Reconfigure

Reports Support

Support for querying, importing and running Reports is now available. Access to reports and report results is through the following collections:

`/api/reports`

`/api/results`

- Querying Reports
- Running Reports
- Scheduling Reports
- Requesting Report Result Downloads
- Importing Reports

Querying Reports

Querying Available Reports

`GET /api/reports`

Querying a Single Report

`GET /api/reports/:id`

Querying Results of a Particular Reports

`GET /api/reports/:id/results`

Optionally, expanding all results

`GET /api/reports/:id/results?expand=resources`

Querying a single result of a report

`GET /api/reports/:id/results/:result_id`

Querying report results

```
GET /api/results
```

Running Reports

Running reports is done via the **run** action on a report resource as follows:

```
POST /api/reports/:id

{
  "action" : "run"
}
```

Example for running a report on the following:

```
{
  "href": "http://localhost:3000/api/reports/80",
  "id": "80",
  "name": "VM Relationships"
}
```

Request:

```
POST /api/reports/80

{
  "action" : "run"
}
```

Response:

```
{
  "success": true,
  "message": "running report 80",
  "href": "http://localhost:3000/api/reports/80",
  "result_id": "27",
  "result_href": "http://localhost:3000/api/results/27",
  "task_id": "726",
  "task_href": "http://localhost:3000/api/tasks/726"
}
```

The report run's task can be queried periodically via the task_href specified above as follows:

```
GET /api/tasks/726

{
  "href": "http://localhost:3000/api/tasks/726",
  "id": "726",
  "name": "Generate Report: 'VM Relationships'",
  "state": "Queued",
  "status": "Ok",
  "message": "Task has been queued",
  "userid": "system",
  "created_on": "2015-11-09T18:44:41Z",
  "updated_on": "2015-11-09T18:44:41Z"
}

{
  "href": "http://localhost:3000/api/tasks/726",
  "id": "726",
  "name": "Generate Report: 'VM Relationships'",
  "state": "Finished",
  "status": "Ok",
  "message": "Generating report complete",
  "userid": "system",
  "created_on": "2015-11-09T18:44:41Z",
  "updated_on": "2015-11-09T18:47:13Z"
}
```

With the results queried via the result_href provided above:

```
GET /api/results/27

{
  "href": "http://localhost:3000/api/results/27",
  "id": "27",
  "name": "VM Relationships",
  "miq_report_id": "80",
  "miq_task_id": "726",
  "userid": "system",
  "report_source": "Requested by user",
  "db": "Vm",
  "report": {
    "name": "VM Relationships",
    "title": "VM Relationships",
    "rpt_group": "Relationships - Virtual Machines, Folders, Clusters",
    "rpt_type": "Default",
    "priority": 10,
    "db": "Vm",
```

```
    "cols": [
      "name",
      "v_owning_datacenter",
      "v_owning_folder",
      "v_owning_resource_pool"
    ],
    "include": {
      "ext_management_system": {
        "columns": [
          "name"
        ]
      },
      "host": {
        "columns": [
          "v_owning_cluster",
          "hostname"
        ]
      },
      "storage": {
        "columns": [
          "name"
        ]
      }
    },
    "col_order": [
      "name",
      "ext_management_system.name",
      "v_owning_datacenter",

      "Resource Pool",
      "Datastore"
    ],
    "conditions": {
      "exp": {
        "IS NOT EMPTY": {
          "field": "Vm.host-name"
        }
      },
      "col_details": {
        "Vm.host-name": {
          "data_type": "string",
          "virtual_reflection": false,
          "virtual_column": false,
          "excluded_by_preprocess_options": false,
          "tag": false,
          "include": {
            "host": {
            }
          },
          "format_sub_type": "string"
        }
      },
      "pexp": {
        "IS NOT EMPTY": {
          "field": "Vm.host-name"
        }
      },
      "ruby": "<value ref=vm, type=string>/virtual/host/name</value> != \"\""
    },
    "order": "Ascending",
    "sortby": [
      "name"
    ],
    "filename": "450_Relationships - Virtual Machines, Folders, Clusters/010_VMs Relationships.yaml",
    "file_mtime": "2015-08-19T13:23:50Z",
    "template_type": "report",
    "col_formats": [

    ],
    "rpt_options": {
    },
    "extras": {
      "total_html_rows": 1709
    },
    "user_categories": [

    ],
    "trend_data": {
    }
```

```
  },
  "created_on": "2015-11-09T18:52:48Z",
  "last_run_on": "2015-11-09T18:52:56Z",
  "last_accessed_on": "2015-11-09T18:52:56Z",
  "result_set": [
    {
      "name": "aab-vm1",
      "v_owning_datacenter": "",
      "v_owning_folder": "",
      "v_owning_resource_pool": "",
      "host.v_owning_cluster": "",
      "host.hostname": "test-host.testdomain.com",
      "storage.name": "StarStorage1"
      "id": "320"
    },
    {
      "name": "aab_demo_vm",
      "v_owning_datacenter": "",
      "v_owning_folder": "",
      "v_owning_resource_pool": "",
      "host.v_owning_cluster": "",
      "host.hostname": "test-host2.testdomain.com",
      "storage.name": "StarStorage2",
      "id": "1"
    },
    ...
  ]
}
```

Note that one can query all the results run for a report as follows:

```
GET /api/reports/80/results?expand=resources&attributes=created_on
```

```
{
  "name": "results",
  "count": 27,
  "subcount": 2,
  "resources": [
    {
      "href": "http://localhost:3000/api/reports/80/results/27",
      "id": "27",
      "created_on": "2015-11-09T18:52:48Z"
    },
    {
      "href": "http://localhost:3000/api/reports/80/results/13",
      "id": "13",
      "created_on": "2015-07-29T18:24:35Z"
    }
  ]
}
```

Scheduling Reports

Scheduling a report is done via the **schedule** action on a report resource as follows

```
POST /api/reports/:id
```

```
{
  "action" : "schedule"
  "resource": {
    "send_email": true|false,
    "start_date": DateTime,
    "time_zone":  TZ,
    "interval": {
      "unit":  "minutely"|"hourly"|"daily"|"weekly"|"monthly"|"once",
      "value": "once"
    },
    ...
  }
}
```

Example: “One off” report

Request

```
POST /api/reports/5
```

```
{
  "action": "schedule",
  "resource": {
    "name":        "Chargeback Report Schedule - 2000/01/01",
    "description": "Chargeback Report 2000 New Year Report",
    "resource_type": "MiqReport",
    "start_date": "2000-01-01T00:00:00Z",
    "time_zone": "UTC",
    "interval": { "unit": "once" },
    "enabled": true
  }
}
```

Response

```
{
  "success":       true,
  "message":       "scheduling of report 5",
  "schedule_id":   "10",
  "schedule_href": "http://localhost:3000/api/reports/5/schedules/10",
  "href":          "http://localhost:3000/api/reports/5"
}
```

Requesting Report Result Downloads

Requesting a **txt**, **csv** or **pdf** download of the report results can be done via the **request_download** action requiring the desired *result_type* as follows:

Request:

```
POST /api/results/22

{
  "action" : "request_download",
  "result_type" : "csv"
}
```

This triggers an async request of the report and returns an action response as follows:

Response:

```
{
  "success": true,
  "message": "Requesting a download of a csv report for Result id:22 name:VMware VM Summary",
  "task_id": "46",
  "task_href": "http://localhost:3000/api/tasks/46",
  "task_results_href": "http://localhost:3000/api/tasks/46/task_results"
}
```

The task can simply be queried for a *Finished* state and the results then fetched via the *task_results_href* provided above.

Querying for the task completion:

```
GET /api/tasks/46

{
  "href": "http://localhost:3000/api/tasks/46",
  "id": "46",
  "name": "Generate Report result [csv]: 'VMware VM Summary'",
  "state": "Finished",
  "status": "Ok",
  "message": "Generate Report result [csv]",
  "userid": "admin",
  "created_on": "2020-05-06T17:15:29Z",
  "updated_on": "2020-05-06T17:15:30Z",
  "pct_complete": null,
  "context_data": {
    "result_id": "22",
    "result_type": "csv",
    "session_id": "1cae5e9c-9b3e-4ee1-a286-bc2a0131233d-7f4bc905"
  },
  "results": null,
  "miq_server_id": "3",
  "identifier": null,
  "started_on": "2020-05-06T17:15:30Z",
  "zone": null,
  "actions": [
    {
      "name": "delete",
      "method": "post",
      "href": "http://localhost:3000/api/tasks/46"
    },
    {
      "name": "delete",
      "method": "delete",
      "href": "http://localhost:3000/api/tasks/46"
    }
  ]
}
```

And the results can be fetched as follows:

```
GET /api/tasks/46/task_results
```

This will return the report with the appropriately typed **Content-Type**, *application/txt*, *application/csv*, or *application/pdf* as per the requested download.

With a **request_download** action targeted at the collection level, one can also request the download for multiple report results as follows:

```
POST /api/results

{
  "action" : "request_download",
  "resources" : [
```

```
      { "id" : "15", "result_type" : "txt" },
      { "id" : "17", "result_type" : "txt" },
      { "id" : "22", "result_type" : "csv" }
   ]
}
```

```
{
  "results" : [
    {
      "success": true,
      "message": "Requesting a download of a txt report for Result id:15 name:VMware VM Summary",
      "task_id": "54",
      "task_href": "http://localhost:3000/api/tasks/54",
      "task_results_href": "http://localhost:3000/api/tasks/54/task_results"
    },
    {
      "success": true,
      "message": "Requesting a download of a txt report for Result id:17 name:VMware VM Summary",
      "task_id": "55",
      "task_href": "http://localhost:3000/api/tasks/55",
      "task_results_href": "http://localhost:3000/api/tasks/55/task_results"
    },
    {
      "success": true,
      "message": "Requesting a download of a txt report for Result id:22 name:VMware VM Summary",
      "task_id": "56",
      "task_href": "http://localhost:3000/api/tasks/56",
      "task_results_href": "http://localhost:3000/api/tasks/56/task_results"
    }
  ]
}
```

Each can then be individually queried and downloaded upon completion.

Importing Reports

Importing reports to the system can be done by posting an **import** action to the reports collection as follows:

```
POST /api/reports
```

```
{
  "action" : "import",
  "resource" : {
    "report" : { JSON serialized report },
    "options" : { "save" : true }
  }
}
```

Here's an example:

Request:

```
POST /api/reports
```

```
{
  "action" : "import",
  "resource" : {
    "report" : {
      "menu_name" : "Test Report",
      "col_order" : ["col1", "col2", "col3"],
      "cols"      : ["col1", "col2", "col3"],
      "rpt_type"  : "Custom",
      "title"     : "Test Report",
      "db"        : "My::Db",
      "rpt_group" : "Custom"
    },
    "options" : { "save" : true }
  }
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Imported Report: [Test Report]",
      "result": {
        "id": "199",
        "name": "Test Report",
        "title": "Test Report",
        "rpt_group": "Custom",
        "rpt_type": "Custom",
        "db": "My::Db",
        "cols": [
          "col1",
          "col2",
          "co3l"
        ],
        "col_order": [
```

```
          "col1",
          "col2",
          "col3"
        ],
        "created_on": "2015-11-09T19:44:37Z",
        "updated_on": "2015-11-09T19:44:37Z",
        "miq_group_id": "1",
        "user_id": "1"
      }
    }
  ]
}
```

- Role Management
  - Querying Roles
  - Creating Roles
  - Editing Roles
    - Assigning features to a role
    - Unassigning features from a role
  - Deleting Roles

Role Management

Management of User Roles is provided via the following collection:

`/api/roles`

as well as the associated product features via:

`/api/features`

Full CRUD actions on roles is available:

- Querying Roles
- Creating Roles
- Editing Roles
- Deleting Roles

Querying Roles

Querying all roles in the system is simply:

`GET /api/roles`

Getting details on a specific role:

`GET /api/roles/:id`

Including the features it entitles:

`GET /api/roles/:id?expand=features`

Or simply querying the features entitled by the role:

`GET /api/roles/:id/features?expand=resources`

Querying all product features of the system that can be assigned to a role.

`GET /api/features`

Creating Roles

Roles can be created via a POST to the roles collection or via the **create** action signature which also allows creation of multiple roles in a single request.

`POST /api/roles`

```
{
  "action" : "create",
  "resource" : {
    "name" : "sample_role",
    "settings" : { "restrictions" : { "vms" : "user" } },
    "features" : [
      { "identifier" : "vm_explorer" },
      { "identifier" : "ems_infra_tag" },
      { "identifier" : "miq_report_run" }
    ]
  }
}
```

Note:

restrictions for **vms** can be either *user* or *user_or_group*

features can be specified via **identifier**, **href**, or **id**

or creating multiple roles:

```
{
  "action" : "create",
  "resources" : [
    { "name" : "sample_role1", ... },
    { "name" : "sample_role2", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Roles.

Editing Roles

```
POST /api/roles/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "name" : "updated_sample_role",
    "settings" : { "restrictions" : { "vms" : "user_or_group" } }
  }
}
```

or editing multiple roles:

```
POST /api/roles
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/roles/101",
      "name" : "updated_sample_role1"
    },
    {
      "href" : "http://localhost:3000/api/roles/102",
      "name" : "updated_sample_role2"
    },
    ...
  ]
}
```

Assigning features to a role

```
POST /api/roles/:id/features
```

```
{
  "action" : "assign",
  "resource" : {
    "identifier" : "miq_request_view"
  }
}
```

or assigning multiple features:

```
{
  "action" : "assign",
  "resources" : [
    { "identifier" : "miq_request_view" },
    { "identifier" : "storage_manager_show_list" },
    ...
  ]
}
```

Unassigning features from a role

```
POST /api/roles/:id/features
```

```
{
  "action" : "unassign",
  "resource" : {
    { "identifier" : "miq_request_view" }
  }
}
```

or unassigning multiple features:

```
{
  "action" : "unassign",
  "resources" : [
    { "identifier" : "miq_request_view" },
    { "identifier" : "storage_manager_show_list" },
    ...
  ]
}
```

Deleting Roles

Non system roles (i.e. read_only false) can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/roles/101

{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/roles/101
```

Deleting multiple roles can be done as follows:

```
POST /api/roles

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/roles/101" },
    { "href" : "http://localhost:3000/api/roles/102" },
    ...
  ]
}
```

- Security Groups
  - Querying Security Groups
  - Managing Security Groups
  - Add Security Group
  - Remove Security Group

Security Groups

Management of Security Groups is available via the following collection:

```
/api/security_groups
```

Querying Security Groups

Querying all available Security Groups:

```
GET /api/security_groups
```

Getting details on a specific Security Group:

```
GET /api/security_groups/:id
```

Querying the Security Groups of a specific resource is also possible for the following collections:

Collection
/api/cloud_tenants
/api/instances
/api/providers
/api/vms

```
GET /api/cloud_tenants/:id/security_groups
GET /api/cloud_tenants/:id/security_groups/:security_group_id

GET /api/instances/:id/security_groups
GET /api/instances/:id/security_groups/:security_group_id

GET /api/providers/:id/security_groups
GET /api/providers/:id/security_groups/:security_group_id

GET /api/vms/:id/security_groups
GET /api/vms/:id/security_groups/:security_group_id
```

Managing Security Groups

Management of Security Groups is available for Instances with the following actions:

Action	Description
add	Add security group(s) to the Instance
remove	Remove security group(s) from the Instance

Add Security Group

Security Groups can be added to Instances individually:

```
POST /api/instances/:id/security_groups

{
  "action" : "add",
```

```
  "resource" : {
    "name" : "security_group_a"
  }
}
```

Or in bulk as follows:

```
{
  "action" : "add",
  "resources" : [
    { "name" : "security_group_a" },
    { "name" : "security_group_b" }
  ]
}
```

Remove Security Group

Security groups can be removed from Instances individually:

```
POST /api/instances/:id/security_groups
```

```
{
  "action" : "remove",
  "resource" : {
    "name" : "security_group_c"
  }
}
```

Or in bulk as follows:

```
{
  "action" : "remove",
  "resources" : [
    { "name" : "security_group_d" },
    { "name" : "security_group_e" },
    { "name" : "security_group_f" }
  ]
}
```

Service Management

Service management is provided via the following collections:

Path	Description
/api/service_catalogs	Service Catalogs
/api/service_templates	Service Templates
/api/services	Services
/api/service_requests	Service Requests

Service Catalogs

Full CRUD is available on service catalogs.

- Creating Service Catalogs
- Editing Service Catalogs
- Assigning/Unassigning Service Templates from Service Catalogs
- Ordering Services
- Refresh Service Dialog Fields
- Deleting Service Catalogs

Creating Service Catalogs

`/api/service_catalogs`

Creating service catalog is provided via the following actions:

Method	Versions	Comment
create	2.0.0	Preferred
add	since v1.0	

Example of creating service catalog with *create* method:

```
POST /api/service_catalogs
```

```
{
   "action" : "create",
   "resource" : {
     "name" : "Sample Service Catalog",
     "description" : "Description of Sample Service Catalog",
     "service_templates" : [
       { "href" : "http://localhost:3000/api/service_templates/3" },
       { "href" : "http://localhost:3000/api/service_templates/4" }
     ]
   }
}
```

Optionally without the create action signature:

```
{
  "name" : "Sample Service Catalog",
  "description" : "Description of Sample Service Catalog",
  "service_templates" : [
    { "href" : "http://localhost:3000/api/service_templates/3" },
    { "href" : "http://localhost:3000/api/service_templates/4" }
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Service Catalogs.

Editing Service Catalogs

Editing a service catalog via the *edit* action as follows:

```
POST /api/service_catalogs/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "description" : "Updated Description of Third Service Catalog"
   }
}
```

Assigning Service Templates

Assign and Unassigning service templates to service catalogs is done via the *assign* and *unassign* actions as follows:

```
POST /api/service_catalogs/:id
```

```
{
  "action" : "assign",
  "resources" : [
    { "href" : "http://localhost:3000/api/service_templates/5" },
```

```
    { "href" : "http://localhost:3000/api/service_templates/6" }
  ]
}
```

```
POST /api/service_catalogs/:id
```

```
{
  "action" : "unassign",
  "resources" : [
    { "href" : "http://localhost:3000/api/service_templates/1" },
    { "href" : "http://localhost:3000/api/service_templates/2" }
  ]
}
```

Ordering Services Service Templates

Ordering services is done by triggering an *order* action on service templates in a service catalog as follows:

```
POST /api/service_catalogs/:id/service_templates
```

```
{
  "action" : "order",
  "resource" : {
    "href" : "http://localhost:3000/api/service_templates/3",
    "option_0_vm_target_name" : "test-vm-0001",
    "option_0_vm_target_hostname" : "test-vm-0001"
  }
}
```

Note: If you need to include a password in the call to the Ordering Services, you can use the **`password::dialog_password`** field to supply the password as a parameter. This password is passed as a **`string`** datatype.

```
{
  "action" : "order",
  "resource" : {
    "href" : "http://localhost:3000/api/service_templates/3",
    "option_0_vm_target_name" : "test-vm-0001",
    "option_0_vm_target_hostname" : "test-vm-0001",
    "password::dialog_password" : "password"
  }
}
```

Refresh Service Dialog Fields

Refreshing dialog fields is done via a *refresh_dialog_fields* action as shown in the following cases:

Refresh Dialog Fields of Service Templates Service Dialogs

Refreshing dialog fields for a service template service dialogs is done as follows:

```
POST /api/service_catalogs/:id/service_templates
```

```
{
  "action" : "refresh_dialog_fields",
  "resource" : {
    "href" : "http://localhost:3000/api/service_templates/3",
    "dialog_fields" : {
      "my_field1" : "my field1 value",
      "my_field2" : "my field2 value",
      "my_field3" : "my field3 value",
      ...
    },
    "fields" : [ "my_field1", "my_field3" ]
  }
}
```

Refresh Dialog Fields of Service Dialogs

Refreshing dialog fields for a service dialog is done as follows:

```
POST /api/service_dialogs/:id
```

```
{
  "action" : "refresh_dialog_fields",
  "resource" : {
    "dialog_fields" : {
      "my_field1" : "my field1 value",
      "my_field2" : "my field2 value",
      "my_field3" : "my field3 value",
      ...
    },
    "fields" : [ "my_field1", "my_field3" ]
  }
}
```

Deleting Service Catalogs

Single service catalogs can simply be deleted via the DELETE method as follows:

```
DELETE /api/service_catalogs/:id
```

Multiple service catalogs can also be deleted with a single request as follows:

```
POST /api/service_catalogs
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/service_catalogs/11" },
    { "href" : "http://localhost:3000/api/service_catalogs/12" },
    { "href" : "http://localhost:3000/api/service_catalogs/13" }
  ]
}
```

Service Templates

Management of Service Templates is available via the following collection:

```
/api/service_templates
```

Full CRUD is available on service templates.

- Creating Service Templates
- Editing Service Templates
- Deleting Service Templates

Creating Service Templates

Service Templates can be created via a POST to the /api/service_templates collection:

```
/api/service_templates
```

```
{
  "name" : "Atomic Service Template",
  "service_type" : "atomic",
  "prov_type"    : "amazon",
  "display"      : "false",
  "config_info"  : {
    "miq_request_dialog_name" : "Dialog_Name",
    "placement_auto"          : [true, 1],
    "number_of_vms"           : [1, "1"],
    "src_vm_id"               : [11, "test_vm"],
    "vm_name"                 : "AtomicVMName",
    "schedule_type"           : ["immediately", "Immediately on Approval"],
    "instance_type"           : [21, "instance_flavor"],
    "src_ems_id"              : [5, "test_provider"],
    "provision"               : {
      "fqname"    : "/Sample/System/ProvisionEndpoint",
      "dialog_id" : "21"
    },
    "retirement"              : {
      "fqname"    : "/Sample/System/RetirementEndpoint",
      "dialog_id" : "22"
    }
  }
}
```

Editing Service Templates

Editing a single service template as follows:

```
POST /api/service_templates/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "name" : "svc_template_01",
    "description" : "This is a sample service template"
  }
}
```

Deleting Service Templates

Deleting single service template via the DELETE method:

```
DELETE /api/service_templates/:id
```

or via the *delete* action as follows:

```
POST /api/service_templates/:id
```

```
{
  "action" : "delete"
}
```

Multiple service templates can also be deleted in bulk as follows:

```
POST /api/service_templates
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/service_templates/11" },
    { "href" : "http://localhost:3000/api/service_templates/12" }
  ]
}
```

Services ===

Accessing services is via the **services** collection as follows:

```
/api/services
```

or addressing an individual Service via the **services** resource:

```
/api/services/:id
```

Creating Services ====

In general, services are created once ordered from service catalogs.

Service resources can also be created as follows:

```
POST /api/services
```

```
{
  "action" : "create",
  "resource" : {
    "name" : "test_service_name",
    "description" : "Test Service",
    "parent_service" : { "href" : "http://localhost:3000/api/services/15" }
  }
}
```

In the above example *parent_service* is an *href* or *id* reference to an existing service.

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Services.

Service Actions ====

Once services are ordered from a catalog, they can be:

- Edited (Basic)
- Retired now
- Retired in future
- Reconfigured
- Started
- Stopped
- Suspended
- Deleted

Additional Service actions include:

- Adding and Removing Resources from Services
- Adding Provider VMs to Services
- Requesting a Chargeback Report for a Service

Other than service creates and edits, service actions return the action response as in the following example:

Request:

```
POST /api/services/12
```

```
{
  "action" : "start"
}
```

Response:

```
{
  "success": true,
  "message": "Service id:12 name:'SampleService' starting",
  "task_id": "62",
  "task_href": "http://localhost:3000/api/tasks/62",
```

```
  "href": "http://localhost:3000/api/services/12"
}
```

Service Editing

```
POST /api/services/:id

{
   "action" : "edit",
   "resource" : {
     "name" : "Updated Service Name",
     "description" : "Updated Service Description"
   }
}
```

Adding and Removing Resources from Services

Adding and removing resources from services is made available with the following actions:

Action
add_resource
remove_resource
remove_all_resources

The following example adds a single resource to a service:

```
POST /api/services/:id

{
  "action" : "add_resource",
  "resource" : { "resource" : { "href" : "http://localhost:3000/api/vms/11" } }
}
```

The following example bulk adds resources to multiple services:

```
POST /api/services

{
   "action" : "add_resource",
   "resources" : [
      {
        "href" : "http://localhost:3000/api/services/3",
        "resource" : { "href" : "http://localhost:3000/api/vms/11" }
      },
      {
        "href" : "http://localhost:3000/api/services/3",
        "resource" : { "href" : "http://localhot:3000/api/vms/12" }
      },
      {
        "href" : "http://localhost:3000/api/services/4",
        "resource" : { "href" : "http://localhost:3000/api/vms/21" }
      },
      {
        "href" : "http://localhost:3000/api/services/5",
        "resource" : { "href" : "http://localhost:3000/api/vms/22" }
      }
   ]
}
```

The following example removes a single resource from a service:

```
POST /api/services/:id

{
  "action" : "remove_resource",
  "resource" : { "resource" : { "href" : "http://localhost:3000/api/vms/11" } }
}
```

The following example removes resources in bulk from multiple services:

```
POST /api/services

{
  "action" : "remove_resource",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/services/3",
      "resource" : { "href" : "http://localhost:3000/api/vms/11" }
    },
    {
      "href" : "http://localhost:3000/api/services/3",
      "resource" : { "href" : "http://localhot:3000/api/vms/12" }
    },
    {
      "href" : "http://localhost:3000/api/services/4",
      "resource" : { "href" : "http://localhost:3000/api/vms/21" }
    },
    {
      "href" : "http://localhost:3000/api/services/5",
      "resource" : { "href" : "http://localhost:3000/api/vms/22" }
```

```
    }
  ]
}
```

The following example removes all resources from a single service:

```
POST /api/services/:id

{
  "action" : "remove_all_resources"
}
```

The following example removes all resources in bulk from multiple services:

```
POST /api/services

{
  "action" : "remove_all_resources",
  "resources" : [
    { "href" : "http://localhost:3000/api/services/11" },
    { "href" : "http://localhost:3000/api/services/12" },
    { "href" : "http://localhost:3000/api/services/13" }
  ]
}
```

Adding Provider VMs to Services

For cases where VMs are created externally, i.e. via Ansible Playbooks, this action allows the system to identify the VMs created and link those VMs back to the service.

```
POST /api/services/:id

{
  "action" : "add_provider_vms",
  "resource" : {
    "provider" : { "href" : "http://localhot:3000/api/providers/11" }
    "uid_ems" : [
      "provider_vm_id1",
      "provider_vm_id2",
      ...
    ]
  }
}
```

Requesting a Chargeback Report for a Service

This action will request a chargeback report for the service.

```
POST /api/services/:id

{
  "action" : "queue_chargeback_report"
}
```

The queue_chargeback_report action will return an action response which includes the task reference as shown here:

```
{
  "success": true,
  "message": "Queued chargeback report generation for Service id:1 name:'test_service1'",
  "task_id": "39",
  "task_href": "http://localhost:3000/api/tasks/39"
}
```

The task_href can be queried and upon completion of the task, the chargeback report for the service can be queried as follows:

```
GET /api/services/:id?attributes=chargeback_report
```

Service Retiring (now)

```
POST /api/services/:id

{
  "action" : "request_retire"
}
```

Service Retiring (future)

```
POST /api/services/:id

{
  "action" : "request_retire",
  "resource" : { "date" : "10/30/2015", "warn" : "5" }
}
```

Service Reconfiguring

When a service is defined with a Reconfigure Automation Entrypoint, the *reconfigure* action is shown as a valid action for that service.

This action takes any of the dialog fields the service supports during reconfiguration.

```
POST /api/services/:id

{
  "action" : "reconfigure",
  "resource" : {
    "field1" : "updated field1 value",
    "field2" : "updated field2 value",
    ...
  }
}
```

Starting Services

```
POST /api/services/:id

{
  "action" : "start"
}
```

Stopping Services

```
POST /api/services/:id

{
  "action" : "stop"
}
```

Suspending Services

```
POST /api/services/:id

{
  "action" : "suspend"
}
```

Deleting Services

```
DELETE /api/services/:id
```

Or via the delete action for deleting multiple services:

```
POST /api/services

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/services/101",
    { "href" : "http://localhost:3000/api/services/102",
    { "href" : "http://localhost:3000/api/services/103"
    ...
  ]
}
```

Service Requests ===

- Querying Service Requests
- Approving or Denying Service Requests
- Adding Approvers to Service Requests
- Removing Approvers to Service Requests
- Editing Request Tasks

Querying Service Requests

Once services are ordered from a catalog, service requests can be monitored as follows:

```
GET /api/service_requests/:id
```

Note:

The request tasks of service requests can be queried by expanding the request_tasks as follows:

```
GET /api/service_requests/:id?expand=request_tasks
```

or by fetching them directly as follows:

```
GET /api/service_requests/:id/request_tasks?expand=resources
```

Approving or Denying Service Requests

If a service request is not auto approved, it can be approved or denied via the actions *approve* and *deny* on the service request resource.

Approving a Service Request

```
POST /api/service_requests/:id

{
  "action" : "approve",
  "reason" : "reason for approval"
}
```

Denying a Service Request

```
POST /api/service_requests/:id

{
  "action" : "deny",
  "reason" : "reason for denial"
}
```

Adding Approvers to Service Requests

Approvers can be added to service requests with the *add_approver* action. Approvers can be specified by *user_id* or *user* reference including an *href* or *id* of the approver.

```
POST /api/service_requests/:id

{
  "action" : "add_approver",
  "resource" : {
    "user_id" : 11
  }
}
```

Or one of the following signatures:

```
{
  "action" : "add_approver",
  "resource" : {
    "user" : { "id" : 11  }
  }
}

{
  "action" : "add_approver",
  "resource" : {
    "user" : { "href" : "http://localhost:3000/api/users/11" }
  }
}
```

Approvers can also be added in bulk as follows:

```
POST /api/service_requests

{
  "action" : "add_approver",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/service_requests/101",
      "user_id" : "11"
    },
    {
      "href" : "http://localhost:3000/api/service_requests/102",
      "user" : { "id" : 11 }
    },
    {
      "href" : "http://localhost:3000/api/service_requests/103",
      "user" : { "href" : "http://localhost:3000/api/users/11" }
    }
  ]
}
```

Removing Approvers from Service Requests

Approvers can be removed from service requests with the *remove_approver* action. Approvers can be specified by *user_id* or *user* reference including an *href* or *id* of the approver.

```
POST /api/service_requests/:id

{
  "action" : "remove_approver",
  "resource" : {
    "user_id" : "11"
  }
}
```

Approvers can also be removed in bulk as follows:

```
POST /api/service_requests

{
  "action" : "remove_approver",
  "resources" : [
    {
```

```
      "href" : "http://localhost:3000/api/service_requests/101",
      "user_id" : "11"
    },
    {
      "href" : "http://localhost:3000/api/service_requests/102",
      "user" : { "id" : "11" }
    },
    {
      "href" : "http://localhost:3000/api/service_requests/103",
      "user" : { "href" : "http://localhost:3000/api/users/11" }
    }
  ]
}
```

Editing Request Tasks

Request tasks of Service Requests can be updated as follows:

```
POST /api/service_requests/:id/request_tasks/:request_task_id
```

```
{
  "action" : "edit",
  "resource" : {
    "options" : {
      "request_param_a" : "value_a",
      "request_param_b" : "value_b"
    }
  }
}
```

- Service Queries
  - Querying Pictures pertaining to services
  - Querying Provision Dialogs on services and service requests
  - Querying Resource Actions
  - Querying Service and Provision Dialogs
  - Querying Service Dialogs
  - Querying Users that ordered services
  - Querying VMs of Services
  - Querying Orchestration Stacks of Services

Service Queries

Queries to services and related service dialogs are provided via the following collections:

Path	Description
/api/services	Services
/api/service_requests	Service Requests
/api/service_templates	Service Templates
/api/service_dialogs	Service Dialogs

- Querying Pictures
- Querying Provision Dialogs
- Querying Resource Actions
- Querying Service and Provision Dialogs
- Querying Service Dialogs
- Querying Users
- Querying VMs
- Querying Orchestration Stacks

Querying Pictures pertaining to services

Access to pictures for service related collections is made available with the *picture* virtual attribute and related *image_href* attribute.

Querying all resources:

```
GET /api/services?expand=resources&attributes=picture,picture.image_href
```

```
GET /api/service_requests?expand=resources&attributes=picture,picture.image_href
```

```
GET /api/service_templates?expand=resources&attributes=picture,picture.image_href
```

Querying specific resources:

```
GET /api/services/:id?attributes=picture,picture.image_href
```

```
GET /api/service_requests/:id?attributes=picture,picture.image_href
```

```
GET /api/service_templates/:id?attributes=picture,picture.image_href
```

Querying Provision Dialogs on services and service requests

Querying provision dialogs on ordered services and related service_requests is provided by the *provision_dialog* virtual attribute:

```
GET /api/services/:id?attributes=provision_dialog

GET /api/service_requests/:id?attributes=provision_dialog
```

Querying Resource Actions

Querying resource_actions is provided as a subcollection of service_templates as follows:

```
GET /api/service_templates/:id/resource_actions
```

This allows queries like:

```
GET /api/service_templates/:id/resource_actions
GET /api/service_templates/:id/resource_actions/:resource_action_id
GET /api/service_templates/:id/resource_actions?expand=resources
GET /api/service_templates/:id/resource_actions?expand=resources&filter[]=action='Provision'
```

Querying Service and Provision Dialogs

Access to service and provision dialogs is provided by the primary collections:

/api/service_dialogs
/api/provision_dialogs

Querying Service Dialogs

Service dialogs can be queried directly from the primary collection:

```
GET /api/service_dialogs
GET /api/service_dialogs/:id
GET /api/service_dialogs/:id?resource_action_id=:ra_id
                           &target_id=:target_id
                           &target_type=:target_type
```

Note:

Above :target_type would be a valid resource type containing the service dialog like *service_template* or *service*.

Or from the Service Template where they are defined and from the related ordered services as follows:

```
GET /api/service_templates/:id/service_dialogs
GET /api/service_templates/:id/service_dialogs/:service_dialog_id

GET /api/services/:id/service_dialogs
GET /api/services/:id/service_dialogs/:service_dialog_id
```

Querying Users that ordered services

This is made available via the *user* virtual attribute which reflect the user object.

```
GET /api/services/:id?attributes=user

GET /api/service_requests/:id?attributes=user
```

Optionally, specific user attribute can also be queried as follows:

```
GET /api/services/:id?attributes=user.name,user.email
GET /api/services/:id?attributes=user.name,user.email
```

Querying VMs of Services

This is made available via the *vms* subcollection of services as follows:

```
GET /api/services/:id/vms

GET /api/services/:id?expand=vms
```

It is also possible to fetch additional attributes for the vms of a service all within the same request by using the *vms.* prefix in the attributes specification as follows:

```
GET /api/services/:id?expand=vms&attributes=vms.num_cpu
```

Accessing decorators for VM resources is also made available here as follows:

```
GET /api/services/:id?expand=vms
                     &attributes=vms.num_cpu
                     &decorators=vms.supports_console?,vms.supports_cockpit?,vms.supports_vnc_console?
```

Querying Orchestration Stacks of Services

This is made available via the *orchestration_stacks* subcollection of services as follows:

```
GET /api/services/:id/orchestration_stacks
```

Fetching the orchestration stacks in addition to the service as follows:

```
GET /api/services/:id?expand=orchestration_stacks
```

Accessing a specific orchestration stack of a service as follows:

```
GET /api/services/:id/orchestration_stacks/:orchestration_stack_id
```

    - Response:

Service Custom Actions

With button groups, custom buttons and related dialogs defined on Service Templates, the REST API provides visibility to custom buttons on service templates and related ordered services.

This is made available with the *custom_actions* and *custom_action_buttons* virtual attributes on service_templates and services.

- *custom_actions* returns the custom buttons as layed out in the UI on the service. The information returned includes any Resource Actions and related Dialogs for the custom button.
- *custom_action_buttons* returns the array of custom buttons without the custom button groups hierarchy or details on related dialogs.

Fetching custom actions and custom action buttons for a service_template or a deployed service

```
GET /api/service_templates/:id?attributes=custom_actions,custom_action_buttons
```

```
GET /api/services/:id?attributes=custom_actions,custom_action_buttons
```

Example Service Template with custom buttons:

Request:

```
GET /api/service_templates/7?attributes=custom_actions,custom_action_buttons
```

Response:

```

      "name": "Simulate",
      "visibility": {
        "roles": [
          "_ALL_"
        ]
      },
      "applies_to_id": "7"
    }
  }
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "http://localhost:3000/api/service_templates/7"
    },
    {
      "name": "delete",
      "method": "delete",
      "href": "http://localhost:3000/api/service_templates/7"
    }
  ]
}
```

When service templates define custom buttons, the ordered services are extended with custom actions which can be triggered via a POST action.

Note that the custom actions are exposed as actions on the deployed services, not the service_templates. The action name to trigger the action is the lower-cased name of the custom button.

As an example, here's a service without custom buttons:

```
{
  "href": "http://localhost:3000/api/services/91",
  "id": "91",
  "name": "new_service_91",
  "description": "This is a description for the new service 91",
  ...
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "http://localhost:3000/api/services/91"
    },
    {
      "name": "request_retire",
      "method": "post",
      "href": "http://localhost:3000/api/services/91"
    },
    {
      "name": "delete",
      "method": "delete",
      "href": "http://localhost:3000/api/services/91"
    }
  ]
}
```

Here is an example of a service with custom buttons:

```
{
  "href": "http://localhost:3000/api/services/92",
  "id": "92",
  "name": "enhanced_service_92",
  "description": "This is a description for the enhanced service 92",
  "guid": "24c193a2-57c8-11e5-9332-000a27020067",
```

```
  "service_template_id": "7",
  "options": {
    "button_order": [
      "cb-1",
      "cb-2",
      "cb-3"
    ],
    "dialog": {
      "dialog_DynamicMemory": "t"
    }
  },
  "display": true,
  "created_at": "2015-09-10T14:28:02Z",
  "updated_at": "2015-09-10T14:28:02Z",
  "evm_owner_id": "1",
  "miq_group_id": "1",
  "actions": [
    {
      "name": "edit",
      "method": "post",
      "href": "http://localhost:3000/api/services/92"
    },
    {
      "name": "request_retire",
      "method": "post",
      "href": "http://localhost:3000/api/services/92"
    },
    {
      "name": "delete",

    },
    {
      "name": "ping",
      "method": "post",
      "href": "http://localhost:3000/api/services/92"
    },
    {
      "name": "simulate",
      "method": "post",
      "href": "http://localhost:3000/api/services/92"
    }
  ]
}
```

Here, the *rescan*, *ping* and *simulate* are custom buttons for the service and are returned after the common actions.

For example, to request the *rescan* custom action shown above, this is simply a POST action as follows:

Request:

```
POST /api/services/92

{
  "action" : "rescan"
}
```

Response:

Responses from custom action are the normal action responses from the REST API:

```
{
  "success": true,
  "message": "Invoked custom action rescan for services id: 92",
  "href": "http://localhost:3000/api/services/92"
}
```

- Service Dialogs
  - Creating Service Dialogs
  - Editing Service Dialogs
  - Copying Service Dialogs
  - Refreshing Dialog Fields of Service Dialogs
  - Deleting Service Dialogs

Service Dialogs

Management of Service Dialogs is provided via the collection:

```
/api/service_dialogs
```

The following actions are provided on service_dialogs resources:

- Creating Service Dialogs
- Editing Service Dialogs
- Copying Service Dialogs
- Refreshing Dialog Fields of Service Dialogs
- Deleting Service Dialogs

Creating Service Dialogs

Service Dialogs can be created via a POST to the *service_dialogs* collection or via the **create** action signature which also allows creation of multiple service_dialogs in a single request.

```
POST /api/service_dialogs

{
  "description" : "Dialog",
  "label" : "dialog_label",
  "dialog_tabs" : [
    {
      "description" : "Dialog Tab",
      "position"    : 0,
      "label"       : "dialog_tab_label",
      "dialog_groups" : [
        {
          "description" : "Dialog Group",
          "label"       : "group_label",
          "dialog_fields" : [
            {
              "name"  : "A Dialog Field",
              "label" : "dialog_field_label"
            }
          ]
        }
      ]
    }
  ]
}
```

or creating multiple Service Dialogs:

```
{
  "action" : "create",
  "resources" : [
    { "description" : "Dialog 1", "label" : "dialog_1_label", ... },
    { "description" : "Dialog 2", "label" : "dialog_2_label", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Service Dialogs.

Editing Service Dialogs

Service Dialogs can be updated via the *edit* action as follows:

```
POST /api/service_dialogs/:id

{
  "action" : "edit",
  "resource" : {
    "label" : "updated_label",
    "content" : {
      "dialog_tabs" : [
        "id" : "11",
        "label" : "updated_tab_label",
        "dialogs_groups" : [
          {
            "id" : "31",
            "dialog_fields" : [
               { "id" : "41" }
            ]
          }
        ]
      ]
    }
  }
}
```

or editing multiple Service Dialogs in a single request as follows:

```
POST /api/service_dialogs

{
  "action" : "edit",
  "resources" : [
```

```
    {
      "href" : "http://localhost:3000/api/service_dialogs/21",
      "label" : "updated_label_1",
      "content" : ...
    },
    {
      "href" : "http://localhost:3000/api/service_dialogs/22",
      "label" : "updated_label_2",
      "content" : ...
    },
    ...
  ]
}
```

Copying Service Dialogs

Service Dialogs can be copied to create new Service Dialogs via the *copy* action as follows:

```
POST /api/service_dialogs/:id

{
  "action" : "copy"
}
```

When a label is not specified, the new Service Dialog will be named **Copy of ...** the name of the Service Dialog being copied

Optionally, the label of the new Service Dialog can also be specified as follows:

```
{
  "action" : "copy"
  "resource" : {
    "label" : "test_service_dialog_label"
  }
}
```

Multiple Service Dialogs can also be copied in a single request as follows:

```
POST /api/service_dialogs

{
  "action" : "copy",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/service_dialogs/11",
      "label" : "test_service_dialog_label_1"
    },
    {
      "href" : "http://localhost:3000/api/service_dialogs/12",
      "label" : "test_service_dialog_label_2"
    },
    ...
  ]
}
```

Refreshing Dialog Fields of Service Dialogs

Refreshing dialog fields for a Service Dialog is done as follows:

```
POST /api/service_dialogs/:id

{
  "action" : "refresh_dialog_fields",
  "resource" : {
    "resource_action_id" : "6",
    "target_id" : "12",
    "target_type" : "service_template_ansible_tower",
    "dialog_fields" : {
      "my_field1" : "my field1 value",
      "my_field2" : "my field2 value",
      "my_field3" : "my field3 value",
      ...
    },
    "fields" : [ "my_field1", "my_field3" ]
  }
}
```

Deleting Service Dialogs

Deleting a Service Dialog can be done via the *delete* action as follows:

```
POST /api/service_dialogs/:id

{
  "action" : "delete"
}
```

or via the DELETE HTTP method as follows:

```
DELETE /api/service_dialogs/:id
```

One can also delete multiple Service Dialogs via the *delete* action on the collection with references to the service dialogs to delete as follows:

```
POST /api/service_dialogs
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/service_dialogs/101" },
    { "href" : "http://localhost:3000/api/service_dialogs/102" },
    { "href" : "http://localhost:3000/api/service_dialogs/103" },
    ...
  ]
}
```

- Service Orders

  - Deleting Service Orders
  - Ordering Service Orders

Service Orders

The service orders collection and actions are provided for managing Shopping Carts and their related service requests.

```
/api/service_orders
```

Available actions on service_orders instances include:

Action	Description
create	Creating the Shopping Cart
clear	Clearing the Shopping Cart
order	Ordering all service requests in the Shopping Cart
copy	Copying the Shopping Cart
delete	Deleting the Shopping Cart

Some important points on Shopping Carts:

- There is one and only one shopping cart for the authenticated user
- A shopping cart is an /api/service_orders resource with a state of **cart**
- Shopping carts can be referenced by their resource id or preferably via the alphanumeric **cart** identifier.
- resource id's need to be used for accessing non-cart service_orders states of **wish** list and **ordered**

Items to add to a shopping cart are *service_requests* that are specified similarly to when services are ordered from a service template.

- Querying Service Orders
- Creating Service Orders
- Adding Service Requests
- Removing Service Requests
- Clearing Service Orders
- Copying Service Orders
- Deleting Service Orders
- Ordering Service Orders

Querying Service Orders

All the queries listed here below return the service orders for the authenticated user.

Getting all service_orders:

```
GET /api/service_orders
```

Getting the shopping cart:

```
GET /api/service_orders/cart
```

Getting the shopping cart with expanded service_requests:

```
GET /api/service_orders/cart?expand=service_requests,resources
```

Getting the service requests of the shopping cart:

```
GET /api/service_orders/cart/service_requests
```

Creating Service Orders with multiple service requests

```
POST /api/service_orders

{
  "service_requests" : [
    {
      "service_template_href" : "http://localhost:3000/api/service_templates/3",
      "Basic_Host_Name" : "super_vm_a",
      "Basic_Host_Ip" : "192.168.120.101"
    },
    {
      "service_template_href" : "http://localhost:3000/api/service_templates/3",
      "Basic_Host_Name" : "super_vm_b",
      "Basic_Host_Ip" : "192.168.120.102"
    },
    ...
  ]
}
```

Creating a wish list service_order:

```
POST /api/service_orders

{
  "state" : "wish",
  "service_requests" : [
    {
      "service_template_href" : "http://localhost:3000/api/service_templates/2",
      "host_name" : "sample_service_order_host_name",
      "host_ip" : "192.168.120.101"
    }
  ]
}
```

Adding Service Requests

Adding service requests to a shopping cart can be done by either of the create methods shown above which will all add the service requests to the existing shopping cart:

```
POST /api/service_orders
```

or specifically to the shopping cart or any wish list service_orders via its *id* instead of **cart** as follows:

```
POST /api/service_orders/cart/service_requests

POST /api/service_orders/:id/service_requests

{
  "action" : "add",
  "resources" : [
    {
      "service_template_href" : "http://localhost:3000/api/service_templates/3",
      "Basic_Host_Name" : "sample_service_order_host_name_2",
      "Basic_Host_Ip" : "192.168.120.102"
    },
    {
      "service_template_href" : "http://localhost:3000/api/service_templates/3",
      "Basic_Host_Name" : "sample_service_order_host_name_3",
      "Basic_Host_Bad_Ip" : "192.168.120.103"
    },
    ...
  ]
}
```

Note: * POST /api/service_orders is atomic, requests are validated for all requests before adding them. * POST /api/service_orders/cart/service_requests will add the requests one by one, the action responses have the **success** field for each requests reflecting the success or failure of each request.

Removing Service Requests

Removing requests from the shopping cart is available via the *remove* action:

```
POST /api/service_orders/cart/service_requests

{
  "action" : "remove",
  "resources" : [
    { "href" : "http://localhost:3000/api/service_orders/6/service_requests/56" },
    { "href" : "http://localhost:3000/api/service_orders/6/service_requests/57" }
  ]
}
```

Clearing Service Orders

Clearing the shopping cart can be done via the *clear* action:

```
POST /api/service_orders/cart

{
  "action" : "clear"
}
```

Copying Service Orders

A service order can be copied into a new service order via the *copy* action:

```
POST /api/service_orders/:id
```

```
{
   "action" : "copy",
   "resource" : {
      "name" : "new_service_order_name"
   }
}
```

Service orders can also be copied in bulk as follows:

```
POST /api/service_orders/:id
```

```
{
   "action" : "copy",
   "resources" : [
      {
        "href" : "http://localhost:3000/api/service_orders/1",
        "name" : "new_service_order_name_1"
      },
      {
        "href" : "http://localhost:3000/api/service_orders/2",
        "name" : "new_service_order_name_2"
      },
      ...
   ]
}
```

Deleting Service Orders

Deleting the shopping cart can be done via the *delete* action:

```
POST /api/service_orders/cart
```

```
{
   "action" : "delete"
}
```

or simply via the DELETE method:

```
DELETE /api/service_orders/cart
```

Ordering Service Orders

Ordering the shopping cart is done via the *order* action as follows:

```
POST /api/service_orders/cart
```

```
{
   "action" : "order"
}
```

- Setting Ownership
  - Specifying Ownership
  - Setting Ownership to single resource
    - Request:
    - Response:
  - Setting Ownership to multiple resources
    - Request:
    - Response:

Setting Ownership

Setting ownership of resources is provided with the **set_ownership** action. This action is available for the following resources:

/api/auth_key_pairs
/api/cloud_templates
/api/instances
/api/service_templates
/api/services
/api/templates
/api/vms

- Specifying Ownership
- Setting Ownership to single resource
- Setting Ownership to multiple resources

Specifying Ownership

Specifying ownership in requests is done via the **owner** and **group** specification.

```
{
  "owner" : { "href" : "http://localhost:3000/api/users/:id"  },
  "group" : { "href" : "http://localhost:3000/api/groups/:id" }
}
```

Note:

Specifying an owner can be done via **href**, **id**, **name** or **userid**

Note:

Specifying a group can be done via **href**, **id** or **description**

Setting ownership can be done on a specific resource or multiple resources in a single request:

Setting Ownership to single resource

Example setting ownership to a single resource:

Request:

```
POST /api/vms/320

{
  "action" : "set_ownership",
  "resource" : {
    "owner" : { "userid" : "jdoe" },
    "group" : { "description" : "TestGroup" }
  }
}
```

Response:

```
{
  "success": true,
  "message": "setting ownership of vms id 320 to owner: jdoe, group: TestGroup",
  "href": "http://localhost:3000/api/vms/320"
}
```

Setting Ownership to multiple resources

Example setting ownership to multiple resources with a single request:

Request:

```
POST /api/services

{
  "action" : "set_ownership",
  "resources" : [
    { "href" : "http://localhost:3000/api/services/104", "owner" : { "name" : "John Doe" } },
    { "href" : "http://localhost:3000/api/services/105", "owner" : { "name" : "John Doe" } },
    { "href" : "http://localhost:3000/api/services/106", "owner" : { "name" : "John Doe" } }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "setting ownership of services id 104 to owner: John Doe",
      "href": "http://localhost:3000/api/services/104"
    },
    {
      "success": true,
      "message": "setting ownership of services id 105 to owner: John Doe",
      "href": "http://localhost:3000/api/services/105"
    },
    {
      "success": true,
      "message": "setting ownership of services id 106 to owner: John Doe",
      "href": "http://localhost:3000/api/services/106"
    }
}
```

- Settings Management
  - Querying Settings
  - Updating Settings
    - Request:
    - Response:

- Deleting Settings
  - Example:

Settings Management

Management of advanced settings is available on servers, zones and regions. They are provided with the following collection:

`/api/settings`

for the server processing the API, or for a particular server, zone or region as follows:

`/api/servers/:id/settings`

`/api/zones/:id/settings`

`/api/regions/:id/settings`

The following actions are available with advanced settings:

- Querying Settings
- Updating Settings
- Deleting Settings

Querying Settings

Settings can be queried as follows:

`GET /api/servers`

`GET /api/servers/:id/settings`

`GET /api/zones/:id/settings`

`GET /api/regions/:id/settings`

Note:

Authorization

- For users with an *EvmGroup-super_administrator* role, the complete advanced settings are returned.
- For users with roles that include the *Configuration Settings* feature, only a whitelisted set of settings are returned.
- Requests from all other users will be rejected with a Forbidden error.

Updating Settings

Updating settings can only be performed by users with an *EvmGroup-super_administrator* role.

Updates to settings is available with the HTTP PATCH method as follows:

`PATCH /api/servers/:id/settings`

`PATCH /api/zones/:id/settings`

`PATCH /api/regions/:id/settings`

The following is an example updating the policy_events's purge_window_size:

Request:

`PATCH /api/servers/1/settings`

```
{
  "policy_events" : {
    "purge_window_size" : 500
  }
}
```

Response:

The complete updated settings is returned:

```
{
  "ems": {
    "ems_ansible_tower": {
      "blacklisted_event_names": [

      ],
  ...
  "policy_events" : {
    "history": {
      "keep_policy_events": "6.months",
      "purge_window_size": 1000
    },
    "purge_window_size" : 500
```

```
  },
  ...
}
```

Deleting Settings

Deleting settings can only be performed by users with an *EvmGroup-super_administrator* role.

Deleting settings is available with the HTTP DELETE method as follows:

```
DELETE /api/servers/:id/settings
```

```
DELETE /api/zones/:id/settings
```

```
DELETE /api/regions/:id/settings
```

Requests must include an array representing the path of the setting to delete.

Example:

```
DELETE /api/servers/1/settings
```

```
[ "policy_events", "purge_window_size" ]
```

This request deletes the policy_event's purge_window_size setting for /api/servers/1 and its value would revert to its default.

- Snapshot Management
  - Snapshot Actions
  - Querying Snapshots
  - Creating Snapshots
  - Reverting Snapshots
  - Deleting Snapshots

Snapshot Management

Management of snapshots is provided for virtual machines and instances via the snapshots subcollection:

```
/api/vms/:id/snapshots
```

```
/api/instances/:id/snapshots
```

Snapshot Actions

The following snapshot actions are available for the supported resources:

Snapshot Action	Vms	Instances
read	X	X
create	X	X
revert	X	
delete	X	X

- Querying Snapshots
- Creating Snapshots
- Reverting Snapshots
- Deleting Snapshots

Querying Snapshots

Snapshots of machines are queried via the subcollection of vms and instances as follows:

Querying all snapshots of a VM:

```
GET /api/vms/:id/snapshots
```

Querying all snapshots of an Instance:

```
GET /api/instances/:id/snapshots
```

Filtering, sorting and paging on the subcollection as mentioned on the Querying page.

For example:

```
GET /api/vms/11/snapshots?expand=resources&filter[]=name=test*
```

One can also fetch a single snapshot by id:

```
GET /api/vms/:id/snapshots/:snapshot_id
```

```
GET /api/instances/:id/snapshots/:snapshot_id
```

Creating Snapshots

Creating snapshots on Vms and Instances is done by posting the request to the snapshots subcollection.

```
POST /api/vms/:id/snapshots
```

```
POST /api/instances/:id/snapshots
```

```
{
  "name" : "name_of_new_snapshot",
  "description" : "Description of new Snapshot",
  "memory" : false
}
```

In the above example, only *name* is required. *memory* can be set to true to have the snapshot include physical memory.

Reverting Snapshots

Reverting snapshots is only available for Vms.

```
POST /api/vms/:id/snapshots/:snapshot_id
```

```
{
  "action" : "revert"
}
```

Deleting Snapshots

Individual snapshots of Vms and Instances can be deleted via the DELETE method as follows:

```
DELETE /api/vms/:id/snapshots/:snapshot_id
```

```
DELETE /api/instances/:id/snapshots/:snapshot_id
```

As well as the *delete* POST action as follows for VMs:

```
POST /api/vms/:id/snapshots/:snapshot_id
```

or instances:

```
POST /api/instances/:id/snapshots/:snapshot_id
```

```
{
  "action" : "delete"
}
```

Snapshots can also be deleted in bulk via the *delete* action on the snapshots subcollection as follows:

```
POST /api/vms/11/snapshots
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/vms/11/snapshots/3" },
    { "href" : "http://localhost:3000/api/vms/11/snapshots/4" },
    { "href" : "http://localhost:3000/api/vms/11/snapshots/5" }
  ]
}
```

As well as for instances:

```
POST /api/instances/201/snapshots
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/instances/201/snapshots/7" },
    { "href" : "http://localhost:3000/api/instances/201/snapshots/8" }
  ]
}
```

- Tags & Tagging
  - Tag Management
  - Querying Tags
  - Querying Tags of a Resource
  - Assigning Tags
    - Tag specification
    - Assigning tags to a resource
      - Response:
    - Unassigning tags from a resource
      - Response:
    - Bulk Assigning Tags
      - Response:
    - Bulk Unassigning Tags
      - Response:

Tags & Tagging

- Tag Management
- Querying Tags
- Querying Tags of a Resource
- Assigning Tags
- Tag Specification
- Assigning Tags to a Resource
- Unassigning Tags from a Resource
- Bulk Assigning Tags
- Bulk Unassigning Tags

Tag Management

Management of Tags is provided in the following forms:

- Querying of tags via the primary collection:

`/api/tags`

- Assigning and Unassigning tags to resources via the tags subcollection of a resource

`/api/:collection/:id/tags`

and posting **assign** or **unassign** actions to the tags subcollection.

Querying Tags

Querying all tags in the system is simply:

`GET /api/tags`

However, that only gives us the href's of the tags:

```
{
  "name": "tags",
  "count": 1385,
  "subcount": 1385,
  "resources": [
    {
      "href": "http://localhost:3000/api/tags/1"
    },
    {
      "href": "http://localhost:3000/api/tags/2"
    },
    {
      "href": "http://localhost:3000/api/tags/3"
    }
    ...
  ]
}
```

Which is not too useful.

Expanding the resources, does provide us with the tag name as follows:

`GET /api/tags?expand=resources`

```
{
  "name": "tags",
  "count": 1385,
  "subcount": 1385,
  "resources": [
    {
      "href": "http://localhost:3000/api/tags/1",
      "id": "1",
      "name": "/managed/roles/change_managers"
    },
    {
      "href": "http://localhost:3000/api/tags/2",
      "id": "2",
      "name": "/managed/roles/operators"
    },
    {
      "href": "http://localhost:3000/api/tags/3",
      "id": "3",
      "name": "/managed/roles/cfme_administrators"
    },
    {
      "href": "http://localhost:3000/api/tags/4",
      "id": "4",
      "name": "/managed/location"
    },
    {
```

```
      "href": "http://localhost:3000/api/tags/5",
      "id": "5",
      "name": "/managed/location/ny"
    }
    ...
  ]
}
```

For additional details on tags, the **category** and **classification** attributes can be queried on tags as follows:

```
GET /api/tags/5?attributes=category,classification
```

Additionally, a compound attribute called **categorization** is provided to return key information from both **category** and **classification** of tags as follows:

```
GET /api/tags/5?attributes=categorization
```

```
{
  "href": "http://localhost:3000/api/tags/5",
  "id": "5",
  "name": "/managed/location/ny",
  "categorization": {
    "name": "ny",
    "description": "New York",
    "category": {
      "name": "location",
      "description": "Location"
    },
    "display_name": "Location: New York"
  }
}
```

Querying Tags of a Resource

To find out which tags are assigned to a resource, the tags subcollection can be expanded for that particular resource as follows:

```
GET /api/vms/320?expand=tags
```

This will provide the id, href and name of the tags:

```
{
  "href": "http://localhost:3000/api/vms/320",
  "id": "320",
  "vendor": "vmware",
  "name": "aab-vm1",
  "description": "this is a test",
  "raw_power_state": "poweredOn",
  ...
  "tags": [
    {
      "href": "http://localhost:3000/api/vms/320/tags/81",
      "id": "81",
      "name": "/managed/quota_max_cpu/4"
    },
    {
      "href": "http://localhost:3000/api/vms/320/tags/61",
      "id": "61",
      "name": "/managed/cc/001"
    },
    ...
  ]
}
```

Optionally, one can also query just the tags subcollection of the resource to get additional information about them like the categorization:

```
GET /api/vms/320/tags?expand=resources&attributes=categorization
```

```
{
  "name": "tags",
  "count": 1385,
  "subcount": 5,
  "resources": [
    {
      "href": "http://localhost:3000/api/vms/320/tags/81",
      "id": "81",
      "name": "/managed/quota_max_cpu/4",
      "categorization": {
        "name": "4",
        "description": "4",
        "category": {
          "name": "quota_max_cpu",
          "description": "Quota - Max CPUs"
        },
        "display_name": "Quota - Max CPUs: 4"
      }
    },
    {
      "href": "http://localhost:3000/api/vms/320/tags/61",
      "id": "61",
      "name": "/managed/cc/001",
      "categorization": {
        "name": "001",
```

```
        "description": "Cost Center 001",
        "category": {
          "name": "cc",
          "description": "Cost Center"
        },
        "display_name": "Cost Center: Cost Center 001"
      }
    },
    ...
  ]
}
```

Assigning Tags

Tag management on resources can be done by POSTing **assign** and **unassign** actions to the tags subcollection of resources. Tags can be managed as subcollections of the following primary collections:

Collection
/api/categories
/api/clusters
/api/data_stores
/api/generic_objects
/api/groups
/api/hosts
/api/lans
/api/providers
/api/resource_pools
/api/services
/api/service_templates
/api/templates
/api/tenants
/api/users
/api/vms

Tag specification

Tags can be specified using one of the following forms:

By Tag category and name:

```
{
  "category" : "department",
  "name"     : "finance"
}
```

By Tag path:

```
{
  "path" : "/managed/department/finance"
}
```

By Tag href:

```
{
  "href" : "http://localhost:3000/api/tags/10"
}
```

Assigning tags to a resource

```
POST /api/vms/320/tags
```

```
{
  "action" : "assign",
  "resources" : [
    { "category" : "department", "name" : "finance" },
    { "category" : "cc", "name" : "001" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Assigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/vms/320",
      "tag_category": "department",
      "tag_name": "finance",
      "tag_href": "http://localhost:3000/api/tags/81"
    },
    {
      "success": true,
```

```
      "message": "Assigning Tag: category:'cc' name:'001'",
      "href": "http://localhost:3000/api/vms/320",
      "tag_category": "cc",
      "tag_name": "001",
      "tag_href": "http://localhost:3000/api/tags/91"
    }
}
```

Unassigning tags from a resource

```
POST /api/vms/320/tags
```

```
{
  "action" : "unassign",
  "resources" : [
    { "category" : "department", "name" : "finance" },
    { "category" : "cc", "name" : "001" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Unassigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/vms/320",
      "tag_category": "department",
      "tag_name": "finance",
      "tag_href": "http://localhost:3000/api/tags/81"
    },
    {
      "success": true,
      "message": "Unassigning Tag: category:'cc' name:'001'",
      "href": "http://localhost:3000/api/vms/320",
      "tag_category": "cc",
      "tag_name": "001",
      "tag_href": "http://localhost:3000/api/tags/91"
    }
}
```

Additional Tag Management examples can be found on the main REST API Examples section.

Bulk Assigning Tags

While the general URL for tag assignment via the subcollection as follows:

```
POST /api/vms/320/tags
```

allows one to assign multiple tags to a single resource in one call, it does not provide the ability to assign tags to multiple resources in one call.

Bulk assignment of tags is available via the *assign_tags* action to the following collections:

Collection
/api/vms
/api/services

The *assign_tags* action allows adding one or more tags to one or more resources.

```
POST /api/vms
```

```
{
  "action" : "assign_tags",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/vms/11",
      "tags" : [
        { "category" : "department", "name" : "finance" }
      ]
    },
    {
      "href" : "http://localhost:3000/api/vms/12",
      "tags" : [
        { "category" : "cc", "name" : "001" }
      ]
    }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Assigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/vms/11",
      "tag_category": "department",
```

```
      "tag_name": "finance",
      "tag_href": "http://localhost:3000/api/tags/81"
    },
    {
      "success": true,
      "message": "Assigning Tag: category:'cc' name:'001'",
      "href": "http://localhost:3000/api/vms/12",
      "tag_category": "cc",
      "tag_name": "001",
      "tag_href": "http://localhost:3000/api/tags/91"
    }
  ]
}
```

Bulk Unassigning Tags

Tags can also be unassigned in bulk from multiple resources for the following collections via the *unassign_tags* action:

Collection
/api/vms
/api/services

```
POST /api/services

{
  "action" : "unassign_tags",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/services/5",
      "tags" : [
        { "href" : "http://localhost:3000/api/services/5/tags/81" }
      ]
    },
    {
      "href" : "http://localhost:3000/api/services/6",
      "tags" : [
        { "category" : "cc", "name" : "001" }
      ]
    }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Unassigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/services/5",
      "tag_category": "department",
      "tag_name": "finance",
      "tag_href": "http://localhost:3000/api/tags/81"
    },
    {
      "success": true,
      "message": "Unassigning Tag: category:'cc' name:'001'",
      "href": "http://localhost:3000/api/services/6",
      "tag_category": "cc",
      "tag_name": "001",
      "tag_href": "http://localhost:3000/api/tags/91"
    }
  ]
}
```

- Tasks
  - Querying Tasks
  - Deleting Tasks

Tasks

Management of Tasks is available via the following endpoint:

```
/api/tasks
```

Querying Tasks

Querying all Tasks:

```
GET /api/tasks
```

Getting details of a specific Task:

```
GET /api/tasks/:id
```

The following actions are available on tasks:

- Deleting Tasks

Deleting Tasks

Tasks can be deleted via either the **delete** POST action or the DELETE HTTP method.

```
POST /api/tasks/101
```

```
{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/tasks/101
```

Deleting multiple Tasks can be done as follows:

```
POST /api/tasks
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/tasks/101" },
    { "href" : "http://localhost:3000/api/tasks/102" },
    ...
  ]
}
```

- Tenant Management
- Tenant Quota Management
  - Creating Tenants
  - Editing Tenants
  - Deleting Tenants
  - Creating Tenant Quotas
  - Editing Tenant Quotas
  - Deleting Tenant Quotas

Tenant Management

Tenant management including CRUD operations is available via the REST API. Management of tenants is through:

```
/api/tenants
```

- Creating Tenants
- Editing Tenants
- Deleting Tenants

Tenant Quota Management

Tenant Quota management is made available via the *quotas* subcollection of tenant resources as follows:

```
/api/tenants/:id/quotas
```

- Creating Tenant Quotas
- Editing Tenant Quotas
- Deleting Tenant Quotas

Creating Tenants

Creating a Tenant is done via the **create** action as follows:

```
POST /api/tenants
```

```
{
  "action" : "create",
  "resource" : {
    # New Tenant JSON
  }
}
```

And like other **create** actions, the new tenant data can simply be posted to the /api/tenants URL.

```
POST /api/tenants
```

```
{
  # New Tenant JSON
}
```

For example, creating a new tenant:

```
POST /api/tenants

{
  "name" : "Test Tenant",
  "description" : "Test Tenant Description",
  "parent" : { "href" : "http://localhost:3000/api/tenants/1" }
}
```

Parent can be specify by *id* or *href*

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Tenants.

Editing Tenants

Editing a Tenant is available via the **edit** action with the **resource** specifying the attributes to update for that tenant.

```
POST /api/tenants/:id

{
  "action" : "edit" ,
  "resource" : {
    "description" : "Updated Description for Tenant"
  }
}
```

Note:

type is a restricted attribute and cannot be edited.

Deleting Tenants

Deleting a Tenant is done via the delete method:

```
DELETE /api/tenants/:id
```

or via the **delete** action as follows:

```
POST /api/tenants/:id

{
  "action" : "delete"
}
```

or by href:

```
POST /api/tenants

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/tenants/:id" }
  ]
}
```

Creating Tenant Quotas

Creating a quota for a specific tenant is done as follows:

```
POST /api/tenants/:id/quotas

{
  "name" : "cpu_allocated",
  "value" : 1
}
```

Editing Tenant Quotas

```
POST /api/tenants/:id/quotas/:quota_id

{
  "action" : "edit",
  "resource" : {
    "value" : 5
  }
}
```

Multiple quotas for a tenant can also be edited in a single request as follows:

```
POST /api/tenants/1/quotas

{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/tenants/1/quotas/5",
      "value" : 11
    },
    { "href" : "http://localhost:3000/api/tenants/1/quotas/6",
      "value" : 12
```

```
    },
    ...
  ]
}
```

Deleting Tenant Quotas

Quotas of a tenant can be deleted via the *delete* action as follows:

```
POST /api/tenants/:id/quotas/:quota_id
```

```
{
  "action" : "delete"
}
```

or via the DELETE HTTP method

```
DELETE /api/tenants/:id/quotas/:quota_id
```

Multiple quotas of a tenant can be deleted in a single request as shown in the following example:

```
POST /api/tenants/1/quotas
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/tenants/1/quotas/7" },
    { "href" : "http://localhost:3000/api/tenants/1/quotas/8" },
    ...
  ]
}
```

- User Management
  - Querying Users
  - Creating Users
  - Editing Users
  - Editing Authenticated User
  - Deleting Users

User Management

Management of Users is provided via the following collection:

```
/api/users
```

Full CRUD actions on users is available:

- Querying Users
- Creating Users
- Editing Users
- Editing Authenticated User
- Deleting Users

Querying Users

Querying all users in the system is simply:

```
GET /api/users
```

Getting details on a specific user:

```
GET /api/users/:id
```

Creating Users

Users can be created via a POST to the users collection or via the **create** action signature which also allows creation of multiple users in a single request.

```
POST /api/users
```

```
{
  "userid" : "testuser",
  "password" : "secret",
  "name" : "Test User",
  "group" : { "id" : "11" }
}
```

Note:

group can be specified via **description**, **href**, or **id**

or creating multiple users:

```
{
  "action" : "create",
  "resources" : [
    { "userid" : "testuser1", "name" : "Test User1", ... },
    { "userid" : "testuser2", "name" : "Test User2", ... },
    ...
  ]
}
```

Note:

Please refer to the Resource Attributes page for a list of available attributes when creating Users.

Editing Users

```
POST /api/users/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "group" : { "id" : "12" }
  }
}
```

or editing multiple users:

```
POST /api/users
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/users/101",
      "group" : { "href" : "http://localhost:3000/api/groups/15" }
    },
    {
      "href" : "http://localhost:3000/api/users/102",
      "group" : { "href" : "http://localhost:3000/api/groups/15" }
    },
    {
      "href" : "http://localhost:3000/api/users/103",
      "group" : { "href" : "http://localhost:3000/api/groups/15" }
    },
    ...
  ]
}
```

Editing Authenticated User

An API Authenticated User can edit some of their own attributes without having general user edit permissions. Editable attributes for the authenticated user are:

password
email
settings

Users can also update their currently selected group with the **set_current_group** action as follows:

```
POST /api/users/:id
```

```
{
  "action" : "set_current_group",
  "resource" : {
    "group" : { "description" : "EvmGroup-auditor" }
  }
}
```

Note:

The group reference can be via **description**, **href** or **id**. Also, only a group that the user belongs to can be specified.

Deleting Users

users can be deleted via either the **delete** POST action or via the DELETE HTTP method.

```
POST /api/users/101
```

```
{
  "action" : "delete"
}
```

or simply:

```
DELETE /api/users/101
```

Deleting multiple users can be done as follows:

```
POST /api/users
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/users/101" },
    { "href" : "http://localhost:3000/api/users/102" },
    ...
  ]
}
```

- Virtual Machine Management
  - Targeting Virtual Machines
  - Querying Virtual Machines
  - Starting a Virtual Machine
  - Stopping a Virtual Machine
  - Suspending a Virtual Machine
  - Refreshing a Virtual Machine
  - Retiring a Virtual Machine
  - Resetting a Virtual Machine

  - Setting Server of a Virtual Machine
  - Setting Owner of a Virtual Machine
  - Adding an Event to a Virtual Machine
  - Editing a Virtual Machine
  - Deleting a Virtual Machine

Virtual Machine Management

Management of virtual machines adds support of the following actions:

Action	Description
start	Starts a virtual machine
stop	Stops a virtual machine
suspend	Suspends a virtual machine
refresh	Refreshes a virtual machine
request_retire	Retires a virtual machine
reset	Resets a virtual machine
reboot_guest	Reboots guest in virtual machine
shutdown_guest	Shuts down guest in virtual machine
scan	Scans a virtual machine (Perform SmartState Analysis)
set_miq_server	Sets the server of a virtual machine
set_owner	Sets the owner of a virtual machine
add_event	Adding an event to a virtual machine
edit	Edits a virtual machine
delete	Deletes a virtual machine in the appliance

- Targeting VMs
- Querying VMs
- Starting a VM
- Stopping a VM
- Suspending a VM
- Refreshing a VM
- Retiring a VM
- Resets a VM
- Reboots guest in VM
- Shuts down guest in VM
- Scanning a VM
- Setting Server of a VM
- Setting Owner of a VM
- Adding an Event to a VM
- Editing a VM

- Deleting a VM

Targeting Virtual Machines

These actions can be triggered on individual virtual machine resources:

```
/api/vms/:id
```

As simply as POSTing the following action to a virtual machine.

```
{
  "action" : "start"
}
```

Requests can also be made on multiple vms by targetting the primary collection:

```
/api/vms
```

```
{
  "action" : "start",
  "resources" : [
    { "href" : "http://localhost:3000/api/vms/11" },
    { "href" : "http://localhost:3000/api/vms/12" },
    ...
  ]
}
```

Querying Virtual Machines

Virtual machines are queried via the primary collection URL:

```
/api/vms
```

Filtering, sorting and paging as mentioned on the Querying page.

When querying vms, expanding the resources themselves as well as the following subcollections:

accounts
software

For example:

```
GET /api/vms?expand=resources,accounts,software
```

Or querying an individual virtual machine

```
GET /api/vms/:id?expand=accounts,software
```

Starting a Virtual Machine

```
{
  "action" : "start"
}
```

Stopping a Virtual Machine

```
{
  "action" : "stop"
}
```

Suspending a Virtual Machine

```
{
  "action" : "suspend"
}
```

Refreshing a Virtual Machine

```
{
  "action" : "refresh"
}
```

Retiring a Virtual Machine

```
{
  "action" : "request_retire"
}
```

Resetting a Virtual Machine

```
{
  "action" : "reset"
}
```

Rebooting guest in Virtual Machine

```
{
  "action" : "reboot_guest"
}
```

Shutting Down Guest in a Virtual Machine

```
{
  "action" : "shutdown_guest"
}
```

Scanning a Virtual Machine

```
{
  "action" : "scan"
}
```

Setting Server of a Virtual Machine

```
{
  "action" : "set_miq_server",
  "resource" : {
    "miq_server" : { "href" : "http://localhost:3000/api/servers/5" }
  }
}
```

```
{
  "action" : "set_miq_server",
  "resource" : {
    "miq_server" : { "id" : "6" }
  }
}
```

To remove the server from the virtual machine, pass in an empty reference as follows:

```
{
  "action" : "set_miq_server",
  "resource" : {
    "miq_server" : {}
  }
}
```

Setting Owner of a Virtual Machine

```
{
  "action" : "set_owner",
  "resource" : {
    "owner" : "admin"
  }
}
```

Adding an Event to a Virtual Machine

```
{
  "action" : "add_event",
  "resource" : {
    "event_type" : "...",
    "event_message" : "...",
    "event_time" : "UTC Time"
  }
}
```

Note:

event_time above is optional. If skipped, current time will be used.

Editing a Virtual Machine

Basic information of virtual machines can be edited. This includes the following:

VM Info	Attribute
description	description
custom attributes	custom_1 ... custom_9
parent resource	parent_resource - resource href reference
child resources	child_resources - array of resource href references

Virtual machine resources can be edited as follows:

```
POST /api/vms/:id
```

```
{
  "action" : "edit",
  "resource" : {
    "description" : "Updated VM Description",
    "custom_1" : "custom_attribute_1",
    "parent_resource" : { "href" : "http://localhost:3000/api/vms/11" },
    "child_resources" : [
      { "href" : "http://localhost:3000/api/vms/101" },
      { "href" : "http://localhost:3000/api/vms/102" },
```

```
      { "href" : "http://localhost:3000/api/vms/103" },
      { "href" : "http://localhost:3000/api/vms/104" }
    ]
  }
}
```

Virtual machines can also be edited in bulk as follows:

```
POST /api/vms
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/vms/11",
      "custom_9" : "vm_class_a"
    },
    {
      "href" : "http://localhost:3000/api/vms/12",
      "custom_9" : "vm_class_a"
    },
    {
      "href" : "http://localhost:3000/api/vms/13",
      "custom_9" : "vm_class_a"
    }
  ]
}
```

Deleting a Virtual Machine

```
{
  "action" : "delete"
}
```

Or simply doing the following:

```
DELETE /api/vms/:id
```

See the main REST API examples section for additional virtual machine management examples.

Infrastructure Management API Appendices

In this guide you will find appendices for the Infrastructure Automation – Infrastructure Management REST API.

- Quick Reference
- Collection Metadata
- Resource Attributes
- Provider Types
- Provision Request Supported Attributes
- Advanced Provisioning Attributes

- Authentication
- HTTP Headers
- Listing and Querying Collections and Sub-Collections
- Collection Queries:
- Sub-Collection Queries

This document presents the currently available features and capabilities of the REST API.

Authentication

Type	Mechanism
Basic Authentication	Basic HTTP Authorization with user and password
Token Based Authentication	
- Acquiring Token	/api/auth with Basic Authentication
- Authenticating with Token	X-Auth-Token Header

HTTP Headers

Header	Value
Authorization	Basic base64_encoded(user:password)
X-Auth-Token	Token provided by /api/auth
X-MIQ-Group	Group to authorize externally authenticated user
Accept	application/json

Header	Value
Content-Type	application/json

Listing and Querying Collections and Sub-Collections

Feature	Path
Listing Available Collections	/api
Listing Collections	/api/<collection>
Listing Sub-Collections	/api/<collection>/<id>/<sub-collection>

Querying Capability	Query Parameters	
Paging	offset, limit	
Sorting	sort_by=attr, sort_order=asc	desc
	Can sort by database columns and SQL friendly virtual attributes	
Filtering	filter[]=...	
Querying by Tag	i.e. by_tag=/department/finance	
Querying by Multiple Tags	i.e. by_tag=/department/finance,/department/engineering	
Expanding Results	expand=<what>, i.e. expand=resources,tags,service_templates,...	
Selecting Attributes	attributes=<attr1>,<attr2>,... i.e. attributes=id,name,type,...	
	Attributes can be:	
	Database columns	
	Virtual attributes	
	Relationships	

Example Queries

Collection Queries:

For a complete list of supported primary collections please refer to the Primary Collections

Sub-Collection Queries

When applicable, the following subcollections are available:

Sub-Collection	URL
Tagging	/api/<collection>/:id/tags
Policies	/api/<collection>/:id/policies
Policy Profiles	/api/<collection>/:id/policy_profiles
Service Requests	/api/service_templates/:id/service_requests
Request Tasks	
	/api/service_requests/:id/request_tasks
	/api/automation_requests/:id/request_tasks
	/api/provision_requests/:id/request_tasks
Request Tasks can also be accessed via the tasks alias	
	/api/service_requests/:id/tasks
	/api/automation_requests/:id/tasks
	/api/provision_requests/:id/tasks

- Collection Metadata
  - Optional Metadata

Collection Metadata

Collection specific metadata can be queried by sending an HTTP OPTIONS request on the specific collection:

```
OPTIONS /api/:collection
```

What gets returned is the following structure:

```
{
  "attributes": [
  ],
  "virtual_attributes": [
  ],
  "relationships": [
  ],
  "subcollections": [
  ],
  "data": {
  }
}
```

Entry	Description
attributes	Physical attributes of the collection
virtual_attributes	Virtual attributes of the collection
relationships	Physical or Virtual associations to other resources
subcollections	Subcollections that can be queried
data	Optional meta-data for the collection

The following is an example for the **groups** collection:

```
OPTIONS /api/groups
```

```
{
  "attributes": [
    "created_on",
    "description",
    "group_type",
    "id",
    "sequence",
    "settings",
    "tenant_id",
    "updated_on"
  ],
  "virtual_attributes": [
    "allocated_memory",
    "allocated_storage",
    "allocated_vcpu",
    "custom_1",
    "custom_2",
    "custom_3",
    "custom_4",
    "custom_5",
    "custom_6",
    "custom_7",
    "custom_8",
    "custom_9",
    "href_slug",
    "miq_user_role_name",
    "provisioned_storage",
    "read_only",
    "region_description",
    "region_number",
    "user_count"
  ],
  "relationships": [
    "active_vms",
    "custom_action_buttons",
    "custom_actions",
    "custom_attributes",
    "custom_button_sets",
    "custom_buttons",
    "entitlement",
    "miq_custom_attributes",
    "miq_report_results",
    "miq_reports",
    "miq_templates",
    "miq_user_role",
    "miq_widget_contents",
    "miq_widget_sets",
    "taggings",
    "tags",
    "tenant",
    "users",
    "vms"
  ],
  "subcollections": [
    "tags"
  ],
  "data": {
  }
}
```

Optional Metadata

Most collections do not declare additional metadata as shown by the empty *data* hash entry above. Optional metadata is made available as needed for API clients. They are generally used to provide additional information needed for user-interfaces, help complete or validate data for additional API calls, etc.

Currently, optional metadata is made available for the following collections:

Collection
/api/authentications
/api/clusters
/api/container_deployments
/api/custom_buttons
/api/generic_object_definitions
/api/hosts
/api/providers

There is no enforced structure for the *data* element as each collection may need to provide different types of metadata. The following is a partial meta-data example:

```
OPTIONS /api/generic_object_definitions
```

```
{
  "attributes": [
    "created_at",
    "description",
    "id",
    "name",
    "properties",
    "updated_at"
  ],
  "virtual_attributes": [
    "generic_objects_count",
    "href_slug",
    "region_description",
    "region_number"
  ],
  "relationships": [
    "custom_action_buttons",
    "custom_actions",
    "custom_button_sets",
    "custom_buttons",
    "generic_objects",
    "picture"
  ],
  "subcollections": [
    "generic_objects"
  ],
  "data": {
    "allowed_association_types": [
      [
        "Availability Zone",
        "AvailabilityZone"
      ],
      ...
      [
        "VM and Instance",
        "Vm"
      ],
      [
        "Zone",
        "Zone"
      ]
    ],
    "allowed_types": [
      [
        "Boolean",
        "boolean"
      ],
      [
        "Date/Time",
        "datetime"
      ],
      [
        "Float",
        "float"
      ],
      [
        "Integer",
        "integer"
      ],
      [
        "String",
        "string"
      ],
      [
        "Time",
        "time"
      ]
    ]
  }
}
```

Resource Attributes

This page lists the available attributes when creating resources with the REST API

- Actions
- Alert Definitions
- Authentications
- Categories
- Chargeback Rates
- Conditions
- Configuration Script Sources
- Generic Objects
- Generic Object Definitions
- Groups
- Orchestration Templates

- Policies
- Providers
- Roles
- Services
- Service Catalogs
- Service Dialogs
- Tags
- Tenants
- Users

Actions

`POST /api/actions`

Required attributes:

Attribute	Type	Description
action_type	string	Action Type
description	string	Description (unique)

Optional attributes:

Attribute	Type	Description
name	string	Name
options	hash	Options

Alert Definitions

`POST /api/alert_definitions`

Required attributes:

Attribute	Type	Description
description	string	Description
db	string	Database
expression	hash	Expression
options	hash	Options

Optional attributes:

Attribute	Type	Description
enabled	boolean	Enable the Alert Definition or not - Defaults to true

Authentications

`POST /api/authentications`

Required attributes:

Attribute	Type	Description
manager_resource	hash	**href** of the provider

Optional attributes:

Attribute	Type	Description
type	string	Authentication class

Note:

For a complete list of authentication classes supported and the related attributes for each type, send the *OPTIONS /api/authentications* request.

Category Attributes

`POST /api/categories`

Required attributes:

Attribute	Type	Description
name	string	Name
description	string	Description

Optional attributes:

Attribute	Type	Description
example_text	string	Detailed description
show	boolean	Show Category flag
single_value	boolean	Single Value flag
syntax	string	Syntax of value, **string**, **integer** or **boolean**

Chargeback Rate Attributes

`POST /api/rates`

Required attributes:

Attribute	Type	Description
chargeback_rate_id	integer	Reference to parent Chargeback. `<chargeback_rate>` can be used instead.
group	string	Group rate belongs to, i.e. **cpu**, **memory**, **net_io**, **disk_io**, etc.
source	string	The input value for calculation, i.e. **allocated**, **used**, etc.
chargeback_tiers	Array of hashes	Each tier is represented by hash `{“start”: 0.0, “finish”: ‘infinity’, “fixed_rate”: 2.0, “variable_rate”: 0.0}]

Optional attributes:

Attribute	Type	Description
description	string	Description of the chargeback rate
enabled	boolean	Rate enabled flag
friendly_rate	string	Friendly name of the rate
metric	string	Metrics, i.e. **derived_memory_available**, etc.
per_time	string	Measured per time, **hourly**, **daily**, **weekly**, **monthly** or **yearly**
per_unit	string	Measured per unit, i.e. **megabytes**, **gigabytes**, etc.
chargeback_rate	hash	`id` or `href` from `api/chargebacks` collection.
detail_currency	hash	`id` or `href` from `api/currencies` collection. Details of related currency.
chargeable_field	hash	`id` or `href` from `api/chargeable_fields` collection. Record representing metric. Contains equivalent columns: `metric, group, source`

Conditions

`POST /api/conditions`

Required attributes:

Attribute	Type	Description
description	string	Condition Description
expression	hash	Expression
modifier	string	Modifier
towhat	string	Class name

Optional attributes:

Attribute	Type	Description
name	string	Condition name

Configuration Script Sources

`POST /api/configuration_script_sources`

Required attributes:

Attribute	Type	Description
manager_resource	hash	**href** or **id** of the provider

Optional attributes:

Attribute	Type	Description
description	string	Description
name	string	Project Name
related	hash	Related attributes and values

Generic Objects

`POST /api/generic_objects`

Required attributes:

Attribute	Type	Description
name	string	Name of the generic object
generic_object_definition	hash	Generic object definition to create new generic object for, requires an **href** or **id** attribute in the hash

`POST /api/generic_object_definitions/:id/generic_objects`

Required attributes:

Attribute	Type	Description
name	string	Name of the generic object

Optional attributes:

Attribute	Type	Description
uid	string	Uid string
property_attributes	hash	Attribute/Value pairs to define for the generic object
associations	hash	Hash containing association keys each being an array of resource references

Generic Object Definitions

Required attributes:

Attribute	Type	Description
name	string	Name of the generic object definition

Optional attributes:

Attribute	Type	Description
description	string	Description for the generic object definition
properties	hash	Hash containing the **attributes**, **associations** and **methods** of the generic object definition
picture	hash	Picture to use, either an **href** or **id** of the picture resource, or the actual picture including the **extension** and Base64 encoded **content**

Group Attributes

`POST /api/groups`

Required attributes:

Attribute	Type	Description
description	string	Description
role	hash	Role the group is assigned to, requires an **href**, **id** or **name** attribute in the hash
tenant	hash	Tenant the group belongs to, requires an **href** or **id** attribute in the hash

Optional attributes:

Attribute	Type	Description
filters	hash	Hash that contains the **belongsto** and **managed** arrays of filters to assign to the group
filter_expression	hash	Hash representing the expression used for filtering by Tag

Filters hash:

The `filters` hash can include the following keys:

- **belongsto**
  - Array of tags representing the following types of objects:
    - VMs & Templates
    - Clusters, Datastores, Hosts, Managers & Providers
- **managed**
  - Array of tag arrays representing:
    - My Company Tags

Example:

```
"filters" : {
  "managed" : [
    ["/managed/location/ny"],
    ["/managed/environment/prod"]
  ],
  "belongsto" : [
    "/belongsto/ExtManagementSystem|dev-vc60/EmsFolder|Datacenters/EmsFolder|dev-vc60-DC/EmsFolder|vm/EmsFolder|Alberto-
```

```
Dev,
    "/belongsto/ExtManagementSystem|dev-vc60/EmsFolder|Datacenters/EmsFolder|dev-vc60-DC/EmsFolder|host/EmsCluster|dev-
vc60-cluster"
  ]
}
```

Alternatively, company tags can be represented with an expression via the *filter_expression* instead of the *managed* tag array in the *filters* element as follows:

Example with Tags based on expression:

```
"filters" : {
  "managed" : null,
  "belongsto" : [
    "/belongsto/ExtManagementSystem|dev-vc60/EmsFolder|Datacenters/EmsFolder|dev-vc60-DC/EmsFolder|vm/EmsFolder|Alberto-
Dev,
    "/belongsto/ExtManagementSystem|dev-vc60/EmsFolder|Datacenters/EmsFolder|dev-vc60-DC/EmsFolder|host/EmsCluster|dev-
vc60-cluster"
  ]
},
"filter_expression" : {
  "exp": {
    "and": [
      {
        "CONTAINS": {
          "tag": "managed-location",
          "value": "ny"
        }
      },
      {
        "CONTAINS": {
          "tag": "managed-environment",
          "value": "prod"
        }
      }
    ]
  }
}
```

Orchestration Templates

`POST /api/orchestration_templates`

Required attributes:

Attribute	Type	Description
name	string	Name
content	text	Template content

Optional attributes:

Attribute	Type	Description
type	string	Type
description	string	Description
draft	boolean	**true** or **false**
ems_id	integer	Id of the provider
orderable	boolean	**true** or **false**

Policies

`POST /api/policies`

Required attributes:

Attribute	Type	Description
name	string	Name
description	string	Description
mode	string	Mode (i.e. *compliance*)
towhat	string	Target Class
condition_ids	array	Ids of Conditions to assign to the Policy
policy_contents	array	Array of hashes including *event_id* and *actions*, an array of hashes comprising of an *action_id* and *opts*.

Provider Attributes

`POST /api/providers`

Required attributes:

Attribute	Type	Description
name	string	Name of the provider
type	string	Provider class

Attribute	Type	Description
hostname	string	Hostname of the Provider
credentials or connection_configurations	hash or array	Credentials information for the provider either via the **credentials** hash or **connection_configurations** array

Optional attributes:

Attribute	Type	Description
api_version	string	API Version for communicating with the Provider
uid_ems	string	Domain for OpenStack provider. Required when “api_version” is “v3”
certificate_authority	string	CA for the Provider
connection_configurations	array	Endpoints for the Provider
credentials	hash	Credentials to use for communicating with the Provider, see Provider Support for examples
host_default_vnc_port_start	integer	Starting VNC port
host_default_vnc_port_end	integer	Ending VNC port
ipaddress	string	IP Address of the Provider
port	string	Port of the Provider
realm	string	Realm of the Provider
security_protocol	string	Security Protocol
url	string	URL of the Provider
zone	hash	In which zone to add provider to, hash needs to include an **href** or **id** attribute.

Credentials hash specification attributes are:

Type	Auth Types	Auth Attributes
ManageIQ::Providers::Amazon::CloudManager	default	userid, password
ManageIQ::Providers::Atomic::ContainerManager	default, password, bearer	userid, password
ManageIQ::Providers::Azure::CloudManager	default	userid, password
ManageIQ::Providers::Kubernetes::ContainerManager	default, password, bearer	userid, password
ManageIQ::Providers::Microsoft::InfraManager	default	userid, password
ManageIQ::Providers::Openshift::ContainerManager	default, password, bearer	userid, password, auth_key
ManageIQ::Providers::Openstack::InfraManager	default, amqp, ssh_keypair	userid, password, auth_key
ManageIQ::Providers::Openstack::CloudManager	default, amqp	userid, password
ManageIQ::Providers::Redhat::InfraManager	default, metrics	userid, password
ManageIQ::Providers::Vmware::InfraManager	default	userid, password
ManageIQ::Providers::Foreman::Provider	default	userid, password
ManageIQ::Providers::Openstack::Provider	default	userid, password

Role Attributes

`POST /api/roles`

Required Attributes:

Attribute	Type	Description
name	string	Name of user role

Optional Attributes:

Attribute	Type	Description
features	array	Features to assign to the role. Array of { “identifier” OR “href” OR “id” : ... }
settings	hash	Settings for the role, normally: { “restrictions” : { “vms” : “user” OR “user_or_group” } }

Service Attributes

`POST /api/services`

Required attributes:

Attribute	Type	Description
name	string	Name

Optional attributes:

Attribute	Type	Description
description	string	Description
orchestration_template	hash	**href** or **id** of the Orchestration Template
orchestration_manager	hash	**href** or **id** of the Orchestration Provider
parent_service	hash	Parent service **href** or **id** reference
type	string	Type of Service

Service Catalog Attributes

`POST /api/service_catalogs`

Attribute	Type	Description
name	string	Name of service catalog
description	string	Description of service catalog

Optional attributes:

Attribute	Type	Description
service_templates	array	Array of Service Template hashes to assign to the new Service Catalog. Hash entries to include the **href** of the service_templates to assign and must not currently be assigned to any Service Catalog.

Service Dialogs

`POST /api/service_dialogs`

Required attributes:

Attribute	Type	Description
label	string	Label
dialog_tabs	array	Dialog content - array of dialog tabs

Optional attributes:

Attribute	Type	Description
description	string	Description

Tag Attributes

`POST /api/tags`

Required attributes:

Attribute	Type	Description
name	string	Name of tag
description	string	Description of tag
category	hash	Category identifier for which the tag is getting added to, requires an **href**, **id** or **name** attribute in the hash

Note:

When adding with a **create** action on the tags subcollection of the category via /api/categories/:id/tags, the category should not be specified in the resource.

Tenant Attributes

`POST /api/tenants`

Required attributes:

Attribute	Type	Description
name	string	Name of Tenant
parent	hash	Parent tenant identifier for which the sub-tenant is getting added to, requires an **href** or **id** attribute in the hash

Optional attributes:

Attribute	Type	Description
description	string	Description of Tenant
domain	string	Domain
logo_file_name	string	Logo file name, must be available via /uploads/**logo_file_name**
login_logo_file_name	string	Login Logo file name, must be available via /uploads/**login_logo_file_name**
login_text	string	Login text
subdomain	string	Subdomain

User Attributes

`POST /api/users`

Required attributes:

Attribute	Type	Description
userid	string	Username
password	string	Password
name	string	Full Name
group	hash	Group the user belongs to, requires a **description**, **href** or **id** attribute in the hash

Optional attributes:

Attribute	Type	Description
email	string	E-mail Address

- Provider Types

Provider Types

The provider types available with earlier appliances have changed with this release. This is what gets specified with the *type* attribute when creating a new provider:

```
POST /api/providers

{
  "name" : "vCenter 5",
  "type" : "ManageIQ::Providers::Vmware::InfraManager",
  "hostname" : "my_vcenter_50",
  ...
}
```

The following table lists the type from previous appliance releases (*v2.0.0* of the REST API), and their mapping to the new *v2.1.0* types:

v2.0.0 Provider Type	v2.1.0 Provider Type
EmsAmazon	ManageIQ::Providers::Amazon::CloudManager
	ManageIQ::Providers::Atomic::ContainerManager (**new**)
	ManageIQ::Providers::Azure::CloudManager (**new**)
EmsKubernetes	ManageIQ::Providers::Kubernetes::ContainerManager
EmsMicrosoft	ManageIQ::Providers::Microsoft::InfraManager
	ManageIQ::Providers::Openshift::ContainerManager (**new**)
EmsOpenstackInfra	ManageIQ::Providers::Openstack::InfraManager
EmsOpenstack	ManageIQ::Providers::Openstack::CloudManager
EmsRedhat	ManageIQ::Providers::Redhat::InfraManager
EmsVmware	ManageIQ::Providers::Vmware::InfraManager

And when *provider-class* is set to **provider**, the following mapping table applies:

v2.0.0 Provider Type	v2.1.0 Provider Type
ProviderForeman	ManageIQ::Providers::Foreman::Provider
ProviderOpenstack	ManageIQ::Providers::Openstack::Provider

- Provision Request Supported Attributes
  - Requester Attributes
  - Custom Attributes
  - Service Catalog Attributes
  - Schedule Attributes
  - Network Attributes
  - Hardware Attributes
  - Environment Attributes

Provision Request Supported Attributes

Attribute Class	Provision Request Attribute Group
Requester Attributes	requester
Custom Attributes	vm_fields
Service Catalog Attributes	vm_fields
Schedule Attributes	vm_fields
Network Attributes	vm_fields
Hardware Attributes	vm_fields
Environment Attributes	additional_values

Requester Attributes

Attribute	Type	Description
owner_phone	string	Phone
owner_country	string	Country/Region
owner_phone_mobile	string	Mobile phone
owner_title	string	Title
owner_first_name	string	First name
owner_manager	string	Manager name
owner_address	string	Address
owner_company	string	Company
owner_last_name	string	Last name
owner_manager_email	string	Manager e-mail address

Attribute	Type	Description
owner_city	string	City
owner_department	string	Department
owner_load_ldap	button	Look up LDAP e-mail address
owner_manager_phone	string	Manager phone
owner_state	string	State
owner_office	string	Office
owner_zip	string	Zip code
owner_email	string	E-Mail
request_notes	string	Notes

Custom Attributes

Attribute	Type	Description	Values	Default
dns_servers	string	DNS server list		
sysprep_organization	string	Organization		
sysprep_password	string	New Administrator Password		
sysprep_custom_spec	string	Name		
sysprep_server_license_mode	string	Identification	perServer, perSeat	
ldap_ous	string	LDAP Group		
sysprep_timezone	string	Timezone		
dns_suffixes	string	DNS Suffix list		
sysprep_product_id	string	ProductID		
sysprep_identification	string	Identification	domain, workgroup	
sysprep_per_server_max_connections	string	Maximum Connections		5
sysprep_computer_name	string	Computer Name		
sysprep_workgroup_name	string	Workgroup Name		WORKGROUP
sysprep_spec_override	boolean	Override Specification		false
addr_mode	string	Address Mode	static, dhcp	dhcp
linux_host_name	string	Computer Name		
sysprep_domain_admin	string	Domain Admin		
sysprep_change_sid	boolean	Change SID		true
sysprep_domain_name	string	Domain Name		
sysprep_upload_file	string	Upload		
gateway	string	Gateway		
ip_addr	string	IP Address		
linux_domain_name	string	Domain Name		
sysprep_domain_password	string	Domain Password		
sysprep_auto_logon	boolean	Auto Logon		true
sysprep_enabled	string	Customize		disabled
sysprep_delete_accounts	boolean	Delete Accounts		false
sysprep_upload_text	string	Sysprep Text		
wins_servers	string	WINS Server list		
subnet_mask	string	Subnet Mask		
sysprep_full_name	string	Full Name		
sysprep_auto_logon_count	integer	Auto Logon Count	1, 2, 3	1
customization_template_id	integer	Script Name		
root_password	string	Root Password		
hostname	string	Host Name		
customization_template_script	string	Script Text		

Service Catalog Attributes

Attribute	Type	Description	Default
number_of_vms	integer	Count. *Max*: 50	1
vm_description	string	VM Description. *Max length*: 100	
vm_prefix	string	VM Name Prefix/Suffix	
src_vm_id	integer	Name	
vm_name	string	VM Name	
pxe_image_id	string	Image	
pxe_server_id	integer	Server	
host_name	string	Host Name	
provision_type	string	Provision Type	vmware
linked_clone	boolean	Linked Clone	false
snapshot	string	Snapshot	
vm_filter	integer	Filter	

Schedule Attributes

Attribute	Type	Description	Values	Default
schedule_type	string	When to Provision	schedule, immediately (*On Approval*)	immediately
vm_auto_start	boolean	Power on virtual machines after creation		true
schedule_time	time	Time to Provision on		
retirement	integer	Time until Retirement	0 (*Indefinite*), 1.month, 3.months, 6.months	0
retirement_warn	integer	Retirement Warning	1.week, 2.weeks, 30.days	1.week

Network Attributes

Attribute	Type	Description
vlan	string	vLan
mac_address	string	MAC Address

Hardware Attributes

Attribute	Type	Description	Values	Default
disk_format	string	Disk Format	thick, thin, unchanged	unchanged
cpu_limit	integer	CPU (MHz)		
memory_limit	integer	Memory (MB)		
number_of_sockets	integer	Number of Sockets	1, 2, 4, 8	1
cores_per_socket	integer	Cores per Socket	1, 2, 4, 8	1
cpu_reserve	integer	CPU (MHz)		
vm_memory	string	Memory (MB)	1024, 2048, 4096	1024
memory_reserve	integer	Memory (MB)		
network_adapters	integer	Network Adapters	1, 2, 3, 4	1

Environment Attributes

These attributes cannot be passed directly. To use these attributes, provide them in the **additional_values** attribute group and have customization methods use them and modify the request accordingly.

Attribute	Type	Description	Values	Default
new_datastore_grow_increment	integer	Grow Increment (GB)		
new_datastore_create	boolean	Create Datastore		false
placement_cluster_name	integer	Name		
new_datastore_aggregate	string	Aggregate		
new_datastore_max_size	integer	Max Size (GB)		
new_datastore_storage_controller	string	Controller		
cluster_filter	integer	Filter		
host_filter	integer	Filter		
ds_filter	integer	Filter		
new_datastore_volume	string	Volume		
placement_host_name	integer	Name		
placement_ds_name	integer	Name		
new_datastore_fs_type	string	FS Type	NFS, VMFS	NFS
rp_filter	integer	Filter		
new_datastore_thin_provision	string	Thin Provision		
placement_auto	boolean	Choose Automatically		false
new_datastore_size	integer	Size (GB)		
new_datastore_autogrow	string	Autogrow		false
placement_folder_name	integer	Name		
new_datastore_name	string	Name		
placement_rp_name	integer	Name		
placement_dc_name	integer	Name		

- Advanced Provisioning Attributes
  - Defining new vLans adapters
  - Defining new SCSI Controller
  - Defining new Disks
  - Cloning Type
  - Limit Template Selection

Advanced Provisioning Attributes

This appendix lists parameters that apply to REST API initiated provisioning via /api/provision_requests.

- Defining new vLans adapters

- Defining new SCSI Controller
- Defining new Disks
- Cloning Type
- Limit Template Selection

Defining new vLans adapters

These attributes allow adding new vLan adapters during the provisioning request.

Attribute	Type	Required	Values	Default
network##	string	Required	Network Name	
network##.mac_address	string	Optional	MAC Address	
network##.deviceType	string	Optional	VirtualE1000, VirtualPCNet32, VirtualVmxnet	VirtualPCNet32
network##.connectable.allowGuestControl	boolean	Optional		true
network##.connectable.startConnected	boolean	Optional		true
network##.connectable.connected	boolean	Optional		true

Example:

```
"network0" : "VM Network",
"network0.mac_address" : "00:50:56:57:58:59"
```

Defining new SCSI Controller

The SCSI Controller attributes are optional. If a controller is required, it will be added with the defined defaults. These settings are only required if you need to override a default value.

Attribute	Type	Required	Values	Default
ctrlscsi##	string	Required	VirtualBusLogicController, VirtualLsiLogicController	VirtualLsiLogicController
ctrlscsi##.sharedBus	string	Optional	noSharing, physicalSharing, virtualSharing	noSharing

Note:

The ## value defines the controller bus number

Example:

```
"ctrlscsi00" : "VirtualBusLogicController"
"ctrlscsi00.sharedBus" : "virtualSharing"
```

Defining new Disks

The Disk attributes allow adding disks as part of the provisioning request.

Attribute	Type	Required	Values	Default
diskscsi##	string	Required	“controller_#:controller_position_#:size_in_mb”	
diskscsi##.datastore	string	Optional	Datastore Name	
diskscsi##.filename	string	Optional	Filename	
diskscsi##.connectable.allowGuestControl	boolean	Optional		false
diskscsi##.connectable.startConnected	boolean	Optional		true
diskscsi##.connectable.connected	boolean	Optional		true
diskscsi##.backing.diskmode	string	Optional	persistent, independent_persistent, independent_nonpersistent, nonpersistent	persistent
diskscsi##.backing.split	boolean	Optional		false
diskscsi##.backing.thinProvisioned	boolean	Optional		false
diskscsi##.backing.writeThrough	boolean	Optional		false

Example:

```
"diskscsi0" : "0:0:10"
"diskscsi1" : "0:0:8"
"diskscsi1.datastore" : "storage1"
"diskscsi1.backing.diskmode" : "independent_persistent"
```

Cloning Type

This attribute sets the type of cloning request, either clone to vm or clone to template. It is an attribute to set with the *template_fields* hash.

Attribute	Type	Required	Values	Default
request_type	string	Optional	clone_to_vm, clone_to_template	clone_to_vm

Example:

```
"template_fields" : {
  "guid" : "afe6e8a0-89fd-11e3-b6ac-b8e85646e742",
  "request_type" : "clone_to_template"
}
```

Limit Template Selection

This attribute value limits the template selection to the Datacenters contained in the specified cluster. It is an attribute to be specified with the *additional_values* hash.

Attribute	Type	Required
cluster	string	Optional

Example:

```
"additional_values" : {
  "request_id" : "87458",
  "cluster" : "sales_prod"
}
```

Control Web Services

SOAP API	HTTP Method	REST API URLs	Actions	Examples
ClusterSetTag	POST	/api/clusters/:id/tags	assign	Assigning Tags
DatastoreSetTag	POST	/api/data_stores/:id/tags	assign	Assigning Tags
EmsSetTag	POST	/api/providers/:id/tags	assign	Assigning Tags
EVMActionList	GET	/api/policies/:id/policy_actions		Policy Actions
	GET	/api/policies/:id?expand=policy_actions		
	GET	/api/policies?filter[]=guid='... .'\&expand=resources,policy_actions		
EVMAssignPolicy	POST	/api/hosts/:id/policies	assign	Assigning Policies
EVMConditionList	GET	/api/policies/:id/conditions		Policy Conditions
	GET	/api/policies/:id?expand=conditions		
	GET	/api/policies?filter[]=guid='....'\&expand=resources,conditions		
EVMEventList	GET	/api/policies/:id/events		Policy Events
	GET	/api/policies/:id?expand=events		
	GET	/api/policies?filter[]=guid='....'\&expand=resources,events		
EVMGetPolicy	GET	/api/policies		Querying Policies
	GET	/api/policies/:id		
	GET	/api/policies?filter[]=name='....'		
EVMPolicyList	GET	/api/hosts/:id/policies		Policy Management
	GET	/api/hosts/:id?expand=policies		
	GET	/api/hosts?filter[]=guid='....'\&expand=resources,policies		
EVMVmEventByProperty	POST	/api/vms/:id	add_event	Add VM Event
EVMVmScanByProperty	POST	/api/vms/:id	scan	Scan VM
EVMSmartStart	POST	/api/vms/:id	start	Start VM
EVMSmartStop	POST	/api/vms/:id	stop	Stop VM
EVMSmartSuspend	POST	/api/vms/:id	suspend	Suspend VM
EVMUnassignPolicy	POST	/api/hosts/:id/policies	unassign	Unassigning Policies
EVMVmRsop	POST	/api/vms/:id/policies/:id	resolve	Resolving Policies
	POST	/api/vms/:id/policy_profiles/:id	resolve	Resolving Policy Profiles
HostSetTag	POST	/api/hosts/:id/tags	assign	Assigning Tags
ResourcePoolSetTag	POST	/api/resource_pools/:id/tags	assign	Assigning Tags
VmAddCustomAttribute	POST	/api/vms/:id/custom_attributes	add	Adding Custom Attributes
VmAddCustomAttributes	POST	/api/vms/:id/custom_attributes	add	
VmAddCustomAttributeByFields	POST	/api/vms/:id/custom_attributes	add	
VmDeleteCustomAttribute	POST	/api/vms/:id/custom_attributes	delete	Deleting Custom Attributes
VmDeleteCustomAttributes	POST	/api/vms/:id/custom_attributes	delete	

SOAP API	HTTP Method	REST API URLs	Actions	Examples
VmSetTag	POST	/api/vms/:id/tags	assign	Assigning Tags
VmSetOwner	POST	/api/vms/:id	set_owner	Set Owner of VM

Automate Web Services

SOAP API	HTTP Method	REST API URLs	Actions	Examples
CreateAutomationRequest	POST	/api/automation_requests	create	Create Automation Request, Create Automation Requests
EVMProvisionRequestEx	POST	/api/provision_requests	create	Create Provision Request, Create Provision Requests
GetAutomationRequest	GET	/api/automation_requests/:id		
GetAutomationTask	GET	/api/automation_requests/:id?expand=request_tasks		
	GET	/api/automation_requests/:id/request_tasks/:id		
GetVmProvisionRequest	GET	/api/provision_requests/:id		
	GET	/api/provision_requests/:id?expand=request_tasks		
VmProvisionRequest	POST	/api/provision_requests	create	Create Provision Request, Create Provision Requests

- Deprecated Types
  - API v2.4.0 ⇒ v3.0.0

Deprecated Types

This page lists the types that have been deprecated in previous releases and have been updated to newer types. They are *temporarily* supported in the listed releases but will be removed in future releases.

API v2.4.0 ⇒ v3.0.0

For Orchestration Templates:

Old Type	New Type
OrchestrationTemplateAzure	ManageIQ::Providers::Azure::CloudManager::OrchestrationTemplate
OrchestrationTemplateHot	ManageIQ::Providers::Openstack::CloudManager::OrchestrationTemplate
OrchestrationTemplateCfn	ManageIQ::Providers::Amazon::CloudManager::OrchestrationTemplate
OrchestrationTemplateVnfd	ManageIQ::Providers::Openstack::CloudManager::VnfdTemplate

- Deprecated Resource Attributes
  - API v2.2.0 ⇒ v2.3.0

Deprecated Resource Attributes

This page lists the resource attributes that have been deprecated in earlier releases and have been either renamed to newer attribute names or simply removed.

API v2.2.0 ⇒ v2.3.0

For Hardware:

Old Attribute Name	New Attribute Name
numvcpus	cpu_sockets
memory_cpu	memory_mb

For Metrics:

Old Attribute Name	New Attribute Name
v_derived_logical_cpus_used	v_derived_cpu_total_cores_used

For Provision Workflows:

Old Attribute Name	New Attribute Name
allowed_datastore_aggregate	**removed**
allowed_datastore_storage_controller	**removed**

For all:

Old Attribute Name	New Attribute Name
cores_per_socket	cpu_cores_per_socket
logical_cpus	cpu_total_cores
aggregate_logical_cpus	aggregate_cpu_total_cores

Infrastructure Management API Examples

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Foundation
- Automation Requests
- Providers
- Provisioning Requests
- Service Catalogs
- Service Templates
- Services
- VM Management
- Tag Management
- Usage Flows

Infrastructure Management API Examples - Foundation

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Querying Examples
- Paging Queries

- Example Queries:
  - Query All VMs
  - Query A Specific VM
  - Query all VMs, but return only return name and vendor
  - Query VMs named sample* and return name and vendor
  - Query VMs but only return the first 500
  - Query VMs but return the second 500
  - Query first 1000 VMs, named test*, get name, vendor and guid and sort by name in ascending order
  - Query Services tagged for the finance department
  - Query Services tagged with the finance or engineering department
  - Get details on the Tags of the first service
  - Get details of the first service catalog and related details on the assigned service templates
  - Get services requests created from a specific template and get details on all related request tasks.
  - Get a specific provision request with expanded details on the associated provision request tasks

Example Queries:

Query All VMs

```
GET /api/vms
```

Query A Specific VM

```
GET /api/vms/1386
```

Query all VMs, but return only return name and vendor

```
GET /api/vms?expand=resources&attributes=name,vendor
```

Query VMs named sample* and return name and vendor

```
GET /api/vms?expand=resources&attributes=name,vendor&filter[]=name='sample%'
```

Query VMs but only return the first 500

```
GET /api/vms?offset=0&limit=500
```

Query VMs but return the second 500

```
GET /api/vms?offset=500&limit=500
```

Query first 1000 VMs, named test*, get name, vendor and guid and sort by name in ascending order

```
GET /api/vms?offset=0&limit=1000&filter[]=name='test%'
    &expand=resources&attributes=name,vendor,guid
    &sort_by=name&sort_order=asc
```

Query Services tagged for the finance department

```
GET /api/services?by_tag=/department/finance
```

Query Services tagged with the finance or engineering department

```
GET /api/services?by_tag=/department/finance,/department/engineering
```

Get details on the Tags of the first service

```
GET /api/services/1/tags?expand=resources
```

Get details of the first service catalog and related details on the assigned service templates

```
GET /api/service_catalogs/1?expand=service_templates
```

Get services requests created from a specific template and get details on all related request tasks.

```
GET /api/service_templates/25/service_requests?expand=resources,request_tasks
```

Get a specific provision request with expanded details on the associated provision request tasks

```
GET /api/provision_requests/120?expand=request_tasks
```

Paging Queries

In this series of requests, we will show the paging queries and the expected responses for each subsequent page.

Request:

```
GET /api/vms?offset=0&limit=500
    &sort_order=asc&sort_by=name
    &expand=resources&attributes=name
```

Response:

```
{
  "name": "vms",
  "count": 1912,
  "subcount": 500,
  "resources": [
    {
      "href": "http://localhost:3000/api/vms/176",
      "id": "176",
      "name": "53 Zone1"
    },
    ...
    {
      "href": "http://localhost:3000/api/vms/1575",
      "id": "1575",
      "name": "VmEmpty-3de98f0f-c6f3-4f8b-a932-554713a61067"
    }
  ],
  "actions": [
  ]
}
```

Request:

```
GET /api/vms?offset=500&limit=500
    &sort_order=asc&sort_by=name
    &expand=resources&attributes=name
```

Response:

```
{
  "name": "vms",
  "count": 1912,
  "subcount": 500,
  "resources": [
    {
      "href": "http://localhost:3000/api/vms/1574",
      "id": "1574",

    }
  ],
  "actions": [
  ]
}
```

Request:

```
GET /api/vms?offset=1000&limit=500
    &sort_order=asc&sort_by=name
    &expand=resources&attributes=name
```

Response:

```
{
  "name": "vms",
  "count": 1912,
  "subcount": 500,
  "resources": [
    {
      "href": "http://localhost:3000/api/vms/1074",
      "id": "1074",
      "name": "VmEmpty-9ab9e101-92b0-4b6b-864e-e196538da8a8"
    },
    ...
    {
      "href": "http://localhost:3000/api/vms/575",
      "id": "575",
      "name": "VmEmpty-f251f135-01c8-4d44-b8e1-37b30844a9dd"
    }
  ],
  "actions": [
  ]
}
```

Request:

```
GET /api/vms?offset=1500&limit=500
    &sort_order=asc&sort_by=name
    &expand=resources&attributes=name
```

Response:

```
{
  "name": "vms",
  "count": 1912,
  "subcount": 412,
  "resources": [
    {
      "href": "http://localhost:3000/api/vms/574",
      "id": "574",
      "name": "VmEmpty-f28912f3-b096-487f-9763-97b39b67364b"
    },
    ...
    {
      "href": "http://localhost:3000/api/vms/1907",
      "id": "1907",
      "name": "yy_vm"
    }
  ],
  "actions": [
  ]
}
```

Note:

In this last request, the **subcount** was less than the requested page size thus denoting the last page of data being returned.

Infrastructure Management API Examples - Automation Requests

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Create an Automation Request
- Create multiple Automation Requests
- Trigger a single Automation Request
  - Request:
  - Request:
  - Response:

Trigger a single Automation Request

In the automation requests:

- version defaults to “1.1” if not specified.
- user_name defaults to the REST API authenticated user if not specified.

Request:

```
POST /api/automation_requests

{
  "version" : "1.1",
  "uri_parts" : {
    "namespace" : "System",
    "class" : "Request",
    "instance" : "InspectME",
    "message" : "create"
  },
  "parameters" : {
    "var1" : "xxxxx",
    "var2" : "yyyyy",
    "var3" : 1024,
    "var4" : true,
    "var5" : "last value"
  },
  "requester" : {
    "user_name" : "admin",
    "auto_approve" : true
  }
}
```

Optionally, the action based request format is also supported:

Request:

```
POST /api/automation_requests

{
  "action" : "create",
  "resource" : {
    "version" : "1.1",
    "uri_parts" : {
      "namespace" : "System",
      "class" : "Request",
      "instance" : "InspectME",
      "message" : "create"
    },
    "parameters" : {
      "var1" : "xxxxx",
      "var2" : "yyyyy",
      "var3" : 1024,
      "var4" : true,
      "var5" : "last value"
    },
    "requester" : {
      "user_name" : "admin",
      "auto_approve" : true
    }
  }
}
```

Response:

```
{
  "results": [
    {
      "id": "12",
      "href" : "http://localhost:3000/api/automation_requests/12",
      "description": "Automation Task",
      "approval_state": "approved",
      "type": "AutomationRequest",
      "created_on": "2015-04-16T21:49:55Z",
      "updated_on": "2015-04-16T21:49:55Z",
      "requester_id": "1",
      "requester_name": "Administrator",
      "request_type": "automation",
      "request_state": "pending",
      "status": "Ok",
      "options": {
        "message": "create",
        "namespace": "System",
        "class_name": "Request",
        "instance_name": "InspectME",
        "user_id": "1",
        "attrs": {
          "var1": "xxxxx",
          "var2": "yyyyy",
          "var3": 1024,
          "var4": true,
          "var5": "last value",
          "userid": "admin"
        }
      },
      "userid": "admin"
    }
```

```
  ]
}
```

- Trigger multiple Automation Requests
  - Request:
  - Response:

Trigger multiple Automation Requests

In the automation requests:

- version defaults to “1.1” if not specified.
- user_name defaults to the REST API authenticated user if not specified.

Request:

```
POST /api/automation_requests

{
  "action" : "create",
  "resources" : [
    {
      "version" : "1.1",
      "uri_parts" :  {
        "namespace" : "System",
        "class" : "Request",
        "instance" : "InspectME",
        "message" : "create"
      },
      "parameters" : {
        "vm_name" : "test_1",
        "var2" : "yyyyy",
        "var3" : 1024,
        "var4" : true,
        "var5" : "last value"
      },
      "requester" :  {
        "user_name" : "jdoe",
        "auto_approve" : true
      }
    },
    {
      "uri_parts" :  {
        "namespace" : "System",
        "class" : "Request",
        "instance" : "InspectME",
        "message" : "create"
      },
      "parameters" : {

Infrastructure Management API Examples - Providers

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Create a Provider
- Create a Provider with multiple credentials
- Update a Provider
- Refresh a Provider
- Delete a Provider

- Create Provider
  - Request:
  - Response:

Create Provider

Request:

```
POST /api/providers
```

```
{
  "type"       : "ManageIQ::Providers::Redhat::InfraManager",
  "name"       : "rhevm101",
  "hostname"   : "rhevm101",
  "ipaddress"  : "100.200.300.101",
  "credentials" : {
    "userid"     : "admin_account",
    "password"   : "admin_password"
  }
}
```

Response:

```
{
  "results": [
    {
      "id": "105",
      "href" : "http://localhost:3000/api/providers/105",
      "name": "rhevm101",
      "hostname": "rhevm101",
      "ipaddress": "100.200.300.101",
      "created_on": "2015-05-05T15:47:41Z",
      "updated_on": "2015-05-05T15:47:41Z",
      "guid": "10360312-f33e-11e4-86c7-b8e85646e742",
      "zone_id": "1",
      "type": "ManageIQ::Providers::Redhat::InfraManager"
    }
  ]
}
```

- Create Provider
  - Request:
  - Response:

Create Provider

Request:

```
POST /api/providers
```

```
{
  "type"      : "ManageIQ::Providers::Redhat::InfraManager",
  "name"      : "rhevm102",
  "hostname"  : "rhevm102",
  "ipaddress" : "100.200.300.102",
  "credentials" : [
    {
      "userid"    : "default_userid",
      "password"  : "default_password"
    },
    {
      "userid"    : "metrics_userid",
      "password"  : "metrics_password",
      "auth_type" : "metrics"
    }
  ]
}
```

Response:

```
{
  "results": [
    {
      "id": "106",
      "href" : "http://localhost:3000/api/providers/106",
      "name": "rhevm102",
      "hostname": "rhevm102",
      "ipaddress": "100.200.300.102",
      "created_on": "2015-05-05T15:57:44Z",
      "updated_on": "2015-05-05T15:57:44Z",
      "guid": "acbd610e-f3f6-11e4-aaba-b8e85646e742",
      "zone_id": "1",
      "type": "ManageIQ::Providers::Redhat::InfraManager"
    }
  ]
}
```

- Update Provider
  - Request:
  - Response:

Update Provider

Request:

```
POST /api/providers/106
```

```
{
  "action"    : "edit",
  "ipaddress" : "100.200.300.112",
  "credentials" : [
    {
      "userid"    : "updated_metrics_userid",
      "password"  : "updated_metrics_password",
      "auth_type" : "metrics"
    }
  ]
}
```

Response:

```
{
  "href": "http://localhost:3000/api/providers/106",
  "id": "106",
  "name": "rhevm102",
  "hostname": "rhevm102",
  "ipaddress": "100.200.300.112",
  "created_on": "2015-05-06T13:49:11Z",
  "updated_on": "2015-05-06T13:53:06Z",
  "guid": "acbd610e-f3f6-11e4-aaba-b8e85646e742",
  "zone_id": "1",
  "type": "ManageIQ::Providers::Redhat::InfraManager"
}
```

- Refresh Provider
  - Request:

- Response:

Refresh Provider

Request:

```
POST /api/providers/105

{
  "action" : "refresh"
}
```

Response:

```
{
  "success": true,
  "message": "Provider id:105 name:'sample_provider' refreshing",
  "href": "http://localhost:3000/api/providers/105",
  "task_id" : "23",
  "task_href" : "http://localhost:3000/api/tasks/23",
  "tasks" : [
    { "id" : "23", "href" : "http://localhost:3000/api/tasks/23"},
    { "id" : "24", "href" : "http://localhost:3000/api/tasks/24"}
  ]
}
```

Note: In the above example a multi-manager provider was refreshed and in the response, a task id and href pair is returned for each of the provider managers. This allows the caller to check the status of each manager refresh for completion.

- Delete Provider
  - Deleting a single Provider
    - Request:
    - Response:
    - Request:
    - Response:
  - Deleting multiple Providers
    - Request:
    - Response:

Delete Provider

Deleting a single Provider

Request:

```
DELETE /api/provider/105
```

Or via the delete action as follows:

```
POST /api/provider/105

{
  "action" : "delete"
}
```

Response:

```
{
  "success": true,
  "message": "Provider id:106 name:'rhevm102' deleting",
  "task_id": "625",
  "task_href": "http://localhost:3000/api/tasks/625",
  "href": "http://localhost:3000/api/providers/106"
}
```

Note:

Delete actions are done asynchronously as it could take a while to complete. The delete task can be queried if needed as follows

Request:

```
GET /api/tasks/625
```

Response:

```
{
  "href": "http://localhost:3000/api/tasks/625",
  "id": "625",
  "name": "Provider id:106 name:'rhevm102' deleting",
  "state": "Finished",
  "status": "Ok",
  "message": "Task completed successfully",
  "userid": "admin",
  "created_on": "2015-05-06T14:02:26Z",
```

```
  "updated_on": "2015-05-06T14:02:32Z"
}
```

Deleting multiple Providers

Request:

```
POST /api/providers

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/providers/107" },
    { "href" : "http://localhost:3000/api/providers/108" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Provider id:107 name:'rhevm102' deleting",
      "task_id": "626",
      "task_href": "http://localhost:3000/api/tasks/626",
      "href": "http://localhost:3000/api/providers/107"
    },
    {
      "success": true,
      "message": "Provider id:108 name:'rhevm103' deleting",
      "task_id": "627",
      "task_href": "http://localhost:3000/api/tasks/627",
      "href": "http://localhost:3000/api/providers/108"
    }
  ]
}
```

Infrastructure Management API Examples - Provisioning Requests

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Create a Provision Request
- Create multiple Provision Requests
- Trigger a single Provision Request
  - Request:
  - Response:

Trigger a single Provision Request

In the provision requests:

- version defaults to “1.1” if not specified.
- user_name defaults to the REST API authenticated user if not specified.

Request:

```
POST /api/provision_requests

{
  "version" : "1.1",
  "template_fields" : {
    "guid" : "afe6e8a0-89fd-11e3-b6ac-b8e85646e742"
  },
  "vm_fields" : {
    "number_of_cpus" : 1,
    "vm_name" : "aab_rest_vm1",
    "vm_memory" : "1024",
    "vlan" : "rhevm"
  },
  "requester" : {
    "user_name" : "jdoe",
    "owner_first_name" : "John",
    "owner_last_name" : "Doe",
    "owner_email" : "jdoe@sample.com",
    "auto_approve" : true
  },
  "tags" : {
    "network_location" : "Internal",
    "cc" : "001"
  },
  "additional_values" : {
```

```
    "request_id" : "1001"
  },
  "ems_custom_attributes" : { },
  "miq_custom_attributes" : { }
}
```

Optionally, the action based request format is also supported:

```
POST /api/provision_requests
```

```
{
  "action" : "create",
  "resource" : {
    "version" : "1.1",
      "template_fields" : {
        "guid" : "afe6e8a0-89fd-11e3-b6ac-b8e85646e742"
      },
      "vm_fields" : {
        "number_of_cpus" : 1,
        "vm_name" : "aab_rest_vm1",
        "vm_memory" : "1024",
        "vlan" : "rhevm"
      },
      "requester" : {
        "user_name" : "jdoe",
        "owner_first_name" : "John",
        "owner_last_name" : "Doe",
        "owner_email" : "jdoe@sample.com",
        "auto_approve" : true
      },
      "tags" : {
        "network_location" : "Internal",
        "cc" : "001"
      },
      "additional_values" : {
        "request_id" : "1001"
      },
      "ems_custom_attributes" : { },
      "miq_custom_attributes" : { }
  }
}
```

Response:

```
{
  "results": [
    {
      "href" : "http://localhost:3000/api/provision_requests/18",
      "id": "18",

- Trigger multiple Provision Requests
  - Request:
  - Response:

Trigger multiple Provision Requests

In the provision requests:

- version defaults to “1.1” if not specified.
- user_name defaults to the REST API authenticated user if not specified.

Request:

```
POST /api/provision_requests

Infrastructure Management API Examples - Service Catalogs

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Add a Service Catalog
- Add multiple Service Catalogs
- Edit a Service Catalog
- Edit Service Catalogs
- Assign Service Templates
- Unassign Service Templates
- Delete Service Catalogs

- Adding a simple Service Catalog
  - Request:
  - Response:

Adding a simple Service Catalog

Request:

```
POST /api/service_catalogs
```

```
{
   "action" : "create",
   "resource" : {
        "name" : "Sample Service Catalog",
        "description" : "Description of Sample Service Catalog",
        "service_templates" : [
          { "href" : "http://localhost:3000/api/service_templates/3" },
          { "href" : "http://localhost:3000/api/service_templates/4" }
        ]
   }
}
```

Response:

```
{
  "results": [
    {
      "id": "7",
      "href" : "http://localhost:3000/api/service_catalogs/7",
      "name": "Sample Service Catalog",
      "description": "Description of Sample Service Catalog"
    }
  ]
}
```

- Adding multiple Service Catalogs
  - Request:
  - Response:

Adding multiple Service Catalogs

Request:

```
POST /api/service_catalogs
```

```
{
   "action" : "create",
   "resources" : [

```

Infrastructure Management API Examples - Service Templates

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Edit a Service Template
- Edit Service Templates
- Delete Service Templates

- Edit Service Template
  - Request:
  - Response:

Edit Service Template

Request:

```
POST /api/service_templates/2

{
  "action" : "edit",
  "resource" : {
    "name" : "updated_svc_template_02",
    "description" : "This is an updated description for service template 02"
  }
}
```

Response:

```
{
  "href": "http://localhost:3000/api/service_templates/2",
  "id": "2",
  "name": "updated_svc_template_02",
  "description": "This is an updated description for service template 02",
  "guid": "6f7918b4-d6e7-11e4-9837-b8e85646e742",
  "options": {
  },
  "created_at": "2015-03-30T14:17:02Z",
  "updated_at": "2015-04-16T22:30:02Z",
  "service_type": "unknown",
  "service_template_catalog_id": "6"
}
```

- Edit Service Templates
  - Request:
  - Response:

Edit Service Templates

Request:

```
POST /api/service_templates
```

```
{
  "action" : "edit",
  "resources" : [
    {
      "href" : "http://localhost:3000/api/service_templates/1",
      "description" : "This is an updated description for the first sample service template"
    },
    {
      "href" : "http://localhost:3000/api/service_templates/2",

      "message": "service_templates id: 5 deleting",
      "href": "http://localhost:3000/api/service_templates/5"
    }
  ]
}
```

Infrastructure Management API Examples - Services

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Order a Service
- Order Multiple Services
- Edit a Service
- Edit a Service with Patch Method
- Edit a Service with PUT
- Edit Services
- Reconfigure a Service
- Refresh Service Template Dialog Fields
- Refresh Service Dialog Fields
- Retire a Service
- Retire Multiple Services
- Trigger a Custom Action on a Service
- Delete Services

- Order a single service from Service Catalog 1
  - Request:
  - Response:

Order a single service from Service Catalog 1

Request:

```
POST /api/service_catalogs/1/service_templates
```

```
{
  "action" : "order",
  "resource" : {
    "href" : "http://localhost:3000/api/service_templates/3",
    "option_0_vm_target_name" : "test-vm-0001",
    "option_0_vm_target_hostname" : "test-vm-0001"
  }
}
```

Response:

```
{
  results: [
    {
      "approval_state": "pending_approval",
      "created_on": "2014-07-02T19:28:12Z",

- Retire Service Immediately
  - Request:
  - Response:
  - Response:
- Retire Service In the Future
  - Request:
  - Response:

Retire Service Immediately

Request:

```
POST /api/services
```

```
{
  "action" : "request_retire",
  "resource" : { "href" : "http://localhost:3000/api/services/35" }
}
```

Response:

```
{
  "results" : [
    {
```

```
      "href": "http://localhost:3000/api/services/95",
      "id": "95",
      "name": "sample_service_95",
      "description": "Description for sample_service_95",
      "guid": "eb713538-7c9b-11e4-8a3a-b8e85646e742",

      "method": "post",
      "href": "http://localhost:3000/api/services/110"
    }
  ]
}
```

Showing the **queryvm** custom action being returned in the actions list.

The following is the request triggering a **queryvm** action on the service:

Request:

```
POST /api/services/110

{
  "action" : "queryvm",
  "resource" : {
    "hostname": "updated_hostname",
    "ipaddress": "192.168.100.2",
    "environmenttype" : "medium"
  }
}
```

Response:

```
{
  "success": true,
  "message": "Invoked custom dialog action queryvm for services id: 110",
  "href": "http://localhost:3000/api/services/110"
}
```

- Delete Services
  - Request:
  - Response:

Delete Services

Request:

```
POST /api/services

{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/services/97" },
    { "href" : "http://localhost:3000/api/services/98" },
    { "href" : "http://localhost:3000/api/services/99" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "services id: 97 deleting",
      "href": "http://localhost:3000/api/services/97"
    },
    {
      "success": true,
      "message": "services id: 98 deleting",
      "href": "http://localhost:3000/api/services/98"
    },
    {
      "success": true,
      "message": "services id: 99 deleting",
      "href": "http://localhost:3000/api/services/99"
    }
  ]
}
```

Infrastructure Management API Examples - VM Management

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Start a VM
- Stop a VM
- Suspend a VM
- Scan a VM
- Set owner of a VM
- Add Event to a VM
- Add Lifecycle Event to VM
- Delete a VM

- Start a VM
  - Request:
  - Response:
- Querying task progress:
  - Request:
  - Response:

Start a VM

Request:

```
POST /api/vms/1921

{
  "action": "start"
}
```

Response:

```
{
  "success": true,
  "message": "VM id:1921 name:'aab_demo_vm' starting",
  "task_id": "610",
  "task_href": "http://localhost:3000/api/tasks/610",
  "href": "http://localhost:3000/api/vms/1921"
}
```

Querying task progress:

Request:

```
GET /api/tasks/620
```

Response:

```
{
  "href": "http://localhost:3000/api/tasks/610",
  "id": "610",
  "name": "VM id:1921 name:'aab_demo_vm' starting",
  "state": "Queued",
  "status": "Ok",
  "message": "Queued the action: [VM id:1921 name:'aab_demo_vm' starting] being run for user: [admin]",
  "userid": "admin",
  "created_on": "2015-05-05T15:58:08Z",
  "updated_on": "2015-05-05T15:58:08Z"
}
```

- Stop a VM
  - Request:
  - Response:

Stop a VM

Request:

```
POST /api/vms/1921

{
  "action": "stop"
}
```

Response:

```
{
  "success": true,
  "message": "VM id:1921 name:'aab_demo_vm' stopping",
  "task_id": "619",
  "task_href": "http://localhost:3000/api/tasks/619",
  "href": "http://localhost:3000/api/vms/1921"
}
```

- Suspend a VM
  - Request:
  - Response:

Suspend a VM

Request:

```
POST /api/vms/1921

{
  "action": "suspend"
}
```

Response:

```
{
  "success": true,
  "message": "VM id:1921 name:'aab_demo_vm' suspending",
  "task_id": "620",
  "task_href": "http://localhost:3000/api/tasks/620",
  "href": "http://localhost:3000/api/vms/1921"
}
```

- Scan a VM
  - Request:
  - Response:
  - Response:

Scan a VM

Request:

```
POST /api/vms/1922

{
  "action": "scan"
}
```

Response:

```
{
  "success": true,
  "message": "VM id:1922 name:'aab_test_vm' scanning",
  "task_id": "618",
  "task_href": "http://localhost:3000/api/tasks/618",
  "href": "http://localhost:3000/api/vms/1922"
}
```

And then optionally waiting for the task to complete as follows:

```
GET /api/tasks/618
```

Response:

```
{
  "href": "http://localhost:3000/api/tasks/618",
  "id": "618",
  "name": "VM id:1922 name:'aab_test_vm' scanning",
  "state": "Finished",
  "status": "Ok",
  "message": "Task completed successfully",
  "userid": "admin",
  "created_on": "2015-05-05T19:37:32Z",
  "updated_on": "2015-05-05T19:37:38Z"
}
```

- Set owner of a VM
  - Request:
  - Response:

Set owner of a VM

Request:

```
POST /api/vms/1921

{
  "action": "set_owner",
  "resource" : {
    "owner" : "admin"
  }
}
```

Response:

```
{
  "success": true,
  "message": "VM id:1921 name:'aab_demo_vm' setting owner to 'admin'",
  "href": "http://localhost:3000/api/vms/1921"
}
```

- Add event to a VM
  - Request:
  - Response:

Add event to a VM

Request:

```
POST /api/vms/1921
```

```
{
  "action": "add_event",
  "resource" : {
    "event_type" : "BadUserNameSessionEvent",
    "event_message" : "Cannot login user@test.domain"
  }
}
```

Response:

```
{
  "success": true,
  "message": "Adding Event type=BadUserNameSessionEvent message=Cannot login user@test.domain",
  "href": "http://localhost:3000/api/vms/1921"
}
```

- Delete VMs
  - Deleting a single VM
    - Request:
  - Deleting multiple VMs
    - Request:
    - Response:
    - Request:
    - Response:

Delete VMs

Deleting a single VM

Request:

```
DELETE /api/vms/334
```

Upon success, Vm targeted for deletion asynchronously and No Response Content with HTTP status code 204

Deleting multiple VMs

Request:

```
DELETE /api/vms
```

```
{
  "action" : "delete",
  "resources" : [
    { "href" : "http://localhost:3000/api/vms/348" },
    { "href" : "http://localhost:3000/api/vms/349" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "VM id:348 name:'aab-temp1' deleting",
      "task_id": "616",
      "task_href": "http://localhost:3000/api/tasks/616",
      "href": "http://localhost:3000/api/vms/348"
    },
    {
      "success": true,
      "message": "VM id:349 name:'aab-temp2' deleting",
      "task_id": "617",
      "task_href": "http://localhost:3000/api/tasks/617",
      "href": "http://localhost:3000/api/vms/349"
```

```
    }
  ]
}
```

Optionally monitoring the asynchronous Vm deletion by accessing the related Task as follows:

Request:

```
GET /api/tasks/616
```

Response:

```
{
  "href": "http://localhost:3000/api/tasks/616",
  "id": "616",
  "name": "VM id:348 name:'aab-temp1' deleting",
  "state": "Finished",
  "status": "Ok",
  "message": "Task completed successfully",
  "userid": "admin",
  "created_on": "2015-05-05T19:33:35Z",
  "updated_on": "2015-05-05T19:33:40Z"
}
```

Infrastructure Management API Examples - Tag Management

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Assign Tags
- Assign Tags to Service Template
- Unassign Tags
- Unassign Tags from Service Template
- Assign Tags to a Service
  - Request:
  - Response:
- Assign Tags by Name to a Service
  - Request:
  - Response:
- Assign a Tag by Reference to a Service
  - Request:
  - Response:

Assign Tags to a Service

Request:

```
POST /api/services/101/tags
```

```
{
  "action" : "assign",
  "resources" : [
    { "category" : "location", "name" : "ny" },
    { "category" : "department", "name" : "finance" },
    { "category" : "environment", "name" : "dev" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Assigning Tag: category:'location' name:'ny'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "location",
      "tag_name": "ny"
    },
    {
      "success": true,
      "message": "Assigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "department",
      "tag_name": "finance"
    },
    {
      "success": true,
      "message": "Assigning Tag: category:'environment' name:'dev'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "environment",
      "tag_name": "dev"
```

```
    }
  ]
}
```

Assign Tags by Name to a Service

Request:

```
POST /api/services/101/tags

{
  "action" : "assign",
  "resources" : [
    { "name" : "/department/finance" },
    { "name" : "/location/ny" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Assigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "department",
      "tag_name": "finance"
    },
    {
      "success": true,
      "message": "Assigning Tag: category:'location' name:'ny'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "location",
      "tag_name": "ny"
    }
  ]
}
```

Assign a Tag by Reference to a Service

Request:

```
POST /api/services/101/tags

{
  "action" : "assign",
  "resources" : [
    { "href" : "http://localhost:3000/api/services/1/tags/49" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Assigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "department",
      "tag_name": "finance",
      "tag_href": "http://localhost:3000/api/tags/49"
    }
  ]
}
```

- Assign Tags to service template 1
  - Request:
  - Response:

Assign Tags to service template 1

Request:

```
POST /api/service_templates/1/tags

{
  "action" : "assign",
  "resources" : [
    { "category" : "location", "name" : "ny" },
    { "category" : "department", "name" : "finance" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Assigning Tag: category:'location' name:'ny'",
      "href": "http://localhost:3000/api/service_templates/1",
      "tag_category": "location",
      "tag_name": "ny"
    },
    {
      "success": true,
      "message": "Assigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/service_templates/1",
      "tag_category": "department",
      "tag_name": "finance"
    }
  ]
}
```

- Unassign Tags from a Service
  - Request:
  - Response:
- Unassign a Tag by Name from a Service
  - Request:
  - Response:
- Unassign a Tag by Reference from a Service
  - Request:
  - Response:

Unassign Tags from a Service

Request:

```
POST /api/services/101/tags

{
  "action" : "unassign",
  "resources" : [
    { "category" : "department", "name" : "finance" },
    { "category" : "environment", "name" : "dev" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Unassigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "department",
      "tag_name": "finance"
    },
    {
      "success": true,
      "message": "Unassigning Tag: category:'environment' name:'dev'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "environment",
      "tag_name": "dev"
    }
  ]
}
```

Unassign a Tag by Name from a Service

Request:

```
POST /api/services/101/tags

{
  "action" : "unassign",
  "resources" : [
    { "name" : "/managed/department/finance" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Unassigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "department",
```

```
      "tag_name": "finance"
    }
  ]
}
```

Unassign a Tag by Reference from a Service

Request:

```
POST /api/services/101/tags

{
  "action" : "unassign",
  "resources" : [
    { "href" : "tags/49" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Unassigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/services/101",
      "tag_category": "department",
      "tag_name": "finance",
      "tag_href": "http://localhost:3000/api/tags/49"
    }
  ]
}
```

- Unassign Tags from service template 1
  - Request:
  - Response:

Unassign Tags from service template 1

Request:

```
POST /api/service_templates/1/tags

{
  "action" : "unassign",
  "resources" : [
    { "category" : "location", "name" : "ny" },
    { "category" : "department", "name" : "finance" }
  ]
}
```

Response:

```
{
  "results": [
    {
      "success": true,
      "message": "Unassigning Tag: category:'location' name:'ny'",
      "href": "http://localhost:3000/api/service_templates/1",
      "tag_category": "location",
      "tag_name": "ny"
    },
    {
      "success": true,
      "message": "Unassigning Tag: category:'department' name:'finance'",
      "href": "http://localhost:3000/api/service_templates/1",
      "tag_category": "department",
      "tag_name": "finance"
    }
  ]
}
```

Infrastructure Management API Examples - Usage Flows

In this guide you will find examples for the Infrastructure Automation – Infrastructure Management REST API.

- Compliance Policy Flow
- Compliance Policy Flow
  - Create a couple of conditions for the new compliance policy
    - Request:
    - Response:

- Find the Policy action to use
  - Request:
  - Response:
- Find the Policy event to use
  - Response:
- Create the Compliance Policy for Finance Servers
  - Request:
  - Response:
- Create the Compliance Policy Profile for Finance Servers
  - Request:
  - Response:
- Assigning new policy to policy profile
  - Request:
  - Response:
- Assigning the policy profile to a virtual machine
  - Request:
  - Response:
- Querying the policy profiles and related policies of the virtual machine
  - Request:
  - Response:
- Requesting a compliance check on the virtual machine
  - Request:
  - Response:
- Waiting for the compliance check to complete
  - Response:
- Querying all compliances run for the virtual machine
  - Request:
  - Response:
- Querying the virtual machine and its latest compliance result including the last compliance status
  - Request:
  - Response:

Compliance Policy Flow

Create a couple of conditions for the new compliance policy

Request:

```
POST /api/conditions
```

```
{
  "action" : "create",
  "resources" : [
    {
      "name" : "finance_mem_req",
      "description" : "System Memory Requirement for Finance Systems",
      "expression" : {
        ">=": {
          "field": "Vm-mem_cpu",
          "value": "4096"
        }
      },
      "towhat" : "Vm"
    },
    {
      "name" : "finance_cpu_req",
      "description" : "System CPU Requirement for Finance Systems",
      "expression" : {
        ">=": {
          "field": "Vm-num_cpu",
          "value": "2"
        }
      },
      "towhat" : "Vm"
    }
  ]
}
```

Response:

```
{
  "results": [
    {

      "policy_id": "12",
      "policy_href": "http://localhost:3000/api/policies/11"
    }
  ]
}
```

Assigning the policy profile to a virtual machine

Request:

```
POST /api/vms/171/policy_profiles

{
  "action" : "assign",
  "resources" : [
    { "id" : "35" }
  ]
}
```

Response:

```
{
  "results": [
    {
```

```
      "success": true,
      "message": "Assigning Policy Profile: id:'35' description:'Finance Servers Policy Profile' guid:'d4546f30-15a7-48f3-
a793-cfd6d1d849a2'",
      "href": "http://localhost:3000/api/vms/171",
      "policy_profile_id": "35",
      "policy_profile_href": "http://localhost:3000/api/policy_profiles/35"
    }
  ]
}
```

Querying the policy profiles and related policies of the virtual machine

Request:

```
GET /api/vms/171/policy_profiles?expand=resources&attributes=miq_policies
```

Response:

```
{
  "name": "policy_profiles",
  "count": 6,
  "subcount": 1,
  "pages": 1,
  "resources": [
    {
      "href": "http://localhost:3000/api/vms/171/policy_profiles/35",
      "id": "35",
      "name": "finance_policy_profile",
      "description": "Finance Servers Policy Profile",
      "set_type": "MiqPolicySet",
      "created_on": "2020-03-24T18:56:23Z",
      "updated_on": "2020-03-24T18:56:23Z",
      "guid": "d4546f30-15a7-48f3-a793-cfd6d1d849a2",
      "read_only": null,
      "set_data": null,
      "mode": "compliance",

      "userid": null,
      "group_id": null,
      "miq_policies": [
        {
          "href": "http://localhost:3000/api/policies/12",
          "id": "12",
          "name": "finance_server_policy",
          "description": "Finance Server Policy",
          "created_on": "2020-03-25T16:44:19Z",
          "updated_on": "2020-03-25T16:44:19Z",
          "expression": null,
          "towhat": "Vm",
          "guid": "e56d468c-1b1b-42f1-a4cb-4ea11924d7b3",
          "created_by": null,
          "updated_by": null,
          "notes": null,
          "active": true,
          "mode": "compliance",
          "read_only": null
        }
      ]
    }
  ],
  "actions": [
    {
      "name": "assign",
      "method": "post",
      "href": "http://localhost:3000/api/vms/171/policy_profiles"
    },
    {
      "name": "unassign",
      "method": "post",
      "href": "http://localhost:3000/api/vms/171/policy_profiles"
    },
    {
      "name": "resolve",
      "method": "post",
      "href": "http://localhost:3000/api/vms/171/policy_profiles"
    }
  ],
  "links": {
    "self": "http://localhost:3000/api/vms/171/policy_profiles?attributes=miq_policies&expand=resources&offset=0",
    "first": "http://localhost:3000/api/vms/171/policy_profiles?attributes=miq_policies&expand=resources&offset=0",
    "last": "http://localhost:3000/api/vms/171/policy_profiles?attributes=miq_policies&expand=resources&offset=0"
  }
}
```

At this point, the compliance policy is properly assigned to the virtual machine. If configured via a schedule for the encompassing region, the compliance checks will run as scheduled. They can also be executed on the specific virtual machine via the API as follows:

Requesting a compliance check on the virtual machine

Request:

```
POST /api/vms/171

{
  "action" : "check_compliance"
}
```

Response:

```
{
  "success" : true,
  "message": "VM id:171 name:'aab-ldap' check compliance requested",
  "task_id": "35",
  "task_href": "http://localhost:3000/api/tasks/41",
  "href": "http://localhost:3000/api/vms/171"
}
```

Waiting for the compliance check to complete

One can find out when the compliance check completes by querying the task generated for it and look for the state attribute as follows:

```
GET /api/tasks/41
```

Response:

```
{
  "href": "http://localhost:3000/api/tasks/41",
  "id": "41",
  "name": "VM id:171 name:'aab-ldap' check compliance requested",
  "state": "Finished",
  "status": "Ok",
  "message": "Task completed successfully",
  "userid": "admin",
  "created_on": "2020-04-09T21:16:07Z",
  "updated_on": "2020-04-09T21:16:12Z",
  "pct_complete": null,
  "context_data": null,
  "results": null,
  "miq_server_id": "3",
  "identifier": null,
  "started_on": "2020-04-09T21:16:09Z",
  "zone": null,
  "actions": [
    {
      "name": "delete",
      "method": "post",
      "href": "http://localhost:3000/api/tasks/41"
    },
    {
      "name": "delete",
      "method": "delete",
      "href": "http://localhost:3000/api/tasks/41"
    }
  ]
}
```

Querying all compliances run for the virtual machine

Request:

```
GET /api/vms/171/compliances?expand=resources
```

Response:

```
{
  "name": "compliances",
  "count": 430,
  "subcount": 2,
  "pages": 1,
  "resources": [
    {
      "href": "http://localhost:3000/api/vms/171/compliances/40",

      "resource_type": "VmOrTemplate",
      "compliant": false,
      "timestamp": "2020-03-26T14:30:24Z",
      "updated_on": "2020-03-26T14:30:24Z",
      "event_type": "vm_compliance_check"
    },
    {
      "href": "http://localhost:3000/api/vms/171/compliances/41",
      "id": "41",
      "resource_id": "171",
      "resource_type": "VmOrTemplate",
      "compliant": false,
      "timestamp": "2020-03-26T20:11:53Z",
```

```
      "updated_on": "2020-03-26T20:11:53Z",
      "event_type": "vm_compliance_check"
    }
  ],
  "links": {
    "self": "http://localhost:3000/api/vms/171/compliances?expand=resources&offset=0",
    "first": "http://localhost:3000/api/vms/171/compliances?expand=resources&offset=0",
    "last": "http://localhost:3000/api/vms/171/compliances?expand=resources&offset=0"
  }
}
```

Querying the virtual machine and its latest compliance result including the last compliance status

Request:

```
GET /api/vms/171?attributes=last_compliance,last_compliance_status
```

Response:

    }
  ]
}
```

Managed services APIs

This section includes the prerequisites to use Managed services APIs, Common Managed services APIs, sample Python script, and API reference.

- API reference
- Prerequisites
- Common APIs
- Sample Python script
- Content APIs
- Retrieve deployed APIs

API reference

You can use REST APIs to integrate Managed services with your application.

About the task

The terms in the swagger files for your reference:

- Stack is the API name for a deployed template instance.
- Stackstate is a separate table that keeps a history of all the detailed states the stack has been in. When you do a `stack/<stack_id>/retrieve`, it includes the latest state.
- Foreign key (fk) is the ID of that particular stackstate.

Procedure

1. Before you run API commands, generate access tokens. For more information about the steps, see Generating access tokens.
2. Copy the following Swagger files and save them in yaml format:
   - **`Managed services: cam-iaas`**

     The Managed services IaaS component provides support for defining connections to various clouds, templates that can be used to deploy stack instances.

   - **`Managed services: cam-service-composer-api`**

     The Managed services service composer.

   - **`Managed services: cam-tenant-api`**

     The Managed services tenant service provides a way to retrieve information about the tenant for the current user.

3. Managed services API needs tenantId, IBM Cloud Pak for AIOps team (ace_orgGuid), and IBM Cloud Pak for AIOps namespace (cloudOE_spaceGuid) for authorization. For the procedure to get these values, see Prerequisites for using Managed services APIs topic.
4. Load the yaml files onto any swagger browser.

Prerequisites for using Managed services APIs

This section includes prerequisite steps to use Managed services APIs.

The following table describes the variables that are used throughout the API calls.

Variable	Description
TSA_HOSTNAME	**TSA_HOSTNAME** is the **HOST/PORT** value in the output of the command: oc get routes cam -o=jsonpath='{.spec.host}'.
TSA_USER	**TSA_USER** is the IBM Cloud Pak for AIOps user you want to use. You can use either the default admin user or any user you have added/configured in the IBM Cloud Pak for AIOps.
TSA_USER_PASSWORD	**TSA_USER_PASSWORD** is the password for the **TSA_USER**.
MCM_CLUSTER_HOSTNAME	**MCM_CLUSTER_HOSTNAME** is the cluster hostname for IBM Cloud Pak for AIOps. It is the **HOST/PORT** value in the output of the command: **$ oc -n <IA_installation_namespace> get route cp-console**

Where **<IA_installation_namespace>** is the namespace that Infrastructure Automation is installed in.

1. Preparing to run Managed services APIs:
    1. Set the following environment variables:
        1. Run **vi setenv** to create a script.
        2. In **setenv**, paste the following environment variables:
            - **export TSA_HOSTNAME=<Replace_with_your_TSA_HOSTNAME>**
            - **export TSA_USER=<Replace_with_your_CloudPak_for_MCM_User>**
            - **export TSA_USER_PASSWORD=<Replace_with_your_TSA_ADMIN_USER_PASSWORD>**
            - **export MCM_CLUSTER_HOSTNAME=<Replace_with_your_MCM_CLUSTER_HOSTNAME>**
    2. Run **chmod +x setenvAdd** to execute permissions.
    3. Run **. ./setenv** script within the context of your current session.
2. To get an access token to your API calls and authenticate your credentials, see Get access token by using your username and password.
3. Most Managed services APIs require **tenantId** and IBM Cloud Pak for AIOps **team (ace_orgGuid)** as query parameters. Managed services APIs related to deployed template or service instances also require **namespace (cloudOE_spaceGuid)** as a query parameter. The "Admin" user has access to all teams and namespaces.

    To determine the Managed services **tenantId**, IBM Cloud Pak for AIOps **team**, and **namespace** issue the following API by using the access token from the previous API:

    ```
    curl -k -X GET -H "Authorization: Bearer ${TSA_BEARER_TOKEN}"
    https://${TSA_HOSTNAME}/cam/tenant/api/v1/tenants/getTenantOnPrem
    ```

    - For tenantId, save the "id" value from the output:

      export TSA_TENANT_ID=<response.id>

    - For IBM Cloud Pak for AIOps **team (ace_orgGuid)**, save the "teamId" from the namespace you would like to use:

      export MCM_TEAM=<response.namespaces[0].teamId>

    - For **namespace (cloudOE_spaceGuid)**, save the "uid" from the namespace you would like to use:

      export NAMESPACE=<response.namespaces[0].uid>

      The following examples of getTenantOnPrem API are for "Admin" user and LDAP user:

        - When you call **https://${TSA_HOSTNAME}/cam/tenant/api/v1/tenants/getTenantOnPrem** with the admin account

          ```
          {
            "id": "1ed535a5-c895-4e5c-85fe-d8403a6c5331",  <-- tenantId
            "name": "ICP Account",
            "ownerId": "On_Prem",
            "wlpClientId": "XRw1JM5pQ0scGpwTNzN2gA3dTL1xDt07",
            "namespaces": [
             {
               "name": "default",
               "uid": "default",      <-- namespace (cloudOE_spaceGuid)
               "teamId": "all",         <-- MCM team (ace_orgGuid)
               "teamName": "all",
               "roles": [
                {
                  "id": "crn:v1:icp:private:iam::::role:Administrator"
                }
                      ]
                    },
             {
               "name": "kube-public",
               "uid": "kube-public",
          ```

```
      "teamId": "all",
      "teamName": "all",
      "roles": [
      {
         "id": "crn:v1:icp:private:iam::::role:Administrator"
      }
            ]
      },
    {
      "name": "kube-system",
      "uid": "kube-system",
      "teamId": "all",
      "teamName": "all",
      "roles": [
        {
          "id": "crn:v1:icp:private:iam::::role:Administrator"
        }
          ]
     },
     {
       "name": "services",
       "uid": "services",
       "teamId": "all",
       "teamName": "all",
       "roles": [
         {
           "id": "crn:v1:icp:private:iam::::role:Administrator"
         }
            ]
       }
          ]
    }
```

- For the "admin" user example, the following output must be saved:
  - `tenantId = response.id = 1ed535a5-c895-4e5c-85fe-d8403a6c5331`

    `export TSA_TENANT_ID=1ed535a5-c895-4e5c-85fe-d8403a6c5331`
  - IBM Cloud Pak for AIOps `team (ace_orgGuid) = response.namespaces[0].teamId = all`

    `export MCM_TEAM=all`

    Note: The admin does not belong to a team so use the value "all".
  - IBM Cloud Pak for AIOps `namespace (cloudOE_spaceGuid)= response.namespaces[0].uid = default`

    `export NAMESPACE=default`
- When calling `https://${TSA_HOSTNAME}/cam/tenant/api/v1/tenants/getTenantOnPrem` with an LDAP user who is assigned to team "camusers" with access to the "default" namespace.

```
  {
    "id": "1ed535a5-c895-4e5c-85fe-d8403a6c5331",   <-- tenantId
    "name": "ICP Account",
    "ownerId": "On_Prem",
    "wlpClientId": "kSNhTWdjPWGVhqk8RdHcuNVl19uOCkrf",
    "namespaces": [
     {
       "name": "camdefault - default",
       "uid": "default",                              <-- namespace (cloudOE_spaceGuid)
       "teamId": "camdefault",                <-- MCM team (ace_orgGuid)
       "teamName": "camdefault",
       "roles": [
        {
          "id": "crn:v1:icp:private:iam::::role:Editor"
        }
              ]
            }
       ]
  }
```

For the LDAP user example, the following output can be saved:

- `tenantId = response.id = 1ed535a5-c895-4e5c-85fe-d8403a6c5331`

  `export TSA_TENANT_ID=1ed535a5-c895-4e5c-85fe-d8403a6c5331`
- IBM Cloud Pak for AIOps `team (ace_orgGuid) = response.namespaces[0].teamId = camdefault`

  `export MCM_TEAM=camdefault`
- `namespace (cloudOE_spaceGuid)= response.namespaces[0].uid = default`

  `export NAMESPACE=default`

Common Managed services APIs

This section includes common Managed services APIs with examples.

- Provider and connection APIs
- Template and template instance APIs
- Terraform version APIs
- Terraform file APIs
- Resource specific APIs
- Service and service instance APIs
- Dynamic parameter discovery APIs
- Application APIs
- Shared parameter APIs
- SMTP connection APIS
- Usage specific APIs
- Example: Retrieve deployed templates list

Provider and connection APIs

This section includes all provider and connection related APIs with examples.

- Accessing APIs
- Retrieve the list of providers
- Create a cloud connection
- Retrieve the list of cloud connections
- Retrieve a specific cloud connection
- Update a specific cloud connection
- Delete a specific cloud connection

Accessing APIs

To get an access token to your API calls and authenticate your credentials, see Accessing APIs.

Retrieve the list of providers

Retrieve the list of providers.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/providers?tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Example response:

```
[
    {
        "configuration_parameters": [],
        "connection_parameters": [
            {
                "name": "ibmcloud_api_key",
                "type": "password",
                "description": "The API key for IBM Cloud",
                "required": "true",
                "secured": "true",
                "label": "IBM Cloud API Key",
                "value": ""
            },
            {
                "name": "iaas_classic_username",
                "type": "string",
                "description": "The User Name for IBM Cloud Classic Infrastructure",
                "required": "true",
                "secured": "false",
                "label": "IBM Cloud Classic Infrastructure User Name",
            },
            {
                "name": "iaas_classic_api_key",
                "type": "password",
                "description": "The API key for IBM Cloud Classic Infrastructure",
                "required": "true",
                "secured": "true",
                "label": "IBM Cloud Classic Infrastructure API Key",
                "value": ""
            }
        ],
        "name": "IBM",

        },
        {
          "label": "EU (London) Region",
          "value": "eu-west-2"
        },
        {
          "label": "AWS GovCloud (US)",
          "value": "us-gov-west-1"
        }
      ],
      "value": "us-east-1"
    }
  ],
  "configuration_parameters": [
  ],
  "providerId": "5bb76eb78e04ec001c19466f",
  "additional_Parameters": [
    {
      "plugin": "plugin-terraform",
      "supported_api_types": [
        "stack",
        "iaas"
      ],
      "supported_template_types": [
        {
          "template_type": "Terraform",
          "template_formats": [
            "JSON",
            "HCL"
          ]
        }
      ],
      "configuration_parameters": [
      ]
    }
  ]
}
```

- Provider Id - Using the Retrieve the list of providers GET API call, retrieve the Provider id. In this example, AWS provider is used.
- **cloudOE_spaceGuid** query parameter governs the namespace to be used when a cloud connection is created. In this example, the cloud connection gets created in the namespace that **$NAMESPACE** resolves to. Now, if you want to create the cloud connection to be globally available and not tied to any specific namespace, then omit the cloudOE_spaceGuid query parameter.

GET the list of cloud connections

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/cloudconnections?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example output:

```
[
    {
        "name": "MyVMware",
        "description": "My VMware vSphere Connection",
        "connection_parameters": [
            {
                "name": "vsphere_user",
                "value": "username@vsphere.local",
                "secured": "false"
            },
            {
                "name": "vsphere_password",
                "value": "*****",
                "secured": "true"
            },
            {
                "name": "vsphere_server",
                "value": "1.2.3.4",
                "secured": "false"
            }
        ],
        "validate": true,
        "message": "",
        "id": "59f3b11bd1b007002263c5f3",
        "providerId": "59f38667d1b007002263c578",
        "additional_Parameters": {
            "0": {
                "plugin": "plugin-terraform"
            }
        },
        "tenantId": "5c0e0a5e-d431-468c-9a11-a3df3978e424"
    }
]
```

The **cloudOE_spaceGuid** query parameter is optional and the search results display all cloud connections that **$NAMESPACE** resolves to.

GET a specific cloud connection (filter)

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/cloudconnections?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&filter=%7B%22where%22%3A%20%7B%22name%22%3A%20%22vmware.octravis%22%20%7
D%7D"
```

Example output:

```
[
  {
    "name": "vmware.octravis",
    "description": "vmware.octravis",
    "connection_parameters": [
      {
        "name": "vsphere_user",
        "value": "octravis@vsphere.local",
        "secured": "false"
      },
      {
        "name": "vsphere_password",
        "value": "*****",
        "secured": "true"
      },
      {
        "name": "vsphere_server",
        "value": "1.2.3.123",
        "secured": "false"
      }
    ],
    "configuration_parameters": [
      {
        "name": "",
        "value": ""
      }
    ],
    "validate": true,
    "message": "",
    "id": "5a4d094a47ff9c0022728759",
    "providerId": "5a4cf14b47ff9c0022728676",
    "additional_Parameters": [
      {
        "plugin": "plugin-terraform"
      }
    ],
    "tenantId": "15e7d67e-9f73-43cd-9759-b39ebeea85e8"
  }
]
```

Update a specific cloud connection

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @cc_update.json \
"https://${TSA_HOSTNAME}/cam/api/v1/cloudconnections/${CAM_CLOUD_CONNECTION_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example request body:

```
{
  "name": "Updated connection name",
  "description": "Updated connection description"
}
```

Delete a specific cloud connection

```
curl -k -X DELETE \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/cloudconnections/${CAM_CLOUD_CONNECTION_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Template and template instance APIs

This section includes template and template instance APIs with examples.

- Create a template from a file
- Create a template from a source
- Duplicate a template
- Retrieve the list of templates

- Retrieve a specific template using filter
- Retrieve a specific template by id
- Create new template version for an existing template
- Deploy a template
- Retrieve the list of deployed templates
- Retrieve details for a template instance
- Modify a template instance
- Apply the changes to a template instance
- Destroy a template instance
- Delete a template instance (stack) after destroying it
- Retrieve stack information
- Download the Terraform state (tfstate) for a template instance
- Download the Terraform state (tfstate) for a specific stack state
- Upload the Terraform state (tfstate) for a template instance
- Download the execution plan for a template instance
- Retrieve the execution plan in json format for a template instance

Create a template from a file

```
curl -k -X POST \
-H "Authorization: ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @template_create.json \
"https://${TSA_HOSTNAME}/cam/api/v1/templates?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

```
template_create.json:
{
    "name": "mytemplate",
    "description": "here is the description",
    "type": "userCreated",
    "manifest": {
        "template_type": "Terraform",
        "template": {
            "templateData": "variable \"region\" {\n   default = \"us-east-1\"\n}\n",
            "templateOutput": "",
            "templateVariables": {
                "template_input_params": [
                    {
                        "name": "region",
                        "description": "variable description",
                        "default": "us-east-1",
                        "type": "string",
                        "required": true,
                        "secured": false,
                        "label": "region",
                        "hidden": false,
                        "immutable": false
                    }
                ]
            }
        },
        "template_provider": "IBM"
    },
    "metadata": {
        "displayName": "the template display name"
    }
}
```

The **cloudOE_spaceGuid** query parameter governs the namespace to be used when a template is created. In this example, the template gets created in the namespace that **$NAMESPACE** resolves to. Now, if you want to create the template to be globally available and not tied to any specific namespace, then omit the **cloudOE_spaceGuid** query parameter.

Example output:

```
{
    "description": "here is the description",
    "name": "mytemplate",
    "type": "userCreated",
    "manifest": {
        "template_type": "Terraform",
        "template_provider": "IBM",
        "template": {
            "templateData": "variable \"region\" {\n   default = \"us-east-1\"\n}\n",
            "templateVariables": {
                "template_input_params": [
                    {
                        "name": "region",
                        "description": "variable description",
                        "default": "us-east-1",
                        "type": "string",
                        "required": true,
                        "secured": false,
                        "label": "region",
                        "hidden": false,
```

```
                        "immutable": false
                    }
                ]
            }
        }
    },
    "metadata": {
        "displayName": "the template display name"
    },
    "created_at": "2018-01-09T05:10:48.523Z",
    "id": "5a544ed88bec4000200dc328",
    "tenantId": "cd3ed377-8167-4078-b486-309b1f237928",
    "default_template_version": "5a544ed88bec4000200dc329",
    "template_version": {
        "id": "5a544ed88bec4000200dc329",
        "name": "v1.0.0",
        "enabled": true
    },
    "template_versions": [
        {
            "id": "5a544ed88bec4000200dc329",
            "name": "v1.0.0",
            "enabled": true
        }
    ]
}
```

Create a template from a source

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @template_input.json \
"https://${TSA_HOSTNAME}/cam/api/v1/templates/createFromSource?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

```
template_input.json:
{
    "template_type": "Terraform",
    "template_format": "HCL",
    "template_source": {
        "github": {
            "url": "https://github.com/org/provider-terraform-base",
            "token": "access token for github repository",
            "dir": "subdir/testTemplate",
            "ref": "master"
        }
    }
}
```

The **cloudOE_spaceGuid** query parameter governs the namespace to be used when a template is created. In this example, the template gets created in the namespace that **$NAMESPACE** resolves to. Now, if you want to create the template to be globally available and not tied to any specific namespace, then omit the **cloudOE_spaceGuid** query parameter.

Example output:

```
{
    "description": "Template contents are hosted in a git repository.",
    "name": "New template hosted in git 129c26100b5b9fe7",
    "type": "userCreated",
    "manifest": {
        "template_type": "Terraform",
        "template_source": {
            "github": {
                "url": "https://github.com/org/provider-terraform-base",
                "token": "1234567890",
                "dir": "subdir/testTemplate1",
                "ref": "master"
            },
            "displayUrl": "https://github.com/org/provider-terraform-base/tree/master/subdir/testTemplate1",
            "displayUrlReplaceRef": "https://github.com/org/provider-terraform-base/tree/REPLACE_REF/subdir/testTemplate1"
        },
        "template": {
            "templateVariables": {}
        }
    },
    "metadata": {
        "displayName": "",
        "longDescription": ""
    },
    "created_at": "2018-01-09T05:24:30.288Z",
    "id": "5a54520e8bec4000200dc32a",
    "tenantId": "cd3ed377-8167-4078-b486-309b1f237928",
    "default_template_version": "5a54520e8bec4000200dc32b",
    "template_version": {
        "id": "5a54520e8bec4000200dc32b",
        "ref": "master",
```

```
        "name": "master",
        "enabled": true,
        "displayUrl": "https://github.com/org/provider-terraform-base/tree/master/subdir/testTemplate1"
    },
    "template_versions": [
        {
            "id": "5a54520e8bec4000200dc32b",
            "ref": "master",
            "name": "master",
            "enabled": true,
            "displayUrl": "https://github.com/org/provider-terraform-base/tree/master/subdir/testTemplate1"
        }
    ]
}
```

Example data to import a template whenever you use a compressed file:

```
{
"template_type": "Terraform",
"template_source": {
  "archive": {
    "url": "https://myserver.myorg.com/templates/template1.zip",
  }
}
}
```

The **artifactory_api_key** is an optional parameter that allows you to specify an API key to an artifactory location. If the file is hosted in artifactory and an API key is needed, then use the **artifactory_api_key**. For example:

```
{
"template_type": "Terraform",
"template_source": {
  "archive": {
    "url": "https://myserver.myorg.com/templates/template1.zip",
    "artifactory_api_key": "YOURKEYHERE"
  }
}
}
```

If you get an error during the API call, ensure that your archive is in "zip" format and your file is downloadable through HTTP/HTTPS.

Duplicate a template

This API duplicates the template along with all versions.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @duplicate_template.json \
"https://${TSA_HOSTNAME}/cam/api/v1/templates/${CAM_TEMPLATE_ID}/duplicate?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

The **cloudOE_spaceGuid** query parameter governs the namespace to be used when the duplicate template is created. In this example, the template gets created in the namespace that **$NAMESPACE** resolves to. Now, if you want to create the template to be globally available and not tied to any specific namespace, then omit the **cloudOE_spaceGuid** query parameter.

Example request body:

```
{
 "name": "mynewname"
}
```

Retrieve the list of templates

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/templates?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

The **cloudOE_spaceGuid** query parameter is optional and the search results display all templates that are created for the namespace **$NAMESPACE**. The result also includes all the templates that are globally available.

Example output:

```
[
    {
        "description": "Kubernetes - An orchestration system for containerized applications, e.g., Nginx.",
        "name": "Kubernetes Cluster with Nginx Deployment",
        "type": "prebuilt",
        "manifest": {
            "template_type": "Terraform",
            "template_format": "HCL",
            "template_provider": "VMware vSphere"
        },
        "metadata": {
            "displayName": "Kubernetes Cluster with Nginx Deployment",
```

```
            "longDescription": "Deploys a Kubernetes Cluster in VMware, where Kubernetes is an open-source system for
automating deployment, scaling, and management of containerized applications. This deployment also deploys the NGINX
sample application to validate the deployment is operational, where NGINX is an open source web server and load balancer
for high-traffic sites.",
            "bullets": [
                {
                    "title": "Clouds",
                    "description": "VMware"
.
.
        "created_at": "2017-10-27T19:17:59.874Z",
        "id": "59f38667d1b007002263c581",
        "tenantId": "DEFAULT",
        "default_template_version": "59f38667d1b007002263c582"
    },
```

Retrieve a specific template using filter

This API returns the template metadata along with all the template versions.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/templates?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&filter=%7B%22where%22%3A%20%7B%22name%22%3A%20%22SingleVirtualMachine%22
%20%7D%7D"
```

Example output:

```
[
    {
        "description": "Create Virtual Machine with single vnic",
        "name": "SingleVirtualMachine",
        "type": "prebuilt",
        "manifest": {
            "template_type": "Terraform",
            "template_format": "HCL",
            "template_provider": "VMware vSphere"
        },
        "metadata": {
            "displayName": "SingleVirtualMachine",
            "longDescription": "Create Virtual Machine with single vnic on a network label by cloning"
        },
        "created_at": "2017-11-03T15:19:30.566Z",
        "id": "59fc89024722a1001ff2974c",
        "tenantId": "DEFAULT",
        "default_template_version": "59fc89024722a1001ff2974d"
    }
]
```

Retrieve a specific template by id

This API returns the template metadata along with all the template versions.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/templates/${CAM_TEMPLATE_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Create new template version for an existing template

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @template_version.json \
"https://${TSA_HOSTNAME}/cam/api/v1/templateVersions?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Examples of input template_version.json:

- Create a new template version from git:

  ```
  {
   "name": "v2.0",
   "ref": "master",
   "templateId": "parent template id"
  }
  ```

- Create a template version from file:

  ```
  {
   "name": "v2.0",
   "templateId": "parent template id",
   "templateData": "variable \"region\" {\n   default = \"us-east-1\"\n}\n",
   "templateVariables": {
  ```

```
      "template_input_params": [
            {
                "name": "region",
                "description": "variable description",
                "default": "us-east-1",
                "type": "string",
                 "required": true,
                 "secured": false,
                 "label": "region",
                 "hidden": false,
                 "immutable": false
             }
         ]
  }
}
```

Deploy a template

Get the template versions using the Retrieve a specific template by id if you want to specify a particular template version while deploying the template.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @template_input.json \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example input:

```
template_input.json:
{
  "name": "vSphere95",
  "cloud_connection_ids": [
    "5a00ab148af3f3002010ab45"
  ],
  "parameters": [
    {
      "name": "datacenter",
      "value": "Rack-8283_1000167"
    },
    {
      ....
    },
  ]
  "templateId": "5a00a2448af3f3002010aae1",
  "templateVersionId": "5a00a2448af3f3002010aae2",
  "catalogName": "SingleVirtualMachine",
  "catalogType": "userCreated",
  "forceCreate": "true"
  }
```

Note: `templateVersionId` is an optional parameter, if it is not provided, the default provided template version is used for deployment.

When the template to be deployed has input_datatypes, then use the following information:

Pass the input dataobjects that you want to use as your input to a stack by using the name and Data Type. It uniquely identifies the dataobject instance you want to use. For example:

```
"input_dataobjects": [
    {
      "name": "DefaultNoBastionHostRequired",
      "datatype": "bastionhost"
    }
  ],
```

Where:

- `bastionhost` is the Data Type name. It matches the datatype in the `input_datatypes` of the template you are deploying.
- `name` is the name of the Data Object instance you want to use when you deploy this instance.

For each input_datatype, the template requires an input_dataobject.

In this example, the template requires an input_datatype of "bastionhost". When you deploy a stack from this template, provide the dataobject to use that implements the "bastionhost" datatype:

```
"input_dataobjects": [
    {
      "name": "DefaultNoBastionHostRequired",
      "datatype": "bastionhost"
    }
  ],
```

Example Response:

```
{
  "name": "vSphere95",
  "created_at": "2017-11-06T20:18:11.697Z",
  "templateId": "5a00a2448af3f3002010aae1",
  "namespaceId": "default",
  "templateName": "SingleVirtualMachine",
  "templateCategory": "prebuilt",
  "templateProvider": "VMware vSphere",
  "template_type": "Terraform",
  "template_format": "HCL",
  "applied_state_id": "5a00c3838af3f3002010ab53",
  "latest_state_id": "5a00c3838af3f3002010ab53",
  "cloud_connection_ids": [
    "5a00ab148af3f3002010ab45"
  ],
  "id": "5a00c3838af3f3002010ab53",
  "tenantId": "df87bf8a-2ea9-478d-9b37-2b36da4af6ed",
  "status": "IN_PROGRESS",
  "message": "",
  "action": "CREATE",
  "stack_id": "9cb55c20-c32f-11e7-8d7f-d1b85b52d79c",
  "applied_status": "IN_PROGRESS",
  "applied_action": "CREATE",
  "data": {
    "stack_id": "9cb55c20-c32f-11e7-8d7f-d1b85b52d79c",
    "stack_job_id": "5a00c3838af3f3002010ab53",
    "stack_job_is_latest": true,
    "action": "CREATE",
    "status": "IN_PROGRESS",
    "tenantId": "df87bf8a-2ea9-478d-9b37-2b36da4af6ed"
  }
}
```

Create a stack (advanced scenario)

Use this procedure if you want to do a plan on the stack before you deploy:

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @template_input.json \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example input:

```
{
  "name": "vSphere95",
  "cloud_connection_ids": [
    "5a00ab148af3f3002010ab45"
  ],
  "parameters": [
    {
      "name": "datacenter",
      "value": "Rack-8283_1000167"
    },
    {
      ....
    },
  ]
  "templateId": "5a00a2448af3f3002010aae1",
  "templateVersionId": "5a00a2448af3f3002010aae2",
  "catalogName": "SingleVirtualMachine",
  "catalogType": "userCreated",
  "forcePlan": "true"
  }
```

Retrieve the list of deployed templates

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example output:

```
[
  {
        "name": "My WAS Liberty",
        "created_at": "2017-10-29T16:03:20.985Z",
        "templateId": "59f38692d1b007002263c5e3",
        "namespaceId": "default",
        "templateName": "IBM WebSphere Application Server Liberty V17 on a single virtual machine - VMware vSphere",
        "templateCategory": "chefcontent",
        "templateProvider": "VMware vSphere",
        "template_type": "Terraform",
        "template_format": "HCL",
        "applied_state_id": "59f5fbc9d1b007002263c5fa",
```

```
        "latest_state_id": "59f5fbc9d1b007002263c5fa",
        "cloud_connection_ids": [
            "59f3b11bd1b007002263c5f3"
        ],
        "id": "59f5fbc8d1b007002263c5f9",
        "tenantId": "5c0e0a5e-d431-468c-9a11-a3df3978e424",
        "status": "SUCCESS",
        "message": "",
        "action": "CREATE",
        "stack_id": "afa51b40-bcc2-11e7-bbfe-b56e007b5b00",
        "applied_status": "SUCCESS",
        "applied_action": "CREATE",
        "applied_output_namespace": "content_template_output"
    }
]
```

The **cloudOE_spaceGuid** query parameter is optional and the search results display all template instances that **$NAMESPACE** resolves to.

Retrieve details for a template instance

Example:

```
export STACK_ID=5a00c3838af3f3002010ab53
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${STACK_ID}/retrieve?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example response:

```
{
  "name": "vSphere95",
  "created_at": "2017-11-06T20:18:11.697Z",
  "templateId": "5a00a2448af3f3002010aae1",
  "namespaceId": "default",
  "templateName": "SingleVirtualMachine",
  "templateCategory": "prebuilt",
  "templateProvider": "VMware vSphere",
  "template_type": "Terraform",
  "template_format": "HCL",
  "applied_state_id": "5a00c3838af3f3002010ab54",
  "latest_state_id": "5a00c3838af3f3002010ab54",
  "cloud_connection_ids": [
    "5a00ab148af3f3002010ab45"
  ],
  "id": "5a00c3838af3f3002010ab53",
  "tenantId": "df87bf8a-2ea9-478d-9b37-2b36da4af6ed",
  "status": "SUCCESS",
  "message": "",
  "action": "CREATE",
  "stack_id": "9cb55c20-c32f-11e7-8d7f-d1b85b52d79c",
  "applied_status": "SUCCESS",
  "applied_action": "CREATE",
  "data": {
    "stack_id": "9cb55c20-c32f-11e7-8d7f-d1b85b52d79c",
    "stack_job_id": "5a00c3834e13b5001f4aecd1",
    "stack_job_is_latest": true,
    "status": "SUCCESS",
    "action": "CREATE",
    "message": "\nInitializing provider plugins...\nTerraform has been successfully initialized!\n\nYou may now begin
working with Terraform. Try running \"terraform plan\" to see\nany changes that are required for your infrastructure. All
Terraform commands\nshould now work.\n\nIf you ever set or change modules or backend configuration for Terraform,\nrerun
this command to reinitialize your working directory. If you forget, other\ncommands will detect it and remind you to do so
if necessary.\ndata.vsphere_datacenter.datacenter: Refreshing state...\nvsphere_virtual_machine.vm_1: Creating...\n
cluster:
```

Modify a template instance (stack)

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @plan_input.json \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${STACK_ID}/plan?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

```
plan_input.json:
{
  "templateVersionId": "59fc89024722a1001ff2974d",
  "parameters": [
    {
      "name": "datacenter",
      "value": "Rack-8283_1000167"
    },
    {
      ...
    },
```

```
  ]
 }
```

For the plan request body, the parameters are optional and the execution plan gets created by using the parameter values from the initial deploy.

Example response:

```
{
    "name":"vSphere95",
    "created_at":"2017-12-13T14:48:22.937Z",
    "templateId":"5a2b00d7b17b800020af2e7c",
    "namespaceId":"default",
    "templateName":"SingleVirtualMachine",
    "templateCategory":"prebuilt",
    "templateProvider":"VMware vSphere",
    "template_type":"Terraform",
    "applied_state_id":"5a313db7b17b800020af300a",
    "latest_state_id":"5a314639b17b800020af3023",
    "cloud_connection_ids":[
        "5a2b0513b17b800020af2f2b"
    ],
    "id":"5a313db6b17b800020af3009",
    "tenantId":"a8fbbe67-1480-49c0-be60-0084b31a0942",
    "status":"IN_PROGRESS",
    "message":"",
    "action":"PLAN",
    "stack_id":"ab100110-e014-11e7-85f3-c3bc8b9fdda1",
    "applied_status":"SUCCESS",
    "applied_action":"CREATE",
    "data":{
        "stack_id":"ab100110-e014-11e7-85f3-c3bc8b9fdda1",
        "stack_job_id":"5a3146396e53230020466164",
        "stack_job_is_latest":true,
        "action":"PLAN",
        "status":"IN_PROGRESS",
        "tenantId":"a8fbbe67-1480-49c0-be60-0084b31a0942"
    }
}
```

A successful plan has two states, namely SUCCESS AND SUCCESS_WITH_CHANGES:

- The SUCCESS indicates that the plan is successful and there will not be any changes to your environment even if you apply the plan.
- The SUCCESS_WITH_CHANGES indicates that the plan is successful, but when you apply it, there will be changes to your environment. Go through the logs to understand more about the changes to the environment. For example, a template is defined to create a virtual machine. You make modifications to the template such that it creates a second virtual machine. The resultant SUCCESS_WITH_CHANGES indicates that if you apply the plan, the second virtual machine will get created.

Apply the changes to a template instance (stack)

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${STACK_ID}/apply?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example output:

```
{
    "name":"vSphere95",
    "created_at":"2017-12-13T14:48:22.937Z",
    "templateId":"5a2b00d7b17b800020af2e7c",
    "namespaceId":"default",
    "templateName":"SingleVirtualMachine",
    "templateCategory":"prebuilt",
    "templateProvider":"VMware vSphere",
    "template_type":"Terraform",
    "applied_state_id":"5a314892b17b800020af3042",
    "latest_state_id":"5a314892b17b800020af3042",
    "cloud_connection_ids":[
        "5a2b0513b17b800020af2f2b"
    ],
    "id":"5a313db6b17b800020af3009",
    "tenantId":"a8fbbe67-1480-49c0-be60-0084b31a0942",
    "status":"IN_PROGRESS",
    "message":"",
    "action":"APPLY",
    "stack_id":"ab100110-e014-11e7-85f3-c3bc8b9fdda1",
    "applied_status":"IN_PROGRESS",
    "applied_action":"APPLY",
    "data":{
        "stack_id":"ab100110-e014-11e7-85f3-c3bc8b9fdda1",
        "stack_job_id":"5a3148926e53230020466174",
        "stack_job_is_latest":true,
        "action":"APPLY",
        "status":"IN_PROGRESS",
        "tenantId":"a8fbbe67-1480-49c0-be60-0084b31a0942"
    }
}
```

Destroy a template instance (stack)

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${STACK_ID}/delete?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example response:

```
  {
  "name": "vSphere95",
  "created_at": "2017-11-06T20:18:11.697Z",
  "templateId": "5a00a2448af3f3002010aae1",
  "namespaceId": "default",
  "templateName": "SingleVirtualMachine",
  "templateCategory": "prebuilt",
  "templateProvider": "VMware vSphere",
  "template_type": "Terraform",
  "template_format": "HCL",
  "applied_state_id": "5a00c4a08af3f3002010ab57",
  "latest_state_id": "5a00c4a08af3f3002010ab57",
  "cloud_connection_ids": [
    "5a00ab148af3f3002010ab45"
  ],
  "id": "5a00c3838af3f3002010ab53",
  "tenantId": "df87bf8a-2ea9-478d-9b37-2b36da4af6ed",
  "status": "SUCCESS",
  "message": "",
  "action": "DELETE",
  "stack_id": "9cb55c20-c32f-11e7-8d7f-d1b85b52d79c",
  "applied_status": "SUCCESS",
  "applied_action": "DELETE",
  "data": {
    "stack_id": "9cb55c20-c32f-11e7-8d7f-d1b85b52d79c",
    "stack_job_id": "5a00c4a04e13b5001f4aecd2",
    "stack_job_is_latest": true,
    "status": "SUCCESS",
    "action": "DELETE",
    "message": "\nInitializing provider plugins...\nTerraform has been successfully initialized!\n\nYou may now begin
working with Terraform.
```

Delete a template instance (stack) after destroying it

```
curl -k -X DELETE \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${STACK_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example response: `{"count":1}`

Retrieve stack information

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/{STACK_ID}/retrieve?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

This retrieves information about the stack including its parameters. However, if any of those parameters have **`secured:true`**, then the values for those parameters are hidden, that is, replaced with asterisks by default.

To return secured values back in plain text, run the POST with **`showSecured=true`** parameter.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/{STACK_ID}/retrieve?
showSecured=true&tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Download the Terraform state (tfstate) for a template instance

This API downloads the Terraform state (tfstate) of a template instance.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-o terraform.tfstate \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${CAM_STACK_ID}/tfstate?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Note: The `-o` file option is optional. It writes the output to a file instead of stdout.

Download the Terraform state (tfstate) for a specific stack state

This API downloads the Terraform state (tfstate) for a specific stack state.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-o terraform.tfstate \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${CAM_STACK_ID}/stackstates/${CAM_STACK_STATE_ID}/tfstate?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Upload the Terraform state (tfstate) for a template instance

This API uploads the Terraform state (tfstate) to a template instance.

You must have Administrator, cluster administrator, or editor role to run this API.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-F 'tfstate=@your_tfstate_file' \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${CAM_STACK_ID}/tfstate?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Download the execution plan for a template instance

This API downloads an execution plan for a template instance.

You must have Administrator, cluster administrator, or editor role to run this API.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-o terraform_execution_plan \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${CAM_STACK_ID}/executionPlan?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Note: The execution plan file is base64 encoded. You must decode the file content before using it.

Retrieve the execution plan in json format for a template instance

This API retrieves the execution plan in json format for a template instance. The API works only for template instances that use Terraform engine 0.12.x or newer.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${CAM_STACK_ID}/executionPlan/show?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Terraform version APIs

This section includes Terraform version APIs.

- Retrieve Terraform versions
- Create a Terraform version
- Update a Terraform version
- Delete a Terraform version
- Set Terraform version as Default
- Enable/disable a Terraform version

Retrieve Terraform versions

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/providerengineversions?tenantId=${TSA_TENANT_ID}"
```

Create a Terraform version

You must have Administrator or cluster administrator role to run this API.

```
curl -k -X POST -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
  -F "template_type=Terraform" \
  -F "version=0.15.5" \
  -F "default=false" \
  -F "enabled=true" \
  -F "zipfile=@terraform_0.15.5.zip" \
  "https://${TSA_HOSTNAME}/cam/api/v1/providerengineversions?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Update a Terraform version

You must have Administrator or cluster administrator role to run this API.

```
curl -k -X PUT \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @update_terraform_version.json \
"https://${TSA_HOSTNAME}/cam/api/v1/providerengineversions/${TERRAFORM_VERSION_ID}?tenantId=${TSA_TENANT_ID}"
```

Example of the request body:

```
{
     version: '0.12.15',
     default: true
}
```

Delete a Terraform version

You must have Administrator or cluster administrator role to run this API.

```
curl -k -X DELETE \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/providerengineversions/${TERRAFORM_VERSION_ID}?tenantId=${TSA_TENANT_ID}"
```

Set Terraform version as default

You must have Administrator or cluster administrator role to run this API.

```
curl -k -X PUT \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @default_terraform_version.json \
"https://${TSA_HOSTNAME}/cam/api/v1/providerengineversions/${TERRAFORM_VERSION_ID}?tenantId=${TSA_TENANT_ID}"
```

Example of the request body:

```
{
     default: true
}
```

Enable/disable a Terraform version

You must have Administrator or cluster administrator role to run this API.

```
curl -k -X PUT \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @enable_terraform_version.json \
"https://${TSA_HOSTNAME}/cam/api/v1/providerengineversions/${TERRAFORM_VERSION_ID}?tenantId=${TSA_TENANT_ID}"
```

Example of the request body to enable the Terraform version:

```
{
     enabled: true
}
```

Example of the request body to disable the Terraform version:

```
{
     enabled: false
}
```

Terraform Provider Engine file APIs

The following section includes Terraform Provider Engine file APIs. You can upload Terraform plug-in files to Terraform pods by using these APIs.

- Retrieve Terraform system and user plug-ins
- Retrieve user-uploaded Terraform plug-ins
- Create a Terraform Provider Engine file
- Delete a Terraform Provider Engine file

Retrieve Terraform system and user plug-ins

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/providerenginefiles?tenantId=${TSA_TENANT_ID}"
```

Retrieve user-uploaded Terraform plug-ins

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/providerenginefiles?filter[where][category]=user&tenantId=${TSA_TENANT_ID}"
```

Create a Terraform Provider Engine file

You must have an Administrator or cluster administrator role to run this API.

```
curl -k -X POST -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
  -F "template_type=Terraform" \
  -F "type=file" \
  -F "zipfile=@customer_files.zip" \
  "https://${TSA_HOSTNAME}/cam/api/v1/providerenginefiles?tenantId=${TSA_TENANT_ID}"
```

In the previous example, the user uploads a new Terraform plug-in. The archive can contain multiple plug-ins that are copied to the following path on each provider Terraform pod when they are restarted.

```
/home/terraform/.terraform.d/plugins
```

Delete a Terraform Provider Engine file

You must have an Administrator or cluster administrator role to run this API.

```
curl -k -X DELETE \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/providerenginefiles/${PROVIDERENGINEFILES_ID}?tenantId=${TSA_TENANT_ID}"
```

Resource-specific APIs

This section includes resource specific APIs with examples.

- Restart OS
- Import VM by IDs
- Import VM by Name
- Create snapshots
- Revert to snapshot
- Delete a snapshot
- Revert to current snapshot
- Get snapshots
- Taint a resource from a stack
- Untaint a resource from a stack
- Retrieve and change power states for resources
- Start a virtual machine
- Stop a virtual machine
- Reset virtual machine
- Get the status of a stopping or starting a virtual machine
- Retrieve all IaaS resource settings
- Retrieve a specific IaaS resource settings
- Create IaaS resource settings
- Update IaaS resource settings
- Delete IaaS resource settings

Note: There are three possible statuses for a resource task:

- IN_PROGRESS
- SUCCESS
- FAILED

Restart OS

The API call restarts the OS. It is available only for VMware vSphere virtual machine actions. The option is enabled only when the virtual machine powerstate is ON.

Note: The virtual machine`resource.id` can be retrieved from the update the state of the template instance API.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-H "Content-Type: application/json" \
-d '{"task_name":"restart"}' \
"https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

POST method.

```
Body:{ "task_name: "restart" }
```

Example response:

```
{
  "cloud_resource_id": "421ac557-7793-fdd5-7b83-c3525571abfe",
  "task_name": "restart",
  "status": "IN_PROGRESS",
  "created": "2017-11-13T16:47:58.298Z",
  "updated": "2017-11-13T16:47:58.298Z",
  "stack_id": "7d55d130-c239-11e7-b95f-c5cc4d245984",
  "resource_id": "59ff272d4ba47e0020cb6583",
  "resource_name": "vsphere_virtual_machine.vm_1",
  "id": "5a09ccbe9fe5890020316467"
}
```

Import VM by IDs

Imports an existing virtual machine by using the ID. You can view stack instance in the template deployed instances page.

```
https://${TSA_HOSTNAME}/cam/api/v1/stacks/import?tenantId=${TSA_TENANT_ID}&cloudOE_spaceGuid=${NAMESPACE}
```

POST method

For example, import a virtual machine's resources that are available in stack "fit-vm17-76":

```
Body
{
  "name": "fit-vm17-76",
  "cloudConnectionId": "5a8983938f22883ee775"
  "templateId": "5b39493e3984938943eb8b6",
  "templateVersionId: "5b39493e3984938943eb8c5",
  "idFromProvider": "/Rack-8283_1000167/vm/shared/fit-vm17-76"
}
```

Where,

- `name` is the name of the stack.
- `cloudConnectionId` is the ID of the connection where the virtual machine can be found. Use the credentials used in that cloud to find the virtual machine.
- `templateId` is to associate a template to a stack instance server.
- `templateVersionId` is the version of the template. It is an optional parameter.
- `idFromProvider` is the id of the virtual machine. The format differs for PowerVC and OpenStack.
- `resourceName` is an optional parameter. If resourceName is set, then you can import from providers other than vSphere and OpenStack. If you do not use this parameter, then the default values are as follows:
  - openstack_compute_instance_v2.vm_1 for OpenStack instances
  - vsphere_virtual_machine.vm_1 for VMWare vSphere instances

Import VM by Name

Imports an existing virtual machine by using the name. You can view the stack instance in the template deployed instances page.

```
https://${TSA_HOSTNAME}/cam/api/v1/stacks/import?tenantId=${TSA_TENANT_ID}&cloudOE_spaceGuid=${NAMESPACE}
```

POST method

For example, import a virtual machine resource from stack "fit-vm17-76":

```
Body
{
  "name": "fit-vm17-76",
  "cloudConnectionName": "fit3",
  "templateName": "Import existing VM with a single disk - VMware vSphere",
  "templateVersionName": "1.0",
  "idFromProvider": "/Rack-8283_1000167/vm/Shared/fit-vm17-76"
}
```

Where,

- `name` is the name of the stack.
- `CloudConnectionName` is the connection name where the virtual machine can be found. Use the credentials used in that cloud to find the virtual machine.
- `templateName` is to associate a template to a stack instance server. It can be VMware vSphere or PowerVC/OpenStack.
- `templateVersionName` is the version of the template. It is an optional parameter.
- `idFromProvider` is the id of the virtual machine. The format differs for PowerVC and OpenStack.
- `resourceName` is an optional parameter. If resourceName is set, then you can import from providers other than vSphere and OpenStack. If you do not use this parameter, then the default values are as follows:
  - openstack_compute_instance_v2.vm_1 for OpenStack instances
  - vsphere_virtual_machine.vm_1 for VMWare vSphere instances

Create snapshot

This API creates a virtual machine snapshot for a VMware instance.

Note: The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.

Sample URL:

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-H "Content-Type: application/json" \
-d '{"task_name":"snapshot", "parameters": [ \
   { \
       "name": "snapshot_name", \
       "value": ${SNAPSHOT_NAME} \
   }, \
   { \
       "name": "quiesce", \
       "value": true || false \
   }, \
   { \
       "name": "memory", \
       "value": true || false \
   }, \
   { \
       "name": "description", \
       "value":${DESCRIPTION} # Optional \
   } \
   ]}' \
   "https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

POST method

BODY:

```
{
  "task_name": "snapshot",
  "parameters": [
    {
       "name": "snapshot_name",
       "value": "NAME"
    },
    {
       "name": "quiesce",
       "value": false
    },
    {
       "name": "memory",
       "value": false
    },
    {
       "name": "description",
       "value": "DESCRIPTION"
    }
   ]
  }
```

Note:

- The long ID in the URL after `iaasResources` is the RESOURCE_ID or the ID of the virtual machine.
- The description is an optional parameter.

Revert to a snapshot

This API reverts to the selected snapshot.

Note:

- The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.
- The `snapshot_id` can be retrieved from the Get snapshots API.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-H "Content-Type: application/json" \
-d '{"task_name":"revertToSnapshot", "parameters": [ \
   { \
       "name": "snapshot_id", \
       "value": ${SNAPSHOT_ID} \
   } \
   ]}' \
   "https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

POST method

Sample BODY:

```
{
  "task_name": "revertToSnapshot",
  "parameters": [
    {
      "name": "snapshot_id",
```

```
      "value": "snapshot-19477"
    }
   ]
}
```

Note: The long ID in the URL after `iaasResources` is the RESOURCE_ID or the ID of the virtual machine.

Delete snapshot

This API deletes the selected snapshot.

Note:

- The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.
- The `snapshot_id` can be retrieved from the Get snapshots API.

Sample URL:

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-H "Content-Type: application/json" -d '{"task_name":"deleteSnapshot", "parameters": [ \
   { \
       "name": "snapshot_id", \
       "value": ${SNAPSHOT_ID} \
   } \
   ]}' "https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

POST method

Sample BODY:

```
{
  "task_name": "deleteSnapshot",
  "parameters": [
   {
     "name": "snapshot_id",
     "value": "snapshot-19477"
   }
  ]
 }
```

Note: The long ID in the URL after `iaasResources` is the RESOURCE_ID or the ID of the virtual machine.

Revert to current snapshot

This API restores to the parent snapshot of the current state of a virtual machine.

Note: The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-H "Content-Type: application/json" -d '{"task_name":"revertToCurrent"}' \
"https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Sample URL:

```
https://cam-proxy/cam/api/v1/iaasresources/5c47740ef76392001eb4d073/tasks
```

POST method

BODY:

```
{
  "task_name": "revertToCurrent"
}
```

Note: The long ID in the URL after `iaasResources` is the RESOURCE_ID or the ID of the virtual machine.

Get snapshots

This API retrieves a list of snapshots.

Note: The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/query/getsnapshots?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Sample URL:

```
https://cam-proxy/cam/api/v1/iaasresources/5c47740ef76392001eb4d073/query/getsnapshots
```

GET method

Note: The long ID in the URL after `iaasResources` is the RESOURCE_ID or the ID of the virtual machine.

Taint a resource from a stack

Note: The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.

```
export CAM_RESOURCE_ID=<resource.id>
```

Note: The `resource.id` can be retrieved from Update state of template instance POST /stacks/id/retrieve call.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/stacks/${CAM_TEMPLATE_ID}/taint/${CAM_RESOURCE_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example output:

```
{
    "name": "vSphere95",
    "created_at": "2018-01-10T18:35:52.140Z",
    "templateId": "5a4fe8f98bec4000200dc310",

    }
}
```

Retrieve and change power states for resources

This API retrieves and changes power states for resources.

Note: The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/query/getPowerState?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

GET method

```
Response: {
"poweredOn": true || false
}
```

Start a virtual machine

Note: The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-H "Content-Type: application/json" \
-d '{"task_name":"start"}' \
"https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example response

```
{
  "cloud_resource_id": "421ac557-7793-fdd5-7b83-c3525571abfe",
  "task_name": "start",
  "status": "IN_PROGRESS",
  "created": "2017-11-13T16:51:37.972Z",
  "updated": "2017-11-13T16:51:37.972Z",
  "stack_id": "7d55d130-c239-11e7-b95f-c5cc4d245984",
  "resource_id": "59ff272d4ba47e0020cb6583",
  "resource_name": "vsphere_virtual_machine.vm_1",
  "id": "5a09cd999fe5890020316468"
}
```

Stop a virtual machine

```
export CAM_RESOURCE_ID=<resource.id>
```

Note: The virtual machine `resource.id` can be retrieved from the update the state of the template instance API.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-H "Content-Type: application/json" \
-d '{"task_name":"stop"}' \
"https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example response

```
{
  "cloud_resource_id": "421ac557-7793-fdd5-7b83-c3525571abfe",
  "task_name": "stop",
  "status": "IN_PROGRESS",
  "created": "2017-11-13T16:47:58.298Z",
  "updated": "2017-11-13T16:47:58.298Z",
  "stack_id": "7d55d130-c239-11e7-b95f-c5cc4d245984",
  "resource_id": "59ff272d4ba47e0020cb6583",
  "resource_name": "vsphere_virtual_machine.vm_1",
  "id": "5a09ccbe9fe5890020316467"
}
```

Reset a virtual machine

You can reset and restart a VMware virtual machine.

Note: The virtual machine **resource.id** can be retrieved from the update the state of the template instance API.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-H "Content-Type: application/json" \
-d '{"task_name":"reset"}' \
"https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example response

```
{
  "cloud_resource_id": "421ac557-7793-fdd5-7b83-c3525571abfe",
  "task_name": "reset",
  "status": "IN_PROGRESS",
  "created": "2017-11-13T16:47:58.298Z",
  "updated": "2017-11-13T16:47:58.298Z",
  "stack_id": "7d55d130-c239-11e7-b95f-c5cc4d245984",
  "resource_id": "59ff272d4ba47e0020cb6583",
  "resource_name": "vsphere_virtual_machine.vm_1",
  "id": "5a09ccbe9fe5890020316467"
}
```

Get the status of a stopping or starting a virtual machine

```
export CAM_IAASTASK_ID=<response.id>
```

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" \
-d '{"task_name":"stop"}' \
"https://${TSA_HOSTNAME}/cam/api/v1/iaasresources/${CAM_RESOURCE_ID}/tasks/${CAM_IAASTASK_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Example response:

```
{
  "cloud_resource_id": "421ac557-7793-fdd5-7b83-c3525571abfe",
  "task_name": "stop",
  "status": "SUCCESS",
  "created": "2017-11-13T16:47:58.298Z",
  "updated": "2017-11-13T16:48:03.728Z",
  "stack_id": "7d55d130-c239-11e7-b95f-c5cc4d245984",
  "resource_id": "59ff272d4ba47e0020cb6583",
  "resource_name": "vsphere_virtual_machine.vm_1",
  "message": "",
  "id": "5a09ccbe9fe5890020316467"
}
```

Retrieve all IaaS resource settings

This API allows you to get all Terraform resource settings.

```
curl -k -X GET \
  -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
  "https://${TSA_HOSTNAME}/cam/api/v1/iaasresourcesettings?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Note: The cloudOE_spaceGuid query parameter is optional and the search results display all IaaS resource settings that **${NAMESPACE}** resolves to.

Retrieve a specific IaaS resource settings

This API allows you to show the details about a Terraform resource setting.

```
curl -k -X GET \
  -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
 "https://${TSA_HOSTNAME}/cam/api/v1/iaasresourcesettings/${IAAS_RESOURCE_SETTINGS_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Create IaaS resource settings

This API allows an administrator to hide specific information about the Terraform resource.

```
curl -k -X POST \
 -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
 -H "Content-Type: application/json" \
 "https://${TSA_HOSTNAME}/cam/api/v1/iaasresourcesettings?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}" \
 -d '{
     "type": "aws_virtual_machine",
     "attributes": ["cpu_reservation", "guest_ip_addresses"],
     "hidden": true
   }'
```

This example hides two attributes from all the **aws_virtual_machine** resources. In case you want to hide all the attributes from all the resource types, create an IaaS resource settings with type as **__all__**.

Request body parameters:

- **type** - the provider resource type (that is, vpshere_virtual_machine). This is not the resource name.
- **attributes** - list of attributes to be hidden. This parameter is optional. In case it is omitted, all the attributes for that specific resource type are hidden.
- **hidden** - It accepts true or false depending on whether you want to hide or show the attribute.

Note: The cloudOE_spaceGuid query parameter is optional and the IaaS resource setting is created in the namespace that ${NAMESPACE} resolves to.

Update IaaS resource settings

This API allows the cluster administrator and administrator to modify the settings for a Terraform resource type.

```
curl -k -X PUT \
  -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
  -H "Content-Type: application/json" \
  -d '{"type": "aws_virtual_machine"}' \
 "https://${TSA_HOSTNAME}/cam/api/v1/iaasresourcesettings/${IAAS_RESOURCE_SETTINGS_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Delete IaaS resource settings

This API allows the cluster administrator and administrator to delete settings for a Terraform resource type.

```
curl -k -X DELETE \
 -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
 "https://${TSA_HOSTNAME}/cam/api/v1/iaasresourcesettings/${IAAS_RESOURCE_SETTINGS_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Service and service instance APIs

This section includes all service and service instance APIs with examples.

- Service APIs
  - Create a service with default version
  - Add a service version to an existing service
  - Set a default version for a service
  - Edit a Service version
  - Delete a Service version in a service
  - Delete a Service (with all its versions)
  - GET the list of services
  - Get Service versions for a service using **service-id**
  - Get Service version manifest by service version ID
  - Publish a service version
  - Duplicate a service
  - Change the category of a service
  - Rename a service
  - Change service image for a service
  - Assign access to a service
  - Retire a service version
  - Unretire a service version
  - Auto-retire a service version
- Service Instance APIs
  - Deploy a Service Instance
  - Get the list of deployed instance: GET call
  - Get details of a Service Instance by using the id
  - Get input parameters of a Service Instance
  - Edit Service Instance
  - Retry Service Instance
  - Resume Service Instance
  - Upgrade or downgrade a Service Instance
  - Bind a service instance
  - Unbind Instance
  - Get custom actions
  - Invoke custom action
  - Terminate Service Instance
  - Cleanup Service Instance
  - Cleanup Service Instance in inprogress state
- Standalone action APIs
  - Create Standalone Action
  - Invoke Standalone Action
- ICON APIs
  - Upload service icons

- Delete service icons
- Retrieve all service icons
- Download service icon

Service APIs

Create a service with default version

This API call creates a service version and adds a default version. The service and the service version are returned in response.

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/Service/createService?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @service_create.json
```

Payload, content of 'service_create.json'

```
{
  "service": {
    "specVersion": "v3",
    "catalog_metadata": {
      "name": "SampleV1",

Set a default version for a service

```
curl -k -X POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/Service/${SERVICE_ID}/updateServiceDetails?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @service_default_version.json
```

Payload sample1:

```
"default_version_id": "<<version id>>"
```

Payload sample2:

```
{
 "default_version_name": "1.0.0.1"
}
```

Response:

```
{
  "service": {
    "id": "5df38f28a051bd001d16117d",
    "name": "SampleV1",
    "serviceManifestId": "5df38f30a051bd001d161181",
    "author": "admin",
    "image": "serviceicon_1.svg",
    "tag": "5c6e73077077fc001715703b",
    "creationTime": "2019-12-13T13:16:23.237Z",
    "lastUpdated": "2019-12-13T13:25:01.646Z",
    "namespaceId": "default",
    "tenantId": "674a6a42-76c0-450c-a225-e743772c49f3",
    "description": "A Sample Single Virtual Machine Service",
    "longDescription": ""
  }
}
```

Edit a Service Version

This API edits a service version. This API cannot change service name, category, and image.

```
curl -k -X POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceManifest/${SERVICE_VERSION_ID}/updateServiceVersion?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
```

```
 -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
 -H 'Content-Type: application/json' \
 -H 'cache-control: no-cache' \
 -d @service_version_edit.json
```

Payload: content of service_version_edit.json

```

```

Delete a Service version in a service

```
curl -k -X POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/Service/${SERVICE_ID}/deleteService?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @service_version_delete.json
```

Payload sample1:

```
{
  "version_id": "{{VERION_ID}}"
}
```

Payload sample2:

```
{
  "version": "{{VERSION}}"
}
```

Delete a Service (with all its versions)

```
curl -k -X POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/Service/${SERVICE_ID}/deleteService?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @service_delete.json
```

Payload

```
 {}
```

Response

```
{
  "count": "1"
}
```

GET the list of services

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" "https://${TSA_HOSTNAME}/cam/composer/api/v1/service?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

The service records that belong to the namespace value provided for **cloudOE_spaceGuid** are fetched as a result of this curl command. If you specify any value for **cloudOE_spaceGuid**, then all default services are fetched along with services that belong to globally accessible namespace.

Example response:

```

Duplicate a service

Creates a copy of the Service with all its versions in a new Service.

```
curl -k -X POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/Service/${SERVICE_ID}/duplicateService?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @service_duplicate.json
```

Payload

```
{
    "service_name": "{{NEW-SERVICE-NAME}}"
}
```

Response

```

Copy service version to a service

```
curl -k -X POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceManifest/${SOURCE_SERVICE_VERSION_ID}/copyService?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @service_version_copy.json
```

Payload

```
{
  "to_service_id": "{{SERVICE_ID}}",
  "new_version_name": "{{NEW-VERSION-LABEL}}"
}
```

Response

```

Assign access to a service

Assigns a single or multiple namespaces to a service.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Accept: application/json" "https://${TSA_HOSTNAME}/cam/composer/api/v1/Service/<id>/setNamespaceId?tenantId=
<tenantId>&cloudOE_spaceGuid=<comma separated list of namesapces>"
```

For scenarios of assigning access, see Assigning access to a service

Retire a service version

This API retires both published services and draft services.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceManifest/${SERVICE_VERSION_ID}/retire?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}
```

Unretire a service version

This API unretires the already retired service and moves it back to Published state.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
"https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceManifest/${SERVICE_VERSION_ID}/unretire?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}
```

Auto-retire a service version

This API retires a service version on the set date. The service version is retired at mid-night of the set day.

```
curl -k --location --request POST
'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceManifest/${SERVICE_VERSION_ID}/setRetireOnDate?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}' \
-H 'Accept: application/json' \
-H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
-H 'Content-Type: application/json' \
-d @set_retire_on_date.json
```

set_retire_on_date.json:

```
{
    "retire_on_date": "2020-10-28T07:03:11.612Z"
}
```

Service Instance APIs

Deploy a service instance

```
curl -k -X POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceManifest/{SERVICEMANIFEST_ID}/deploy?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @service__instance_create.json
```

service__instance_create.json:

```
{
  "name": "Service_Instance_Name",
  "instance_plan": "Standard",
  "instance_plan_id": "5dc13f03ec19fe001508e539",
```

```
  "tags_input": [
    {
      "value": "${svc_instance.group}",
      "label": "request_group",
      "name": "request_group",
      "secured": false
    },
    {
      "value": "${svc_instance.owner}",
      "label": "request_user",
      "name": "request_user",
      "secured": false
    },
    {
      "value": "${svc_instance.name}",
      "label": "service_name",
      "name": "service_name",
      "secured": false
    },
    {
      "value": "${svc_instance.service_instance_id}",

Get the list of deployed instance: GET call

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances?tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Where **namespace** is **namespace Id** and **team** is **organization Id**.

Headers required:

- Content-Type: **application/json**
- Authorization: **<bearer token>**

Get details of a Service Instance by using the id

This GET call fetches the details of a specific by its id:

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/<service-instance-id>?tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}"
```

Headers remain the same as in the terminate service instance call.

Get Input Parameters of a service instance

The API retrieves the inputs parameters of a service instance. It is recommended to use this API before Retry/Resume/Edit service instance so that you can verify the input parameters before Retry/Resume/Edit service instance. This API also resolves the shared parameters and parameters of type connection, if any. Earlier this API (**GET ServiceManifest/5e4f5a51826bc70015dfaece?service_filter[resolve_params][action_name]=Provision**) was used for the same purpose.

Note: It is recommended to use the **getInputParameters** API instead of **ServiceManifest** API if you want to try Retry or Resume after a service version change.

To use this API, you need a service instance ID. To get the service instance ID:

1. Retrieve all the service instances using the following API Get the list of deployed instance. The response contains an array of service instances
2. Locate the instance by name and get the ID.
3. Use the following curl command to get the input parameters for the service instance:

   ```
   curl --location --request GET \
   'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/${ServiceInstanceId}/getInputParameters?cloudOE_spaceGuid=development&ace_orgGuid=all&tenantId=c26b3dd4-4e74-4545-8ac9-bc30a6167b33' \
   --header 'Content-Type: application/json'
   ```

   Response

   ```
   {

Edit Service Instance

The **updateServiceInstance** command edits the service instance parameters.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json"
-H "Accept: application/json"
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/{{SERVICE_INSTANCE_ID}}/update?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

POST call

Headers:

```
"Authorization": <bearer token>

"Content-Type": "applcation/json"
```

cc_create.json

```
{
"update_details": {
    "instance_parameters": {
    "in1": "https://jsonplaceholder.typicode.com/todos/22"
  }
```

```
}
}
```

<service_instance_id> - It is the ID of the service instance for which you want to edit.

You must provide all the updated values of service instance parameters to edit this service instance.

Retry Service Instance

The **retryServiceInstance** command attempts to retry all terminate service instances that failed.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/${SERVICE_INSTANCE_ID}/retry?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

POST call

Headers:

```
"Authorization": <bearer token>

"Content-Type": "applcation/json"
```

cc_create.json

```
{
"retry_details": {
  "is_partial": false,
  "instance_parameters": {
    "in1": "https://jsonplaceholder.typicode.com/todos/22"
  }
}
}
```

<service_instance_id> - It is the ID of the service instance for which you want to retry.

You can run retry with all the updated values for service instance parameters. If the updated service instance parameters are not provided, the values of the previous deployments are used.

If **is_partial** not provided, then by default its value is false. Support is not available for a true value of **is_partial**.

Resume Service Instance

The **resumeServiceInstance** command attempts to resume all terminated service instances that failed.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/${SERVICE_INSTANCE_ID}/resume?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

POST call

Headers:

```
"Authorization": <bearer token>

"Content-Type": "application/json"
```

Sample cc_create.json:

```
{
"resume_details": {
  "is_partial": false,
  "instance_parameters": {
    "in1": "https://jsonplaceholder.typicode.com/todos/22"
  }
}
}
```

<service_instance_id> - It is the ID of the service instance for which you want to resume.

You can resume deployment with all the updated values for service instance parameters. If the updated service instance parameters are not provided, the values of the previous deployments are used.

If **is_partial** not provided, then by default its value is false. Support is not available for a true value of **is_partial**.

Upgrade or downgrade a Service Instance

To upgrade or downgrade a particular service instance to higher or lower service version, the following APIs must be used in sequence:

- getServiceInstance: Returns the service instance details along with the available version change paths (upgrade/downgrade).
- versionChangeInputParameters: Returns the list of input parameters that are needed for service instance version change.
- submitversionChange: Upgrade/downgrade a version of service instance.

getServiceInstance

This API returns the service instance details along with the available version change paths (upgrade or downgrade).

```
curl --location --request GET \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/5e574fe2dc44840015c8093b?
filter[include]=UpgradePaths&filter[include]=DowngradePaths&cloudOE_spaceGuid=development&ace_orgGuid=all&tenantId=c26b3dd
4-4e74-4545-8ac9-bc30a6167b33' \
--header 'Content-Type: application/json'
```

Response

      "id": "5e57566fdc44840015c8094e"
    }
  ]
}
```

Note: **id** present inside the UpgradePaths or DowngradePaths should be used as **versionChangeId** in payloads of the **versionChangeInputParameters** and **submitVersionChange** APIs.

versionChangeInputParameters

This API returns the list of input parameters that are needed for service instance version change.

```
curl --location --request POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/5e574fe2dc44840015c8093b/versionChangeInputParameters?
cloudOE_spaceGuid=development&ace_orgGuid=all&tenantId=c26b3dd4-4e74-4545-8ac9-bc30a6167b33' \
--header 'Content-Type: application/json' \
--data-raw '{
  "versionChangeId": "5e575d04dc44840015c80963"
}
```

versionChangeId is the ID that is present inside the **UpgradePaths** or **DowngradePaths**, which is returned with the **getServiceInstance** API.

Request Body

```
{
  "versionChangeId": "5e575c44dc44840015c80959"
}
```

Response

```
{
  "VersionChangeInputParameters": {
    "versionChangeId": "5e575d04dc44840015c80963",
    "toVersion": "3.3.3.3",
    "type": "UPGRADE",
    "input_parameters": [
      {
        "name": "url",
        "label": "Rest URL",
        "customtype": "string",
        "type": "string",
        "immutable": false,
        "hidden": false,
        "required": false,
        "secured": false,
        "isDynamic": false,
        "editable": true,
        "default": "https://jsonplaceholder.Invalid"
      },
      {
        "name": "url2",
        "label": "URL 2",
        "customtype": "string",
        "type": "string",
        "immutable": false,
        "hidden": false,
        "required": false,
        "secured": false,
        "isDynamic": false,
        "editable": true,
        "default": "https://jsonplaceholder.typicode.com/todos/2"
      }
    ],
    "pre_action_input_parameters": [],
    "post_action_input_parameters": [],
    "new_parameters": [
      "url2"
    ],
    "used_old_parameters": [
      "url"
    ],
    "ignored_old_parameters": [
      "nsxt_transport_zone"
    ]
  }
}
```

Note:

- `input_parameters` - A list of input parameters needed for service instance version change.
- `new_parameters` - A list of new input parameters present in the new version.
- `used_old_parameters`- A list of input parameters present from the old version which are used in new version.
- `ignored_old_parameters` - A list of input parameters present from the old version which are not used in new version.
- `pre_action_input_parameters` and `post_action_input_parameters` are not supported in this release.

submitVersionChange

This API upgrades/downgrades a version of the service instance.

```
curl --location --request POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/5e574fe2dc44840015c8093b/submitVersionChange?
cloudOE_spaceGuid=development&ace_orgGuid=all&tenantId=c26b3dd4-4e74-4545-8ac9-bc30a6167b33' \
--header 'Content-Type: application/json' \
--data-raw '{
    "versionChangeId": "5e575d04dc44840015c80963",
    "instance_parameters": {
        "url": "https://jsonplaceholder.typicode.com/todos/1",
        "url2": "https://jsonplaceholder.typicode.com/todos/2"
    },
    "pre_action_parameters": {},
    "post_action_parameters": {},
    "plan": ""
}
```

Request Body

```
{
    "versionChangeId": "5e575d04dc44840015c80963",
    "instance_parameters": {
        "url": "https://jsonplaceholder.typicode.com/todos/1",
        "url2": "https://jsonplaceholder.typicode.com/todos/2"
    },
    "pre_action_parameters": {},
    "post_action_parameters": {},
```

```
    "plan": ""
}
```

Bind a service instance

The API call creates a bind instance.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/${SERVICE_INSTANCE_ID}/createBind?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

POST call

Headers:

```
"Authorization":  "bearer <token>"

"Content-Type": "application/json"
```

cc_create.json

```
{
 "bindDetails": {
   "instance_parameters": {
     "resturl2": "https://jsonplaceholder.typicode.com/todos/33""
   }
 }
```

- `<service_instance_id>` - It is the ID of the service instance for which you want to create a bind instance.
- `<instance_parameters>` - Optionally, you can run bind with updated values for service instance parameters. If not provided, then earlier values are used.

Unbind Instance

The API call unbinds or deletes a bind instance.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/${SERVICE_INSTANCE_ID}/terminateBind?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

BODY:

cc_create.json

```
"name":"<name_of_bind_instance>"}
```

`<name_of_bind_instance>` - It is the name of the bind instance that you want to unbind.

Get custom actions

List the custom actions of a service instance.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json"
"https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/<serviceInstanceID>/getCustomActions?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

This GET call fetches the list of custom actions of service instance.

```
Headers:

"Authorization": "bearer <token>"
"Content-Type": "application/json"
```

Response

```
{
  "customActions": [
    {
      "type": "custom",
      "name": "custom1",
      "description": "customaction",
      "pre_or_post": false,
      "input_parameters": [
        {
          "name": "resthook_url",
          "label": "resthook_url",
          "customtype": "string",
          "type": "string",
          "immutable": false,
          "hidden": false,
          "required": false,
          "secured": false,
```

```
          "isDynamic": false
        }
      ],
      "flow": {
        "conditions": [],
        "templates": [],
        "resthooks": [
          {
            "resthook": {
              "title": "resthook_f428a5",
              "id": "resthook56a3f1fc",
              "headers": {
                "accept": "application/json",
                "Content-Type": "application/json"
              },
              "editable": true,
              "url": "${input_parameters.resthook_url}",
              "method": "GET"
            }
          }
        ],
        "notifications": [],
        "sequence": {
          "0": "resthook56a3f1fc"
        },
        "error_sequence": {}
      },
      "output_parameters": []
    }
  ]
}
```

Invoke custom action

To execute a custom action on a service instance.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @custom_action.json
"https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/<serviceInstanceID>/invokeCustomAction?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

POST call

```
Headers:

"Authorization": "bearer <token>"
"Content-Type": "application/json"
```

custon_action.json

```
{
  "customDetails": {
    "serviceInstanceId": "<serviceInstanceId>"
    "name":"actionInstanceName",
    "instance_parameters": {
      "resthook_url":"https://jsonplaceholder.typicode.com/todos/33"
    },
    "currentCustomAction":"<actionName>"
  }
}
```

instance_parameters - Optionally, you can run custom action with updated values for service instance parameters. The default values are used, if parameters are not provided.

Terminate Service Instance

```
curl -k -X POST \
'https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/${ServiceInstanceId}/terminate?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
-H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
-H 'Content-Type: application/json' \
-H 'cache-control: no-cache' \
-d @service__instance_terminate.json
```

Content of service__instance_terminate.json:

```
{}
```

Response

```
{"name":"upgarde_downgrade_service_instance56857d10-0220-11eb-859b-
adea70bdca6d","Status":"Terminating","id":"5f72d9ac2401e29758629ce9"}
```

Cleanup Service Instance

It deletes all service instances based on the value of **force** flag. If the **force = false**, then the instances in active state are not deleted. The instances in error state are deleted irrespective of the **force** flag value.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/{{SERVICE_INSTANCE_ID}}/cleanup?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"

POST call

Headers:

"Authorization": <bearer token>
"Content-Type": "applcation/json"

Body: {
 "force": <true/false>
}
```

Cleanup Service Instance in inprogress state

If a service instance is stuck in IN_PROGRESS state for a long time without any backend activity, then use this API to delete the service instance entry from the database.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/ServiceInstances/{{SERVICE_INSTANCE_ID}}/cleanup?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Sample Request BODY:

```
{
  "serviceInstanceId": "5cf0c20cbdf17d001786d1a9",
  "force": true
}
```

The **`force = true`** deletes the service instance entry from the Managed services database forcefully. However, the activities that are running does not get cleaned up and they throw the following error exception:

```
{
  "error": {
    "statusCode": "419",
    "name": "Error",
    "message": "ResourceLockError: Failed to obtain lock for resource stack_e19dd5d0-85f5-11e9-8609-cf2b57a8a189.; caused
by Error: unable to obtain lock"
  }
}
```

The **`ResourceLockError`** is related to Mongo DB lock. Whenever any deployment starts, Mongo DB lock associated with the stack_id is placed and it remains locked for 1 hour. If service instance is stuck and the cleanup API gives ResourceLockError, try the same API after 1 hour, that is, after the lock expires. It is a precautionary step to avoid cleaning up of service instances that are in running state at the backend, which might cause inconsistency. Also, there can be side effects if an instance having dangled resources gets cleaned up.

Standalone action APIs

Create Standalone Action

Creates a stand-alone action independent of any service.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" -H "Accept: application/json" \
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/Actions/createAction?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid={NAMESPACE}"
```

The **`cloudOE_spaceGuid`** contains the value of the namespace. Note that the **`NAMESPACE`** must be the desired namespace to deploy to.

POST method

Example BODY:

cc_create.json

```
{
    "type": "provision",
    "name": "newAct44f",
    "description": "Default action for deployment of service",
    "input_parameters": [],
    "flow": {
        "conditions": [],
        "templates": [
            {
                "Template With Output Parameters": {
                    "title": "Template With Output Parameters_343311",
                    "template_name": "Template With Output Parameters ce0c21",
                    "version": "master",
                    "id": "template46b48313",
```

```
                    "template_type": "Terraform",
                    "template_content_type": "VMware vSphere",
                    "template_provider": "VMware vSphere",
                    "instance_name": "",
                    "cloud_connection_name": "Global-VV1",
                    "template_data_objects": {},
                    "template_params": {
                        "sleep": "10000",
                        "cam-ip": "9.5.29.229",
                        "data-server": "9.5.28.159",
                        "data-as-query-string": "id=1&name=test",
                        "region": "us-east-1"
                    },
                    "outputs": [
                        "resource-id",
                        "selected-region",
                        "data"
                    ]
                }
            }
        ],
        "resthooks": [],
        "notifications": [],
        "sequence": {
            "0": "template46b48313"
        }
    },
    "output_parameters": []
}
```

After your create an action, an action ID is generated automatically:

Example response:

```
{
   "ServiceEngine_InputFile": {
      "service": {
         "specVersion": "v3",
         "catalog_metadata": {

       "Template doesnt exists or no access: response.statusCode: 400",
       " Template amazoneceeb670ee does not have cloud connection name.",
       "Templates- 'template_params' of type json object should have non-empty keys , template.id : amazoneceeb670ee"
    ]
}
```

For complete format of the action, see action section in the Editing a service file section.

Invoke Standalone Action

Use the action id generated in the **Create Action** API call to invoke an action.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d @cc_create.json "https://${TSA_HOSTNAME}/cam/composer/api/v1/ActionInstances/invokeAction?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid={NAMESPACE}"
```

The **cloudOE_spaceGuid** contains the value of the namespace. Note that the **NAMESPACE** must be the desired namespace to deploy to.

POST method

Example BODY:

```
"action_data": {
        "action_id": "5caf3b64b52b5a00182116af",
        "name": "inst2 "
    }
```

Example response:

```
{
    "actionInstance": {
        "id": "5cd01a095253de001918ce2c"
    }
}
```

It returns Action instance ID.

ICON APIs

Upload service icons

This API uploads new icons. Select the file to upload.

POST method

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}"  \
-F "icon=@PATH_TO_FILE" "https://${TSA_HOSTNAME}/cam/composer/api/v1/icons/upload?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

It returns the name and id of the image.

BODY example:

```
{
   "res": {
       "name": "serviceicon_1.svg",
       "id": "5czdb1bc1b47001cbc556"
     }
}
```

Note:

- The size of the icon file must be less than one MB.
- The name of the icon must be unique.
- The supported content types are as follows:

  CONTENT_TYPE = ['image/jpeg', 'image/gif', 'image/png','application/xml'];

- Upload images with the key name as ‘icon’.

Delete service icons

This API deletes service icons.

```
curl -k -X DELETE \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" "https://${TSA_HOSTNAME}/cam/composer/api/v1/icons/${ICON_ID}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Retrieve all service icons

This API returns metadata of all available icons.

GET method.

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" "https://${TSA_HOSTNAME}/cam/composer/api/v1/icons?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

BODY example:

```
[
   {
     "ContentTye": "application/xml",
     "name": "serviceicon_1.svg",
     "id": "5czdb1bc1b47001cbc556"
   },
   {
      "ContentTye": "application/xml",
      "name": "serviceicon_2.svg",
      "id": "5czdb1bc1b47001cbc557"
    },
    {
      "ContentTye": "application/xml",
      "name": "serviceicon_3.svg",
      "id": "SCZ5czdb1bc1b47001cbc559"
     }
]
```

You can also set the filter to retrieve the metadata of a service icon based on its name, ID, or type.

```
GET /cam/composer/api/v1/icons/?tenantId=62c6ce6e-1f62-4fe1-b176-259037a7bff2&ace_orgGuid=all&filter[where]
[name]=serviceicon_1.svg
```

BODY example:

```
{
   {
       "ContentTye": "application/xml",
       "name": "serviceicon_1.svg",
       "id": "5czdb1bc1b47001cbc556"
     }
}
```

Download service icon

This API call downloads the specified icon.

GET method

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" "https://${TSA_HOSTNAME}/cam/composer/api/v1/icons/name/${ICON_NAME}?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Custom action APIs

This section includes all the custom action APIs with examples.

- Create a custom action category
- Create a custom action
- Lock a custom action
- Unlock a custom action
- Get the list of custom actions
- Assign a custom action to service version (service manifest)
  - Additional information for the custom action to a service version (service manifest) API

Custom action APIs

Create a custom action category

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/customActionCategories?ace_orgGuid=${MCM_TEAM}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d {"Name": "demo-category"}
```

Response

```
{
    "Name": "demo-category",
    "id": "621cc8e6218004001ac4bc00",
    "tenantId": "cf5c3f7d-a70d-435c-9554-55d8e3441380"
}
```

Create a custom action

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/CustomAction/createCustomAction?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
```

```
  -H 'cache-control: no-cache' \
  -d @custom_action_create.json
```

custom_action_create.json`

```
{
  "action": {
    "type": "custom",
    "name": "ind-action",
    "category": "demo-category",
    "description": " Independent custom action",

```

Additional information for the custom action to a service manifest API

1. You can follow either one of the steps to assign custom input parameters. In this case, **inputurl** values are assigned as shown:

   a. While assigning custom actions, you can attach the provison action output parameters of a service manifest to the custom action by using interpolation **${svc_instance.output_parameters.<o/p param>}**, which gets resolved when you try to deploy the independent custom action.

   Example

   ```
   {
       "custom_action_details": [
       {
           "customActionName": "ind-action",
           "customActionId": "<custom action id>",
           "customInputParams": {
           "inputurl": "${svc_instance.output_parameters.todosUrl3}"
   ```

```
        }
    }
  ]
}
```

b. You can directly assign the values which overrides the default values at the time of deployment of the custom action.

Example

```
{
    "custom_action_details": [
    {
        "customActionName": "ind-action",
        "customActionId": "<custom action id>",
        "customInputParams": {
        "inputurl": "http://example.com"
        }
    }
  ]
}
```

2. You can assign custom actions for both publish and draft service manifest.
3. Reassigning custom actions for a service manifest overrides the previous assigned custom actions.

Unlock a custom action

You cannot unlock the custom action until it is unassigned with all the service versions associated with it.

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/CustomAction/<customid>/unlock?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d {}
```

Response

Dynamic parameter discovery APIs

This section includes all dynamic parameter discovery related APIs.

- Clean Cache Data
- Update clear cache frequency

Clean Cache Data

You must be a cluster administrator or administrator to run this API. Otherwise, an unauthorized error message is displayed.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/dynamicparameterdiscovery/clean-cache?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Update clear cache frequency

You must be a cluster administrator or administrator to run this API. Otherwise, an unauthorized error message is displayed.

```
curl -k -X POST \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/dynamicparameterdiscovery/update-cache-config?
frequency=10&tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Application APIs

This section includes all application APIs with examples.

- Creating category for applications
- Creating an application
- Importing an application from GitHub repository
- Pushing an application to GitHub
- Duplicating an application
- Editing an application
- Deploying an application
- Publishing an application
- Retrieving application template

Creating category for applications

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/AppCategories?ace_orgGuid=${MCM_TEAM}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d {"name": "AppCategorySample"}
```

Result

```
{
  {
    "name": "AppCategorySample",
    "id": "5fc9df7661b3e8001b7c2511",
    "tenantId": "83d50ee1-849b-4b33-bb25-9cb05f9bd87c"
}
```

Creating an application

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/AppModel/createApp?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @application_create.json
```

application_create.json

```
{
  "data": {
    "name": "ApplicationSample",

}
```

Importing an application from GitHub repository

This API call imports an application from the GitHub repository.

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/AppModel/pullAppModelFromGIT?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @application_import.json
```

application_import.json

```
{
  "app_details": {
    "name": "Application",
    "categoryId": "5fc9df7661b3e8001b7c2511",
    "description": "ImportFromGitHub",
    "git_details": {
      "git_type": "github",
      "git_token": <github_token>,
      "file_path": "mysubdir/application.yaml",
      "git_ref": "master",
      "git_url": "http://mygithub/user/reponame"
    }
  }
}
```

Response:

```
{
  "pullAppModelFromGITResponse": {
    "statusCode": 200,
    "status": "success",
    "message": "Application imported successfully"
  }
}
```

Pushing an application to GitHub

This API pushes an application to GitHub.

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/AppModel/${APP_ID}/pushAppToGit?
ace_orgGuid=${MCM_TEAM}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @push_application.json
push_application.json
{
    "git_details": {
      "git_type": "github",
      "git_token": <github_token>,
      "file_path": "mysubdir/application.yaml",
      "git_ref": "master",
      "git_url": "http://mygithub/user/reponame"
    },
    "commit_details": {
      "commit_message": "Sample file to push an Application"
    }
}
```

Response:

```
{
    "pushAppToGITResponse": {
        "statusCode": 200,
        "status": "success",
        "message": "App pushed successfully"
    }
}
```

Duplicating an application

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/AppModel/${APP_ID}/duplicateApp?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d {"app_name": <Duplicate_APP_Name>}
```

Response:

```
{
    "data": {
        "name": <Duplicate_APP_Name>,
        "spec": "apiVersion: app.k8s.io/v1beta1\nkind: Application\nmetadata:\n  labels:\n    app: nginx-app-details\n

}
```

Deploying an application

This API deploys a published application.

```
curl -k -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/AppModel/${APP_ID}/deploy?
ace_orgGuid=${MCM_TEAM}&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer ${TSA_BEARER_TOKEN}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d @application_deploy.json
```

application_deploy.json

```
{
  "name": "nginx-app-3",
  "parameters": [
    {
      "name": "matchLabel",
      "value": "nginx-app-details"
    }
  ]
}
```

Response:

```
{
    "instance": {
        "name": "nginx-app-3",
        "status": "Submitted",
        "creationTime": "2020-12-04T08:38:17.933Z",

Shared parameter APIs

This section includes all APIs for shared parameters.

- Create new Data Type
- List all Data Types
- Lookup Data Objects (implicit or explicit) for the Data Types specified in the request
- Resolve the Data Type variables for the template parameters
- Update Data Type
- Delete Data Type
- Create new Data Object
- Retrieve Data Object
- Update Data Object
- Delete Data Object

Create new Data Type

This API creates a new Data Type

```
curl -X POST \
  'https://{TSA_HOSTNAME}/cam/api/v1/datatypes?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId={{TSA_TENANT_ID}}' \
  -H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  --insecure \
  -d '{
    "name": "DemoOneType",
    "label": "Demo One Type",
    "description": "Datatype for DemoOne",
    "attributes": [
```

```
        {
            "name": "hostip",
            "default": "0.0.0.0",
            "regex": "[0-9]+\\.[0-9]+\\.[0-9]+\\.[0-9]+",
            "type": "string",
            "required": "true",
            "secured": "false",
            "label": "Host IP address",
            "hidden": "false",
            "immutable": "false"
        },
        {
            "name": "port",
            "description": "Port number",
            "default": "80",
            "range": {
                "min": "80",
                "max": "9999"
            },
            "type": "counter",
            "required": "true",
            "secured": "false",
            "label": "Port",
            "hidden": "false",

            "type": "string"
        },
        {
            "name": "password",
            "description": "Password for the host",
            "hidden": false,
            "immutable": false,
            "label": "Password",
            "regex": "[\\w]{8}",
            "required": true,
            "secured": true,
            "type": "password"
        }
    ]
}';
```

- **ROLE:**

  ADMINISTRATOR

- **Params:**

```
{
  name : [string],
  label: [string],
  description : [string],
  attributes : [
  {
    name: [string],
    default: [string],
    type: [string],
    label: [string],
    required: [boolean],
    hidden: [boolean],
    immutable: [boolean],
    secured: [boolean]
  }
 ]
}
```

- **Success Response:**
  - Code: `200` Content: `{ id : 1, name : "LDAPServer", description: "LDAP server data type", attributes: [...] }`
- **Error Response:**
  - Code: `400 BAD REQUEST` Content: `{ error : "Data type ${name} already defined." }`

  Or

  - **Code:** `401 UNAUTHORIZED` **Content:** `{ error : "You are unauthorized to make this request." }`

List all Data Types

This API lists all available Data Types.

```
curl -X GET \
  'https://{TSA_HOSTNAME}/cam/api/v1/datatypes?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId={{TSA_TENANT_ID}}' \
  -H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  --insecure
```

- **ROLE:**

  ADMINISTRATOR

- **Success Response:**

  - Code: `200` Content: `[{ id : 1, name : "LDAPServer", description: "LDAP server data type", attributes: [...] }, ...]`

Lookup Data Objects (implicit or explicit) for the Data Types specified in the request

```
curl -X POST \
  'https://{TSA_HOSTNAME}/cam/api/v1/datatypes/lookup?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId=
{{TSA_TENANT_ID}}' \
  -H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d '{
  "datatypes" : [
    "DemoOneType"
  ]
}'
```

- **ROLE:**

  tenantMember

- **Params:**

  ```
  {
    datatypes : [datatype_name1, datatype_name2, ...]
  }
  ```

- **Success Response:**

  - Code: `200` Content:

    Example

    ```
    [
      {
        "name": "datatype_name1",
        "label": "datatype_label1",
        "dataobjects": [
        {
        "id": "1234567890",
        "name" : "dataobject name",
        "datatype": "datatype_name1",
        "provider": "IBM"
         }
       ]
      }
    ]
    ```

Resolve the Data Type variables for the template parameters

`POST /datatypes/resolve`

- **ROLE:**

  tenantMember

- **Params:**

  Example:

  ```
  {
     "input_dataobjects": [
     {
       "id": "1234567890",
       "name" : "dataobject name",
       "datatype": "datatype_name1",
       "provider": "IBM"
     }
    ],
     "parameters": {
     "template_input_params": [
     {
       "name": "param1",
       "type": "string",
       "default": "${ContentRuntime.output1}",
      }
  ```

```
    ]
  }
}
```

- **Success Response:**
  - Code: `200` Content: `{ template_input_params: [{ name: 'param1', type: 'string', default: 'output1 value'}]}`

Update Data Type

```
curl -X PUT \
  'https://{TSA_HOSTNAME}/cam/api/v1/datatypes/{{DATATYPE_ID}}?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId=
{{TSA_TENANT_ID}}' \
  -H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d '{"description": "updated description"}'
```

- **ROLE:**

  ADMINISTRATOR

- **URL params:**

  datatype ID or datatype name

- **Params:**

  The following parameters are optional, for example, if you only want to update the 'attributes' the request body can contain only the 'attributes'.

```
{
  name : [string],
  label: [string],
  description: [string],
  attributes:[
   {
    name: [string],
    default: [string],
    type: [string],
    label: [string],
    required: [boolean],
    hidden: [boolean],
    immutable: [boolean],
    secured: [boolean]
    }
  ]
}
```

- **Success Response:**
  - Code: `200` Content: `{ id : 1, name : "LDAPServer", description: "LDAP server data type", attributes: [...] }`
- **Error Response:**
  - Code: `400 BAD REQUEST` Content: `{ error : "Data type ${name} already defined." }`

  Or
  - **Code:** `401 UNAUTHORIZED` **Content:** `{ error : "You are unauthorized to make this request." }`

Delete Data Type

```
curl -X DELETE \
  'https://{TSA_HOSTNAME}/cam/api/v1/datatypes/{{DATATYPE_ID}}?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId=
{{TSA_TENANT_ID}}' \
  -H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache'
```

- **ROLE:**

  ADMINISTRATOR

- **URL params:**

  datatype ID or datatype name

- **Success Response:**
  - Code: `201` Content: None
- **Error Response:**
  - Code: `404 NOT FOUND` Content: `{ error : "Data type ${id} does not exist." }`

  Or
  - **Code:** `401 UNAUTHORIZED` **Content:** `{ error : "You are unauthorized to make this request." }`

Create new Data Object for specific namespace

This API creates a new Data Object.

```
curl -X POST \
  'https://{TSA_HOSTNAME}/cam/api/v1/dataobjects?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId={{TSA_TENANT_ID}}' \
  -H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  --insecure \
  -d '{
  "datatype": "DemoOneType",
  "name": "DemoOneObject",
  "namespaceId": "{{NAMESPACE}}",
  "label": "DemoOneObject",
  "attributes": [
    {
      "name": "hostip",
      "value": "127.0.0.1"
    },
    {
      "name": "port",
      "value": 587
    },
    {
      "name": "username",
      "value": "user1"
    },
    {
      "name": "password",
      "value": "test1234"
    }
  ]
}'
```

- **ROLE:**

  ADMINISTRATOR

- **Success Response:**

  - Code: `200` Content: `{ id : 1, name : "LDAPServer.production", description: "My LDAP server for production", attributes:[...] }`

- **Error Response:**

  - Code: `400 BAD REQUEST` Content: `{ error : "Data object ${name} already defined." }`

  Or

  - **Code:** `401 UNAUTHORIZED` **Content:** `{ error : "You are unauthorized to make this request." }`

Optionally, you can add `cloudOE_spaceGuid=${NAMESPACE}` query parameter to create the Data Object in the namespace that **`NAMESPACE`** resolves to.

Retrieve Data Object

```
curl -X GET
'https://{TSA_HOSTNAME}/cam/api/v1/dataobjects?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId={{TSA_TENANT_ID}}'
-H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}'
-H 'Content-Type: application/json'
-H 'cache-control: no-cache'
```

- **ROLE:**

  ADMINISTRATOR

- **URL params:**

  dataobject ID

- **Success Response:**

  - Note: The attributes are merged with the datatype's attributes.
  - Code: `200` Content:

```
 {
   "id" : 1,
   "name": "production",
   "label": "Production LDAP server",
   "datatype": "com.ibm.cam.ldapserver",
   description: "My LDAP server for production",
   attributes:[
   {
    "name": "ipaddress",
    "value": "127.0.0.1",
    "default": "",
    "type": "string",
    "required": "true",
    "secured": "false",
```

```
    "label": "IP address",
    "hidden": "false",
    "immutable": "false"
    },
    {
     "name": "port",
     "value": "367",
     "default": "",
     "type": "string",
     "required": "true",
     "secured": "false",
     "label": "Port",
     "hidden": "false",
     "immutable": "false"
     }
    ]
 }
```

- **Error Response:**
  - Code: `400 BAD REQUEST` Content: `{ error : "Data object ${name} already defined." }`

  Or
  - Code: `404 NOT FOUND` Content: `{ error : "Data object ${id} does not exist." }`

  Or
  - **Code:** `401 UNAUTHORIZED` **Content:** `{ error : "You are unauthorized to make this request." }`

Optionally, you can add `cloudOE_spaceGuid=${NAMESPACE}` query parameter to create the Data Object in the namespace that **NAMESPACE** resolves to.

Update Data Object

```
curl -X PUT \
  'https://{TSA_HOSTNAME}/cam/api/v1/dataobjects/{{Dataobjects_ID}}?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId=
{{TSA_TENANT_ID}}' \
  -H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d '{"description": "updated description"}'
```

- **ROLE:**

  ADMINISTRATOR

- **URL params:**

  dataobject ID

- **Params:**

```
{
  name: [string],
  label: [string],
  datatype: [string],
  description: [string],
  attributes:[
   {
    // attribute definition
    ...
   }
  ]
}
```

- **Success Response:**
  - Code: 200 Content: `{ id : 1, name : "LDAPServer.production", description: "My LDAP server for production", attributes:[...] }`
- **Error Response:**
  - Code: `400 BAD REQUEST` Content: `{ error : "Data object ${name} already defined." }`

  Or
  - Code: `404 NOT FOUND` Content: `{ error : "Data object ${id} does not exist." }`

  Or
  - **Code:** `401 UNAUTHORIZED` **Content:** `{ error : "You are unauthorized to make this request." }`

Optionally, you can pass `cloudOE_spaceGuid=${NAMESPACE}` in the query parameter to change the namespace of the Data Object. The modified namespace value is the value that **NAMESPACE** resolves to.

Delete Data Object

```
curl -X DELETE \
  'https://{TSA_HOSTNAME}/cam/api/v1/dataobjects/{{Dataobjects_ID}}?ace_orgGuid=all&cloudOE_spaceGuid=default&tenantId=
{{TSA_TENANT_ID}}' \
```

```
-H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
-H 'Content-Type: application/json' \
-H 'cache-control: no-cache'
```

- **ROLE:**

  ADMINISTRATOR

- **URL params:**

  dataobject ID

- **Success Response:**

  - Code: `200` Content: `{ id : 1, name : "LDAPServer.production", description: "My LDAP server for production", attributes:[...] }`

- **Error Response:**

  - Code: `404 NOT FOUND` Content: `{ error : "Data object ${id} does not exist." }`

  Or

  - **Code:** `401 UNAUTHORIZED` **Content:** `{ error : "You are unauthorized to make this request." }`

SMTP Connections APIs

Learn more about SMTP connection APIs.

- Create SMTP connection
- Modify SMTP connection
- Test SMTP connection
- Get list of all SMTP connections
- Get list of SMTP connections by ID
- Delete SMTP connection

Create SMTP connection

To use email notifications, you must configure a connection to the SMTP server by running this API. Creating a secondary connection is optional.

1. Create a primary connection.

   ```
   curl -k -X POST \
   -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
   -H "Content-Type: application/json" \
   -H "Accept: application/json" \
   -d @cc_create_primary.json \
   "https://${TSA_HOSTNAME}/cam/composer/api/v1/smtpconnections?tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}
   ```

   POST method

   Example request body:

   cc_create_primary.json for primary connection:

   ```
   {
      "name": "PRIMARY",
      "connection_parameters": [{
          "name": "hostname",
          "value": "smtp.example.com"
      }, {
          "name": "port",
          "value": 25
      }, {
          "name": "username",
          "value": "myusername"
      }, {
          "name": "password",
          "value": "mypassword"
    }]
   }
   ```

2. Create a secondary connection.

   ```
   curl -k -X POST \
   -H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
   -H "Content-Type: application/json" \
   -H "Accept: application/json" \
   -d @cc_create_secondary.json \
   "https://${TSA_HOSTNAME}/cam/composer/api/v1/smtpconnections?tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}
   ```

   POST method

   Example request body: cc_create_secondary.json for secondary connection

```
    {
        "name": "SECONDARY",
        "connection_parameters": [{
                "name": "hostname",
                "value": "test"
        }, {
                "name": "port",
                "value": 25
        }, {
                "name": "username",
                "value": "test"
        }, {
                "name": "password",
                "value": "test"
        }]
    }
```

The notification tries to connect to the SMTP server defined in the primary connection. If this connection fails, the notification tries to connect to the SMTP server defined in the secondary connection.

Modify SMTP connection

```
curl -X POST \
 'https://${TSA_HOSTNAME}/cam/composer/api/v1/smtpconnections/patchConnectionParametersById?
ace_orgGuid=all&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
  -H "Authorization: Bearer ${TSA_BEARER_TOKEN}"\
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d '{
        "id":"{{SMTPCONNECTION_ID}}",
        "connection_parameters":[
           {"name":"port","value": 587},
           {"name":"password","value":"my-new-password"}
         ]
      }'
```

Where **TSA_TENANT_ID** cannot be null.

POST method

The **patchConnectionParameterById** is used to update some of the parameters in the existing SMTP Connection record. Both **patchConnectionParameterById** and **connection_parameters** are mandatory. **TSA_TENANT_ID** cannot be null.

Test SMTP connection

Run this API to test SMTP connection parameters before you create or save a connection.

```
curl -X POST \
  'https://${TSA_HOSTNAME}/cam/composer/api/v1/smtpconnections/testEmail?ace_orgGuid=all&tenantId=${TSA_TENANT_ID}' \
  -H 'Authorization: Bearer {{TSA_BEARER_TOKEN}}' \
  -H 'Content-Type: application/json' \
  -H 'cache-control: no-cache' \
  -d '{
    "to":"{{SEND-TEST-EMAIL-TO}}",
    "conn_params":[
        {"name":"hostname","value":"{{SMTP_HOST}}"},
        {"name":"port","value": "{{SMTP_PORT}}" },
        {"name":"username","value":"{{USERNAME}}"},
        {"name":"password","value":"{{PASSWORD}}"}
    ]
}'
```

Where **TSA_TENANT_ID** cannot be null.

POST method

The **/testEmailByID** is similar to **/testEmail** but it uses persisted parameters from a particular record. Optionally, you can send **conn_params** argument whenever you want to use some parameters with changed values.

POST method

```
curl -X POST \
    'https://${TSA_HOSTNAME}/cam/composer/api/v1/smtpconnections/testEmailById?
ace_orgGuid=all&cloudOE_spaceGuid=${NAMESPACE}&tenantId=${TSA_TENANT_ID}' \
    -H "Authorization: Bearer ${TSA_BEARER_TOKEN}"\
    -H 'Content-Type: application/json' \
    -H 'cache-control: no-cache' \
    -d '{
        "id":"{{SMTPCONNECTION_ID}}",
        "to":"my-test-email@test.xyz.net",
        "conn_params":[
           {"name":"port","value": 587},
           {"name":"password","value":"my-new-password"}
      ]
     }'
```

Where,

- The `conn_params` is optional argument. It can contain subset of parameters that you edit in the user interface. The rest of the parameters are taken from SMTPConnection for the id.
- The `id` and `to` values are mandatory arguments.
- `TSA_TENANT_ID` cannot be null.

Get list of all SMTP connections

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}"\
 "https://${TSA_HOSTNAME}/cam/composer/api/v1/smtpconnections?tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}
```

GET method

Get list of SMTP connections by ID

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/composer/api/v1/smtpconnections/<connection-id>?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}
```

GET method

Delete SMTP connection

```
curl -k -X DELETE \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}"\
 "https://${TSA_HOSTNAME}/cam/composer/api/v1/smtpconnections/<connection-id>?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}
```

DELETE Method

Usage specific APIs

As a cluster administrator, you can run the usage specific APIs.

- Retrieve the current number of deployed virtual machines
- Retrieve the maximum number of virtual machines for each month
- Download the managed virtual machines report

You must be a cluster administrator to run these APIs. Otherwise, an unauthorized error message is displayed.

Retrieve the current number of deployed virtual machines

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/managedvirtualmachines/countActive?tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Retrieve the maximum number of virtual machines for each month

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/managedvirtualmachines/highwatermark?
tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Download the managed virtual machines report

```
curl -k -X GET \
-H "Authorization: Bearer ${TSA_BEARER_TOKEN}" \
"https://${TSA_HOSTNAME}/cam/api/v1/managedvirtualmachines/download?tenantId=${TSA_TENANT_ID}&ace_orgGuid=${MCM_TEAM}"
```

Example to retrieve the list of deployed templates

Example API flow to retrieve the list of deployed templates.

A series of API calls to get the list of deployed templates:

```
curl -k -X POST \
-H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" \
-d "grant_type=password&username=${TSA_USER}&password=${TSA_USER_PASSWORD}&scope=openid"\
https://${MCM_CLUSTER_HOSTNAME}/idprovider/v1/auth/identitytoken
```

Example:

```
curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" -d
"grant_type=password&username=admin&password=admin&scope=openid"
https://<MCM_CLUSTER_HOSTNAME>/idprovider/v1/auth/identitytoken
```

Response:

```
{
"access_token":"gvWTQGcb9DzZZb5Oj6GYRJm0OOUBYTCxgjJUlI0dDURsw6p2uWdG3jDCe8S8UCqLVSoU3wwr9toWKGtISkcMrttBBGzET8hDHbLd3DXUlP

print("order", order)
```

Managed services Content APIs

The Managed services Content APIs manage cookbooks and roles in the pattern manager.

The Managed services Content APIs are used to list, update, and delete content on the pattern manager. The pattern manager interacts with the Chef server and software repository to manage cookbooks, recipes, and roles in your Content Runtime environment. When deploying a content runtime, you can install a new Chef server or bring your own; the pattern manager will interact with either. Managed services has a set of middleware cookbooks that can be loaded automatically when deploying the Content Runtime environment or can be loaded manually after the Content Runtime has been created. Load cookbooks, recipes, and roles from IBM, from your own repositories, or from Chef Supermarket.

Access to these APIs is granted with either the access token or the admin token. The access and admin tokens were specified when deploying the Content Runtime. Any API that accepts the access token also accepts the admin token. When using these APIs, the access or admin token must be specified with an authorization HTTP header. For example,

```
# curl -H "Authorization: Bearer $ACCESS_TOKEN" https://pattern_manager:5443/v1/info/chef
```

Upload cookbooks and roles

Uploads cookbooks from a git repository, chef supermarket, or local repository to the pattern manager.

```
POST /v1/upload/chef
```

Description

Uploads cookbooks from a git repository, Chef supermarket, or local repository to the pattern manager. Valid sources are the chef supermarket, github.com, gitlab.com, and local repository on the pattern manager file system. To ensure the latest updates are available on your pattern manager, call this API every time there is an update to the cookbooks and roles in your repository.

The pattern manager access token is required to perform this request.

Directory Structure

For cookbooks that are loaded from a git or local repository, it is assumed that they are in a folder named cookbooks. This cookbooks folder can either be at the root directory of your repository or in a folder named Chef that is at the root directory of your repository. Similarly, it is assumed that roles are in a folder named roles, which is either at the root directory of your repository or in a folder named chef within the root directory of your repository.

Directory Structure Example

The following code block depicts an example directory structure:

```
.
|-- github.ibm.com
    |-- example_org
        |-- example_repository
            |-- chef
                |-- cookbooks
                    |-- README.md
                    |-- attributes.json
                    |-- components.json
                    |-- cookbook_metadata.json
                    |-- metadata.rb
                    |-- recipes.json
                |-- roles
                    |-- create_user.json
                    |-- database_v10_install.json
                    |-- database_v15_install.json
```

Parameters

The following table lists the parameters that are used to upload cookbooks and roles to the pattern manager:

Type	Name	Description	Schema	Default	Required
Body	authorization	JSON object containing a personal_access_token property	JSON object		Yes for git repository
Body	cookbook_name	Name of the cookbook to load when uploading from the chef supermarket. Only valid when setting source_repos to chef_supermarket	String		Yes, when using chef supermarket
Body	cookbook_version	Version of the cookbook to load when uploading from the chef supermarket. Only valid when setting source_repos to chef_supermarket	String		No
Body	deps	JSON array of dependencies required for the cookbook being installed from the chef supermarket. Each item must contain the cookbook_name and an optional cookbook_version parameter. Only valid when setting source_repos to chef_supermarket	JSON array		No
Body	personal_access_token	GitHub personal access token	String		Yes for git repository
Body	cookbooks	States whether cookbooks should be uploaded	Boolean	True	No
Body	org	Organization where your repositories reside. For GitLab, this is your group name	String		Yes for git repository
Body	branch	GitHub branch for your repositories	String	master	No
Body	repos	For git or local repositories, the regular expression to filter repositories (GitHub) or projects (GitLab) where you want to search for cookbooks and roles	String	.*	No
Body	repos_hostname	The hostname or IP address of your git repository if it does not match the value in source_repos	String	Value of source_repos	No
Body	repos_protocol	The protocol (http or https) used by your git repository	String	https	No
Body	roles	States whether roles should be uploaded	Boolean	False when source_repos is set to chef_supermarket, True otherwise	No
Body	source_repos	Hostname of the git repository. Valid options include chef_supermarket, github.com, gitlab.com, or a path to your local repository in file URI scheme.	String		Yes

Example

The following example shows the request that would be used to import all cookbooks and roles from the preceding example directory structure.

```
POST /v1/upload/chef

Header: Authorization = Bearer $ACCESS_TOKEN

{
  "authorization": {
    "personal_access_token": "38eab5732f7411bedb976afcc90a25432d798bda"
  },
  "cookbooks": "True",
  "source_repos": "github.com",
```

```
  "org": "example_org",
  "repos": "example_.*",
  "roles": "True"
}
```

This example shows a request to import from a GitLab repository that is hosted somewhere other than the gitlab.com. The value specified for org is the GitLab group name and the repos regular expression will filter projects belonging to that group.

```
POST /v1/upload/chef

Header: Authorization = Bearer $ACCESS_TOKEN

{
  "authorization": {
    "personal_access_token": "7411bedb9738eab5732f6afc32d798bdac90a254"
  },
  "cookbooks": "True",
  "source_repos": "gitlab.com",
  "org": "production_group",
  "repos": "cookbooks_.*",
  "roles": "True",
  "repos_hostname": "gitlab-pc.ibm.com",
  "protocol": "http"
}
```

This example shows a request to import the Java cookbook from the chef supermarket. The Java cookbook is dependent on the four other cookbooks listed in the **deps** parameter. If a cookbook in the **dep** array already exists on the Chef server and the **overwrite_existing** parameter is set to true, then it gets overwritten.

```
POST /v1/upload/chef

Header: Authorization = Bearer $ACCESS_TOKEN

{
  "cookbook_name": "java",
  "cookbook_version": "1.50.0",
  "source_repos": "chef_supermarket",
  "deps": [
    {
      "cookbook_name": "apt",
      "cookbook_version": "6.1.4"
    },
    {
      "cookbook_name": "homebrew",
      "overwrite_existing": "true"
    },
    {
      "cookbook_name": "windows"
    },
    {
      "cookbook_name": "ohai"
    }
  ]
}
```

This example shows a request to import cookbooks and roles from the pattern manager local filesystem.

```
POST /v1/upload/chef

Header: Authorization = Bearer $ACCESS_TOKEN

{
  "cookbooks": "True",
  "roles": "True",
  "source_repos": "file:///var/local_repo"
}
```

Responses

The following table lists responses that are returned for a request to upload cookbooks and roles to the pattern manager:

HTTP Code	Description	Schema
200	OK	No content
400	Bad Request	
403	The requester has not specified the correct access token in the Authorization HTTP header	
500	Internal server error	

List cookbooks and roles

List the cookbooks and roles that have been uploaded to the pattern manager

```
GET /v1/info/chef
```

Description

Return a list of all cookbooks and roles that have been uploaded to the pattern manager

Responses

The following table lists API responses:

HTTP Code	Description	Schema
200	Returns the list of cookbooks and roles that reside on the pattern manager.	See example
403	The requester has not specified the correct access token in the Authorization HTTP header.	
500	An internal error occurred while processing the request.	

Example

The following block is an example of a successful request:

```
Header: Authorization = Bearer $ACCESS_TOKEN

{
  "cookbooks": [
    "db2                0.1.36",
    "httpd              1.1.27",
    "ibm_cloud_utils    0.1.29"
  ],
  "recipes": [
    "db2",
    "db2::cleanup",
    "db2::create_db",
    "db2::fixpack",
    "db2::gather_evidence",
    "db2::harden",
    "db2::install",
    "db2::license",
    "db2::prereq",
    "db2::prereq_check",
    "httpd",
    "httpd::cleanup",
    "httpd::config_httpd_conf",
    "httpd::config_ssl",
    "httpd::config_vhosts",
    "httpd::gather_evidence",
    "httpd::install",
    "httpd::prereq",
    "httpd::service",
    "ibm_cloud_utils",
    "ibm_cloud_utils::gather_evidence",
    "ibm_cloud_utils::install",
    "ibm_cloud_utils::prereq"
  ],
  "roles": [
    "db2_create_db",
    "db2_v105_install",
    "db2_v111_install",
    "httpd24-base-install",
    "httpd24-ssl-vhosts"
  ]
}
```

Clear cookbooks and roles

Clears cookbooks and roles from the pattern manager.

```
POST /v1/clear_env/chef
```

Description

Deletes cookbooks and roles from the pattern manager. You can specify to delete cookbooks, roles, or both. By default all cookbooks and roles are deleted.

This API requires the pattern manager admin token.

Parameters

The following table lists the parameters that are used to clear cookbooks and roles from the pattern manager:

Type	Name	Description	Schema	Default	Required
Body	cookbooks	States whether cookbooks should be deleted	Boolean	True	No

Type	Name	Description	Schema	Default	Required
Body	pattern	Delete cookbooks and roles that match this pattern	String	•	No
Body	roles	States whether roles should be deleted	Boolean	True	No

Example Request

```
POST /v1/clear_env/chef

Header: Authorization = Bearer $ADMIN_TOKEN

{
  "cookbooks": "true",
  "roles": "true",
  "pattern": "db2.*"
}
```

Responses

The table lists responses that are returned for a request to clear cookbooks and roles from the pattern manager:

HTTP Code	Description	Schema
200	OK	No content
400	Bad Request	
403	The requester has not specified the correct access token in the Authorization HTTP header	
500	Internal server error	

Get service logs

Return the pattern manager service logs

```
GET /v1/admin/log
```

Description

Return the pattern manager service logs in one of three formats. The format returned is based on the value of the Accept HTTP header, with application/json being the default response format.

This request requires the pattern manager admin token. The following table lists the accept HTP header options:

Accept Header Value	Description
application/json	Filtered service log entries in JSON format
application/gzip	All service logs in a tar.gz file
application/zip	All service logs in a zip file
text/plain	The latest service log file

Parameters

These parameters are only valid when requesting a response in JSON format. If no parameters are specified, then the last 5000 entries in the service log file will be returned.

The following table lists the parameters that are used to filter service log entries returned in JSON response:

Table 2.

Type	Name	Description	Schema	Default	Required
Body	contains	Returns all log entries that contain the specified value	String		No
Body	end_dts	Date timestamp to end log entries collections. Accepted formats include YYYY-mm-dd HH:MM:SS,fff, YYYY-mm-dd HH:MM:SS, and YYYY-mm-dd	String		No
Body	levels	List of logging levels to include: CRITICAL, ERROR, WARNING, INFO, and DEBUG	Array		No
Body	request_id	Returns entries associated with a specific request ID. Can be used to narrow logs down to a single request train	String		No
Body	remote	List of properties to remove from the JSON response including body, dts, level and request_id	Array		No
Body	start_dts	Date timestamp to start log entries collections. Accepted formats include YYYY-mm-dd HH:MM:SS,fff, YYYY-mm-dd HH:MM:SS, and YYYY-mm-dd	String		No

Example Request

```
Header: Authorization = Bearer $ADMIN_TOKEN

{
    "contains": "/v1/info/chef",
    "levels": ["DEBUG"],
    "start_dts": "2017-08-03 14:50:10"
}
```

Responses

The following table lists the API responses:

HTTP Code	Description	Schema
200	Returns the requested pattern manager service log entries	
403	The requester has not specified the correct admin token in the Authorization HTTP header.	
500	An internal error occurred while processing the request.	

Example Response

The following block is an example of a successful response in JSON format.

```
{
  log: [
    {
      body: "API response: Status = 200. Data log suppressed******* '/v1/info/chef GET ",

- Infrastructure Automation

Operator cluster service versions (CSVs)

For more information about the operator cluster service versions (CSVs) which are installed with IBM Cloud Pak for AIOps, see the following information.

You can use the following command to get the list of CSVs that are present in a Red Hat OpenShift Container Platform cluster.

```
oc get csv
```

The following table lists the CSVs, which are installed with IBM Cloud Pak for AIOps and present in a Red Hat OpenShift Container Platform cluster.

Important: Versions are correct at time of release, but newer patch versions may have been released subsequently.

Table 1. Operators

NAME	DISPLAY	VERSION
aimanager-operator.v4.6.0	IBM AIOps AI Manager	4.6.0
aiopsedge-operator.v4.6.0	IBM AIOps Edge	4.6.0
asm-operator.v4.6.0	IBM Netcool Agile Service Manager	4.6.0
cloud-native-postgresql.v1.18.12	EDB Postgres for Kubernetes	1.18.12
ibm-aiops-ir-ai.v4.6.0	IBM Watson AIOps Issue Resolution AI & Analytics	4.6.0
ibm-aiops-ir-core.v4.6.0	IBM Watson AIOps Issue Resolution Core	4.6.0
ibm-aiops-ir-lifecycle.v4.6.0	IBM Cloud Pak for Watson AIOps Lifecycle	4.6.0
ibm-aiops-orchestrator.v4.6.0	IBM Cloud Pak for AIOps	4.6.0
ibm-automation-elastic.v1.3.16	IBM Elastic	1.3.16
ibm-automation-flink.v1.3.16	IBM Automation Foundation Flink	1.3.16
ibm-cert-manager-operator.v4.2.4	IBM Cert Manager	4.2.4

NAME	DISPLAY	VERSION
ibm-common-service-operator.v4.6.2	IBM Cloud Pak foundational services	4.6.2
ibm-commonui-operator.v4.4.1	Ibm Common UI	4.4.1
ibm-events-operator.v5.0.1	IBM Events Operator	5.0.1
ibm-iam-operator.v4.5.1	IBM IM Operator	4.5.1
ibm-redis-cp.v1.1.9	ibm-redis-cp-operator	1.1.9
ibm-secure-tunnel-operator.v4.6.0	IBM Secure Tunnel	4.6.0
ibm-watson-aiops-ui-operator.v4.6.0	IBM AIOps UI	4.6.0
ibm-zen-operator.v5.1.4	IBM Zen Service	5.1.4
operand-deployment-lifecycle-manager.v4.3.1	Operand Deployment Lifecycle Manager	4.3.1

You can use the following command to get the subscriptions in a Red Hat OpenShift Container Platform cluster.

```
oc get sub
```

Permissions (IBM Cloud Pak for AIOps)

The following content shows the permissions and cluster permissions that are required by the IBM Cloud Pak for AIOps operators.

Alert and Event schemas

See the following tables to understand Cloud Pak for AIOps alert and event properties.

Cloud Pak for AIOps Alert schema

An alert is a mutable record of something that has happened over a certain period of time. It indicates an anomalous condition.

Cloud Pak for AIOps alert property	Description	Example
id	A system-generated unique id for the alert.	1a2a6787-59ad-4acd-bd0d-46c1ddfd8e06
state	The current state of this alert.	Open
eventCount	The count of events that have contributed to this alert.	2
acknowledged	Flag indicating alert acknowledgement.	false
team	Team with responsibility for the alert.	Db2 admin group
owner	Individual with responsibility for the alert.	user123
deduplicationKey	The key that uniquely identifies the anomalous condition that this alert represents.	{hostname=users-db.myapp.example.com, name=users-db.myapp.example.com, service=users-db.myapp.example.com, type=Service}-High query timeout count:++:Database query timeout-
signature	An id which uniquely identifies an anomalous condition on a resource. This may be used to identify historic alerts which refer to the same condition on the same resource.	{hostname=users-db.myapp.example.com, name=users-db.myapp.example.com, service=users-db.myapp.example.com, type=Service}-High query timeout count:++:Database query timeout-
firstOccurrenceTime	The time at which the anomalous condition was first detected, in millisecond granularity. Format: yyyy-mm-ddThh:mm:ss.sssZ (ISO8601)	2022-06-14 3:14:10.862
lastOccurrenceTime	The time at which the anomalous condition was last detected, in millisecond granularity. Format: yyyy-mm-ddThh:mm:ss.sssZ (ISO8601)	2022-06-14 3:14:10.862
lastStateChangeTime	The time in millisecond granularity for which the alert was last updated.	2022-06-14 3:14:10.862
summary	A human-readable description of the event.	Fan failure detected on server1.example.com.
langId	ISO 639-3 encoding if not specifed assumption is eng.	eng
severity	Indicates the alert severity level, which indicates how the perceived capability of the managed object has been affected.	5 - Major

Cloud Pak for AIOps alert property	Description	Example
sender	Identifies the resource which sent this alert. This may be the resource that is the subject of the event, or it may be some external system which is monitoring the subject.	{"service":"DemoMon","name":"hyper.example.com","type":"Netcool/OMNIbus"}
resource	Identifies the resource that is the subject of this alert. This is made up of multiple fields that describe the resource. There are a set of standard fields which should be used where applicable, but additional fields may be set. **Tip:** If (when querying the topology service APIs for resource data) the optional parameter `_include_status_severity` is set to `true`, the `_hasStatus` field will reflect the maximum and most severe severity of all of the status records related to the resource, for example `"_hasStatus": "critical"`.	{"service":"hyper.example.com","name":"hyper.example.com","hostname":"hyper.example.com","type":"Service"}
expirySeconds	The number of seconds before the event should automatically expire. A value of zero indicates that there is no expiration.	0
links	An optional array of links to external systems which provide addition information or control over the event, or its subject. This may include a management console for the subject resource, or a page containing further event information from the source monitoring system. Each link should be in the form of a fully qualified URL.	[{"url":"`https://fan-controller.example.com/?fanId=1234`","linkType":"webpage","name":"management-console","description":"Fan controller management console"}]
details	Additional properties that describe the alert. **Note:** You can include custom fields in the `details` object. Their values must be of type string.	{"additionalProp1":"string","additionalProp2":"string","additionalProp3":"string"}
insights	An array of insights associated with the alert with one or more other entities or groupings.	insights.topology, insights.runbook, insights.scopeGroup
relatedIncidentIds	The set of incident id's that this alert is a member of either as a trigger or related context.	["related-incident-2","related-incident-1","related-incident-3"]

Cloud Pak for AIOps Event schema

An event is an immutable record of something happening at a certain time point. It may or may not indicate an anomalous condition.

Cloud Pak for AIOps event property	Description	Example
id	A system-generated unique id for the event.	1a2a6787-59ad-4acd-bd0d-46c1ddfd8e06
occurrenceTime	The time at which this event occurred.	6/15/2022, 3:14:10 PM
summary	A human-readable description of the event.	Fan failure detected on server1.example.com.
severity	Indicates the event severity level, which indicates how the perceived capability of the managed object has been affected.	5 - Major
sender	Identifies the resource which sent this event. This may be the resource that is the subject of the event, or it may be some external system which is monitoring the subject.	{"service":"DemoMon","name":"hyper.example.com","type":"Netcool/OMNIbus"}

Cloud Pak for AIOps event property	Description	Example
resource	Identifies the resource that is the subject of this event. This is made up of multiple fields that describe the resource. There are a set of standard fields which should be used where applicable, but additional fields may be set. **Tip:** If (when querying the topology service APIs for resource data) the optional parameter `_include_status_severity` is set to `true`, the `_hasStatus` field will reflect the maximum and most severe severity of all of the status records related to the resource, for example `"_hasStatus": "critical"`.	{"service":"hyper.example.com","name":"hyper.example.com","hostname":"hyper.example.com", "type":"Service"} . For additional fields in property, see Resource property.
expirySeconds	The number of seconds before the event should automatically expire. A value of zero indicates that there is no expiration.	0
links	An optional array of links to external systems which provide addition information or control over the event, or its subject. This may include a management console for the subject resource, or a page containing further event information from the source monitoring system. Each link should be in the form of a fully qualified URL.	[{"url":"`https://fan-controller.example.com/?fanId=1234`","linkType":"webpage","name":"management-console", "description":"Fan controller management console"}] . For additional fields in property, see Links property.
details	Additional properties that describe the event. **Note:** You can include custom fields in the `details` object. Their values must be of type string.	{"additionalProp1":"string","additionalProp2":"string", "additionalProp3":"string" }
insights	An array of insights associated with the event with one or more other entities or groupings.	insights.topology, insights.runbook, insights.scopeGroup. . For additional fields in property, see Insights property.
type	Values in an object that indicate the type of an event, such as a problem event or a resolution event, and the classification of an event.	{ "classification":":++:CEASelfMonitoring", "eventType":"problem"}. For additional fields in property, see EventType properties.

Alerts and Events schema fields

On this page, find fields that can be included in an Event or Alert schema in IBM Cloud Pak for AIOps for these properties:

- EventType
- Insights
- Links
- Resource

Note: format type used is Open API v3 definition.

EventType property schema

```
EventType:
      description: >
        The classification of the event, i.e. a description of what happened.
      type: object
      properties:
        eventType:
          description: >
            String description of whether the event is a problem
            or resolution event.
          type: string
          enum:
            - problem
            - resolution
          default: problem
        classification:
          description: >
            Description of the type of the event. E.g. Utilization, System
            status, Threshold breach
          type: string
          example: Utilization
```

```
        condition:
          description: >
            The condition/status or threshold causing the event. E.g. Down, 95%,
            Unavailable
          type: string
          example: "> 30 seconds"
```

Insights property schema

```
Insight:
      description: >
        Represents an insight reference to one or more other entities provided
        by a specified source that is related to associated element.
      type: object
      properties:
        id:
          description: >
            The unique identifier for this specific relationship, used to
            identify other related entities. Entities with the same insight
            id will participate in the same insight (i.e. this may act as a
            correlation key).
          type: string
          example: 98aa5f81-7da7-4063-bd66-dccaf59097d1
        type:
          description: The type of insight being described
          type: string
          example: ibm.com/causal-alert-relationship
        source:
          description: The source of the insight information
          type: string
          example: ibm.com/causal-correlation/temporal
        details:
          description: >
            Additional details about this insight. The schema of this object
            depends on the insight type.
          type: object
          $ref: "#/components/schemas/InsightDetails"

    AssociatedChange:
      type: object
      properties:
        link:
          type: string
          description: The URL to the associated change in source system.

    Conversation:
      type: object
      properties:
        link:
          type: string
          description: The URL to the conversation in source system.

    Grouping:
      type: object
      properties:
        policyId:
          type: string
          description: The id of the policy that creates the grouping.
        groupDetails:
          type: object
          description: >
            Details or links on group and/or to explain the reasons for the
            grouping.
    Runbook:
      type: object
      additionalProperties: false
      required:
        - policyId
        - runbookId
        - isAutomated
      properties:
        policyId:
          type: string
          description: The id of the policy that connected this insight.
        runbookId:
          type: string
          format: uuid
          description: The ID of the runbook
        runbookVersion:
          type: integer
          minimum: 1
          description: Optional. Defines whether a fixed version of a runbook should be linked. If, not specified latest
version is used.
        order:
          type: integer
          minimum: 1
          description: Optional. Order for runbook actions. Defines in which order runbooks should be executed.
        isAutomated:
          type: boolean
          description: Defines whether or not the connected Runbook will be automatically executed, once the policy
matches.
```

```
        mappings:
          type: array
          description: In order to execute a runbook all required runbook parameters need to be filled out. If the
incident wants to define the values based on the policy or on its own attributes a suitable mapping has to be created.
This is required if automatically triggered execution is desired.
          items:
            type: object
            additionalProperties: false
            properties:
              mappingType:
                type: string
                description: Choose how a parameter is mapped. 'parameter' means using a field/property from the Incident.
'fixed' means the same value will always be used. 'useDefault' will use the default from the runbook. 'runtime' leave
entry up to the operator.
                enum:
                  - parameter
                  - fixed
                  - useDefault
                  - runtime
              runbookParameterName:
                type: string
                description: The name of the runbook parameter as valued is mapped to.
              parameterValue:
                type: string
                description: The value put into the runbook for the parameter. Depending on the 'mappingType' this value
is optional (useDefault), represents the name of an incident parameter (parameter) or is the value to be put in (fixed).

    Seasonality:
      type: object
      properties:
        policyId:
          type: string
          description: >
            The id of the policy that relates to the seasonality insight.
        seasonalDetails:
          type: object
          description: >
            Details or links on seasonality and/or to explain the reasons for
            the grouping.
    SimiliarIncident:
      type: object
      properties:
        incidentid:
          type: string
          description: id of incident that it related to
        link:
          type: string
          description: The URL to the incident in source system.
        distance:
          description: this should be a double but open API does not seem to like it  :-(
          type: integer

    SimilarIncidents:
      description: >
        Represents a list of similar historical tickets, based on query
        submitted to the service. It also includes a list of recommended
        actions that are extracted from resolutions, which can be highlighted
        with help of their offset information.
      type: object
      properties:
        similar_incidents:
          description: The list of similar incients for the query.
          type: array
          items:
            $ref: "./similar_incidents.schema.yaml#/components/schemas/SimilarIncidentItem"
        recommended_actions:
          description: The list of extracted actions from resolutions in related incidents.
          type: array
          items:
            $ref: "./similar_incidents.schema.yaml#/components/schemas/RecommendedActionItem"

    AlertResolutions:
      description: Represents a list of resolution links for current alert.
      type: object
      properties:
        shortDescription:
          type: string
          description: Short description of the log anomaly alert.
        description:
          type: string
          description: Description about the current log anomaly alert.
        category:
          type: string
          description: Detected error category.
        subCategory:
          type: string
          description: Detected error sub category.
        resolutionLinks:
          type: array
          description: A list of resolution url links for current alert.
          items:
```

```
          type: object
          properties:
            url:
              type: string
              description: URL link for the resolution.
            title:
              type: string
              description: Title for the resolution.
            content:
              type: string
              description: Content excerpt for the resolution.

    AssociatedAlertTemplates:
      description: >
        Represents the error template info for explainable purpose.
      type: object
      properties:
        error_template_list:
          type: array
          items:
            type: string
          description: A list of error template
        error_count_vector:
          type: array
          items:
            type: integer
          description: Count vector corresponding to error template list.
        significant_message_code:
          type: string
          description: Message code for the significant error template.
        type_window:
          type: string
          description: Indicates the window type, e.g., "liberty_twas"

    TopologicalGroup:
      description: >
        Signifies that one of the resources that this entity pertains to is a member
        of a resource group. The id of the insight is the id of the resource group
        within the topology store.
      type: object
      properties:
        name:
          type: string
          description: Human readable name of the resource group
        tags:
          description: A list of any tags assigned to the resource group
          type: array
          items:
            type: string
        entityTypes:
          description: >
            An array of group types that pertain to this group, ex. AiopsApplication which
            signifies this resource group represents an application.
          type: array
          items:
            type: string

    TopologicalResource:
      description: >
        Signifies that this entity pertains to a specific resource within the topology.
        The id of this insight will be set to the unique id of the resource within the topology.
      type: object
      properties:
        name:
          type: string
          description: Human readable name of the resource
        compositeOfIds:
          type: string
          description: >
            If this resource is a composite resource, contains a comma
            separated list of id's of composed resources.
        compositeId:
          type: string
          description: id of the compositeId

    ProbableCauseRanking:
      type: object
      description: the ranking of alerts in the group
      properties:
        id:
          type: string
          description: in the alert it is the correlationId or the eventId if in the incident
        rank:
          type: integer
          description: the rank of the alert

    IncidentTopology:
      type: object
      description: >
        details of the group id where incident topology is stored.  The incident topology is
        generated by probable cause component
```

```
      properties:
        id:
          type: string
          description: asm group id
        time:
          type: integer
          description: time in ms when the last resource in the asm group was added

    Union:
      type: object
      description: >
        Represents a union of insights of a particular type across entities. The
        union is uniquely identified by the id field of the insight.
      properties:
        subsumedUnions:
          type: array
          description: >
            An array of ids of previous union insights which were subsumed by
            this one, due to a new entity occurring that joined them.
          items:
            type: string
            description: The id of a subsumed union insight

    ProposedIncident:
      type: object
      description: >
        Represent a suggested incident to create for this alert.
      properties:
        policyId:
          type: string
          description: The id of the policy that proposes this incident.
        delay:
          type: integer
          description: Suggested hold-off delay in seconds before creating the incident.

    ChatOpsIntegrators:
      type: object
      description: >
        An array of configured integrators for a given incident to hold integrator specific details.
      properties:
        id:
          type: string
          description: Unique id for this integrator
        channel_name:
          type: string
          description: Chatops channel name
        name:
          type: string
          description: kind of chat ops i.e. slack, teams etc
        app_state:
          type: string
          description: Custom state field
        permalink:
          type: string
          description: Permalink for Integrators

    ITSMIntegrators:
      type: object
      description: >
        An array of configured ITSMs for a given incident to hold integrator specific details.
      properties:
        id:
          type: string
          description: Unique id for this platform
        ticket_num:
          type: string
          description: Ticket number associated with the ITSM system
        name:
          type: string
          description: kind of ITSM i.e. ServiceNow, etc
        app_state:
          type: string
          description: Custom state field
        permalink:
          type: string
          description: Permalink for ITSM platform
        type:
          type: string
          description: type of ITSM Integrators

    ActionHistory:
      description: >
        Represents the actions this entity has passed through.
      type: object
      properties:
        policyId:
          type: string
          description: The id of the policy that triggered the action
        actionId:
          type: string
          description: The id of the action the entity has passed through

Links property schema

```
Link:
      description: >
        Represents a link to an external system which has further information
        or control over an event.
      type: object
      properties:
        linkType:
          description: >
            Describes what type of link this is, giving a hint as to what may
            consume it.
          type: string
          example: webpage
        name:
          description: >
            An identifier for this link that can be referred to programmatically
          type: string
          example: management-console
        description:
          description: Descriptive text which defines what the link leads to
          type: string
          example: Fan controller management console
        url:
          description: >
            A fully qualified URL that can be used to locate the target of the
            link
          type: string
          example: https://fan-controller.example.com/?fanId=1234
```

Resource property schema

```
Resource:
      description: >
        Identifies a resource within the environment. This is made up of
        multiple fields that describe the resource. There are a set of standard
        fields which should be used where applicable, but additional fields may
        be set.
      type: object
      additionalProperties:
        description: Additional event-specific resource locators
        $ref: '#/components/schemas/StringOrInteger'
      properties:
        type:
          description: The type of resource
          type: string
          example: host
        name:
          description: The name of the resource
          type: string
          example: myhost.example.com
        sourceId:
          type: string
          description: The id the resource is known by in the source system
        hostname:
          description: The hostname of the resource
          type: string
          example: myhost.example.com
        ipAddress:
          description: The IP address of the resource
          type: string
          example: 9.123.123.1
        service:
          description: The name of the service that the resource is serving
          type: string
          example: mobile-app
        port:
          description: The port that is the subject of this event
          $ref: '#/components/schemas/StringOrInteger'
          example: "80"
```

```
      interface:
        description: The interface that is the subject of this event
        type: string
        example: eth0
      application:
        type: string
        description: The application that is the subject of this event
      controller:
        type: string
        description: The controller that is the subject of this event
      component:
        type: string
        description: The component that is the subject of this event
      cluster:
        type: string
        description: The cluster that is the subject of this event
      location:
        description: The location of the resource
        type: string
        example: Dallas 10
      accessScope:
        type: string
        description: The project or namespace the resource is part of
        example: default
      connectionId:
        type: string
        description: >-
          Configuration unique identifier of the integration this event
          came from.
        example: 'f5aa7fa9-92eb-4bec-942c-37eb3e3e9601'
```

Resource schemas

For more information about IBM Cloud Pak® for AIOps resource properties, see the following table.

Table. Resource schemas

Cloud Pak for AIOps resource property	Description	Type	Example
type	The type of the resource	string	host
name	The name of the resource	string	myhost.example.com
sourceId	The ID that the resource is known by in the source system	string	`7045b61d-e59c-4270-b525-545d55ecd06e`
hostname	The hostname of the resource	string	myhost.example.com
ipAddress	The IP address of the resource	string	9.123.123.1
service	The name of the service that the resource is serving	string	mobile-app
port	The port that is the subject of this event	string or integer	`ssh` or `22`
interface	The interface that is the subject of this event	string	eth0
application	The application that is the subject of this event	string	mobile-app-1
controller	The controller that is the subject of this event	string	controller1
component	The component that is the subject of this event	string	database
cluster	The cluster that is the subject of this event	string	staging-cluster
location	The location of the resource	string	Dallas 10
accessScope	The project or namespace that the resource is part of	string	default
connectionId	The unique identifier of the integration that this event came from	string	`f5aa7fa9-92eb-4bec-942c-37eb3e3e9601`
scopeId	The scope identifier value for this event from the originating system	string	myhost.example.com:location01

You can also define more resource properties for resources that are not included in the table. Added properties with valid JSON are stored and available, but special knowledge or handling of them is not included.

EventType schemas

EventType schemas indicate whether an event is a problem or a resolution and how it is classified. For more information about IBM Cloud Pak® for AIOps EventType properties, see the following table.

Cloud Pak for AIOps resource property	Description	Type	Example
eventType	Describes whether the event is a problem or resolution event. The only possible values that can be set are `problem` or `resolution`.	string	`problem`, `resolution`
classification	Describes the type of the event. This property is used to determine the golden signals for an alert.	string	`system status`, `threshold breach`, `utilization`

Cloud Pak for AIOps resource property	Description	Type	Example
condition	Provides context to the type of the event and states the condition, status, or threshold that caused the event.	string	`> 30 seconds`, `95%`, `Down`, `Unavailable`

Normalized Mapping Rules

To help you map event data from incoming data sources review the following event schemas and samples.

- Kafka integration normalized event schema
  - Normalized PagerDuty events sample
  - Normalized IBM Netcool Operations Insight events sample
- PagerDuty normalized mapping rules
  - Sample PagerDuty event
- IBM Netcool Operations Insight normalized mapping rules
  - Sample IBM Netcool Operations Insight event

IBM Netcool Operations Insight normalized mapping rules

Note: Rules take precedence, that is the mapped value is taken from the highest rules that fulfils the condition.

Table. IBM Netcool Operations Insight normalized mapping rules

Resultant Normalized Alert			Mapping rules
{			
	"sender": {		
		"service": "Ping Probe",	{{**Agent**}}
		"name": "Ping Probe",	{{**Manager**}}
		"type": "Netcool/OMNIbus"	"Netcool/OMNIbus"
	},		
	"resource": {		
		"name": "RNIB-MPLS-FTTC013",	Rule 1: Take {{**Node**}} if it is not empty
			Rule 2: Take {{**NodeAlias**}} if it is not empty
			Rule 3: Rule 3: Otherwise "unknown"
		"hostname": "RNIB-MPLS-FTTC013",	Rule 1: {{**Node**}} if not empty and is valid hostname
			Rule 2: {{**NodeAlias**}} if not empty and is valid hostname
		"type": "host",	Rule 1: "host" if either {{**Node**}} or {{**NodeAlias**}} is not empty,
			Rule 2: Otherwise, "unknown".
		"ipaddress"10.44.113.88",	Rule 1: {{**Node**}} if not empty and is valid IPv4
			Rule 2: {{**NodeAlias**}} if not empty and is valid IPv4
			Rule 3: Otherwise, empty
		"location": "Paper St"	{{**Location**}}
	},		
	"type": {		

Resultant Normalized Alert			Mapping rules
		"classification": "probeping-icmptimeout:++:Ping Status",	{{**EventId**}} ":++:" {{**AlertGroup**}}
		"eventType": "problem"	Rule 1: "resolution" if {{**Severity**}} is 0.
			Rule 2: "resolution" if {{**Type**}} is one of {2,4}
			Rule 3: Otherwise, "problem"
	},		
	"severity": 3,		Rule 1: {{**Severity**}} + 1 if {{**Severity**}} falls within 2 to 5.
			Rule 2: 1 if {{**Severity**}} is 1
			Rule 3: 2 if {{**Severity**}} is > 0
	"summary": "RNIB-MPLS-FTTC013 is not reachable",		{{**Summary**}}
	"occurrenceTime": "2021-02-23T09:56:46.000Z",		Output format: yyyy-mm-ddThh:mm:ss.SSSZ
			Rule 1: If {{**NetcoolEventAction**}} is "INSERT", then {{**FirstOccurrence**}} - yyyy-mm-ddThh:mm:ss {{**FirstOccurrenceUSec**}} - if available then .SSSZ, otherwise .000Z
			Rule 2: If {{**NetcoolEventAction**}} is "UPDATE", then {{**LastOccurrence**}} - yyyy-mm-ddThh:mm:ss {{**LastOccurrenceUSec**}} - if available then .SSSZ, otherwise .000Z
			Note: {{**FirstOccurrence**}} and {{**LastOccurrence**}} can be in Unix epoch or datetime string.
	"expirySeconds": 0		Rule 1: Take {{**ExpireTime**}} if the field exists.
			Rule 2: Otherwise, 0.
}

Installation parameters

The following table lists the Managed services installation parameters and their default values. These parameters are in the **spec** section of the **ibm-management-cam-install** operator.

Notes:

- The storage class **rook-ceph-cephfs-internal** is specified as an example in this documentation, use the storage class configured in your environment.
- The global resource parameters are used while creating the following containers:

cam-controller-manager, **cam-iaas**, **cam-portal-ui**, **cam-provider-ansible**, **cam-provider-bpm**, **cam-provider-helm**, **cam-provider-terraform-api**, **cam-provider-terraform-runtime**, **cam-proxy**, **cam-service-composer-api**, **cam-service-composer-ui**, **cam-tenant-api**, **cam-ui-basic**.

Table 1. Managed services parameters

Parameter	Description	Default
Authentication		
oauthClientSecret	Name of the OAuth client secret	cam-oauth-client-secret
authIdpCredentialsSecret	Name of the secret with the auth IDP credentials	ibm-iam-bindinfo-platform-auth-idp-credentials
Architecture		
arch	Select the value based on the architecture. Linux = amd64 Linux on Power (ppc64le) = ppc64le Linux on IBM Z and LinuxONE = s390x	amd64
Audit service		
auditService.config.journalPath	The journal path	/run/systemd/journal
auditService.image.pullPolicy	Pull policy for the audit image	IfNotPresent
auditService.image.pullSecret	Image pull secret for the audit image	
auditService.image.repository	Repository for the audit image	quay.io/opencloudio/
auditService.image.tag	Image tag of the audit service	IBM Cloud Pak foundational services version
auditService.resources.limits.cpu	CPU resource limits	200m
auditService.resources.limits.memory	Memory resource limits	512Mi
auditService.resources.requests.cpu	CPU resource request	100m
auditService.resources.requests.memory	Memory resource request	256Mi
API		
camAPI.camSecret.secretName	Name of the secret used by the API	**cam-api-secret**
camAPI.certificate.certName	Name of the certificate used by the API	**cert**
camAPI.replicaCount	Number of API pods	**1**
Ansible provider		
camAnsibleProvider.replicaCount	Number of pods. Set to **1** if you want to use Ansible provider. After you install Managed services, to enable or disable Ansible integration, see Enable or disable Ansible Integration.	**0**
Cloud Discovery		
camBPDCDS.options.customSettingsFile	Cloud Discovery Service custom settings file	Nil
camBPDCDS.options.debug.enabled	Enable Cloud Discovery Service debug mode	**false**
camBPDCDS.replicaCount	Number of Cloud Discovery Service pods	**1**
camBPDCDS.resources.limits.cpu	CPU resource limits	**200m**
camBPDCDS.resources.limits.memory	Memory resource limits	**256Mi**
camBPDCDS.resources.requests.cpu	CPU resource requests	**100m**
camBPDCDS.resources.requests.memory	Memory resource requests	**128Mi**
Business Process Management		

Parameter	Description	Default
`camBpmProvider.replicaCount`	Number of pods. Set to `1` if you want to use IBM Business Process Manager. After you install Managed services, to enable or disable IBM Business Process Manager integration, see Enable or disable IBM Business Process Manager.	`0`
`camBpmProvider.bpmEndpoint`	IBM Business Process Manager endpoint	""
`camBpmProvider.bpmUserName`	IBM Business Process Manager user	""
`camBpmProvider.bpmUserPwd`	IBM Business Process Manager user password	""
Terraform		
`camProviderTerraform.isolateRuntime`	Set to `true` to enable isolation mode for Provider Terraform runtime. In this mode, the runtime runs on separate pods.	`false`
`camProviderTerraform.runtime.replicaCount`	Number of replicas for Provider Terraform Runtime. This value is applicable only when `camProviderTerraform.isolateRuntime` is enabled.	`0`
`camProviderTerraform.terraformSSHDir.terraformSSHDirSecret`	Secret that contains the contents of /home/terraform/.ssh directory. See Configuring Managed services to set the SSH keys and known hosts in provider terraform pod for more details.	""
Controller		
`camController.replicaCount`	Set this to 1 to install the CAM controller.	`1`
Logging policy		
`camLoggingPolicies.logLevel`	Logging level.	`info`
MongoDB PV		
`camMongoPV.name`	Name of MongoDB volume	`cam-mongo-pv`
`camMongoPV.persistence.accessMode`	PV access mode. Do not change the default value.	ReadWriteOnce
`camMongoPV.persistence.enabled`	Database persistence	`true`
`camMongoPV.persistence.existingClaimName`	Database PVC name	`nil`
`camMongoPV.persistence.existingDynamicVolume`	Whether to use an existing PV	`false`
`camMongoPV.persistence.size`	Database PV size	`15Gi`
`camMongoPV.persistence.storageClassName`	Database storage class	`rook-ceph-cephfs-internal`
`camMongoPV.persistence.useDynamicProvisioning`	The default is true. The IBM Cloud Pak for AIOps default storage class is used if you do not change the storage class in the `camLogsPV.persistence.storageClassName` parameter.	`true`
Proxy		
`camProxy.replicaCount`	Number of proxy pods	`1`
Managed services console		
`camUI.camUISecret.secretName`	Secret that is used by the UI	`cam-ui-secret`
`camUI.camUISecret.sessionKey`	Session key that is used by the UI	`opsConsole.sid`
`camUI.camUISecret.sessionTTL`	UI session expiry time	`43200` seconds
`camUI.replicaCount`	Number of UI pods	1
MongoDB setting - External or internal		
`database.bundled`	Use internal MongoDB. Set to false for external. For more information, see Using an external MongoDB	`true`
Global parameters		
`global.audit`	Controls whether the audit container is added to the build or not. It also enables or disables audit in the service.	false
`global.iam.deployApiKey`	It is used to generate Managed services specific Service ID and API Key. The Managed services API Key is used to interact with the platform authorization. If this value is not specified, the installation generates it automatically.	
`global.id.productID`	Managed services Product Identifier	Defaults to the Managed services product ID. If you are downloading the package from Passport Advantage, you can specify the part number here.
`global.id.productVersion`	IBM Cloud Pak for AIOps version	IBM Cloud Pak for AIOps version

Parameter	Description	Default
`global.id.cloudpakID`	IBM Cloud Pak for AIOpsID	Defaults to the IBM Cloud Pak for AIOps product ID.
`global.id.cloudpakVersion`	IBM Cloud Pak for AIOps version	IBM Cloud Pak for AIOps version
`global.image.secretname`	Entitled registry image pull secret	Type `default` to use your namespace default service account image pull secret or enter your Entitled registry image pull secret name. Required if you are downloading images from the Entitled registry.
`global.offline`	Select to optimize the installation for offline. For example, skip attempting to access the internet for public starter templates.	false
Cluster parameters		
`icp.cluster_name`	Your IBM Cloud Pak for AIOps cluster name.	mycluster.
`icp.port`	Port for accessing IBM Cloud Pak for AIOps. The port is used to communicate with the services in IBM Cloud Pak for AIOps.	443
Image parameters		
`image.pullPolicy`	Pull Policy for the Managed services images	IfNotPresent
`image.repository`	Repository for the Managed services images	`quay.io/opencloudio/` (online installation image repository) `mycluster.icp:8500/services/` (offline installation image repository)
`image.tag`	Tag for the Managed services images	IBM Cloud Pak foundational services version
Managed services console hostname and port		
`managementConsole.hostname`	Hostname of the Managed services management console. If this field is kept blank, the installer generates a hostname. You can access the hostname by running the command `oc get route -n cp4aiops`.	NA
`managementConsole.port`	Port for Managed services management console. If this field is kept blank, a random valid port is chosen.	The default is 30000 and the valid range is 30000-32767.
Environment parameters		
`platform`	Platform name.	icp
Proxy parameters		
`proxy.useProxy`	Select to use a proxy with Managed services.	`false`
Global resource parameters		
`resources.limits.cpu`	CPU resource limits	`1`
`resources.limits.memory`	Memory resource limits	`8Gi`
`resources.requests.cpu`	CPU resource requests	`100m`
`resources.requests.memory`	Memory resource requests	`256Mi`
Custom secrets		
`secureValues.secretName`	Name of a secret that you created before the installation of Managed services. It contains secure values, such as proxy, database, and encryption passwords.	Nil. To generate the secret, see Using pre-created secrets in Managed services chart.
Red Hat® OpenShift® on IBM Cloud® service		
`roks`	Indicates if it is a Red Hat® OpenShift® on IBM Cloud® service system	False
`roksRegion`	Red Hat® OpenShift® on IBM Cloud® service storage region	""
`roksZone`	Red Hat® OpenShift® on IBM Cloud® service storage zone	""

Supported platforms and features in Infrastructure Management

Infrastructure Management includes support for different platforms and features.

- Introduction
- Supported Browsers
- Supported Platforms
- Supported Providers
- Provisioning Support on Infrastructure Providers
- Provisioning Support on Cloud Providers
- Feature Support on Infrastructure Providers
- Feature Support on Cloud Providers
- Feature Support on Container Providers
- Feature Support on Network Providers
- Feature Support on Configuration Management Providers

- Remote Console Support
- Operating System Support
- Smart State Analysis Support
- Supported Guest Operating Systems

Chapter 1. Introduction

Infrastructure Management is also delivered as a virtual appliance that includes the following key components:

- CentOS Linux release (Core)
- Rails
- Ruby
- PostgreSQL
- Infrastructure Management Engine
- Apache

Chapter 2. Supported Browsers

The following table outlines the browsers that are supported for viewing the Infrastructure Management web user interface.

Browser support is divided into tiers:

- Tier 1: Browser and operating system combinations that are fully tested and fully supported. IBM is committed to fixing issues with browsers on this tier.
- Tier 2: Browser and operating system combinations that are partially tested, and are likely to work. Limited support is provided for this tier. IBM attempts to fix issues with browsers on this tier.
- Tier 3: Browser and operating system combinations that are not tested, but might work. Minimal support is provided for this tier. IBM attempts to fix only minor issues with browsers on this tier.

Table 2.1. Supported Browsers

Support tier	Browser
Tier 1	Google Chrome - Chrome for Business. See Chapter 6. Remote Console Support for information on VMRC plug-in support. Mozilla Firefox - Firefox Extended Support Release
Tier 2	Microsoft Internet Explorer Edge - version 44 and newer
Tier 3	Safari on MacOS (Mojave) - version 12.1.x

Chapter 3. Supported Platforms for Infrastructure Management

The following table lists platforms that can host the Infrastructure Management appliance, and platforms that can be managed by Infrastructure Management as providers.

Table 3.1. Supported Platforms

Platform	Support for Infrastructure Management Appliance	Supported for Management
Amazon EC2 [a]	Yes	Yes
IBM Cloud	Yes	Yes
Microsoft Azure [a]	No	Yes
Google Compute Engine	No	Yes
Oracle Cloud	No	Yes
OpenShift Container Platform (OCP) 4.2, 4.3, and 4.4	Yes	Yes
OpenShift Container Platform (OCP) 4.5, 4.6, 4.7, 4.8, 4.9, 4.10, and 4.11, 4.13, 4.14, 4.15	Yes	Yes
Red Hat OpenStack Platform (OSP) 10 [b]	Yes	Yes
Red Hat OpenStack Platform (OSP) 13 [b]	Yes	Yes
Red Hat OpenStack Platform (OSP) 16 [b]	Yes	Yes
Red Hat Virtualization (RHV) 4.2 [c]	Yes	Yes
Red Hat Virtualization (RHV) 4.3 [c]	Yes	Yes
Red Hat Virtualization (RHV) 4.4 [c]	Yes	Yes
Red Hat Virtualization (RHV) 4.4SP1 [c]	Yes	Yes
VMware vSphere 6.0	Yes	Yes
VMware vSphere 6.5	Yes	Yes
VMware vSphere 6.7	Yes	Yes
VMware vSphere 7	Yes	Yes
VMware vSphere 8	Yes	Yes

[a] As the pace of change in public cloud features is high, constantly changing and evolving, the compatibility for Infrastructure Management is as of the time of the GA of the product. Best effort basis during errata cycle for public cloud vendor introduced breaking changes (intended or unintended) to existing functionality. Any other changes or additions would be considered as a Request For Enhancement (RFE) which is evaluated for potential inclusion in future releases. RFE can be requested by way of your standard support mechanisms.

[b] See Red Hat OpenStack Platform Life Cycle for product lifecycle information.

[c] See Red Hat Enterprise Virtualization Life Cycle for product lifecycle information.

Chapter 4. Supported Providers

Provider support is divided into tiers:

- Tier 1: These providers are developed, tested, maintained, and supported by IBM. IBM accepts support and enhancement requests.
- Tier 2: These providers are delivered by an IBM partner. IBM accepts support and enhancement requests, but all support and enhancements updates are provided by the partner.
- Tier 3: These providers are delivered by various sources into the ManageIQ open source community. IBM packages and ships these providers and accepts support cases. All support and enhancement updates need to come from the open source community.

Table 4.1. Supported Providers

Support tier	Provider
Tier 1	Amazon, Amazon EKS, Azure, OpenStack, VMware vCenter, Google Cloud, IBM Cloud, Oracle Cloud, Ansible, OpenShift, RHEV, and Satellite, IBM Power HMC, IBM PowerVC, IBM Power Systems Virtual Server
Tier 2	IBM SDE Storage Automation
Tier 3	Microsoft System Center VMM (Hyper-V), OpenStack Platform Director, Azure Stack, Redfish, Nuage Network Manager, VMware vCloud, VMware NSX-t, Lenovo XClarity, and Kubernetes

Chapter 5. Provisioning Support

5.1. Infrastructure Providers

The following table outlines the status of support for provisioning on infrastructure providers.

Table 5.2. Infrastructure Provider Provisioning Support

Feature	Red Hat Virtualization (RHV) Manager	VMware vCenter	IBM Power HMC		
Provision VM/Instance using PXE	Yes	No	No		
Provision VM/Instance using ISO	Yes	No	No		
Clone from VM/Instance to VM/Instance	No	Yes	No		
Provision from Template/Image to VM/Instance	Yes	Yes	Yes		
Provision from VM/Instance to Template/Image	No	Yes	Yes		

5.2. Cloud Providers

The following table outlines the status of support for provisioning on cloud providers.

Table 5.3. Cloud Provider Provisioning Support

Feature	OpenStack Platform (OSP)	Amazon EC2	Microsoft Azure	Google Compute Engine	IBM Cloud VPC	IBM PowerVS	IBM Power Systems Virtual Server
Provision VM/Instance using PXE	No	No	No	No	No	No	No
Provision VM/Instance using ISO	No	No	No	No	No	No	No
Clone from VM/Instance to VM/Instance	No	No	No	No	No	No	No
Provision from Template/Image to VM/Instance	Yes	Yes	Yes	Yes	No	Yes	Yes
Provision from VM/Instance to Template/Image	No	No	No	No	Yes	No	No
Orchestration Template Provisioning	Yes	Yes	Yes	No	No	No	No

Chapter 6. Feature Support

Infrastructure Management allows you to perform actions on the providers that it manages, and provides features for interacting with and providing information about those providers. This section outlines the status of support for actions that you can perform on providers, and the Infrastructure Management features that allow you to interact with those providers.

Note: You can run a rake command to retrieve a list of provider features supported across all platforms. Run the following command in your Infrastructure Management appliance to retrieve the supported features in a comma-separated values (.csv) file format. The comma-separated values are displayed on the command-line interface (CLI) by default. You can use a pipe to redirect the output to a file.

```
ruby /var/www/miq/vmdb/tools/feature_support_matrix.rb
```

6.1. Infrastructure Providers

The following tables outline the status of support for Infrastructure Management features on infrastructure providers.

6.1.1. Red Hat Virtualization

The following table outlines the status of support for Infrastructure Management features on Red Hat Virtualization (RHV) infrastructure providers.

Table 6.1. Red Hat Virtualization Provider Feature Support

Feature	RHV 4.2	RHV 4.3	RHV 4.4
Relationship Discovery	Yes	Yes	Yes
VM Drift Comparison	Yes	Yes	Yes
Track VM Genealogy	Yes	Yes	Yes
Capacity & Utilization	Yes	Yes	Yes
Capture VM/Instance Event Timelines	Yes	Yes	Yes
Reporting	Yes	Yes	Yes
Right Sizing	Yes	Yes	Yes
Chargeback	Yes	Yes	Yes
Remote Console VM Access	Yes [a]	Yes [a]	Yes [a]
Snapshot Creation and Removal	Yes	Yes	Yes
VM / Instance Compliance Enforcement	Yes	Yes	Yes
VM / Instance Policy Enforcement	Yes	Yes	Yes
VM / Instance Power Operations	Yes	Yes	Yes
VM / Instance Retirement	Yes	Yes	Yes
Alerts - VM Value Changed	Yes	Yes	Yes
Alerts - VM Reconfigured	Yes	Yes	Yes
Integrate with Service Catalogs	Yes	Yes	Yes
Virtual Machine Reconfiguration	Yes	Yes	Yes
Automation Work Flows	Yes	Yes	Yes
Tag Mapping from Provider	No	No	No
Tag Mapping to Provider	No	No	No
Provision VM/Instance using PXE	Yes	Yes	Yes
Provision VM/Instance using ISO	Yes	Yes	Yes
Provision from Template/Image to VM/Instance	Yes	Yes	Yes
Provision from VM/Instance to Template/Image	Yes	Yes	Yes
Host Power Operations	No	No	No
Provision Host	No	No	No
Clone from VM/Instance to VM/Instance	No	No	No
Cloud-Init	Yes	Yes	Yes
Customize Windows Templates with Sysprep during Provisioning	Yes	Yes	Yes
OVN Provider	Yes	Yes [b]	Yes [b]

[a] On some operating system and browser combinations.

[b] Technology preview.

6.1.2. VMware vSphere

The following table outlines the status of support for Infrastructure Management features on VMware vSphere infrastructure providers.

Table 6.2. VMware vSphere Provider Feature Support

Feature	vSphere 6.0	vSphere 6.5	vSphere 6.7	vSphere 7	vSphere 8
Relationship Discovery	Yes	Yes	Yes	Yes	Yes
VM Drift Comparison	Yes	Yes	Yes	Yes	Yes
Track VM Genealogy	Yes	Yes	Yes	Yes	Yes
Capacity & Utilization	Yes	Yes	Yes	Yes	Yes
Capture VM/Instance Event Timelines	Yes	Yes	Yes	Yes	Yes
Disk Addition to VM/Instance	Yes	Yes	Yes	Yes	Yes
Reporting	Yes	Yes	Yes	Yes	Yes
Right Sizing	Yes	Yes	Yes	Yes	Yes
Chargeback	Yes	Yes	Yes	Yes	Yes
Remote Console VM Access	Yes [a]	Yes [a]	Yes [a]	Yes [a]	Yes [a]
Snapshot Creation and Removal	Yes	Yes	Yes	Yes	Yes
VM / Instance Compliance Enforcement	Yes	Yes	Yes	Yes	Yes
VM / Instance Policy Enforcement	Yes	Yes	Yes	Yes	Yes
VM / Instance Power Operations	Yes	Yes	Yes	Yes	Yes
VM / Instance Retirement	Yes	Yes	Yes	Yes	Yes
Alerts - Real Time	Yes	Yes	Yes	Yes	Yes
Alerts - VM Value Changed	Yes	Yes	Yes	Yes	Yes
Alerts - VM Reconfigured	Yes	Yes	Yes	Yes	Yes

Feature	vSphere 6.0	vSphere 6.5	vSphere 6.7	vSphere 7	vSphere 8
Integrate with Service Catalogs	Yes	Yes	Yes	Yes	Yes
Virtual Machine Reconfiguration	Yes	Yes	Yes	Yes	Yes
Automation Work Flows	Yes	Yes	Yes	Yes	Yes
Tag Mapping from Provider	No	No	No	No	No
Tag Mapping to Provider	No	No	No	No	No
Provision VM/Instance using PXE	Yes	Yes	Yes	Yes	Yes
Provision VM/Instance using ISO	No	No	No	No	No
Provision from Template/Image to VM/Instance	Yes	Yes	Yes	Yes	Yes
Provision from VM/Instance to Template/Image	Yes	Yes	Yes	Yes	Yes
Host Power Operations	Yes	Yes	Yes	Yes	Yes
Customize Windows Templates with Sysprep during Provisioning	Yes	Yes	Yes	Yes	Yes
Clone from VM/Instance to VM/Instance	Yes	Yes	Yes	Yes	Yes
[a] On some operating system and browser combinations					

6.1.3. IBM Power HMC

The following table outlines the status of support for IBM Power HMC infrastructure providers.

Table 6.3. IBM Power HMC Provider Feature Support

Feature	IBM Power HMC
Relationship Discovery	Yes
VM Drift Comparison	No
Track VM Genealogy	No
Capacity & Utilization	Yes
Capture VM/Instance Event Timelines	Yes
Reporting	Yes
Right Sizing	Yes
Chargeback	No
Remote Console VM Access	No
Snapshot Creation and Removal	No
VM / Instance Compliance Enforcement	No
VM / Instance Policy Enforcement	No
VM / Instance Power Operations	Yes
VM / Instance Retirement	Yes
Alerts - Real Time	No
Alerts - VM Value Changed	No
Alerts - VM Reconfigured	No
Integrate with Service Catalogs	No
Virtual Machine Reconfiguration	No
Automation Work Flows	No
Tag Mapping from Provider	No
Tag Mapping to Provider	No
Provision VM/Instance using PXE	No
Provision VM/Instance using ISO	No
Provision from Template/Image to VM/Instance	Yes
Provision from VM/Instance to Template/Image	Yes
Host Power Operations	Yes
Provision Host	No
Clone from VM/Instance to VM/Instance	No

6.2. OpenStack Platform Director Infrastructure Providers

The following table outlines the status of support for Infrastructure Management features on OpenStack Platform (OSP) director infrastructure providers.

Table 6.5. OpenStack Platform Director Infrastructure Provider Feature Support

Feature	OpenStack Platform (OSP) Director
Relationship Discovery	Yes
Nodes Inventory	Yes
OpenStack Services Inventory	Yes
Nodes Drift Comparison	Yes
Nodes Smart State	Yes
Capacity & Utilization	Yes
Capture Infrastructure Event Timelines	Yes
Node Power Operation	Yes

Feature	OpenStack Platform (OSP) Director
Capacity Planning	Yes
Reporting	Yes
Add/Remove Node	Yes
Scale Down Node	Yes (Compute nodes only)
Scale Up Nodes	Yes (Compute nodes only)
Nodes Policy Enforcement	Yes
Nodes Evacuate	Yes
OpenStack Upgrade	No

6.3. Cloud Providers

The following section outlines the status of support for Infrastructure Management features on cloud providers.

6.3.1. OpenStack Platform

The following table outlines the status of support for Infrastructure Management features on OpenStack Platform (OSP) cloud providers.

- The following feature support information for IBM Cloud is based on:
  - IBM Cloud PowerVC Manager 1.4.4.0 Build: 20191205-1007
  - IBM Cloud Infrastructure Center 1.2.0

Table 6.6. OpenStack Platform Feature Support

Feature	Red Hat OSP 10	Red Hat OSP 13	Red Hat OSP 16	OpenStack	IBM PowerVC	IBM Cloud Infrastructure Center
Relationship Discovery	Yes	Yes	Yes	Yes	Yes	Yes
Instance Drift Comparison	Yes	Yes	Yes	Yes	No	No
Track Instance Genealogy	Yes	Yes	Yes	Yes	Yes	Yes
Capacity & Utilization	Yes	Yes	Yes	Yes	Yes	Yes
Capture Cloud Layer Timelines	Yes	Yes	Yes	Yes	Yes	Yes
Capture Instance Event Timelines	Yes	Yes	Yes	Yes	Yes	Yes
Disk Addition to Instance	Yes	Yes	Yes	Yes	N/A	Yes
Key Pairs Inventory	Yes	Yes	Yes	Yes	Yes	Yes
Key Pairs Management	Yes	Yes	Yes	Yes	Yes	Yes
Reporting	Yes	Yes	Yes	Yes	Yes	Yes
Right Sizing	Yes	Yes	Yes	Yes	Yes	Yes
Chargeback	Yes	Yes	Yes	Yes	Yes	Yes
Remote Console Instance Access	Yes	Yes	Yes	Yes (VNC)	Yes (for NovaLink-managed hosts only)	No
Snapshot Creation and Removal	Yes	Yes	Yes	Yes	Yes	Yes
Instance Compliance Enforcement	Yes	Yes	Yes	Yes	No	No
Instance Policy Enforcement	Yes	Yes	Yes	Yes	Yes	Yes
Instance Power Operations	Yes	Yes	Yes	Yes	Yes	Yes
Instance Retirement	Yes	Yes	Yes	Yes	Yes	Yes
Alerts - Real Time	Yes	Yes	Yes	Yes	Yes	Yes
Alerts - Instance Value Changed	No	No	No	No	No	No
Alerts - Reconfigured	No	No	No	No	No	No
Integrate with Service Catalogs	Yes	Yes	Yes	Yes	Yes	Yes
Virtual Machine Reconfiguration	Yes	Yes	Yes	Yes	Yes	Yes
Volume Inventory	Yes	Yes	Yes	Yes	Yes	Yes
Volume Creation/Deletion	Yes	Yes	Yes	Yes	Yes	Yes
Instance Migration	Yes	Yes	Yes	Yes	Yes	Yes**
Automation Work Flows	Yes	Yes	Yes	Yes	Yes	Yes
Tag Mapping from Provider	No	No	No	No	Yes	No
Tag Mapping to Provider	No	No	No	No	No	No
Storage Manager	Yes	Yes	Yes	Yes	Yes	Yes
Provision Instance using PXE	No	No	No	N/A	N/A	N/A
Provision Instance using ISO	No	No	No	N/A	N/A	N/A
Provision from Template/Image to Instance	Yes	Yes	Yes	Yes	Yes	Yes
Provision from Image Snapshot to Instance	Yes	Yes	Yes	Yes	No	N/A
Provision from Volume to Instance	Yes	Yes	Yes	Yes	No	N/A
Provision from Volume Snapshot to Instance	Yes	Yes	Yes	Yes	No	N/A
Clone from Instance to Instance	No	No	No	No	No	No
Cloud-Init	Yes	Yes	Yes	Yes	Yes	N/A

Feature	Red Hat OSP 10	Red Hat OSP 13	Red Hat OSP 16	OpenStack	IBM PowerVC	IBM Cloud Infrastructure Center
Sysprep Windows Templates	Yes	Yes	Yes	Yes	N/A	N/A

Note:

Features marked with "*" are only supported with z/VM hypervisor.

Features marked with "**" are only supported with KVM hypervisor.

Features not marked with "*" or "**" are valid and supported for both z/VM and KVM hypervisors.

Features listed with a “NO” are not valid for both KVM and z/VM.

6.3.2. IBM Cloud Feature Support

The following table outlines the status of support for Infrastructure Management features on IBM Cloud providers.

Table 6.7. IBM Cloud Feature Support

Feature	IBM Cloud VPC	IBM Power Systems Virtual Server
Relationship Discovery	Yes	Yes
Instance Drift Comparison	No	No
Track Instance Genealogy	Yes	Yes
Capacity & Utilization	No	No
Capture Cloud Layer Timelines	No	No
Capture Instance Event Timelines	Yes	No
Disk Addition to Instance	No	Yes
Key Pairs Inventory	Yes	Yes
Key Pairs Management	No	Yes
Reporting	Yes	Yes
Right Sizing	No	No
Chargeback	Yes (Limited to inventory allocation)	Yes (Limited to inventory allocation)
Remote Console Instance Access	No	No
Snapshot Creation and Removal	No	No
Instance Compliance Enforcement	No	No
Instance Policy Enforcement	Yes	Yes
Instance Power Operations	Yes	Yes
Instance Retirement	No	Yes
Alerts - Real Time	No	No
Alerts - Instance Value Changed	No	No
Alerts - Reconfigured	No	No
Integrate with Service Catalogs	No	Yes
Virtual Machine Reconfiguration	No	No
Volume Inventory	Yes	Yes
Volume Creation/Deletion	Yes	Yes
Instance Migration	N/A	N/A
Automation Work Flows	No	No
Tag Mapping from Provider	Yes	No
Tag Mapping to Provider	No	No
Storage Manager	Yes	Yes
Provision Instance using PXE	No	No
Provision Instance using ISO	No	No
Provision from Template/Image to Instance	Yes	Yes
Provision from Image Snapshot to Instance	No	No
Provision from Volume to Instance	No	No
Provision from Volume Snapshot to Instance	No	No
Clone from Instance to Instance	No	No
Cloud-Init	No	Yes
Sysprep Windows Templates	N/A	N/A

6.3.3. Amazon EC2

The following table outlines the status of support for Infrastructure Management features on Amazon EC2 cloud providers.

Table 6.8. Amazon EC2 Feature Support

Feature	Amazon EC2
Relationship Discovery	Yes
VM Drift Comparison	Yes
Track VM Genealogy	Yes

Feature	Amazon EC2
Capacity & Utilization	Yes
Capture VM/Instance Event Timelines	Yes
Disk Addition to VM/Instance	Yes
Key Pairs Inventory	Yes
Key Pairs Management	Yes
Reporting	Yes
Right Sizing	Yes
Chargeback	Yes
Remote Console VM Access	No
Snapshot Creation and Removal	No
VM / Instance Compliance Enforcement	Yes
VM / Instance Policy Enforcement	Yes
VM / Instance Power Operations	Yes
VM / Instance Retirement	Yes
Alerts - Real Time	No
Alerts - VM Value Changed	No
Alerts - Reconfigured	No
Integrate with Service Catalogs	Yes
Virtual Machine Reconfiguration	No
Volume Inventory	No
Volume Creation/Deletion	No
VM Migration	No
Automation Work Flows	Yes
Tag Mapping from Provider	Yes
Tag Mapping to Provider	No
Network Manager - Read Only	Yes
Network Manager - CRUD Actions Supported	No
Storage Manager	Yes
Provision VM/Instance using PXE	No
Provision VM/Instance using ISO	No
Provision from Template/Image to VM/Instance	Yes
Clone from VM/Instance to VM/Instance	No

6.3.4. Microsoft Azure

The following table outlines the status of support for Infrastructure Management features on Microsoft Azure cloud providers.

Table 6.9. Microsoft Azure Feature Support

Feature	Microsoft Azure
Relationship Discovery	Yes
VM Drift Comparison	Yes
Track VM Genealogy	Yes
Capacity & Utilization	Yes
Capture Cloud Layer Timelines	N/A
Capture VM/Instance Event Timelines	Yes
Disk Addition to VM/Instance	Yes
Key Pairs Inventory	No
Key Pairs Management	Yes
Optimization - Bottleneck Identification	No
Reporting	Yes
Right Sizing	Yes
Chargeback	Yes
Remote Console VM Access	No
Snapshot Creation and Removal	No
VM / Instance Compliance Enforcement	Yes
VM / Instance Policy Enforcement	Yes
VM / Instance Power Operations	Yes
VM / Instance Retirement	Yes
Alerts - Real Time	No
Alerts - VM Value Changed	No
Alerts - Reconfigured	No
Integrate with Service Catalogs	Yes
Virtual Machine Reconfiguration	No
Volume Inventory	No

Feature	Microsoft Azure
Volume Creation/Deletion	No
VM Migration	No
Automation Work Flows	No
Tag Mapping from Provider	Yes
Tag Mapping to Provider	No
Network Manager - Read Only	Yes
Network Manager - CRUD Actions Supported	No
Provision VM/Instance using PXE	No
Provision VM/Instance using ISO	No
Provision from Template/Image to VM/Instance	Yes
Clone from VM/Instance to VM/Instance	No

6.3.5. Google Compute Engine

The following table outlines the status of support for Infrastructure Management features on Google Compute Engine cloud providers.

Table 6.10. Google Compute Engine Feature Support

Feature	Google Compute Engine
Relationship Discovery	Yes
VM Drift Comparison	No
Track VM Genealogy	Yes
Capacity & Utilization	Yes
Capture Cloud Layer Timelines	No
Capture VM/Instance Event Timelines	Yes
Disk Addition to VM/Instance	No
Key Pairs Inventory	Yes
Key Pairs Management	No
Optimization - Bottleneck Identification	No
Reporting	Yes
Right Sizing	Yes
Chargeback	Yes
Remote Console VM Access	No
Snapshot Creation and Removal	No
VM / Instance Compliance Enforcement	Yes
VM / Instance Policy Enforcement	Yes
VM / Instance Power Operations	Yes
VM / Instance Retirement	Yes
Alerts - Real Time	No
Alerts - VM Value Changed	No
Alerts - Reconfigured	No
Integrate with Service Catalogs	Yes
Virtual Machine Reconfiguration	No
Volume Inventory	Yes
Volume Creation/Deletion	No
VM Migration	No
Automation Work Flows	Yes
Tag Mapping from Provider	No
Tag Mapping to Provider	No
Network Manager - Read Only	Yes
Network Manager - CRUD Actions Supported	No
Storage Manager	No
Provider TLS	No
Provision VM/Instance using PXE	No
Provision VM/Instance using ISO	No
Provision from Template/Image to VM/Instance	Yes
Provision from VM/Instance to Template/Image	No
Host Power Operations	No
Provision Host	No
Clone from VM/Instance to VM/Instance	No

6.3.6. Oracle Cloud

The following table outlines the status of support for Infrastructure Management features on Oracle cloud providers.

Table 6.11. Oracle Cloud Feature Support

Feature	Oracle Cloud
Relationship Discovery	Yes
VM Drift Comparison	No
Track VM Genealogy	Yes
Capacity & Utilization	Yes
Capture Cloud Layer Timelines	No
Capture VM/Instance Event Timelines	Yes
Disk Addition to VM/Instance	No
Key Pairs Inventory	Yes
Key Pairs Management	No
Optimization - Bottleneck Identification	No
Reporting	Yes
Right Sizing	No
Chargeback	No
Remote Console VM Access	No
Snapshot Creation and Removal	No
VM / Instance Compliance Enforcement	No
VM / Instance Policy Enforcement	Yes
VM / Instance Power Operations	Yes
VM / Instance Retirement	Yes
Alerts - Real Time	No
Alerts - VM Value Changed	No
Alerts - Reconfigured	No
Integrate with Service Catalogs	Yes
Virtual Machine Reconfiguration	No
Volume Inventory	Yes
Volume Creation/Deletion	No
VM Migration	No
Automation Work Flows	Yes
Tag Mapping from Provider	No
Tag Mapping to Provider	No
Network Manager - Read Only	Yes
Network Manager - CRUD Actions Supported	No
Storage Manager	No
Provider TLS	No
Provision VM/Instance using PXE	No
Provision VM/Instance using ISO	No
Provision from Template/Image to VM/Instance	Yes
Provision from VM/Instance to Template/Image	No
Host Power Operations	No
Provision Host	No
Clone from VM/Instance to VM/Instance	No

6.4. Container Providers

The following section outlines the status of support for Infrastructure Management features on Red Hat OpenShift Container Platform container providers.

Table 6.12. Red Hat OpenShift Container Platform Provider Feature Support

Feature	Red Hat OpenShift Container Platform 4.x
Relationship Discovery	Yes
Track Container Image Relationship	Yes
Capacity & Utilization	Yes
Capture Container Event Timelines	Yes
Reporting	Yes
Chargeback	Yes
Remote Cockpit Node Access	No
Container Node Compliance Enforcement	Yes
Container Node Policy Enforcement	Yes
Replicator Compliance Enforcement	Yes
Replicator Policy Enforcement	Yes
Pod Compliance Enforcement	Yes
Pod Policy Enforcement	Yes
Image Compliance Enforcement	Yes
Image Policy Enforcement	Yes
Template Provisioning	No

Feature	Red Hat OpenShift Container Platform 4.x
Smart State	No
OpenSCAP Execution and Report	No
Cross Linking Underlying Infrastructure	Yes
Tag Mapping From Provider	No
Tag Mapping To Provider	Yes

6.5. Network Providers

This section outlines the status of support for Infrastructure Management features on network providers.

Table 6.13. Network Provider Feature Support

Feature	Red Hat OpenStack Platform (OSP)	Amazon EC2	Microsoft Azure	Google Compute Engine	Nuage	VMware NSX-t
Network Manager Relationships	Yes	Yes	Yes	Yes	Yes	Yes
Relationship Discovery	Yes	Yes	Yes	Yes	Yes	Yes
Cloud Network Inventory	Yes	Yes	Yes	Yes	Yes	Yes
Cloud Subnet Inventory	Yes	Yes	Yes	Yes	Yes	Yes
Network Router Inventory	Yes	No	No	Yes	Yes	Yes
Security Groups	Yes	Yes	Yes	Yes	No	Yes
Floating IP Addresses	Yes	Yes	Yes	Yes	Yes	No
Network Ports	Yes	Yes	Yes	Yes	Yes	Yes
Load Balancer Inventory	No	Yes	Yes	Yes	No	No
Create/Update/Delete Network	Yes	No	No	No	Yes	Yes
Create/Update/Delete Subnet	Yes	No	No	No	Yes	No
Create/Update/Delete Routers	Yes	No	No	No	Yes	Yes

6.6. Configuration Management Providers

The following table outlines the status of support for Infrastructure Management features on configuration management providers.

Table 6.14. Configuration Management Provider Feature Support

Feature	Ansible
Groups Inventory	Yes
Configured Systems Inventory	Yes
Job Template Inventory	Yes
Integrate with Service Catalog	Yes
Automate Workflows	Yes

Note: Infrastructure Management supports Ansible 3.7 and later as a configuration management provider.

Chapter 7. Remote Console Support

Infrastructure Management allows you to access the console of virtual machines and instances on the providers it managers using HTML5-based VNC consoles. This section outlines the status of support for remote consoles in Infrastructure Management.

Note: For VMware vSphere providers, Infrastructure Management supports the versions of VMRC that VMware supports. However, VMware does not support VMRC for Mac operating systems. See VMware VMRC documentation for more information.

For all other providers, Infrastructure Management supports HTML5-based VNC consoles. The following have been tested with Infrastructure Management Engine:

- Windows: UltraVNC 1.1.8.8 - http://www.uvnc.com/
- Linux/Mac: SSVNC 1.0.29 - At the time of this writing, this is the only client that supports the VNC repeater configuration.

Note: As of 1 September 2015, new versions of Chrome no longer support VMRC consoles. VMRC requires NPAPI plug-in support. Chrome removed support for NPAPI plug-ins in version 45.0.2454, which was released on this date.

7.1. Support on IBM Red Hat CloudForms by Providers and Browsers

The following tables outline the status of support for remote consoles on providers for IBM Red Hat CloudForms 6 and IBM Red Hat CloudForms 7.

Table 7.1. Remote Console Support on IBM Red Hat CloudForms 6

Provider	Connection Type	Support	Chrome	Firefox
VMware vSphere 6.0	VNC	Yes	No	Yes
	VMRC		No	Yes
	WebMKS		No	Yes
VMware vSphere 6.5	VMRC	Yes	No	Yes

Provider	Connection Type	Support	Chrome	Firefox
	WebMKS		No	Yes
Red Hat Virtualization (RHV) 4.2	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.3	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.4	SPICE	Yes	No	No
Red Hat OpenStack Platform 10	VNC	Yes	No	No
Red Hat OpenStack Platform 13	VNC	Yes	No	No
Red Hat OpenStack Platform 16	VNC	Yes	No	No

Table 7.2. Remote Console Support on IBM Red Hat CloudForms 7

Provider	Connection Type	Support	Chrome	Firefox
VMware vSphere 6.0	VNC	Yes	Yes	Yes
	VMRC		Yes	Yes
	WebMKS		Yes	Yes
VMware vSphere 6.5	VMRC	Yes	Yes	Yes
	WebMKS		Yes	Yes
Red Hat Virtualization (RHV) 4.2	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.3	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.4	SPICE	Yes	No	No
Red Hat OpenStack Platform 10	VNC	Yes	No	No
Red Hat OpenStack Platform 13	VNC	Yes	No	No
Red Hat OpenStack Platform 16	VNC	Yes	No	No

7.2. Support on Fedora by Providers and Browsers

The following tables outline the status of support for remote consoles on providers for Fedora 25, 26, and 27.

Table 7.3. Remote Console Support on Fedora 25

Provider	Connection Type	Support	Chrome	Firefox
VMware vSphere 6.0	VNC	Yes	Yes	Yes
	VMRC		Yes	Yes
	WebMKS		Yes	Yes
VMware vSphere 6.5	VMRC	Yes	Yes	Yes
	WebMKS		Yes	Yes
Red Hat Virtualization (RHV) 4.2	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.3	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.4	SPICE	Yes	No	No
Red Hat OpenStack Platform 10	VNC	Yes	No	No
Red Hat OpenStack Platform 13	VNC	Yes	No	No
Red Hat OpenStack Platform 16	VNC	Yes	No	No

Table 7.4. Remote Console Support on Fedora 26

Provider	Connection Type	Support	Chrome	Firefox
VMware vSphere 6.0	VNC	Yes	Yes	Yes
	VMRC		Yes	Yes
	WebMKS		Yes	Yes
VMware vSphere 6.5	VMRC	Yes	Yes	Yes
	WebMKS		Yes	Yes
Red Hat Virtualization (RHV) 4.2	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.3	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.4	SPICE	Yes	No	No
Red Hat OpenStack Platform 10	VNC	Yes	No	No
Red Hat OpenStack Platform 13	VNC	Yes	No	No
Red Hat OpenStack Platform 16	VNC	Yes	No	No

Table 7.5. Remote Console Support on Fedora 27

Provider	Connection Type	Support	Chrome	Firefox
VMware vSphere 6.0	VNC	Yes	Yes	Yes
	VMRC		Yes	Yes
	WebMKS		Yes	Yes
VMware vSphere 6.5	VMRC	Yes	Yes	Yes
	WebMKS		Yes	Yes
Red Hat Virtualization (RHV) 4.2	SPICE	Yes	No	No
Red Hat Virtualization (RHV) 4.3	SPICE	Yes	No	No

Provider	Connection Type	Support	Chrome	Firefox
Red Hat Virtualization (RHV) 4.4	SPICE	Yes	No	No
Red Hat OpenStack Platform 10	VNC	Yes	No	No
Red Hat OpenStack Platform 13	VNC	Yes	No	No
Red Hat OpenStack Platform 16	VNC	Yes	No	No

7.3. Support on Windows by Providers and Browsers

The following tables outline the status of support for remote consoles on providers for Windows 7, 10, and 2012 Server.

Table 7.6. Remote Console Support on Windows 7

Provider	Connection Type	Support	Chrome	Firefox	IE 11	IE 10
VMware vSphere 6.0	VNC	Yes	Yes	Yes	Yes	No
	VMRC		Yes	Yes	Yes	No
	WebMKS		Yes	Yes	Yes	No
VMware vSphere 6.5	VMRC	Yes	Yes	Yes	Yes	No
	WebMKS		Yes	Yes	Yes	No
Red Hat Virtualization (RHV) 4.2	SPICE	Yes	No	No	No	No
Red Hat Virtualization (RHV) 4.3	SPICE	Yes	No	No	No	No
Red Hat Virtualization (RHV) 4.4	SPICE	Yes	No	No	No	No
Red Hat OpenStack Platform 10	VNC	Yes	No	No	No	No
Red Hat OpenStack Platform 13	VNC	Yes	No	No	No	No
Red Hat OpenStack Platform 16	VNC	Yes	No	No	No	No
Amazon EC2	N/A	No	N/A	N/A	N/A	N/A

Table 7.7. Remote Console Support on Windows 10

Provider	Connection Type	Support	Chrome	Firefox	IE 11	IE 10	Edge
VMware vSphere 6.0	VNC	Yes	No	No	No	No	Yes
	VMRC		No	No	No	No	Yes
	WebMKS		No	No	No	No	Yes
VMware vSphere 6.5	VMRC	Yes	No	No	No	No	Yes
	WebMKS		No	No	No	No	Yes
Red Hat Virtualization (RHV) 4.2	SPICE	Yes	No	No	No	No	No
Red Hat Virtualization (RHV) 4.3	SPICE	Yes	No	No	No	No	No
Red Hat Virtualization (RHV) 4.4	SPICE	Yes	No	No	No	No	No
Red Hat OpenStack Platform 10	VNC	Yes	No	No	No	No	No
Red Hat OpenStack Platform 13	VNC	Yes	No	No	No	No	No
Red Hat OpenStack Platform 16	VNC	Yes	No	No	No	No	No
Amazon EC2	N/A	No	N/A	N/A	N/A	N/A	N/A

Table 7.8. Remote Console Support on Windows 2012 Server

Provider	Connection Type	Support	Chrome	Firefox	IE 11	IE 10
VMware vSphere 6.0	VNC	Yes	Yes	Yes	Yes	No
	VMRC		No	No	No	No

Chapter 8. Operating System Support

This section outlines the supported operating systems by infrastructure and cloud providers.

Table 8.1. Windows Support by Infrastructure Providers

Infrastructure Provider	Windows 7 SP1	Windows 8.1	Windows 10	Windows 2012	Windows 2016
Red Hat Virtualization 4.2			Yes		
Red Hat Virtualization 4.3			Yes		
Red Hat Virtualization 4.4			Yes		

Infrastructure Provider	Windows 7 SP1	Windows 8.1	Windows 10	Windows 2012	Windows 2016
Red Hat OpenStack Platform 10 [a]	Yes	Yes	Yes	Yes	Yes
Red Hat OpenStack Platform 13 [a]	Yes	Yes	Yes	Yes	Yes
Red Hat OpenStack Platform 16 [a]	Yes	Yes	Yes	Yes	Yes
VMware vCenter 6.0 [b]	Yes	Yes	Yes	Yes	Yes
VMware vCenter 6.5 [c]	Yes	Yes	Yes	Yes	Yes
VMware vCenter 6.7 [d]	Yes	Yes	Yes	Yes	Yes

[a] See Section 9.2, Supported Guest Operating Systems.

[b] Install the VMware VDDK 6.0 so that SmartState analysis is successful.

[c] Install the VMware VDDK 6.5 so that SmartState analysis is successful. Alternatively, you can use VMware VDDK 6.0.

[d] Install the VMware VDDK 6.7 so that SmartState analysis is successful. Alternatively, you can use VMware VDDK 6.0.

Table 8.2. Windows Support by Cloud Providers

Cloud Provider	Windows 7 SP1	Windows 8.1	Windows 10	Windows 2012	Windows 2016
Red Hat OpenStack Platform 10 [a]	Yes	Yes	Yes	Yes	Yes
Red Hat OpenStack Platform 13 [a]	Yes	Yes	Yes	Yes	Yes
Red Hat OpenStack Platform 16 [a]	Yes	Yes	Yes	Yes	Yes
Microsoft Azure	Yes	Yes	Yes	Yes	Yes
Amazon EC2	Yes	Yes	Yes	Yes	Yes
[a] See Section 9.2, Supported Guest Operating Systems.					

Table 8.3. Linux Support by Infrastructure Providers

Infrastructure Provider	RHEL 6	RHEL 7	Ubuntu	SUSE
Red Hat Virtualization 4.2		Yes		
Red Hat Virtualization 4.3		Yes		
Red Hat Virtualization 4.4		Yes		
Red Hat OpenStack Platform 10 [a]	Yes	Yes	Yes	Yes
Red Hat OpenStack Platform 13 [a]	Yes	Yes	Yes	Yes
Red Hat OpenStack Platform 16 [a]	Yes	Yes	Yes	Yes
VMware vCenter 6.0 [b]	Yes	Yes	Yes	Yes
VMware vCenter 6.5 [c]	Yes	Yes	Yes	Yes
VMware vCenter 6.7 [d]	Yes	Yes	Yes	Yes

[a] See Section 9.2, Supported Guest Operating Systems.

[b] Install the VMware VDDK 6.0 so that SmartState analysis is successful.

[c] Install the VMware VDDK 6.5 so that SmartState analysis is successful. Alternatively, you can use VMware VDDK 6.0.

[d] Install the VMware VDDK 6.7 so that SmartState analysis is successful. Alternatively, you can use VMware VDDK 6.0.

Table 8.4. Linux Support by Cloud Providers

Cloud Provider	RHEL 6	RHEL 7	Ubuntu	SUSE
Red Hat OpenStack Platform 10 [a]	Yes	Yes	Yes	Yes
Red Hat OpenStack Platform 13 [a]	Yes	Yes	Yes	Yes
Red Hat OpenStack Platform 16 [a]	Yes	Yes	Yes	Yes
Microsoft Azure	Yes	Yes	Yes	Yes
Amazon EC2	Yes	Yes	Yes	Yes

[a] See Section 9.2, Supported Guest Operating Systems.

Chapter 9. Smart State Analysis Support

Infrastructure Management allows you to analyze virtual machines and instances on the providers it manages to collect information about the base operating system on those virtual machines or instances, their virtual hardware, installed applications, and other details. This operation is known as SmartState analysis. This section outlines the status of support for SmartState analysis of virtual machines and instances by guest operating system, file system, and by provider.

9.1. File Systems

The following tables outline SmartState analysis support for different file systems by infrastructure and cloud providers.

Table 9.1. Windows File System SmartState Analysis Support by Infrastructure Providers

Infrastructure Provider	ReFS	NTFS	FAT32	FAT
Red Hat Virtualization 4.2	No			
Red Hat Virtualization 4.3	No			
Red Hat Virtualization 4.4	No			
Red Hat OpenStack Platform 10 [a]	No	Yes	No	No
Red Hat OpenStack Platform 13 [a]	No	Yes	No	No

Infrastructure Provider	ReFS	NTFS	FAT32	FAT
Red Hat OpenStack Platform 16 [a]	No	Yes	No	No
Red Hat OpenShift	No			
VMware vCenter 6.0 [b]	No	Yes	Yes	Yes
VMware vCenter 6.5 [c]	No	Yes	Yes	Yes
VMware vCenter 6.7 [d]	No	Yes	Yes	Yes

[a] See Section 9.2, Supported Guest Operating Systems.

[b] Install the VMware VDDK 6.0 so that SmartState analysis is successful.

[c] Install the VMware VDDK 6.5 so that SmartState analysis is successful. Alternatively, you can use VMware VDDK 6.0.

[d] Install the VMware VDDK 6.7 so that SmartState analysis is successful. Alternatively, you can use VMware VDDK 6.0.

Table 9.2. Windows File System SmartState Analysis Support by Cloud Providers

Cloud Provider	ReFS	NTFS	FAT32	FAT
Red Hat OpenStack Platform 10 [a]	No	Yes	No	No
Red Hat OpenStack Platform 13 [a]	No	Yes	No	No
Red Hat OpenStack Platform 16 [a]	No	Yes	No	No
Microsoft Azure	No	Yes	Yes	Yes
Amazon EC2	No	Yes	Yes	Yes

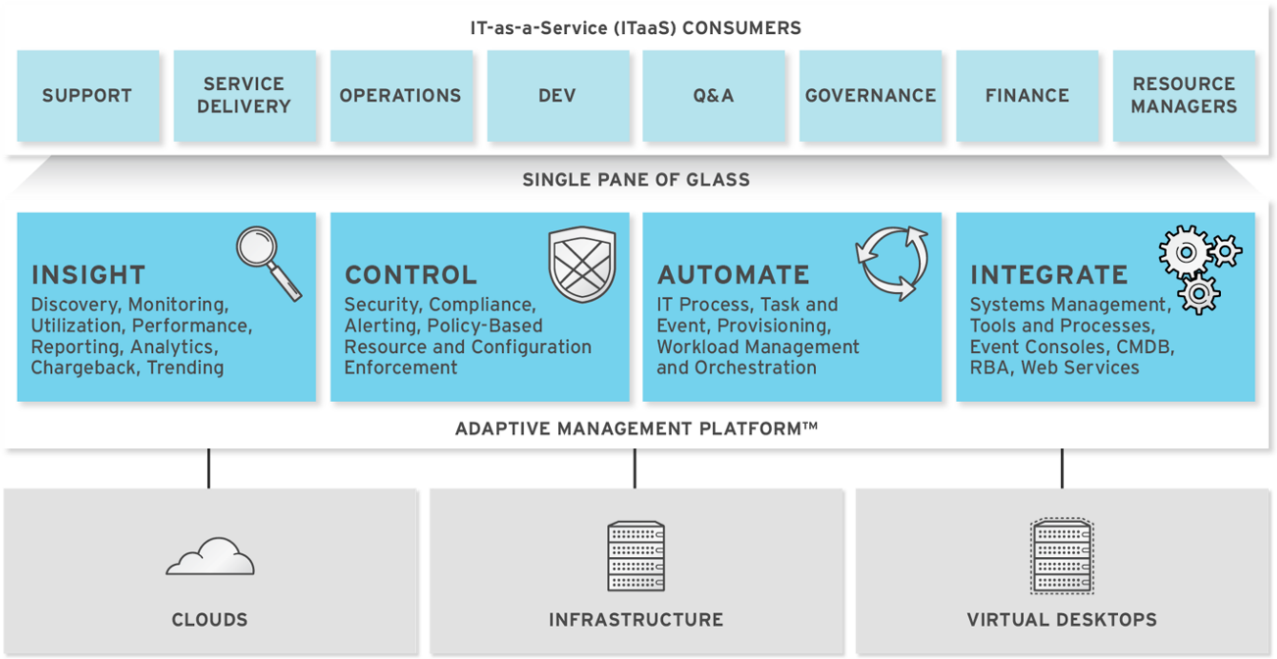
Deployment Planning Guide

Introduction to Infrastructure Automation



Infrastructure Automation delivers the insight, control, and automation that enterprises need to address the challenges of managing virtual environments. This technology enables enterprises with existing virtual infrastructures to improve visibility and control, and those starting virtualization deployments to build and operate a well-managed virtual infrastructure.

Infrastructure Automation provides the following feature sets:

- Insight: Discovery, Monitoring, Utilization, Performance, Reporting, Analytic, Chargeback, and Trending.
- Control: Security, Compliance, Alerting, and Policy-Based Resource, and Configuration Enforcement.
- Automate: IT Process, Task and Event, Provisioning, and Workload Management and Orchestration.
- Integrate: Systems Management, Tools and Processes, Event Consoles, Configuration Management Database (CMDB), Role-based Administration (RBA), and Web Services.

Architecture

The diagram below describes the capabilities of Infrastructure Automation. Its features are designed to work together to provide robust management and maintenance of your virtual infrastructure.

The architecture comprises the following components:

- The Infrastructure Automation appliance (appliance) which is supplied as a secure, high-performance, preconfigured virtual machine. It provides support for HTTPS communications.
- The Infrastructure Automation Server (Server) resides on the appliance. It is the software layer that communicates between the SmartProxy and the Virtual Management Database. It includes support for HTTPS communications.
- The Virtual Management Database (VMDB) resides either on the appliance or another computer accessible to the appliance. It is the definitive source of intelligence collected about your Virtual Infrastructure. It also holds status information regarding appliance tasks.
- The Infrastructure Automation Console (Console) is the Web interface used to view and control the Server and appliance. It is consumed through Web 2.0 mash-ups and web services (WS Management) interfaces.
- The SmartProxy can reside on the appliance or on an ESX Server. If not embedded in the Server, the SmartProxy can be deployed from the appliance. A SmartProxy agent must configured in each storage location, and must be visible to the appliance. The SmartProxy acts on behalf of the appliance communicating with it over HTTPS on standard port 443.

Requirements

To use Infrastructure Automation, certain virtual hardware, database, and browser requirements must be met in your environment.

Virtual Hardware Requirements

The Infrastructure Automation appliance requires the following virtual hardware at minimum:

- 4 VCPUs
- 12 GB RAM

- 44 GB HDD + optional database disk + optional messaging disk

Database Requirements

Red Hat recommends allocating the virtual machine disk fully at the time of creation. Three main factors affect the size of your database over time:

- Virtual Machine Count: the most important factor in the calculation of virtual machine database (VMDB) size over time.
- Host Count: the number of hosts associated with the provider.
- Storage Count: the number of individual storage elements as seen from the perspective of the provider or host. It is not the total number of virtual disks for all virtual machines.

Use the following table as a guideline to calculate minimum requirements for your database:

			Estimated VMDB Size in GB	
Virtual Machine Count	Host Count	Storage Count	1 year	2 year
100	5	50	3.5	5
500	10	100	17	25
5000	50	500	173	251

Note:

When enabling capacity and utilization for metrics gathering over a period of time, it is recommended that the VMDB size scale accordingly. Evaluate the number of instances in your provider inventory and storage duration requirements to plan for increased VMDB sizing requirements.

Use the following information to plan for your increased VMDB needs when working with metrics gathering:

- Realtime metrics data are stored for 4 hours.
- Rollup metrics data are stored for 6 months.

Example:

	Minute	**Hour**	**Day**
OpenStack Provider Instance	**3** Realtime Metrics	**181** (3 records * 60 minutes = 180 Realtime Metrics + 1 hourly Rollup Metric)	**4,345** (3 records * 60 minutes * 24 hours =4320 Realtime Metrics + 1 daily Rollup Metric)

- Metrics data storage times can be configured by editing the Advanced Settings.

Browser Requirements

To use Infrastructure Automation, the following browser requirements must be met:

- One of the following web browsers:
  - Google Chrome
  - Mozilla Firefox
  - Safari
  - Internet Explorer 10 or higher

Additional Requirements

Additionally, the following must be configured to use Infrastructure Automation:

- The Infrastructure Automation appliance must already be installed and activated in your enterprise environment.
- The SmartProxy must have visibility into the virtual machines and cloud instances that you want to control.
- For more information, see SmartProxies in the Infrastructure Automation *General Configuration* guide.

Terminology

The following terms are used throughout the documentation. Review them before proceeding.

- Account Role The level of access a user has to different parts and functions of the Infrastructure Automation console. There are a variety of Account Roles, which can be assigned to users to restrict or allow access to parts of the console and virtual infrastructure.
- Action An execution that is performed after a condition is evaluated.
- Alert Infrastructure Automation alerts notify administrators and monitoring systems of critical configuration changes and threshold limits in the virtual environment. The notification can take the form of either an email or an SNMP trap.
- Analysis Profile A customized scan of hosts, virtual machines, or instances. You can collect information from categories, files, event logs, and registry entries.

- Cloud A pool of on-demand and highly available computing resources. The usage of these resources are scaled depending on the user requirements and metered for cost.
- Infrastructure Automation Appliance A virtual machine where the virtual management database (VMDB) and Infrastructure Automation reside.
- Infrastructure Automation Console A web-based interface into the Infrastructure Automation appliance.
- Infrastructure Automation Role A designation assigned to a Infrastructure Automation server that defines what a Infrastructure Automation server can do.
- Infrastructure Automation Server The application that runs on the Infrastructure Automation appliance and communicates with the SmartProxy and the VMDB.
- Cluster Hosts that are grouped together to provide high availability and load balancing.
- Condition A control policy test triggered by an event, which determines a subsequent action.
- Discovery Process run by the Infrastructure Automation server which finds virtual machine and cloud providers.
- Drift The comparison of a virtual machine, instance, host, cluster to itself at different points in time.
- Event A trigger to check a condition.
- Event Monitor Software on the Infrastructure Automation appliance which monitors external providers for events and sends them to the Infrastructure Automation server.
- Host A computer running a hypervisor, capable of hosting and monitoring virtual machines. Supported hypervisors include RHV-H, VMware ESX hosts, Windows Hyper-V hosts.
- Instance/Cloud Instance A on-demand virtual machine based upon a predefined image and uses a scalable set of hardware resources such as CPU, memory, networking interfaces.
- Managed/Registered VM A virtual machine that is connected to a host and exists in the VMDB. Also, a template that is connected to a provider and exists in the VMDB. Note that templates cannot be connected to a host.
- Managed/Unregistered VM A virtual machine or template that resides on a repository or is no longer connected to a provider or host and exists in the VMDB. A virtual machine that was previously considered registered may become unregistered if the virtual machine was removed from provider inventory.
- Provider An external management system that Infrastructure Automation integrates in order to collect data and perform operations.
- Policy A combination of an event, a condition, and an action used to manage a virtual machine.
- Policy Profile A set of policies.
- Refresh A process run by the Infrastructure Automation server which checks for relationships of the provider or host to other resources, such as storage locations, repositories, virtual machines, or instances. It also checks the power states of those resources.
- Regions A region is the collection of zones that share the same database for reporting and charting. A master region may be added to synchronize multiple VMDBs into one VMDB for higher-level reporting, providing a “single pane of glass” view.
- Resource A host, provider, instance, virtual machine, repository, or datastore.
- Resource Pool A group of virtual machines across which CPU and memory resources are allocated.
- Repository A place on a datastore resource which contains virtual machines.
- SmartProxy The SmartProxy is a software agent that acts on behalf of the Infrastructure Automation appliance to perform actions on hosts, providers, storage and virtual machines.

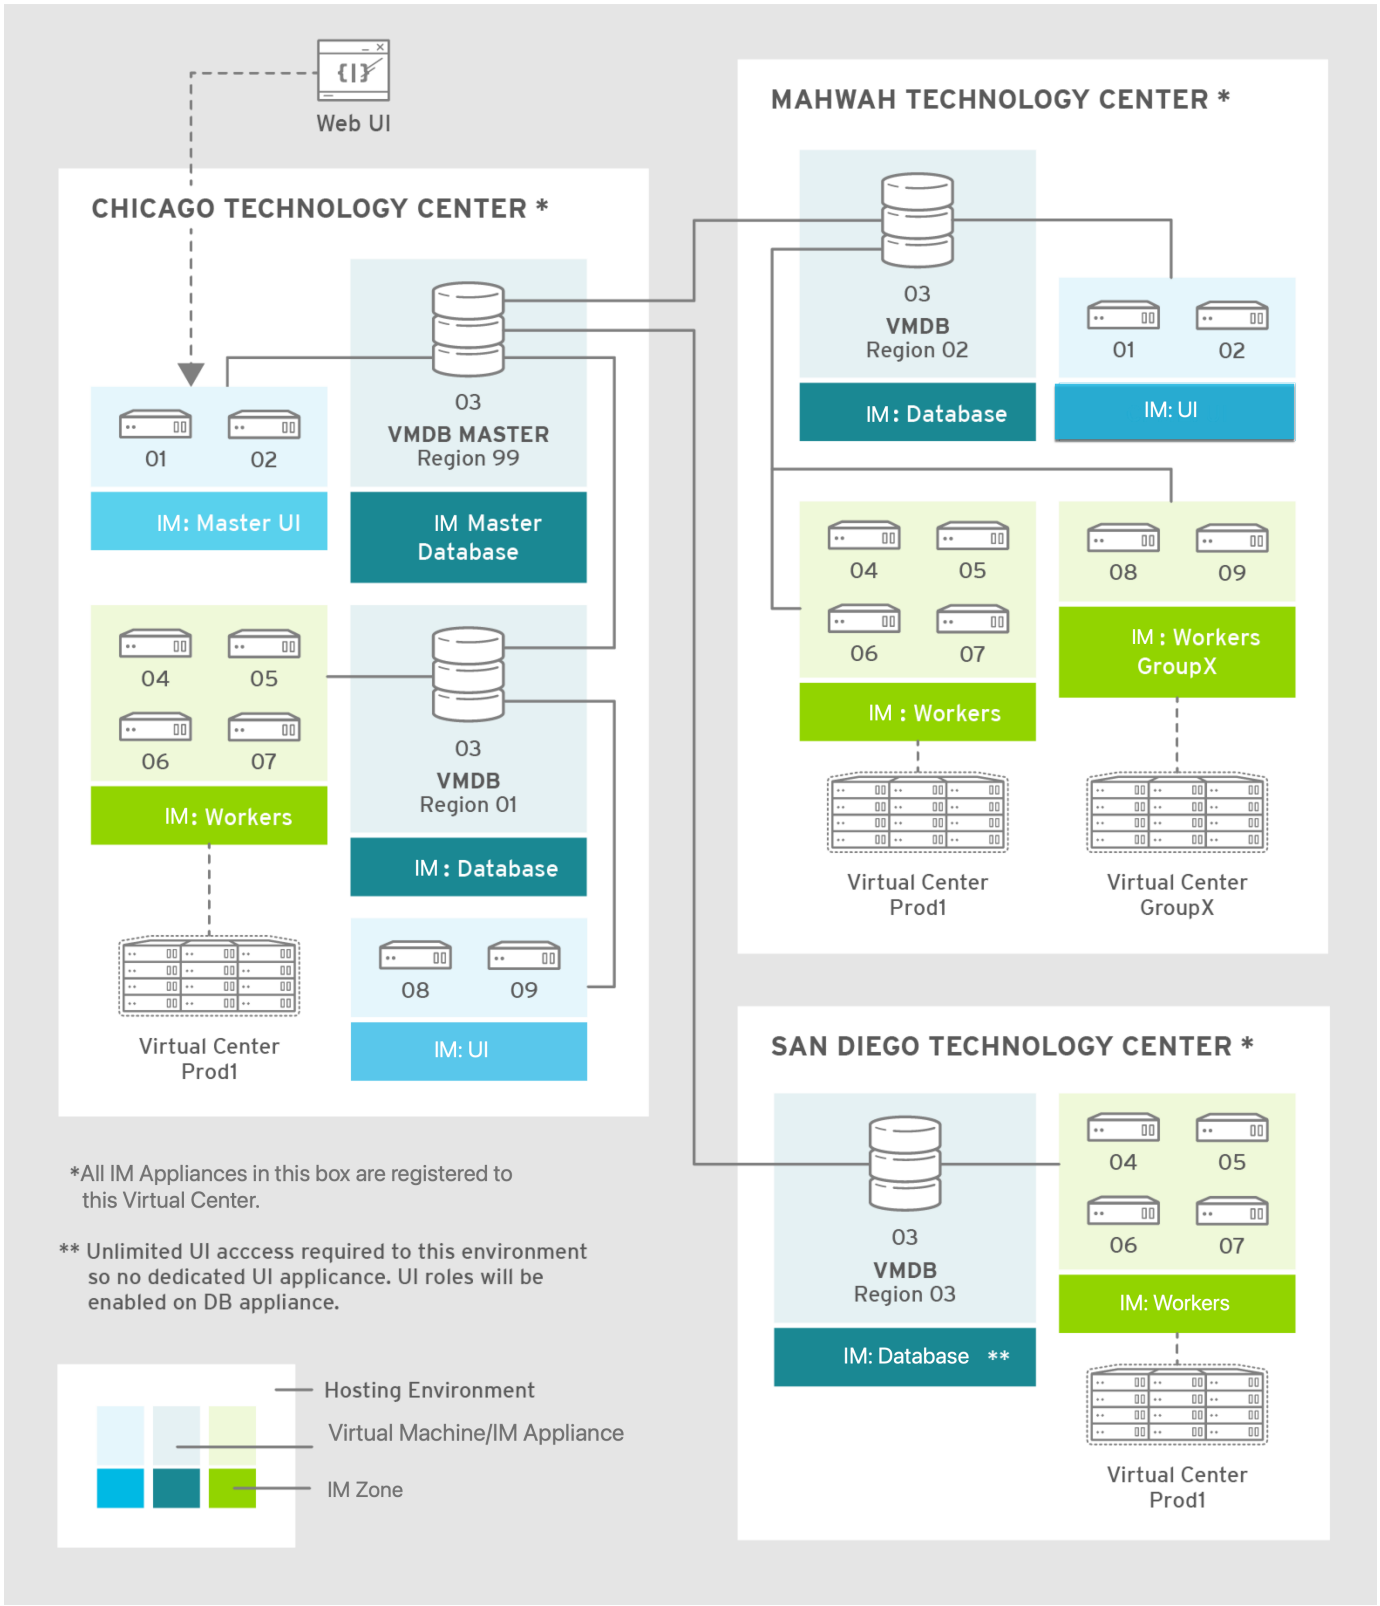
- The SmartProxy can be configured to reside on the Infrastructure Automation appliance or on an ESX server version. The SmartProxy can be deployed from the Infrastructure Automation appliance, and provides visibility to the VMFS storage. Each storage location must have a SmartProxy with visibility to it. The SmartProxy acts on behalf of the Infrastructure Automation appliance. If the SmartProxy is not embedded in the Infrastructure Automation server, it communicates with the Infrastructure Automation appliance over HTTPS on standard port 443.

- SmartState Analysis Process run by the SmartProxy which collects the details of a virtual machine or instance. Such details include accounts, drivers, network information, hardware, and security patches. This process is also run by the Infrastructure Automation server on hosts and clusters. The data is stored in the VMDB.
- SmartTags Descriptors that allow you to create a customized, searchable index for the resources in your clouds and infrastructure.
- Storage Location A device, such as a VMware datastore, where digital information resides that is connected to a resource.
- Tags Descriptive terms defined by a Infrastructure Automation user or the system used to categorize a resource.
- Template A template is a copy of a preconfigured virtual machine, designed to capture installed software and software configurations, as well as the hardware configuration, of the original virtual machine.
- Unmanaged Virtual Machine Files discovered on a datastore that do not have a virtual machine associated with them in the VMDB. These files may be registered to a provider that the Infrastructure Automation server does not have configuration information on. Possible causes may be that the provider has not been discovered or that the provider has been discovered, but no security credentials have been provided.
- Virtual Machine A software implementation of a system that functions similar to a physical machine. Virtual machines utilize the hardware infrastructure of a physical host, or a set of physical hosts, to provide a scalable and on-demand method of system provisioning.

- Virtual Management Database (VMDB) Database used by the Infrastructure Automation appliance to store information about your resources, users, and anything else required to manage your virtual enterprise.
- Virtual Thumbnail An image in the web interface representing a resource, such as a provider or a virtual machine, showing the resource's properties at a glance. Each virtual thumbnail is divided into quadrants, which provide information about the resource, such as its software and power state.
- Worker Appliance A Infrastructure Automation appliance dedicated to a role other than user interface or database.
- Zones Infrastructure Automation Infrastructure can be organized into zones to configure failover and to isolate traffic. Zones can be created based on your environment. Zones can be based on geographic location, network location, or function. When first started, new servers are put into the default zone. ## Planning

This guide provides some general guidelines to planning a deployment on Infrastructure Automation. This includes creating multiple regions containing Infrastructure Automation appliances, CPU sizing recommendations, database sizing recommendations, and database configuration.

Regions



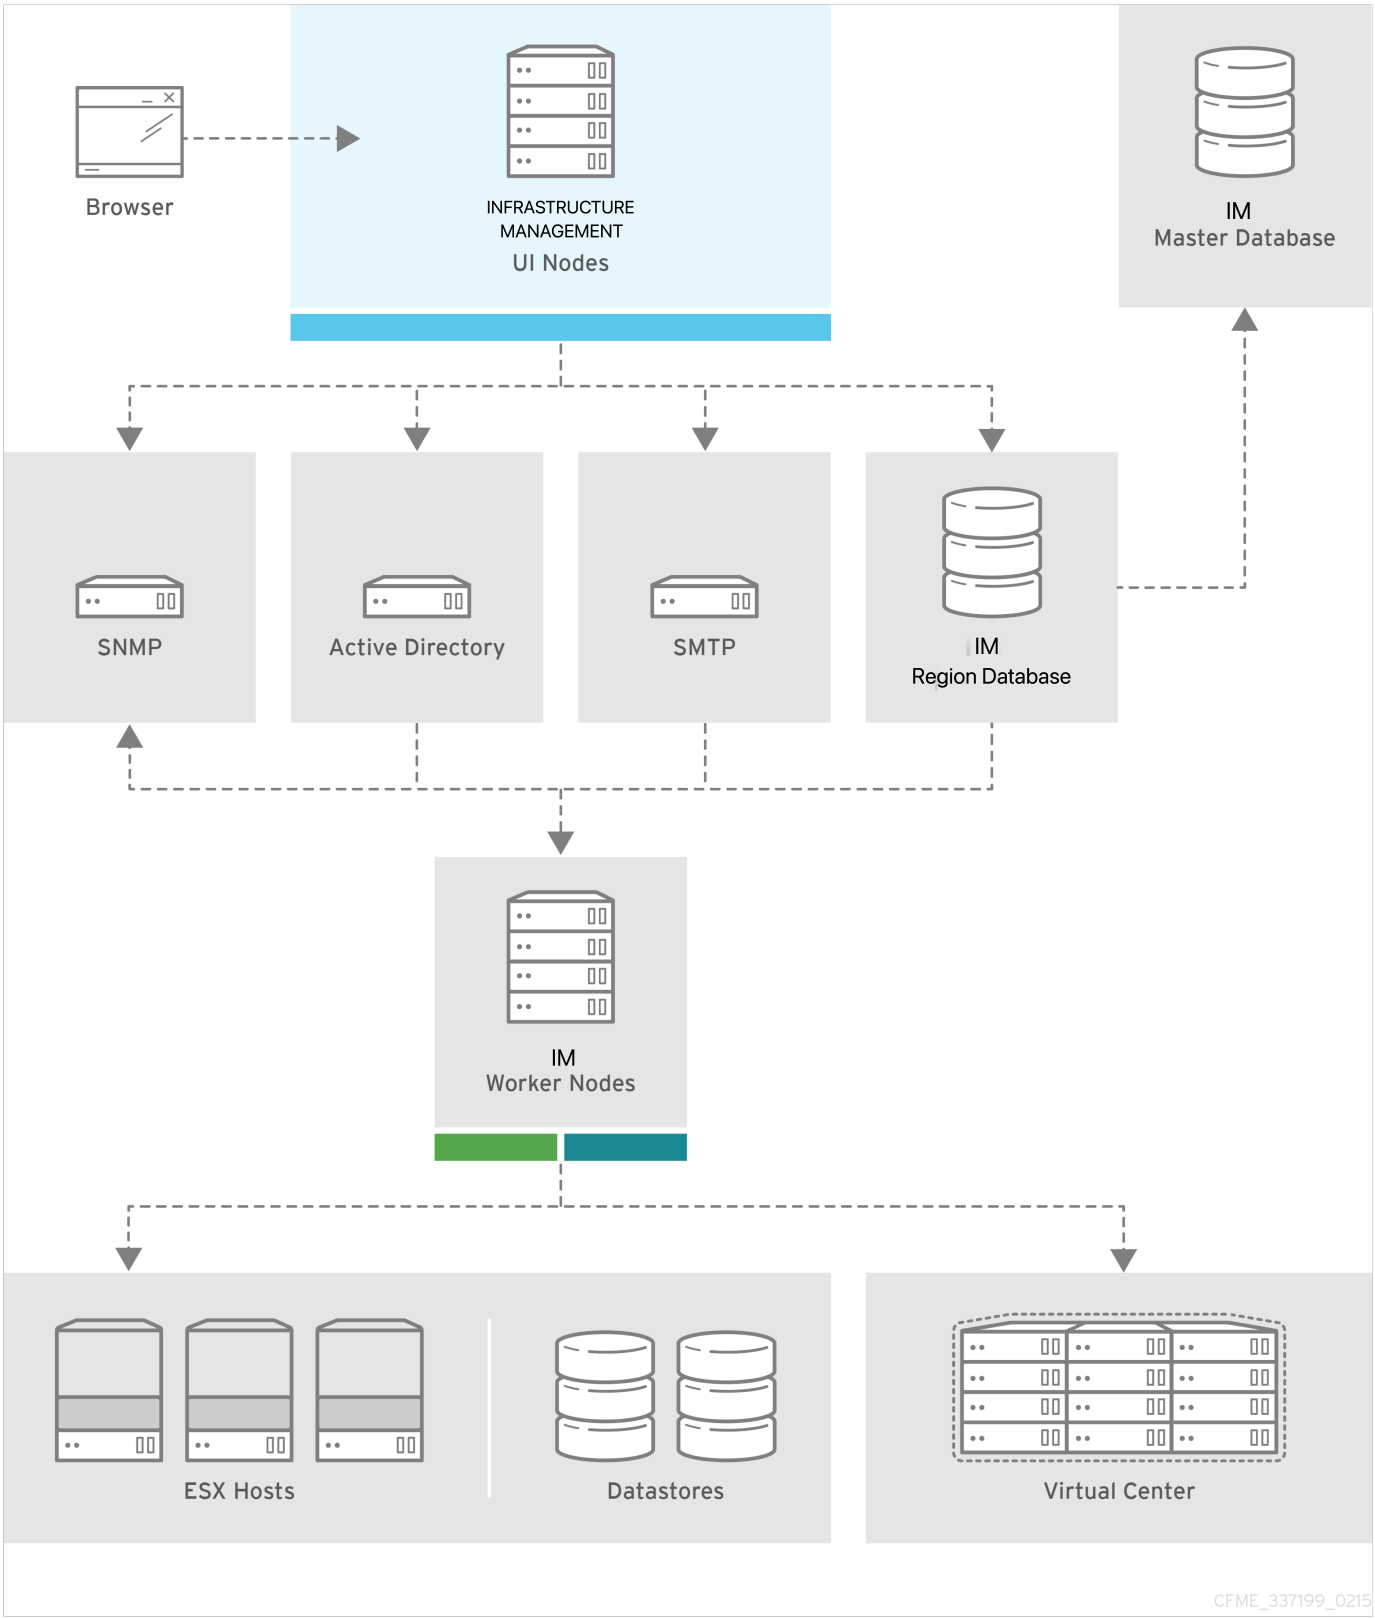
Regions are used for centralizing data which is collected from public and private virtualization environments. A region is ultimately represented as a single database for the VMDB. Regions are particularly useful when multiple geographical locations need to be managed, as they enable all the data collection to happen at each particular location and avoid data collection traffic across slow links between networks.

When multiple regions are being used, each with their own unique ID, a master region can be created to centralize the data of all the children regions into a single master database. To do this, configure each child region to replicate its data to the master region database (the recommended region is 99, though any number up to three digits will work). This parent and child region is a one-to-many relationship.

Regions can contain multiple zones, which in turn contain appliances. Zones are used for further segregating network traffic along with enabling failover configurations. Each appliance has the capability to be configured for a number of specialized server roles. These roles are limited to the zone containing the appliance they run on.

Only one failover type of each server role can run in a zone. If multiple appliances have the same failover role, the extras are used as backups that activate only if the primary appliance fails. Non-failover server roles can run on multiple appliances simultaneously in a zone, so resources can be adjusted according to the workload those roles are responsible for.

The following diagram demonstrates an example of the multiple regions working together in a Infrastructure Automation environment.



The master appliance is located in Chicago and contains a master region and a subregion that manages the worker appliances. The Mahwah technology center contains a single subregion that manages two zones. Likewise, the San Diego technology center contains a single subregion managing a single zone.

Note:

- Replicating a parent region to a higher-level parent is not supported.
- Parent regions can be configured after the child regions are online.

The following diagram provides a closer look at a region:

In this region, we have several Infrastructure Automation appliances acting as UI nodes and worker nodes. These worker nodes execute tasks on the providers in your environment. The region also uses a region database that reports to a master database on the main Infrastructure Automation appliance. All appliances can connect to the authentication services (Active Directory, LDAP, Identity Management), outgoing mail (SMTP), and network services (SNMP).

Note:

Infrastructure Automation can be configured in a highly available setup. In this case, all PostgreSQL instances must be running on a server that is deployed from the Infrastructure Automation appliance. High availability is achieved by database replication between two or more database servers.

Roles

Server roles define what a server can do. Assigning different server roles to appliances can allow them to focus on specific functions. When planning a deployment, consider which roles to assign to each appliance. Some server roles are enabled by default in Infrastructure Automation. Many server roles start worker processes.

Some roles are also dependent on other roles. For example, because the Infrastructure Automation user interface relies on the API for access, the Web Services role must be enabled with the User Interface role for users to log in to the appliance. See Server Roles in *General Configuration* for details on each server role and its function.

Appliance Types

Depending on the needs of your environment, you may choose to separate worker and database tasks between appliances. One example of this is to implement a highly available configuration so that certain appliances are running the PostgreSQL database and providing failover. For more details about configuring high availability, see the High Availability Guide.

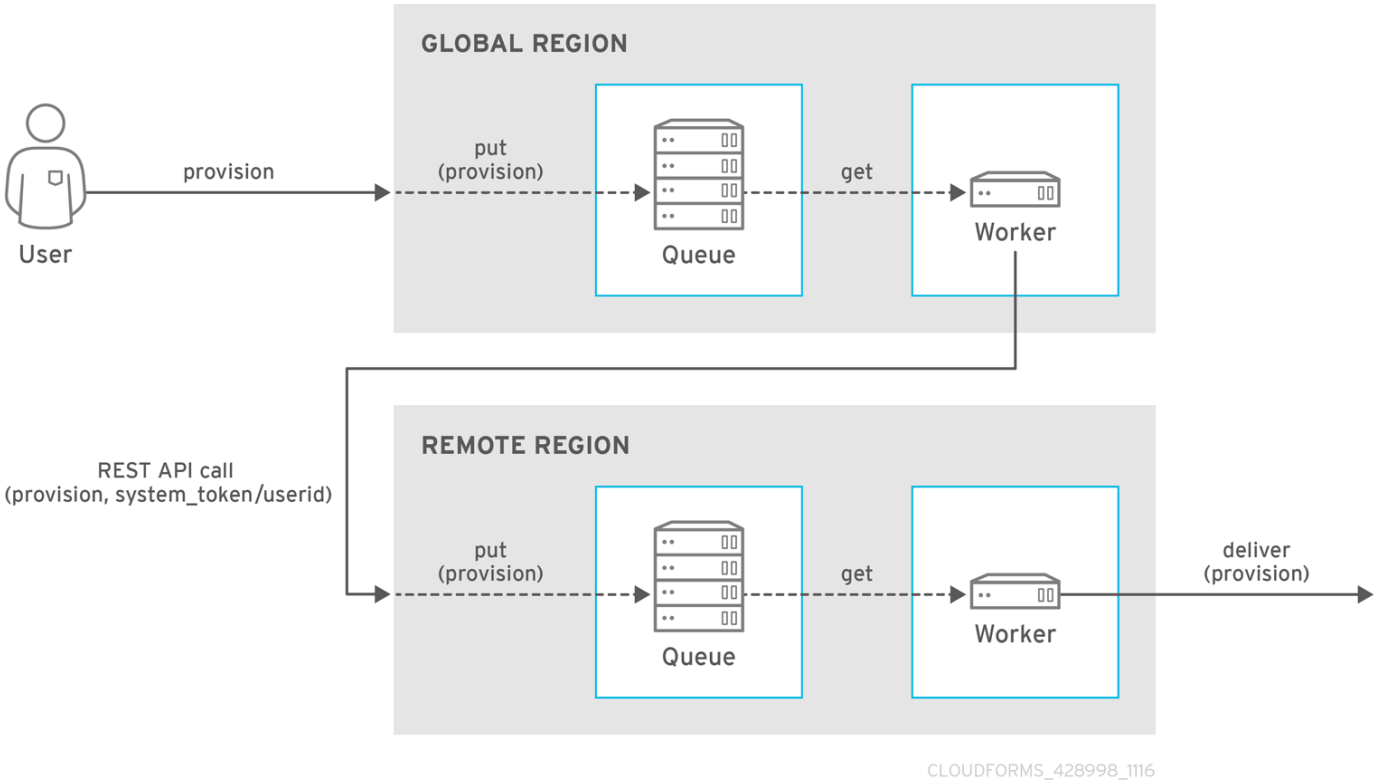
The following provides a summary of types of appliances:

Appliance Type	Database	Workers	Description
VMDB appliance	Yes	Yes	Worker processes are running, and it also hosts its own database that other appliances can connect to.
Non-database appliance	No	Yes	Worker processes are running on the appliance, but it does not host a database. The appliance is connected to an external database.
Dedicated-database appliance	Yes	No	This appliance contains no worker processes, only a database for other appliances to connect to.
Non-Infrastructure Automation VM with database	Yes	No	This appliance contains no worker processes, only a database. As this is not a Infrastructure Automation appliance, you cannot run any Infrastructure Automation `rake` tasks on it. This appliance must be migrated using a non-database appliance that is pointed at it, using it as a database.

Appliance types

Centralized Administration

Infrastructure Automation includes centralized administration capabilities, where certain operations can be initiated from the global region and processed and executed on remote regions. From the global region, you can also access the user interfaces of virtual machines residing in remote regions.



The following life cycle management operations can be initiated from the global region using centralized administration:

- Virtual machine provisioning
- Virtual machine power operations
- Virtual machine retirement
- Virtual machine reconfiguration
- Service provisioning
- Service retirement
- Opening a virtual machine in the remote region

Note:

Infrastructure Automation life cycle operations other than those listed above are not supported. Centralized administration capabilities are not supported from the Self Service user interface.

With centralized administration, the remote_queue_put leverages a new system-to-system REST API request to forward the original request to the remote region. This request is put in the local queue in the remote region, which is then delivered by a worker in the remote region as if it was queued there all along. As a result, a Infrastructure Automation operator in the global region can be seen as provisioning on behalf of a remote region.

Note:

The operations initiated from the global region are subject to the role-based access control (RBAC) rules on the remote region. The user in the remote region which matches the logged-in user's **user ID** will be used to enforce RBAC in the target region. The operation will fail on the remote system if the user does not have the required permissions.

Tenancy

Infrastructure Automation supports multitenancy. Tenants can be totally separate or they can be in a parent-child or peer relationship. Tenants in a relationship can share or inherit a certain configuration. You can subdivide and create child tenants and they, in turn, can have child tenants, and so on. The ability to have multi-level (nested) tenants in a hierarchy enables those at the bottom to inherit permissions from those above. This configuration allows for granular user permissions to be set on specific tenants.

A tenant can also contain a self-contained child tenant known as a 'project'. A project cannot have a child tenant, but is useful for allocating resources to a small group or team within a larger organization.

Note:

If you do not add any additional tenants, all resources and user accounts are contained in a single base tenant which is your Infrastructure Automation appliance itself. In Infrastructure Automation, is sometimes referred as 'tenant zero'.

Tenancy Account Roles.

In Infrastructure Automation, the following two account roles are associated with tenancy:

- Tenant administrator
- Tenant quota administrator

Tenant administrator and tenant quota administrator roles are like administrator and super administrator. These roles are not limited to the tenant upon which they are acting and act across all tenants, and therefore should be considered privileged users. These are not roles inside a tenant.
Tenancy Models.

The following two approaches exist for tenancy planning:

- **Tenantless** - You can create a single large tenant, sometimes referred as 'tenant zero', and perform all your operations in there without any subdivision of resources or user accounts.
- **Enterprise model** - A common scenario is to create a single tenant, and then subdivide it based on the structures or departments within your organization. Those departments are then able to further subdivide their resources into distinct projects. With this model, you have a single URL for user access, while still having the ability to divide resources into nested hierarchical tenants.

Tenancy Configuration.

You can create and configure tenancy using the Infrastructure Automation user interface in the same place you set up users, groups and roles by selecting **Configuration** from the settings menu, and then clicking on the **Access Control** accordion.

Tenancy in Automation.

One of the features of tenancy is that each tenant can have its own automate domain. Tenant-based domains can help in several use cases, such as if you have:

- groups that need their own naming routines
- varying types of approval needs
- departments that use different end ticketing systems
- a customer who is a holding company or centralized IT organization for managing different business units

Just like standard domains are nested, you can also add automate domains that are nested at the tenant level.

Tenancy Quota and Reporting.

You can allocate and enforce quotas for the following attributes:

- Virtual CPUs
- Memory in GB
- Storage in GB
- Number of virtual machines
- Number of templates

You can generate or schedule a report for **Tenant Quotas** similar to other reports.

Note:

Currently, in tenant quota reports you will see all of the tenants but there is no nesting information available by parent and child tenants.

Example:

In the following example of a tenant quota report, *DevOps Teams* is a parent tenant and *Team Alpha* and *Team Bravo* are child tenants.

Tenant Name	Quota Name	Total Quota	In Use	Allocated	Available
DevOps Teams	Allocated Virtual CPUs	125 Count	0 Count	75 Count	50 Count
DevOps Teams	Allocated Memory in GB	255.0 GB	0.0 GB	125.0 GB	130.0 GB
DevOps Teams	Allocated Storage in GB	1505.0 GB	0.0 GB	1100.0 GB	405.0 GB

- Total Quota: Total quota enforced per attribute for a tenant
- In Use: Amount of quota currently in use by tenants
- Allocated: Amount of quota given to all child tenants
- Available: *Total Quota* minus (-) *In Use* minus (-) *Allocated*

Tenancy Chargeback.

You have the ability to do tenancy in chargeback where you are able to assign rates and have a different rate for each tenant. You can make use of the default rate or create your own set of rates depending on the tenant. As well, there is an ability to create chargeback reports by tenant.

Tenancy Service Catalogs.

Similar to automate domains, you can have service catalogs at each level of tenancy. Once you add a service catalog at a particular level of tenancy, it is visible to that tenant and its children (unless you use tagging to exclude).

Tenancy Providers.

Providers can be added at any level of tenancy. Once added, a provider is visible to any child or lower tenants, making it possible to easily separate resources that are owned or accessed by one group, and should not be available to other tenants.

Tenancy Relationships and Properties.

The tenant summary page found in **Configuration > Access Control > Tenants > Tenant** provides detailed information about the tenant and its relationships including:

- Catalog items and bundles
- Automate domains
- Provider relationships

Using a Load Balancer

Deploying multiple user interface worker appliances and placing them behind a third-party load balancer allows for redundancy and improved performance. This requires extra configuration in both the load balancer and in the Infrastructure Automation user interface worker appliances.

Configuring the Load Balancer

- Configure the load balancer to use sticky sessions. This ensures that when a session is started, all requests for that session are sent to the same worker appliance.
- Configure the load balancer to test for connectivity using the Infrastructure Automation ping response page: **`https://appliance_name/ping`**. The expected reply from the appliance is the text string *pong*. Using this URL is preferable to the appliance login URL as it does not establish a connection to the database.

Configuring Worker Appliances for Load Balancing

When using a load balancer, configure appliances that have the **User Interface** role enabled to store session data in the database. As a result, the user does not need to re-login if the load balancer redirects them to an alternative server in the case the original user interface worker is unresponsive.

On each appliance, configure the session data storage location using the **`session_store`** parameter within the advanced settings page in the Infrastructure Automation user interface:

1. Click  (**Configuration**).
2. Click the **Advanced** tab.
3. Change the **`session_store`** parameter to **`sql`** in the following line (the default parameter is **`cache`**):

```
:server:
...
 :session_store: sql
```

4. Click **Save**.

Configure the `session_store` parameter to point to `sql` on each user interface appliance behind the load balancer.

Database Configuration

This section describes the Infrastructure Automation PostgreSQL database configuration. The below table provides information on each file: its location, primary function, and notes regarding behavior or recommendations.

File	Location	Description	Note
`postgresql.conf`	Data Directory	Default server configuration	Adds directive to include **`/etc/manageiq/postgresql.conf.d`** directory
`postgresql.auto.conf`	Data Directory	Contains configuration set by the **`ALTER SYSTEM`** command	**Do not edit manually**
`01_miq_overrides.conf`	**`/etc/manageiq/postgresql.conf.d`**	Contains Infrastructure Automation default overrides	Overwritten on upgrades
<other files>	**`/etc/manageiq/postgresql.conf.d`**	Contains user overrides	Takes precedence if alphabetically after **`01_miq_overrides.conf`**

Database files

User Overrides

Store custom configurations, or user overrides, in **`/etc/manageiq/postgresql.conf.d`**. Name the user override file so that it follows **`01_miq_overrides.conf`** alphabetically. This ensures custom configurations are not overwritten on Infrastructure Automation upgrades.

The following file name example follows **`01_miq_overrides.conf`** alphabetically in the **`/etc/manageiq/postgresql.conf.d`** directory:

Example:

`test_miq_overrides.conf`

Reading Configuration Settings

Query the Infrastructure Automation PostgreSQL database directly to read configuration settings. See the PostgreSQL Documentation for more information.

The following example queries the Infrastructure Automation for current value set for **`max_wal_senders`**:

Example:

```
`psql -d vmdb_production -c 'show max_wal_senders'
```

Capacity Planning

Capacity and Utilization Collection

Infrastructure Automation server can collect and analyze capacity and utilization data from your virtual infrastructure. Use this data to understand the limitations of your current environment and plan for growth.

For some capacity and utilization data, Infrastructure Automation calculates and shows trend lines in the charts. Trend lines are created by using linear regression, which is calculated by using the capacity and utilization data that is collected by Infrastructure Automation during the interval you specify for the chart. The more data that you have the better the predictive value of the trend line.

Three server roles are associated with the collection and metric creation of capacity and utilization.

- The Capacity & Utilization Coordinator role checks to see whether it is time to collect data, somewhat like a scheduler. If it is time, a job is queued for the Capacity & Utilization Data Collector. The Coordinator role is required to complete capacity and utilization data collection. If more than one server in a specific zone has this role, only one is active at a time.
- The Capacity & Utilization Data Collector performs the actual collection of capacity and utilization data. This role has a dedicated worker, and there can be more than one server with this role in a zone.
- The Capacity & Utilization Data Processor processes all of the data that is collected, allowing Infrastructure Automation to create charts. This role has a dedicated worker, and there can be more than one server with this role in a zone.

Assigning the Capacity and Utilization Server Roles

1. Click **Configuration**, then select the server to configure from menu: **Settings > Zone** in the accordion menu on the left.
2. Browse to the **Server Roles** list in the menu: **Server > Server Control** section. From there, set the required capacity and utilization roles to **ON**, namely:
    1. **Capacity & Utilization Coordinator**
    2. **Capacity & Utilization Data Collector**
    3. **Capacity & Utilization Data Processor**
3. Click **Save**.

Data collection is enabled immediately. However, the first collection begins 5 minutes after the server is started, and every 10 minutes after that. Therefore, the longest the collection takes after enabling the Capacity & Utilization Collector role is 10 minutes. The first collection from a particular provider may take a few minutes since Infrastructure Automation is gathering data points going one month back in time.

Note:

In addition to setting the server role, you must also select which clusters and data stores to collect data for. For more information, see the **General Configuration** guide. You must have super administrator privileges to edit these settings.

Adding Database Credentials for Data Collection

After you create the new user, add the user's credentials to the settings for the provider.

1. From menu: **Compute > Infrastructure > Providers**, select an infrastructure provider to update its settings.
2. Click **Configuration**, and then **Edit Selected Infrastructure Provider**.
3. In the **Credentials** area, click **C & U Database**.
4. Type in the credentials for the new database user you created.
5. Click **Save**.
6. Restart the Capacity and Utilization Data Collector.

Data Collection for Red Hat Virtualization

To collect capacity and utilization data for Red Hat Virtualization (RHV), you must add a user to the RHV-M history database for Infrastructure Automation to use.

Perform this procedure on the PostgreSQL server where the history database (ovirt_engine_history) is located. Usually, this is the RHV-M server.

1. Using SSH, access the RHV-M database server as the root user:

    ```
    $ ssh root@example.postgres.server
    ```

2. Switch to the postgres user:

```
# su - postgres
```

For RHV 4.2 and 4.3, the PostgreSQL database is delivered as a software collection in version 9.5 and must be enabled first. Therefore, to run the following psql commands, you need to enable the *rh-postgresql95* collection and load into the current shell prompt by using the source command: $ source /opt/rh/rh-postgresql95/enable

3. Create the user for Infrastructure Automation to be granted read-only access to the history database:

```
$ psql -U postgres -c "CREATE ROLE example_role_name WITH LOGIN ENCRYPTED PASSWORD '[password]';" -d
ovirt_engine_history
```

4. Grant the newly created user permission to connect to the history database:

```
$ psql -U postgres -c "GRANT CONNECT ON DATABASE ovirt_engine_history TO example_role_name;"
```

5. Grant the newly created user usage of the public schema:

```
$ psql -U postgres -c "GRANT USAGE ON SCHEMA public TO example_role_name;" ovirt_engine_history
```

6. Generate the rest of the permissions that will be granted to the newly created user and save them to a file:

```
$ psql -U postgres -c "SELECT 'GRANT SELECT ON ' || relname || ' TO example_role_name;' FROM pg_class JOIN
pg_namespace ON pg_namespace.oid = pg_class.relnamespace WHERE nspname = 'public' AND relkind IN ('r', 'v', 'S');" --
pset=tuples_only=on  ovirt_engine_history > grant.sql
```

7. Use the file that you created in the previous step to grant permissions to the newly created user:

```
$ psql -U postgres -f grant.sql ovirt_engine_history
```

8. Remove the file that you used to grant permissions to the newly created user:

```
$ rm grant.sql
```

9. Exit to the RHV-M database server prompt:

```
$ exit
```

10. Update the server's firewall to accept TCP communication on port 5432:

```
# firewall-cmd --add-port=5432/tcp --permanent
```

11. Enable external md5 authentication.

    1. For RHV 4.0, 4.1, and 4.4 update the following line in **/var/lib/pgsql/data/pg_hba.conf**:

       ```
       host    all      all    0.0.0.0/0     md5
       ```

    2. For RHV 4.2 and 4.3, update the following line in **/var/opt/rh/rh-postgresql95/lib/pgsql/data/pg_hba.conf**:

       ```
       host    all      all    0.0.0.0/0     md5
       ```

12. Enable PostgreSQL to listen for remote connections.

    1. For RHV 4.0, 4.1, and 4.4 ensure the **listen_addresses** line in **/var/lib/pgsql/data/postgresql.conf** matches the following example:

       ```
       listen_addresses  =  '*'
       ```

    2. For RHV 4.2 and 4.3, ensure the **listen_addresses** line in **/var/opt/rh/rh-postgresql95/lib/pgsql/data/postgresql.conf** matches the following example:

       ```
       listen_addresses  =  '*'
       ```

13. Reload the PostgreSQL configuration.

    1. For RHV 4.0, 4.1, and 4.4:

       ```
       # systemctl reload postgresql
       ```

    2. For RHV 4.2 and 4.3:

       ```
       # systemctl reload rh-postgresql95-postgresql
       ```

Data Collection for Red Hat Enterprise Linux OpenStack Platform

Before you can collect data from a Red Hat Enterprise Linux OpenStack Platform (RHEL-OSP) provider, you must install Ceilometer and configure it to accept queries from external systems.

These instructions require a Red Hat Enterprise Linux 6.4 @base installation of RHEL-OSP and registration to a satellite that has access to both the **RHEL-OSP** and **RHEL Server Optional** channels. Perform all steps on your RHEL-OSP system.

1. Add the required channels and update your system:

```
# rhn-channel --add -c rhel-x86_64-server-6-ost-3 -c rhel-x86_64-server-optional-6
# yum update -y
# reboot
```

2. Install **Ceilometer**:

```
# yum install *ceilometer*
```

3. Install and start the MongoDB store:

```
# yum install mongodb-server
# sed -i '/--smallfiles/!s/OPTIONS=\"/OPTIONS=\"--smallfiles /' /etc/sysconfig/mongod
# service mongod start
```

4. Create the following users and roles:

```
# SERVICE_TENANT=$(keystone tenant-list | grep services | awk '{print $2}')
# ADMIN_ROLE=$(keystone role-list | grep ' admin ' | awk '{print $2}')
# SERVICE_PASSWORD=servicepass
# CEILOMETER_USER=$(keystone user-create --name=ceilometer \
--pass="$SERVICE_PASSWORD" \
--tenant_id $SERVICE_TENANT \
--email=ceilometer@example.com | awk '/ id / {print $4}')
# RESELLER_ROLE=$(keystone role-create --name=ResellerAdmin | awk '/ id / {print $4}')
# ADMIN_ROLE=$(keystone role-list | awk '/ admin / {print $2}')
# for role in $RESELLER_ROLE $ADMIN_ROLE ; do
keystone user-role-add --tenant_id $SERVICE_TENANT \
--user_id $CEILOMETER_USER --role_id $role
done
```

5. Configure the authtoken in **ceilometer.conf**:

```
# openstack-config --set /etc/ceilometer/ceilometer.conf keystone_authtoken auth_host 127.0.0.1
# openstack-config --set /etc/ceilometer/ceilometer.conf keystone_authtoken auth_port 35357
# openstack-config --set /etc/ceilometer/ceilometer.conf keystone_authtoken auth_protocol http
# openstack-config --set /etc/ceilometer/ceilometer.conf keystone_authtoken admin_tenant_name services
# openstack-config --set /etc/ceilometer/ceilometer.conf keystone_authtoken admin_user ceilometer
# openstack-config --set /etc/ceilometer/ceilometer.conf keystone_authtoken admin_password $SERVICE_PASSWORD
```

6. Configure the user credentials in **ceilometer.conf**:

```
# openstack-config --set /etc/ceilometer/ceilometer.conf DEFAULT os_auth_url http://127.0.0.1:35357/v2.0
# openstack-config --set /etc/ceilometer/ceilometer.conf DEFAULT os_tenant_name services
# openstack-config --set /etc/ceilometer/ceilometer.conf DEFAULT os_password $SERVICE_PASSWORD
# openstack-config --set /etc/ceilometer/ceilometer.conf DEFAULT os_username ceilometer
```

7. Start the Ceilometer services:

```
# for svc in compute central collector api ; do
  service openstack-ceilometer-$svc start
  done
```

8. Register an endpoint with the service catalog. Replace **$EXTERNALIFACE** with the IP address of your external interface:

```
# keystone service-create --name=ceilometer \
--type=metering --description="Ceilometer Service"
# CEILOMETER_SERVICE=$(keystone service-list | awk '/ceilometer/ {print $2}')
# keystone endpoint-create \
--region RegionOne \
--service_id $CEILOMETER_SERVICE \
--publicurl "http://$EXTERNALIFACE:8777/" \
--adminurl "http://$EXTERNALIFACE:8777/" \
--internalurl "http://localhost:8777/"
```

9. Enable access to Ceilometer from external systems:

```
# iptables -I INPUT -p tcp -m multiport --dports 8777 -m comment --comment "001 ceilometer incoming" -j ACCEPT
# iptables save
```

10. Confirm the status of OpenStack and the Ceilometer services:

```
# openstack-status
# for svc in compute central collector api ; do
  service openstack-ceilometer-$svc status
  done
```

11. Verify that Ceilometer is working correctly by authenticating as a user with running instances, for example **admin**. Pipe the sample for the CPU meter to count lines, and confirm that the value changes according to the interval specified in **/etc/ceilometer/pipeline.yaml**. The default interval is 600 seconds.

```
# . ~/keystonerc_admin
# ceilometer sample-list -m cpu |wc -l
```

12. Add the configured OpenStack provider to Infrastructure Automation. See After adding the provider, capacity, and utilization data for your instances populate in a few minutes.

Capacity and Utilization Data Collected

Infrastructure Automation generates charts from the collected data that can be used to plan your hardware and virtual machine needs. Depending on the type of data, these charts can include lines for averages, maximums, minimums, and trends.

Note:

For reporting of daily capacity and utilization data, incomplete days (days with less than 24 hourly data points from midnight to midnight) that are at the beginning or end of the requested interval are excluded. Days with less than 24 hourly data points would be inaccurate and including them would skew trend lines. Therefore, at least one full day of hourly data from midnight to midnight is necessary for displaying the capacity and utilization charts under the menu: **Compute > Infrastructure** tab.

Capacity and Utilization Charts for Hosts, Clusters, and Virtual Machines

Resource Type	CPU Usage	CPU States	Disk I/O	Memory Usage	Network I/O	Running VMS	Running Hosts
Host	Y	Y	Y	Y	Y	Y	NA
Cluster	Y	Y	Y	Y	Y	Y	Y
Virtual Machine	Y	Y	Y	Y	Y	NA	NA

Capacity and Utilization Charts for Hosts, Clusters, and Virtual Machines

Capacity and Utilization Charts for Datastores

Charts that are created include:

Space by VM Type	Virtual Machines and Hosts
Used Space	Number of VMs by Type
Disk files Space	Hosts
Snapshot Files Space	Virtual Machines
Memory Files Space	
Non-VM Files	
Used Disk Space	

Capacity and Utilization Charts for Datastores

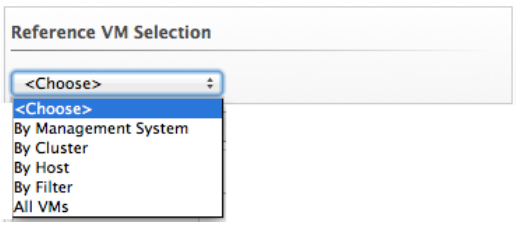
Capacity and Utilization Chart Features

Capacity and utilization charts for host, clusters, virtual machines, and datastore provides its own set of special features that include zooming in on a chart and shortcut menus.

Zooming into a Chart

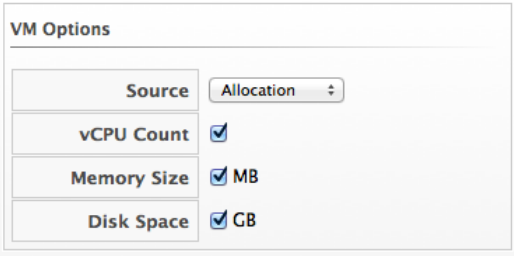
1. Browse to the chart you want to zoom. If you hover anywhere on the chart, two dashed lines appear to target a coordinate of the chart.
2. Click (**Click to zoom in**) in the lower left corner of the chart to zoom into it.
3. To go back to the regular view click (**Click to zoom out**) on the enlarged chart.

Drilling into Chart Data



1. Browse to the chart you want to get more detail from.
2. Hover over a data point to see the coordinates.
3. Click a data point to open a shortcut menu for the chart. In this example, you can use the shortcut menu to go to the hourly chart or display the virtual machines that were running at the time the data was captured.
    - If you are viewing the **CPU**, **Disk**, **Memory**, or **Network** charts, selecting from the **Chart** option will change all of the charts on the page to the new interval selected.
    - If you are viewing the **CPU**, **Disk**, **Memory**, or **Network** charts, selecting from the **Display** option will allow you to drill into the virtual machines or **Hosts** that were running at the time.
    - If you are viewing the **VM** or **Hosts** chart, the **Display** menu allows you to view running or stopped virtual machines. The time of the data point will be displayed in addition to the virtual machines that apply. From here, click a virtual machine to view its details.

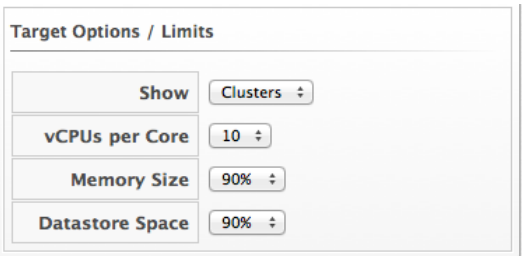
Planning Where to Put a New Virtual Machine



You can use the data that is collected in the VMDB to plan where you can put more virtual machines. With Infrastructure Automation, you can use a reference virtual machine as an example to plan on which hosts and clusters you can place a new virtual machine.

** Note:** For more information about utilization trends and identifying bottlenecks in your environment, see Data Optimization in Managing Infrastructure and Inventory.

1. Browse to **Optimize > Planning**.
2. From **Reference VM Selection**, use the drop-down menu to select the virtual machine that is most like the one that you want to add.



3. Select the required VM Options for what you want to base the calculations on.

From the **Source** list, select the type of data to use as the source for your projections. For example, select **Allocation** to calculate based on the current allocation values of each resource (CPU, memory, or disk space) for the reference virtual machine. Use **Reservation** to project based on the current guaranteed value of the specific resource (CPU Speed, CPU count, memory, or disk space) although that amount might not be allocated to the virtual machine at a specific moment in time. Select **Usage** if you want to calculate based on usage history of the reference virtual machine. Use **Manual Input** to enter your own set of parameters for each resource.

4. From **Target Options / Limits**, select if you want to use clusters or hosts as your targets.

Also, select the limit of how high the projection can go for CPU, memory, and datastore space. If you are targeting hosts, you are able to select a filter for which hosts can be targets.

5. From Trend Options, select how far back you want to use the trend data for, a Time Profile and Time Zone if applicable. Note that Time Profile will only show if the logged on user has a Time Profile available.
6. Click Submit.

The **Summary** tab shows the best clusters or hosts on which to place the virtual machines. The **Report** tab shows the best fit and statistics on the reference virtual machine in a tabular format. From the **Report** tab, you can also create a PDF of the report or download the data in `txt` or `csv` format.

Appendix

Example PostgreSQL Configuration File

```
# -----------------------------
# PostgreSQL configuration file - MIQ Dedicated Appliance Configuration
# -----------------------------
#
# This file consists of lines of the form:
#
#   name = value
#
# (The "=" is optional.)  Whitespace may be used.  Comments are introduced with
# "#" anywhere on a line.  The complete list of parameter names and allowed
# values can be found in the PostgreSQL documentation.
#
# The commented-out settings shown in this file represent the default values.
# Re-commenting a setting is NOT sufficient to revert it to the default value;
# you need to reload the server.
#
# This file is read on server startup and when the server receives a SIGHUP
# signal.  If you edit the file on a running system, you have to SIGHUP the
# server for the changes to take effect, or use "pg_ctl reload".  Some
# parameters, which are marked below, require a server shutdown and restart to
# take effect.
#
# Any parameter can also be given as a command-line option to the server, e.g.,
# "postgres -c log_connections=on".  Some parameters can be changed at run time
# with the "SET" SQL command.
#
# Memory units:  kB = kilobytes        Time units:  ms  = milliseconds
#                MB = megabytes                     s   = seconds
#                GB = gigabytes                     min = minutes
#                                                   h   = hours
#                                                   d   = days

#------------------------------------------------------------------------------
# FILE LOCATIONS
#------------------------------------------------------------------------------
```

```
# The default values of these variables are driven from the -D command-line
# option or PGDATA environment variable, represented here as ConfigDir.

#data_directory = 'ConfigDir'       # use data in another directory
                    # (change requires restart)

Integration with OpenShift Container Platform

Overview

This guide walks you through adding a Red Hat OpenShift Container Platform cluster to a Infrastructure Automation container provider catalog. This deployment focuses on enabling the OpenShift Container Platform cluster metrics plug-in, so that Infrastructure Automation can collect information from an OpenShift Container Platform cluster upon integration.

Each procedure in this guide is covered in greater detail in the Infrastructure Automation and OpenShift Container Platform product documentation. However, links to the corresponding sections are provided for more detail.

The following sections will describe the required configuration for both products prior to integration.

Prerequisites

This guide assumes that you have:

- Already deployed Infrastructure Automation on your chosen platform
- Already deployed OpenShift Container Platform

When enabling metrics on OpenShift Container Platform, you can store your metrics data on *persistent* or *non-persistent* storage. To use persistent storage, you need to provision a persistent volume specifically for this purpose before configuring the metrics components. See Persistent Volumes in the OpenShift Container Platform *Architecture* documentation for more information.

Retrieving the OpenShift Container Platform Management Token

After enabling cluster metrics on your OpenShift Container Platform deployment, retrieve the *management token* while you are still logged in to the OpenShift Container Platform host. This will be required later in Adding OpenShift Container Platform as a Container Provider.

Run the following to obtain the token needed to add a Red Hat OpenShift provider:

1. Obtain the **management** service account token name:

```
# oc describe sa -n $project_name $service_account_name
...
Tokens:  management-admin-token-0f3fh
         management-admin-token-q7a87
```

2. Select and describe one of the tokens to retrieve the full token output, replacing **management-admin-token-0f3fh** with the name of your token:

```
# oc describe secret -n $project_name management-admin-token-0f3fh
...
Data
====
token:  eyJhbGciOiJSUzI1NiI...
```

Configuring Infrastructure Automation

Configuring Infrastructure Automation involves two steps:

1. Configuring Infrastructure Automation Capacity and Utilization, and

2. Enabling SmartState Analysis

These steps are required to allow Infrastructure Automation to collect metrics from OpenShift Container Platform Enabling OpenShift Container Platform Metrics and use them to perform a SmartState analysis. You can choose different servers to perform either function; the following sections assume that you will.

Configuring Infrastructure Automation Capacity and Utilization

For metrics collection to work properly, you also need to configure Infrastructure Automation to allow for all three **Capacity & Utilization** server roles, which are available from the settings menu under **Configuration > Server > Server Control**.

To enable these server roles:

1. Click **Configuration**, then select the server to configure from menu: **Settings > Zone** in the accordion menu on the left.
2. Browse to the **Server Roles** list in the menu: **Server > Server Control** section. From there, set the required capacity and utilization roles to **ON**, namely:
    1. **Capacity & Utilization Coordinator**
    2. **Capacity & Utilization Data Collector**
    3. **Capacity & Utilization Data Processor**
3. Click **Save**.

Data collection is enabled immediately. However, the first collection begins 5 minutes after the server is started, and every 10 minutes after that. Therefore, the longest the collection takes after enabling the Capacity & Utilization Collector role is 10 minutes. The first collection from a particular provider may take a few minutes since Infrastructure Automation is gathering data points going one month back in time.

For more information, see Capacity and Utilization Collection in the *Deployment Planning Guide*.

Enabling SmartState Analysis

After enabling the required server roles, enable SmartState analysis. See Smart State Analysis Support from the Support Matrix.

Enabling SmartState analysis is similar to Assigning the Capacity and Utilization Server Roles, in that the procedure also involves enabling server roles on a specific server. To do so:

1. Click **Configuration**.
2. Select the server to configure from menu: **Settings**[Zone] in the left pane of the appliance.
3. Browse to the **Server Roles** list in the menu: **Server > Server Control** section. From there, set the appropriate SmartState roles to **ON**. Namely:
    1. **SmartProxy**
    2. **SmartState Analysis**
4. Click **Save**.

Adding OpenShift Container Platform as a Container Provider

At this point, you should now be ready to add your OpenShift cluster to Infrastructure Automation as a container provider. To do so, prepare the token you retrieved in Retrieving the OpenShift Container Platform Management Token and follow the procedure below:

1. Browse to menu: **Compute > Containers > Providers**.
2. Click **Configuration**, then click (**Add a New Containers Provider**).
3. Enter a **Name** for the provider.
4. From the **Type** list, select **OpenShift Container Platform**.
5. Enter the appropriate **Zone** for the provider. If you do not specify a zone, it is set to **`default`**.
6. In the **Default** tab, configure the following for the OpenShift provider:
    1. Select a **Security Protocol** method to specify how to authenticate the provider:
        - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.
        - **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.

          Note:

          You can obtain your OpenShift Container Platform provider's CA certificate for all endpoints (default, metrics, alerts) from **`/etc/origin/master/ca.crt`**. Paste the output (a block of text starting with **`-----BEGIN CERTIFICATE-----`**) into the **Trusted CA Certificates** field.
        - **SSL without validation**: Authenticate the provider insecurely (not recommended).

2. Enter the **Hostname** (or IPv4 or IPv6 address) of the provider.

   Important:

   The **Hostname** must use a unique fully qualified domain name.

3. Enter the **API Port** of the provider. The default port is **6443**.

4. Enter a token for your provider in the **Token** box.

   Note:

   To obtain a token for your provider, run the **oc get secret** command on your provider; see Obtaining an OpenShift Container Platform Management Token.

   For example:

   # oc get secret –namespace management-infra management-admin-token-8ixxs –template='' | base64 –decode

5. Click **Validate** to confirm that Infrastructure Automation can connect to the OpenShift Container Platform provider.

7. In the **Metrics** endpoint tab optionally configure the metrics service details:

   1. Select a service type (e.g.: Prometheus) or leave disabled

   2. Select a **Security Protocol** method to specify how to authenticate the service:

      - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.
      - **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.
      - **SSL without validation**: Authenticate the provider insecurely using SSL. (Not recommended)

   3. Enter the **Hostname** (or IPv4 or IPv6 address) of the metrics service.

      In order to find the hostname you can use the **oc get route** command.

      You can retrieve the Prometheus route by running:

      ```
      oc get route prometheus-k8s -n openshift-monitoring
      ```

      Example:

      ```
      oc get route prometheus-k8s -n openshift-monitoring
      NAME              HOST/PORT                                          PATH              SERVICES   PORT
      TERMINATION          WILDCARD
      prometheus-k8s   prometheus-k8s-openshift-monitoring.ocp.example.com  prometheus-k8s   web
      reencrypt/Redirect   None
      ```

      In this example you would use **prometheus-k8s-openshift-monitoring.ocp.example.com** as the metrics hostname.

   4. Enter the **API Port** of your metrics endpoint uses a non-standard port for access. The default port is **443**.

   5. Click **Validate** to confirm that Infrastructure Automation can connect to the metrics endpoint.

8. In the **Virtualization** endpoint tab optionally configure the virtualization service details:

   1. Select a service type (OpenShift Virtualization / KubeVirt) or leave disabled

   2. Select a **Security Protocol** method to specify how to authenticate the service:

      - **SSL**: Authenticate the provider securely using a trusted Certificate Authority. Select this option if the provider has a valid SSL certificate and it is signed by a trusted Certificate Authority. No further configuration is required for this option.
      - **SSL trusting custom CA**: Authenticate the provider with a self-signed certificate. For this option, copy your provider's CA certificate to the **Trusted CA Certificates** box in PEM format.
      - **SSL without validation**: Authenticate the provider insecurely using SSL. (Not recommended)

   3. Enter the **Hostname** (or IPv4 or IPv6 address) of the virtualization service.

   4. Enter the **API Port** of your virtualization service. The default port is **443**.

   5. Enter a token for your provider in the **Token** box.

9. Click the **Advanced** tab to add image inspector settings for scanning container images on your provider using OpenSCAP.

   Note:

   - These settings control downloading the image inspector container image from the registry and obtaining the Common Vulnerabilities and Exposures (CVE) information (for effective scanning) via a proxy.
   - CVE URL that Infrastructure Automation requires to be open for OpenSCAP scanning: https://www.redhat.com/security/data/metrics/ds/. This information is based on the source code of OpenSCAP.

1. Enter the proxy information for the provider in either **HTTP**, **HTTPS**, or **NO Proxy** depending on your environment.
2. Enter the **Image-Inspector Repository** information. For example, `openshift3/image-inspector`.
3. Enter the **Image-Inspector Registry** information. For example, `registry.access.redhat.com`.
4. Enter the **Image-Inspector Tag** value. A tag is a mark used to differentiate images in a repository, typically by the application version stored in the image.
5. Enter `https://www.redhat.com/security/data/metrics/ds/` in **CVE location**.

10. Click **Add**.

Note:

You can also set global default image-inspector settings for all OpenShift providers in the advanced settings menu by editing the values under `ems_kubernetes`, instead of setting this for each provider.

For example:

```
:image_inspector_registry: registry.access.redhat.com
:image_inspector_repository: openshift3/image-inspector
```

Container Image Scanning

Configuring Image Scanning

Infrastructure Automation manages vulnerability scanning of container images. When an OpenShift provider is added, OpenShift images from the internal registry are discovered. To enable image scanning, perform the following configuration steps:

1. Browse to menu: **Compute > Containers > Providers**.
2. Select the checkboxes of the OpenShift providers on which to enable scanning.
3. From the **Policy** pull-down menu, click **Manage Policies**.
4. Select the **OpenSCAP profile** checkbox.
5. Click **Save**.

This action will trigger a SmartState analysis, or scan, of all images referenced by the OpenShift provider. The initial scan may take several hours to complete, depending on the number and size of images. The scan occurs in the OpenShift provider, which Infrastructure Automation receives and records in the database. OpenShift limits the number of scanning pods; only three images can be scanned simultaneously.

Scheduling A Recurring Scan

Software vulnerability databases are updated frequently. To apply these updates, a rescan is required. To schedule a recurring scan of container images:

 :schedule openscap scan

1. Click **Configuration**.
2. From **Settings > Zones** in the left pane of the appliance, select **Schedules**.
3. From the drop-down menu, click **Configuration > Add a new Schedule**.
4. Type an arbitrary **Name**.
5. Type an arbitrary **Description**.
6. Ensure the **Active** checkbox is selected.
7. In **Action**, select **Container Image Analysis**.
8. In **Filter**, select **All Container Images for Containers Provider**, **OpenShift**.
9. In **Run**, set the schedule as desired.
10. Set the **Time Zone**, **Starting Date**, and **Starting Time**.
11. Click **Add**.

Working with Images

Viewing Results

Image scanning results are displayed in each image summary page.

1. Select menu: **Compute > Containers > Container Images**.
2. Click the desired image.

For an OpenSCAP HTML report, locate the **Configuration** section and select **OpenSCAP HTML**.

:container configuration

For compliance and scanning history information, locate the **Compliance** section and note the **Status** field or select **Available** from the **History** field.

:container scan history

Manual Scanning

SmartState analysis scanning may be initiated manually for images. From an image summary page, select **Configuration > Perform SmartState Analysis**. Refreshing the image page will reflect the latest scan results and compliance history.

Evaluating Compliance

If the image scan policy has been updated since the last scan, compliance conditions may be re-evaluated. From an image summary page, select **Policy > Check Compliance of Last Known Configuration**. Refreshing the image page will reflect the latest compliance history.

Generating a Report on Images

You can output the results of an OpenSCAP scan of images to a report for an overview of the security risk level of images. The **Images by Failed OpenSCAP Rule Results are included with Infrastructure Automation and shows whether the image passed or failed OpenSCAP policy criteria, and the security risk.

Note: You can also create a copy of this report and edit it to contain additional information, such as the project name where the image is used to produce more useful results. For more information, see Editing a Report and Reportable Fields in Infrastructure Automation in *Monitoring, Alerts, and Reporting* for instructions on customizing reports.

Steps to create a report to show image compliance:

1. Browse to menu: **Overview > Reports**.
2. Click the menu: **Reports > All Reports** accordion.
3. Browse to menu: **Configuration Management > Containers > Images by Failed OpenSCAP Rule Results** to run a report that shows which images failed the OpenSCAP compliance.
4. Click **Queue**.
5. The report generation is placed in the queue and its status shows in the reports page.

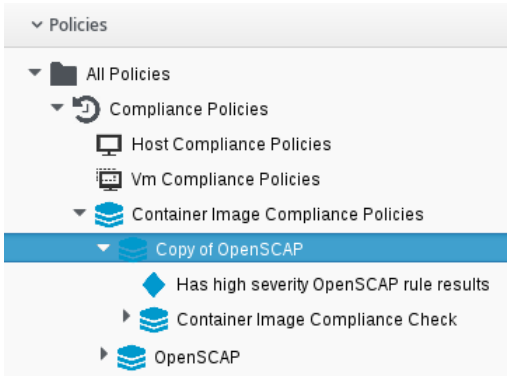
		Queued At	Run At	Source	Username	Group	Status
☐		03/12/18 04:31:57 UTC		Requested by user	ocpadmin	EvmGroup-container_administrator_updated	Queued
☐		03/07/18 08:43:25 UTC	03/07/18 08:44:00 UTC	Requested by user	ocpadmin	EvmGroup-container_administrator_updated	Complete

6. Click **(Refresh this page)** to update the status.
7. Browse to the **Saved Reports** accordion, and click the report when it completes.
8. Click the report download buttons for the type of export you want. The report is automatically named with the type of report and date.
   - Click **Download this report in text format** to download as text.
   - Click **Download this report in CSV format** to download as a comma-separated file.
   - Click **Download this report in PDF format** to download as PDF.

OpenSCAP Policy Profile

Infrastructure Automation is pre-configured with a default scanning policy profile. This includes conditions to scan and identify compliance, as well as annotate compliance failure. SmartState analysis is performed when new images are added to OpenShift.

Customizing the Scanning Policy Profile



The built-in OpenSCAP policy profile cannot be edited. However, you can assign *edited* copies of these policies to a new policy profile. This provides you the ability to create a customized version of the built-in OpenSCAP policy profile.

To do so, you must first copy the policy that you want to customize:

1. Browse to menu: **Control > Explorer**.
2. Click the **Policies** accordion, select **Container Image Compliance Policies**, and click **OpenSCAP**.

3. Click **Configuration**, and an option to copy the policy appears; for example, **Copy this Container Image Policy**.
4. Click **OK** to confirm.

The new policy is created with a prefix of **Copy of** in its description, and it can be viewed in the Policies accordion.

You can now edit the copied policy. After editing copied policies, you can add them to a new policy profile. For instructions on how to edit policies, create a new policy profile, and add policies to it, see the Policies and Profiles guide. Once you have a customized policy profile, you can assign it to a containers provider.

Controlling OpenShift Pod Execution

Through the default policy profile, non-compliant images receive the control policy action **Mark as Non-Compliant**. This action annotates the **image** object (not to be confused with the **imagestream** object) with *images.openshift.io/deny-execution=true*. This annotation may be used to prevent nodes from running non-compliant images.

High Availability Guide

Environment Overview

Learn how to configure and manage database high availability in a Infrastructure Automation environment. This configuration allows for disaster mitigation: a failure in the primary database does not result in downtime, as the standby database takes over the failed database's processes. This is made possible by database

replication between two or more database servers. In Infrastructure Automation, these servers are *database-only Infrastructure Automation appliances*, which do not have **evmserverd** processes that are enabled. This is configured from the **appliance_console** menu at the time of deployment.

Two types of appliances that are used in high availability:

- *Database-only Infrastructure Automation appliances*, which do not have **evmserverd** processes that are enabled or a user interface.
- *Non-database Infrastructure Automation appliances*, which are standard appliances that contain a user interface and which have **evmserverd** processes that are enabled.

In this configuration, a failover monitor daemon is configured and running on each non-database Infrastructure Automation appliance. The failover monitor watches the **repmgr** metadata about the database-only appliances present in the cluster. When the primary database-only appliance goes down, the non-database Infrastructure Automation appliances start polling each of the configured standby database-only appliances to monitor which one comes up as the new primary. The promotion is orchestrated either by **repmgrd** on the database-only appliances or is done manually. When the non-database Infrastructure Automation appliances find that a standby has been promoted, Infrastructure Automation reconfigures the setup by writing the new IP address in the **database.yml** file to point to the new primary.

Note:

Manual steps are required to reintroduce the failed database node back as the standby server. See Reintroducing the Failed Node.

Note, this procedure also does not provide scalability or a multi-master database setup. While a Infrastructure Automation environment is comprised of an engine tier and a database tier, this configuration affects only the database tier and does not provide load balancing for the appliances.

Requirements

For a high availability Infrastructure Automation environment, you need a virtualization host containing at minimum four virtual machines with Infrastructure Automation installed, consisting of:

- One virtual machine for the primary external database containing a minimum of 4 GB dedicated disk space
- One virtual machine for the standby external database containing a minimum of 4 GB dedicated disk space
- Two virtual machines for the non-database Infrastructure Automation appliances

The database-only appliances must reside on a highly reliable local network in the same location.

Important:

It is essential to use the same Infrastructure Automation appliance template version to install each virtual machine in this environment.

Correct time synchronization is required before installing the cluster. After installing the appliances, configure time synchronization on all appliances by using **chronyd**.

Installing the Appliances

This chapter outlines the steps for installing and configuring the Infrastructure Automation components needed for high availability: a database cluster comprised of primary and standby database-only appliances, and two (at minimum) non-database Infrastructure Automation appliances.

Installing the Primary Database-Only Appliance

The primary database-only appliance functions as an external database to the non-database Infrastructure Automation appliances.

1. Deploy a Infrastructure Automation appliance with an extra (and unpartitioned) disk for the database at a size appropriate for your deployment. For recommendations on disk space, see Database Requirements in the *Deployment Planning Guide*.
2. Configure time synchronization on the appliance by editing **/etc/chrony.conf** with valid NTP server information.
3. From your host environment, open the appliance and configure the network:
    1. Log in to the appliance and run the **appliance_console** command to access the appliance console menu.
    2. Configure networking as desired by selecting the **Set DHCP Network Configuration** or **Set Static Network Configuration** option.
4. Resynchronize time information across the appliances:

```
# systemctl enable chronyd.service
# systemctl start chronyd.service
```

5. In the appliance console, configure the following:
    1. Configure the hostname by selecting **Set Hostname**.
    2. Select **Configure Application**.
    3. Select **Create key** to create the encryption key. You can create a new key, or use an existing key on your system by selecting **Fetch key from remote machine** and following the prompts.
    4. Select **Create Internal Database**.
    5. Select the database disk. Infrastructure Automation then activates the configuration.
    6. For **Should this appliance run as a standalone database server?**, select **y**. Selecting this option configures this appliance as a database-only appliance, and therefore the CP4AIOPS:IA application and **evmserverd** processes will not run. This is required in highly available database

deployments.

Warning:

This configuration is not reversible.

7. Create the database password.

Note:

Do not create a region at this stage in the procedure.

You have now created the empty database.

You can check the configuration on the appliance console details screen. If configured successfully, **Local Database Server** shows as **`running (primary)`**.

Running the **`psql vmdb_production`** command also provides information about the database.

Installing the First Infrastructure Automation Appliance

Install and configure a Infrastructure Automation appliance to point to the primary database server. You can then create a database region and configure the primary database. This appliance does not serve as a database server.

After installing and configuring an empty database-only appliance in Installing the Primary Database-Only Appliance, the steps in this section create the database schema used by Infrastructure Automation on the primary database-only appliance, and populate the database with the initial data.

Region metadata is required to configure the primary database-only appliance as a primary node in the replication cluster. This must be configured from the Infrastructure Automation appliance before the primary and secondary database-only appliances can be configured.

1. Deploy a Infrastructure Automation appliance. There is no requirement for an extra disk on this appliance.
2. Configure time synchronization on the appliance by editing **`/etc/chrony.conf`** with valid NTP server information.
3. From your host environment, open the appliance and configure the network:
    1. Log in to the appliance and run the **`appliance_console`** command to access the appliance console menu.
    2. Configure networking as desired by selecting the **Set DHCP Network Configuration** or **Set Static Network Configuration** option.
4. Re-synchronize time information across the appliances:

```
# systemctl enable chronyd.service
# systemctl start chronyd.service
```

5. In the appliance console, configure the following:
    1. Configure the hostname by selecting **Set Hostname**.
    2. Select **Configure Application**.
    3. Configure this appliance to use the encryption key from the primary database-only appliance:
        1. For **Encryption Key**, select **Fetch key from remote machine**.
        2. Enter the hostname for the primary database-only appliance you previously configured containing the encryption key.
        3. Enter the primary database-only appliance's username.
        4. Enter the primary database-only appliance's password.
        5. Enter the path of the remote encryption key. (For example, **`/var/www/miq/vmdb/certs/v2_key`**.)

            All appliances in the same region must use the same v2 key.
    4. Configure the database:
        1. Select **Create Region in External Database**, since the database is external to the appliances.

            Creating a database region will destroy any existing data and cannot be undone.
        2. Assign a unique database region number.
        3. Enter the port number.
        4. For **Are you sure you want to continue?** Select **`y`**.
    5. Enter the primary database-only appliance's name and access details:
        1. Enter the hostname for the primary database-only appliance.
        2. Enter a name to identify the database.
        3. Enter the primary database-only appliance's username.
        4. Enter a password for the database and confirm the password.

This initializes the database, which takes a few minutes.

You can check the configuration on the appliance console details screen. When configured successfully, **CP4AIOPS:IA Server** will show as **`running`**, and **CP4AIOPS:IA Database** will show the hostname of the primary database-only appliance.

Configuring the Primary Database-Only Appliance

On the primary database-only appliance you created in Installing the Primary Database-Only Appliance, initialize the nodes in the database cluster to configure the database replication. Run these steps from the appliance console:

1. In the appliance console menu, select **Configure Database Replication**.
2. Select **Configure Server as Primary**.
3. Set a unique identifier number for the server and enter the database name and credentials:
    1. Select a number to uniquely identify the node in the replication cluster.
    2. Enter the name of the database you configured previously.
    3. Enter the cluster database username.
    4. Enter the cluster database password and confirm the password.
    5. Enter the primary database-only appliance hostname or IP address.

       Note:

       The hostname must be visible to all appliances that communicate with this database, including the non-database Infrastructure Automation appliances and any global region databases.
    6. Confirm that the replication server configuration details are correct, and select **`y`** to apply the configuration.

This configures database replication in the cluster.

Installing the Standby Database-Only Appliance

The standby database-only appliance is a copy of the primary database-only appliance and takes over the role of primary database in case of failure.

Follow these steps to create a new standby appliance, or to add another standby appliance to the cluster.

1. Deploy a Infrastructure Automation appliance with an extra (and unpartitioned) disk for the database that is the same size as the primary database-only appliance, as it will contain the same data. For recommendations on disk space, see Database Requirements in the *Deployment Planning Guide*.
2. Configure time synchronization on the appliance by editing **`/etc/chrony.conf`** with valid NTP server information.
3. From your host environment, open the appliance and configure the network:
    1. Log in to the appliance and run the **`appliance_console`** command to access the appliance console menu.
    2. Configure networking as desired by selecting the **Set DHCP Network Configuration** or **Set Static Network Configuration** option.
4. Re-synchronize time information across the appliances:

   ```
   # systemctl enable chronyd.service
   # systemctl start chronyd.service
   ```

5. In the appliance console, configure the hostname by selecting **Set Hostname**.

You can now configure this appliance as a standby database-only appliance in the cluster.

Configuring the Standby Database-Only Appliance

The steps to configure the standby database-only appliance are similar to that of the primary database-only appliance, in that they prepare the appliance to be database-only, but as the standby.

On the standby database-only appliance, configure the following from the appliance console:

1. In the appliance console menu, select **Configure Database Replication**.
2. Select **Configure Server as Standby**.
3. Select the database disk. Infrastructure Automation then activates the configuration.
4. Set a unique identifier number for the standby server and enter the database name and credentials:
    1. Select a number to uniquely identify the node in the replication cluster.
    2. Enter the cluster database name.
    3. Enter the cluster database username.
    4. Enter and confirm the cluster database password.
    5. Enter the primary database-only appliance hostname or IP address.
    6. Enter the standby database-only appliance hostname or IP address.

Note:

The hostname must be visible to all appliances that communicate with this database, including the engine appliances and any global region databases.

7. Select **y** to configure the replication manager for automatic failover.
8. Confirm that the replication standby server configuration details are correct, and select **y** to apply the configuration.

The standby server will then run an initial synchronization with the primary database, and start locally in standby mode. This takes a few minutes.

Verify the configuration on the appliance console details screen for the standby server. When configured successfully, **Local Database Server** shows as **`running (standby)`**.

Installing Additional Infrastructure Automation Appliances

Install a second virtual machine with a Infrastructure Automation appliance and any additional appliances in the region using the following steps:

1. Deploy a Infrastructure Automation appliance. There is no requirement for an extra disk on this appliance.
2. Configure time synchronization on the appliance by editing **`/etc/chrony.conf`** with valid NTP server information.
3. From your host environment, open the appliance and configure the network:
    1. Log in to the appliance and run the **`appliance_console`** command to access the appliance console menu.
    2. Configure networking as desired by selecting the **Set DHCP Network Configuration** or **Set Static Network Configuration** option.
4. Re-synchronize time information across the appliances:

```
# systemctl enable chronyd.service
# systemctl start chronyd.service
```

5. In the appliance console, configure the following:
    1. Configure the hostname by selecting **Set Hostname**.
    2. Select **Configure Application**.
    3. Configure this appliance to use the encryption key from the primary database-only appliance:
        1. For **Encryption Key**, select **Fetch key from remote machine**.
        2. Enter the hostname for the primary database-only appliance you previously configured containing the encryption key.
        3. Enter the port number.
        4. Enter the primary database-only appliance's username.
        5. Enter the primary database-only appliance's password.
        6. Enter the path of the remote encryption key. (For example, **`/var/www/miq/vmdb/certs/v2_key`**.)
        7. Select **Join Region in External Database** from the appliance console menu.
    4. Enter the primary database-only appliance's name and access details:
        1. Enter the hostname for the primary database-only appliance.
        2. Enter a name to identify the database.
        3. Enter the primary database-only appliance's username.
        4. Enter a password for the database and confirm the password.

This configuration takes a few minutes to process.

You can check the configuration on the appliance console details screen. When configured successfully, **CP4AIOPS:IA Server** will show as **`running`**, and **CP4AIOPS:IA Database** will show the hostname of the primary database-only appliance.

Configuring Database Failover

The failover monitor daemon must run on all of the non-database Infrastructure Automation appliances to check for failures. In case of a database failure, it modifies the database configuration accordingly.

This configuration is crucial for high availability to work in your environment. If the database failover monitor is not configured, non-database Infrastructure Automation appliances will not react to the failover event and will not be reconfigured against the new primary database host.

Failover Configuration Settings

Configuration settings are located in **`/var/www/miq/vmdb/config/ha_admin.yml`**.

Default settings:

Parameter	Default Value	Description

Parameter	Default Value	Description
`failover_attempts`	10	The number of times the `failover_monitor` will attempt to failover after discovering the connection to the current database is no longer active.
`db_check_frequency`	120s	The sleep interval in the monitor loop, it defines how frequently the connection to the database is checked.
`failover_check_frequency`	60s	The sleep interval between attempting to failover additional times.

Note:

`failover_attempts` and `failover_check_frequency` determine the time limit for the cluster to elect a new primary. To produce quicker failovers, reduce the value for `failover_check_frequency` and increase the value for `failover_attempts`.

Configuring the Failover Monitor

Configure the failover monitor only on the non-database Infrastructure Automation appliances with the following steps:

1. In the appliance console menu, select **Configure Application Database Failover Monitor**.
2. Select **Start Database Failover Monitor**.

Testing Database Failover

Test that failover is working correctly between your databases with the following steps:

1. Simulate a failure by stopping the database on the primary server:

   ```
   # systemctl stop postgresql.service
   ```

2. To check the status of the database, run:

   ```
   # systemctl status postgresql.service
   ```

   Note:

   You can check the status of the simulated failure by viewing the evm log on the engine appliances with `journalctl -t evm`.

3. Check the appliance console summary screen for the primary database. If configured correctly, the **CP4AIOPS:IA Database** value in the appliance console summary should have switched from the hostname of the old primary database to the hostname of the new primary on all Infrastructure Automation appliances.

Upon database server failover, the standby server becomes the primary. However, the failed node cannot switch to standby automatically and must be manually configured. Data replication from the new primary to the failed and recovered node does not happen by default, so the failed node must be reintroduced into the configuration.

Reintroducing the Failed Node

Manual steps are required to reintroduce the failed primary database node back into the cluster as a standby. This allows for greater control over the configuration, and to diagnose the failure.

To reintroduce the failed node, reinitialize the standby database. On the standby database-only appliance, configure the following:

1. In the appliance console menu, select **Configure Database Replication**.
2. Select **Configure Server as Standby**.
3. Select `y` to remove all previous data from the server and configure it as a new standby database.
4. Set a unique identifier number for the standby server and enter the database name and credentials:
   1. Select a number to uniquely identify the node in the replication cluster. This number can be the same as the node's original identification number.
   2. Enter the cluster database name.
   3. Enter the cluster database username.
   4. Enter the cluster database password.
   5. Enter the new primary database-only appliance hostname or IP address.
   6. Enter the new standby database-only appliance hostname or IP address.

      Note:

      The hostname must be visible to all appliances that communicate with this database, including the engine appliances and any global region databases.

   7. Select `y` to configure the replication manager for automatic failover.

      Note:

      If re-using the node's identification number, select `y` to overwrite the existing node ID (this cannot be undone). Additionally, select `y` to overwrite and reconfigure the replication settings in `/etc/repmgr/*/repmgr.conf` when prompted.

   8. Confirm that the replication standby server configuration details are correct, and select `y` to apply the configuration.

The standby server will then run an initial synchronization with the primary database, and start locally in standby mode.

Verify the configuration on the appliance console details screen for the standby server. When configured successfully, **Local Database Server** shows as **`running (standby)`**.

Your Infrastructure Automation environment is now re-configured for high availability.

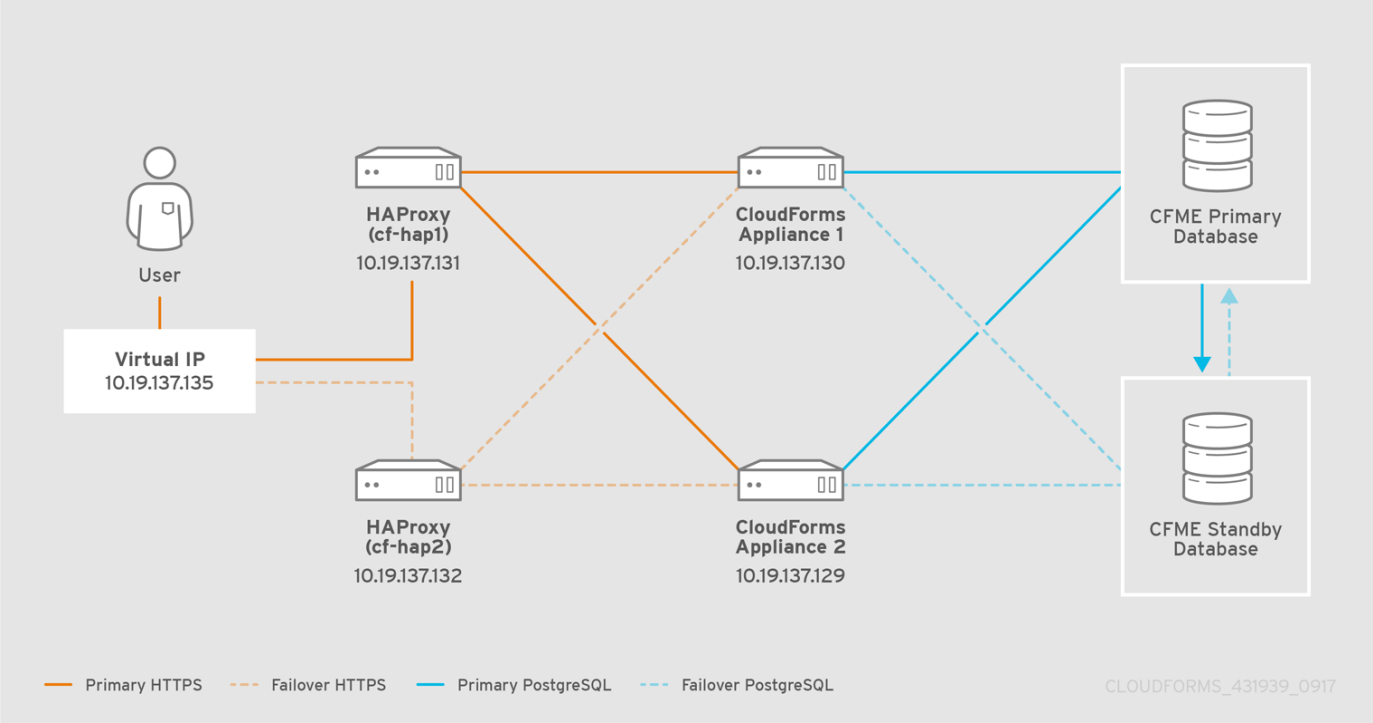
Configuring the HAProxy Load Balancer

After configuring the appliances as described in Installing the Appliances, configure a load balancer to direct traffic to the non-database Infrastructure Automation appliances.

The following steps highlight the configuration requirements for the load balancer, which in this case is HAProxy. The load balancer is assigned a virtual IP address for the Infrastructure Automation user interface and is pointed to one of the many non-database Infrastructure Automation appliances behind the load balancer in a round robin fashion.

Additionally, to avoid the HAProxy server being a single point of failure, two redundant HAProxy servers are configured in active-passive mode. The failover is orchestrated by using the **`keepalived`** daemon. **`keepalived`** monitors the health of the active load balancer and in case of a failure, the virtual IP is failed over to the passive load balancer, which then becomes active. The virtual IP is configured by `keepalived`.

The virtual IP is the single IP address that is used as the point of access to the Infrastructure Automation appliance user interfaces and is configured in the HAProxy configuration along with a load balancer profile. When an end user accesses the virtual IP, it directs traffic to the appropriate Infrastructure Automation appliance based on the configured HAProxy policy.



Note:

Additional configuration is required to run HAProxy on Red Hat OpenStack Platform. See the OpenStack Networking Guide for more information.

This configuration uses two HAProxy servers and a virtual IP (configured by **`keepalived`**). The following example procedure uses the following IP addresses and names; substitute values for your environment as needed:

- HAProxy1: 10.19.137.131 (cf-hap1.example.com)
- HAProxy2: 10.19.137.132 (cf-hap2.example.com)
- Virtual IP (to be configured by **`keepalived`**): 10.19.137.135 (cf-ha.example.com)
- CP4AIOPS:IA Appliance 1: 10.19.137.130 (cfme1.example.com)
- CP4AIOPS:IA Appliance 2: 10.19.137.129 (cfme2.example.com)

The following diagram shows the HAProxy configuration in this procedure:

To configure HAProxy load balancing:

1. Install two servers (virtual or physical) running Red Hat Enterprise Linux 7.2 or above, to be used as the HAProxy servers.
2. Configure subscriptions on both HAProxy servers (**`cf-hap1`** and **`cf-hap2`**) so that the **`rhel-7-server-rpms`** repository is enabled:

```
[root@cf-hap1 ~]# subscription-manager repos --list-enabled
+----------------------------------------------+
Available Repositories in /etc/yum.repos.d/redhat.repo
+----------------------------------------------+
Repo Name:   Red Hat Enterprise Linux Server 7 Server (RPMs)
```

```
Repo ID:     rhel-7-server-rpms

Repo URL: https://cdn.redhat.com/content/dist/rhel/server/7/$release/$basearch/os
Enabled: 1

[root@cf-hap2 ~]# subscription-manager repos --list-enabled
+----------------------------------------------+
Available Repositories in /etc/yum.repos.d/redhat.repo
+----------------------------------------------+
Repo Name:   Red Hat Enterprise Linux Server 7 Server (RPMs)

Repo ID:     rhel-7-server-rpms

Repo URL: https://cdn.redhat.com/content/dist/rhel/server/7/$release/$basearch/os
Enabled: 1
```

3. Configure the firewall on both HAProxy servers.

    1. On the **cf-hap1** server, run the following:

        Note:

        keepalived uses VRRP (Virtual Redundancy Router Protocol) to monitor the servers and determine which node is the master and which node is the backup. VRRP communication between routers uses multicast IPv4 address 224.0.0.18 and IP protocol number 112.

        ```
        [root@cf-hap1 ~]# firewall-cmd --permanent  --add-port=80/tcp --add-port=443/tcp --add-port=8443/tcp &&
        firewall-cmd --reload

        [root@cf-hap1 ~]# firewall-cmd --direct --permanent --add-rule ipv4 filter INPUT 0 \ --in-interface eth0 --
        destination 224.0.0.18 --protocol vrrp -j ACCEPT

        [root@cf-hap1 ~]#firewall-cmd --direct --permanent --add-rule ipv4 filter OUTPUT 0 \ --out-interface eth0 --
        destination 224.0.0.18 --protocol vrrp -j ACCEPT

        [root@cf-hap1 ~]# firewall-cmd --reload
        ```

    2. On the **cf-hap2** server, repeat the same commands by running the following:

        ```
        [root@cf-hap2 ~]# firewall-cmd --permanent  --add-port=80/tcp --add-port=443/tcp --add-port=8443/tcp &&
        firewall-cmd --reload

        [root@cf-hap2 ~]# firewall-cmd --direct --permanent --add-rule ipv4 filter INPUT 0 \ --in-interface eth0 --
        destination 224.0.0.18 --protocol vrrp -j ACCEPT

        [root@cf-hap2 ~]# firewall-cmd --direct --permanent --add-rule ipv4 filter OUTPUT 0 \ --out-interface eth0 --
        destination 224.0.0.18 --protocol vrrp -j ACCEPT

        [root@cf-hap2 ~]# firewall-cmd --reload
        ```

4. Install and configure **keepalived** on both servers.

    1. On the **cf-hap1** server, run the following:

        ```
        [root@cf-hap1 ~]# yum install keepalived -y

        [root@cf-hap1 ~]# cat /etc/keepalived/keepalived.conf
        vrrp_script chk_haproxy {
        script "killall -0 haproxy" # check the haproxy process
        interval 2 # every 2 seconds
        weight 2 # add 2 points if OK
        }
        vrrp_instance VI_1 {
        interface eth0              # interface to monitor
        state MASTER              # MASTER on haproxy1, BACKUP on haproxy2
        virtual_router_id 51
        priority 101              # 101 on haproxy1, 100 on haproxy2
        virtual_ipaddress {
        10.19.137.135/21 # virtual ip address
        }
        track_script {
        chk_haproxy
        }
        }
        ```

    2. On the **cf-hap2** server, run the following:

        ```
        [root@cf-hap2 ~]# yum install keepalived -y

        [root@cf-hap2 ~]# cat /etc/keepalived/keepalived.conf
        vrrp_script chk_haproxy {
        script "killall -0 haproxy" # check the haproxy process
        interval 2 # every 2 seconds
        weight 2 # add 2 points if OK
        }
        vrrp_instance VI_1 {
        interface eth0              # interface to monitor
        state BACKUP              # MASTER on haproxy1, BACKUP on haproxy2
        virtual_router_id 51
        priority 100              # 101 on haproxy1, 100 on haproxy2
        virtual_ipaddress {
        ```

```
10.19.137.135/21 # virtual ip address
}
track_script {
chk_haproxy
}
}
```

3. On both servers, configure IP forwarding and non-local binding by appending the following to the **sysctl.conf** file. In order for the **keepalived** service to forward network packets properly to the real servers, each router node must have IP forwarding turned on in the kernel. On the **cf-hap1** server, run the following:

```
[root@cf-hap1 ~]# cat /etc/sysctl.conf
# System default settings live in /usr/lib/sysctl.d/00-system.conf.
# To override those settings, enter new settings here, or in an /etc/sysctl.d/<name>.conf file
#
# For more information, see sysctl.conf(5) and sysctl.d(5).
net.ipv4.ip_forward = 1
net.ipv4.ip_nonlocal_bind = 1
```

4. On the **cf-hap2** server, run the following:

```
[root@cf-hap2 ~]# cat /etc/sysctl.conf
# System default settings live in /usr/lib/sysctl.d/00-system.conf.
# To override those settings, enter new settings here, or in an /etc/sysctl.d/<name>.conf file
#
# For more information, see sysctl.conf(5) and sysctl.d(5).
net.ipv4.ip_forward = 1
net.ipv4.ip_nonlocal_bind = 1
```

5. Verify that the **sysctl.conf** settings were saved on each server:

```
[root@cf-hap1 ~]# sysctl -p
net.ipv4.ip_forward = 1
net.ipv4.ip_nonlocal_bind = 1

[root@cf-hap2 ~]# sysctl -p
net.ipv4.ip_forward = 1
net.ipv4.ip_nonlocal_bind = 1
```

5. Install HAProxy on both servers:

```
[root@cf-hap1 ~]# yum install haproxy -y

[root@cf-hap2 ~]# yum install haproxy -y
```

6. Configure the appropriate IPs for load balancing on the **cf-hap1** server as follows:

```
[root@cf-hap1 ~]# cat /etc/haproxy/haproxy.cfg
global
    log                 127.0.0.1 local0
    chroot              /var/lib/haproxy
    pidfile             /var/run/haproxy.pid
    maxconn         4000
    user                haproxy
    group               haproxy
    daemon
defaults
    mode                        http
    log                         global
    option                      httplog
    option                      dontlognull
    option             http-server-close
    option     forwardfor       except 127.0.0.0/8
    option                      redispatch
    retries                     3
    timeout http-request    10s
    timeout queue           1m
    timeout connect         10s
    timeout client              1m
    timeout server          1m
    timeout http-keep-alive     10s
    timeout check           10s
# Infrastructure Automation Management UI URL
listen apache
  bind 10.19.137.135:80
  mode tcp
  balance source
  server cfme1 10.19.137.130:80 check inter 1s
  server cfme2 10.19.137.129:80  check inter 1s
#
listen apache-443
  bind 10.19.137.135:443
  mode tcp
  balance source
  server cfme1 10.19.137.130:443 check inter 1s
  server cfme2 10.19.137.129:443  check inter 1s
#
listen apache-8443
  bind 10.19.137.135:8443
  mode tcp
  balance source
```

```
  server cfme1 10.19.137.130:8443 check inter 1s
  server cfme2 10.19.137.129:8443  check inter 1s
```

Note:

- The virtual IP in this configuration is 10.19.137.135 (cf-haproxy.example.com).
- The IP of CP4AIOPS:IA Appliance 1 is 10.19.137.130 (cfme1.example.com).
- The IP of CP4AIOPS:IA Appliance 2 is 10.19.137.129 (cfme2.example.com).

7. Configure the appropriate IPs for load balancing on the **cf-hap2** server as well:

```
[root@cf-hap2 ~]# cat /etc/haproxy/haproxy.cfg
global
    log                 127.0.0.1 local0
    chroot              /var/lib/haproxy
    pidfile             /var/run/haproxy.pid
    maxconn         4000
    user                haproxy
    group               haproxy
    daemon
defaults
    mode                        http
    log                         global
    option                      httplog
    option                      dontlognull
    option             http-server-close
    option     forwardfor       except 127.0.0.0/8
    option                      redispatch
    retries                     3
    timeout http-request    10s
    timeout queue           1m
    timeout connect         10s
    timeout client              1m
    timeout server          1m
    timeout http-keep-alive     10s
    timeout check           10s
# Infrastructure Automation Management UI URL
listen apache
  bind 10.19.137.135:80
  mode tcp
  balance source
  server cfme1 10.19.137.130:80 check inter 1s
  server cfme2 10.19.137.129:80  check inter 1s
#
listen apache-443
  bind 10.19.137.135:443
  mode tcp
  balance source
  server cfme1 10.19.137.130:443 check inter 1s
  server cfme2 10.19.137.129:443  check inter 1s
#
listen apache-8443
  bind 10.19.137.135:8443
  mode tcp
  balance source
  server cfme1 10.19.137.130:8443 check inter 1s
  server cfme2 10.19.137.129:8443  check inter 1s
```

8. On each server, start the **keepalived** and **haproxy** services:

```
[root@cf-hap1~]# systemctl enable keepalived
[root@cf-hap1~]# systemctl start keepalived
[root@cf-hap1~]# systemctl enable haproxy
[root@cf-hap1~]# systemctl start haproxy

[root@cf-hap2~]# systemctl enable keepalived
[root@cf-hap2~]# systemctl start keepalived
[root@cf-hap2~]# systemctl enable haproxy
[root@cf-hap2~]# systemctl start haproxy
```

Verifying the HAProxy Configuration

Verify the HAProxy configuration by inspecting the following:

On the master node (**cf-hap1**):

```
[root@cf-hap1 ~]# ip addr show dev eth0
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP qlen 1000
    link/ether 00:01:a4:ac:32:4e brd ff:ff:ff:ff:ff:ff
    inet 10.19.137.131/21 brd 10.19.143.255 scope global eth0
       valid_lft forever preferred_lft forever
    inet 10.19.137.135/21 scope global eth0
       valid_lft forever preferred_lft forever
    inet6 2620:52:0:1388:201:a4ff:feac:324e/64 scope global mngtmpaddr dynamic
       valid_lft 2591800sec preferred_lft 604600sec
    inet6 fe80::201:a4ff:feac:324e/64 scope link
       valid_lft forever preferred_lft forever
```

On the backup node (**cf-hap2**):

```
[root@cf-hap2 ~]# ip addr show dev eth0
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP qlen 1000
    link/ether 00:01:a4:ac:33:a6 brd ff:ff:ff:ff:ff:ff
    inet 10.19.137.132/21 brd 10.19.143.255 scope global eth0
       valid_lft forever preferred_lft forever
    inet6 2620:52:0:1388:201:a4ff:feac:33a6/64 scope global noprefixroute dynamic
       valid_lft 2591982sec preferred_lft 604782sec
    inet6 fe80::201:a4ff:feac:33a6/64 scope link
       valid_lft forever preferred_lft forever
```

Notice the virtual IP 10.19.137.135 has been started by **keepalived** (VRRP).

Simulate a failure on the master node:

```
[root@cf-hap1 ~]# systemctl stop keepalived
```

Notice the virtual IP failover on the master node (**cf-hap1**):

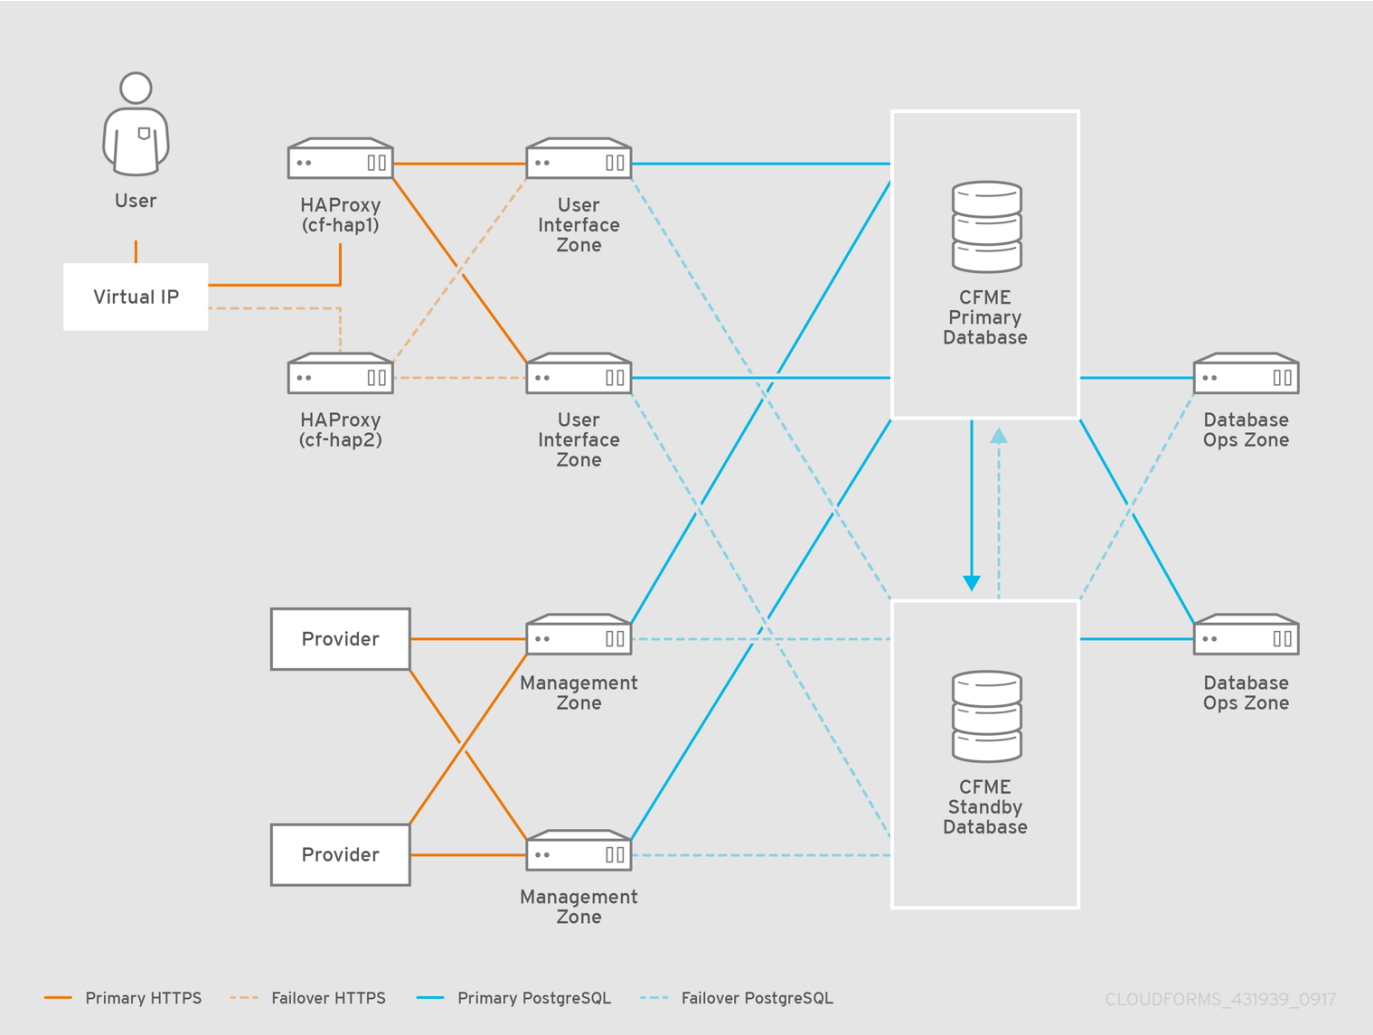
```
[root@cf-hap1 ~]# ip addr show dev eth0
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP qlen 1000
    link/ether 00:01:a4:ac:32:4e brd ff:ff:ff:ff:ff:ff
    inet 10.19.137.131/21 brd 10.19.143.255 scope global eth0
       valid_lft forever preferred_lft forever
    inet6 2620:52:0:1388:201:a4ff:feac:324e/64 scope global mngtmpaddr dynamic
       valid_lft 2591800sec preferred_lft 604600sec
    inet6 fe80::201:a4ff:feac:324e/64 scope link
       valid_lft forever preferred_lft forever
```

The backup node (**cf-hap2**) shows the following:

```
[root@cf-hap2 ~]# ip addr show dev eth0
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP qlen 1000
    link/ether 00:01:a4:ac:33:a6 brd ff:ff:ff:ff:ff:ff
    inet 10.19.137.132/21 brd 10.19.143.255 scope global eth0
       valid_lft forever preferred_lft forever
    inet 10.19.137.135/21 scope global eth0
       valid_lft forever preferred_lft forever
    inet6 2620:52:0:1388:201:a4ff:feac:33a6/64 scope global noprefixroute dynamic
       valid_lft 2591982sec preferred_lft 604782sec
    inet6 fe80::201:a4ff:feac:33a6/64 scope link
       valid_lft forever preferred_lft forever
```

Your environment is now configured for high availability.

The following additional configuration in the Infrastructure Automation user interface worker appliances and the load balancer are recommended for improved performance in worker appliances: - For each Infrastructure Automation appliance behind the load balancer, change the `session_store` setting to `sql` in the appliance's advanced settings. - Configure sticky sessions in the load balancer. - Configure the load balancer to test for appliance connectivity using the `https://appliance_name/ping` URL.



Scaling a Highly Available Infrastructure Automation Environment

After creating high availability for the database tier and the user interface tier, the rest of the infrastructure should be sized appropriately for the roles and the environments that they manage. These roles and tiers use built-in high availability mechanisms like primary, secondary, and tertiary failover.

You can configure additional worker appliances as needed using the steps in Installing Additional Appliances, and then assign zones and server roles. The non-database Infrastructure Automation appliances and roles can be configured in any order.

The following diagram shows an example of a highly available database configuration that contains worker appliances, providers, and the HAProxy load balancer configured in Configuring the HAProxy Load Balancer.

The worker appliances in the diagram are labeled by server role (**User Interface**, **Management**, and **Database Ops**) and corresponding zone to show how a highly available environment might be scaled with server roles and zones.

See Regions and Servers in *General Configuration* for more information on configuring servers and roles.

Updating a Highly Available Infrastructure Automation Environment

Applying software package minor updates (referred to as *errata*) to appliances in a high availability environment must be performed in a specific order to avoid migrating your databases to the next major Infrastructure Automation version.

Prerequisites.

Ensure each appliance is registered to Red Hat Subscription Manager and subscribed to the update channels required by Infrastructure Automation in order to access updates.

To verify if your appliance is registered and subscribed to the correct update channels, run:

```
# yum repolist
```

Appliances must be subscribed to the following channels:

- {product-repo_cfme}
- {product-repo_ansible}
- {product-repo_extras}

Updating the Appliances.

Follow this procedure to update appliances in your environment without migrating the database to the next major version of Infrastructure Automation. Note the appliance to perform each step on: some steps are to be performed only on the database-only appliances, and other steps only on the non-database Infrastructure Automation appliances, while some steps apply to all appliances.

1. Power off the non-database Infrastructure Automation appliances.
2. Power off the database-only appliances.

3. Back up each appliance:
    1. Back up the database of your appliance. Take a snapshot if possible.
    2. Back up the following files for disaster recovery, noting which appliance each comes from:
        - **/var/www/miq/vmdb/GUID**
        - **/var/www/miq/vmdb/REGION**
    3. Note the hostnames and IP addresses of each appliance. This information is available on the summary screen of the appliance console.
4. Start each database-only appliance.
5. Start each non-database Infrastructure Automation appliance again, and stop **evmserverd** on each just after boot:

    ```
    # systemctl stop evmserverd
    ```
6. Apply updates by running the following on each appliance:

    ```
    # yum update
    ```
7. On one of the non-database Infrastructure Automation appliances, apply any database schema updates included in the errata, and reset the Red Hat and ManageIQ automation domains:

    ```
    # vmdb
    # rake db:migrate
    # rake evm:automate:reset
    ```
8. Power off the non-database Infrastructure Automation appliances.
9. Reboot the database-only appliances.
10. Wait five minutes, then start the non-database Infrastructure Automation appliances again.

The appliances in your high availability environment are now up to date.

Updating Hostnames on Database-Only Appliances

When updating the hostnames of database-only appliances in a cluster, you must also re-configure high availability on the primary and standby database-only appliances.

Preparing to Update Appliance Hostnames

Before updating the hostnames of your appliances, complete the following:

1. Note the hostnames of the active database (primary) appliance and the standby database appliances in the appliance console.

    You can verify this from the appliance summary screen of a database-only appliance, where the status for **Local Database Server** shows *primary* or *standby*, for example:

    ```
    ...
    Local Database Server:   running (primary)
    ...
    ```
2. On the non-database Infrastructure Automation appliances, stop the failover monitor:
    1. In the appliance console menu, select **Configure Application Database Failover Monitor**.
    2. Select **Stop Database Failover Monitor**.
3. On the *standby* database-only appliances, stop the **postgresql** database service:

    ```
    # systemctl stop postgresql.service
    ```
4. Stop **evmserverd** on each non-database Infrastructure Automation appliance:

    ```
    # systemctl stop evmserverd
    ```

Updating the Primary Database-Only Appliance Hostname

Run the following steps on your primary database-only appliance:

1. In the appliance console menu, configure the new hostname or IP address from the **Configure Network** option.
2. Restart the appliance.
3. Update the **host** key to the primary database appliance's new hostname in **/var/www/miq/vmdb/config/database.yml**.

Updating the Standby Database-Only Appliance Hostname

Run the following steps on your standby database-only appliances:

1. In the appliance console menu, configure the new hostname or IP address from the **Configure Network** option.
2. Restart the appliance.

3. Update the **host** key to the standby database appliance's new hostname in **/var/www/miq/vmdb/config/database.yml**.

Repeat these steps on any additional standby database-only appliances.

Your primary and standby appliances must be reachable to each other by their hostnames. If all appliances are on the same network and are resolvable, no additional updates are needed. If your appliances exist on different networks, edit the `/etc/hosts` file on each database appliance to include entries for the IP address and hostname of each other database appliance in the cluster.
Proceed to re-configure high availability on the primary and standby database-only appliances.

Re-configuring High Availability on Database-Only Appliances

Re-configure replication on the database-only appliances, and restart services on your cluster.

Configuring the Primary Database-Only Appliance

On the primary database-only appliance, initialize the nodes in the database cluster to re-configure the database replication:

1. In the appliance console menu, select **Configure Database Replication**.
2. Select **Configure Server as Primary**.
3. Set a unique identifier number for the server and enter the database name and credentials:
    1. Select a number to uniquely identify the node in the replication cluster.
    2. Enter the cluster database name.
    3. Enter the cluster database username.
    4. Enter the cluster database password and confirm the password.
    5. Enter the new primary database-only appliance hostname or IP address.

        Note:

        The hostname or IP address must be visible to all appliances that communicate with this database, including the non-database Infrastructure Automation appliances and any global region databases.

    6. Confirm that the replication server configuration details are correct, and select **y** to apply the configuration.

Configuring the Standby Database-Only Appliance

The steps to re-configure the standby database-only appliances are similar to that of the primary database-only appliance, in that they prepare the appliance to be database-only, but as the standby.

On the standby database-only appliances, configure the following:

1. In the appliance console menu, select **Configure Database Replication**.
2. Select **Configure Server as Standby**.
3. Select the database disk. Infrastructure Automation then activates the configuration.
4. Set a unique identifier number for the standby server and enter the database name and credentials:
    1. Select a number to uniquely identify the node in the replication cluster.
    2. Enter the cluster database name.
    3. Enter the cluster database username.
    4. Enter the cluster database password.
    5. Enter the new primary database-only appliance hostname or IP address.
    6. Enter the new standby database-only appliance hostname or IP address.

        Note:

        The hostname or IP address must be visible to all appliances that communicate with this database, including the engine appliances and any global region databases.

    7. Select **y** to configure the replication manager for automatic failover.
    8. Confirm that the replication standby server configuration details are correct, and select **y** to apply the configuration. The standby server will then run an initial synchronization with the primary database, and start locally in standby mode.
5. Verify the configuration on the appliance console details screen for the standby server. When configured successfully, **Local Database Server** shows as **running (standby)**.

Repeat these steps on any additional standby database-only appliances.

If you are using non-dedicated database appliances, also stop `evmserverd` on those appliances before changing their hostnames, and reconfigure `database.yml` before restarting.

Restarting Services

1. Start **evmserverd** on each non-database Infrastructure Automation appliance:

   ```
   # systemctl start evmserverd
   ```

   After **evmserverd** has started successfully, all appliances will be able connect to the database.

2. Restart the failover monitor on the non-database Infrastructure Automation appliances:

   1. In the appliance console menu, select **Configure Application Database Failover Monitor**.
   2. Select **Start Database Failover Monitor**.

Note:

You can view a summary of the updated appliances by running **repmgr cluster show** on one of the database appliances.

Your Infrastructure Automation environment is now re-configured for high availability.

Appliance Hardening Guide

Introduction to Hardening Infrastructure Automation

The Infrastructure Automation appliance is distributed as a virtual machine image, which provides users with a simple installation process. The appliance also contains a set of factory default settings that can expose appliances to vulnerabilities if left unset. This guide provides a set of procedures to enhance security on your Infrastructure Automation appliance. This ensures your appliance has enhanced protection against any unwarranted intrusion.

It is recommended to perform these steps immediately after installing all appliances in your infrastructure.

SSH Security

Setting the Root Password on the Appliance

The Infrastructure Automation appliance is a virtual machine image that runs on a Red Hat Enterprise Linux-based operating system. This means users can access the base operating system through SSH. This is why it is advisable to change the default password. Continuing to use the default password leaves the appliance vulnerable to any user attempting to gain root access.

Changing the **root** password on the appliance 'uses' **the** same process as changing any user password on a Linux-based system.

1. Access your appliance through SSH as the **root** user:

   ```
   [user@localhost ~]$ ssh root@10.1.1.205
   ```

   Substitute **10.1.1.205** with the address of your appliance.

2. Enter the **passwd** command, which changes the password for the current user:

   ```
   [root@ ~]# passwd
   ```

3. Enter and Confirm and new password for the **root** user.

```
Changing password for user root.
New password: ************
Confirm password: ************
```

4. Log out of the appliance.

The Infrastructure Automation appliance now has a non-default **root** password. This prevents unauthorized access to your appliance through SSH.

Setting SSH Keys on the Appliance

Another recommended practice is to use SSH keys to access the appliance from a single machine. An SSH key provides access from one machine to another through the SSH protocol. The following procedure shows how to create an SSH key on your local machine and add it to the appliance.

1. Check the **.ssh/** directory in your home directory for any existing key pairs:

   ```
   [user@localhost ~]$ ls ~/.ssh/
   ```

   A key pair usually consists of two files. One file is the private key, which stays on your local machine, and the other is the public key, which you copy to another machine. But files are named the same except the public key ends with a **.pub** extension.

   If a key pair already exists, you can use this key pair. Otherwise, use the next few steps to create your own.

2. On your local machine, start the key pair generation process using the **ssh-keygen** command:

   ```
   [user@localhost ~]$ ssh-keygen -t rsa
   ```

3. A prompt asks for the file and location to store these keys:

   ```
   Enter file in which to save the key (/home/user/.ssh/id_rsa):
   ```

   Accept the default path if you do not have a **id_rsa** key pair.

4. Another prompt asks for a passphrase:

   ```
   Enter passphrase (empty for no passphrase):
   ```

   This encrypts the key pair with a password. This protects the key pair if it ever falls into the wrong hands. Alternatively, you can leave the passphrase empty, which provides an automatic login between your local machine and the remote machine.

5. The **ssh-keygen** command generates two files:

   - The private key - the default is */home/user/.ssh/id_rsa*
   - The public key - the default is */home/user/.ssh/id_rsa.pub*

     Copy the public key to the appliance using the **ssh-copy-id** command:

     ```
     [user@localhost ~]$ ssh-copy-id ~/.ssh/id_rsa.pub root@10.1.1.205
     ```

     The command copies the public key to the appliance. You might receive a prompt for the password of the root user on the appliance.

6. Test the SSH key authentication:

   ```
   [user@localhost ~]$ ssh root@10.1.1.205
   ```

   This authenticates using the SSH key pair. If you entered a passphrase for the key, the command prompts you for the passphrase.

7. As an additional security measure, edit the **/etc/ssh/sshd_config** on the appliance and modify the following parameter:

   ```
   PermitRootLogin without-password
   ```

   This forces the **root** user account to use certificates instead of passwords for SSH login. This means only your local system can access the appliance.

The appliance now restricts access to only a single machine using the SSH key.

Appliance Security

Setting the Password for the Administrative User

Infrastructure Automation uses a unique **admin** user to control all functions in the web-based user interface. After installing the appliance, change the default password of the **admin** to restrict administrative access to the appliance's UI.

Changing the **admin** password uses the same process as changing any standard user in the appliance.

1. Access the appliance through your web browser and log in.
2. Click (**Configuration**).
3. In the accordion tree on the left, click on **Access Control**, then select the **Administrator** under the **Users** section. This displays the details for the **admin** user.
4. On the details page, select **Configuration > Edit this user** from the toolbar.
5. Enter a new password in the **Change Password / Confirm Password** fields.
6. Click **Save** at the bottom of the page.

7. Log out of the user interface.
8. Test your new password by logging into the user interface. Additionally, test your new password in the appliance console.

The Infrastructure Automation appliance now has a non-default **admin** password. This restricts access to your appliance's administrative functions.

Configuring Host-Based Access Control Rules on your IPA Server

Infrastructure Automation provides support for external authentication using an IPA server. However, there are certain recommendations to enhance security to your appliance, such as creating a specific user group and host group that can access the appliance authentication service.

Run the following steps on your IPA server:

1. Create a user group and restrict access to only the Infrastructure Automation users:

```
[root@ipa ~]# ipa group-add infrastructure_automation_users --desc="infrastructure_automation Users"
[root@ipa ~]# ipa group-add-member infrastructure_automation_users --users=testuser1,testuser2
```

2. Create a host group and restrict access to your appliance hosts:

```
[root@ipa ~]# ipa hostgroup-add infrastructure_automation_hosts --desc "Infrastructure Automation hosts"
[root@ipa ~]# ipa hostgroup-add-member infrastructure_automation_hosts --
hosts=appliance1.example.com,appliance2.example.com
```

3. Add rules to allow the host group and user group access to the Infrastructure Automation HTTP service:

```
[root@ipa ~]# ipa hbacrule-add infrastructure_automation_access --srchostcat=all
[root@ipa ~]# ipa hbacrule-add-service infrastructure_automation_access --hbacsvcs httpd-auth
[root@ipa ~]# ipa hbacrule-add-user infrastructure_automation_access --groups infrastructure_automation_users
[root@ipa ~]# ipa hbacrule-add-host infrastructure_automation_access --hostgroups infrastructure_automation_hosts
```

4. Remove the default rule on your IPA server to allow access to all:

```
[root@ipa ~]# ipa hbacrule-disable allow_all
```

This ensures only users in the **infrastructure_automation_users** group can access the authentication service (**http-auth**) on the appliances in the **infrastructure_automation_hosts** host group.

Server Security

Configuring Firewall Ports

A new appliance starts with a few standard ports open:

- 22 for SSH communication
- 80 for HTTP access to the appliance
- 443 for HTTPS access to the appliance
- 5432 for the appliance database

You might need to restrict or open access to certain services on your appliance in the future. In such situations, use the following method:

- Use **firewalld** to enable a service or port, specifying the zone in use. For example, to open the LDAP port:

```
[root@ ~]# firewall-cmd --zone=manageiq --permanent --add-port=389/tcp
```

The following table lists the appliance's main services and their respective ports.

Initiator (CFME Role if applicable)	Receiver (CFME Role if applicable)	Application	TCP Port	UDP Port	Purpose
Administrator (Internet Browser)	CFME appliance (User Interface)	HTTPS	443		Access to CFME appliance User Interface
Administrator (Internet Browser)	CFME appliance (User Interface)	HTTP	80		Redirect Web Browser to HTTPS service (443)
Service Catalog or other integration through Web Service	CFME appliance (Web Service)	HTTPS	443		Access to CFME appliance Web Service
CFME appliance	NFS Server	NFS	2049	2049	Embedded NFS VM scanning
CFME appliance (User Interface)	Any Virtual Machine	TCP	903		VM Remote Console (if using MKS plug-in)
CFME appliance (User Interface)	Any Virtual Machine	TCP	5900-5999		VM Remote Console (if using VNC)
CFME appliance (any role)	CFME appliance running the VMDB	PostgreSQL Named Pipes	5432		CFME appliance connectivity to the CFME Database (PostgreSQL)
CFME Subordinate Region VMDB appliance (Database Operations)	CFME Master Region VMDB appliance	PostgreSQL Named Pipes	5432		Regional VMDB node replication up to Master VMDB node (PostgreSQL only)

Initiator (CFME Role if applicable)	Receiver (CFME Role if applicable)	Application	TCP Port	UDP Port	Purpose
CFME Subordinate Region VMDB appliance	CFME Master Region VMDB appliance (Web Services and/or User Interface)	PostgreSQL Named Pipes	5432		Subscription validation (PostgreSQL only)
CFME appliance(Authentication through LDAP)	LDAP Server (AD or other)	LDAP	389		LDAP integration
CFME appliance (Authentication through LDAPs)	LDAP Server (AD or other)	LDAPs	636		LDAPS integration
SNMP Agent	CFME appliance (Notifier)	SNMP (UDP)		161	SNMP Polling
CFME appliance (Notifier)	SNMP Server	SNMP (TCP)	162		SNMP Trap Send
CFME appliance (Notifier)	Mail server	SMTP	25		SNMP Trap Send
CFME appliance (any role)	NTP Server	NTP		123	Time Source
CFME appliance	CFME SmartProxy installed on VMware ESX Server	HTTPS	1139		Communication with SmartProxy
CFME appliance	DNS Server	UDP		53	DNS Lookups

Ports Used by Infrastructure Automation

The following tables detail the ports used by Infrastructure Automation to communicate with providers.

Initiator (CFME Role if applicable)	Receiver (CFME Role if applicable)	Application	TCP Port	UDP Port	Purpose
CFME appliance (SmartProxy)	RHEV-M Server	HTTPS	8443		API communications to RHEV-M environment (Inventory, Operations, SmartProxy)
CFME appliance (C\&U)	RHEV-M Server	PostgreSQL	5432		RHEV-M History Database (Database connectivity not enabled by default). See How to access the RHEV-M Postgres DB from a remote machine.
CFME appliance	RHEV-H Hosts or RHEL Hypervisors	SSH	22		SSH connections.
CFME appliance	RHEV-H Hosts or RHEL Hypervisors	DirectLUN			Direct LUN hook must be installed and enabled for embedded VM scanning on FC or iSCSI storage devices. Not a tcp/udp connection.

Red Hat Enterprise Virtualization Ports Used by Infrastructure Automation

Initiator (CFME Role if applicable)	Receiver (CFME Role if applicable)	Application	TCP Port	UDP Port	Purpose
CFME appliance	RHOS (Keystone)	HTTP REST API	5000		Authentication and Service Entry Point
CFME appliance	RHOS (Nova)	HTTP REST API	8774		Compute Resources
CFME appliance (C\&U)	RHOS (Ceilometer)	HTTP REST API	8777		Metrics for Capacity and Utilization
CFME appliance	RHOS (Glance)	HTTP REST API	9292		Authentication and Service Entry Point
CFME appliance	RHOS (AMQP)	AMQP	5672		Events Integration
CFME appliance	RHOS (Neutron)	HTTP REST API	9696		Networking
CFME appliance	RHOS (Cinder)	HTTP REST API	8776		Block Storage

Red Hat OpenStack Platform Ports Used by Infrastructure Automation

Initiator (CFME Role if applicable)	Receiver (CFME Role if applicable)	Application	TCP Port	UDP Port	Purpose
CFME Appliance	OpenShift Master Node(s) (or Load Balancer)	HTTPS	8443 or 443		Required for communication to the OpenShift API. Dependent on OpenShift configuration.
CFME Appliance	OpenShift Infrastructure Node(s) (or Load Balancer)	HTTPS	443		Metrics and logging

OpenShift Container Platform Ports Used by Infrastructure Automation

Initiator (CFME Role if applicable)	Receiver (CFME Role if applicable)	Application	TCP Port	UDP Port	Purpose
CFME appliance(Management System Inventory, Management System Operations, C & U Data Collection, SmartProxy)	vCenter	HTTPS	443		CFME appliance running any of these roles will initiate communication with vCenter on this port
CFME appliance (SmartProxy)	ESX, ESXi Host	HTTPS	443		CFME appliance
CFME appliance (SmartProxy)	ESX Hosts (if analyzing VMs through host)	SOAP over HTTPS	902		Communication from CFME appliance to hosts
CFME appliance (SmartProxy)	vCenter (if analyzing VMs through VC)	SOAP over HTTPS	902		Communication from CFME appliance to vCenters
CFME appliance(SmartProxy)	ESX Hosts (not needed for ESXi)	SSH	22		CFME appliance console access (ssh) to ESX hosts

VMware vSphere Ports Used by Infrastructure Automation

Initiator (CFME Role if applicable)	Receiver (CFME Role if applicable)	Application	TCP Port	UDP Port	Purpose
CFME appliance	Hyper-V Host (VMM agent)	WinRM/RPC/NetBIOS/SMB (over TCP)	80/135/139/445		Communication from CFME appliance to Host
CFME appliance	Hyper-V Host (file transfer)	HTTPS (using BITS)	443		Communication from CFME appliance to Host
CFME appliance	VM Guest Agent (file transfer)	HTTPS (using BITS)	443		Communication from CFME appliance to VM Guest Agent
CFME appliance	VMware ESX 3.0/3.5 Host (file transfer)	SFTP	22		Communication from CFME appliance to ESX Host
CFME appliance	VMware ESXi Host (file transfer)	SSH/HTTPS (using BITS)	443		Communication from CFME appliance to ESX Host
CFME appliance	WSUS Server (data channel)	HTTP	80/443		Communication from CFME appliance to Server
CFME appliance	SQL Server database (remote)	TDS	1433		CFME appliance connectivity to the Database
CFME appliance	Load Balancer	Load balancer config provider	80/443		
CFME appliance	Hyper-V host in untrusted domain or perimeter network (File Transfer)	TCP	443		CFME appliance connectivity to the host
CFME appliance	Hyper-V Host (file transfer)	BITS	443		Communication from CFME appliance to Host
CFME appliance	VMware Web Services	WCF	443		

SCVMM Ports Used by Infrastructure Automation

Initiator (CFME Role if applicable)	Receiver (CFME Role if applicable)	Application	TCP Port	UDP Port	Purpose
CFME appliance	SQL Management (*.database.windows.net)	TDS	1433		CFME appliance connectivity to the Database
CFME appliance	Upload into Storage (*.blob.core.windows.net)	HTTP/HTTPS	80/443		
CFME appliance	Service Bus Relay HTTP Mode (*.servicebus.windows.net)	SB over HTTP	80		
CFME appliance	Service Bus Pubsub over REST (*.servicebus.windows.net)	HTTPS	443		
CFME appliance	Access Control (*.accesscontrol.windows.net)	HTTPS	443		

Azure Ports Used by Infrastructure Automation

To provide your Infrastructure Automation infrastructure with an extra layer of security, use a network layer firewall to restrict port access.

Generating SSL Certificates for Your Appliance and Database

It is important to enhance the security of SSL communication of your appliances, which, depending on your setup, may include your database appliance. The appliance image ships with a default SSL certificate. It is recommended to replace this certificate with your own certificate, either signed by a trusted Certificate Authority (CA) or self-signed.

Creating a Certificate Signing Request

The first step is to determine the host name of your appliance or database appliance by running the following command:

```
$ hostname
```

The next step is to create a Certificate Signing Request (CSR) using the **openssl** command:

```
[root@ ~]# openssl req -new -newkey rsa:2048 -out appliance.csr -keyout appliance.key
```

This command generates a 2048-bit RSA private key and asks for a passphrase for the key.

```
Generating a 2048 bit RSA private key
..................+++
............................+++
writing new private key to 'appliance.key'
Enter PEM pass phrase: **********
Verifying - Enter PEM pass phrase: **********
```

The command then provides a questionnaire requesting certain details for the key. Fill out this questionnaire. Use the output of the **hostname** command to specify the **Common Name**.

For example:

```
Country Name (2 letter code) [XX]:US
State or Province Name (full name) []:North Carolina
Locality Name (eg, city) [Default City]:Raleigh
Organization Name (eg, company) [Default Company Ltd]:Infrastructure Automation
```

```
Organizational Unit Name (eg, section) []:Customer Content Services
Common Name (eg, your name or your server's hostname) []:$(hostname)
Email Address []:example@example.com

Please enter the following 'extra' attributes to be sent with your certificate request
A challenge password []:
An optional company name []:
```

Running the command produces two files:

- **appliance.key** - The private key
- **appliance.csr** - The Certificate Signing Request (CSR)

At this stage, you would send the CSR to a trusted Certificate Authority (CA) and in return they would send you a signed certificate.

Creating a Self-signed Certificate

As an alternative to obtaining a signed certificate, you can use the **appliance.key** and **appliance.csr** files to create a self-signed certificate by running the following **openssl** commands:

```
[root@ ~]# openssl rsa -in appliance.key -out server.cer.key
[root@ ~]# openssl x509 -in appliance.csr -out server.cer -req -signkey server.cer.key -days 3650
```

This produces two files:

- **server.cer.key** - The private key for your signed certificate
- **server.cer** - The self-signed certificate

Enabling Your Certificate

Despite whether you used a trusted CA or self-signed the certificate, you should now have your own certificate for your appliance.

Copy the certificate and key files to the certificate directory on the appliance:

```
[root@ ~]# cp ~/server.cer.key /var/www/miq/vmdb/certs/server.cer.key
[root@ ~]# cp ~/server.cer /var/www/miq/vmdb/certs/server.cer
```

After the certificate and key files have been copied, restart the appliance:

```
[root@ ~]# systemctl restart evmserverd
```

The appliance now uses your own certificate.

If your environment consists of multiple appliances connecting to a single database appliance, you can use your certificate and key files to set up SSL for the database connection. For more information, see Configuring the Database to use SSL.

Important:

Updates from the Red Hat Content Delivery Network might overwrite these certificate and key files. Make sure to copy your own certificate and key files to the certificate directory after performing an update to your appliance.

Note:

See also the following article for information on replacing SSL certificates in Infrastructure Automation : https://access.redhat.com/articles/449033.

Creating Custom Encryption Keys

To avoid storing passwords in plain text, Infrastructure Automation appliances use an encryption key to encode and decode passwords. Each appliance stores the key in the **/var/www/miq/vmdb/certs/v2_key**. Changing the encryption key is recommended during setting up new Infrastructure Automation appliances only.

Red Hat does not recommend changing the encryption key for an existing appliance as the ability to decrypt the password will be lost, affecting all stored passwords in Infrastructure Automation.
To generate a new encryption key:

1. Log in to the console of your master appliance as the **root** user.
2. Run the **appliance_console** command. The Infrastructure Automation appliance information screen appears.
3. Press any key to view the appliance menu.
4. Select **Generate Custom Encryption Key**.
5. A prompt asks if for confirmation to overwrite the existing key. Enter **Y**.
6. Enter **1** for **1) Create key**.
7. The appliance generates the new key. Press any key to complete this procedure.

This completes the procedure for generating the new key. If you have external Infrastructure Automation appliances, you must share this key to ensure your whole Infrastructure Automation infrastructure is using consistent encryption. Failure to use the same key results in encryption and decryption problems.

To copy an encryption key:

1. Log in to the console of an external appliance as the **root** user.

2. Run the **appliance_console** command. The Infrastructure Automation appliance information screen appears.
3. Press any key to view the appliance menu.
4. Select **Generate Custom Encryption Key**.
5. A prompt asks if for confirmation to overwrite the existing key. Enter **Y**.
6. Select **Fetch key from remote machine**.
7. Enter the hostname or IP address of the master appliance.
8. Enter the username for SSH access to the master appliance. Use the default **root** user.
9. Enter the password for SSH access to the master appliance.
10. Enter the location of the remote key. Accept the default as **/var/www/miq/vmdb/certs/v2_key**.
11. The appliance copies the new key from the remote server. Press any key to complete this procedure.

After distributing the new key, all appliances require an update to the database configuration. For all appliances, log in as the **root** user and run the following commands replacing **dbpassword** with your database password:

```
[root@{productname_short_l} ~]# fix_auth --databaseyml --hostname localhost --password dbpassword
[root@{productname_short_l} ~]# systemctl restart evmserverd
```

This completes the new encryption key generation for your Infrastructure Automation infrastructure.

Applying SCAP Standards

The Security Content Automation Protocol (SCAP) is a set of standards to assist with vulnerability management and policy compliance. Infrastructure Automation provides a set of SCAP standards to apply to your appliance. View these SCAP rules in the **/var/www/miq/vmdb/productization/appliance_console/config/scap_rules.yml** file.

To apply the SCAP standards to your appliance's server:

1. Log in to the appliance as the **root** user.
2. Enter the **appliance_console** command. The Infrastructure Automation Appliance summary screen displays.
3. Press **Enter** to manually configure settings.
4. Select **Harden Appliance Using SCAP Configuration**.
5. The appliance console displays the following:

   ```
   Harden Appliance Using SCAP Configuration

   Locking down the appliance for SCAP...
   ```

   The appliance applies the SCAP settings from the **scap_rules.yml** file.
6. When complete, press any key to return to the summary screen.

The appliance now meets the SCAP standards set in the **scap_rules.yml** file.

Database Security

Restricting Hosts Access to the Database

Strengthening the host-based authentication (HBA) settings on a database appliance helps with preventing unauthorized access from external hosts. The HBA settings restrict access to an IP address range so that only hosts within that range have access.

Restricting access to the database requires modifications to the **/var/lib/pgsql/data/pg_hba.conf** file. This file contains a text-based table with some initial settings:

```
# TYPE    DATABASE USER  ADDRESS       METHOD
local     all      all                  peer map=usermap
host      all      all   all            md5
#hostssl  all      all   all            md5
```

This format for this table uses the following header columns:

- TYPE This defines the access type, either local access from the database host (**local**), remote access from an external host regardless of encryption (**host**), external access with encryption (**hostssl**), or external access without encryption (**nohostssl**).
- DATABASE The name of the database the host can access. Use **all** for all databases.
- USER The name of the user the host can use to access the database. Use **all** for all users.
- ADDRESS The IP address of the host or address range of hosts with access to the database. This can either be:
  - A single address:

    ```
    host    all      all   192.168.1.10          md5
    ```

- An address range using a CIDR mask:

```
host    all      all   192.168.1.0/24          md5
```

- An address range using a separate subnet mask value

```
host    all      all   192.168.1.0  255.255.255.0           md5
```

Note:

ADDRESS is not required for **local** connections.

- METHOD The authentication method, which includes:
  - **trust** - Allow the connection unconditionally. This method allows anyone that can connect to the PostgreSQL database server to login as any PostgreSQL user they wish, without the need for a password or any other authentication.
  - **reject** - Reject the connection unconditionally. This is useful for "filtering out" certain hosts from a group, for example a **reject** line could block a specific host from connecting, while a later line allows the remaining hosts in a specific network to connect.
  - **md5** - Require the client to supply an MD5-encrypted password for authentication.
  - **password** - Require the client to supply an unencrypted password for authentication. Since the password is sent in clear text over the network, this should not be used on untrusted networks.
  - **ident** - Obtain the operating system user name of the client by contacting the ident server on the client and check if it matches the requested database user name. Ident authentication can only be used on TCP/IP connections. When specified for local connections, peer authentication will be used instead.
  - **peer** - Obtain the client's operating system user name from the operating system and check if it matches the requested database user name. This is only available for local connections.

Using a combination of these options, you create a series of rules that govern which hosts can access your database and which hosts are denied. For example, you might change the default HBA rules to only allow remote access to the Infrastructure Automation database (**vmdb_production**) from hosts in a certain subnet. The modified HBA table would looks like this:

```
# TYPE  DATABASE           USER  ADDRESS          METHOD
local   all                all                    peer map=usermap
host    vmdb_production    all   192.168.1.0/24   md5
#hostssl all               all   all              md5
```

These restrictions help when structuring your Infrastructure Automation appliances in relationships. For example, use these database restrictions to grant access only between a master database appliance in one region and appliances connecting from a separate region.

Configuring the Database to use SSL

Infrastructure Automation initially connects to the database through an unencrypted communication. If you are using multiple appliances that are connecting to a single database appliance, you can set up the database connection to use SSL. An SSL connection encrypts the communication between the Infrastructure Automation and the database.

The procedures in this section use the SSL certificate and the following key files. These files can be found on your main Infrastructure Automation database appliance.

Note:

The appliance image ships with a default SSL certificate and it is recommended to change this certificate. You can use a certificate that is signed by a trusted CA, or generate a self-signed certificate.

For more information, see Generating SSL Certificates for Your Appliance and Database.

- **/var/www/miq/vmdb/certs/server.cer** - Signed or self-signed certificate for the database appliance.
- **/var/www/miq/vmdb/certs/server.cer.key** - Private key for server certificate.

It is also recommended to stop all Infrastructure Automation services before configuring the database to use SSL.

Configure SSL on the database appliance

To configure SSL on the database appliance:

1. Log in as **root** to the appliance where the database resides.
2. Stop the **evmserverd** and **postgresql** services:

```
$ systemctl stop evmserverd
$ systemctl stop postgresql.service
```

3. Install the server key file in the correct location and set the ownership and permissions for it:

```
$ install -m 600 -o postgres -g postgres \
/var/www/miq/vmdb/certs/server.cer.key /var/lib/pgsql/data/postgres.key
```

4. Install the server certificate file in the correct location and set the ownership and permissions for it:

```
$ install -m 644 -o postgres -g postgres \
/var/www/miq/vmdb/certs/server.cer /var/lib/pgsql/data/postgres.crt
```

5. Open the **/var/lib/pgsql/data/postgresql.conf** file and uncomment and edit the **ssl** option:

   ```
   ssl=on
   ```

   In the same file, locate the options **ssl_cert_file** and **ssl_key_file** that specify the location of SSL certificates and edit them so that they are uncommented and point to the correct certificate files:

   ```
   ssl_cert_file = 'postgres.crt'   # (change requires restart)
   ssl_key_file  = 'postgres.key'   # (change requires restart)
   ```

6. Open the **/var/lib/pgsql/data/pg_hba.conf** file and locate the two lines that contain:

   ```
   host      all      all   all           md5
   #hostssl  all      all   all           md5
   ```

   Modify the two lines to comment the **host** entry and uncomment the **hostssl** entry:

   ```
   #host     all      all   all           md5
   hostssl   all      all   all           md5
   ```

   This changes the incoming communication protocol to use SSL and refuse any unencrypted PostgreSQL connections.

7. Start the **postgresql** and **evmserverd** services so that the changes take effect:

   ```
   $ systemctl start postgresql.service
   $ systemctl start evmserverd
   ```

Configure SSL on all connected appliances

The database appliance now accepts only connections from connecting appliances that use SSL. The following procedure sets up connecting appliances to communicate to the database by using SSL. Use this procedure for each connecting appliance:

1. Log in as **root** to the connecting appliance.

2. Copy the root certificate file from the database to the operating system's list of valid certificates:

   ```
   $ DATABASE=[database_appliance_fqdn]
   $ scp root@${DATABASE}:/var/www/miq/vmdb/certs/root.crt /etc/pki/ca-trust/source/anchors/${DATABASE}-postgres
   $ update-ca-trust extract
   $ export PGSSLROOTCERT=/etc/pki/tls/certs/ca-bundle.crt
   ```

   Where **[database_appliance_fqdn]** is the fully qualified domain name of the database appliance.

3. Test the certificate got added to the certificate database:

   ```
   $ openssl x509 -in /etc/pki/tls/certs/ca-bundle.crt -text -noout
   ```

4. Test the connection between the connecting appliance and the database appliance by using the **psql**command:

   ```
   $ PGSSLMODE=verify-full psql -h [database_appliance_fqdn] -d vmdb_production \
     -c "SELECT * from pg_stat_ssl WHERE pid=pg_backend_pid()"
   Password: ********
   psql (9.2.8)
   SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
   Type "help" for help.

   vmdb_production=#
   ```

   The **psql** displays information about the SSL connection, which indicates that the configuration succeeded. Enter **\q** to leave **psql**. The **PGSSLMODE** variable forces a certain level of SSL. To learn more, please see postgress sslmode documentation.

5. Ensure **/etc/default/manageiq.properties** has the proper ssl key file location defined:

   ```
   $ grep PGSSLROOTCERT /etc/default/manageiq.properties || \
   echo PGSSLROOTCERT=/etc/pki/tls/certs/ca-bundle.crt >> /etc/default/manageiq.properties
   ```

   The standard **manageiq.properties** should already have the **PGSSLROOTCERT** defined. The above command adds an entry to **manageiq.properties** if it is not already present.

Complete this procedure for each external appliance. This enhances the security of all database transactions in your Infrastructure Automation infrastructure.

Hardening TLS Protocol Version

After configuring the database to use SSL, protocol TLS version 1.2 is used as default. The older versions of this protocol (TLS 1.0 and 1.1) are still available for clients to choose. You can disable older versions by inserting the following lines into **/var/lib/pgsql/data/postgresql.conf**:

```
ssl_ciphers = 'TLSv1.2:!aNULL'
ssl_prefer_server_ciphers=true
```

Methods Available for Automation

Methods Available for Use with Infrastructure Automation

Methods can be used from within Infrastructure Automation to create custom actions and workflows for the objects managed for your Infrastructure Automation Infrastructure. This document describes the methods available for use in Infrastructure Automation. This document is organized by the object hierarchy in the Automate Model.

Note:

Users of Infrastructure Automation can construct custom automation methods in Ruby to extend the product. Infrastructure Automation ships with a core set of Ruby gems used by the Infrastructure Automation Rails Application. The Ruby gems in this set are subject to change, and have changed since the previous version. If

you are calling gems using Automate that are no longer in the Infrastructure Automation appliance, you can install them by using the **`gem install`** command.

While gems can be imported into automation methods using **`require`**, it is recommended that the authors of the automation methods clearly document the use of gems either in the core set or a custom set. It is the responsibility of the author of such custom automation to own the life cycle of any gem being referenced in those methods.

$evm.root

When an Automate method is launched, it has one global variable: **`$evm`**. The **`$evm`** variable allows the method to communicate back to Infrastructure Automation. The **`$evm.root`** is the root object in the workspace, it provides access to the data currently loaded in the Infrastructure Automation model. It uses the object's data to solve more complex problems by integrating with Infrastructure Automation methods.

The following is an excerpt from the **InspectMe** method that can be found in the **ManageIQ\System\Request** namespace. The dumpRoot method accesses the **`$evm.root`** object, and sends all of its attributes to the Infrastructure Automation Automate log for review. In the dumpServer Method, the inspect method is run based on the value of the miq_server obtained from the **`$evm.root`** object.

```
#########################
  #
  # Method: dumpRoot
  # Description: Dump Root information
  #
  ##########################
  def dumpRoot
    $evm.log("info", "#{@log_prefix} - Root:<$evm.root> Begin Attributes")
    $evm.root.attributes.sort.each { |k, v| $evm.log("info", "#{@log_prefix} - Root:<$evm.root> Attributes - #{k}: #{v}")}
    $evm.log("info", "#{@log_prefix} - Root:<$evm.root> End Attributes")
    $evm.log("info", "")
  end

  ##########################
  #
  # Method: dumpServer
  # Inputs: $evm.root['miq_server']
  # Description: Dump MIQ Server information
  #
  ##########################
  def dumpServer
    $evm.log("info","#{@log_prefix} - Server:<#{$evm.root['miq_server'].name}> Begin Attributes")
    $evm.root['miq_server'].attributes.sort.each { |k, v| $evm.log("info", "#{@log_prefix} - Server:<#
{$evm.root['miq_server'].name}> Attributes - #{k}: #{v.inspect}")}
    $evm.log("info","#{@log_prefix} - Server:<#{$evm.root['miq_server'].name}> End Attributes")
    $evm.log("info", "")
  end
```

The result of dumpRoot is below. The value of miq_server is what gets passed into the dumpServer method.

```

Method Hierarchy

The Automate Model inline methods have a hierarchy. The sublevels in the hierarchy have access to the methods for itself and the levels above it. For example, Red Hat Hosts have access to the Red Hat Host methods, Host Methods, and Base Methods.

The following nested list displays the hierarchy.

- Top Level: Base
    - Authentication (authentication)
        - Private Keys (auth_private_key)
            - Key Pair for Clouds (auth_key_pair_cloud)
                - Amazon (auth_key_pair_amazon)
                - OpenStack (auth_key_pair_openstack)

- Availability Zones (availability_zone)
  - Amazon (availability_zone_amazon)
  - OpenStack (availability_zone_openstack)
- Classification (classification)
- Cloud Networks (cloud_network)
- Cloud Resource Quotas (cloud_resource_quota)
  - OpenStack (openstack_resource_quota)
- Cloud Subnets (cloud_subnet)
- Cloud Tenants (cloud_tenant)
- Customization Templates (customization_template)
  - Cloud Init (customization_template_cloud_init)
  - Kickstart (customization_template_kickstart)
  - Sysprep (customization_template_sysprep)
- Cluster (ems_cluster)
- Event (ems_event)
- Folder (ems_folder)
- Providers (ext_management_system)
  - Cloud (ems_cloud)
    - Amazon (ems_amazon)
    - Openstack (ems_openstack)
  - Infrastructure (ems_infra)
    - Microsoft System Center VMM (ems_microsoft)
    - Red Hat Enterprise Virtualization (ems_redhat)
    - VMware vCenter (ems_vmware)
- Filesystems (filesystem)
- Firewall Rules (filewall_rule)
- Flavors
  - Amazon (flavor_amazon)
  - OpenStack (flavor_openstack)
- Floating IPs (floating_ip)
  - Amazon (floating_ip_amazon)
  - OpenStack (floating_ip_openstack)
- Guest Applications (guest_application)
- Guest Devices (guest_device)
- Hardware (hardware)
- Hosts (host)
  - Red Hat Enterprise Virtualization (host_redhat)
  - VMware (host_vmware)
    - VMware ESX (host_vmware_esx)
- ISO Images (iso_image)
- Jobs (job)
- LANs (lan)
- Groups (miq_group)
- Policies (miq_policy)
- Proxies (miq_proxy)

- Requests (miq_request)
  - Automation (automation_request)
  - Host Provisioning (miq_host_provision_request)
  - VM Provisioning (miq_provision_request)
    - VM Templates (miq_provision_request_template)
  - Service Reconfiguration (service_reconfigure_request)
  - Service Template Provisioning (service_template_provision_request)
  - VM Migration (vm_migrate_request)
  - VM Reconfiguration (vm_reconfigure_request)
- Request Task (miq_request_task)
  - Automation (automation_task)
  - Host Provisioning (miq_host_provision)
  - VM Provisioning (miq_provision)
    - Cloud (miq_provision_cloud)
      - Amazon (miq_provision_amazon)
      - OpenStack (miq_provision_openstack)
    - Red Hat Enterprise Virtualization (miq_provision_redhat)
      - Via ISO (miq_provision_redhat_via_iso)
      - Via PXE (miq_provision_redhat_via_pxe)
    - VMware (miq_provision_vmware)
      - Via NetApp RCU (miq_provision_vmware_via_net_app_rcu)
      - Via PXE (miq_provision_vmware_via_pxe)
  - Service Reconfiguration (service_reconfigure_task)
  - Service Template Provisioning (service_template_provision_task)
  - VM Migratation (vm_migrate_task)
  - VM Reconfiguration (vm_reconfigure_task)
- Servers (miq_server)
- Networks (network)
- Operating Systems (operating_system)
- PXE Images (pxe_image)
  - iPXE (pxe_image_ipxe)
  - PXELINUX (pxe_image_pxelinux)
- PXE Servers (pxe_server)
- Resource Pools (resource_pool)
- Security Groups (security_group)
  - Amazon (security_group_amazon)
  - OpenStack (security_group_openstack)
- Services (service)
- Service Resources (service_resource)
- Service Templates (service_template)
- Snapshots (snapshot)
- Storages (storage)
- Switches (switch)
- Users (user)

- VMs or Templates (vm_or_template)
  - Templates (miq_template)
    - Cloud (template_cloud)
      - Amazon (template_amazon)
      - OpenStack (template_openstack)
    - Infrastructure (template_infra)
      - Microsoft (template_microsoft)
      - Red Hat Enterprise Virtualization (template_redhat)
      - VMware (template_vmware)
  - VMs (vm)
    - Clouds (vm_cloud)
      - Amazon (vm_amazon)
      - OpenStack (vm_openstack)
    - Infrastructure (vm_infra)
      - Microsoft (vm_microsoft)
      - Red Hat Enterprise Virtualization (vm_redhat)
      - Vmware (vm_vmware)
- Windows Images (windows_images)

Base Methods

These methods may be used with all objects available in the Automate Model.

Method	Usage
inspect	Returns a string containing a list of attributes of the object. See the InspectMe method in Samples class
inspect_all	Returns all information for an object
virtual_column_names	Returns the objects virtual columns names
virtual_columns_inspect	Returns the objects virtual columns and values
reload	Returns to original object to prevent the internal object from being returned
model_suffix	Returns objects suffix. For an object of type MiqAeServiceVmVmware, returns “Vmware”
tagged_with?(category, name)	Is the object tagged with the category and name specified?
tags(category = nil)– this means that category is an optional parameter, with a default of nil	Returns the tags.
tag_assign(tag)	Assigns tag to the object, except for the miq_provision object, which uses add_tag(category, tag_name)
tag_unassign(tag)	Unassigns tag to the object, except for the miq_provision object, which uses clear_tag(category, tag_name)

The **InspectMe Sample Method** uses many of the Methods shown in this document. The method returns attributes of the Infrastructure Automation Server and then returns attributes for the host, cluster, and virtual machine from the provider of invocation. In many environments it is linked to a button.

```
###################################
# EVM Automate Method: InspectMe
#
# Notes: Dump the objects in storage to the automation.log
#
###################################
begin
  @method = 'InspectMe'
  @log_prefix = "[#{@method}]"
  $evm.log("info", "#{@log_prefix} - EVM Automate Method Started")

  # Turn on verbose logging
  @debug = true

  # List the types of object we will try to detect
  obj_types = %w{ vm host storage ems_cluster ext_management_system }
  obj_type = $evm.root.attributes.detect { |k,v| obj_types.include?(k)}

  # uncomment below to dump root object attributes
  dumpRoot

  # uncomment below to dump miq_server object attributes
```

```
  dumpServer

  # If obj_type is NOT nil
  unless obj_type.nil?
    rootobj = obj_type.first
    obj = obj_type.second

  #
  $evm.log("info", "#{@log_prefix} - EVM Automate Method Ended")
  exit MIQ_OK

  #
  # Set Ruby rescue behavior
  #
rescue => err
  $evm.log("error", "#{@log_prefix} - [#{err}]\n#{err.backtrace.join("\n")}")
  exit MIQ_ABORT
end
```

Availability Zones (availability_zone)

Method	Use
ext_management_system	Returns object's Management System
vms	Returns object's VMs
vms_and_templates	Returns object's VMs and templates
cloud_subnets	Returns object's cloud subnets

Classifications (classification)

Method	Use
parent	Returns object's parent object
namespace	Returns object's namespace
category	Returns object's category
name	Returns object's name
to_tag	Returns object's tag mapping

Cloud Networks (cloud_network)

Method	Use
ext_management_system	Returns object's Management System
cloud_tenant	Returns object's cloud tenant
cloud_subnets	Returns object's cloud subnets
security_groups	Returns object's security groups
vms	Returns object's VMs

Cloud Resource Quotas (cloud_resource_quota)

Method	Use
ext_management_system	Returns object's Management System
cloud_tenant	Returns object's cloud tenant

Cloud Subnets (cloud_subnet)

Method	Use
cloud_network	Returns object's cloud network
availability_zone	Returns object's availability zone
vms	Returns object's VMs

Cloud Tenants (cloud_tenant)

Method	Use
ext_management_system	Returns object's Management System
security_groups	Returns object's security groups
cloud_networks	Returns object's cloud network
vms	Returns object's VMs

Method	Use
vms_and_templates	Returns object's VMs and templates
miq_templates	Returns object's templates
floating_ips	Returns object's floating IP addresses
cloud_resource_quotas	Returns object's quotas

Customization Template (customization_template)

Method	Use
Pxe_images	Returns customization templates pxe images

Clusters (ems_cluster)

Method	Use
all_resource_pools	Return all of the objects Resource Pools
all_vms	Return all of the objects Virtual Machines
default_resource_pool	Return the objects default Resource Pool
ems_events	Returns an array of EmsEvent records associated with the object
ext_management_system	Return objects Management System
hosts	Return objects Hosts
parent_folder	Return objects Parent Folder
register_host(host)	Register Host to this Cluster
resource_pools	Return objects Resource Pools
storages	Return objects datastores
vms	Return objects Virtual Machines

```
  ##########################
  #
  # Method: dumpCluster
  # Inputs: $evm.root['ems_cluster']
  # Description: Dump Cluster information
  #
  ##########################
  def dumpCluster(cluster)
    $evm.log("info","#{@log_prefix} - Cluster:<#{cluster.name}> Begin Attributes")
    cluster.attributes.sort.each { |k, v| $evm.log("info", "#{@log_prefix} - Cluster:<#{cluster.name}> Attributes - #{k}:
#{v.inspect}")}
    $evm.log("info","#{@log_prefix} - Cluster:<#{cluster.name}> End Attributes")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Cluster:<#{cluster.name}> Begin Associations")
    cluster.associations.sort.each { |assc| $evm.log("info", "#{@log_prefix} - Cluster:<#{cluster.name}> Associations - #
{assc}")}
    $evm.log("info","#{@log_prefix} - Cluster:<#{cluster.name}> End Associations")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Cluster:<#{cluster.name}> Begin Virtual Columns")
    cluster.virtual_column_names.sort.each { |vcn| $evm.log("info", "#{@log_prefix} - Cluster:<#{cluster.name}> Virtual
Columns - #{vcn}: #{cluster.send(vcn)}")}
    $evm.log("info","#{@log_prefix} - Cluster:<#{cluster.name}> End Virtual Columns")
    $evm.log("info","")
  end
```

Management System Events (ems_event)

Method	Use
ext_management_system	Returns object's provider
ems	Shortcut to ext_management_system
src_vm	Source VM for the event
vm	VM for the event
src_host	Source Host for the event
host	Host for the event
dest_vm	Destination VM for the event
service	Service for the event
dest_host	Destination Host for the event
refresh(*targets)	Refresh the target types specified (ems, vm, host, src_vm, src_host, dest_vm, or dest_host)

Management System Folders (ems_folder)

Method	Use
hosts	Returns hosts that are in the folder
vms	Returns VMs that are in folder
register_host(host)	Registers specified host to the folder
folder_path(*options)	Returns folders path

Providers (ext_management_system)

Method	Use
authentication_password_encrypted	Returns credentials password encrypted
authentication_password	Returns credentials password unencrypted
authentication_userid	Returns credentials user id
ems_clusters	Returns objects clusters
ems_events	Returns an array of EmsEvent records associated with the object
ems_folders	Returns objects folders
hosts	Returns objects hosts
refresh	Refreshes relationships and power states for objects related to the object
resource_pools	Returns objects resource pools
storages	Returns objects storages
vms	Returns objects vms
to_s	Converts object to string

```
  ##########################
  #
  # Method: dumpEMS
  # Inputs: $evm.root['ext_management_system']
  # Description: Dump EMS information
  #
  ##########################
  def dumpEMS(ems)
    $evm.log("info","#{@log_prefix} - EMS:<#{ems.name}> Begin Attributes")
    ems.attributes.sort.each { |k, v| $evm.log("info", "#{@log_prefix} - EMS:<#{ems.name}> Attributes - #{k}: #
{v.inspect}")}
    $evm.log("info","#{@log_prefix} - EMS:<#{ems.name}> End Attributes")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - EMS:<#{ems.name}> Begin Associations")
    ems.associations.sort.each { |assc| $evm.log("info", "#{@log_prefix} - EMS:<#{ems.name}> Associations - #{assc}")}
    $evm.log("info","#{@log_prefix} - EMS:<#{ems.name}> End Associations")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - EMS:<#{ems.name}> Begin EMS Folders")
    ems.ems_folders.each { |ef| ef.attributes.sort.each { |k,v| $evm.log("info", "#{@log_prefix} - EMS:<#{ems.name}> EMS
Folder:<#{ef.name}> #{k}: #{v.inspect}")}}
    $evm.log("info","#{@log_prefix} - EMS:<#{ems.name}> End EMS Folders")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - EMS:<#{ems.name}> Begin Virtual Columns")
    ems.virtual_column_names.sort.each { |vcn| $evm.log("info", "#{@log_prefix} - EMS:<#{ems.name}> Virtual Columns - #
{vcn}: #{ems.send(vcn)}")}
    $evm.log("info","#{@log_prefix} - EMS:<#{ems.name}> End Virtual Columns")
    $evm.log("info","")
  end
```

Cloud Providers (ems_cloud)

Method	Use
availability_zones	Return the provider's availability zones
cloud_networks	Return the provider's available networks
cloud_tenants	Return the provider's available tenants
flavors	Return the provider's hardware flavors
floating_ips	Return the provider's floating IP addresses
key_pairs	Return the provider's key pairs
security_groups	Return the provider's security groups
cloud_resource_quotas	Return the provider's resource quotas

Firewall Rules (firewall_rule)

Method	Use
resource	Return object's resource
source_security_group	Return object's source security group

Flavors (flavor)

Method	Use
ext_management_system	Returns object's Management System
vms	Returns object's VMs

Floating IPs (floating_ip)

Method	Use
ext_management_system	Returns object's Management System
vm	Returns object's VMs
cloud_tenant	Returns object's cloud tenant

Guest Applications (guest_application)

Method	Use
vm	Returns objects VM
host	Returns objects Host

Guest Device (guest_device)

Method	Use
hardware	Returns objects hardware
switch	Returns objects switch
lan	Returns objects LAN
network	Returns objects network

Hardware (hardware)

Method	Use
ipaddresses	Returns objects IP addresses
guest_devices	Returns objects guest devices
storage_adapters	Returns objects storage adapters
nics	Returns objects nics
ports	Returns objects ports
vm	Returns objects Virtual Machine
host	Returns objects Host
mac_addresses	Returns objects MAC addresses

Hosts (host)

Method	Use
authentication_password	Returns credential password
authentication_userid	Returns credential user
datacenter	Returns datacenter
directories	Returns list of directories for the object
domain	Returns the domain portion of the hostname
ems_cluster	Returns cluster
ems_events	Returns an array of EmsEvent records associated with the object
ems_folder	Returns hosts folder on Management System
event_log_threshold?(options)	Searches event log records to determine if an event has occurred x number of times within a defined time frame. Returns true if the number of matching records found are greater or equal to the specified freq_threshold, otherwise it returns false Options values: :message_filter_type - Must be one of "STARTS WITH", "ENDS WITH", "INCLUDES", "REGULAR EXPRESSION" :message_filter_value - <string value to search for> :time_threshold - Options time interval to search. Example: 2.days (Search the past 2 days of event logs) Default 10.days :freq_threshold - Number of occurrences to check for. Default = 2 :source, :event_id, :level, :name - Options filter values
ext_management_system	Returns Management System
files	Returns list of files for the object
guest_applications	Returns Guest Applications
hardware	Returns hardware
lans	Returns LANs
operating_system	Returns Operating System
storages	Returns datastores
switches	Returns network switches
vms	Returns VMs.

Method	Use
credentials(type = :remote)	Returns credentials for a Host for the specified type as an array for username/pwd. (Default type is :remote if no type is specified.) Supports 4 different types of credentials: :default = Default :remote = Remote Login (think SSH for ESX) :ws = Web Services :ipmi = IPMI Example 1: cred = host.credentials cred ⇒ ["user", "pwd"] Example 2: user_str, pwd_str = host.credentials(:ipmi) user_str ⇒ "user" pwd_str ⇒ "pwd"
ems_custom_keys	Returns Management Systems custom keys
ems_custom_get(key)	Gets Value for specified Management Systems custom key
ems_custom_set(attribute, value)	Sets value for specified custom key of the Management System
custom_keys	Lists Infrastructure Automation Server custom keys
custom_get(key)	Gets value for specified Infrastructure Automation Server custom key
custom_set(key, value)	Sets value for specified Infrastructure Automation Server custom key
ssh_exec(script)	Runs the specified script on the host
get_realtime_metric(metric, range, function)	Returns specified realtime metric
current_memory_usage	Returns current memory usage
current_cpu_usage	Returns current cpu usage
current_memory_headroom	Returns current memory headroom
to_s	Converts object to string
scan	Performs SmartState Analysis on the object

The following table lists the metric types available for the **`get_realtime_metric(metric, range, function)`** method for hosts.

Metric	Description
v_derived_storage_used	Capacity - Used space in bytes
v_pct_cpu_ready_delta_summation	CPU - Percentage ready
v_pct_cpu_wait_delta_summation	CPU - Percentage wait
v_pct_cpu_used_delta_summation	CPU - Percentage used
v_derived_host_count	State - Number of hosts (Hourly Count / Daily Average)
v_derived_cpu_reserved_pct	CPU - Percentage available
v_derived_memory_reserved_pct	Memory - Percentage available

The following Ruby snippet demonstrates using the **`get_realtime_metric(metric, range, function)`** method using the **`v_pct_cpu_ready_delta_summation`** metric.

```
host = $evm.root['host']
cpu_rdy = host.get_realtime_metric(:v_pct_cpu_ready_delta_summation, [15.minutes.ago.utc,5.minutes.ago.utc], :avg)

#########################
  #
  # Method: dumpHost
  # Inputs: $evm.root['host']
  # Description: Dump Host information
  #
  #########################
  def dumpHost(host)
    host = $evm.object['host'] || $evm.root['host']
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> Begin Attributes")
    host.attributes.sort.each { |k, v| $evm.log("info", "#{@log_prefix} - Host:<#{host.name}> Attributes - #{k}: #
{v.inspect}")}
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> End Attributes")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> Begin Associations")
    host.associations.sort.each { |assc| $evm.log("info", "#{@log_prefix} - Host:<#{host.name}> Associations - #{assc}")}
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> End Associations")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> Begin Hardware")
    host.hardware.attributes.each { |k,v| $evm.log("info", "#{@log_prefix} - Host:<#{host.name}> Hardware - #{k}: #
```

```
{v.inspect}")}
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> End Hardware")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> Begin Lans")
    host.lans.each { |lan| lan.attributes.sort.each { |k,v| $evm.log("info", "#{@log_prefix} - Host:<#{host.name}> Lan:<#
{lan.name}> - #{k}: #{v.inspect}")}}
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> End Lans")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> Begin Switches")
    host.switches.each { |switch| switch.attributes.sort.each { |k,v| $evm.log("info", "#{@log_prefix} - Host:<#
{host.name}> Swtiche:<#{switch.name}> - #{k}: #{v.inspect}")}}
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> End Switches")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> Begin Operating System")
    host.operating_system.attributes.sort.each { |k, v| $evm.log("info", "#{@log_prefix} - Host:<#{host.name}> Operating
System - #{k}: #{v.inspect}")}
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> End Operating System")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> Begin Guest Applications")
    host.guest_applications.each { |guest_app| guest_app.attributes.sort.each { |k, v| $evm.log("info", "#{@log_prefix} -
Host:<#{host.name}> Guest Application:<#{guest_app.name}> - #{k}: #{v.inspect}")}}
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> End Guest Applications")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> Begin Virtual Columns")
    host.virtual_column_names.sort.each { |vcn| $evm.log("info", "#{@log_prefix} - Host:<#{host.name}> Virtual Columns - #
{vcn}: #{host.send(vcn).inspect}")}
    $evm.log("info","#{@log_prefix} - Host:<#{host.name}> End Virtual Columns")
    $evm.log("info", "")
  end
```

Hosts: Vmware ESX (host_vmware_esx)

Method	Use
disable_vmotion(device = nil)	Disable vMotion
enable_vmotion(device = nil)	Enable vMotion
enter_maintenance_mode(timeout = 0, evacuate = false)	Put Host in Maintenance Mode
exit_maintenance_mode(timeout = 0)	Leave Maintenance Mode
in_maintenance_mode?	Check to see if the host is in Maintenance Mode
power_down_to_standby(timeout = 0, evacuate = false)	Put Host in standby
power_up_from_standby(timeout = 0)	Take Host out of standby
reboot(force = false)	Reboot Host
shutdown(force = false)	Shutdown Host
vmotion_enabled?(device = nil)	Check to see if vMotion is enabled

LAN (lan)

Method	Use
switch	Returns objects switch
guest_devices	Returns objects guest devices
vms	Returns objects Virtual Machines
templates	Returns objects templates
hosts	Returns objects Hosts

Groups (miq_group)

Method	Use
users	Returns users in the current miq_group
vms	Returns Virtual Machines that this group owns
custom_keys	Returns all custom keys for the group
custom_get(key)	Returns the value of the specified custom key for the group
custom_set(key, value)	Sets the value for the specified key

```
  ##########################
  #
  # Method: dumpGroup
  # Inputs: $evm.root['user'].miq_group
  # Description: Dump User's Group information
  #
  ##########################
  def dumpGroup
    user = $evm.root['user']
    unless user.nil?
      miq_group = user.miq_group
      unless miq_group.nil?
        $evm.log("info","#{@method} - Group:<#{miq_group.description}> Begin Attributes [miq_group.attributes]")
        miq_group.attributes.sort.each { |k, v| $evm.log("info", "#{@method} - Group:<#{miq_group.description}> Attributes
```

```
- #{k}: #{v.inspect}")} unless $evm.root['user'].miq_group.nil?
        $evm.log("info","#{@method} - Group:<#{miq_group.description}> End Attributes [miq_group.attributes]")
        $evm.log("info", "")

        $evm.log("info","#{@method} - Group:<#{miq_group.description}> Begin Associations [miq_group.associations]")
        miq_group.associations.sort.each { |assc| $evm.log("info", "#{@method} - Group:<#{miq_group.description}>
Associations - #{assc}")}
        $evm.log("info","#{@method} - Group:<#{miq_group.description}> End Associations [miq_group.associations]")
        $evm.log("info","")

        $evm.log("info","#{@method} - Group:<#{miq_group.description}> Begin Virtual Columns
[miq_group.virtual_column_names]")
        miq_group.virtual_column_names.sort.each { |vcn| $evm.log("info", "#{@method} - Group:<#{miq_group.description}>
Virtual Columns - #{vcn}: #{miq_group.send(vcn).inspect}")}
        $evm.log("info","#{@method} - Group:<#{miq_group.description}> End Virtual Columns
[miq_group.virtual_column_names]")
        $evm.log("info","")
      end
    end
  end
```

Request (miq_request)

Request objects are submitted to Infrastructure Automation Server for processing. After the request phase, the request becomes a task object. The table below shows the relationship between a request object and a task object.

Request Object	Task Object
automation_request	automation_task
miq_host_provision_request	miq_host_provision
miq_provision_request	miq_provision
vm_reconfigure_request	vm_reconfigure_task
service_template_provision_request	service_template_provision_task
vm_migrate_request	vm_migrate_task

If you set something on the request object, it will be inherited by the task instance that does the work. This may be useful if you are provisioning multiple virtual machines at a time and need to modify the same setting for all. Otherwise, the item can be modified on the individual task.

Method	Use
add_tag(category, tag_name)	Add a tag to a provision instance by specifying the category and tag name Example: miq_provision.add_tag(:location, "CHI")
approve(approver,reason for approval)	Approves the miq_request. Example: $evm.root["miq_request"].approve("admin", "Auto-Approved")
approvers	Returns request approvers.
authorized?	Returns true if authorized, false if not.
clear_tag(category=nil, tag_name=nil)	Without any parameters, the clear_tag method will clear all tags from the provision request. Providing a category will clear all tags selected in that category. Clear a specific category/tag by providing it. Example: miq_provision.clear_tag(:location, "CHI")
deny	Denies the miq_request Example: # Deny the request $evm.log('info',"Request denied because of Quota") $evm.root["miq_request"].deny("admin", "Quota Exceeded")
get_classification(category)	Works the same as get_tag(category) but the returned data is a hash with :name and :description Example: request.get_classification(:department) Returns: [{:name⇒"accounting", :description⇒"Accounting"}, {:name⇒"engineering", :description⇒"Engineering"}]
get_classifications	Works the same as get_tag but the returned tag data is a hash with :name and :description Example: request.get_classifications Returns: {:cc⇒{:name⇒"001", :description⇒"Cost Center 001"}, :department⇒[{:name⇒"accounting", :description⇒"Accounting"}, {:name⇒"engineering", :description⇒"Engineering"}]}
get_option(key)	Returns a value from the options hash based on the name of the key name passed in. Internally many of the values are stored as an array of items. (For example, a target host would be stored as the index to the host object in the db and the display name.) Calling this method will return the first item if it is an array. For non-array values the item is returned unmodified. Example: miq_provision_request.get_option(:number_of_cpus)

Method	Use
get_tag(category)	Returns the tags selected for the specified tag category. Example: request.get_tag(:department) Returns: ["accounting", "engineering"]
get_tags	Get all selected tags stored in a hash by category. If more than one tag is selected in a category, the hash will contain an array of tag names. Otherwise it will contain the tag name as a string. Example: request.get_tags Returns: {:cc⇒"001", :department⇒["accounting", "engineering"]}
miq_request	(Legacy support) Internal Note: The miq_request instance use to be a separate instance from the specific request instance (like miq_provision_request). When the classes were refactored into 1 this method was added to allow existing code and automate methods to continue to run unchanged.)
miq_request_tasks	Returns the requests tasks
options	Returns a hash containing all the options set for the current provision object
pending	Puts the object in a pending state for approval Example: # Raise automation event: request_pending $evm.root["miq_request"].pending
reason	Returns reason for approval or denial of request
requester	Returns the requester
resource	Returns the resource for the request
set_message(value)	Sets the message for the request
set_option(key, value)	Sets the specified key/value pair for the object

Automation Request (automation_request)

Method	Use
automation_tasks	Returns objects automate tasks

Host Provision Request (miq_host_provision_request)

Method	Use
miq_host_provisions	Returns the miq_host_provisions objects
ci_type	Returns the cloud infrastructure type: host

VM Provision Request (miq_provision_request)

Method	Use
check_quota(quota_type, options={})	Returns the quota information for the specified type
ci_type	Returns the cloud infrastructure type: vm
eligible_clusters	Returns an array of available Cluster objects filtered by previously selected resources
eligible_customization_templates	Returns an array of available Customization Templates filtered by previously selected resources
eligible_folders	Returns an array of available Folder objects filtered by previously selected resources
eligible_hosts	Returns an array of available Host objects filtered by previously selected resources
eligible_iso_images	Returns an array of available ISO image objects filtered by previously selected resources
eligible_pxe_images	Returns an array of available PXE Image objects filtered by previously selected resources
eligible_pxe_servers	Returns an array of available PXE Server objects filtered by previously selected resources
eligible_resource_pools	Returns an array of available Resource Pool objects filtered by previously selected resources
eligible_resources(rsc_type)	Returns eligible resources given the type specified
eligible_storages	Returns an array of available Storage (Datastore) objects filtered by previously selected resources
eligible_windows_images	Returns an array of available Windows Image objects filtered by previously selected resources

Method	Use
get_folder_paths	Returns a hash where the key is an index and the value is the fully-qualified path name of the folder. (Sample: {7 ⇒ Dev/Dept1/QA, 8 ⇒ Test/Dept2/QA}) This format is useful when a fully-qualified path is required to match the folder name. For example, if you had multiple QA folders under different departments in the sample above. To find the proper QA folder you need to evaluate the entire folder path.
get_retirement_days	Returns the number of dates until retirement
miq_provision	Returns the task.
miq_request	Returns the miq_provision_requests miq_request object
set_cluster(rsc)	Set the cluster to use based on object returned from eligible_clusters
set_customization_template(rsc)	Set the customization_template to use based on object returned from eligible_customization_templates
set_folder(folder_path)	Set the folder to use based on object returned from eligible_folders. In addition, set_folder accepts the following folder types: Folder Paths - separated by forward slashes. (Must include Data-center name.) Example: Prod/Discovered virtual machine where Prod is the Data-center name and Discovered virtual machine is the folder name. Object returned from the get_folder_paths method
set_host(rsc)	Set the host to use based on object returned from eligible_hosts
set_network_adapter(idx, nic_hash, value=nil)	Modifies the network card attached to the VM container Available settings: :is_dvs true / false (Default: false) :network (Network Name) :mac_address :devicetype (Default: VirtualPCNet32) Defined by VMware: http://www.vmware.com/support/developer/vc-sdk/visdk400pubs/ReferenceGuide/vim.vm.device.VirtualEthernetCard.html :connectable ⇒ {:allowguestcontrol ⇒ true / false} (Default: true) :connectable ⇒ {:startconnected ⇒ true / false} (Default: true) :connectable ⇒ {:connected ⇒ true / false} (Default: true) Example: prov.set_network_adapter(1, {:network ⇒ dvs_net1, :is_dvs ⇒ true})
set_network_address_mode(mode)	Sets IP address type. Available modes are dhcp and static
set_nic_settings(idx, nic_hash, value=nil)	Modifies the network interface settings at the operating system level Available settings: :addr_mode "dhcp" / "static" (Default: static) :ip_addr :subnet_mask :gateway :dns_domain :dns_servers (Windows Only) Comma separated values :sysprep_netbios_mode (Windows Only) Defined by VMware: http://www.vmware.com/support/developer/vc-sdk/visdk400pubs/ReferenceGuide/vim.vm.customization.IPSettings.NetBIOSMode.html :wins_servers Passed as a string specifying the Primary and Secondary WINS servers separated by a comma. "<PrimaryWINS>, <SecondaryWINS>" Example: prov.set_nic_settings(1, {:ip_addr⇒10.226.133.55, :subnet_mask⇒'255.255.255.192', :gateway⇒'10.226.133.5', :addr_mode⇒["static", "Static"] })
set_iso_image(rsc)	Set the iso_image to use based on object returned from eligible_iso_images
set_pxe_image(rsc)	Set the pxe_image to use based on object returned from eligible_pxe_images
set_pxe_server(rsc)	Set the pxe_server to use based on object returned from eligible_pxe_servers
set_resource_pool(rsc)	Set the resource_pool to use based on object returned from eligible_resource_pools
set_resource(rsc)	Sets the resource for the request. (Helper method, should not be called directly)
set_retirement_days	Set the number of days until retirement.

Method	Use
set_storage(rsc)	Set the Datastore (storage object) to use based on object returned from eligible_storages
set_vm_notes(note)	Sets text for the VM notes (aka annotation) field
set_windows_image(rsc)	Set the windows_image to use based on object returned from eligible_windows_images
source_type	Returns the provision source type. (values are 'vm' or 'template')
src_vm_id	Returns ID of the template being cloned
target_type	Returns the provision target type. (values are 'vm' or 'template')
vm_template	Returns the requests template

Request Task (miq_request_task)

Method	Use
add_tag(category, tag_name)	Add a tag to a provision instance by specifying the category and tag name. Example: miq_provision.add_tag(:location, "CHI")
clear_tag(category=nil, tag_name=nil)	Without any parameters, the clear_tag method will clear all tags from the provision request. Providing a category will clear all tags selected in that category. Clear a specific category/tag by providing it. Example: miq_provision.clear_tag(:location, "CHI")
destination	Returns the destination object. (The resultant object from running the task. In the case of provisioning, this would be the newly created VM.)
execute	Executes or processes the request.
finished(msg)	Sets the task to finished with the supplied message.
get_classification(category)	Works the same as get_tag(category) but the returned data is a hash with :name and :description. Example: request.get_classification(:department) Returns: [{:name⇒"accounting", :description⇒"Accounting"}, {:name⇒"engineering", :description⇒"Engineering"}]
get_classifications	Works the same as get_tag but the returned tag data is a hash with :name and :description. Example: request.get_classifications Returns: {:cc⇒{:name⇒"001", :description⇒"Cost Center 001"}, :department⇒[{:name⇒"accounting", :description⇒"Accounting"}, {:name⇒"engineering", :description⇒"Engineering"}]}
get_option_last(key)	This method is the same as get_option, except that it returns the last array value.
get_option(key)	Returns a value from the options hash based on the name of the key name passed in. Internally many of the values are stored as an array of items. (For example, a target host would be stored as the index to the host object in the db and the display name.) Calling this method will return the first item if it is an array. For non-array values the item is returned unmodified. Example: miq_provision_request.get_option(:number_of_cpus)
get_tag(category)	Returns the tags selected for the specified tag category. Example: request.get_tag(:department) Returns: ["accounting", "engineering"]
get_tags	Get all selected tags stored in a hash by category. If more than one tag is selected in a category, the hash will contain an array of tag names. Otherwise it will contain the tag name as a string. Example: request.get_tag Returns: {:cc⇒"001", :department⇒["accounting", "engineering"]}
message=(msg)	Sets the message for the request task.
miq_request	Returns the miq_request for the task.
miq_request_task	Returns the parent miq_request task.
miq_request.user_message=(msg)	Allows automate method to override the default request status message. As a result, you can set custom messages for the progression of the state machine and its success or failure. This message will appear as the last message for the service request.
miq_request_tasks	Returns the children miq_request tasks.
options	Returns a hash containing all the options set for the current object.
set_option(key, value)	Updates a key/value pair in the options hash for the provision object. Often the value is required to be an array.
source	Returns the source object. (The source, or input, object that the task runs against. In the case of provisioning, this would be the VM or template selected to be provisioned.)

Automation Task (automation_task)

Method	Use

Method	Use
automation_request	Returns associated automation_request object
status	Returns status of the task

Host Provision Task (miq_host_provision)

Method	Use
host	Returns objects host
miq_host_provision_request	Returns the request that created the task
status	Returns status of host provision

VM Provision Task (miq_provision)

Method	Use
check_quota(quota_type, options={})	Returns the quota information for the specified type
eligible_clusters	Returns an array of available Cluster objects filtered by previously selected resources
eligible_customization_templates	Returns an array of available Customization Templates
eligible_folders	Returns an array of available Folder objects filtered by previously selected resources
eligible_hosts	Returns an array of available Host objects filtered by previously selected resources
eligible_iso_images	Returns an array of available ISO Image objects filtered by previously selected resources
eligible_pxe_images	Returns an array of available PXE Image objects filtered by previously selected resources
eligible_pxe_servers	Returns an array of available PXE Servers filtered by previously selected resources
eligible_resource_pools	Returns an array of available Resource Pool objects filtered by previously selected resources
eligible_resources(rsc_type)	Returns the eligible resources for the resource type specified
eligible_storages	Returns an array of available Storage (Datastore) objects filtered by previously selected resources
eligible_windows_images	Returns an array of available Windows Image objects filtered by previously selected resources
get_domain_details	Returns domain information
get_domain_name	Returns domain name
get_folder_paths	Returns a hash where the key is an index and the value is the fully-qualified path name of the folder. (Sample: {7 ⇒ Dev/Dept1/QA, 8 ⇒ Test/Dept2/QA}) This format is useful when a fully-qualified path is required to match the folder name. For example, if you had multiple QA folders under different departments in the sample above. To find the proper QA folder you need to evaluate the entire folder path.
get_network_details	Returns network information
get_network_scope	Returns network scope
miq_provision_request	Returns the provision request object
set_cluster(rsc)	Set the cluster to use based on object returned from eligible_clusters
set_customization_spec(name=nil, override=false)	Sets the name of the custom spec to use as defined by its name in Virtual Center (Note: This is not supported when being passed by VMware.)
set_customization_template(rsc)	Set the customization_template to use based on object returned from eligible_customization_templates
set_dvs(portgroup, switch = portgroup)	Set the name of the Distributed Virtual Switch (portgroup). An options <switch> name can also be passed Example: miq_provision.set_dvs('default')
set_folder(folder_path)	Set the folder to use based on object returned from eligible_folders. In addition, set_folder accepts the following folder types: Folder Paths - separated by forward slashes. (Must include Data-center name.) Example: Prod/Discovered virtual machine where Prod is the Data-center name and Discovered virtual machine is the folder name. Object returned from the get_folder_paths method
set_host(rsc)	Set the host to use based on object returned from eligible_hosts

Method	Use
set_network_adapter(idx, nic_hash, value=nil)	Modifies the network card attached to the VM container Available settings: :is_dvs true / false (Default: false) :network (Network Name) :mac_address :devicetype (Default: VirtualPCNet32) Defined by VMware: http://www.vmware.com/support/developer/vc-sdk/visdk400pubs/ReferenceGuide/vim.vm.device.VirtualEthernetCard.html :connectable ⇒ {:allowguestcontrol ⇒ true / false} (Default: true) :connectable ⇒ {:startconnected ⇒ true / false} (Default: true) :connectable ⇒ {:connected ⇒ true / false} (Default: true) Example: prov.set_network_adapter(1, {:network ⇒ dvs_net1, :is_dvs ⇒ true})
set_network_address_mode(mode)	Available modes are dhcp and static
set_nic_settings(idx, nic_hash, value=nil)	Modifies the network interface settings at the operating system level Available settings: :addr_mode "dhcp" / "static" (Default: Statis) :ip_addr :subnet_mask :gateway :dns_domain :dns_servers (Windows Only) Comma separated values :sysprep_netbios_mode (Windows Only) Defined by VMware: http://www.vmware.com/support/developer/vc-sdk/visdk400pubs/ReferenceGuide/vim.vm.customization.IPSettings.NetBIOSMode.html :wins_servers Passed as a string specifying the Primary and Secondary WINS servers separated by a comma. "<PrimaryWINS>, <SecondaryWINS>" Example: prov.set_nic_settings(1, {:ip_addr⇒10.226.133.55, :subnet_mask⇒'255.255.255.192', :gateway⇒'10.226.133.5', :addr_mode⇒["static", "Static"] })
set_iso_image(rsc)	Set the iso_image to use based on object returned from eligible_iso_images
set_pxe_image(rsc)	Set the pxe_image to use based on object returned from eligible_pxe_images
set_pxe_server(rsc)	Set the pxe_server to use based on object returned from eligible_pxe_servers
set_resource_pool(rsc)	Set the resource_pool to use based on object returned from eligible_resource_pools
set_storage(rsc)	Set the Datastore (storage object) to use based on object returned from eligible_storages
set_vlan(vlan)	Sets the name of the VLan to use Example: miq_provision.set_vlan('default')
set_vm_notes(note)	Sets text for the VM notes (aka annotation) field
set_vm_notes(notes)	Sets text for the VM notes (aka annotation) field
set_windows_image(rsc)	Set the windows_image to use based on object returned from eligible_windows_images
source_type	Returns the provision source type. (values are 'vm' or 'template')
status	Returns provision status
target_type	Returns the provision target type. (values are 'vm' or 'template')
vdi_farm	Returns VDI Farm information
vm	The newly created vm
vm_template	Returns the template selected to be provisioned

```
begin
  miq_provision = $evm.root["miq_provision"] || $evm.root['miq_provision']
  prov = $evm.root["miq_provision"]
  user = prov.miq_request.requester
```

```
  raise "User not specified" if user.nil?

  ###################################
  # Process Change Request Number and set VM Annotation
  ###################################

  exit MIQ_OK

rescue => err
  $evm.log("info", "Set_folder err [#{err}]\n#{err.backtrace.join("\n")}")
end
```

Adding Disks to OpenStack Instance Provisioning

Using the clone_options, construct the keys and values required to define new disks as well as override or set other keys if needed.

Include the following settings with prov.set_options to set one or multiple volumes to attach. Note that each hash requires the :volume_id and :device_name keys.

```
clone_options = {
  :block_device_mapping => [
    {:volume_id => "d4xxxx92-5xx0-4xx9-bxx4-f1xxxxxxxx19", :device_name => "/dev/sdb"},
    {:volume_id => "e7xxxxf5-dxxd-4xx0-8xx3-a2xxxxxxxx12", :device_name => "/dev/sdc"},
```

```
  ]
}

prov = $evm.root["miq_provision"]
prov.set_option(:clone_options, clone_options)
```

Booting OpenStack Instances from Volume

You can boot instances created in Red Hat Enterprise Linux OpenStack Platform from a specified volume from an existing selection of block volumes. You can enable automate to pass the required parameters to OpenStack to use volumes as booting devices on an instance.

Include the following settings in the prov.set_option for provisioning instances created in OpenStack.

```
prov.set_option(
  :clone_options, {
    :image_ref => nil,
    :block_device_mapping_v2 => [{
      :boot_index => 0,
      :uuid => "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxx",
      :device_name => "vda",
      :source_type => "volume",
      :destination_type => "volume",
      :delete_on_termination => false
    }]
  }
)
```

You can allow passing “block_device_mapping_v2” in the clone options and remove keys from clone_options by setting value to nil.

VM Provisioning for Clouds Task (miq_provision_cloud)

Method	Use
availability_zones	Returns object’s availability zones
instance_types	Returns object’s instance types
security_groups	Returns object’s security groups
floating_ip_addresses	Returns object’s floating IP addresses
cloud_networks	Returns object’s cloud network
cloud_subnets	Returns object’s cloud subnet
guest_access_key_pairs	Returns object’s guest key pair
cloud_tenants	Returns object’s cloud tenant

Service Template Provision Task (service_template_provision_task)

Method	Use
dialog_options	Returns objects dialog options hash
dialog_parser	Provides consolidated and configurable dialog parsing
get_dialog_option(key)	Returns objects dialog value for the specified key
service_resource	Returns the service resource for the task
set_dialog_option(key, value)	Sets a dialog option Example: set_dialog_option('memory',memory_size)
status	Returns the tasks status

Service Reconfiguration Task (service_reconfigure_task)

Method	Use
dialog_options	Show all dialog options for object
get_dialog_option(key)	Show a dialog option based stored in key
set_dialog_option(key, value)	Set value as a dialog option in key
status	Returns status of the task
finished(msg)	Sets the task to finished with the supplied message

VM Migrate Task (vm_migrate_task)

Method	Use
status	Returns status of the migration task

Proxies (miq_proxy)

Method	Use
host	Returns object’s hosts
powershell(script, returns = ‘string’)	Submits a powershell script

Servers (miq_server)

These methods are available to the Infrastructure Automation Server.

Method	Use
zone	Returns Infrastructure Automation Servers Zone
region_number	Returns Infrastructure Automation Servers Region Number
region_name	Returns Infrastructure Automation Servers Region Name

```
  ##########################
  #
  # Method: dumpServer
  # Inputs: $evm.root['miq_server']
  # Description: Dump MIQ Server information
  #
  ##########################
  def dumpServer
    $evm.log("info","#{@method} - Server:<#{$evm.root['miq_server'].name}> Begin Attributes")
    $evm.root['miq_server'].attributes.sort.each { |k, v| $evm.log("info", "#{@method} - Server:<#
{$evm.root['miq_server'].name}> Attributes - #{k}: #{v.inspect}")}
    $evm.log("info","#{@method} - Server:<#{$evm.root['miq_server'].name}> End Attributes")
    $evm.log("info", "")
  end
```

Network (network)

Method	Use
hardware	Returns objects hardware
guest_device	Returns objects guest devices

PXE Image (pxe_image)

Method	Use
customization_templates	Returns objects customization templates
pxe_server	Returns objects pxe server

PXE Server (pxe_server)

Method	Use
advertised_images	Returns objects advertised images
advertised_pxe_images	Returns objects advertised pxe images
default_pxe_image_for_windows	Returns objects default pxe image for windows
discovered_images	Returns objects discovered images
discovered_pxe_images	Returns objects discovered pxe images
images	Returns objects images
pxe_images	Returns objects pxe_images
windows_images	Returns objects windows images

Security Groups (security_group)

Method	Use
ext_management_system	Returns object's Management System
cloud_network	Returns object's cloud network
cloud_tenant	Returns object's cloud tenant
firewall_rules	Returns object's firewall rules
vms	Returns object's VMs

Service (service)

Method	Use
custom_keys	Returns custom keys
custom_get(key)	Gets value for specified custom key
custom_set(attribute, value)	Sets value for specified custom key
display=(display)	Set display option
group=(group)	Sets group that owns the service
name=(new_name)	Sets name of service
owner=(owner)	Sets owner of the service
request_retire	Retire Service immediately
retirement_warn=(seconds)	Sets when to send retirement warning
retires_on=(date)	Sets retirement date
shutdown_guest	Shuts downs guest operating system of the Service
start	Start the Service
stop	Stop the Service
suspend	Suspend the Service
vms	Show all virtual machines associated with this service
direct_vms	Show virtual machines directly associated with this service

Method	Use
indirect_vms	Show virtual machines associated with lower level services in the hierarchy
root_service	Show the top level service in the hierarchy for the target service
all_service_children	Show all lower level services to the target service in the hierarchy
direct_service_children	Show direct services associated with the target service
indirect_service_children	Show services associated with lower level services of the target service
parent_service	Show the parent service for the target service
description=(new_description)	Sets the service description
remove_from_vmdb	Delete the service from the database
dialog_options	Returns all dialog options
get_dialog_option(key)	Returns a specific dialog option specified by key
set_dialog_option(key, value)	Sets value of a dialog option specified by key

Service Resource (service_resource)

Method	Use
service	Returns the associated service
service_template	Returns the associated service template
resource	Returns the resource for the request
source	Returns the source object

Service Template (service_template)

Method	Use
group=(group)	Sets group for the service template
owner=(owner)	Sets owner for the service template

Snapshot (snapshot)

These methods can be used on Snapshots

Method	Use
vm	Returns Snapshots VM
current?	Checks to see if this is the current snapshot
get_current_snapshot	Returns the current snapshot id
revert_to	Reverts to specified snapshot
remove	Removes specified snapshot

Datastores (storage)

Method	Use
ext_management_systems,	Returns objects Management System
hosts	Returns objects Hosts
vms	Returns objects Virtual Machines
unregistered_vms	Returns objects unregistered Virtual Machines
to_s	Converts object to string
scan	Performs SmartState Analysis on the object

```
 ##########################
  #
  # Method: dumpStorage
  # Inputs: $evm.root['storage']
  # Description: Dump Storage information
  #
  ##########################
  def dumpStorage(storage)
    $evm.log("info","#{@log_prefix} - Storage:<#{storage.name}> Begin Attributes")
    storage.attributes.sort.each { |k, v| $evm.log("info", "#{@log_prefix} - Storage:<#{storage.name}> Attributes - #{k}:
#{v.inspect}")}
    $evm.log("info","#{@log_prefix} - Storage:<#{storage.name}> End Attributes")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Storage:<#{storage.name}> Begin Associations")
    storage.associations.sort.each { |assc| $evm.log("info", "#{@log_prefix} - Storage:<#{storage.name}> Associations - #
{assc}")}
    $evm.log("info","#{@log_prefix} - Storage:<#{storage.name}> End Associations")
    $evm.log("info","")

    $evm.log("info","#{@log_prefix} - Storage:<#{storage.name}> Begin Virtual Columns")
    storage.virtual_column_names.sort.each { |vcn| $evm.log("info", "#{@log_prefix} - Storage:<#{storage.name}> Virtual
Columns - #{vcn}: #{storage.send(vcn)}")}
    $evm.log("info","#{@log_prefix} - Storage:<#{storage.name}> End Virtual Columns")
    $evm.log("info","")
  end
```

Switch (switch)

These methods can be used on Switches.

Method	Use
host	Returns switch's Host
guest_devices	Returns switch's guest devices
lans	Returns switch's lans

User (user)

These methods can be used on the currently logged on user.

Method	Use
current_group	Returns user's assigned internal group
custom_get(key)	Returns the custom key value specified by "key"
custom_keys	Returns an array of custom keys
custom_set(key,value)	Sets custom value for "key" to "value"
email	Returns user's email address
get_ladap_attribute(name)	Returns the value of the specified LDAP attribute
get_ldap_atttribute_names	Returns user's LDAP attribute names
ldap_group	Returns user's assigned LDAP group
miq_requests	Returns user's requests
name	Returns user's name
userid	Returns user's userid
vms	Returns Virtual Machines that this user owns

```
  ##########################
  #
  # Method: dumpUser
  # Inputs: $evm.root['user']
  # Description: Dump User information
  #
  ##########################
  def dumpUser
    user = $evm.root['user']
    unless user.nil?
      $evm.log("info","#{@method} - User:<#{user.name}> Begin Attributes [user.attributes]")
      user.attributes.sort.each { |k, v| $evm.log("info", "#{@method} - User:<#{user.name}> Attributes - #{k}: #
{v.inspect}")}
      $evm.log("info","#{@method} - User:<#{user.name}> End Attributes [user.attributes]")
      $evm.log("info", "")

      $evm.log("info","#{@method} - User:<#{user.name}> Begin Associations [user.associations]")
      user.associations.sort.each { |assc| $evm.log("info", "#{@method} - User:<#{user.name}> Associations - #{assc}")}
      $evm.log("info","#{@method} - User:<#{user.name}> End Associations [user.associations]")
      $evm.log("info","")

      $evm.log("info","#{@method} - User:<#{user.name}> Begin Virtual Columns [user.virtual_column_names]")
      user.virtual_column_names.sort.each { |vcn| $evm.log("info", "#{@method} - User:<#{user.name}> Virtual Columns - #
{vcn}: #{user.send(vcn).inspect}")}
      $evm.log("info","#{@method} - User:<#{user.name}> End Virtual Columns [user.virtual_column_names]")
      $evm.log("info","")
    end
  end
```

Virtual Machines and Templates (vm_or_template)

The following methods can be used on a virtual machine or template object.

Method	Use
add_disk [1]	Add storage to an existing VM. This method accepts as parameters: disk_name, disk_size_mb, and options to pass values for :thinProvisioned, :dependent, and :persistent. Example: `vm.add_disk("[#{vm.storage_name}]", size_in_mb, thin_provisioned: true)`
changed_vm_value?	Checks the 2 most recent drift state captures , and answers whether the specified value changed between them
collect_running_processes	Collects the running processes of the object
create_snapshot(name, desc = nil)	Create a snapshot of the object. The **name** parameter is not used for Red Hat Virtualization virtual machines when creating a snapshot.
custom_get(key)	Get the value of specified Infrastructure Automation Server key from the object
custom_keys	List all Infrastructure Automation Server custom keys for the object
custom_set(key, value)	Set a custom Infrastructure Automation Server key value
datacenter	Returns objects Datacenter
direct_service	Show the direct service relationship of the virtual machine
directories	Returns number of directories on the object
ems_blue_folder (this will be reworked to be more VMware-specific)	Returns objects blue folder from VMware. These are the folders showing in VM and Templates view in VMware

Method	Use
ems_cluster	Returns objects cluster
ems_custom_get(key)	Gets specified key of custom Management System Attribute
ems_custom_keys	List the custom keys defined by the Management System for the object
ems_custom_set(attribute, value)	Sets specified key and value of custom Management System Attribute
ems_folder	Returns objects folder on Management System
ems_ref_string	Returns unique identifier the Management System uses to identify this resource. For example, in VMware a VM would return a value like: "vm-26622"
event_log_threshold? (options)	Searches event log records to determine if an event has occurred x number of times within a defined time frame. Returns true if the number of matching records found are greater or equal to the specified freq_threshold, otherwise it returns false Options values: :message_filter_type - Must be one of "STARTS WITH", "ENDS WITH", "INCLUDES", "REGULAR EXPRESSION" :message_filter_value - <string value to search for> :time_threshold - Options time interval to search. Example: 2.days (Search the past 2 days of event logs) Default 10.days :freq_threshold - Number of occurrences to check for. Default = 2 :source, :event_id, :level, :name - Options filter values
event_threshold?(options)	Checks if an event (or multiple events) have occurred X number of times in N seconds. The values below are used if no data is passed event_threshold?(options = {:time_threshold ⇒ 30.minutes, :event_types ⇒ ["MigrateVM_Task_Complete"], :freq_threshold ⇒ 2})
ext_management_system	Returns objects Management System
files	Returns number of files on the object
get_realtime_metric(metric, range, function)	Returns specified realtime metric
group=(group)	Sets objects group
guest_applications	Returns objects Guest Application list
hardware	Returns objects Hardware
host	Returns objects Host
migrate(host, pool = nil, priority = "defaultPriority", state = nil)	Migrates the object to another host. The only required parameter is host
miq_provision	If VM was created using Infrastructure Automation Server provisioning, this is the miq_provision task instance that created the VM
move_into_folder(folder) [2]	Use this method to move VMware virtual machines into folders. Example: vm = Vm.find_by_name('<vm_name>') folder = EmsFolder.find_by(:name ⇒ '<folder_name>') vm.move_into_folder(folder) unless folder.nil?
operating_system	Returns objects Operating System
owner	Return objects owner
owner=(owner)	Sets objects owner
performances_maintains_value_for_duration?	Based on options given, checks to see if a performance threshold is maintained for a time period Example: vm.performances_maintains_value_for_duration?(:column ⇒ "cpu_usage_rate_average", :operator ⇒ "=", :value ⇒ 3.51, :duration ⇒ 20.minutes)
reboot_guest	Reboots the guest operating system
reconfigured_hardware_value?	Checks if hardware value has been reconfigured
refresh	Refresh power states and relationships of the object
registered?	Is the object registered?
remove_all_snapshots	Remove all of the objects snapshots
remove_from_disk	Removes the object from disk
remove_from_vmdb	Removes the object from the VMDB
remove_snapshot(snapshot_id)	Remove a specific snapshot based on the snapshot_id
resource_pool	Returns objects Resource Pool
retire_now	Retire the object immediately
retirement_warn=(seconds)	Send a retirement warning
retires_on=(date)	Retire the object on date specified
revert_to_snapshot(snapshot_id)	Revert to a snapshot based on the snapshot_id
scan(scan_categories = nil)	Perform SmartState Analysis on the object. Scan_categories is optional
service	Show the top-level service for a virtual machine in a service hierarchy. For the immediate parent service relationship of a virtual machine, use direct_service
shutdown_guest	Shuts down the guest operating system of the object

Method	Use
snapshots	Returns list of snapshots for the object
standby_guest	Puts the operating system on standby
start	Starts the object See Samples/PowerOn_DHOB
stop	Stops the object
storage	Returns objects Datastore
suspend	Suspends the object
to_s	Converts object to string
unlink_storage	Removes the reference to the VM's Datastore
unregister	Unregisters the object from the Management System

```
  ############################
  #
  # Method: dumpVM
  # Inputs: $evm.root['vm']
  # Description: Dump VM information
  #
  ############################

  # Method: createSnapshot
  #
  ####################

  def createSnapshot(vm, snap_name, snap_desc=snap_name)
    $evm.log("info","#{@method} - VM:<#{vm.name}> Creating Snapshot:<#{snap_name}> Description:<#{snap_desc}>")
    vm.create_snapshot(snap_name, snap_desc)
  end

  ####################
  # Red Hat Virtualization Virtual Machines
  # Method: createSnapshot
  #
  ####################

    def createSnapshot(vm, snap_desc=snap_name)
        $evm.log("info","#{@method} - VM:<#{vm.name}> Creating Snapshot:<#{snap_name}> Description:<#{snap_desc}>")
        vm.create_snapshot(snap_desc)
    end
```

VMs (vm)

Method	Use
add_to_service(service)	Adds the VM to a service object
remove_from_service	Removes the VM from its parent service

The following table lists the metric types available for the **get_realtime_metric(metric, range, function)** method for virtual machines.

Metric	Description
v_derived_storage_used	Capacity - Used space in bytes
v_pct_cpu_ready_delta_summation	CPU - Percentage ready
v_pct_cpu_wait_delta_summation	CPU - Percentage wait
v_pct_cpu_used_delta_summation	CPU - Percentage used
v_derived_vm_count	State - Peak average virtual machines (Hourly Count / Daily Average)
v_derived_cpu_reserved_pct	CPU - Percentage available
v_derived_memory_reserved_pct	Memory - Percentage available

The following Ruby snippet demonstrates using the **get_realtime_metric(metric, range, function)** method using the **v_pct_cpu_ready_delta_summation** metric.

```
host = $evm.root['vm']
cpu_rdy = vm.get_realtime_metric(:v_pct_cpu_ready_delta_summation, [15.minutes.ago.utc,5.minutes.ago.utc], :avg)
```

VMs for Clouds (vm_cloud)

Method	Use
availability_zone	Returns object's availability zone
flavor	Returns object's favor
cloud_network	Returns object's cloud network
cloud_subnet	Returns object's cloud subnet
floating_ip	Returns object's floating IPs
security_groups	Returns object's security groups
key_pairs	Returns object's key pairs

Windows Image (windows_image)

Method	Use
customization_templates	Returns the images customization templates.
pxe_server	Returns the images pxe server.

Creating Categories and Tags

These methods are invoked using $evm.execute. See after the table for usage examples.

Method(parameter)	Use
category_exists?	Checks to see if a tag category exists. Usually used with unless or if to then create a category that does not exist. Example: $evm.execute('category_exists?', "department")
category_create	Creates a new category, and if only one tag value from this category can be assigned to a configuration item, sets that tag value using the **`single_value`** option. Example: $evm.execute('category_create', :name ⇒ "department", :single_value ⇒ false, :description ⇒ "Department") **NOTE:** The **`category_create`** method currently does not work as expected. The user interface shows the value provided for **`:description`** in the **Display Name** field and the value provided for **`:example_text`** is displayed in the **Description** field.
tag_exists?	Checks to see if a tag exists in a category. Example: $evm.execute('tag_exists?', "department", "finance")
tag_create	Creates a new tag in the specified category. Example: $evm.execute('tag_create', "department", :name ⇒ "finance", :description ⇒ "Finance")

Category and Tags Methods Example

In this example, the VMDB is checked to see if the **Department** category exists. If it does, then a message is logged. If not, the category is created and a message is logged. Values are then added to the category.

```
if $evm.execute('category_exists?', "department")
  $evm.log("info", "Classification department exists")
else
  $evm.log("info", "Classification department doesn't exist, creating category")
  $evm.execute('category_create', :name => "department", :single_value => false, :description => "Department")
  $evm.log("info", "Adding new tag in Department Category")
  $evm.execute('tag_create', "department", :name => "finance", :description => "Finance")
```

Quota

Method(parameter)	Use
vms_by_owner, vms_by_group, vms_by_owner_and_group	Collect stats about existing VMs by owner or in the same LDAP group as the owner in the current request. Sample return object: {:class_name⇒"Vm", :count⇒5, :ids⇒[22, 120, 121, 122, 117], :cpu⇒6, :memory⇒5120, :allocated_storage⇒29032972288, :used_storage⇒29032972288}
retired_vms_by_owner, retired_vms_by_group, retired_vms_by_owner_and_group	Collect stats about retired VMs, that have not been deleted from the host, by owner or in the same LDAP group as the owner in the current request. Sample return object: {:class_name⇒"Vm", :count⇒5, :ids⇒[22, 120, 121, 122, 117], :cpu⇒6, :memory⇒5120, :allocated_storage⇒29032972288, :used_storage⇒29032972288}
provisions_by_owner, provisions_by_group	Collect stats based on provisions running on the same day as the current request (based on scheduled date or immediate) by owner or in the same LDAP group as the owner. (Results do not include Provision Requests that have not been approved.) Sample return object: {:class_name⇒"MiqProvisionRequest", :count⇒6, :ids⇒[115, 116, 104, 102, 105, 112], :cpu⇒6, :memory⇒1536, , :storage⇒62914560}
requests_by_owner, requests_by_group	Collect stats based on provision requests made the same day as the request by the same owner or LDAP group as the owner in the current request, regardless of when the provision request is scheduled to run. (Results do not include Provision Requests that have been denied.) Sample return object: {:class_name⇒"MiqProvisionRequest", :count⇒6, :ids⇒[115, 116, 104, 102, 105, 112], :cpu⇒6, :memory⇒1536, , :storage⇒62914560}
active_provisions_by_owner, active_provisions_by_group, active_provisions	Collect stats based on currently active provision requests by the same owner or LDAP group as the owner in the current request. Sample return object: {:class_name⇒"MiqProvisionRequest", :count⇒6, :ids⇒[115, 116, 104, 102, 105, 112], :cpu⇒6, :memory⇒1536, , :storage⇒62914560}

1. Supported for Red Hat Virtualization and VMware virtual machines
2. Supported for VMware virtual machines only

Terminology

- Account Role A designation assigned to a user allowing or restricting a user to parts and functions of the Infrastructure Automation console.
- Action An execution that is performed after a condition is evaluated.
- Alert Infrastructure Automation alerts notify administrators and monitoring systems of critical configuration changes and threshold limits in the virtual environment. The notification can take the form of either an email or an SNMP trap.
- Analysis Profile A customized scan of hosts, virtual machines, or instances. You can collect information from categories, files, event logs, and registry entries.
- Cloud A pool of on-demand and highly available computing resources. The usage of these resources are scaled depending on the user requirements and metered for cost.
- Infrastructure Automation appliance A virtual machine on which the virtual management database (VMDB) and Infrastructure Automation server reside.
- Infrastructure Automation Console A web-based interface into the Infrastructure Automation appliance.
- Infrastructure Automation Role A designation assigned to a Infrastructure Automation server that defines what a Infrastructure Automation server can do.
- Infrastructure Automation Server The application that runs on the Infrastructure Automation appliance and communicates with the SmartProxy and the VMDB.
- Cluster Hosts that are grouped together to provide high availability and load balancing.
- Condition A test of criteria triggered by an event.
- Discovery Process run by the Infrastructure Automation server which finds virtual machine and cloud providers.
- Drift The comparison of a virtual machine, instance, host, cluster to itself at different points in time.
- Event A trigger to check a condition.
- Event Monitor Software on the Infrastructure Automation appliance which monitors external providers for events and sends them to the Infrastructure Automation server.
- Host A computer on which virtual machine monitor software is loaded.
- Instance/Cloud Instance A on-demand virtual machine based upon a predefined image and uses a scalable set of hardware resources such as CPU, memory, networking interfaces.
- Managed/Registered VM A virtual machine that is connected to a host and exists in the VMDB. Also, a template that is connected to a provider and exists in the VMDB. Note that templates cannot be connected to a host.
- Managed/Unregistered VM A virtual machine or template that resides on a repository or is no longer connected to a provider or host and exists in the VMDB. A virtual machine that was previously considered registered may become unregistered if the virtual machine was removed from provider inventory.
- Provider A computer on which software is loaded which manages multiple virtual machines that reside on multiple hosts.
- Policy A combination of an event, a condition, and an action used to manage a virtual machine.
- Policy Profile A set of policies.
- Refresh A process run by the Infrastructure Automation server which checks for relationships of the provider or host to other resources, such as storage locations, repositories, virtual machines, or instances. It also checks the power states of those resources.
- Regions Regions are used to create a central database for reporting and charting. Regions are used primarily to consolidate multiple VMDBs into one master VMDB for reporting.
- Resource A host, provider, instance, virtual machine, repository, or datastore.
- Resource Pool A group of virtual machines across which CPU and memory resources are allocated.
- Repository A place on a datastore resource which contains virtual machines.
- SmartProxy
    - The SmartProxy is a software agent that acts on behalf of the Infrastructure Automation appliance to perform actions on hosts, providers, storage and virtual machines.
    - The SmartProxy can be configured to reside on the Infrastructure Automation appliance or on an ESX server version.
    - The SmartProxy can be deployed from the Infrastructure Automation appliance, and provides visibility to the VMFS storage. Each storage location must have a SmartProxy with visibility to it. The SmartProxy acts on behalf of the Infrastructure Automation appliance.
    - If the SmartProxy is not embedded in the Infrastructure Automation server, it communicates with the Infrastructure Automation appliance over HTTPS on standard port 443.
- SmartState Analysis Process run by the SmartProxy which collects the details of a virtual machine or instance. Such details include accounts, drivers, network information, hardware, and security patches. This process is also run by the Infrastructure Automation server on hosts and clusters. The data is stored in the VMDB.
- SmartTags Descriptors that allow you to create a customized, searchable index for the resources in your clouds and infrastructure.
- Storage Location A device, such as a VMware datastore, where digital information resides that is connected to a resource.
- Tags Descriptive terms defined by a Infrastructure Automation user or the system used to categorize a resource.

- Template A template is a copy of a preconfigured virtual machine, designed to capture installed software and software configurations, as well as the hardware configuration, of the original virtual machine.
- Unmanaged Virtual Machine Files discovered on a datastore that do not have a virtual machine associated with them in the VMDB. These files may be registered to a provider that the Infrastructure Automation server does not have configuration information on. Possible causes may be that the provider has not been discovered or that the provider has been discovered, but no security credentials have been provided.
- Virtual Machine A software implementation of a system that functions similar to a physical machine. Virtual machines utilize the hardware infrastructure of a physical host, or a set of physical hosts, to provide a scalable and on-demand method of system provisioning.
- Virtual Management Database (VMDB) Database used by the Infrastructure Automation appliance to store information about your resources, users, and anything else required to manage your virtual enterprise.
- Virtual Thumbnail An icon divided into smaller areas that summarize the properties of a resource.
- Zones Infrastructure Automation Infrastructure can be organized into zones to configure failover and to isolate traffic. Zones can be created based on your environment. Zones can be based on geographic location, network location, or function. When first started, new servers are put into the default zone.

Managing Authentication for Infrastructure Management stand-alone deployment

You can find details about how to manage authentication of Infrastructure Management in stand-alone mode.

Important: These instructions do not apply to Infrastructure Management when installed with IBM Cloud Pak for AIOps. These instructions are only to be used when you are installing and running Infrastructure Management as a stand-alone instance.

- Active Directory
- 2-Factor-Authentication with IPA
- IPA/AD Trust Authentication
- LDAP
- SAML
- OpenID-Connect

- Active Directory
- Enabling Network Manager
- Discovering AD Domains
- Joining AD Domain
- Allowing AD Users to Login
- Configure SSSD
- Configure Apache
- Configure Administrative UI

Active Directory

In this guide we will cover how to manually configure a 7.1 Appliance's external authentication to work against Active Directory. This provides AD users access to the Appliance UI as well as the REST API.

1. Enabling Network Manager
2. Discovering AD Domain
3. Joining AD Domain
4. Allowing AD Users to Login to appliance
5. Configure SSSD
6. Configure Apache
7. Configure Administrative UI

In these examples, the AD Domain shown will be EXAMPLE.COM

Enabling Network Manager

By default, the appliance is configured with Network Manager enabled. Having Network Manager enabled allows the **realm** command to discover the available Active Directory domains that can be joined. If not enabled, one can still join an AD domain if known by the domain name.

If the appliance has Network Manager disabled, it can be enabled as follows:

```
# systemctl enable NetworkManager
# systemctl start NetworkManager
```

Discovering AD Domains

This only works if Network Manager is enabled.

```
# realm discover
example.com
  type: kerberos
  realm-name: EXAMPLE.COM
  domain-name: example.com
  configured: kerberos-member
  server-software: active-directory
  client-software: sssd
  required-package: oddjob
  required-package: oddjob-mkhomedir
  required-package: sssd
  required-package: adcli
  required-package: samba-common
  login-formats: %U@example.com
  login-policy: allow-realm-logins
```

Joining AD Domain

When joining an AD domain, specify a user that has enough permission to be able to browse the directory.

```
# realm join example.com -U user
Password for user: xxxxxxxx
#
```

Allowing AD Users to Login

```
# realm permit --all
```

Configure SSSD

Update the **/etc/sssd/sssd.conf** file as follows:

Note: Starting with SSSD version 1.15.2, which will be available in CentOS version 7.4, SSSD will provide the domain name as a user attribute. The below examples show how to set *ldap_user_extra_attrs* and *user_attributes* to take advantage of this new feature. If running an appliance built with CentOS version prior to CentOS 7.4 do not include *domainname* for these attributes.

```
    [domain/example.com]
    ad_domain = example.com
    krb5_realm = EXAMPLE.COM
    realmd_tags = manages-system joined-with-samba
    cache_credentials = True
    id_provider = ad
    krb5_store_password_if_offline = True
    default_shell = /bin/bash
    ldap_id_mapping = True
    use_fully_qualified_names = True
    fallback_homedir = /home/%d/%u
    access_provider = ad
=>  ad_gpo_map_permit = +httpd-auth
=>  ldap_user_extra_attrs = mail, givenname, sn, displayname, domainname

=>  [sssd]
=>  domains = example.com
=>  config_file_version = 2
=>  services = nss, pam, ifp
=>  default_domain_suffix = example.com

=>  [nss]
=>  homedir_substring = /home

=>  [pam]
=>  default_domain_suffix = example.com

=>  [ifp]
=>  default_domain_suffix = example.com
=>  allowed_uids = apache, root, manageiq
=>  user_attributes = +mail, +givenname, +sn, +displayname, +domainname
```

Configure Apache

Make sure the Kerberos keytab created by **realm join** above is readable by Apache.

```
# chgrp apache /etc/krb5.keytab
# chmod 640    /etc/krb5.keytab
```

Create the Apache configuration files

```
# TEMPLATE_DIR="/opt/IBM/infrastructure-management-appliance/TEMPLATE"
# cp ${TEMPLATE_DIR}/etc/pam.d/httpd-auth                          \
                    /etc/pam.d/httpd-auth
# cp ${TEMPLATE_DIR}/etc/httpd/conf.d/manageiq-remote-user.conf       \
                    /etc/httpd/conf.d/
# cp ${TEMPLATE_DIR}/etc/httpd/conf.d/manageiq-external-auth.conf.erb \
                    /etc/httpd/conf.d/manageiq-external-auth.conf
```

Update the Apache configuration file **/etc/httpd/conf.d/manageiq-external-auth.conf** as follows to reference the Kerberos keytab appropriately.

```
...
    <Location /dashboard/kerberos_authenticate>
      AuthType            GSSAPI
      AuthName            "GSSAPI Single Sign On Login"
=>    GssapiCredStore     keytab:/etc/krb5.keytab
      GssapiLocalName     on
      Require             pam-account httpd-auth

      ErrorDocument 401 /proxy_pages/invalid_sso_credentials.js
    </Location>

...
```

Set appropriate SELinux permissions:

```
# setsebool -P allow_httpd_mod_auth_pam on
# setsebool -P httpd_dbus_sssd          on
```

Restart Services

```
# systemctl restart sssd
# systemctl restart httpd
```

Configure Administrative UI

Login as admin, then in *Configure→Configuration→Authentication*

- Set mode to External (httpd)
- Check: *Get User Groups from External Authentication (httpd)*
- Check: *Enable Single Signon* if you want to allow Kerberos SSO to AD.
- Click Save.

The above steps need to be done on each UI and WebService enabled appliance.

in *Configure→Configuration→Access Control*

- Make sure the user's AD group for the appliance are created and appropriate roles assigned to those groups.

- 2-Factor Authentication
- Requirements
- Configure Administrative UI
- Configure External Authentication
- Enabling 2-Factor Authentication
- Using 2-Factor Authentication

2-Factor Authentication

Enabling 2-Factor Authentication on the Appliance is currently supported with External Authentication to IPA.

In this guide we will cover how to manually configure a 7.1 Appliance's external authentication to work with 2-Factor Authentication with IPA. This provides IPA Users access to the Appliance Administrative UI and the REST API using their IPA Password followed by a One-Time-Password.

1. Requirements
2. Configuring the Administrative UI
3. Configuring External Authentication
4. Enabling 2-Factor Authentication
5. Using 2-Factor Authentication

Requirements

The following is needed in order to enable 2-Factor-Authentication to the Appliance:

- A CentOS/RHEL 7.1 based Appliance
- IPA Server based on FreeIPA 4.1.0 or later

Configure Administrative UI

Login as admin, then in *Configure→Configuration→Authentication*

- Set mode to External (httpd)

- Check: *Get User Groups from External Authentication (httpd)*
- Do Not Check: *Enable Single Signon*
    - **Note**: Kerberos SSO with OTP is not supported in the current release of FreeIPA 4.1.0 on CentOS/RHEL 7.1
- Click Save.

The above steps need to be done on each UI and WebService enabled appliance.

in *Configure→Configuration→Access Control*

- Make sure the user's groups are created on the Appliance and appropriate roles assigned to those groups.

Configure External Authentication

Using the Appliance Console, simply enable external authentication as you currently would to IPA.

1. Login to console as *root*
2. Run *appliance_console*
3. Summary screen should show **External Auth** as *not configured*, Press any key
4. From the Advanced Setting menu, select the menu item **Configure External Authentication (httpd)**
5. Enter the FQDN of the IPA Server, i.e. *ipaserver.test.company.com*
6. Enter the IPA Server domain, i.e. *test.company.com*
7. Enter the IPA Server realm, i.e. *TEST.COMPANY.COM*
8. Press enter to select the default IPA Server Principal, i.e. *admin*
9. Enter the Password of the IPA Server Principal
10. Review details, and Enter **y** to proceed.

Enabling 2-Factor Authentication

Enabling 2-Factor Authentication is done using the IPA administrative UI.

- The IPA administrator needs to change the User authentication types for the user from Password or Radius to *Two factor authentication (password + OTP)*
- The previous can be done either per user or for all users from the IPA Server global Configuration under User Options.
- The user logs into IPA, then from the OTP Tokens tab, add an OTP token - Time-based (TOTP) or Counter-based (HOTP).
- Specifying a Description for the OTP, then clicking add, brings up a QR Code which can then be scanned into an app like **FreeOTP** for example.
- Then from the main IPA login screen, the user can Synchronize the OTP Token by specifying their Username, password and then two OTP's generated from the **FreeOTP** app.
- After which, the user can login to FreeIPA using their Password+OTP.

Using 2-Factor Authentication

Once the above is done, the user now needs to specify their IPA Username and their Password followed by their One-Time-Password as generated by the **FreeOTP** app, when:

- Logging into the Appliance Administrative UI
- Accessing the REST API

- IPA/AD Trust Authentication
- Requirements
- Set up and configure an IPA server for AD Trust Authentication
- Enable the MiQ Appliance to use the configued IPA server
- Configure the MiQ appliance to use external authentication
- Create groups on the MiQ appliance
- Use AD Trust Authentication

IPA/AD Trust Authentication

Active Directory (AD) Trust Authentication on the Appliance is supported with External Authentication to IPA.

In this guide we will cover how to manually configure an Appliance's external authentication to work with AD Trust Authentication using IPA. This provides IPA Users access to the Appliance Administrative UI and the REST API using their AD credentials.

1. Requirements

2. Set up and configure an IPA server for AD Trust Authentication
3. Enable the MiQ Appliance to use the configued IPA server
4. Configure the MiQ appliance to use external authentication
5. Create groups on the MiQ appliance
6. Use AD Trust Authentication

Requirements

The following is needed in order to enable AD Trust Authentication to the Appliance:

- A CentOS/RHEL 7.2 based MiQ Appliance
- Windows Server 2008 R2 or later with configured AD DC and DNS installed locally on the DC

Set up and configure an IPA server for AD Trust Authentication

- Configure an IPA Server based on FreeIPA 3.3.3 or later

Instructions for setting up and configuring cross-realm trust between an IPA domain and an AD (Active Directory) domain can be found at freeipa.org Active Directory Trust Setup

- Add necessary user attributes to the SSSD configuration on the IPA server

The SSSD configuration file on the IPA Server must be updated to list needed user attributes.

Add the following entry to the SSSD configuration file /etc/sssd/sssd.conf

Note: Starting with SSSD version 1.15.2, which will be available in CentOS version 7.4, SSSD will provide the domain name as a user attribute. The below examples show how to set *ldap_user_extra_attrs* and *user_attributes* to take advantage of this new feature. If running an appliance built with CentOS version prior to CentOS 7.4 do not include *domainname* for these attributes.

```
[ifp]
user_attributes = +mail, +givenname, +sn, +displayname, +domainname
```

and update *ldap_user_extra_attrs* to include *domainname* where appropriate.

```
[domain/example.com]
ldap_user_extra_attrs = mail, givenname, sn, displayname, domainname
```

- DNS Configuration Significance

Special care should be made when configuring DNS as improper DNS configurations can result in poor performance and improper functionality. For more details refer to the following documents:

- freeipa.org Active Directory Trust Setup/DNS configuration
- freeipa.org DNS
- freeipa.org DNSSEC

Enable the MiQ Appliance to use the configued IPA server

Use the Appliance Console to enable external authentication to the IPA Server.

1. Log in to console as *root*
2. Run *appliance_console*
3. Summary screen should show **External Auth** as *not configured*, Press any key
4. From the Advanced Setting menu, select the menu item **Configure External Authentication (httpd)**
5. Enter the FQDN of the IPA Server, i.e. *ipaserver.test.company.com*
6. Enter the IPA Server domain, i.e. *test.company.com*
7. Enter the IPA Server realm, i.e. *TEST.COMPANY.COM*
8. Press enter to select the default IPA Server Principal, i.e. *admin*
9. Enter the Password of the IPA Server Principal
10. Review details, and Enter **y** to proceed.

Configure the MiQ appliance to use external authentication

Log in to the MiQ appliance as admin, then in *Settings→Configuration→Server→Authentication*

- Set mode to External (httpd)
- Check: *Get User Groups from External Authentication (httpd)*
- *Optionally* Check: *Enable Single Signon*
- Click Save.

The above steps need to be done on each UI and WebService enabled appliance.

in *Settings→Configuration→Access Control*

- Make sure the user's groups are created on the Appliance and appropriate roles assigned to those groups.

Create groups on the MiQ appliance

The below steps need to be done on each UI and WebService enabled appliance.

Log in to the MiQ appliance as admin, then in *Settings→Configuration→Access Control→Groups→Configuration→Add a new Group*

- Check: *(Look Up LDAP Groups)*
- Enter the AD user as the *User to Look Up* i.e. *ipauser@ipaserver.test.company.com*
- Click Retrieve.
- Choose a group from the *LDAP Groups for User* dropdown.
- Assign the appropriate roles to the group
- Click Add.

Use AD Trust Authentication

Once the above is done, the user simply needs to specify their AD Username and Password when:

- Logging into the Appliance Administrative UI
- Accessing the REST API
- Using the Self Service UI
- Using the Single Sign On (SSO) to access the MiQ appliance after generating a Kerberos ticket by using kinit with AD credentials.

- LDAP
- Testing OpenLDAP
  - With SSL
  - With User Bind DN and Password
- Configure SSSD
  - Configure sssd.conf with authselect (CentOS 8 and newer)
  - Configure sssd.conf with authconfig (CentOS 7 and older)
  - Update sssd.conf
    - Testing SSSD Updates
- Configure Apache
- Configure SELinux
- Configure Administrative UI

LDAP

This guide covers how to manually configure an appliance's external authentication to work against LDAP. This provides LDAP users access to the Appliance UI as well as the REST API.

1. Testing OpenLDAP
2. Configure SSSD
3. Configure Apache
4. Configure SELinux
5. Configure Administrative UI

In these examples, the LDAP domain used will be *example.com*

Note: The SSSD and OpenLDAP configurations shown below are simply examples. Depending on the Ldap environment, Ldap directory server used, the configurations can widely differ. Many other options are available to the *authconfig* command as well as the *sssd.conf* configuration file.

The following reference are available for customizing SSSD for any LDAP directory:

```
# man authconfig
# man ldap.conf
# man sssd-ldap
```

The document @ https://onemoretech.wordpress.com/2014/02/23/sssd-for-ldap-auth-on-linux/ is also helpful.

Testing OpenLDAP

With SSL

For Configuring external authentication to Ldap, the sssd-ldap communication must be secured (SSL or Start TLS). So an SSL Certificate needs to be created.

The *apacheds-cert.pem* certificate file is used in the examples below.

Update the LDAP Directory Server to point to the keystore for the certificate. This is used for both SSL and Start TLS.

For SSL, update the **/etc/openldap/ldap.conf** accordingly to test:

```
SASL_NOCANON    on

URI             ldaps://ldap-example.com:10636
BASE            dc=example,dc=com
TLS_REQCERT     demand
TLS_CACERTDIR   /etc/openldap/cacerts
TLS_CACERT      /etc/openldap/cacerts/apacheds-cert.pem
```

Then try out a search:

```
# ldapsearch -x -H ldaps://ldap-example:10636 -LLL \
       -b "ou=people,dc=example,dc=com" -s sub     \
       "(objectclass=organizationalPerson)"
```

With User Bind DN and Password

You can also test the ldap directory by specifying a user Bind DN and password on the Ldap search command line as follows:

```
# ldapsearch -x -H ldap://ldap-example:389 -LLL                 \
       -b "ou=people,dc=example,dc=com" -s sub                  \
       -D "ui=:userid,ou=People,dc=example,dc=com" -w :password \
       "(objectclass=organizationalPerson)"
```

Configure SSSD

There are two different ways that SSSD can be configured.

For *CentOS 7* and earlier **authconfig** is used to configure SSSD. Starting with *CentOS 8* a new command, **authselect** is used.

Perform the steps in only one of these two sections below:

- Configure sssd.conf with authselect (CentOS 8 and newer)
- Configure sssd.conf with authconfig (CentOS 7 and older)

Note: SSSD must be configured to communicate with LDAP over SSL or Start TLS. Otherwise an authentication error will be returned to the Appliance login screen.

Configure sssd.conf with authselect (CentOS 8 and newer)

```
  # authselect select sssd --force
```

Seed the sssd.conf configuration file

authselect does not automatically generate the */etc/sssd/sssd.conf* file, however the template, *sssd.conf.erb*, is now delivered with ManageIQ which can be used to seed the */etc/sssd/sssd.conf*.

```
# TEMPLATE_DIR="/opt/IBM/infrastructure-management-appliance/TEMPLATE"
# mkdir -p /etc/sssd
# cp ${TEMPLATE_DIR}/etc/sssd/sssd.conf.erb /etc/sssd/sssd.conf
# chmod 600 /etc/sssd/sssd.conf
```

Update the SSSD configuration file /etc/sssd/sssd.conf to specify the correct *ldap_search_base* and *ldap_uri*:

```
...
ldap_search_base = dc=example,dc=com
id_provider = ldap
auth_provider = ldap
chpass_provider = ldap
ldap_uri = ldaps://ldap-example.com:10636
ldap_id_use_start_tls = False
cache_credentials = True
...
```

Configure sssd.conf with authconfig (CentOS 7 and older)

```
  # authconfig \
    --enablesssd                                \
    --enablesssdauth                            \
```

```
    --enablelocauthorize                        \
    --enableldap                                \
    --enableldapauth                            \
    --ldapserver=ldaps://ldap-example.com:10636 \
    --disableldaptls                            \
    --ldapbasedn=dc=example,dc=com              \
    --enablerfc2307bis                          \
    --enablecachecreds                          \
    --update
```

Update sssd.conf

Edit the different sections in **/etc/sssd/sssd.conf** for the Appliance as in the following example, customizing the main **[domain/example.com]** section for the particular Ldap installation.

Note: Starting with SSSD version 1.15.2, which will be available in CentOS version 7.4, SSSD will provide the domain name as a user attribute. The below examples show how to set *ldap_user_extra_attrs* and *user_attributes* to take advantage of this new feature. If running an appliance built with CentOS version prior to CentOS 7.4 do not include *domainname* for these attributes.

```
=>  [domain/example.com]
    autofs_provider = ldap
    id_provider = ldap
    auth_provider = ldap
    chpass_provider = ldap
    ldap_schema = rfc2307bis

    ldap_uri = ldaps://ldap-example.com:10636
    ldap_id_use_start_tls = False
=>  ldap_tls_cacertdir = /etc/openldap/cacerts
=>  ldap_tls_cacert = /etc/openldap/cacerts/apacheds-cert.pem

=>  ldap_pwd_policy = none

    ldap_search_base = dc=example,dc=com
=>  ldap_network_timeout = 3

=>  ldap_user_search_base = ou=people,dc=example,dc=com
=>  ldap_user_object_class = posixAccount
=>  ldap_user_name = uid
=>  ldap_user_uid_number = uidNumber

=>  ldap_group_object_class = groupOfNames
=>  ldap_group_search_base = ou=user_groups,dc=example,dc=com
=>  ldap_group_name = cn
=>  ldap_group_member = member

    cache_credentials = True
=>  entry_cache_timeout = 600

=>  ldap_user_extra_attrs = mail, givenname, sn, displayname, domainname

    [sssd]
=>  domains = example.com
    config_file_version = 2
=>  services = nss, pam, ifp
=>  sbus_timeout = 30
=>  default_domain_suffix = example.com

    [nss]
    homedir_substring = /home

    [pam]
=>  default_domain_suffix = example.com

=>  [ifp]
=>  default_domain_suffix = example.com
=>  allowed_uids = apache, root, manageiq
=>  user_attributes = +mail, +givenname, +sn, +displayname, +domainname
```

Testing SSSD Updates

The best way to test manual SSSD updates is to query a user via the message bus system (D-Bus) API. When user attributes and groups are properly returned, that is a good indication that the External Authentication would succeed.

For the *dbus-send* command to succeed when run from command line, SELinux must be in permissive mode.

```
# setenforce 0
```

After each update to **sssd.cond**, restart the sssd service before testing the changes.

```
systemctl restart sssd
```

Example query of user attributes for user evmuser. This primarily validates the *ldap_user_* attributes of **sssd.conf**.

```
# dbus-send --print-reply --system --dest=org.freedesktop.sssd.infopipe /org/freedesktop/sssd/infopipe
org.freedesktop.sssd.infopipe.GetUserAttr string:evmuser array:string:mail,givenname,sn,displayname,domainname
```

Query groups of user evmuser. This primarily validates the *ldap_group_* attributes of **sssd.conf**.

```
# dbus-send --print-reply --system --dest=org.freedesktop.sssd.infopipe /org/freedesktop/sssd/infopipe
org.freedesktop.sssd.infopipe.GetUserGroups string:evmuser
```

With logging for each of the **sssd.conf** section in the appropriate /var/log/sssd/ log file. The log files of primary interest are:

Log File	Type of debugging
/var/log/sssd/sssd.log	SSSD communication with processes
/var/log/sssd/sssd_example.com.log	sssd-ldap communication to the LDAP server
/var/log/sssd/sssd_ifp.log	Gathering user and group information from LDAP server

For each of the log file here, an debug level attribute (maximum value of 9) can be added to the appropriate **sssd.conf** section as follows:

```
    [ifp]
=>  debug_level = 9
    default_domain_suffix = example.com
    ...
```

When done testing, re-enable SELinux enforcing mode.

```
# setenforce 1
```

Note: When testing authentication on the Appliance, if updates are done in LDAP and not immediately seen when authenticating, then clean the SSSD cache as follows then retry:

```
# sss_cache -E
```

Configure Apache

Create the Apache configuration files

```
# TEMPLATE_DIR="/opt/IBM/infrastructure-management-appliance/TEMPLATE"
# cp ${TEMPLATE_DIR}/etc/pam.d/httpd-auth                          \
                    /etc/pam.d/httpd-auth
# cp ${TEMPLATE_DIR}/etc/httpd/conf.d/manageiq-remote-user.conf       \
                    /etc/httpd/conf.d/
# cp ${TEMPLATE_DIR}/etc/httpd/conf.d/manageiq-external-auth.conf.erb \
                    /etc/httpd/conf.d/manageiq-external-auth.conf
```

Configure SELinux

For SSSD to Ldap, assure that non-standard Ldap ports (other than 389 or 636) are allowed:

```
# semanage port -a -t ldap_port_t -p tcp 10389
# semanage port -a -t ldap_port_t -p tcp 10636
```

Set appropriate SELinux permissions:

```
# setsebool -P allow_httpd_mod_auth_pam on
# setsebool -P httpd_dbus_sssd          on
```

Restart Services

```
# systemctl restart sssd
# systemctl restart httpd
```

Configure Administrative UI

Log in as admin, navigate to *Settings > Application Settings > Settings*. Select the server, then select the *Authentication tab*

- Set mode to External (httpd)
- Check: *Get User Groups from External Authentication (httpd)*
- Do not check: *Enable Single Signon* since Kerberos is not configured against LDAP.
- Click Save.

The above steps need to be completed on each UI and WebService enabled appliance.

Navigate to *Settings > Application Settings > Access Control*

- Make sure the user's LDAP group for the appliance are created and appropriate roles assigned to those groups.

    - Configure SAML
    - Unconfigure SAML

SAML

External Authentication on the Appliance has been enhanced to support SAML. The SAML implementation has been tested with KeyCloak 1.8.

In this guide we will cover how to manually configure an Appliance's external authentication to work with SAML. The SAML implementation has been tested with KeyCloak but is implemented generically using Apache's mod_auth_mellon module and should work with other SAML Identity Providers.

The current implementation only secures the Appliance's Web administrative UI with SAML.

Note: The REST API and Self-Service UI do not currently support SAML.

1. Requirements
2. Configuring SAML
3. Configuring the Administrative UI
4. Re-Enabling Local Login
5. Configuring SAML using the CLI

Requirements

The following is needed in order to enable SAML Authentication to the Appliance:

- A CentOS/RHEL 7.2 based Appliance
- A SAML Identity Provider, (e.g. KeyCloak 1.8 or Later)

Configure SAML

All SAML related certificates and keys are accessed from /etc/httpd/saml2/

First ssh to the appliance as root, then create that directory:

```
# mkdir -p /etc/httpd/saml2
```

Apache Configuration

Copy the Apache remote user and SAML template configuration files:

```
# TEMPLATE_DIR="/opt/IBM/infrastructure-management-appliance/TEMPLATE"
# cp ${TEMPLATE_DIR}/etc/httpd/conf.d/manageiq-remote-user.conf        \
    /etc/httpd/conf.d/
# cp ${TEMPLATE_DIR}/etc/httpd/conf.d/manageiq-external-auth-saml.conf \
    /etc/httpd/conf.d/
```

SAML Configuration

Notable defaults in the *manageiq-external-auth-saml.conf* file:

Description	Default
Identity Provider Files (i.e. KeyCloak)	
Metadata File	/etc/httpd/saml2/idp-metadata.xml
Service Provider Files (i.e. mod_auth_mellon)	
Private Key File	/etc/httpd/saml2/miqsp-key.key
Certificate File	/etc/httpd/saml2/miqsp-cert.cert
Metadata File	/etc/httpd/saml2/miqsp-metadata.xml

Other mod_auth_mellon parameters must not be modified as the Appliance expects them to be defined as such, i.e. End points, Protected URL, etc.

For the Service Provider files on the Appliance, these can be generated using the mod_auth_mellon command *mellon_create_metadata.sh* as follows:

```
# cd /etc/httpd/saml2
# /usr/libexec/mod_auth_mellon/mellon_create_metadata.sh https://<miq-appliance> https://<miq-appliance>/saml2
```

The mellon_create_metadata.sh script creates file names based on the appliance URL but can be renamed to match the expected file names from the *manageiq-external-auth-saml.conf* file:

```
# mv https_<miq-appliance>.key  miqsp-key.key
# mv https_<miq-appliance>.cert miqsp-cert.cert
# mv https_<miq-appliance>.xml  miqsp-metadata.xml
```

With the service provider metadata.xml file generated, the Service Provider definition can now be defined in the Identity Provider.

For KeyCloak, a Realm can be created for one or more Appliances with individual Clients defined one per Appliance where the Client ID is essentially the URL of the appliance.

Adding a Client in the KeyCloak ManageIQ Realm:

- Select and Import the miqsp-metadata.xml file created for mod_auth_mellon.
- Set Client ID as https://<miq-appliance>
- Set Client protocol as **saml**.

The Client definition for the appliance can then be updated with the following:

Setting	Value
Name ID Format	username
Valid Redirect URIs	https://<miq-appliance/saml2/paosResponse>
	https://<miq-appliance/saml2/postResponse>
Base URL	https://<miq-appliance/>

Fine Grain SAML Endpoint Configuration	
Setting	**Value**
Assertion Consumer Service POST Binding URL	https://<miq-appliance/saml2/postResponse>
Assertion Consumer Service Redirect Binding URL	https://<miq-appliance/saml2/postResponse>
Logout Service Redirect Binding URL	https://<miq-appliance/saml2/logout>

The Identity Provider's Metadata file idp-metadata.xml can then be obtained as follows:

```
# cd /etc/httpd/saml2
# curl -s -o idp-metadata.xml \
    http://<keycloak-server>:8080/auth/realms/<miq-realm>/protocol/saml/descriptor
```

Finally, restart Apache on the appliance as follows:

```
# systemctl restart httpd
```

SAML Assertions

For authenticating to the appliance, the following remote user parameters are looked at by the appliance upon a successful login and redirect from the Identity Provider.

HTTP Environment	SAML Assertion
REMOTE_USER	username
REMOTE_USER_EMAIL	email
REMOTE_USER_FIRSTNAME	firstname
REMOTE_USER_LASTNAME	lastname
REMOTE_USER_FULLNAME	fullname
REMOTE_USER_GROUPS	groups

For KeyCloak, the above SAML Assertions can be created for the Appliance Client in KeyCloak as Mappers.

Name	Mapper Type	Property	Friendly Name	SAML Attribute Name	SAML Attribute Name Format
username	User Property	username	username	username	Basic
email	User Property	email	email	email	Basic
firstname	User Property	firstName	firstname	firstname	Basic
lastname	User Property	lastName	lastname	lastname	Basic
Name	**Mapper Type**	**User Attribute**	**Friendly Name**	**SAML Attribute Name**	**SAML Attribute Name Format**
fullname	User Attribute	fullName	fullname	fullname	Basic

Name	Mapper Type	Group attribute name	Friendly Name	SAML Attribute Name	SAML Attribute Name Format
groups	Group List	groups	groups	groups	Basic

Note: The fullName attribute was not available in the default database as of this writing and must be added to each user as a user attribute.

Configure Administrative UI

After having configured Apache for SAML, the next step is to update the Appliance Administrative UI to be SAML aware and function accordingly.

Login as admin, then in *Configure→Configuration→Authentication*

- Set mode to External (httpd)
- Check: *Enable Single Signon* - With this option enabled, initial access to the Appliance Administrative UI will redirect to the SAML Identity Provider authentication screen. Note that logouts from the Appliance will return the user to the Appliance login screen allowing them to login as admin unless *Disable Local Login* is checked below.
- Check: *provider Type: _Enable SAML* - This enables the SAML login button on the login screen, the redirects to the SAML protected page for authentication, and supports the SAML logout process.
- Optional: Check: *Disable Local Login* - Do this **only** if you need to disable *admin* login to appliance and only allow SAML based authentication. Note that if there are issues with the Identity Provider or you need admin access to the appliance you won't be able to login until you re-enable the Local Login as described

below.

- Check: *Get User Groups from External Authentication (httpd)*
- Click Save.

The above steps need to be done on each UI enabled appliance.

in *Configure→Configuration→Access Control*

- Make sure the user's groups are created on the Appliance and appropriate roles assigned to those groups.

Re-Enabling Local Login

If the Local Login has been disabled in the Administrative UI and there is a need to be able to login as *admin*, the Local Login can be re-enabled as follows:

Administrative UI:

This option is available if the Identity Provider is available and one can login using a user with enough administrative privileges to update it:

- Login as administrative user,
- In then in *Configure→Configuration→Authentication* uncheck *Disable Local Login* and save.

Appliance Console Interface:

- ssh to the appliance as root
- Run *appliance_console*
- Select menu entry *Update External Authentication Options*
- Select *Enable Local Login*
- then *Apply updates*

Appliance Console CLI:

- ssh to the appliance as root
- Run *appliance_console_cli –extauth-opts* **local_login_disabled=false**

Configuring SAML using the CLI

Another way to configure SAML on the appliance is to use the appliance console CLI instead of the above steps. The **`--saml-config`** subcommand of the appliance console CLI allows one to configure the appliance for SAML Authentication by updating both Apache configurations as well as the necessary Administrative UI settings. The **`--saml-unconfig`** subcommand is also provided for unconfiguring the appliance SAML Authentication and reverting the appliance to Database Authentication.

Usage of the new Appliance Console CLI subcommands are as follows:

Configure SAML

To configure the appliance for SAML Authentication:

```
# appliance_console_cli --saml-config [--saml-client-host=miq_appliance.fqdn] \
                                       --saml-idp-metadata=file|url           \
                                      [--saml-enable-sso]
```

When –saml-client-host is not specified, the configured appliance host is used for creating the SP metadata. This host fqdn must be reachable from the SAML IDP.

Configuring SAML requires the IDP metadata file. The –saml-idp-metadata option allows the user to specify the file path of a copy that was downloaded to the appliance or by a URL, in which case the CLI downloads the copy from the IDP.

Examples:

```
--saml-idp-metadata=/tmp/downloaded_idp_metadata.xml
```

```
--saml-idp-metadata=http://<idp-host:port>/auth/realms/<miq-realm>/protocol/saml/descriptor
```

In both cases, the IDP metadata file is copied to **`/etc/httpd/saml2/idp-metadata.xml`**

By default, SSO is not enabled, so from the Appliance login page, the user clicks on Log In to Corporate System to get redirected to the SAML login page. With this option enabled, the Appliance redirects the user to the SAML login page for logging in.

After SAML is configured, the SP metadata file can be fetched from **`/etc/httpd/saml2/miqsp-metadata.xml`** to create the related Client on the SAML IDP.

Unconfigure SAML

To unconfigure the appliance from SAML Authentication and revert to Database authentication:

```
# appliance_console_cli --saml-unconfig
```

This will remove the Apache external authentication SAML configuration files and revert the appliance's authentication settings to Database mode.

- OpenID-Connect
- Requirements
- Configuring Keycloak
  - OIDC Assertions
  - Apache Configuration
  - OIDC Configuration
- Configuring the Administrative UI
- Re-Enabling Local Login
  - Administrative UI:
  - Appliance Console Interface:
  - Appliance Console CLI:
- Configuring OIDC using the CLI
  - Configure OpenID-Connect
  - Unconfigure OpenID-Connect

OpenID-Connect

External Authentication on the Appliance has been enhanced to support OpenID-Connect, which will also be referred to as *OIDC*.

The OIDC implementation has been tested with KeyCloak 3.2.1.

In this guide we will cover how to manually configure an Appliance's external authentication to work with OIDC. The OIDC implementation has been tested with KeyCloak but is implemented generically using Apache's mod_auth_openidc module and should work with other OIDC Identity Providers.

The current implementation secures the Appliance's Web administrative and Self-Service UI with OIDC.

1. Requirements
2. Configuring Keycloak
3. OIDC Assertions
4. Apache Configuration
5. OIDC Configuration
6. Configuring the Administrative UI
7. Re-Enabling Local Login
8. Configuring OIDC using the CLI

Requirements

The following is needed in order to enable OIDC Authentication to the Appliance:

- A CentOS/RHEL 7.5 based Appliance
- A OIDC Identity Provider, (e.g. KeyCloak 3.2.1 or Later)

Configuring Keycloak

For KeyCloak, a Realm can be created for one or more Appliances with individual Clients defined one per Appliance where the Client ID identifies the individual appliance, e.g. the appliance hostname.

Adding a Client in the KeyCloak ManageIQ Realm:

- Set Client ID as <miq-appliance>
- Set Client protocol as **openid-connect**.

The Client definition for the appliance can then be updated with the following:

Setting	Value
Client Protocol	openid-connect
Access Type	confidential
Valid Redirect URIs	https://<miq-appliance>
	https://<miq-appliance/ui/service/>
	https://<miq-appliance/oidc_login/redirect_uri>
User Info Signed	unsigned
Request Object Signature Algorithm	any

Note: The trailing / for the /ui/service/ entry is required.

The value used for OIDCClientSecret (*oidc_client_secret*) in the *manageiq-external-auth-oidc.conf* file is taken from the Keycloak Client's *Credentials / Secret* value. To generate a new client secret, First set the *Credentials / Client Authenticator* to *Client Id and Secret* . Then *Regenerate Secret* button.

OIDC Assertions

For authenticating to the appliance, the following remote user parameters are looked at by the appliance upon a successful login and redirect from the Identity Provider.

HTTP Environment	OIDC Assertion
REMOTE_USER	username
REMOTE_USER_EMAIL	email
REMOTE_USER_FIRSTNAME	firstname
REMOTE_USER_LASTNAME	lastname
REMOTE_USER_FULLNAME	fullname
REMOTE_USER_GROUPS	groups

For KeyCloak, the above OIDC Assertions can be created for the Appliance Client in KeyCloak as Mappers.

The following mappers are automatically generated when the OIDC client is created:

Name	Category	Mapper Type
email	Token mapper	User Property
family name	Token mapper	User Property
given name	Token mapper	User Property
full name	Token mapper	User's full name
username	Token mapper	User Property

The following *Group Membership* mapper must be manually created:

Name	Consent Required	Mapper Type	Token Claim Name	Full group path	Add to ID token	Add to access token	Add to userinfo	Add to token introspection
groups	OFF	Group Membership	groups	OFF	ON	OFF	OFF	ON

The following *User Session Note* mappers must be manually created:

Name	Consent Required	Mapper Type	User Session Note	Token Claim Name	Claim JSON Type	Add to ID token	Add to access token
Client Host	OFF	User Session Note	clientHost	clientHost	String	ON	ON
Client ID	OFF	User Session Note	clientId	clientId	String	ON	ON
Client IP Address	OFF	User Session Note	clientAddress	clientAddress	String	ON	ON

Apache Configuration

Copy the Apache OIDC template configuration files:

```
# TEMPLATE_DIR="/opt/IBM/infrastructure-management-appliance/TEMPLATE"
# cp ${TEMPLATE_DIR}/etc/httpd/conf.d/manageiq-remote-user-openidc.conf \
    /etc/httpd/conf.d/
# cp ${TEMPLATE_DIR}/etc/httpd/conf.d/manageiq-external-auth-openidc.conf.erb \
    /etc/httpd/conf.d/manageiq-external-auth-openidc.conf
```

OIDC Configuration

The Apache */etc/httpd/conf.d/manageiq-external-auth-openidc.conf* configuration files must be updated with installation specific values:

The defaults in the *manageiq-external-auth-oidc.conf* file are:

Name	Value
LogLevel	warn
OIDCCryptoPassphrase	sp-cookie
OIDCOAuthRemoteUserClaim	username

Installation specific values must be specified in the *manageiq-external-auth-oidc.conf* file for the following parameters, where the *parameter* including the <%= ... %> anchors need to be replaced with the appropriate values:

Name	Parameter	Value
ServerName and OIDCRedirectURI	miq_appliance	FQDN of the appliance
OIDCProviderMetadataURL	oidc_provider_metadata_url	The OpenID-Connect Provider URL, i.e. http://<keycloak_server>:8080/auth/realms/miq/.well-known/openid-configuration
OIDCClientID and OIDCOAuthClientID	oidc_client_id	The OpenID-Connect Client ID
OIDCClientSecret end OIDCOAuthClientSecret	oidc_client_secret	The OpenID-Connect Client Secret

Name	Parameter	Value
OIDCOAuthIntrospectionEndpoint	oidc_introspection_endpoint	The OpenID-Connect Introspection Endpoint

Optional parameters can be appended to the end fo the configuration file to avoid SSL verification. These can be used when a valid SSL server certificate is not available for communicating with the OpenID Provider.

NOTE: Using these parameters is insecure and should only be used in a development environment.

Name	Value
OIDCSSLValidateServer	Off
OIDCOAuthSSLValidateServer	Off

Finally, restart Apache on the appliance as follows:

```
# systemctl restart httpd
```

Configuring the Administrative UI

After having configured Apache for OIDC, the next step is to update the Appliance Administrative UI to be OIDC aware and function accordingly.

Login as admin, then in *Configure→Configuration→Authentication*

- Set mode to External (httpd)
- Check: *Provider Type: Enable Enable OpenID-Connect* - This enables the OIDC login button on the login screen, that redirects to the OIDC protected page for authentication, and supports the OIDC logout process.
- Optional: Check: *Enable Single Signon* - With this option enabled, initial access to the Appliance Administrative UI will redirect to the OIDC Identity Provider authentication screen. Note that logouts from the Appliance will return the user to the Appliance login screen allowing them to login as admin unless *Disable Local Login* is checked below.
- Optional: Check: *Disable Local Login* - Do this **only** if you need to disable *admin* login to appliance and only allow OIDC based authentication. Note that if there are issues with the Identity Provider or you need admin access to the appliance you won't be able to login until you re-enable the Local Login as described below.
- Check: *Get User Groups from External Authentication (httpd)*
- Click Save.

The above steps need to be done on each UI enabled appliance.

In Configure→Configuration→Access Control

- Make sure the user's groups are created on the Appliance and appropriate roles assigned to those groups.

Re-Enabling Local Login

If the Local Login has been disabled in the Administrative UI and there is a need to be able to login as *admin*, the Local Login can be re-enabled using either of the following methods:

Administrative UI:

This option is available if the Identity Provider is available and one can login using a user with enough administrative privileges to update it:

- Login as administrative user,
- In then in *Configure→Configuration→Authentication* uncheck *Disable Local Login* and save.

Appliance Console Interface:

- ssh to the appliance as root
- Run *appliance_console*
- Select menu entry *Update External Authentication Options*
- Select *Enable Local Login*
- then *Apply updates*

Appliance Console CLI:

- ssh to the appliance as root
- Run *appliance_console_cli –extauth-opts* **local_login_disabled=false**

Configuring OIDC using the CLI

Another way to configure OpenID-Connect on the appliance is to use the appliance console CLI instead of the above steps. The `--oidc-config` subcommand of the appliance console CLI allows one to configure the appliance for OpenID-Connect Authentication by updating both Apache configurations as well as the

necessary Administrative UI settings. The **--oidc-unconfig** subcommand is also provided for unconfiguring the appliance OpenID-Connect Authentication and reverting the appliance to Database Authentication.

Usage of the new Appliance Console CLI subcommands are as follows:

Configure OpenID-Connect

To configure the appliance for OpenID-Connect Authentication:

```
# appliance_console_cli --oidc-config
                        [--oidc-client-host]
                        --oidc-url
                        --oidc-client-id
                        --oidc-client-secret
                        [--oidc-introspection-endpoint]
                        [--oidc-enable-sso]
                        [--oidc-insecure]
```

When the **--oidc-introspection-endpoint** is not specified, an attempt will be made to fetch the introspection endpoint by querying the OpenID-Connect Provider URL.

When the **--oidc-client-host** is not specified, the configured appliance host is used for the ServerName and OpenID-Connect Redirect URI in the OpenID-Connect Apache configuration file. The **--oidc-client-host** is usually the externally reachable FQDN of the appliance.

When **--oidc-insecure** is specified no SSL verification will be done when attempting to fetch the introspection endpoint and SSL verification will be disabled using parameters **OIDCSSLValidateServer** and **OIDCOAuthSSLValidateServer** as described above.

Configuring OpenID-Connect requires the following parameters:

Parameter	Description
--oidc-url	This is the OpenID-Connect Provider URL
--oidc-client-id	The OpenID-Connect Provider Cliend ID
--oidc-client-secret	The OpenID-Connect Provider Client Secret

The **--oidc-url** varies for different providers. An example provider URL for keycloak:

```
--oidc-url=http://keycloak-server:8080/auth/realms/miq-realm/.well-known/openid-configuration
```

With **miq-realm** being the Keycloak Realm this OpenID-Connect appliance client is being configured for.

The **--oidc-client-id** is the Client ID specified for the appliance in the OpenID-Connect provider, usually just **<miq-appliance-fqdn>**

By default, SSO is not enabled, so from the Appliance login page, the user clicks on Log In to Corporate System to get redirected to the OpenID-Connect login page. With the **--oidc-enable-sso** option specified, the Appliance redirects the user to the OpenID-Connect login page for logging in.

Unconfigure OpenID-Connect

To unconfigure the appliance from OpenID-Connect Authentication and revert to Database authentication:

```
# appliance_console_cli --oidc-unconfig
```

This will remove the Apache external authentication OpenID-Connect configuration files and revert the appliance's authentication settings to Database mode.

Scripting Actions in Infrastructure Automation

The Automate model provides flexibility to not only change parts of the provisioning process, but also to allow you to automate other operational tasks. Below are some scenarios where the Automate model can help accomplish these tasks.

- Intelligent Workload Management - An enterprise had a requirement that when a virtual machine has reached a High CPU Percent Ready for a specified period of time, a vMotion should occur to a more suitable host. For this reason, VMware's Distributed Resource Scheduler (DRS) was not practical, as the CPU Ready metric could not trigger DRS. The solution was to leverage Infrastructure Automation Control and Infrastructure Automation Automate to drive the management of this workflow.
- Power on only during business hours - An organization which gave a group of self-service users Infrastructure Automation access had a requirement to only allow certain virtual machines to be powered during business hours. This was solved with Infrastructure Automation Automate.
- Auto-Tagging virtual machines based on file contents - An IT organization needed a way to consume information from a text file on a virtual machine and dynamically populate vCenter. The data used to auto-tag virtual machines is also used to align unmanaged virtual machines to the business.

Updates to Rails and Ruby

Changes within Ruby and Rails versions can create issues for custom code and automation in Infrastructure Automation environments.

Before proceeding with major upgrades that include changes to versions of Ruby and Rails, review the below resources.

Updates and Changes in Rails

See Rails Releases for information on each release of Rails. To compare versions of Rails, see Comparing changes in Rails.

Updates and Changes in Ruby

See Ruby Releases for information on each release of Ruby by version number. To compare versions of Ruby, see Comparing changes in Ruby.

Understanding the Automate Model

Automate enables real-time, bi-directional process integration. This provides users with a method to implement adaptive automation for management events and administrative or operational activities.

Automate Model

The Automate model is arranged to provide an object oriented hierarchy to control automation functions. The model uses the following organizational units arranged in a hierarchy:

- **Datastore** - The main organization unit that stores the entire model.
- **Domains** - Domains act as collection of automation functions. Functions are executed depending on the order of Domain priority, which means a function in a Domain with a higher priority overrides the same functions specified in a lower-priority Domain. This allows Infrastructure Automation to specify a core Domain (ManageIQ) but allow users to override automate functions with custom Domains. Each Domain contains a set of Namespaces.
- **Namespaces** - Containers that organize and categorize functions of the model. Namespaces can contain child Namespaces as well as Classes.
- **Classes** - Templates for a specific function of the model. Each Class uses a Schema to apply to Instances to populate with default values. Each class also can contain a set of methods.
- **Instances** - An instance is a version of a class populated with initial configuration data. An instance can include a collection of any number of attributes, calls to methods, and relationships.
- **Methods** - Methods are functions within the model. Methods use Ruby code to execute various operations needed for a Class.

Infrastructure Automation contains a preconfigured Domain for users:

- **ManageIQ** - The core domain for Infrastructure Automation Automate operations. This domain is locked with the following Namespaces:
  - **Cloud** - General cloud instance lifecycle from provisioning, retirement, methods, email.
  - **Control** - Control contains email alerts for policy controls.
  - **Infrastructure** - General infrastructure VM lifecycle from provisioning, retirement, methods, email.
  - **Integration** - Used to interface with systems outside of Infrastructure Automation. Use this namespace to integrate with additional systems.
  - **Service** - Service lifecycle from provisioning, retirement, methods, email.
  - **System** - System contains classes that can provide the start points for all Infrastructure Automation Automate activities.

You can copy classes and instances from locked Domains into your own custom domains.

Note:

Changing the existing classes or instances shipped with the product is not recommended because this may hinder the operation of Infrastructure Automation. You can link to these methods using relationships.

To reset the Automate model to default settings, navigate to **Automate > Import/Export** and click the **Reset** option.

Creating a Domain

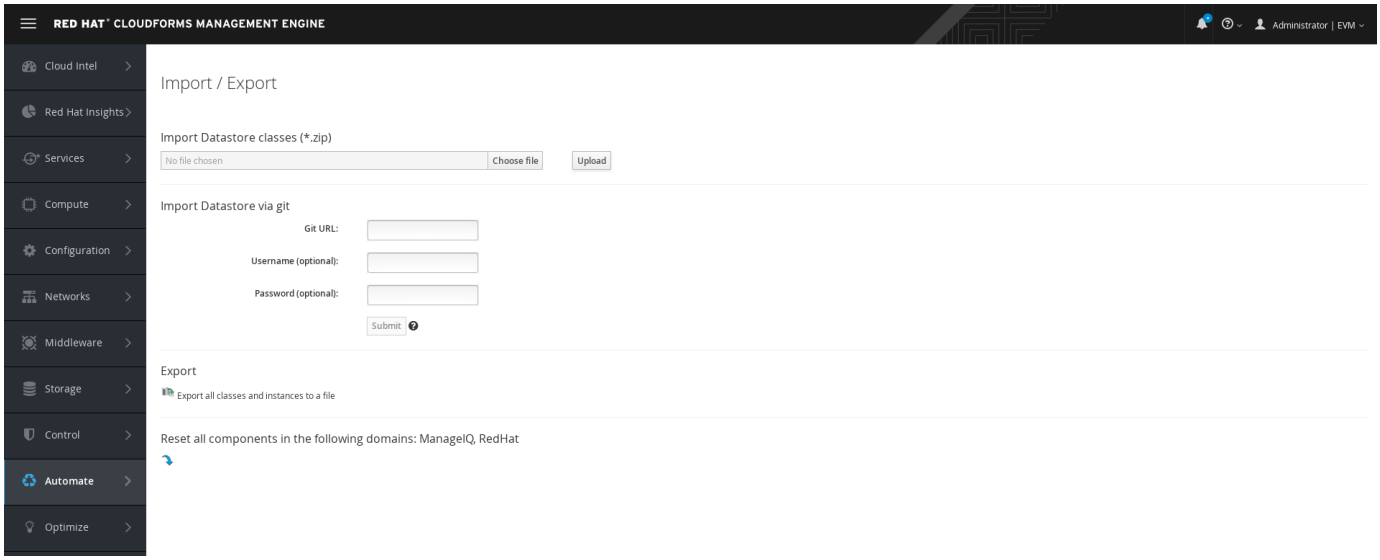
1. Navigate to **Automation > Automate > Explorer**. The default view is the Datastore.
2. Click (**Configuration**), then (**Add a New Domain**).
3. Type in a unique **Name** and **Description**. Choose if the Domain is **Enabled**.
4. Click **Add**.

The new domain is created.

Editing a Domain

1. Navigate to **Automation > Automate > Explorer**. The default view is the Datastore.
2. Select the Domain you want to edit.
3. Click (**Configuration**), then (**Edit Selected Domain**).
4. Make the required edits.
5. Click **Save**.

You have edited the selected domain.



Deleting a Domain

1. Navigate to **Automation > Automate > Explorer**. The default view is the Datastore.
2. Select the **Domain** that you want to delete.
3. Click (**Configuration**), then (**Remove This Domain**).
4. A window to confirm the removal of Domain appears.
5. Click **OK**.

The selected Domain is deleted.

Importing a Domain from a Git Repository

Infrastructure Automation can import an Automate domain from a Git repository by specifying a repository and branch, along with user details. Currently, you can only add git domains via the **Import/Export** area of the user interface.

1. Navigate to **Automation > Automate > Import/Export**.
2. In **Import Datastore via git**, enter the **Git URL**. Select the branch or tag to use.
3. Optionally, enter a **Username** and **Password**.
4. Select **Verify Peer Certificate** if desired.
5. Click **Submit**.

The new domain is imported via Git repository. Note that the domain is validated on import.

Changing Priority Order of Domains

Functions are executed depending on the order of Domain priority. Use this procedure to change the priority order of domains.

1. Navigate to **Automation > Automate > Explorer**. The default view is the Datastore.
2. Select the Domains you want to change the priority order for.
3. Click (**Configuration**), then (**Edit Priority Order of Domains**).
4. The list of Domains selected shows up. Note that you cannot change the priority of locked Domains and therefore locked Domains do not show up on the list.
5. Select one or more consecutive groups to move up or down to change their priority as required.
6. Click **Save**.

Creating a Namespace

1. Navigate to **Automation > Automate > Explorer**. The default view is the Datastore.
2. Navigate through the various Domains and Namespaces until you reach the desired location for your new Namespace.
3. Click (**Configuration**), then (**Add a New Namespace**).
4. Type in a unique **Name** and **Description**.
5. Click **Add**.

The new Namespace is created.

Creating a Class

1. Navigate to **Automation > Automate > Explorer**, navigate to the namespace you want to add a class to.
2. Click (**Configuration**), then (**Add a new Class**).
3. Type in a unique **Name** and **Description**.
4. If you want to use the schema from a class that has already been created, select it from the **Inherits From** dropdown. If the class that the new class inherits from changes, the new class will also change.

5. Click **Add**.

The new class is created and you can create a schema, add instances and methods.

Note:

For each class, create a schema if you did not choose to inherit from an existing class. The schema can include attributes, methods, assertions, and relationships.

Creating a Schema for a Class

This procedure shows you how to create a schema.

1. Navigate to **Automation > Automate > Explorer**, and click the class you want to define a schema for.
2. Click on the **Schema** tab.
3. Click (**Configuration**), then (**Edit selected Schema**).
4. Click (**Click to add a new field**) to create a new field.
5. Type in a **Name** for the new field.
6. From **Type**, select **Assertion**, **Attribute**, **Method**, **Relationship**, or **State**.
7. If applicable, select a **Data Type** and set a **Default Value**.
8. Type in a user friendly **Display Name** and **Description**.
9. Check **Sub** to enable the substitution syntax of **${}**. Uncheck it if you want to use that syntax as a regular string.
10. Fill in **Collect** and **Message** as required. **Collect** is used to roll up values from resolved relationships. For example, a relationship can resolve to a large object tree. Use **collect** to specify how to pull out data from those child objects into the current object. If you give **collect** a name value, it will store the method result in an attribute of the current object with that name.
11. **On Entry**, **On Exit**, **On Error**, **Max Retries**, and **Max Time** are fields used mostly for state machines. Leave blank if not applicable.
12. Click (**Add this entry**) to confirm the fields values.
13. For each new field, repeat steps 4 through 10.
14. When you have created all of the fields, click **Save**.

The class schema is created, and you can now add instances to it.

Note:

You may need to edit a class schema to reorder, add, edit, or remove a field. Classes define the order in which fields are processed and you may need to process some items before others.

Editing a Field in a Schema

This procedure describes how to edit schema fields.

1. Navigate to **Automation > Automate > Explorer**.
2. Click the class you want to define a schema for.
3. Click the **Schema** tab.
4. Click (**Configuration**), then (**Edit selected Schema**).
5. Make required changes to any of the definitions for the field.
6. To remove a field, click (**Click to delete this field from the schema**).
7. Click **Save** when you are finished editing the schema.

Once the schema is created, you can add instances and methods to the class.

Editing Schema Sequence

This procedure shows you how to change schema sequence.

1. Navigate to **Automation > Automate > Explorer**.
2. Click the class you want to change the schema sequence for.
3. Click the **Schema** tab.
4. Click (**Configuration**), then (**Edit Sequence**).
5. In the **Class Schema Sequencing** area, click the field you want to change the sequence for.
   - To move a field up in the order of resolving an instance, click (**Move selected field up**).

- To move a field down in the order of resolving an instance, click (**Move selected field down**).

6. Click **Save** when you are finished editing the sequence.

Adding an Instance to a Class

This procedure shows you how to create an instance.

1. Navigate to **Automation > Automate > Explorer**.
2. Click the class you want to define a schema for.
3. Click the **Instances** tab.
4. Click (**Configuration**), then (**Add a new Instance**).
5. In the **Main Info** area, type in a **Name**, **Display Name** and **Description**.
6. In the **Fields** area, type in an appropriate value for each field, leave the field blank if no value is required, or use the default value.
7. Click **Add**.

Copying a Class or Instance

1. Navigate to **Automation > Automate > Explorer**. The default view is the Datastore.
2. Navigate through the various Domains and Namespaces until you reach the desired class or instance to copy.
3. Click (**Configuration**), then either (**Copy this Class**) or (**Copy this Instance**) depending on the object chosen.
4. Choose the target Domain in the **To Domain** drop-down menu.
5. The object retains the same path as the **From Domain** and overrides the class in **From Domain** if the **To Domain** has a high priority. You can also untick the **Copy to same path** option to specify a new Namespace.
6. Click **Add**.

Relationships

Relationships are used to connect to other instances in the **Automation Datastore**. Relationships are formed using URI syntax. The following can also be passed through a relationship:

- Use **#** to set the message to send to the item in the relationship.
- To pass an input to the method use **?** followed by the item to pass.
- If you want to use a substitution, the syntax is **$\{}** with the substitution located between the brackets.

Example	Explanation
`/Cloud/VM/Provisioning/Naming/Default#create`	This relationships uses the Default instance of the Naming class, which provides a means for other classes to name virtual machines. The relationship sends the `create` message to the class.
`/Cloud/VM/Provisioning/StateMachines/VMProvision_VM/AcquireMACAddress#$\{#ae_message}`	This relationships substitutes the message to send to the AcquireMACAddress instance of the VMProvision_VM class with the value in `ae_message`.
`/Cloud/VM/Retirement/Email/vm_retirement_emails?event=vm_retired`	Invokes the vm_retirement_emails instance of the Email class. Also sends the value `vm_retired` in the `event` attribute, which is used in the vm_retirement_emails method.
`/Service/Lifecycle/Retirement?service_id=$\{process#service_id}`	Invokes the Retirement instance of the Lifecycle class and send a replacement value in `process#service_id` to the `service_id` attribute.

Methods

Methods are pieces of code associated with a class or object to perform a task. Infrastructure Automation allows for Ruby methods or backing a method using an Ansible playbook. You can create your own methods or use relationships to link to pre-existing ones.

Infrastructure Automation ships with a core set of Ruby gems used by the Infrastructure Automation Rails Application. The Ruby gems in this set are subject to change. If you are calling gems using Automate that are no longer in this release, you can install them by using the `gem install` command.

While gems can be imported into automation methods using `require`, it is recommended that the authors of the automation methods clearly document the use of gems either in the core set or a custom set. It is the responsibility of the author of such custom automation to own the life cycle of any gem being referenced in those methods.

The Release Notes list Ruby gems that have been added, updated, or removed in the latest version of Infrastructure Automation.

Creating a Method

This procedure shows you how to create a method.

1. Navigate to **Automation > Automate > Explorer**, navigate to the class where you want to create a method.
2. Click the **Methods** tab.
3. Click (**Configuration**), (**Add a New Method**).

4. In the **Main Info** area, type in a **Name** and **Display Name**.
5. For **Location**, select **inline**. Once selected, you will be presented with a **Data** area in which to write or copy the script.
6. Click **Validate** to check the syntax.
7. Click **Add**.

Creating a Dynamic Content Dialog

The procedure describes the steps to create a dynamic content dialog.

1. Navigate to **Automation > Automate > Explorer**.
2. From the accordion menu, click **DOMAIN > Cloud > VM > Operations > Methods**.

   Note:

   DOMAIN must be a user-defined Domain and not the locked ManageIQ Domain. If necessary, you can copy the class from the ManageIQ domain into a custom domain.

   This example uses the **Cloud** Namespace but can also use the **Infrastructure** namespace.
3. Click (**Configuration**), then (**Add a new Instance**).
4. In the **Main Info** area, enter **Name** = *dynamic_list*, replacing *dynamic_list* with an appropriate name for the method.
5. Enter a **Display Name** and **Description**.
6. In the **Fields** area, enter **Value** = *dynamic_list*. Leave the other fields blank or use the default values.
7. Click **Add**.
8. Navigate to **Methods** tab.
9. In the **Main Info** area, enter **Name** = *dynamic_list* and populate the **Data** section with the example automate method below.
10. Click **Add**.
11. Set the automate entry point for the dialog control; use the new instance created in step four. You can create a new domain and copy the method to that domain.

```
#  Automate Method

dialog_field = $evm.object

# sort_by: value / description / none
dialog_field["sort_by"] = "value"

# sort_order: ascending / descending
#dialog_field["sort_order"] = "ascending"

# data_type: string / integer
dialog_field["data_type"] = "integer"

# required: true / false
# dialog_field["required"] = "true"

dialog_field["values"] = {1 => "one", 2 => "two", 10 => "ten", 50 => "fifty"}
dialog_field["default_value"] = 2
```

Creating a Playbook Automate Method

Infrastructure Automation can choose an Ansible playbook from a repository and execute it as a method. Each playbook method can take additional input parameters specified by the user.

Important:

- You must first sync your playbook repositories before using them to create a method. See Adding a Playbook Repository in *Managing Providers* for information on initial playbook repository set-up.
- Using Ansible playbooks to populate dynamic dialog fields is not recommended due to delay times caused by the overhead of interaction between systems.
- Only users with administrator privileges can run a service dialog based on a playbook automate method.

To create a playbook automate method:

1. Navigate to **Automation > Automate > Explorer**, then click on a domain under **Datastore**.
2. Under a namespace, select the class for which you want to create a new method.
3. Click the **Methods** tab.
4. Click (**Configuration**) then, (**Add a New Method**).
5. In the **Main Info** area, select **Playbook** from the **Type** dropdown menu.

6. Provide a **Name** and **Display Name**.
7. Select a playbook **Repository** from the list.
    1. Choose a **Playbook** to use.
    2. Select the **Machine Credential** the playbook will use when it runs.
    3. Select the **Vault Credential** to use.
    4. From the **Cloud Type** list, select a cloud provider.
    5. Choose the **Cloud Credential** that corresponds to the selected cloud type.
8. Specify the **Hosts** on which the playbook will run. Choose **Localhost** or provide unique values in the **Specify host values** field.
9. Set the **Max TTL** in minutes. The Time To Live (TTL) field allows you to set the maximum execution time for the playbook to run.
10. Select when to receive **Logging Output** from the options in the drop-down menu.
11. Use the **Escalate Privilege** toggle switch to enable user privilege escalation if credentials are called for during the playbook run.
12. Choose a **Verbosity** value to set the debug level for playbook execution.
13. Add required **Input Parameters** using the fields and values available. Click the + to add additional input parameters.

    Note:

    Input parameters become extra vars, with substitution enabled. This overcomes the lack of a dialog which would normally allow for the input of additional information. For more information on extra vars, see the Ansible documentation.
14. Click **Add** when finished.

Once created, the domain including your playbook method can be exported to appliances in your testing or production environments or imported in appliances in multiple regions.

Important:

To import a domain with a playbook method, you must have an existing Ansible playbook on the destination environment with the same name or the import will fail.

See Exporting All Datastore Classes for information.

Passing variables between successive playbook methods

Automate designers can pass variables between successive Ansible playbook methods in a state machine using Infrastructure Automation.

To pass variables between Ansible playbook methods, use the `set_stats` module in your playbooks.

Example.

```
---
# This playbook prints a simple debug message
- name: Echo Hello, Fred and Wilma
  hosts: localhost

  tasks:
  - name: "playbook1 - testing input vars"
    set_stats:
      data:
        pb_var1a: ""
        pb_var1b: ""

  - debug: msg="Hello,  and "
```

For more information on the `set_stats` module, see the Ansible documentation.

Expression Methods

Infrastructure Automation additionally provides support for Expression Methods, that allow you to use advance search filters as Automate Methods, substituting the user input from Automate Objects. Expression methods have several distinct advantages, including: running directly in the worker appliance; removing the overhead of forking a DRb process to run the Automate Methods; no Ruby code required; and prebuilt for Dynamic Dialogs.

Input Parameters

Expression methods allow for substitution of user input through input parameters,

Input Parameter	Explanation
arg	The argument used in the expression. Each argument should employ the prefix **arg**. Example: **arg1**: the first argument in the expression; **arg2**: the second argument in the expression; **argn**: the nth argument in the expression.

Optional Input Parameters

Note:

If attributes and distinct are not specified we try to store the result in a variable called values with a hash consisting of id and name. This makes it compatible with our existing dynamic dialog result set.

Optional Input Parameter	Explanation
attributes	A comma delimited list of attributes to select from the resultant objects. This should me marked as an Array Type in the Input Parameters field.
distinct	A comma delimited list of attributes which are distinct in the resultant objects.This should me marked as an Array Type in the Input Parameters field.
result_obj	The object where the result data should be stored. (default: current object)
result_attr	The name of the attribute which stores the result. (default: values)
result_type	The result type hash or array (default: dialog_hash which matches to our dynamic dialog hash. Valid values are 'hash', 'dialog_hash', 'array', 'simple'
on_empty	The method behavior when the search returns an empty list.
error	Abort. (default: error)
default	The default value in case the result is empty and you select warn.

Creating an Expression Method

Expression methods allow you to use advance search filters as automate methods, substituting user input at runtime, and making them ideal for dynamic dialogs.

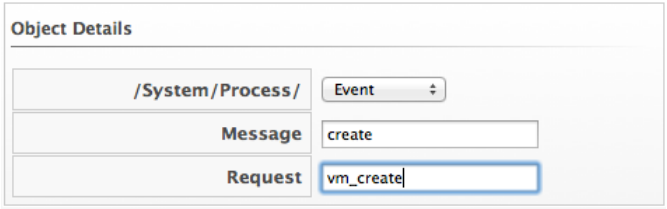
To create an expression method:

1. Navigate to **Automation > Automate > Explorer**, then click on a domain under **Datastore**.
2. Under a namespace, select the class for which you want to create a new method.
3. Click the **Methods** tab.
4. Click (**Configuration**) then, (**Add a New Method**).
5. In the **Main Info** area, select **expression** from the drop-down menu.
6. Provide a **Name** and **Display Name**.
7. Select an **Expression Object** from the drop-down menu.
8. In the **Expression** editor, create the expression by setting the controls and values used at runtime:
    1. Using the drop-down menu, select the value to use. Based on your selection, choose or input additional values from the drop-down menus or text fields that appear.
    2. In the **Contains** field, input a value or click **User will input the value**.
    3. Click to complete the expression.
9. Add **Input Parameters** for each of the user input fields required.
    1. Click to add a new parameter.
    2. Provide a **Name**, **Default Value** and select a **Data Type** for each parameter.
    3. Click to add the parameter.

    Note:

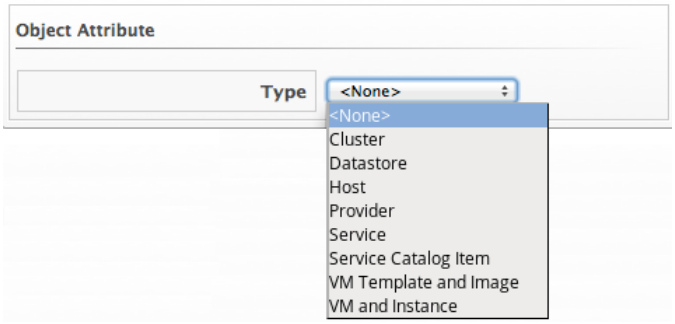
    If **User will input the value** is checked, arguments for each input parameter names using the prefix "arg".

    For example, if there are 3 fields then the input parameter names should be arg1, arg2, and arg3. If there are two runtime parameters arg1 and arg2 must be defined in the input parameters. In the default value for these fields values can be substituted from other objects in the Automate Workspace.
10. Click **Add**.



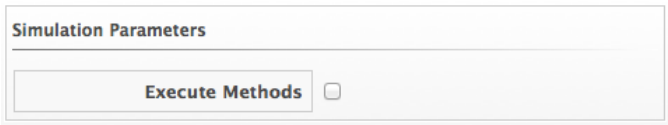
Simulation

After your model is designed, use the simulate page to test it. It allows you to see the results in tree and XML view.



Simulating an Automate Model

This procedure shows you how to simulate an automate model.



1. Navigate to **Automation > Automate > Simulation**.
2. In **Object Details**, select a type of object from `/System/Process/` that will initiate the model. The **Message** should be `create`. Type in the name of the **Request** where you are starting from.

3. Select the **Type** of item you want to run the simulation on. Then, select a specific one to use as the example.

4. Check **Execute Methods** if you want to perform the model and not just simulate it.

5. Type in the **Attribute/Value Pairs** fields if applicable.
6. Click **Submit**.

Click on the **Tree View** or **XML View** tabs to see results.

Importing, Exporting, and Resetting the Datastore

The **Automate Model** can be exported and imported as a YAML file. Infrastructure Automation allows you to back up your model by export. Red Hat may provide you with new or updated classes, and provides an import function for either a class or the entire model. Finally, you can reset the datastore to its default. Always be sure to export the current datastore before importing or resetting.

Note:

The datastores you are exporting or importing between must use the same Infrastructure Automation version.

Exporting All Datastore Classes

This procedure shows you how export datastore classes as a YAML file.

1. Navigate to **Automation > Automate > Import/Export**.
2. Click (**Export all Datastore classes and instances to a file**).
3. Follow your browser's prompts to save the file.

The datastore is zipped and exported as a **`YAML`** file.

Importing Datastore Classes

This procedure shows you how to import datastore classes.

1. Navigate to **Automation > Automate > Import/Export**.
2. Export the datastore so that you have a backup.
3. Click **Choose file** to navigate to the location of the **.zip* file to import.
4. Click **Upload**.
5. After the file has uploaded, specify the following using the dropdown menus:
   - The domain to import into
   - The domain to import from
   - All namespaces you wish to import
6. Click **Commit** to finish importing the selected domain.

The datastore is imported from the uploaded **YAML** files.

Resetting Datastores to the Default

This procedure shows you how reset the datastores to the default.

1. Navigate to **Automation > Automate > Import/Export**.
2. Export the datastore so that you have a backup.
3. Click (**Reset all components in the built-in domains**).
4. Click **OK**.

Invoking Automate

Automate Examples

This chapter describes the ways to invoke an Automate workflow. Automation can be initiated through an alert, an event, a Infrastructure Automation application, or a custom button. The same automation process can be re-used across more than one of these. For example, using automation to remove orphaned virtual machines and instances could be initiated by:

- An administrator request from the Infrastructure Automation console (from a custom button)
- An alert indicating the datastore has less than 20% free-space
- A virtual machine or instance unregistered event is detected

All invocations of an automate model must enter through the **/System/Process** namespace.

You can use automation to create a Provisioning Dialog that modifies the provisioning parameters of a VM service. For more information, see Example: Provisioning a VM service

Invoking Automate using a Custom Button

Invoke an Automate model by mapping an Ansible playbook or instance from the **/System/Process/Request** class to a custom button. Before creating the button, you need to have an Ansible playbook service catalog item or an instance in the **/System/Process/Request** class to map to it and a button group to assign it to.

Create buttons for a cluster, host, datastore, provider, virtual machines or cloud instances. When the button is clicked, the model or playbook will be invoked for the selected item. For each of these, you can have up to 15 buttons.

Creating a Custom Button Group

This procedure shows you how to create a custom button group.

1. Browse to menu: **Automation > Automate > Customization**.
2. Click the **Buttons** accordion.
3. From the **Object Types** tree, select the type of object you want to create the button group for.
4. Click **Configuration**, **Add a new Button Group**.
5. Type in a **Button Group Text** and **Button Group Hover Text**, and select the **Button Group Image** that you want to use.
6. If custom buttons have already been created, assign them to the button group. If not, see Creating a Custom Button.
7. Click **Add**.

The button group will show in the object type you added the button to.

Creating a Custom Button

This procedure shows you how to create a custom button.

Note:

Custom buttons can be migrated to other Infrastructure Automation appliances. See Migrating Custom Buttons for guidance on migrating custom buttons to a new Infrastructure Automation appliance.

1. Browse to menu: **Automation > Automate > Customization**.
2. Click the **Buttons** accordion.
3. From the **Object Types** tree, select the type of object you want to create the button for.
4. Click **Unassigned Buttons**.
5. Click **Configuration**, then **Add a new Button**.

   Note:

If **Add a new Button** is not available, that means you have not created a button group for that object. To continue, create a button group first. See Creating a Custom Button.

6. Under the **Options** tab:
    1. Select the **Button** type from the list.
    2. Enter button **Text** and **Hover Text**, and select the **Icon** and **Icon Color** to use.
    3. Select a **Dialog** if applicable.
    4. Check **Open URL** to open a browser window for the custom URL returned when the button is executed.
    5. Choose a **Display For** option for the button.
    6. Select a **Submit** parameter to choose how to submit objects to automate. Selecting *Submit All* will pass all objects at once when the button is executed, while choosing *One by one* will run execute the button action each time per object.
7. Under the **Advanced** tab:
    1. Set button **Enablement**. Click **Define Expression** to access the expression editor tool. Enter **Disabled Button Text** to display when the custom button is disabled.
    2. Use **Visibility** to determine button appearance based on a custom expression. Click **Define Expression** to access the expression editor tool.

        Note:

        For more about setting visibility and enablement for a custom button, see Filtering.
    3. In **Object Details**, select **Request** from the `/System/Process/` dropdown. By default, the message is `create`. Do not change it.
    4. Enter a **Request** name for the `/System/Process/Request` instance.
    5. Enter the **Attribute/Value Pairs** fields if applicable.
    6. Set **Role Access**. Selecting *<By Role>* will display available roles. Check applicable roles.
8. Click **Add** when you have confirmed that the button accomplishes the task you want.

The button will show in the object type you added the button to.

Please note that there are two ways of creating custom buttons, and creation through the “Automation > Automate > Generic Objects” screen will necessitate adding an attribute/value pair that is not required when adding through the “Automation > Customization > Buttons” screen.

Creating an Ansible Playbook Button

Infrastructure Automation includes an option to create an Ansible Playbook custom button. This feature allows users to select a playbook to run as well as an inventory target to run it against. An Ansible playbook type button can be defined for any object type available.

Note:

An Ansible Playbook catalog item must exist in order to create an Ansible Playbook custom button. For more information, see Creating an Ansible Playbook Service Catalog Item in the Provisioning Virtual Machines and Hosts guide.

1. Navigate to **Automation > Automate > Customization**.
2. Click the **Buttons** accordion.
3. From the **Object Types** tree, select the type of object you want to create the button for.
4. Click **Unassigned Buttons**.
5. Click (**Configuration**), then (**Add a new Button**).

    Note:

    If (**Add a new Button**) is not available, that means you have not created a button group for that object. To continue, see Creating a Custom Button Group.
6. Select **Ansible Playbook** from the **Button Type** drop-down menu.
7. From the **Playbook Catalog Item** choose a playbook-backed catalog item to run.
8. Choose a host from the **Inventory** against which to run the playbook. If **Specific Hosts** is selected, input the IP address or DNS names for each host in the text field, separating each with a comma.

    Note:

    Infrastructure Automation supports two configurations for host value input:

    - To allow user-provided host values, set the custom button to **Specific Hosts** and leave the associated text field blank.
    - To use admin-specified host values, remove the **Hosts** field when creating the dialog the service uses. In this configuration, the field will not appear to users. See Service Dialogs for information on generating a service dialog.

9. Type in a **Text** and **Hover Text**, and select the **Icon** you want to use.
10. Select an **Icon Color** from the color selection palette that pops up.
11. Check **Open URL** to open a browser window for the custom URL returned when the playbook is run.
12. Select display options for the Ansible Playbook button from the **Display for** drop-down menu. Choose for the button to display in the list view, for single entities, or both.
13. Choose how to submit objects to automate by selecting an option from the **Submit** drop-down menu. Selecting **Submit all** will pass all objects at once when the playbook is executed, while choosing **One by one** will run the the playbook each time per object.
14. Click **Add** when you have confirmed that the button accomplishes the task you want.

Editing a Custom Button

This procedure shows you how to edit a custom button.

1. Navigate to **Automation > Automate > Customization**.
2. From the **Object Types** dropdown, select the type of object you want to edit the button for.
3. Click the button you want to edit.
4. Click (**Configuration**), (**Edit this Button**).
5. Modify as required.
6. Click **Save**.

Deleting a Custom Button

This procedure shows you how to delete a custom button.

1. Navigate to **Automation > Automate > Customization**, then select the **Buttons** accordion.
2. From the **Object Type** tree in the accordion menu, select the type of object you want to remove the button from.
3. Click (**Configuration**). then click (**Remove this button**).
4. Click **OK** to confirm that you want to delete this button.

Setting Enablement and Visibility for Custom Buttons

Infrastructure Automation adds methods for evaluating an expression to determine whether a custom button is visible and enabled. Each method has a target object, for example, a virtual machine or host, and expressions can set a custom button to visible, hidden, or disabled.

Note:

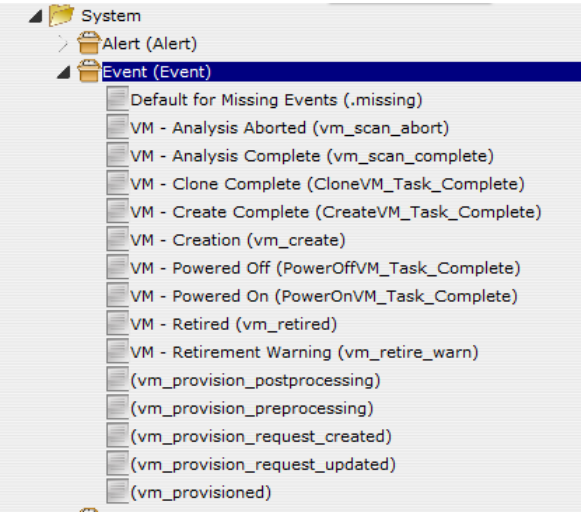
Filtering works on single objects and is not applicable to lists.

To apply filtering actions to a custom button:

1. Navigate to **Automation > Automate > Customization**.
2. Click the **Buttons** accordion. Select the custom button to use.
3. Click (**Configuration**), then (**Edit this Button**).
4. Click the **Advanced** tab.
5. To set enablement filtering on a custom button:
    1. Under **Enablement**, click on **Define Expression**.
    2. Create a visibility expression using the expression editor tools.
    3. Click (**Confirm**) when finished defining the expression.
    4. Provide **Disabled Button Text** in the field.
6. To set visibility filtering on a custom button:
    1. Under **Visibility**, click on **Define Expression**.
    2. Create a visibility expression using the expression editor tools.
    3. Click (**Confirm**) when finished defining the expression.
7. Click **Save**.

Using a Custom Button

This procedure shows you how to use custom buttons to invoke a cluster, host, datastore, provider, virtual machine or instance.



1. Go to the page for the item that you created a button for.
2. Click the custom button group from the taskbar, and then your custom button.

The automate model is invoked for the specified item.

Initiating Automate from an Event

You can also use a Infrastructure Automation Policy Event to initiate automation. You can either use the provided Raise Automation Event action or create a custom automation action. The first case will start in the **`/System/Process`** class, but then go to the Event that initiated the Automate model in the **`/System/Process/Event Class`**. If you create your own custom action, it will start from the **`/System/Process`** class and then go to the **`/System/Process/Request Class`** instead.

For example, suppose that you always want the same Automate model to occur when a virtual machine is created. You would use the Raise Automation Event Action. There are instances in the **`/System/Process/Event Class`** for the following Events that you can select as part of a Policy:

Creating a Policy for Automate

This procedure shows you how to create a policy for automate.

1. Navigate to **Control > Explorer**.
2. Click the **Policies** accordion, and select **Control Policies**.
3. Select **Vm Control Policies**.
4. Click (**Configuration**), then (**Add a New Control Vm Policy**).
5. Type in a **Description**.
6. Uncheck **Active** if you do not want this policy processed even when assigned to a resource.
7. Click **Add**. You are brought to the page where you add conditions and events to your new policy.
8. Click (**Configuration**), then (**Edit this Policy's Event assignments**).
    - Check the events you want to use to send to an **Automate Model**.
    - Click **Save**.
    - From the **Events** area, click on the **Description of the Event** you want to assign an action to.
    - Click (**Edit Actions for this Policy Event**).
9. Select **Raise Automation Event**, and click (**Move selected Actions into this Event**).
10. Click **Save**.

You can now assign this policy to a **Policy Profile**. Then, assign the policy profile to the virtual machines. Every time this event happens on the virtual machine the appropriate Automate Model will be initiated.

Note:

If you want the policy to initiate an Automate Model from the **`/System/Process/Request`** class, then you can create your own custom action. Be sure to have an instance in the **`/System/Process/Request`** class for it to map to.

Creating a Custom Automate Action

This procedure shows you how to create a custom Automate action.

1. Navigate to **Control > Explorer** accordion.
2. Click the **Actions** accordion.
3. Click  (**Configuration**), then  (**Add a new Action**).
4. Type in a **Description** for the Action.
5. Select **Invoke a Custom Automation** from **Action Type**.
6. In **Custom Automation**,
   - For **Message**, type `create`.
   - For **Request**, type in the name of the instance of the `/System/Process/Request Class` in the second.
7. Type in the **Attribute/Value Pairs** fields if applicable.
8. Click **Add**.

The action is created and can be added to a policy.

Methods for use in Ruby Scripts

To use one of these in one of your own Ruby methods, use the syntax of **`vm.method`**. For example, to reboot the guest operating system, use **`vm.rebootGuest`**.

Method	Description
start	Start Virtual Machine container.
stop	Stop Virtual Machine container.
suspend	Suspend Virtual Machine container.
unregister	Unregister Virtual Machine.
collect_running_processes	Collect the running processes from a started Virtual Machine.
shutdownGuest	Shutdown the guest operating system of the VM container. Requires VMware tools (or vendors tools) installed on the guest.
standbyGuest	Put the guest operating system into standby. Requires VMware tools (or vendors tools) installed on the guest.
rebootGuest	Reboot the guest operating system. Requires VMware tools (or vendors tools) installed on the guest.

FAQs and Flows

Phase 1: Create Provision Request

Question	Answer
Where do I create a new provisioning profile based on a users LDAP group?	Navigate to [`VM / Provisioning / Profile`] of either the **Cloud** or **Infrastructure** namespace in your domain.
Where can I specify a pre-dialog to present to a Requester in their LDAP group?	Custom pre-dialogs can be defined in [`VM / Provisioning /
Profile / `\] of either the **Cloud** or **Infrastructure** namespace in your domain.	
I would like to customize our dialogs. Where are all the dialogs kept?	All dialogs are located on each Infrastructure Automation appliance in the `/var/www/miq/vmdb/db/fixtures` directory.
What happens if I do not specify any profiles for provisioning?	Infrastructure Automation searches for a matching LDAP group in the [`VM / Provisioning / Profile`] class of either the **Cloud** or **Infrastructure** namespace in your domain. If an LDAP profile is NOT found then Infrastructure Automation will use the `missing class instance`.

Phase 2: Request Approval

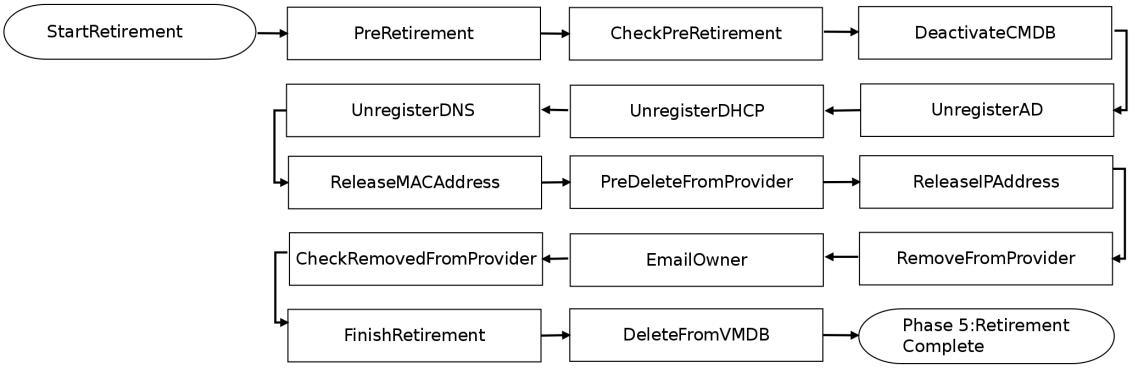
Question	Answer
Where can I specify auto-approval values on a per virtual machine template basis?	Tags can be assigned to templates in the form of [**prov_max_vms**, **prov_max_cpus**, **prov_max_memory**, **prov_max_retirement_days**].
Where can I modify the default Auto-Approval values?	These values can be set in the [`Service / Provisioning / StateMachines /
ServiceProvisionRequestApproval / Default`] class instance in your domain.	
How can I customize the email that is sent when a request is approved?	The Request Approved email message can be modified in [**`VM / Provisioning / Email / MiqProvisionRequest_Approved`**] in either the **Cloud** or **Infrastructure** namespace of your domain.
How can I customize the email that is sent when a request is denied?	The Request Denied email message can be modified in [**`VM / Provisioning / Email / MiqProvisionRequest_Denied`**] in either the **Cloud** or **Infrastructure** namespace of your domain.
How can I customize the email that is sent when a request is not Auto-approved?	The Request Pending email message can be modified in [**`VM / Provisioning / Email / MiqProvisionRequest_Denied`**] in either the **Cloud** or **Infrastructure** namespace of your domain.
If a Request Approval requires manual approval, how does an Approver approve the request?	Log into Infrastructure Automation as an approver/admin and navigate to **Virtual Machines > Requests** and then click on the request.

Phase 3: Quota Validation

Question	Answer
Where in Infrastructure Automation can I set default quota thresholds for users and groups?	These values can be set in the [`VM
Provisioning / StateMachines / ProvisionRequestQuotaVerification`] class instance of either the **Cloud** or **Infrastructure** namespace in your domain.	
Where in Infrastructure Automation can I set individual and group quota thresholds?	Tags can be assigned to groups or users by navigating to **Configuration > Access Control**. The following are valid tags that can be assigned to group or individual users: [**quota_max_cpu**, **quota_max_memory**, **quota_max_storage**].
Where can I customize the way our virtual machines are named?	Virtual machine naming conventions can be altered using the methods in the [`VM /
Provisioning / Naming`] class of either the **Cloud** or **Infrastructure** namespace in your domain.	
How can I customize the email that is sent when a request is denied?	The Request Denied email message can be modified in the [`VM /
Provisioning / Email / MiqProvisionRequest_Denied`] in either the **Cloud** or **Infrastructure** namespace of your domain.	

Phase 4: Provisioning

Target Type: Cloning a Template to a Virtual Machine.



Target Type: Clone to Template.

Target Type: Clone to Template

Question	Answer
Where can I customize the email message that is sent upon provisioning completion?	This can be customized using the [`VM / Provisioning / Email
/ MiqProvision_Complete`] in either the **Cloud** or **Infrastructure** namespace of your domain.	
Where can I change what is put into the virtual machines Annotation after provisioning?	These settings can be modified by leveraging the `_PreProvision Ruby` methods in [`VM / Provisioning / StateMachines /
Methods`] in either the *Cloud</emphasis> or **Infrastructure** namespace of your domain.	
Where do I set the default VC folder location for provisioning virtual machines?	This can be modified by leveraging by leveraging the `_PreProvision Ruby` methods in [`VM / Provisioning / StateMachines /
Methods`] in either the *Cloud</emphasis> or **Infrastructure** namespace of your domain.	
Where can I modify the virtual machine customization spec mapping?	This can be modified by leveraging by leveraging the `_PreProvision
Ruby `methods in \[`VM / Provisioning / StateMachines / Methods`] in either the *Cloud</emphasis> or **Infrastructure** namespace of your domain.	
Where can I modify the Clone_to_Template state_machine?	Navigate to [`VM / Provisioning / StateMachines / VMProvision_VM / template`] in either the **Cloud** or **Infrastructure** namespace of your domain.
Where can I modify the Clone_to_VM state_machine?	Navigate to [`VM /
Provisioning / StateMachines / VMProvision_VM / clone_to_vm`] in either the **Cloud** or **Infrastructure** namespace of your domain.	

Phase 5: Retirement

Question	Answer
Where can I customize the email message that is sent upon completion of virtual machine retirement?	This can be customized using the [`VM /
Retirement / Email / vm_retirement_emails`] in either the **Cloud** or **Infrastructure** namespace of your domain.	
Where can I customize the email message that is sent during virtual machine retirement warnings?	This can be customized using the [`VM /
Retirement / Email / vm_retirement_emails`] in either the **Cloud** or **Infrastructure** namespace of your domain.	
If I want to customize what gets called during the retirement phase where should I look?	This can be customized using the [`VM / Retirement
/ StateMachines / VMRetirement`] in either the **Cloud** or **Infrastructure** namespace of your domain.	
How can I extend the virtual machine retirement date an additional number of days?	Create a custom button for virtual machines that launches [`/System/Request/vm_retire_extend`]. Then navigate to the [`VM /
Retirement / Email / vm_retire_extend`] `Ruby method in the **Cloud** or **Infrastructure** namespaces and set the` vm_retire_extend_days` value.	

Inline Method to Create a Provision Request

Ruby method

```
# Infrastructure Automation Automate Method
#
$evm.log("info", "Infrastructure Automation Automate Method  Building VM Provisioning Request Started")
#
```

```
prov= $evm.root['miq_provision']

  # arg1 = version
  args = ['1.1']
  # arg2 = templateFields
  args << {'name' => 'App'}
  # arg3 = vmFields
  args << {'vm_name' => 'CRM_APP', 'request_type' => 'template'}
  # arg4 =  requester
  args << {'owner_email' => 'admin@asd.com', 'owner_last_name' => 'Admin', 'owner_first_name' => 'Admin', 'user_name' =>
'admin'}
  # arg5 =  tags
  args << {'crm' => 'true'}
  # arg6 =  WS Values
  args << nil
  # arg7 = emsCustomAttributes
  args << nil
  # arg8 = miqCustomAttributes
  args << nil

$evm.log("info","Building provisioning request with the following arguments: <#{args.inspect}>")
result = $evm.execute('create_provision_request', *args)
```

Migrating Custom Buttons

Migrating Custom Buttons

This workflow demonstrates how to export custom buttons from one Infrastructure Automation appliance and import them in another Infrastructure Automation appliance.

1. Export custom buttons from the source Infrastructure Automation appliance:
    1. SSH into the Infrastructure Automation appliance as **root**.
    2. Create a temporary directory:

       ```
       # mkdir /tmp/custom_buttons
       ```

    3. Browse to the Virtual Management Database (VMDB) directory:

       ```
       # vmdb
       ```

    4. Export custom buttons using the following **rake** command:

       ```
       # rake evm:export:custom_buttons -- --directory /tmp/custom_buttons
       ```

    5. Confirm the **yaml** file was created by navigating to the new directory:

       ```
       # cd /tmp/custom_buttons
       ```

2. Copy the directory to the target Infrastructure Automation appliance:

   ```
   scp -r /tmp/custom_buttons/ hostname:/tmp/custom_buttons
   ```

3. Import custom buttons on the target Infrastructure Automation appliance:
    1. SSH to the target Infrastructure Automation appliance as **root**.
    2. Browse to the VMDB directory:

       ```
       # vmdb
       ```

    3. Import custom buttons using the following **rake** command:

       ```
       # rake evm:import:custom_buttons -- --source /tmp/custom_buttons
       ```

To verify successful import of custom buttons:

1. Log in to the target Infrastructure Automation appliance.
2. Browse to menu: **Automation > Automate > Customization**.
3. Click **Buttons** in the accordion menu.

Imported buttons will appear under the parent **Object Type**.

General Configuration

Settings Overview

Use the **Settings** menus of the Infrastructure Automation user interface to view or modify the global configuration of your appliance.

Settings

To view or modify global settings for your appliance, click **Settings > My Settings** to modify. The availability of each menu item depends on the role assigned to your user account. For more information on roles, see Roles.

The following menu items are available from the settings menu:

- **My Settings**

  This menu is available to all Infrastructure Automation users. The settings in this menu control how elements in the user interface are displayed, time profiles, and tags for the currently logged-in individual user.

- **Tasks**

  This menu allows you to view virtual machine SmartState Analysis tasks that can be tracked through the console. The status of each task is displayed, including time started, time ended, what part of the task is currently running, and any errors encountered.

Application Settings

The **Application Settings** menu is now accessible from **Settings > Application Settings** from the user interface.

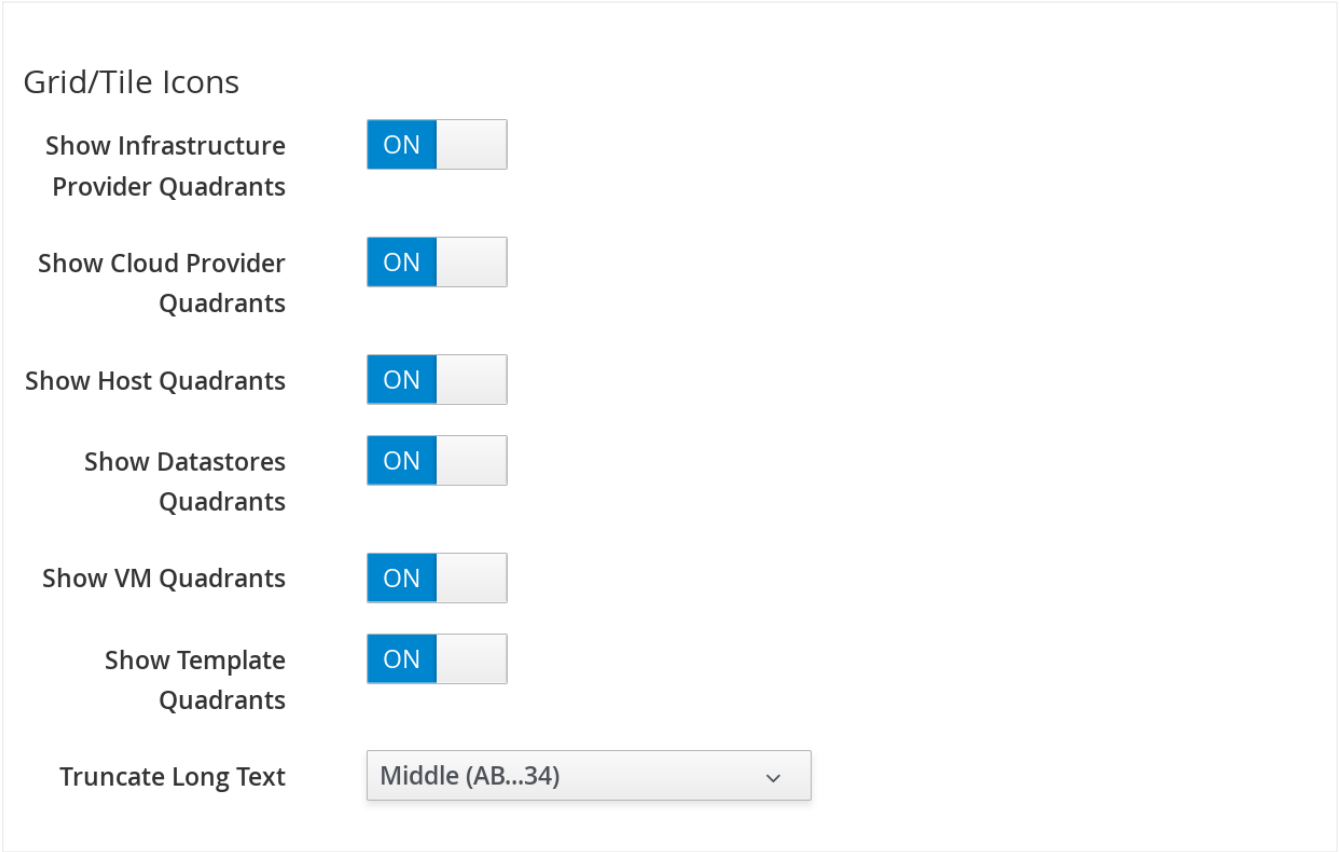
This menu allows you to specify enterprise, region, zone, and server settings for your Infrastructure Automation infrastructure. Diagnostics such as logs and the status of processes are also shown here.

My Settings

The options under the **My Settings** menu allow you to configure user interface display options specific to the user account with which you log in to Infrastructure Automation, such as the default view displayed on login, and personal tags. You can also configure the color scheme, and button options on the main dashboard.

These options are available by clicking **Settings > My Settings**.

Visual Settings



The options under the **Visual** menu allow you to configure how user interface elements are displayed in the web user interface. For all options, click **Save** to update the settings, or click **Reset** to undo any unsaved changes that have been made on the current screen.

Grid and Tile Icons

This group of settings is used to control the view of your virtual thumbnails. Each thumbnail can be viewed as a single icon or as an icon with four quadrants. Use the quadrant view to see a component's properties at a glance.

Use the following procedure to change grid and tile icons:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Visual** tab.
2. In **Grid/Tile Icons**, set items to **ON** to display all four quadrants for the item, or **OFF** to display only one icon.
3. Click **Save**.

- Set **Show Infrastructure Provider Quadrants** to **ON** to see the four icons in your provider under menu: **Compute > Infrastructure > Providers**.
- Set **Show Cloud Provider Quadrants** to **ON** to see the four icons in your hosts under menu: **Cloud > Providers**.
- Set **Show Host Quadrants** to **ON** to see the four icons in your hosts under menu: **Compute > Infrastructure > Hosts**.
- Set **Show Datastores Quadrants** to **ON** to see the four icons in your datastores under menu: **Compute > Infrastructure > Datastores**.
- Set **Show VM Quadrants** to **ON** to see the four icons in your virtual machines under menu: **Compute > Infrastructure > Virtual Machines**.
- Set **Show Template Quadrants** to **ON** to see the four icons in your templates under menu: **Compute > Infrastructure > Virtual Machines > Templates**.

Set any of the above options to **OFF** to see only one icon instead of four quadrants.

- Use the **Truncate Long Text** list to specify how the names of items are displayed if they are too long to show in full. Select the option based on the pattern shown.

Setting Default Items Per Page

Use the following procedure to set the default number of items to display on each resource page.

1. From the **Settings** menu, browse to **My Settings**, then click on the **Visual** tab.
2. In the **Default Items Per Page** area, select the default number of items to display for each view from the corresponding drop down list.

3. Click **Save**.

Setting the Start Page

Use the following procedure to set the default start page after logging in. For example, instead of going to the **Infrastructure Automation** dashboard, you can set the default start page to see a list of your virtual machines.

1. From the **Settings** menu, browse to **My Settings**, then click on the **Visual** tab.
2. In the **Start Page** area, select the page to display at login.
3. Click **Save**.

Setting Display Settings

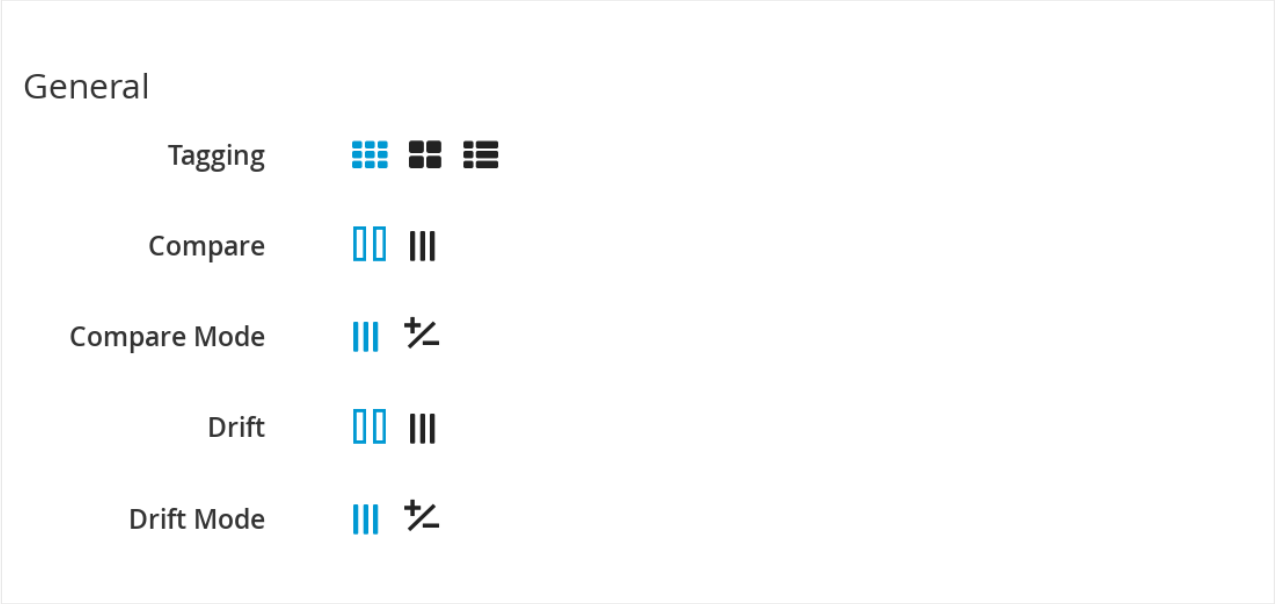
Use the following procedure to set your own themes, colors, and time zone for the console. These settings are specific to the logged-on user.

1. From the **Settings** menu, browse to **My Settings**, then click on the **Visual** tab.
2. Make selections from **Display Settings** for the following items:
    1. Use **Chart Theme** to select a group of colors and font sizes specifically for charts.
    2. Use **Time Zone** to select the time zone in which to display the console.

       Note:

       In time zones where clocks are set forward for daylight savings time, the time zone correctly displays as EDT (Eastern Daylight Time) in the console. When the clocks are set back, it correctly displays as EST (Eastern Standard Time).

    3. Use **Locale** to select the language in which to display the console.
3. Click **Save**.



Default Views

The options under the **Default Views** menu allow you to configure the default layout used to display individual screens in the Infrastructure Automation user interface. The options you select under this menu specify the default options for each screen, but you can also change the layout for each screen using the layout buttons on each screen.

Setting Default Views for the User Interface

Use the following procedure to set general view options:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Views** tab.
2. In the **General** area, click the appropriate button for the way you want to view each type of screen listed. The selected view shows as a blue icon.

3. Click **Grid View** to view virtual thumbnails or icons.
4. Click **Tile View** for a view that combines the virtual thumbnail with some text properties that describe the items.
5. Click **List View** to view a detailed text listing.
6. Click **Expanded View** for an expanded view.
7. Click **Compressed View** for a compressed view.
8. Click **Exists Mode** to view only whether an attribute exists or not.
9. Click **Save**.

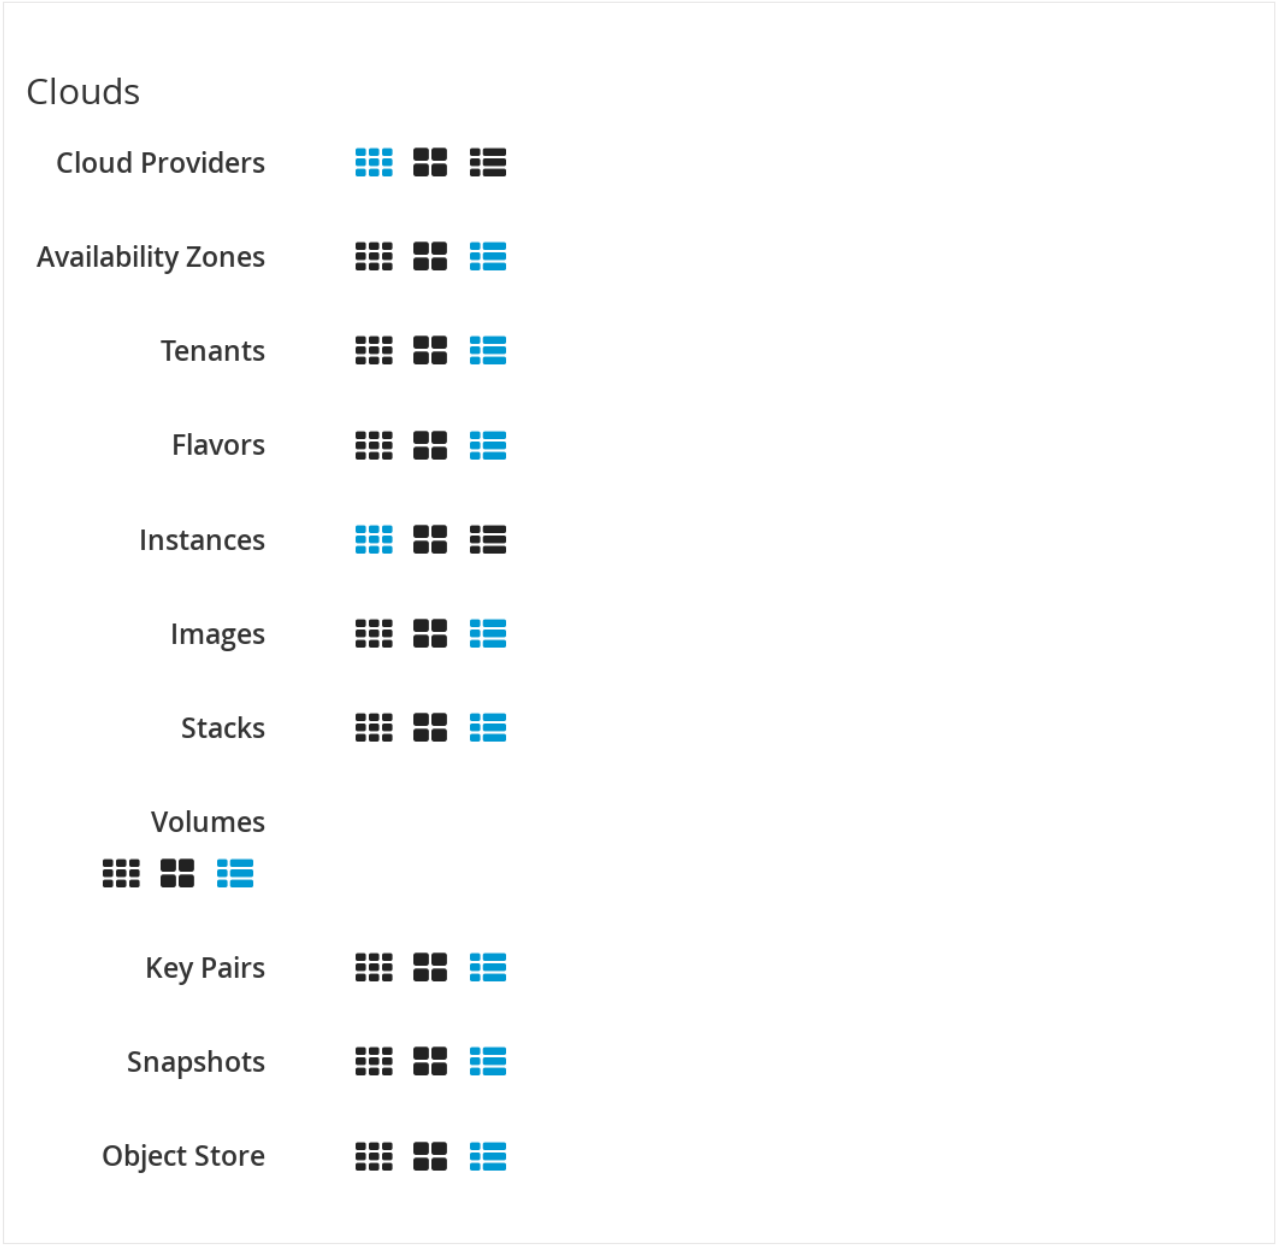
Setting Default Views for Services

Use the following procedure to set default views for services in the menu: **Compute > Services** tab.

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Views** tab.

2. In the **Services** area, click the appropriate button for the way you want to view each item.

- Click **Grid View** to view virtual thumbnails or icons.
- Click **Tile View** for a view that combines the virtual thumbnail with some text properties that describe the items.
- Click **List View** to view a text listing.



3. Click **Save**.

Setting Default Views for Clouds

Use the following procedure to set default views for clouds in the menu: **Compute > Clouds** tab.

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Views** tab.

2. In the **Clouds** area, click the appropriate button for the way you want to view each item.

- Click **Grid View** to view virtual thumbnails or icons.
- Click **Tile View** for a view that combines the virtual thumbnail with some text properties that describe the items.
- Click **List View** to view a detailed text listing.

3. Click **Save**.

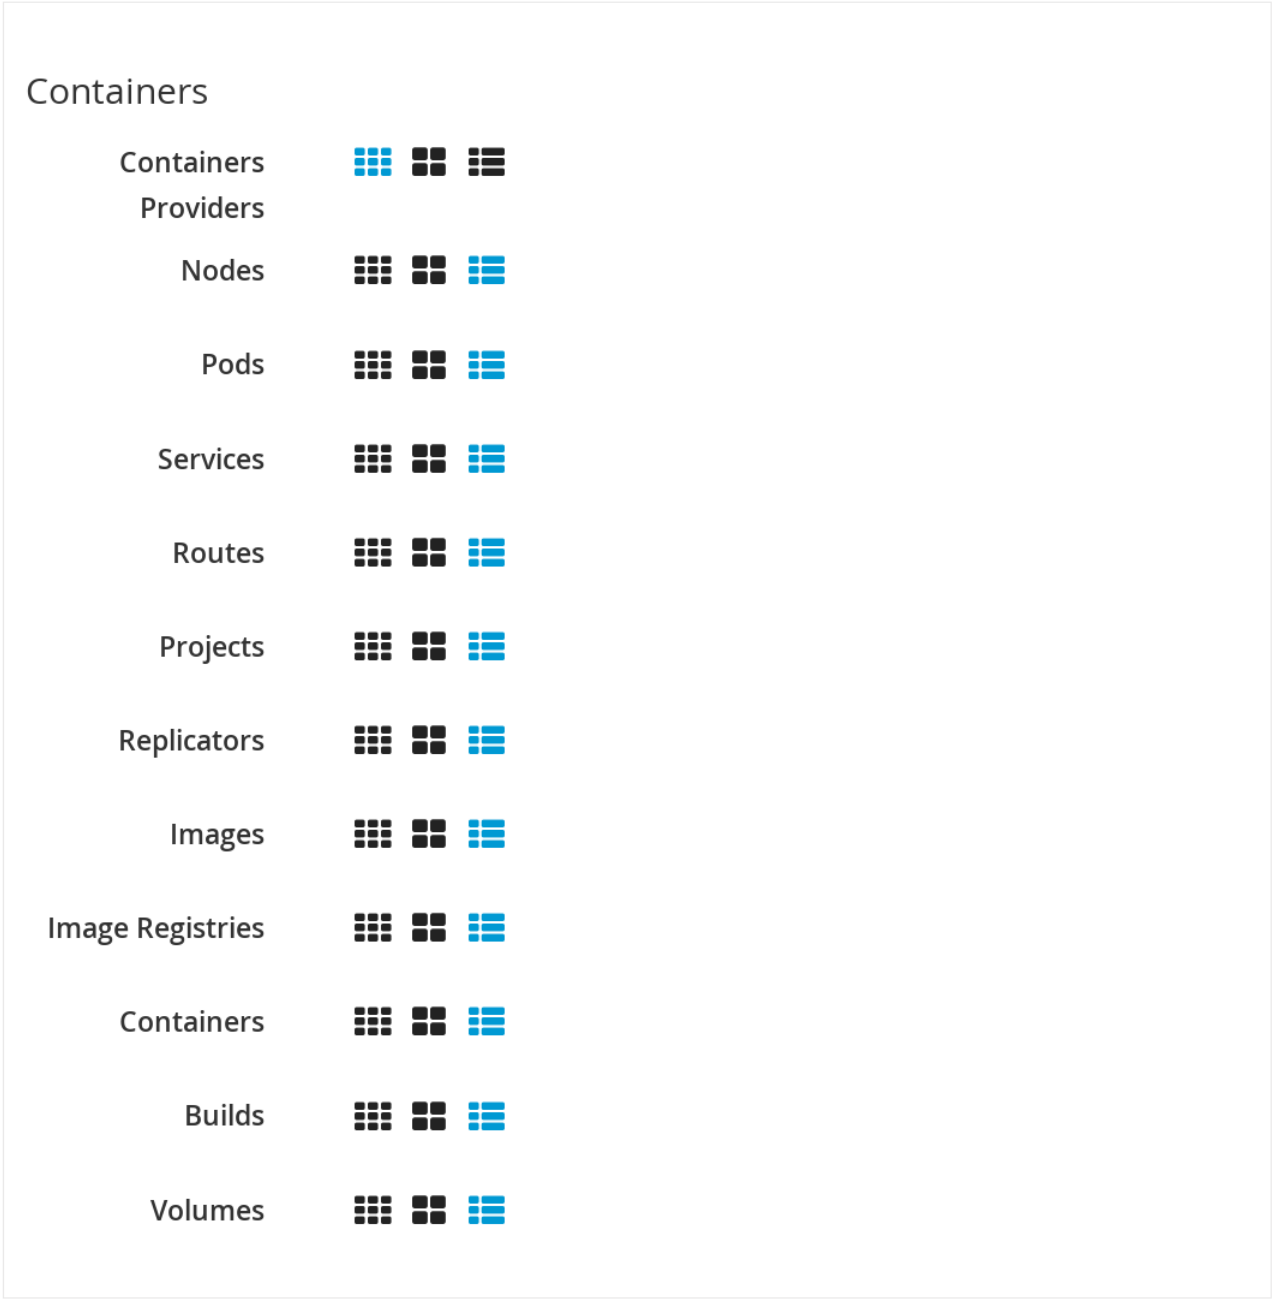
Setting Default Views for Infrastructure Components

Use the following procedure to set default views for infrastructure components in the menu: **Compute > Infrastructure** tab.

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Views** tab.

2. In the **Infrastructure** area, click the appropriate button for the way you want to view each item.

- Click **Grid View** to view virtual thumbnails or icons.
- Click **Tile View** for a view that combines the virtual thumbnail with some text properties that describe the items.
- Click **List View** to view a detailed text listing.



3. Click **Save**.

Setting Default Views for Containers

Use the following procedure to set default views for containers in the menu: **Compute > Containers** tab.

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Views** tab.

2. In the **Containers** area, click the appropriate button for the way you want to view each item.

- Click **Grid View** to view virtual thumbnails or icons.
- Click **Tile View** for a view that combines the virtual thumbnail with some text properties that describe the items.
- Click **List View** to view a text listing.

3. Click **Save**.

Default Filters

The options in the **Default Filters** menu allow you to configure the default filters displayed for your hosts, virtual machines, and templates. These settings are available to all users.

Setting Default Filters for Cloud

To set default filters for cloud components:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Filters** tab.
2. From the **Cloud** folder, check the boxes for the default filters that you want available. Items that have changed show in blue text.
3. Click **Save**.

Setting Default Filters for Containers

To set default filters for containers:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Filters** tab.
2. From the **Containers** folder, check the boxes for the default filters that you want available. Items that have changed show in blue text.
3. Click **Save**.

Setting Default Filters for Infrastructure

To set default filters for infrastructure components:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Filters** tab.
2. In the **Infrastructure** folder, select the default filters that you want available. Items that have changed show in blue text.
3. Click **Save**.

Setting Default Filters for Physical Infrastructure

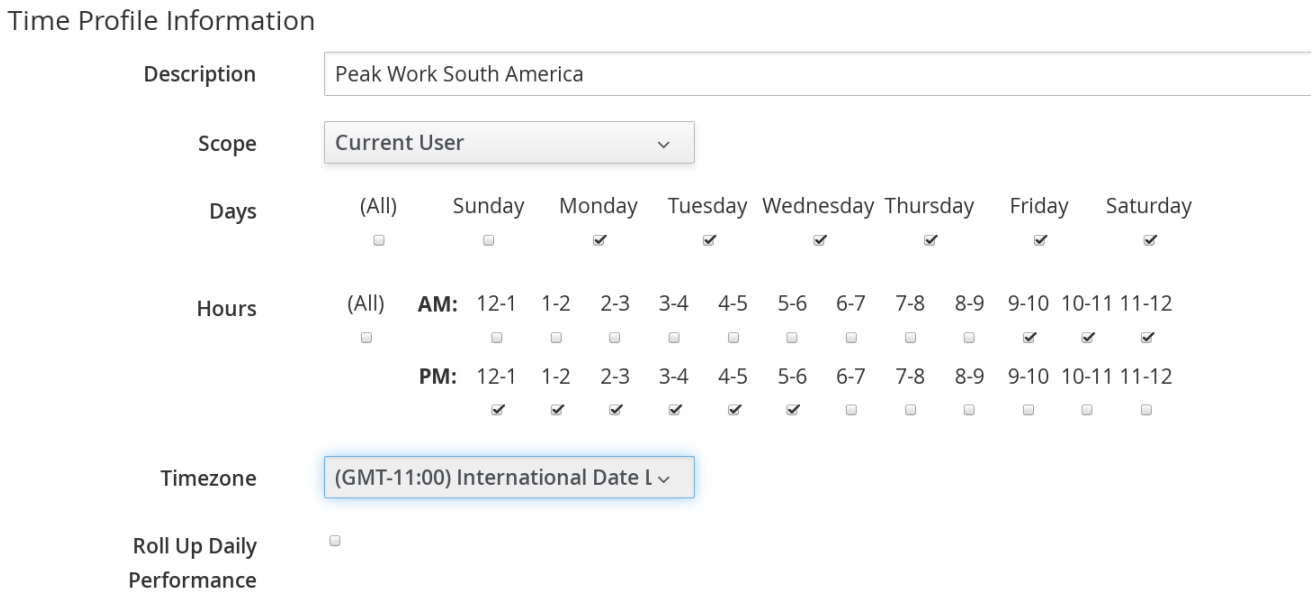
To set default filters for physical infrastructure components:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Filters** tab.
2. In the **Physical Infrastructure** folder, select the default filters that you want available. Items that have changed show in blue text.
3. Click **Save**.

Setting Default Filters for Services

To set default filters for services:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Default Filters** tab.
2. In the **Services** folder, select the default filters that you want available. Items that have changed show in blue text.
3. Click **Save**.



Time Profiles

The options under the **Time Profiles** menu allow you to specify the hours for which data is displayed when viewing capacity and utilization screens. Time profiles are also used to configure performance and trend reports.

Creating a Time Profile

To create a time profile:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Time Profiles** tab.
2. Click **Configuration**, and **Add a new Time Profile**.

3. Type a meaningful name in the **Description** field.

4. Select the users who can access the time profile from the **Scope** list:
    - Select **All Users** to create a time profile that is available to all users. Only the super administration and administration roles can create, edit, and delete a global profile.
    - Select **Current User** if this time profile should only be available to the user creating it.
5. Check the **Days** and **Hours** for the time profile.
6. For **Timezone**, you can select a specific time zone or, you can let the user select a time zone when displaying data.
7. If you select a specific time zone, you also have the option to **Roll Up Daily Performance** data. This option is only available to users with the administration or super administration role. Enabling the **Roll Up Daily Performance option** reduces the time required to process daily capacity and utilization reports and to display daily capacity and utilization charts.
8. Click **Add**.

Note:

The following relationships exist between time zones and performance reports:

- The configured time zone in a performance report is used to select rolled up performance data, regardless of the user's selected time zone.
- If the configured time zone is null, it defaults to UTC time for performance reports.
- If there is no time profile with the report's configured time zone that is also set to roll up capacity and utilization data, the report does not find any records.

For non-performance reports, the user's time zone is used when displaying dates and times in report rows.

Editing a Time Profile

To edit a time profile:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Time Profiles** tab.
2. Check the time profile you want to edit.
3. Click **Configuration**, and **Edit selected Time Profile**.
4. Make the required changes.
5. Click **Save**.

Copying a Time Profile

To copy a time profile:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Time Profiles** tab.
2. Check the time profile you want to copy.
3. Click **Configuration**, and **Copy selected Time Profile**.
4. Make the required changes.
5. Click **Save**.

Deleting a Time Profile

To delete a time profile:

1. From the **Settings** menu, browse to **My Settings**, then click on the **Time Profiles** tab.
2. Check the time profile you want to delete.
3. Click **Configuration**, and **Delete selected Time Profiles**.
4. Click **Save**.

Tasks

The options under the **Tasks** menu allow you to view and control currently running tasks in Infrastructure Automation. The status of each task is displayed, including time started, time ended, what part of the task is currently running, and any errors encountered.

My VM and Container Analysis Tasks

The **My VM and Container Analysis Tasks** menu allows you to view all tasks running on virtual machines and containers for the currently logged-in user.

From the **My VM and Container Analysis Tasks** menu, you can:

- See jobs that the logged on user created for the SmartProxy either through a schedule or by manually initiating a SmartState Analysis of a virtual machine or container.

- See if a job completed successfully, resulted in an error, or is running.
- See the reason for an error.
- Filter the tasks by status and state.
- View the owner or host of the virtual machine or container referenced.
- Delete a task either explicitly or older than another task.

Filtering the VM and Container Analysis Task List

This procedure describes how to filter the virtual machine and container analysis task list. You can filter the task list by zone, time period, task status, and task state.

To filter the virtual machine and container analysis task list:

1. From the **Settings** menu, select **Tasks**.
2. Click **My VM and Container Analysis Tasks**.
3. From the **Zone** list, select a specific zone, or select **All Zones**.
4. From the **24 Hour Time Period** list, select the period of time to view the tasks.
5. For **Task Status**, select the check boxes next to the status to view.
6. From the **Tasks State** list, select the state to view.
7. Click **Apply**.

Deleting a Task from the VM and Container Analysis Task List

To delete a task from the list of virtual machine and container analysis tasks:

1. From the **Settings** menu, select **Tasks**.
2. Click **My Tasks**.
3. Select the tasks to delete. From the **Delete** menu:
    1. Click **Delete** to delete the selected tasks.
    2. Click **Delete Older** to delete the tasks older than the selected tasks.
    3. Click **Delete All** to delete all tasks.
4. Click **OK**.

My Other UI Tasks

The **My Other UI Tasks** menu allows you to view all tasks running in the user interface for the currently logged-in user.

Filtering the My Other UI Tasks List

This procedure describes how to filter the user interface analysis task list. You can filter the task list by time period, task status, and task state.

To filter the other user interface task list:

1. From the settings menu, select **Tasks**.
2. Click **My Other UI Tasks**.
3. From the **24 Hour Time Period** list, select the period of time to view the tasks.
4. For **Task Status**, select the check boxes next to the status to view.
5. From the **Tasks State** list, select the state to view.
6. Click **Apply**.

Deleting a My Task

To delete a task from the list of other user interface tasks:

1. From the settings menu, select **Tasks**.
2. Click **My Tasks**.
3. Select the tasks to delete. From the **Delete** menu:
    1. Click **Delete** to delete the selected tasks.
    2. Click **Delete Older** to delete the tasks older than the selected tasks.
    3. Click **Delete All** to delete all tasks.

4. Click **OK**.

All Tasks

The **All Tasks** menu allows you to view all tasks running on virtual machines and containers for all users.

From the **All Tasks** menu, you can:

- See jobs that all users have created for the SmartProxy either through a schedule or by manually initiating a SmartState Analysis of a virtual machine or container.
- See if a job completed successfully, resulted in an error, or is running.
- See the reason for an error.
- Filter the tasks by status and state.
- View the owner or host of the virtual machine or container referenced.
- Delete a task either explicitly or older than another task.

Filtering the VM and Container Analysis Task List

This procedure describes how to filter virtual machine analysis task lists. You can filter the task list by zone, time period, task status, and task state.

To filter the virtual machine and container analysis task list:

1. From the **Settings** menu, select **Tasks**.
2. Click **All Tasks**.
3. From the **Zone** list, select a specific zone, or select **All Zones**.
4. From the **24 Hour Time Period** list, select the period of time to view the tasks.
5. For **Task Status**, select the check boxes next to the status to view.
6. From the **Tasks State** list, select the state to view.
7. Click **Apply**.

Deleting a VM and Container Analysis Task

To delete a task from the list of all virtual machine and container analysis tasks:

1. From the settings menu, select **Tasks**.
2. Click **All Tasks**.
3. Select the tasks to delete. From the **Delete** menu:
    1. Click **Delete** to delete the selected tasks.
    2. Click **Delete Older** to delete the tasks older than the selected tasks.
    3. Click **Delete All** to delete all tasks.
4. Click **OK**.

All Tasks

The **All Tasks** menu allows you to view all tasks for all users. This menu is only accessible when you are logged in as the **admin** user.

Filtering the All Tasks List

This procedure describes how to filter the list of all other tasks. You can filter the task list by time period, task status, and task state.

To filter the all other tasks list:

1. From the **Settings** menu, select **Tasks**.
2. Click **All Tasks**.
3. From the **24 Hour Time Period** list, select the period of time to view the tasks.
4. For **Task Status**, select the check boxes next to the status to view.
5. From the **Tasks State** list, select the state to view.
6. Click **Apply**.

Deleting a Task from the All Tasks List

To delete a task from the list of all other tasks:

1. From the settings menu, select **Tasks**.
2. Click **All Tasks**.
3. Select the tasks to delete. From the **Delete** menu:
    1. Click **Delete** to delete the selected tasks.
    2. Click **Delete Older** to delete the tasks older than the selected tasks.
    3. Click **Delete All** to delete all tasks.
4. Click **OK**.

Configuration

The options under the **Configuration** menu allow you to configure global options for your Infrastructure Automation environment, view diagnostic information, and view analytics on the servers in the environment. The menu displays the Infrastructure Automation environment at the enterprise, zone, and server levels.

There are four main areas:

- **Settings**

  This menu allows you to configure global settings for your Infrastructure Automation infrastructure. You can also create analysis profiles and schedules for these profiles.

- **Access Control**

  This menu contains options for configuring users, groups, roles, and tenants.

- **Diagnostics**

  This menu displays the status of your servers and their roles and provides access to logs.

- **Database**

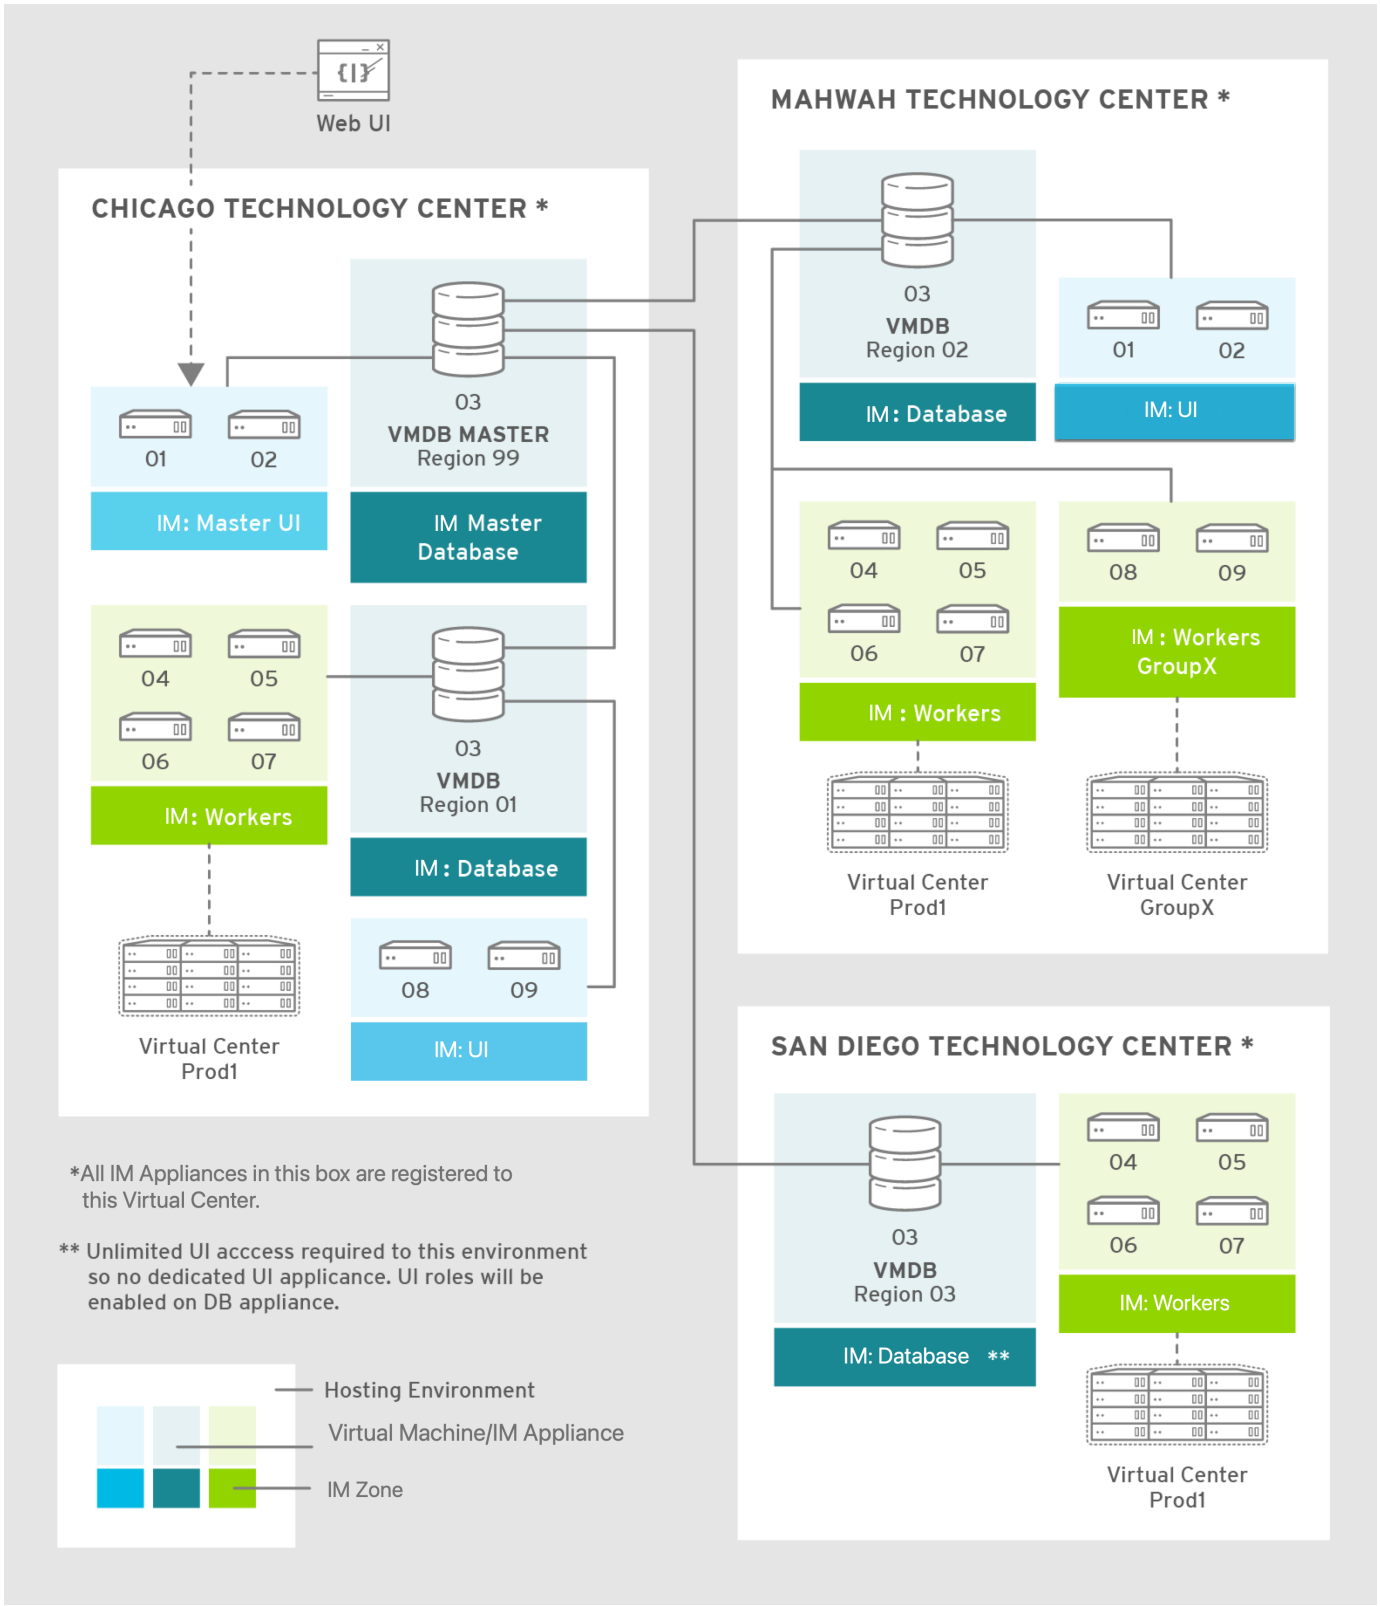
  specify the location of your Virtual Machine Database (VMDB) and its login credentials.

Settings

The options under the **Settings** area provide a hierarchical view of options that allow you to configure global options for the infrastructure of your Infrastructure Automation environment. At the top level, you have **Settings** including users, LDAP Groups, account roles, capacity and utilization collection, tag categories, values, and imports, custom variable imports, and license uploads. When you click on **Settings** and expand it, you can configure **Analysis Profiles**, **Zones**, and **Schedules**.

When you go the **Settings** accordion, you are automatically taken to the server list under **Zones**.

Regions



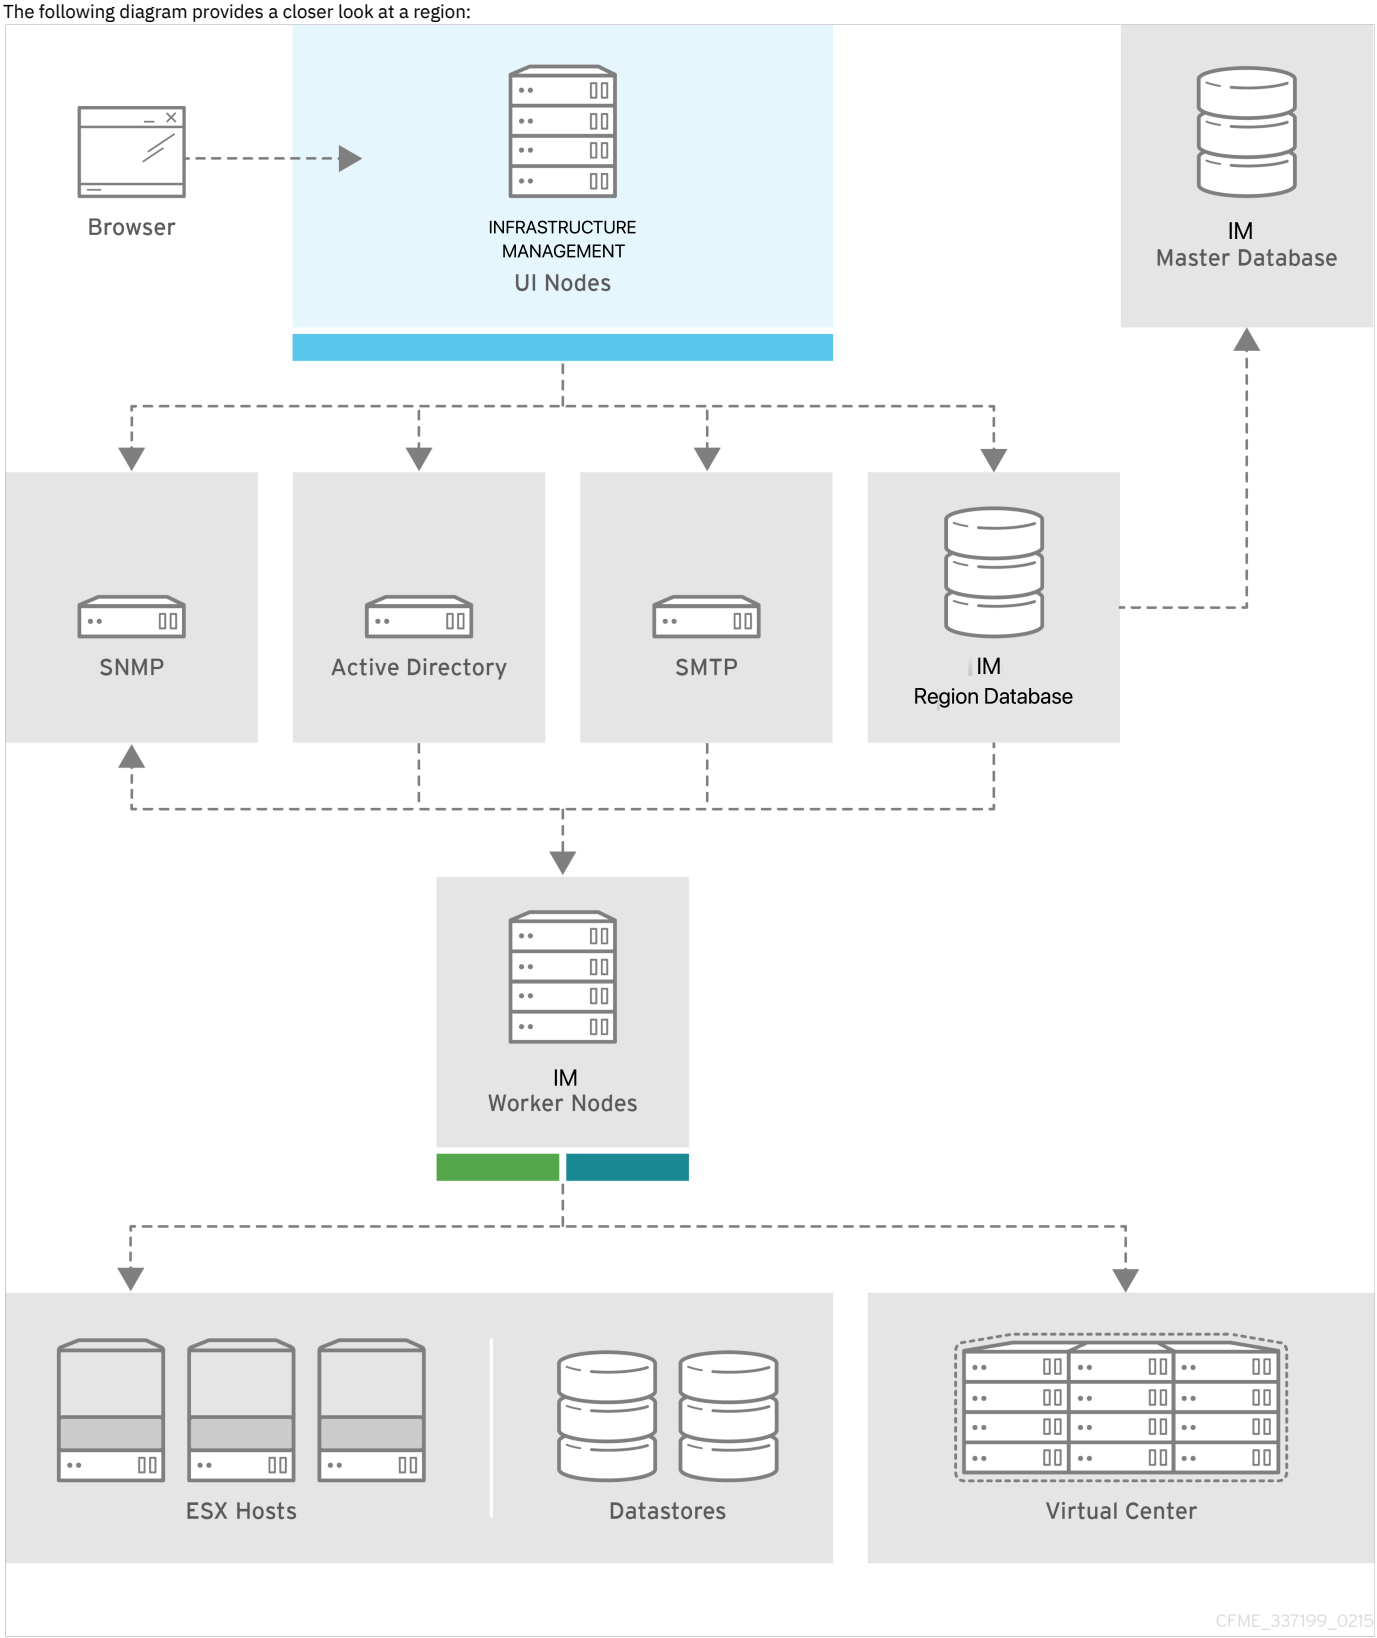
Use **Regions** for centralizing data which is collected from public and private virtualization environments. A region is ultimately represented as a single database for the VMDB. Regions are particularly useful when multiple geographical locations need to be managed as they enable all the data collection to happen at each particular location and avoid data collection traffic across slow links between networks.

When multiple regions are being used, each with their own unique ID, a master region can be created to centralize the data of all the children regions into a single master database. To do this, configure each child region to replicate its data to the master region database (Red Hat recommends use of region 99). This parent and child region is a one-to-many relationship.

Regions can contain multiple zones, which in turn contain appliances. Zones are used for further segregating network traffic along with enabling failover configurations. Each appliance has the capability to be configured for a number of specialized server roles. These roles are limited to the zone containing the appliance they run on.

Only one failover type of each server role can run in a zone. If multiple appliances have the same failover role, the extras are used as backups that activate only if the primary appliance fails. Non-failover server roles can run on multiple appliances simultaneously in a zone, so resources can be adjusted according to the workload those roles are responsible for.

The following diagram demonstrates an example of the multiple regions working together in a Infrastructure Automation environment.



The Master appliance is located in Chicago and contains a master region and a subregion that manages the worker appliances. The Mahwah technology center contains a single subregion that manages two zones. Likewise the San Diego technology center contains a single subregion managing a single zone.

Note:

- Replicating a parent region to a higher-level parent is not supported.
- Parent regions can be configured after the child regions are online.

The following diagram provides a closer look at a region:

In this region, we have several Infrastructure Automation appliances acting as UI nodes and worker nodes. These worker nodes execute tasks on the providers in your environment. The Region also uses a region database that reports to a master database on the main Infrastructure Automation appliance. All appliances can connect to the authentication services (Active Directory, LDAP, Identity Management), outgoing mail (SMTP), and network services (SNMP).

Region Scope

Regions are used to consolidate data from multiple VMDBs to a central database. The database at the top level, the master VMDB, cannot be used for operational tasks such as SmartState Analysis or Capacity and Utilization data collection. It is intended for use as a reporting database that includes all information across multiple subordinate regions. The subordinate regions replicate their information to the master.

Note:

The subordinate regions are not aware of each other from a database perspective. You cannot see information from one subordinate region in another. The only VMDB with data visibility to all subordinate regions is the top level.

Master Regions Scope

- Reports all information from all subordinate VMDBs reporting up to it.
- Can perform power operations on virtual machines from subordinate regions.
- Controls its own access control list.

Subordinate Regions Scope

- Each subordinate controls its own access control independent of the other regions.
- Can only do work (such as SmartState Analysis and Capacity and Utilization collection) in its own region.
- Has no knowledge of the other regions.
- Replicates its data up to the master region.

Region Settings

In the **Region** area, set items that apply to your entire Infrastructure Automation infrastructure such as users, LDAP Groups, capacity and utilization collection, company tags and tag categories, and licensing. Regions are also used for database replication.

Capacity and Utilization Collection

Capacity and Utilization Collection Settings

Use **C & U Collection Settings** to select specifically which clusters and datastores you want to collect usage data for. By selecting a cluster, you are choosing to collect data for all hosts and virtual machines that are part of that cluster. You must also have a server with the Capacity & Utilization **Coordinator**, **Data Collector**, and **Data Processor** roles enabled as well. See Section **Server Control Settings**.

After a provider has been discovered and its relationships refreshed, view the clusters, hosts, and datastores from the settings menu. Navigate to **Settings**, then click on **Application Settings**. Click the menu: **Settings > Region**, then select the **C & U Collection** tab.

Enabling a Cluster, Host, or Datastore for Capacity and

Utilization Collection

To enable a cluster, host, or datastore for Capacity and Utilization Collection:

1. Click **Settings**, then click on **Application Settings**.
2. Click the **Settings** accordion, then select **Region**, then click on the **C & U Collection** tab.
3. In the **Clusters** area, check all clusters and hosts that you want to collect data for.
4. In the **Datastores** area, check all datastores that you want to collect data for.
5. Click **Save**.

Note:

1. As new clusters, hosts, and datastores are discovered, you will need to come back to this configuration to enable collection of capacity and utilization data unless you have used the **Collect for All** check boxes.
2. **Collect for All Clusters** must be checked to be able to collect capacity and utilization data from cloud providers such as Red Hat OpenStack Platform or Amazon EC2.

Tags

Company Tag Categories and Tags

Infrastructure Automation allows you to create your own set of tags and tag categories. Use tags to create a customized, searchable index for your resources. Depending on your database type, your tags may be case sensitive. After creating these values, you can apply them to your resources. There are two kinds of tags.

- **Company tags** which you will see under **My Company Tags** for a resource. Create company tags from the settings menu. Browse to **Settings > Application Settings**. Click the **Settings** accordion, then select the **Region** and click on the **Tags** tab, then **My Company Tags**. A selection of company tags is provided to you by default as samples. These can be deleted if you do not need them, but are not recreated by Infrastructure Automation.
- **System tags** are assigned automatically by Infrastructure Automation.

Creating a Tag Category

To create a tag category:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then **Region**.

3. Select the **Tags** tab, then click on the **My Company Categories** tab.
4. Click **Add** under the **Actions** column to create a new category.
5. In the **Category Information** area:

- Use **Name** to create a short name that refers to category in the VMDB.

  Note:

  The **Name** and **Single Value** fields cannot be changed after the category has been added.
- Use **Description** to type a brief explanation of how the category should be used. This shows when you try to add a value to the category.
- Use **Long Description** to type a detailed explanation of the category.
- Set **Show in Console** to **ON** when the category is ready for use in the console. For example, you want to populate values for the category before exposing it to users.
- Set **Single Value** to **ON** for categories that can only have a single value assigned to a resource. For example, a virtual machine can only be assigned to one location, but could belong to more than one department. This cannot be changed after the category is created.
- Set **Capture C & U Data by Tag** to **ON** for the ability to group capacity and utilization data by this tag category. To use this, be sure to assign this tag to all the resources that you want to group by.

6. Click **Add**.

Repeat these steps for each category you need. After you have created the category, you can add values to it.

Important

If no values are created for a category, you are unable to assign a value from that category nor be able to filter by that category.

Deleting a Tag Category

To delete a tag category:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then **Region**.
3. Select the **Tags** tab, then click on the **My Company Categories** tab.
4. Click **Delete** under the **Actions** column for the category you want to delete.
5. Click **OK** to confirm.

Note:

When you delete a tag category, the category values are removed, and any tags from the category are unassigned from all resources.

Creating a Company Tag

To create a company tag:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then **Region**.
3. Select the **Tags** tab, then click on the **My Company Tags** tab.
4. In the **Choose a Category** area, select a category from the **Category** list.

   Note:

   - Some categories only allow one value to be assigned to a resource.
   - For some databases such as **PostgreSQL**, tags are case sensitive. For example, filtering by 'Linux' in title case give you different results from filtering by 'linux' in lower case.
5. Click **Add** under the **Actions** column, and type a **Name** and **Description** for your new value.
6. Click **Add** once again to add the new entry to the table.

Deleting a Company Tag

To delete a company tag:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then **Region**.
3. Select the **Tags** tab, then click on the **My Company Tags** tab.
4. Click **Delete** under the **Actions** column next to the tag to delete it.

   Note:

   When you delete a tag, the tag is also deleted from any resource to which it was assigned.
5. Click **OK** to confirm.

Importing Tags for Virtual Machines

You can import a **CSV** file with tag assignments into the VMDB. For the import to be successful, be aware of the following:

- The file must be in the following format, with one line for each virtual machine. One virtual machine per tag must be on a separate line even if you are assigning multiple tags of the same category.
- You must use the display names of the category and the display name for the tag for the import to work.

```
name,category,entry
evm2,Provisioning Scope,All
evm2,Exclusions,Do not Analyze
evm2,EVM Operations,Analysis Successful
rhel6,Department,Presales
rhel6,Department,Support
```

Importing Tags for a Virtual Machine from a CSV File

To import tags for a virtual machine from a CSV file:

1. Make sure the **CSV file** is in the required format.
2. Browse to **Settings > Application Settings**.
3. Click on the **Settings** accordion, then **Region**.
4. Select the **Tags** tab, then click on the **Import Tags** tab.
5. Click **Choose file** to go to the location where the file is located.
6. Click **Upload**.

   Note:

   If there are any problems with the file, such as an incorrect column name, unknown virtual machine, unknown tag, or multiple values for a tag that should have only one, an error message will appear in the console for those records.
7. Click **Apply**.

Importing Custom Values for Virtual Machines and Hosts

You can import a **CSV** file with asset tag information into the VMDB for a virtual machine or import custom values for hosts. For the import to be successful, the file must be in the following format, with one line for each virtual machine or host.

- There are two columns.
- The first line of the file must have the column names as shown below.
- The column names are case sensitive.

- Each value must be separated by a comma.

Virtual Machine Import Example

```
name,custom_1
Ecommerce,665432
Customer,883452
SQLSrvr,1090430
Firewall,8230500
```

For virtual machines, the value for custom_1 will show in the **VM Summary** page as the **Custom Identifier** page as the **Custom Identifier** in the **Properties** area. All of the custom values will show in the **Custom Fields** area.

Host Import Example

```
hostname,custom_1,custom_2
esx303.galaxy.local,15557814,19948399
esxd1.galaxy.local,10885574,16416993
esxd2.galaxy.local,16199125,16569419
```

For hosts, the value for custom_1 will show in the **Host Summary** page as the **Custom Identifier** in the **Properties** area. All of the custom values will show in the **Custom Fields** area.

Importing Asset Tags for a Virtual Machine from a CSV File

To import asset tags for a virtual machine from a CSV file

1. Make sure the **CSV file** is in the required format.
2. Browse to **Settings > Application Settings**.
3. Click on the **Settings** accordion, then **Region**.
4. Select the **Tags** tab, then click on the **Import Variables** tab.
5. Select the type of custom variable you want to import, either **Host** or **VM**.
6. Click **Choose file** to go to the location where the custom variable file is located.
7. Click **Upload**.

   Note:

   If there are any problems with the file, such as an incorrect column name, unknown virtual machine or host, a message appears.
8. Click **Apply**.

Tag Mapping

You can map labels from external providers to tags within Infrastructure Automation.

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then select the **Region**.
3. Select the **Tags** tab, then click on the **Map Tags** tab.
4. Click **Add** to create a tag map.
5. In the **Choose a resource entity and label**, select the **Entity** and enter a **Resource label**, then enter a **Tag Category**.
6. Click **Add**.

Customizing the Help Menu

Infrastructure Automation allows administrators to customize the help menu. Use this feature to define menu labels, URLs and how each window opens for users.

Note:

Any change to the help menu will take effect upon a full page reload.

Customize the help menu using the following steps:

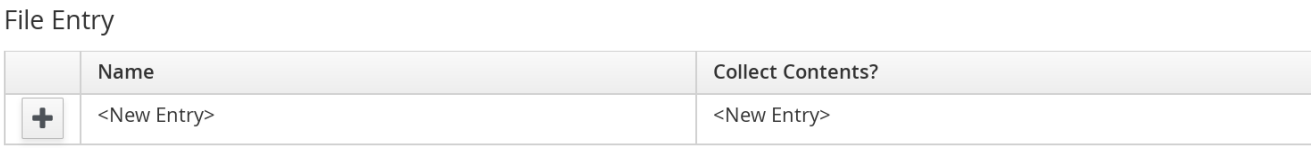
1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then **Region**.
3. Click on the **Help Menu** tab.
4. Provide custom **Menu item labels** and an associated **URL** for each. Define how each window should open by selecting from the options in the **Open in** menu.
5. Click **Submit**.

Profiles

Creating an Analysis Profile

You can create an analysis profile by referring to the sample profiles provided in the console. You can copy the sample profile or create a new one.

Creating a Host Analysis Profile



To create a host analysis profile:

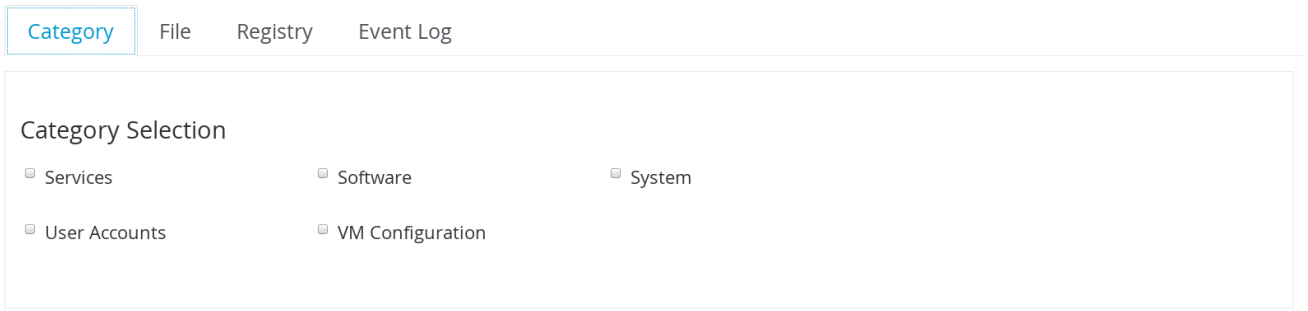
1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Analysis Profiles**.

3. Click **Configuration**, and (**Add Host Analysis Profile**).
4. In the **Basic Information** area, type in a **Name** and **Description** for the analysis profile.

5. Click **File** to collect information about a file or group of files.
6. From the **File Entry** area, click (**Click to add a new entry**) to add a file or group of files.

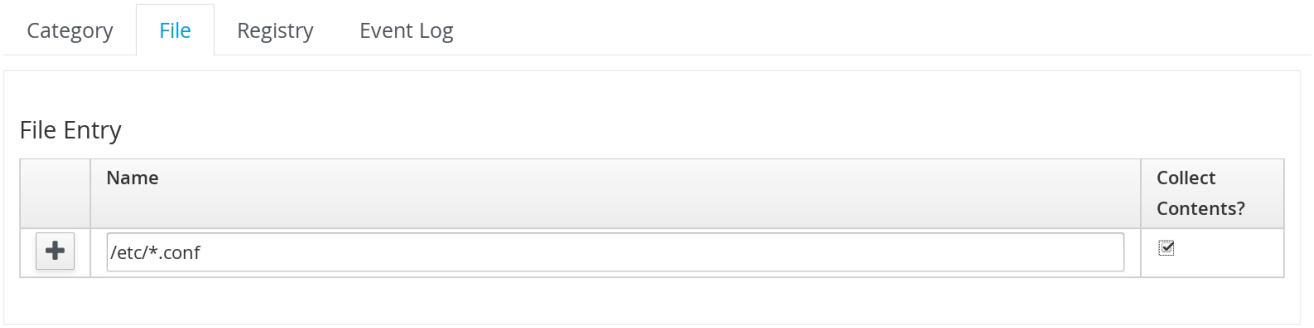
   - Check **Collect Contents** to not only check for existence, but also gather the contents of the file. If you do this, then you can use the contents to create policies in Infrastructure Automation Control.
7. Click **Event Log** to specify event log entries to collect.
8. From the **Event Log Entry** area, click **Click to add a new entry** to add a type of event log entry. Type in a **Name**. You can type in a specific message to find in **Filter Message**. In **Level**, set the value for the level of the entry and above. Specify the **Source** for the entry. Finally, set the # number of days that you want to collect event log entries for. If you set this to 0, it will go as far back as there is data available.

9. Click **Add**.

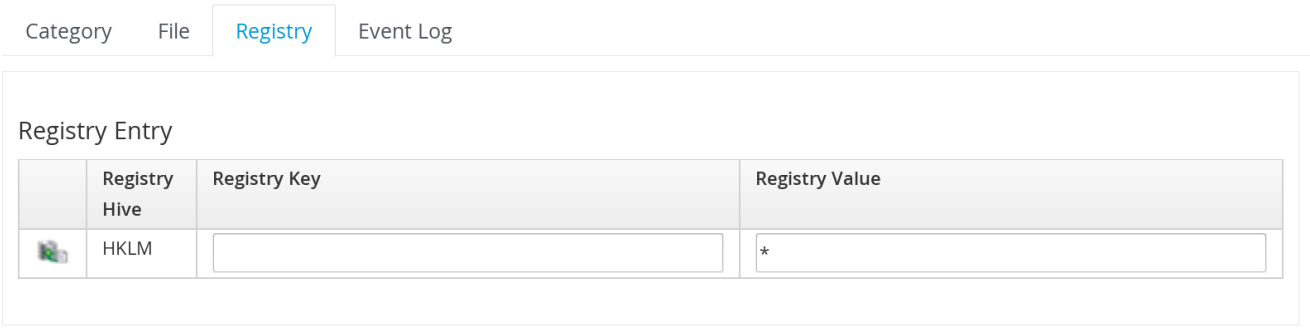


Creating a Virtual Machine Analysis Profile

To create a virtual machine analysis profile:



1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Analysis Profiles**.
3. Click **Configuration**, and **Add VM Analysis Profile**.
4. In the **Basic Information** area, type in a **Name** and **Description** for the analysis profile.



5. You begin in the **Category** tab. From the **Category Selection** area, check the categories you want to collect information for. This is available for virtual machine profiles only.

6. Click the **File** tab to collect information about a file or group of files.
7. From the **File Entry** area, click **Add this entry** to add a file or group of files, then type a name. For virtual machines, specify the file to check for. Check the box under **Collect Contents** if you want to collect the file contents as well. The files can be no larger than 1 MB.

8. Click the **Registry** tab to collect information on a registry key.
9. From the **Registry Entry** area, type your **Registry Key** and **Registry Value**. To evaluate whether a registry key exists or does not exist on a virtual machine, without providing a value, type * in the **Registry Value** field. Then, you do not need to know the registry value to collect the keys. This is available for virtual machine profiles only.

10. Click **Event Log** to specify event log entries to collect.
11. From the **Event Log Entry** area, complete the fields to add a type of event log entry. You can type in a specific message to find in **Filter Message**. In **Level**, set the value for the level of the entry and above. Specify the **Source for the entry**. Finally, set the # (number) of days that you want to collect event log entries for. If you set this to 0, it will go as far back as there is data available.

12. Click **Add**.

Editing an Analysis Profile

To edit an analysis profile:

1. Browse to **Settings > Application Settings**.

2. Click on the **Settings** accordion, then click **Analysis Profiles**.
3. Check the analysis profile you want to edit.
4. Click **Edit the selected Analysis Profiles**.
5. Make any changes.
6. Click **Save**.

The changes are added to the analysis profile. The virtual machines or hosts must be re-analyzed to collect the new or modified information.

Copying an Analysis Profile

To copy an analysis profile:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Analysis Profiles**.
3. Check the analysis profile you want to copy.
4. Click **Configuration**, then **Copy the selected Analysis Profiles**.
5. Type a new **Name** and **Description**.
6. Make required changes.
7. Click **Add**.

Setting a Default Analysis Profile

If you want to set an analysis profile to be used for all virtual machines, you can create a default profile.

To create a default analysis profile:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Analysis Profiles**.
3. Click on the analysis profile you want to set as the default.
4. Click **Configuration**, then **Edit the selected Analysis Profile**.
5. For a virtual machine profile, enter `default` in lower case in **Name**. For a host profile, enter `host default`.

6. Click **Save**.

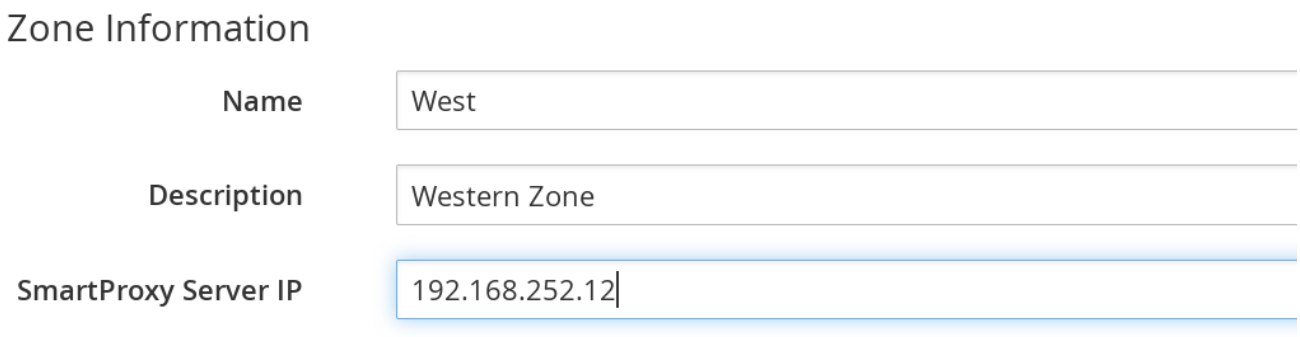
Zones

You can organize your Infrastructure Automation Infrastructure into zones to configure failover and isolate traffic. A provider that is discovered by a server in a specific zone gets monitored and managed in that zone. All jobs, such as a SmartState Analysis or VM power operation, dispatched by a server in a specific zone can get processed by any Infrastructure Automation appliance assigned to that same zone.

Zones can be created based on your own environment. You can make zones based on geographic location, network location, or function. When first started, a new server is put into the default zone.

Suppose you have four Infrastructure Automation appliances with two in the East zone, appliances A and B, and two in the West zone, appliances C and D. VC East is discovered by one of the Infrastructure Automation appliances in the Infrastructure Automation Eastern zone. If Appliance A dispatches a job of analyzing twenty virtual machines, this job can be processed by either Appliance A or B, but not C or D.

Note:



Only users assigned the super administrator role can create zones. There must always be at least one zone. The **Default Zone** is provided and cannot be deleted.

Creating a Zone

To create a zone:

1. Browse to **Settings > Application Settings**.

2. Click on the **Settings** accordion, then click **Zones**.
3. Click **Configuration**, and **Add a new Zone** to create a zone.
4. In the **Zone Information** area, type in a **Name** and **Description** for the new zone.

5. Use **SmartProxy Server IP** to specify the IP address of the server that you want SmartProxies installed in this zone to report to. If this is not set, then the IP address of the server that deployed the SmartProxy is used. This does not apply to embedded SmartProxies.
6. Optionally, you can configure **NTP servers** for the entire zone in the NTP Servers area. These settings will be used if the NTP servers have not been set for the appliance in the menu: **Operations > Server** page.
7. In the **Settings** area, set the number for **Max Active VM Scans**. The default is `Unlimited`.
8. Click **Save**.

Deleting a Zone

To delete a zone:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone you want to remove.

   Note:

   You cannot delete a zone if there are servers assigned to it.
4. Click **Configuration**, then click **Delete this Zone**.
5. Click **OK** to confirm.

Editing a Zone

To edit a zone:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone you want to edit.
4. Click **Configuration**, then click **Edit this Zone**.
5. Complete the required changes.
6. Click **Save**.

Adding SmartProxy Affinity to a Zone:

Enable SmartProxy Affinity for zones containing servers with the SmartProxy role to run a SmartState Analysis.

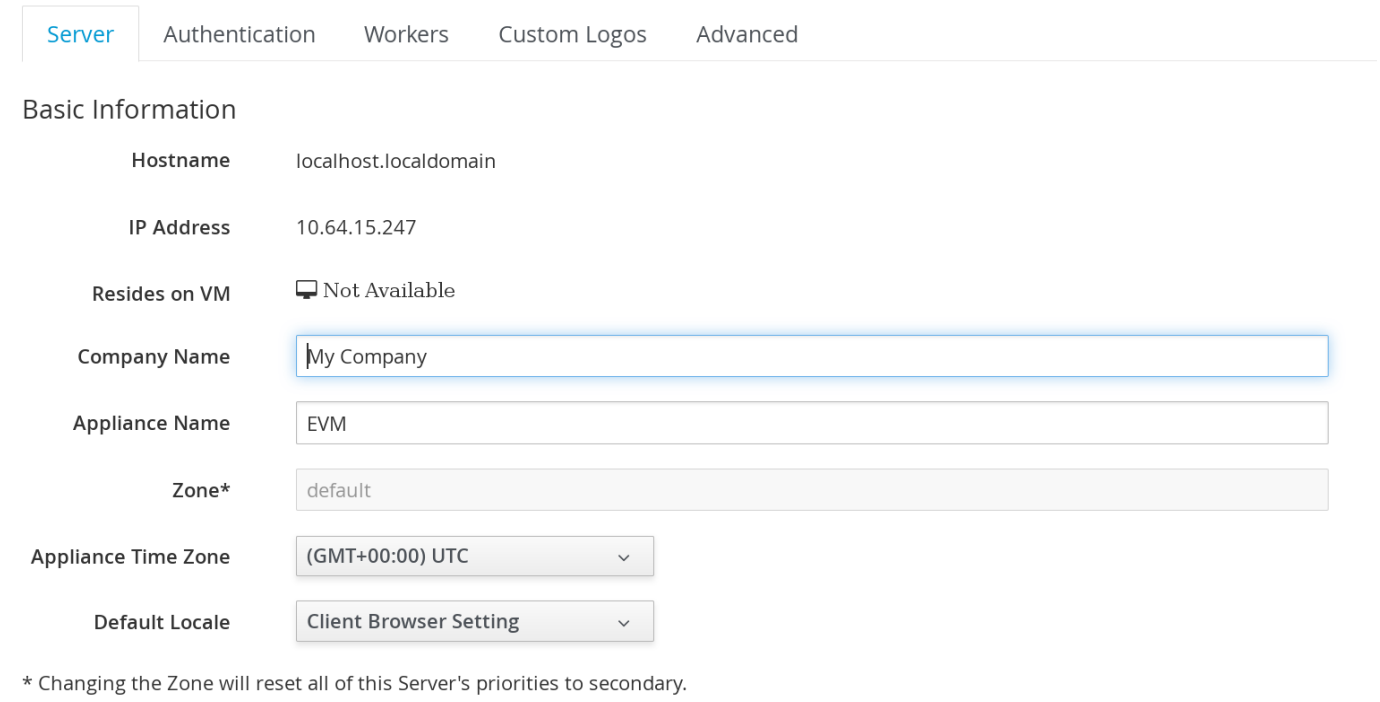
To add SmartProxy Affinity to a zone:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone in which you want to enable SmartProxy Affinity.
4. Click the **SmartProxy Affinity** tab and click the appropriate server.
5. Click **Save**.

Servers

Server settings enables you to control how each Infrastructure Automation server operates including authentication, logging, and email. If you have multiple servers in your environment that are reporting to one central VMDB, then you can edit some of these settings from the console by specifying which server you want to change.

Note:



The server selection options are only available if you have multiple servers sharing one VMDB.

Changing Server Settings

To change server settings:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone where the Infrastructure Automation server is located.
4. In the **Servers** area, click on the Infrastructure Automation server.
5. Click **Server**.
6. Make any required changes.
7. Click **Save**.

Basic Information Settings

- Use **Company Name** (maximum 20 characters) to customize the interface with your company's name. You will see the company name when you are viewing or modifying the tags of an infrastructure object or virtual machine.
- Specify the **Appliance Name** (maximum 20 characters) you want displayed as the appliance that you are logged into. You will see this in the upper right corner of the interface with the name of the consoles logged on user.
- Use **Zone** to isolate traffic and provide load balancing capabilities. Specify the zone that you want this Infrastructure Automation appliance to be a member of. At startup, the zone is set to default.
- Use **Appliance Time Zone** to set the time zone for this server.

  Note:

  This is the time zone used when created scheduled analyses. This is not the same as the **Time Zone** parameter, which is found by navigating to the settings menu, then **My Settings**, then exploring the **Display Settings** area, and is the time zone displayed in the console.
- Use **Default Locale** to specify the default language for this server.

Server Control Settings

A server role defines what a server can do. Red Hat recommends that Database Operations, Event Monitor, Reporting, Scheduler, SmartState Analysis, User Interface, Provider Inventory, Provider Operations, and Web Services be enabled on at least one server in each zone. These roles are enabled by default on all servers.

- Use **Default Repository SmartProxy** to set the SmartProxy from which you refresh your virtual machine repositories. This host must have access to your repositories to analyze its virtual machines.

Note:

- Only super administrators can change server roles.
- If you are using more than one Infrastructure Automation appliance, be sure to set this on all of the appliances.

Server Roles

Note:

- Server roles that are in an active/active high availability configuration *(load balancing and failover protection)* are active in more than one location; whereas, roles that are in an active/passive *(primary/secondary in the case of Infrastructure Automation)* high availability configuration *(failover protection)*, if more than one Infrastructure Automation server in a specific zone or region has this role, only one will be active *(primary)* at a time and a failover has to occur to the passive *(secondary)* appliance with that role.
- For information on region and zone diagnostics and server role priorities, see Diagnostics.

Server Role	Description	Zone or Region Aware	Primary/Secondary or Active/Active
Automation Engine	Use this role if you want to use this Infrastructure Automation server to process automation tasks.	N/A	Active/Active
Capacity and Utilization Coordinator	The Capacity & Utilization Coordinator role checks to see if it is time to collect data, somewhat like a scheduler. If it is time, a job is queued for the Capacity and Utilization Data Collector. The coordinator role is required to complete Capacity and Utilization data collection. If more than one Infrastructure Automation server in a specific zone has this role, only one will be active at a time.	Zone	Primary/Secondary
Capacity & Utilization Data Collector	The Capacity & Utilization Data Collector performs the actual collection of capacity and utilization data. This role has a dedicated worker, and there can be more than one Infrastructure Automation server with this role in a zone.	Zone	Active/Active
Capacity & Utilization Data Processor	The Capacity & Utilization Data Processor processes all of the data collected, allowing Infrastructure Automation to create charts. This role has a dedicated worker, and there can be more than one Infrastructure Automation server with this role in a zone.	Zone	Active/Active
Database Operations	Use Database Operations to enable this Infrastructure Automation server to run database backups or garbage collection.	Zone	Active/Active
Embedded Ansible	This role is disabled by default. The Embedded Ansible role supports Ansible Automation Inside functionality. Enable this role to configure playbook repositories and run playbooks natively to back service catalog items. **NOTE**: Enable the Provider Inventory server role in the same zone as the Embedded Ansible server role to ensure proper functionality.	Region	Primary/Secondary
Event Monitor	This role is enabled by default and provides the information shown in timelines. The Event Monitor is responsible for the work between the Infrastructure Automation server and your providers. It starts 2 workers for each provider. One worker, the monitor, is responsible for maintaining a connection to a provider, catching events, and putting them on the Infrastructure Automation message queue for processing. The second worker, the handler, is a message queue worker responsible for delivering only those messages for a provider. You should have at least one of these in each zone.	Zone	Primary/Secondary
Git Repository	The Git Repositories Owner server role supports importing domains into automate from a git repository. This feature is available from the **Automate > Import/Export** screen in the Infrastructure Automation user interface.	Region	Primary/Secondary
Notifier	Use this role if you will be using Infrastructure Automation Control or Automate to forward SNMP traps to a monitoring system or send e-mails. See Creating an Alert for details on creating SNMP alerts. If more than one Infrastructure Automation server in a specific region has this role, only one will be active at a time.	Region	Primary/Secondary
Provider Inventory	This role is enabled by default. This role is responsible for refreshing provider information including EMS, hosts, virtual machines, and clusters, and is also responsible for capturing datastore file lists. If more than one Infrastructure Automation server in a specific zone has this role, only one will be active at a time. Required in the same zone as a Infrastructure Automation appliance with the Embedded Ansible role enabled.	Zone	Primary/Secondary
Provider Operations	This role is enabled by default. This role sends stop, start, suspend, shutdown guest, clone, reconfigure, and unregister to the provider, directly from the console or through a policy action if you have Infrastructure Automation Control. More than one Infrastructure Automation server can have this role in a zone.	Zone	Active/Active
RHN Mirror	An appliance with RHN Mirror enabled acts as a server containing a repository with the latest Infrastructure Automation packages. This also configures other appliances within the same region to point to the chosen RHN Mirror server for updates. This provides a low bandwidth method to update environments with multiple appliances.	N/A	Active/Active
Reporting	This role is enabled by default. The Reporting role specifies which Infrastructure Automation servers can generate reports. If you do not have a Infrastructure Automation server set to this role in a zone, then no reports can be generated in that zone. You should have at least one of these in each zone.	Zone	Active/Active
Scheduler	This role is enabled by default. The Scheduler sends messages to start all scheduled activities such as report generation and SmartState analysis. This role also controls all system schedules such as capacity and utilization data gathering. One server in each region must be assigned this role or scheduled Infrastructure Automation events will not occur. If more than one Infrastructure Automation server in a specific region has this role, only one will be active at a time.	Region	Primary/Secondary
SmartProxy	Enabling the SmartProxy role turns on the embedded SmartProxy on the Infrastructure Automation server. The embedded SmartProxy can analyze virtual machines that are registered to a host and templates that are associated with a provider. To provide visibility to repositories, install the SmartProxy on a host from the Infrastructure Automation console. This SmartProxy can also analyze virtual machines on the host on which it is installed. Enabling the SmartProxy role on an appliance requires selecting the SmartProxy Affinity for a zone to run a SmartState Analysis. By default, no selections are enabled under SmartProxy Affinity.	Zone	Active/Active

Server Role	Description	Zone or Region Aware	Primary/Secondary or Active/Active
SmartState Analysis	This role is enabled by default. The SmartState Analysis role controls which Infrastructure Automation servers can control SmartState Analyses and process the data from the analysis. You should have at least one of these in each zone.	Zone	Active/Active
User Interface	This role is enabled by default. The Web Services role must also be enabled with this role to log into the user interface, as the User Interface role queries the API to receive tokens for login. Uncheck User Interface if you do not want users to be able to access this Infrastructure Automation server using the Infrastructure Automation console. For example, you may want to turn this off if the Infrastructure Automation server is strictly being used for capacity and utilization or reporting generation. More than one Infrastructure Automation server can have this role in a zone.	Zone	Active/Active
Web Services	This role is enabled by default. The Web Services roles provides API access and must be enabled if the User Interface role is enabled to log into the user interface. You can also enable the Web Services role to provide API-only access to the server. Uncheck Web Services to stop this Infrastructure Automation server from acting as a web service provider. More than one Infrastructure Automation server can have this role in a zone.	N/A	Active/Active
Websocket	This role enables starting or stopping websocket workers required for proxying remote consoles.	N/A	Active/Active

VMware Console Settings

If you are using the Infrastructure Automation control feature set, then you have the ability to connect to a Web console for virtual machines that are registered to a host. To use this feature, you must have VNC installed, VMware's WebMKS SDK enabled in Infrastructure Automation, or the VMRC native desktop application installed for your environment.

Note:

See vendor documentation to ensure you are installing appropriate applications for your virtual infrastructure. Once you have installed the required software, you must specify its version in the Infrastructure Automation configuration settings.

- If you select **VNC**, type in the port number used. This port must be open on the target virtual machine and the VNC software must be installed there. On the computer that you are running the console from, you must install the appropriate version of Java Runtime if it is not already installed.
- If you select **VMware WebMKS**, select the appropriate version.
- If using **VMware VMRC** desktop application, be sure that you have fulfilled the requirements for your vCenter version. The correct version of the VMRC desktop application from VMware must be installed on the client computer. To do this, log into the vCenter Web Service and attempt to open a virtual machine console. The vSphere Web Client must be installed on vCenter version 5, and the provider must be registered to it. For vCenter version 4, the VMware vCenter Management Webservices must be running.

NTP Servers Settings In the NTP Servers area, you can

specify the NTP servers to use as source for clock synchronization here. The NTP settings specified here will override Zone NTP settings. Enter one NTP server hostname or IP address in each text box.

Configuring SNMP

You can use Simple Network Management Protocol (SNMP) traps to send alerts for various aspects of a Infrastructure Automation environment.

Requirements

- Configure your SNMP management station to accept traps from Infrastructure Automation appliances. Consult your management station's documentation.
- Each appliance that could process SNMP traps must have the **`snmpd`** and **`snmptrapd`** daemons running.
- The region where the appliances are located must have the **`Notifier`** role enabled and the failover role priority set.

To enable the **`snmpd`** and **`snmptrapd`** daemons

1. Access each SNMP processing appliance using SSH.

2. Set the SNMP daemons to run on start up:

```
# chkconfig --level 2345 snmpd on
# chkconfig --level 2345 snmptrapd on
```

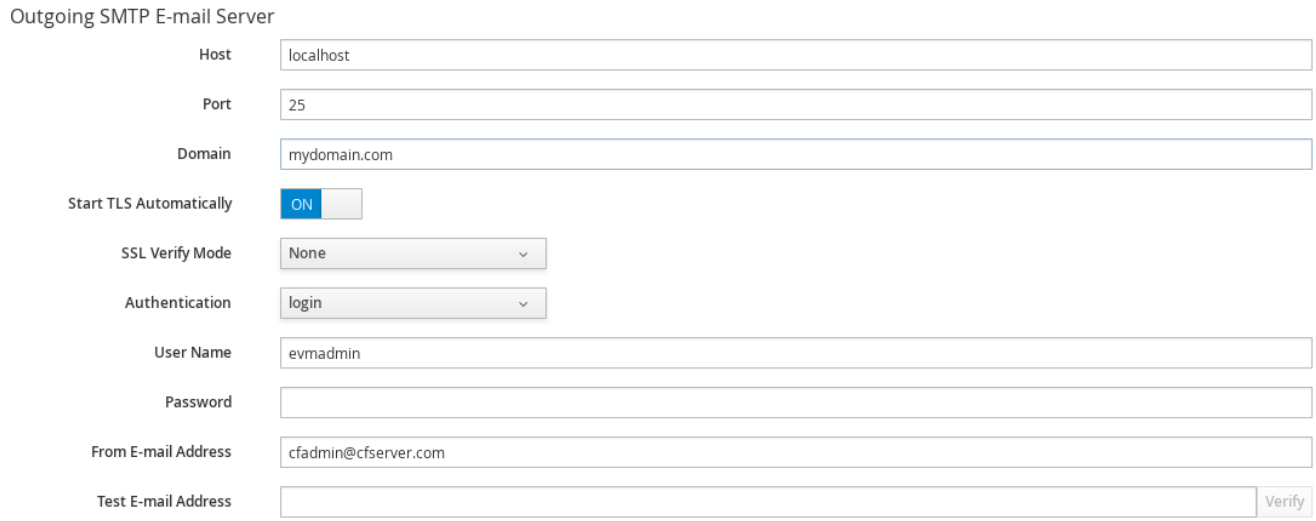
3. The daemons run automatically when the appliance is restarted, but must be started manually now.

```
# service snmpd start
# service snmptrapd start
```

To enable the notifier role:

1. Access each SNMP processing appliance using their web interfaces.
2. Browse to **Settings > Application Settings**.
3. Click on the **Settings** accordion, then click **Zones**. Select the zone where the EVM server is located, and select the EVM server.
4. In the **Server Control** area, set the **Notifier** server role option to **ON**.
5. Click **Save**.

To set the failover priority role:

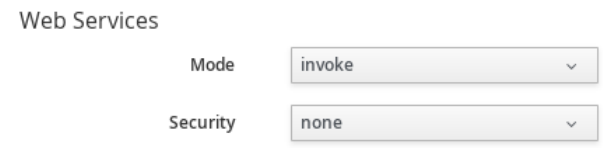


1. Browse to **Settings > Application Settings** then click the **Diagnostics** accordion.
2. Select the zone where the EVM server is located.
3. Click **Roles by Servers** or **Servers by Roles** to view your servers.
4. In the **Status of Roles for Servers** in **Zone Default Zone** area, click the role that you want to set the priority for.
5. Click **Configuration**, and **Promote Server** to make this the primary server for this role.

Outgoing SMTP Email Settings

To use the email action in Infrastructure Automation, set an email address to send emails from.

Note:



To be able to send any emails from the server, you must have the Notifier server role enabled. You can test the settings without the role enabled.

- Use **Host** to specify the host name of the mail server.
- Use **Port** to specify the port for the mail server.
- Use **Domain** to specify the domain name for the mail server.
- Set **Start TLS Automatically** on **ON** if the mail server requires TLS.
- Select the appropriate **SSL Verify Mode**.
- Use the **Authentication** drop down to specify if you want to use **`login`**, **`plain`**, or no authentication.
- Use **User Name** to specify the user name required for login authentication.
- Use **Password** to specify the password for login authentication.
- Use **From E-mail Address** to set the address you want to send the email from.
- Use **Test E-mail Address** if you want to test your email settings. Click **Verify** to send a test email.

Web Services Settings

Web services are used by the server to communicate with the SmartProxy.

- Set **Mode** to invoke to enable 2-way Web services communication between the Infrastructure Automation appliance and the SmartProxy. Set **Mode** to disabled to use Web services from the SmartProxy to the Infrastructure Automation appliance only. When the Infrastructure Automation appliance has work for the SmartProxy, the work will be placed in a queue in the VMDB. The work will be completed either when the Infrastructure Automation appliance is able to contact the SmartProxy or when the next SmartProxy heartbeat occurs, whichever comes first.
- If **Web Services** are enabled, you have the option to use **ws-security**.

Logging Settings

- Use **Log Level** to set the level of detail you want in the log. You can select from **fatal**, **error**, **warn**, **info**, and **debug**. The default setting is 'info'.

Custom Support URL Settings

- Use **URL** to specify a specific URL that you want to be accessible from the **About Product Assistance** area.
- Use **Description** to set a label for the **URL**.

Authentication

Use the **Authentication** tab to specify how you want users authenticated on the console. You can use the VMDB or integrate with LDAP, LDAPS, Amazon, or an external IPA server.

Changing Authentication Settings

To change authentication settings:

1. Browse to **Settings > Application Settings**.
2. Click the **Settings** accordion, then click **Zones**.
3. Click the zone where the server is located.
4. Click the server.
5. Click the **Authentication** tab.
6. Use **Session Timeout** to set the period of inactivity before a user is logged out of the console.
7. Set the authentication method in **Mode**.
8. Click **Save**.

Workers

Use the Workers page to specify the number of workers and amount of memory allowed to be used for each type.

Note:

Only make these changes when directed to by Red Hat Support.

Changing Settings for a Worker

To change the settings for a worker

1. Browse to **Settings > Application Settings**.

2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone where the server is located.
4. Click on the server.
5. Click **Workers**.
6. Go to the type of worker you have been directed to change.
7. If applicable, change Count or Memory Threshold using the dropdown boxes.
8. Click **Save**.

Database

Use the Database page to specify the location of your Virtual Machine Database (VMDB) and its login credentials. By default, the type is PostgreSQL on the Server.

Note:

The server may not start if the database settings are changed. Be sure to validate your new settings before restarting the server.

Changing a Database Setting

To change a database setting:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone where the server is located.
4. Click on the server.
5. Click the **Database** tab.
6. In the **Database** area, select the **Type** of database. You can select from **External Database on another CFME appliance**, **External Postgres Database**, and **Internal Database on this CFME Appliance**.
   - Use **Hostname** to specify the IP address or hostname of the external database server.
   - Use **Database Name** to specify the name of your VMDB.
   - Specify the **User Name** to connect to the VMDB.
   - Use **Password** and **Verify Password** to specify the password for the user name.
7. Click **Validate** to check the settings.
8. Click **Save**.
9. Click **OK** to the warning that the server will restart immediately after you save the changes.

During the restart, you are unable to access the server. When the restart is complete, the new database settings are in effect.

Customization and Logos

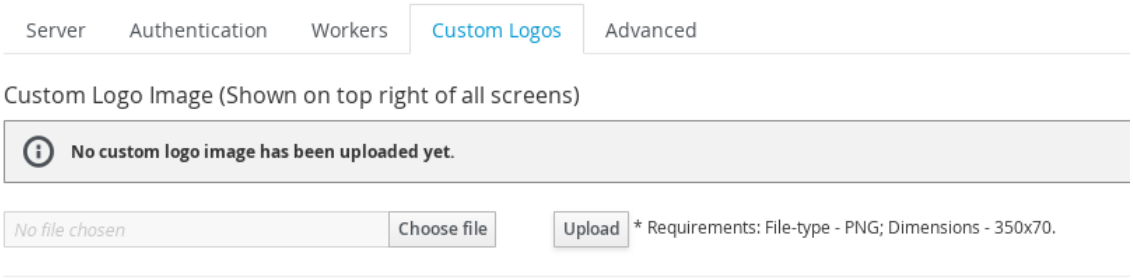
Custom Logos

Use **Custom Logos** to display your own logo in the corner of the Infrastructure Automation user interface and on the login screen. Use the procedures below to upload a custom logo to the user interface, and to customize the login background and login panel text on the user interface.

Note:

- If you have upgraded from an earlier Infrastructure Automation version and your custom logo was already in use before migration, although your logo image file is still in place in `vmdb/public/upload` you may have to uncheck and recheck the option to **Use Custom Logo Image** to re-enable displaying your custom logo. See Uploading a Custom Logo to the User Interface for the procedure on how to access the **Use Custom Logo Image** option, or if you want to upload another custom logo to the user interface and customize the login background image and login panel text.
- Additionally, ensure the option to use configuration settings for the tenant under **Access Control** is set to `Yes`; see Displaying the Custom Configuration Settings for the procedure on how to set the configuration settings.

Uploading a Custom Logo to the User Interface



Note:

Make sure the desired logo is accessible from the computer where you are running the Infrastructure Automation user interface. The file must be in portable network graphics (png) format with dimensions of 350 px x 70 px.

To upload a custom logo to the user interface:

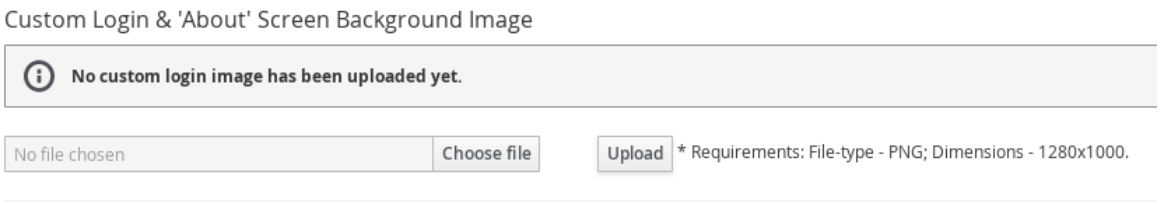
1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Zones**.

3. Click the zone where the Infrastructure Automation server is located.
4. Click on the server.
5. Click the **Custom Logos** tab.

6. In **Custom Logo Image (Shown on top right of all screens)**, click **Choose file** to go to the location where the logo file is located.
7. Click **Upload**. The icon is displayed above the file name box, and an option is shown to use the logo.
8. Check **Use Custom Logo Image** to add the logo to your user interface.
9. Click **Save**.

Note:

To enable displaying your custom logo, ensure the option to use configuration settings for the tenant under **Access Control** is set to `Yes`. See simpara_title for the procedure on how to set the configuration settings.



Customizing the Login Background

Note:

Make sure the background image that you want to use is accessible from the computer where you are running the user interface. The file must be in PNG format with dimensions of 1280 px x 1000 px.

To customize the login background:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone where the server is located.
4. Click on the server.
5. Click the **Custom Logos** tab.
6. In **Custom Login & 'About' Screen Background Image**, click **Choose file** to go to the location where the background image file is located.

7. Click **Upload**. The icon is displayed above the file name box, and an option is shown to use the logo.
8. Check **Use Custom Login Background Image** to add the background image to the login screen of the user interface.
9. Click **Save**.

Customizing the Login Panel Text

To customize the login panel text:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone where the server is located.
4. Click on the server.
5. Click the **Custom Logos** tab.
6. In **Custom Login Panel Text**, enter the text that you want to display on the login screen.

7. Click **Use Custom Login Text** to switch it to **Yes**.

8. Click **Save**.

Displaying the Custom Configuration Settings

To enable displaying your custom logo in the corner of the Infrastructure Automation user interface and on the login screen:

1. Browse to **Settings > Application Settings**.
2. Click the **Access Control** accordion.
3. Click **Tenants**, then click **My Company**.
4. Click (**Configuration**), then click (**Edit this item**).

5. Click **Use Configuration Settings** to switch it to **Yes**.
6. Click **Save**.

Advanced Settings

You may be instructed by Red Hat to edit some configuration settings manually. This feature is available for a limited number of options and can only be used by users assigned the super administrator role. Changing settings using this procedure may disable your Infrastructure Automation server.

- Only make manual changes to your configuration files if directed to do so by Red Hat. - Infrastructure Automation provides the ability to edit advanced configuration settings for all appliances through the **Advanced** tab from the user interface. You can also specify advanced settings for entire zones by clicking the **Advanced** tab at the zone level, with the advanced settings applied to individual appliances in that zone overriding zone-level settings when set.

Editing Configuration Files Manually

To edit configuration files manually:

1. Click **Configuration**.
2. Click on the **Settings** accordion, then click **Zones**.
3. Click the zone where the server is located.
4. You can click the **Advanced** tab at the zone level to set advanced configuration settings for the entire zone. Or, you can click on the server, and then click the **Advanced** tab to set advanced configuration settings at the server (appliance) level, which will override zone-level settings.
5. Make the required changes to the configuration file.
6. Click **Save**.

Configuration Parameters

Table: authentication

Parameters	Description
amazon_key	If using Amazon for the authentication mode, specify your Amazon Key. This is the same as Amazon Access Key in Configuration-Operations-Server-Amazon Settings in the appliance console. Default: blank
amazon_secret	If using Amazon for the authentication mode, specify your Amazon Secret. This is the same as Amazon Secret Key in Configuration-Operations-Server-Amazon Settings in the appliance console. Default: blank
basedn	If using ldap for the authentication mode, specify your Base DN. This is the same as Base DN in Configuration-Operations- Server-LDAP Settings in the appliance console. Default: blank

Parameters	Description
bind_dn	The user name to bind to the LDAP server. This user must have read access to all users and groups that will be used for Infrastructure Automation authentication and role assignment. This is the same as Bind DN in Configuration-Operations-Server-LDAP Settings in the appliance console. Default: blank
bind_pwd:	The password for the bind_dn user. This is the same as Bind Password in Configuration-Operations- Server-LDAP Settings in the appliance console. Default: blank
get_direct_groups	Use this to get the LDAP roles from the LDAP users' home forest. This is the same as Get Roles from Home Forest in the Authentication page for the Infrastructure Automation Server. Default: true
group_memberships_max_depth	When traversing group memberships in the LDAP directory it will stop at this value. Default: 2
ldaphost	Use ldaphost to specify the fully qualified domain name of your LDAP server. This is the same as LDAP Host Name in Configuration-Operations-Server-LDAP Settings in the appliance console. Default: blank
ldapport	Specify the port of your LDAP server. This is the same as LDAP Port in Configuration-Operations- Server-LDAP Settings in the appliance console. Default: 389
mode	Use database to use the VMDB for security. Use ldap or ldaps to use directory services. This is the same as Mode in Configuration-Operations-Server-Authentication in the appliance console. Default: database
user_type	Use userprincipalname to type the user name in the format of user@domainname. Use mail to login with the user's e-mail address. Use dn-cn for Distinguished Name (CN=<user>) or dn-uid Distinguished Name (UID=<user>) to use just the user name, but be sure to enter the proper user_suffix for either one. This is the same as User Type in Configuration-Operations- Server-LDAP Settings in the appliance console. Default: userprincipalname
user_suffix	Domain name to be used with user_type of dn-cn or dn-uid. This is the same as User Suffix in Configuration-Operations- Server-LDAP Settings in the appliance console. Default: blank

Table: coresident_miqproxy

Parameters	Description
use_vim_broker	Specify if you want the coresident SmartProxy to use a shared connection through the VIM broker to communicate with the VC or ESX host for SmartState Analysis. If it is disabled, then each SmartProxy SmartState Analysis would create its own connection. Default: true
concurrent_per_ems	Specify the number of co-resident SmartProxy SmartState Analyses that can be run against a specific management system at the same time. Default: 1
concurrent_per_host	Specify the number of co-resident SmartProxy SmartState Analyses that can be run against a specific host at the same time. Default: 1
scan_via_host	If you change scan_via_host to false, Infrastructure Automation will use the Management System to scan which is limited by the concurrent_per_ems setting instead of the concurrent_per_host setting. Note this will greatly increase traffic to the Management System. Default: true

Table: ems_refresh

Parameters	Description
capture_vm_created_on_date	Set to false to turn off historical event retrieval. Set to true to turn on. By setting the flag to true Infrastructure Automation will try to set the "ems_created_on" column in the vms table after an ems refresh for new VMs and any VMs with a nil "ems_created_on" value. Infrastructure Automation looks at event information in our database as well as looking up historical event data from the management system. This is optional since the historical lookup could timeout. Default: false
collect_advanced_settings	Set to false if you do not want to collect advanced Virtual Machine settings during a management system refresh. This will increase the speed of the refresh, but less data will be collected. If the parameter is not listed, then the value is true. Default: true
ec2	
get_private_images	For EC2 refreshes only; whether or not to retrieve private images. Default: true
get_public_images	For EC2 refreshes only; whether or not to retrieve public images. Default: false. Warning: setting get_public_images to true loads several thousand images in the VMDB by default and may cause performance issues.
get_shared_images	For EC2 refreshes only; whether or not to retrieve shared images. Default: true
public_images_filters	For EC2 refreshes only; a filter to reduce the number of public images. Default: all public images
ignore_terminated_instances	For EC2 refreshes only; whether or not to ignore terminated instances. Default: true
full_refresh_threshold	The number of targeted refreshes requested before they are rolled into a full refresh. For example, if the system and/or the user target a refresh against 7 VMs and 2 Hosts (9 targets), when the refresh actually occurs it will do a partial refresh against those 9 targets only. However, if a 10th had been added, the system would perform a full EMS refresh instead. Default: 100
raise_vm_snapshot_complete_if_created_within:	Raises vm_snapshot_complete event for a snapshot being added to VMDB only if the create time in Virtual Center is within the configured period of time. This prevents raising events for old snapshots when a new VC is added to Infrastructure Automation. Default: 15.minutes
refresh_interval	Scheduler does a periodic full EMS refresh every refresh_interval. Default: 24.hours

Table: host_scan

Parameters	Description
queue_timeout	Time period after which a host SmartState analysis will be considered timed out. Default: 20.minutes

Table: log

Parameters	Description
level	Specify the required level of logging for the Infrastructure Automation appliance. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. This is the same as Log Level in Configuration-Operations-Server-Logging in the appliance console and applies immediately to the evm log. Default: info

Parameters	Description
level_aws	Specify the level of logging for Amazon Web Services communications. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. This applies to the aws log. Default: info
level_aws_in_evm	Specify what level of Amazon Web Services communication log should be also shown in evm log. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. Default: error
level_fog	Specify the level of logging for Fog communications. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. This applies to the fog log. Default: info
level_fog_in_evm	Specify what level of Fog communication log should be also shown in evm log. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. Default: error
level_rails	Specify the level of logging for Rails. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. Once changed, this applies immediately to the production log. Default: info
level_rhevm	Specify the level of logging for Red Hat communications. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. This applies to the rhevm log. Default: warn
level_rhevm_in_evm	Specify what level of Red Hat communication log should be also shown in evm log. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. Default: error
level_vim	Specify the level of logging for VIM (communication with VMware ESX and Virtual Center). Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. This applies to the vim log. Default: warn
level_vim_in_evm	Specify what level of vim logging should be also shown in the evm log. Possible levels from most detailed to least detailed are: debug, info, warn, error, fatal. Default: error

Table: db_stats

Parameters	Description
enabled	Specify if you want to keep track of the number of queries, size of queries, number of responses, size of response, min/max for each, number of established connections at for each server process. This information will show in the EVM log. Default: false
log_frequency	How frequently in seconds the process will log the database statistic in seconds. Default: 60

Table: callsites

Parameters	Description
enabled	Specify if you want keep track of the code that is accessing the database. Enabling call sites will decrease performance because of the amount of information tracked. The db_stats: enabled parameter must be set to true to use this. Default: false
depth	Specify how many levels in the call stack to track for each database access. Default: 10
min_threshold	Do not keep track of code that does not access the database this many times per log_frequency. Default: 10
path	Set the path for the Infrastructure Automation appliance log. This is the same as Log Path in Configuration-Operations- Server-Logging in the appliance console. Default: If no value is present, the path is /var/www/miq/vmdb/log.
line_limit	Limit how many characters are retained in a single log line. 0 means no limit. Default: 0

Table: collection

Parameters	Description
ping_depot	Whether to use TCP port ping to the log depot before performing log collection. Default: true
ping_depot_timeout	Specify how long in seconds to wait for response from log depot before deciding that the TCP port ping failed. Default: 20
current	When collecting logs, specifies what is considered current logging as opposed to archived logging. Default: :pattern: log/*.log log/apache/*.log log/*.txt config/* /var/lib/pgsql/data/*.conf /var/lib/pgsql/data/log/* /var/log/syslog* /var/log/daemon.log* /etc/default/ntp* /var/log/messages* /var/log/cron* BUILD GUID VERSION
archive	Specifies what is considered archived logging. The default pattern is blank which means *.gz files in the log directory.

Table: log_depot

Parameters	Description
uri	Specify the URI for the log depot. This is the same as the URI in **Configuration > Diagnostics > Collect Logs** in the appliance console. Default: blank

Parameters	Description
username	Specify the user name for the log depot. This is the same as the user ID in **Configuration > Diagnostics > Collect Logs** in the appliance console. Default: blank
password	Specify the password for the user for the log depot. This is the same as the password in **Configuration > Diagnostics > Collect Logs** in the appliance console. Default: blank

Table: performance

Parameters	Description
capture_threshold	
vm	Amount of time in minutes to wait after capture before capturing again. Default: 50.minutes
host	Amount of time in minutes to wait after capture before capturing again. Default: 50.minutes
ems_cluster	Amount of time in minutes to wait after capture before capturing again. Default: 50.minutes
storage	Amount of time in minutes to wait after capture before capturing again. Default: 120.minutes
capture_threshold_with_alerts	
host	Amount of time in minutes to wait after capture before capturing again. This value is used instead of capture_threshold for Hosts that have alerts assigned based on real time Capacity & Utilization data. Default: 20.minutes
ems_cluster	Amount of time in minutes to wait after capture before capturing again. This value is used instead of capture_threshold for clusters that have alerts assigned based on real time Capacity & Utilization data. Default: 50.minutes
vm	Amount of time in minutes to wait after capture before capturing again. This value is used instead of capture_threshold for VMs that have alerts assigned based on real time Capacity & Utilization data. Default: 20.minutes
concurrent_requests	
vm	Amount of time in minutes to wait after capture before capturing again. This value is used instead of capture_threshold for VMs that have alerts assigned based on real time Capacity & Utilization data. Default: 20.minutes
hourly	Number of concurrent VC requests to make when capturing hourly raw metrics. Default: 1
realtime	Number of concurrent VC requests to make when capturing real time raw metrics. Default: 20
history	
initial_capture_days	How many days to collect data for on first collection. Default: 0
Keep_daily_performances	How long to keep daily performance data in the VMDB. Default: 6.months
keep_realtime_performances	How long to keep realtime performance data in the VMDB. Default: 4.hours
keep_hourly_performances	How long to keep hourly performance data in the VMDB. Default: 6.months
purge_window_size	When the purge needs to delete rows which are older than the keep_realtime_performances, keep_hourly_performances, and keep_daily_performances values, this value sets how many rows to delete in each batch. For example, a value of 1000 will cause us to issue ten 1,000 row deletes. Default: 1000

Table: repository_scanning

Parameters	Description
defaultsmartproxy	Specify the SmartProxy for repository scanning. This is the same as Default Repository Smartproxy in Configuration-Operations- Server-VM Server Control in the appliance console. Default: blank

Table: server

Parameters	Description
case_sensitive_name_search	Specify if you want the search by name on configuration item screens to be case senstive. Default: false
company	Specify the label you want to use for your company’s tagging. This is the same as Company Name in Configuration-Operations- Server-Basic Info. Default: “My Company”
custom_logo	Specify if you want to use a custom logo. This is the same as Use Custom Logo in Configuration-Custom Logo-Logo Selection. Default: false
events	
disk_usage_gt_percent	For Infrastructure Automation operational alerts, specify at what threshold the disk usage alerts will be triggered. Default: 80
heartbeat_timeout	How long to wait until the server heartbeat is considered timed out. if the timeout is exceeded, other appliances in the zone/region can vie for the roles active on the timed out Infrastructure Automation appliance. Default: 2.minutes
host	Infrastructure Automation Server’s IP address. Default: blank
hostname	Infrastructure Automation Server’s hostname. Default: localhost.localdomain
listening_port	Specify the port number on which the web server is listening. Note that this does not set the port that VMDB listens on. When deploying the SmartHost from the Infrastructure Automation appliance, it tells the SmartHost (miqhost) what port to talk to the VMDB on. Default: “443”
mks_version	Specify the version of the VMware MKS Plugin to use for the VM Console. This is the same as VMware MKS Plugin Version in Configuration-Operations- Server-VM Console. Default : 2.1.0.0
name	Set the name to display for the Infrastructure Automation appliance that you are logged on to in the appliance console. This is the same as appliance Name in Configuration-Operations- Server-Basic Information. Default : EVM

Parameters	Description
role	Specify the roles for this Infrastructure Automation Server, separated by commas without spaces. The possible values are automate, database_operations, ems_inventory, ems_metrics_collector, ems_metrics_coordinator, ems_metrics_processor, ems_operations, event, notifier, reporting, scheduler, smartproxy, smartstate, user_interface, web_services. This is the same as Server Roles in Configuration-Operations- Server- Server Control. Default: database_operations, event, reporting, scheduler, smartstate, ems_operations, ems_inventory, user_interface, web_services
session_store	Where to store the session information for all web requests. The possible values are sql, memory, or cache. SQL stores the session information in the database regardless of the type of database server. Memory stores all the session information in memory of the server process. Cache stores the information in a memcache server. Default: cache
startup_timeout	The amount of time in seconds that the server will wait and prevent logins during server startup before assuming the server has timed out starting and will redirect the user to the log page after login. Default: 300
vnc_port	If using VNC for remote console, the port used by VNC. Default: 5800
zone	Set the Zone for this appliance belongs. This is the same as Zone in Configuration-Operations- Server-Basic Information. Default : default
:worker_monitor	Starts and monitors the workers. Parameters specified here will override those set in the workers:default section.
poll	How often the worker monitor checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 15.seconds
miq_server_time_threshold	How much time to give the server to heartbeat before worker monitor starts to take action against non-responding server. Default: 2.minutes
nice_delta	Tells the worker monitor what Unix “nice” value to assign the workers when starting. A lower number is less nice to other processes. Default: 1
sync_interval	Time interval to sync active roles and configuration for all workers. Default: 30.minutes
wait_for_started_timeout	How long to wait for a started worker to heartbeat before considering the worker timed out. Default: 10.minutes
kill_algorithm	
name	Criteria used to start killing workers. Default: used_swap_percent_gt_value
value	Value of the criteria used. Default: 80
start_algorithm	
name	After server startup, criteria that must be met to decide if the Infrastructure Automation Server can start a new worker. Default: used_swap_percent_lt_value
value	Value of criteria used. Default: 60

Table: session

Parameters	Description
interval	Set the time interval in seconds for checking inactive sessions in appliance console. Default: 60
timeout	Set the time period in seconds in which inactive console sessions are deleted. This is the same as Session Timeout in Configuration-Operations-Server-Authentication in the appliance console. Default: 3600
memcache_server	If you choose memory for session_store, you need to specify the memcache_server to retrieve the session information from. Default: 127.0.1.1:11211
memcache_server_opts	Options to send to memcache server. : blank
show_login_info	Specify whether or not you want to see login info on start page. Default: true

Table: smartproxy_deploy

Parameters	Description
queue_timeout	Timeout for host smartproxy deploy job. Default: 30.minutes

Table: smtp

Parameters	Description
host	Specify the hostname of the smtp mail server. This is the same as Host in Configuration-Operations-Server-Outgoing SMTP E-mail Server. Default: localhost
port	Specify the port of the smtp mail server. This is the same as Port in Configuration-Operations-Server-Outgoing SMTP E-mail Server. Default: “25”
domain	Specify the domain of the smtp mail server. This is the same as Domain in Configuration-Operations-Server-Outgoing SMTP E-mail Server. Default: mydomain.com
authentication	Specify the type of authentication of the smtp mail server. This is the same as Authentication in Configuration-Operations-Server-Outgoing SMTP E-mail Server. Default: login
user_name	Specify the username required for login to the smtp mail server. This is the same as User Name in Configuration-Operations-Server-Outgoing SMTP E-mail Server. Default: evmadmin
password	Specify the encrypted password for the user_name account. This is the same as Password in Configuration-Operations-Server-Outgoing SMTP E-mail Server. Default: blank
from	Set the address that you want to send e-mails from. This is the same as From E-mail Address in Configuration-Operations-Server-Outgoing SMTP E-mail Server. Default: cfadmin@cfserver.com

Table: snapshots

Parameters	Description
create_free_percent	Ensures the % of free space available on the main datastore (datastore where vmx file is located) can support the % growth of the snapshot. The default is to require space for 100% of the provisioned size of all disks that are taking part in the snapshot. A value of 0 means do not check for space before creating the snapshot. Default: 100

Parameters	Description
remove_free_percent	Ensures the % of free space available on the main datastore (datastore where vmx file is located) has the % free space available to support the snapshot deletion process. Note that the deletion process consists of first composing a new snapshot then removing it once the original snapshot to be deleted has been collapsed in the VM. The default is to require 100% of the size of all disks to complete this process. A value of 0 means do not check for space before removing the snapshot. Default: 100

Table: webservices

Parameters	Description
contactwith	Set to ipaddress to contact miqhost using the IP address. Set to hostname to contact miqhost by its hostname. Set to resolved_ipaddress to take the hostname and resolve it to an IP address. Default: ipaddress
mode	Set to invoke to use webservices. Set to disable to turn off webservices. This is the same as Mode in Configuration-Operations- Server-Web Services in the appliance console. Default: invoke
nameresolution	If set to true, the hostname will be resolved to an IP address and saved with the host information in the VMDB. Default: false
security	If Web Services are enabled, you can set this to ws-security. This is the same as Security in Configuration-Operations- Server-Web Services in the appliance console. Note: This is not currently supported. Default: none
timeout	Specify the web service timeout in seconds. Default: 120
password	Specify the encrypted password for the user_name account. This is the same as Password in Configuration-Operations-Server-Outgoing SMTP E-mail Server. Default: blank
use_vim_broker	Controls if the vim_broker is used to communicate with VMware infrastructure. Default: true

Table: workers

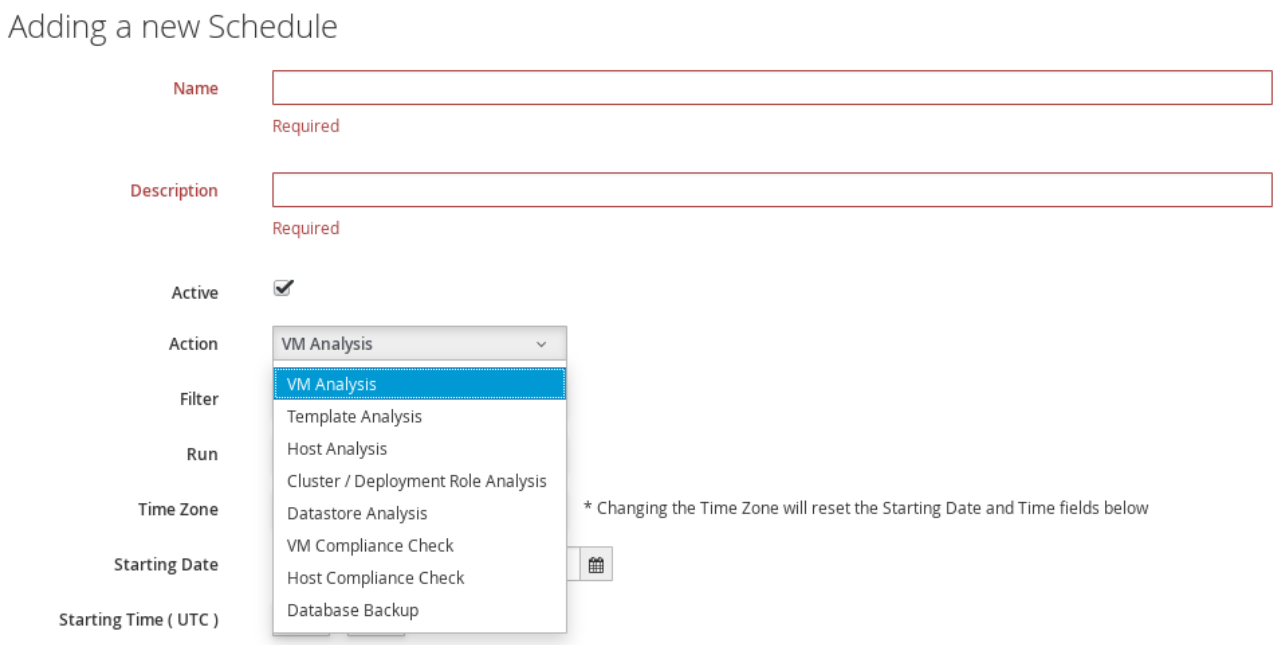
Parameters	Description
worker_base	
defaults	If the following parameters are NOT explicitly defined for a specific worker, then these values will be used.
count	Number of this type of worker. Default: 1
gc_interval	How often to do garbage collection for this worker. Default: 15.minutes
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 3.seconds
poll_method	If set to normal, the worker checks for work the number of seconds set in the poll parameter. If set to escalate, the worker will increase the time between checks when there is no work to be done. Default: normal
poll_escalate_max	The maximum number of time to wait between checks for work. Poll_method must be set to escalate for this option to be used. Default: 30.seconds
heartbeat_freq	How often to “heartbeat” the worker. Default: 60.seconds
heartbeat_method	Set which way to dispatch work. Possible values are sql or drb. Default: drb
heartbeat_timeout	How long to wait until the worker heartbeat is considered timed out. Default: 2.minutes
parent_time_threshold	How long to allow the parent to go without heartbeating before considering the “parent’ not responding. For workers, the worker monitor is the parent. For Worker monitor, the Server is the parent. Default: 3.minutes
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 150.megabytes
nice_delta	Tells the worker monitor what Unix “nice” value to assign the workers when starting. A lower number is less nice to other processes. Default: 10
restart_interval	How long to let a worker remain up before asking it to restart. All queue based workers are set to 2.hours and every other worker does not get restarted by a 0.hours value. Default: 0.hours
starting_timeout	How long to wait before checking a worker’s heartbeat when it is starting up to mark it as not responding, similar to a grace period before you begin monitoring it. Default: 10.minutes
event_catcher	Associated with Event Monitor Server Role. Captures ems events and queues them up for the event_handler to process. Parameters specified here will override those set in the worker_base:default section.
ems_event_page_size	Internal system setting which sets the maximum page size for the event collector history. This should not be modified. Default: 100
ems_event_thread_shutdown_timeout	Internal system setting which determines how long the event catcher at shutdown will wait for the event monitor thread to stop. This should not be modified. Default: 10.seconds
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 2.gigabytes
nice_delta	Tells the worker monitor what Unix “nice” value to assign the workers when starting. A lower number is less nice to other processes. Default: 1
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 1.seconds
event_catcher_redhat	Contains settings that supersede the event_catcher for event_catcher_redhat.
event_catcher_vmware	Contains settings that supersede the event_catcher for event_catcher_vmware.
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 1.seconds
event_catcher_openstack	Contains settings that supersede the event_catcher for event_catcher_openstack.
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 15.seconds
topics	List of AMQP topics that should be monitored by Infrastructure Automation when gathering events from OpenStack.

Parameters	Description
duration	Qpid Specific. Length of time (in seconds) the receiver should wait for a message from the Qpid broker before timing out. Default: 10.seconds
capacity	Qpid Specific. The total number of messages that can be held locally by the Qpid client before it needs to fetch more messages from the broker. Default: 50.seconds
amqp_port	Port used for AMQP. Default: 5672
schedule_worker	Settings for Scheduler Server Role and any other work that runs on a schedule. Parameters specified here will override those set in the worker_base:default section.
db_diagnostics_interval	How frequently to collect database diagnostics statistics. Default: 30.minutes
job_proxy_dispatcher_interval	How often to check for available SmartProxies for SmartState Analysis jobs. Default: 15.seconds
job_proxy_dispatcher_stale_message_check_interval	How often to check for the dispatch message in the queue Default: 60.seconds
job_proxy_dispatcher_stale_message_timeout	Kill a message if this value is reached. Default: 2.minutes
job_timeout_interval	How often to check to see if a job has timed out. Default: 60.seconds
license_check_interval	How often to check for valid license. Default: 1.days
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 150.megabytes
nice_delta	Tells the worker monitor what Unix “nice” value to assign the workers when starting. A lower number is less nice to other processes. Default: 3
performance_collection_interval	Controls how often the schedule worker will put performance collection request on the queue to be picked up by the collection worker. Default: 3.minutes
performance_collection_start_delay	How long after Infrastructure Automation Server has started before starting capacity and utilization collection, if collection needs to be done. Default: 5.minutes
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 15.seconds
server_logs_stats_interval	How often to log the Infrastructure Automation Server statistics. Default: 5.minutes
server_stats_interval	How often to collect the Infrastructure Automation Server statistics. Default: 60.seconds
session_timeout_interval	How often to check to see if a UI (appliance console) session has timed out. Default: 30.seconds
storage_file_collection_interval	How often to perform file inventory of storage locations. Default: 1.days
storage_file_collection_time_utc	What time to perform file inventory of storage locations. Default: “06:00”
vdi_refresh_interval	How often to refresh vdi inventory. Default: 20.minutes
vm_retired_interval	How often to check for virtual machines that should be retired. Default: 10.minutes
vm_scan_interval	How often to check virtual machines to see if scan needs to be done. Default: 10.minutes
smis_refresh_worker	Settings for Storage Inventory Server Role and any other work that runs on a schedule. Parameters specified here will override those set in the worker_base:default section
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 15.seconds
connection_pool_size	Maximum number of database connections allowed per process. Default: 5
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 1.gigabytes
nice_delta	Tells the worker monitor what Unix “nice” value to assign the workers when starting. A lower number is less nice to other processes. Default: 3
smis_update_period	How frequently to update smis information. Default: 1.hours
status_update_period	How frequently to update smis status. Default: 5.minutes
stats_update_period	How frequently to update smis statistics. Default: 10.minutes
vim_broker_worker	Launched for any of these roles: Capacity & Utilization Collector, SmartProxy, SmartState Analysis, Management System Operations, Management System Inventory. Also launched if the use_vim_broker setting is on. Provides connection pooling, caching of data to and from the VMware infrastructure. Parameters specified here will override those set in the workers:default section.
heartbeat_freq	How often to heartbeat the worker. Default: 15.seconds
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 1.gigabytes
nice_delta	Tells the worker monitor what Unix “nice” value to assign the workers when starting. A lower number is less nice to other processes. Default: 3
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 1.seconds

Parameters	Description
reconnect_retry_interval	Period after which connection is retried. Default: 5.minutes
vim_broker_status_interval	Internal system setting which configures how much time to wait after receiving event updates before checking for more updates. Default: 0.seconds
wait_for_started_timeout	Time between the worker's preload and startup time before considering the worker timed out. Default: 10.minutes
ui_worker:	Settings for User Interface Server Role. Parameters specified here will override those set in the worker_base:default section.
connection_pool_size	Maximum number of database connections allowed per process. Default: 5
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 1.gigabytes
nice_delta: 1	Tells the worker monitor what Unix "nice" value to assign the workers when starting. A lower number is less nice to other processes. Default: 1
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 60.seconds
web_service_worker	Settings for Web Services Server Role. Parameters specified here will override those set in the worker_base:default section.
connection_pool_size	Maximum number of database connections allowed per process. Default: 5
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 1.gigabytes
nice_delta	Tells the worker monitor what Unix "nice" value to assign the workers when starting. A lower number is less nice to other processes. Default: 1
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 60.seconds
queue_worker_base	Base class of all queue workers that work off of the queue..
defaults	If the following parameters are NOT explicitly defined for a queue worker, then these values will be used.
cpu_usage_threshold	How much cpu to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 100.percent
queue_timeout	How long a queue message can be worked on before it is considered timed out. Default: 10.minutes
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 400.megabytes
restart_interval	Queue workers restart interval. Default: 2.hours
poll_method	If set to normal, the worker checks for work the number of seconds set in the poll parameter. If set to escalate, the worker will increase the time between checks when there is no work to be done. Default: normal
generic_worker	Performs work that is not classified as any specific type of work. Processes all normal priority or non-specific queue items. Parameters specified here will override those set in the queue_worker_base:default section
count	Number of this type of worker. Default: 4
ems_refresh_worker	Performs all ems (management system) refreshes to keep the vmdb in sync with the state of the components of the virtual infrastructure in the various management systems. Parameters specified here will override those set in the queue_worker_base:default section
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 10.seconds
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 2.gigabytes
nice_delta	Tells the worker monitor what Unix "nice" value to assign the workers when starting. A lower number is less nice to other processes. Default: 7
restart_interval	Queue workers restart interval. Default: 2.hours
queue_timeout	How long a message can be worked on before it is considered timed out. Default: 120.minutes
event_handler	Associated with Event Monitor Server Role. Handles all events caught by the event catcher worker. Parameters specified here will override those set in the workers:default section. Parameters specified here will override those set in the queue_worker_base:default section
cpu_usage_threshold	How much cpu to allow the worker to grow to before gracefully requesting it to exit and restart. The value of 0 means that this worker will never be killed due to CPU usage. Default: 0.percent
nice_delta	Tells the worker monitor what Unix "nice" value to assign the workers when starting. A lower number is less nice to other processes. Default: 7
perf_collector_worker	Connects to VC/ESX to collect the raw performance data. Same as the Capacity & Utilization Data Collector Server Role. Parameters specified here will override those set in the queue_worker_base:default section count. Number of this type of worker. Default: 2
count	Number of this type of worker. Default: 2
poll_method	If set to normal, the worker checks for work the number of seconds set in the poll parameter. If set to escalate, the worker will increase the time between checks when there is no work to be done. Default: escalate
nice_delta	Tells the worker monitor what Unix "nice" value to assign the workers when starting. A lower number is less nice to other processes. Default: 3
perf_processor_worker	Processes the raw performance data into a reportable format. Same as the Capacity & Utilization Data Processor Server Role. Parameters specified here will override those set in the queue_worker_base:default section
count	Number of this type of worker. Default: 2
poll_method	If set to normal, the worker checks for work the number of seconds set in the poll parameter. If set to escalate, the worker will increase the time between checks when there is no work to be done. Default: escalate
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 400.megabytes
nice_delta	Tells the worker monitor what Unix "nice" value to assign the workers when starting. A lower number is less nice to other processes. Default: 7
priority_worker	Performs all high priority queue items including many tasks on behalf of the UI. UI requests are normally executed by a priority worker so they will not to block the UI. Parameters specified here will override those set in the queue_worker_base:default section
count	Number of this type of worker. Default: 2
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 200.megabytes

Parameters	Description
nice_delta	Tells the worker monitor what Unix “nice” value to assign the workers when starting. A lower number is less nice to other processes. Default: 1
poll	How often the workers checks for work. This value only is only used when the worker has no more work to do from the queue. It will wait for an amount of time determined by the poll value and poll method. Therefore, if there is constant work on the queue, the worker will not wait in between messages. Default: 1.seconds
reporting_worker	Compiles reports. Settings for Reporting Server Role. Parameters specified here will override those set in the queue_worker_base:default section
count	Number of this type of worker. Default: 2
nice_delta	Tells the worker monitor what Unix “nice” value to assign the workers when starting. A lower number is less nice to other processes. Default: 7
smart_proxy_worker	Performs the embedded scanning of virtual machines. Settings for SmartProxy Server Role. Parameters specified here will override those set in the queue_worker_base:default section
count	Number of this type of worker. Default: 3
memory_threshold	How much memory to allow the worker to grow to before gracefully requesting it to exit and restart. Default: 600.megabytes
queue_timeout	How long a queue message can be worked on before it is considered timed out. Default: 20.minutes
restart_interval	Queue workers restart interval. Default: 2.hours

Schedules



Scheduling SmartState Analyses

From the **Schedules** area in **Settings**, you can schedule the analyses of virtual machines, hosts, clusters, and datastores to keep the information current. Depending on which resource you want to analyze, you can filter which ones to analyze. You may also specify only one virtual machine or perform an analysis on all virtual machines. In addition, you can schedule compliance checks, and database backups.

Scheduling a SmartState Analysis or Compliance Check

To schedule a SmartState Analysis or Compliance Check:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Schedules**.
3. Click (**Configuration**), and (**Add a new Schedule**).
4. In the **Basic Information** area, type in a **Name** and **Description** for the schedule.
5. Select **Active** to enable this scan.
6. From the **Action** list, select the type of analysis to schedule. Based on the type of analysis you choose, you are presented with one of the following group boxes:

- **VM Analysis**: Displays **VM Selection** where you can choose to analyze **All VMs**, **All VMs for Provider**, **All VMs for Cluster**, **All VMs for Host**, **A single VM**, or **Global Filters**.
- **Template Analysis**: Displays **Template Selection** where you can choose to analyze **All Templates**, **All Templates for Provider**, **All Templates for Cluster**, **All Templates for Host**, **A single Template**, or **Global Filters**.
- **Host Analysis**: Displays **Host Selection** where you can choose to analyze **All Hosts**, **All Hosts for Provider**, **A single Host**, or **Global Filters**.

Note:

You can only schedule host analyses for connected virtual machines, not repository virtual machines that were discovered through that host. Since repository virtual machines do not retain a relationship with the host that discovered them, there is no current way to scan them through the scheduling feature. The host is shown because it may have connected virtual machines in the future when the schedule is set to run.

- **Cluster / Deployment Role Analysis**: Displays **Cluster Selection** where you can choose to analyze **All Clusters**, **All Clusters for Provider**, or **A single Cluster**.
- **Datastore Analysis**: Displays **Datastore Selection** where you can choose to analyze **All Datastores**, **All Datastores for Host**, **All Datastores for Provider**, **A single Datastore**, or **Global Filters**.
- **VM Compliance Check**: Displays **VM Selection** where you can choose to analyze **All VMs**, **All VMs for Provider**, **All VMs for Cluster**, **All VMs for Host**, **A single VM**, or **Global Filters**.
- **Host Compliance Check**: Displays **Host Selection** where you can choose to analyze **All Hosts**, **All Hosts for Provider**, **All Hosts for Cluster**, **A single Host**, or **Global Filters**.
- **Database Backup**: Under **Type**, displays **Network File System**, **Samba**, **Amazon AWS S3** and **OpenStack Swift**..

7. By applying **Global Filters** within any of the above items, you can designate which virtual machines or hosts to analyze.
8. In **Run**, set the frequency of the analysis to run. There are further options based on which **Run** option you choose.
   - Click **Once** to have the analysis run only one time.
   - Click **Daily** to run the analysis on a daily basis. You will be prompted to select the number of days between each analysis.
   - Click **Hourly** to run the analysis hourly. You will be prompted to select the number of hours between each analysis.
9. Select a **Time Zone**.

   Note:

   If you change the **Time Zone**, you will need to reset the stating date and time.
10. Type or select a date to begin the schedule in **Starting Date**.
11. Select a **Starting Time** based on a 24 hour clock in the selected Time Zone.
12. Click **Add**.

Modifying a Schedule

To modify a schedule:

1. Browse to **Settings > Application Settings**.
2. Click on the **Settings** accordion, then click **Schedules**.
3. Click the schedule that you want to edit.
4. Click (**Configuration**), and then click (**Edit this Schedule**).
5. Make the required changes.
6. Click **Save**.

Importing and Exporting Schedules

Infrastructure Automation provides the ability to import and export schedules using the **`import_export_schedules.rb`** script:

```
./var/www/miq/vmdb/tools/import_export_schedules.rb -h
```

Option	Description
-u, –user=<s>	userid (default: admin)
-d, –output-dir=<s>	Output directory (default: ./)
-s, –schedule=<s>	Schedule name or id
-o, –operation=<s>	Export or import (default: export)
-y, –import-yaml=<filename/uri>	Imported yaml
-h, –help	Show this message

Usage Example.

Import:

```
./var/www/miq/vmdb/tools/import_export_schedules.rb -o import -y ./filename.yaml
```

Export:

```
./var/www/miq/vmdb/tools/import_export_schedules.rb -s 158
```

Note that the **`import_export_schedules.rb`** script works for all types of schedules, including:

- Report
- Policy
- Alert
- SmartState Analysis
- Automation Task
- Service Template

Access Control

Browse to **Settings > Application Settings**. Click on the **Access Control** accordion to see a hierarchy of the configurable items for users, groups, roles, and tenants. You can add and modify users, groups, account roles, tenants, and projects.

Creating a Tenant

Tenants are used in Infrastructure Automation for controlling visibility of objects.

To create a tenant:

1. Browse to **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Tenants**.
3. Click on the top-level **Tenant**, click (**Configuration**), and (**Add child Tenant to this Tenant**) to create a tenant.
4. Enter a name for the tenant in the **Name** field.
5. Enter a description for the tenant in the **Description** field.
6. Click **Add**.

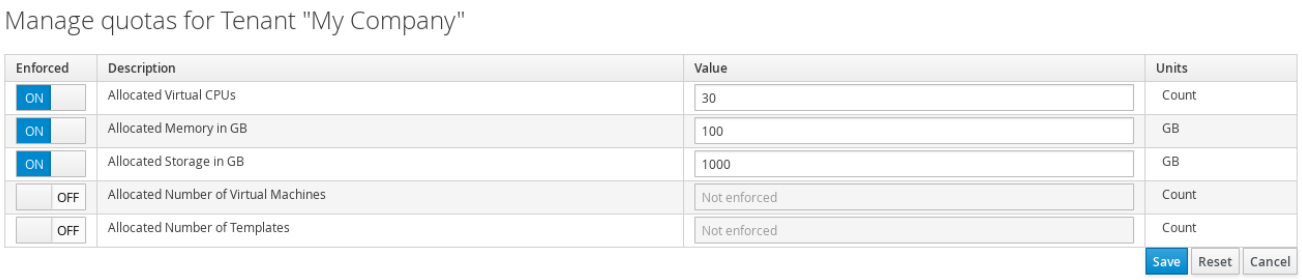
Creating a Project

A tenant can also contain a self-contained child tenant known as a 'project'. A project cannot have a child tenant, but it is useful for allocating resources to a small group or team within a larger organization.

To create a project:

1. Browse to **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Tenants**.
3. Click on the **Tenant** where you want to add a **Project**, click (**Configuration**), and (**Add Project to this Tenant**) to create a project.
4. Enter a name for the project in the **Name** field.
5. Enter a description for the project in the **Description** field.
6. Click **Add**.

Managing Tenant and Project Quotas



Use the following procedure to allocate or edit quotas for tenants and projects.

Note:

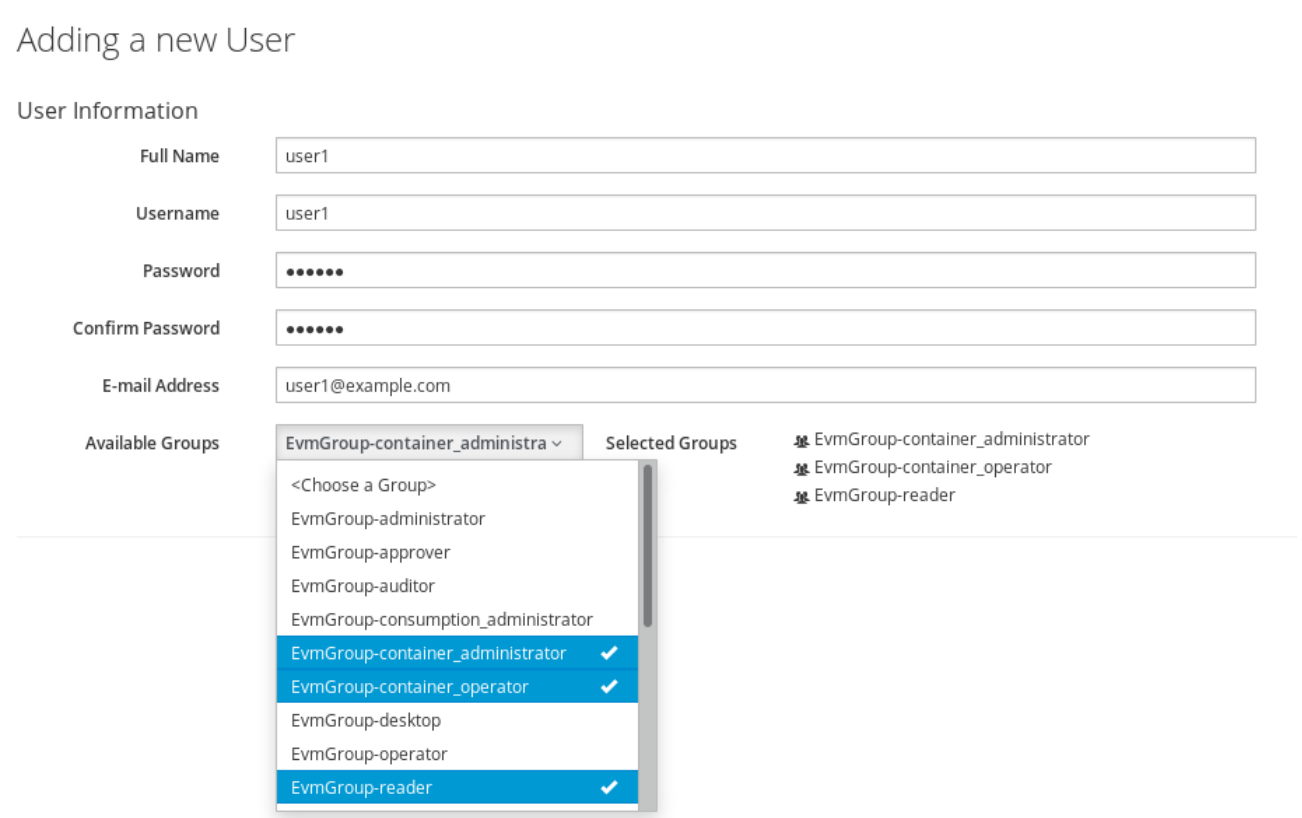
Quota is allocated based on the user's current group. If the user belongs to multiple groups, you must change to the desired group before allocating or editing group quota. See Groups for more details.

1. Browse to **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Tenants**.
3. Click on the **Tenant** or **Project** where you want to add a quota, click (**Configuration**), and (**Manage quotas for the Selected Item**) to create a quota.
4. In the list of pre-built quotas, switch **Enforced** next to the quota item you want to enable to `Yes`.

5. In the **Value** field, enter the constraints you want to apply to the quota.

6. Click **Save**.

Tagging Tenants and Projects



To tag tenants and projects:

1. Browse to **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Tenants**.
3. Select the tenant or project, then click **Policy**, and select **Edit My Company Tags for this Tenant**.
4. In **Tag Assignment**, click **Select a customer tag to assign**, and select a tag from the list. In the next column, set a corresponding value.
5. Click **Save**.

Creating a User

To create a user:

1. Browse to **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Users**.
3. Click (**Configuration**), and (**Add a new User**) to create a user.
4. Enter a **Full Name**, **Username**, **Password** with confirmation, and **Email Address** for the user. An email address is required; omitting the user email address can result in unsuccessful provisioning requests.

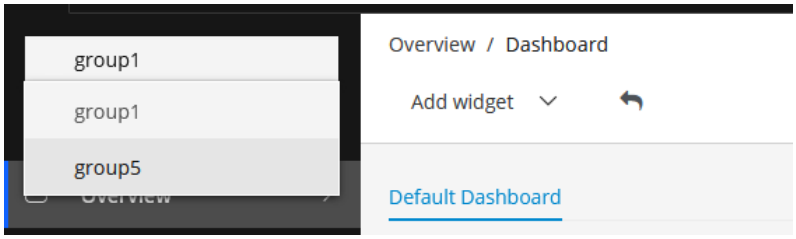
- If you are using LDAP, but did not enable **Get User Groups from LDAP** in your server's **Authentication** tab, you will need to define a user. The UserID must match exactly the user's name as defined in your directory service. Use all lowercase characters to ensure the user can be found in the VMDB. - When the user logs in, they use their LDAP password.

5. Select one or more groups from **Available Groups**.
6. Click **Add**.

Deleting a User

For security reasons, delete any user that no longer needs access to the information or functions of the server.

To delete a user:

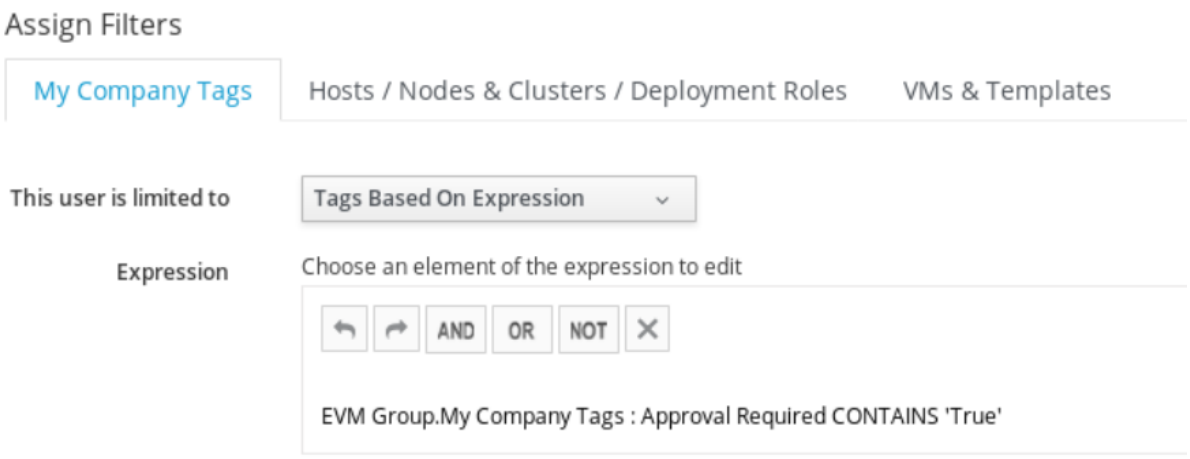


1. Browse to **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Users**.
3. Select the user you want to delete.
4. Click (**Configuration**), and (**Delete selected Users**) to delete a user.

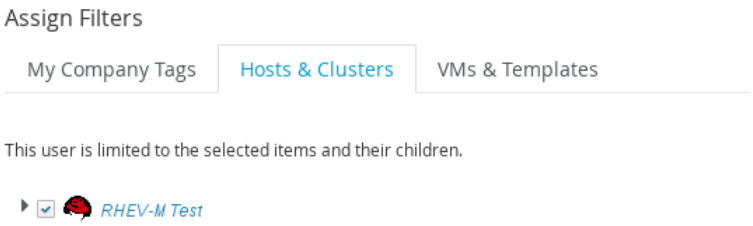
Groups

User groups create filters and assign roles to users. You can either create your own groups, or leverage your LDAP directory service to assign groups of users to account roles. For a list of what each pre-defined account role can do, see Roles.

A user can exist in multiple groups. However, a group can only be assigned one account role.



If you belong to multiple groups, you can change the current group. The Current Group affects quota and other settings for the user, including permissions for controlling the tasks that you can complete and the data that you can view. To change the group, click the group name in the upper left of the screen, and select your preferred group from the listed groups.

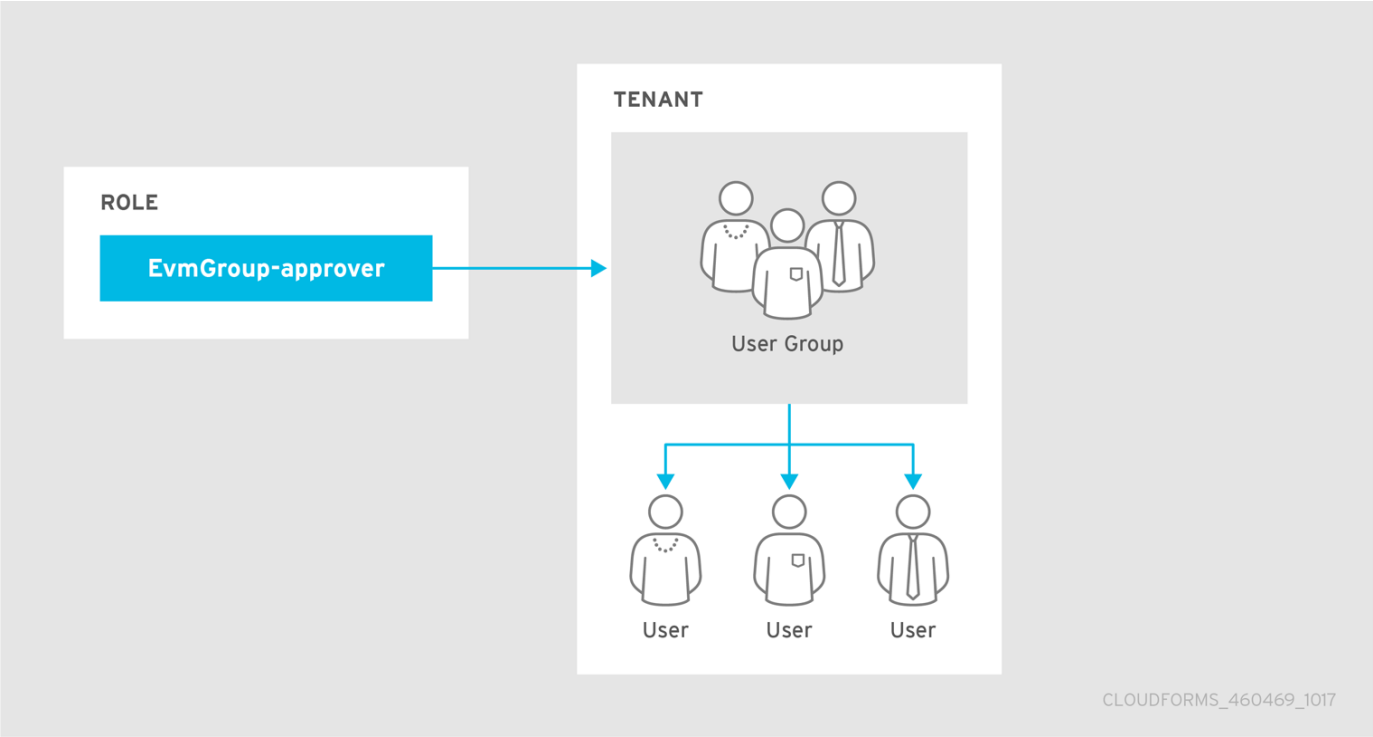


Creating a Group

To create a user group:

1. Browse to **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Groups**.
3. Click (**Configuration**), and (**Add a new Group**) to create a group.
4. Enter a name for the group in the **Name** field. To ensure compatibility with tags, use underscores in place of spaces. For example, Infrastructure Automation-`test_group`.
5. Select a **Role** to map to this group. For a description of each Infrastructure Automation role, see Account Roles and Descriptions.
6. Select the **Project/Tenant** this group must belong to.
7. Limit what users in this group can view by selecting filters in the **Assign Filters** area.
    1. Click the **<My Company> Tags** tab to select the tags that users in this group can access. Resources with the selected tags attached can be accessed by this group. Select tags using one of the options in the **This user is limited to** list:
        - Select **Specific Tags**, then check the boxes for the tags that you want to limit this user to. The items that have changed will show in blue italicized font.
        - Select **Tags Based On Expression**, then create tags based on an expression using AND, OR, or NOT. This allows you to further limit the resources accessible to a user: for example, to specify a combination of tags that must exist on a resource.

2. Click the **Host & Clusters** tab.
    1. Check the boxes for the host and clusters that you want to limit this user to. The items that have changed will show in blue italicized font.



3. Click the **VMs & Templates** tab. This shows folders that you have created in your virtual infrastructure.
    1. Check the boxes for the folders that you want to limit this user to. The items that have changed will show in blue italicized font.
8. Click **Add**.

After creating a group, assign one or more users to the group by editing a user.

Roles

When you create a group, you must specify a role to give the group rights to resources in the console. The group's role determines the scope of access for the users that are members of the group.

Infrastructure Automation provides a default group of roles, but you can also create your own, or copy and edit the default groups.

Note:

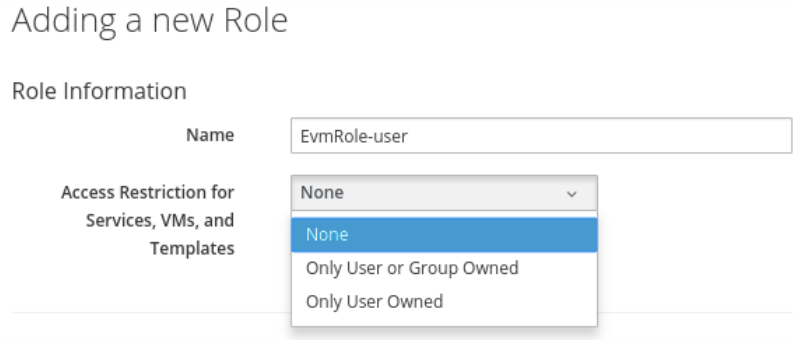
If you have enabled **Get Role from LDAP** under **LDAP Settings**, then the role is determined by the LDAP user's group membership in the directory service.

To view details of a role and its level of access:

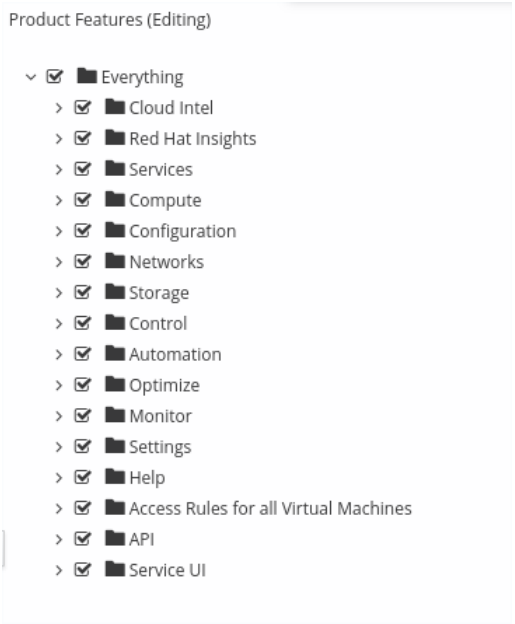
1. Browse to **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Roles**.
3. Click on a role from the list to display role information and the product features the role can access (marked by a checkmark). You can expand the categories under **Product Features** to see further detail.

The table below shows a summary of the functions available to each role.

Account Roles and Descriptions



Role	Description
Administrator	Administrator of the virtual infrastructure. Can access all infrastructure functionality. Cannot change server configuration.
Approver	Approver of processes, but not operations. Can view items in the virtual infrastructure, view all aspects of policies and assign policies to policy profiles. Cannot perform actions on infrastructure items.
Auditor	Able to see virtual infrastructure for auditing purposes. Can view all infrastructure items. Cannot perform actions on them.
Container Administrator	Administrator with capabilities to configure, view and execute tasks on all containers and related underlying infrastructure. Has access to Nodes, Pods and Projects dashboards.
Container Operator	This role can view and execute tasks related to containers and related underlying infrastructure. The Container Operator has access to locked versions of the same dashboards as the Container Administrator.
Desktop	Access to VDI pages.
Operator	Performs operations of virtual infrastructure. Can view and perform all functions on virtual infrastructure items including starting and stopping virtual machines. Cannot assign policy, but can view policy simulation from Virtual Machine page.
Security	Enforces security for the virtual environment. Can assign policies to policy profiles, control user accounts, and view all parts of virtual infrastructure. Cannot create policies or perform actions on virtual infrastructure.
Super Administrator	Administrator of Infrastructure Automation and the virtual infrastructure. Can access all functionality and configuration areas.
Support	Access to features required by a support department such as diagnostics (logs). Can view all infrastructure items and logs. Cannot perform actions on them.
Tenant Administrator	Configures settings applicable to a Tenant. Sets Branding, maps groups/roles, configures LDAP credentials, and configures dashboard settings.
Tenant Quota Administrator	Configures quota limits for the tenant, applying usage constraints for CPU, Memory, Storage, Maximum number of VMs, and Maximum number of Templates.
User	User of the virtual infrastructure. Can view all virtual infrastructure items. Cannot perform actions on them.
User Limited Self Service	Limited User of virtual machines. Can make provision requests. Can access some functions on the virtual machine that the user owns including changing power state.



Role	Description
User Self Service	User of virtual machines. Can make provision requests. Can access some functions on the virtual machine that the user owns and that the user's LDAP groups own including changing power state.
Vm User	User of virtual machines. Can access all functions on the virtual machine including changing power state and viewing its console. Cannot assign policy, but can view policy simulation from virtual machine page.

Creating a Role

To create a role:

1. Click **Settings > Application Settings**.
2. Click on the **Access Control** accordion, then click **Roles**.
3. Click **Configuration**, and **Add a new Role**. Alternatively, you can copy an existing role to a new role by clicking **Copy the selected Role to a new Role**.
4. In the **Role Information** area, type a name for the new role. For **Access Restriction for Catalog Items, Orchestration Stacks, Key Pairs, Services, VMs, and Templates**, select if you want to limit users with this role to only see resources owned by the user or their group, owned by the user, or all resources (**None**):

5. Under **Product Features (Editing)**, navigate to the appropriate feature and enable or disable it:
6. Click **Add**.

Diagnostics

Browse to **Settings > Application Settings**. Click on the **Diagnostics** tab to see the status of the different Infrastructure Automation roles and workers for each server, view and collect logs, and gather data if there are any gaps in capacity and utilization information. The Diagnostics area is designed in a hierarchy.

- At the **region** level, you can see replication status, backup the VMDB, and run garbage collection on the VMDB.
- At the **zone** level, you can see Infrastructure Automation roles by servers and servers by roles. In addition, you can set log collection values for a specific zone, and collect gap data for capacity and utilization.
- At the **server** level, you can see the workers for each server, set log collection values for a specific server, and view current logs.

Region Diagnostics

Using the console, you can set the priority of server regional roles, review and reset replication, and create backups of your database either on demand or on a schedule.

Regions are used primarily to consolidate multiple VMDBs into one master VMDB for reporting while zones are used to define functional groups of servers. There can be only one region per VMDB, but multiple zones per region (or VMDB). Some server roles are aware of each other across Infrastructure Automation appliances at the region level. This means that redundancy and failover rules apply at the region level. You can also set priorities for the server roles that provide failover.

Server Role Priorities

If you have multiple servers in your environment with duplicate failover roles, then you can set the priority of the server role.

- Only server roles that support failover can be marked as primary. These roles only allow one server to be active at a time. These are **Notifier**, **Capacity & Utilization Coordinator**, **Event Monitor**, **Scheduler**, **Storage Inventory**, and **Provider Inventory**.
- All other server roles are additive. The more servers with that role in a zone the more work that can be performed.

There are three role priorities.

- **Primary**: There can only be one primary per zone or region per role. When an appliance is started, the system looks to see if any role is set to primary. If that is the case, the role is activated on that appliance and deactivated from the secondary. In the console, primary roles are shown in bold letters. The text turns red if the server goes down. You must actively set the primary priority.
- **Secondary**: This is the default priority. There can be multiple secondaries. When an appliance is started, if no primary is found in the zone, the first appliance to start takes the role. In the console, secondary roles are displayed normally with the word “secondary”.
- **Tertiary**: If all appliances with primary roles or secondary roles were down, one of the tertiary would be activated. The reason for tertiary is to ensure that if a server with crucial roles such as Provider Inventory or Event Monitor goes down, you have a way to associate those roles to different appliances by organizing the priorities. Tertiary roles simply show as active in the console.

Region Aware Server Roles

Role	More than one per Region	Can have Priority Set
Automation Engine	Y	N
Database Operations	Y	N
Notifier	N	Y
Reporting	Y	N
Scheduler	N	Y
User Interface	Y	N
Web Services	Y	N

Setting the Priority of a Failover Role

To set the priority of a failover role:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Depending on how you want to view your servers, click either the **Roles by Servers** tab or the **Servers by Roles** tab.
4. In the **Status** of **Roles for Servers** in **Zone Default Zone** area, click on the role that you want to set the priority for.
5. Click  (**Configuration**), and  (**Promote Server**) to make this the primary server for this role.
6. Click  (**Configuration**), and  (**Demote Server**) to demote the priority of this server for this role.

Zone Diagnostics

The console provides a way to see all the server roles that a server has been assigned and if these roles are running. This is especially helpful when you have multiple servers with different server roles. For each zone you can also set a central place for all logs to be collected, and collect capacity and utilization data that may be missing.

Viewing the Status of Server Roles

To view the status of server roles:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Depending on how you want to view your servers, click either **Roles by Servers** or the **Servers by Roles**.

Zone Aware Server Roles

Role	More than one per Region	Can have Priority Set
Automation Engine	Y	N
Capacity & Utilization Coordinator	N	Y
Capacity & Utilization Data Collector	Y	N
Capacity & Utilization Data Processor	Y	N
Database Operations	Y	N

Role	More than one per Region	Can have Priority Set
Event Monitor	N	Y
Provider Inventory	N	Y
Provider Operations	Y	N
Notifier	N	Y
Reporting	Y	N
Scheduler	N	Y
SmartProxy	Y	N
SmartState Analysis	Y	N
User Interface	Y	N
Web Services	Y	N

Removing an Inactive Server

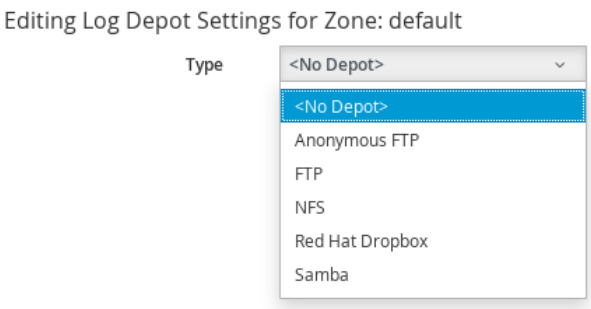
To remove an inactive server:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Click on the name of the server in the tree view.
4. Click (**Delete Server**). This button is available only if the server is inactive.

Zone Log Collections

If you have multiple servers reporting to one central VMDB, then you can collect the configuration files and logs from the console of any of the servers. While you can set this either at the zone or server level, settings at the server level supersede the ones at the zone level.

Log depot options include:



- Anonymous File Transfer Protocol (FTP)
- File Transfer Protocol (FTP)
- Network File System (NFS)
- Red Hat Dropbox
- Samba

See your network administrator if you need to set up one of these shares. You will also need a user that has write access to that location.

Setting the Location of the Log Depot

To set the location of the log depot:

1. Browse to **Settings > Application Settings**.
2. Click the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Click **Collect Logs**.
4. Click (**Edit**).
5. Select the **Type** of share.
6. Using the fully qualified domain name (**FQDN**) of the depot server, type in the appropriate settings for the **URI**.

7. If required, enter your user **ID** and **password** then click **Validate** to confirm the settings.
8. Click **Save**.

Collecting and Downloading Logs from All Servers in a Zone

To collect and download logs from all servers in a zone:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Click the **Collect Logs** tab.
4. Click (**Collect all logs**). All files in the logs directory as well as configuration files are collected from the selected zone.
5. Click **OK**. The status of the log retrieval shows in the Infrastructure Automation console.

Capacity and Utilization Repair

Under certain circumstances, it is possible that Infrastructure Automation is not able to collect capacity and utilization data. This could be due to password expiration, a change in rights to the cloud provider and this change didn't provide enough granularity to the Infrastructure Automation service account, or network connectivity. The gap data is collected directly by extracting the monthly performance data. Gap collection need to be completed for each zone individually. Therefore, the procedure below need to be repeated for each zone.

Repairing Capacity and Utilization Data

To repair capacity and utilization data:

1. Log in to a Infrastructure Automation appliance located in the zone for which you want to gather the data.
2. Browse to **Settings > Application Settings**.
3. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
4. Click **C & U Gap Collection**.
    1. Select the appropriate **Timezone**.

       Note:

       Do not select more than one week unless instructed to do so by Red Hat Support.

    2. Select a **Start Date**.
    3. Select an **End Date**.
5. Click **Submit**.

After the gap collection has completed for this zone, repeat these same steps for the next zone. You can check for completion by going to the clusters page and checking for the capacity and utilization data for the time period specified.

Server Diagnostics

Under **Diagnostics** for a server, you can view the status of Infrastructure Automation workers running on the server, set log collection setting for only that server, and view the server's current Infrastructure Automation and audit logs.

Workers

The **Workers** tab enables you to see the status of and restart Infrastructure Automation workers.

You can see additional information on and restart the following items:

- **C & U Metrics Collectors** that collects capacity and utilization data.
- **C & U Metrics Processors**, which processes the collected capacity and utilization data.
- **Event Handlers** put events from the Event Monitor into the VMDB and starts Infrastructure Automation processes if needed base on that information.
- **Event Monitors** that communicate with the external cloud provider to deliver up to date event information.
- **Generic Workers** that perform long running and priority processes.
- **Priority Workers** that perform high priority, short processes.
- **Schedule Workers** that maintains any items that run on a schedule.
- **Session Broker** that maintains a single connection to the cloud providers .
- **Refresh Workers** that runs the refresh processes.
- **Reporting Workers** that generate reports.
- **SmartProxy Workers** that run SmartState Analyses on virtual machine.
- **User Interface Worker** that allows users access to the console.
- **Web Services Worker** that maintains Infrastructure Automation Web services.
- **VM Analysis Collectors** that run and process SmartState Analyses on virtual machines.

Reloading Worker Display

To reload worker display:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to view.
4. Click the **Workers** tab.
5. Click  (**Refresh Current Workers display**).

Restarting a Worker

To restart a worker:

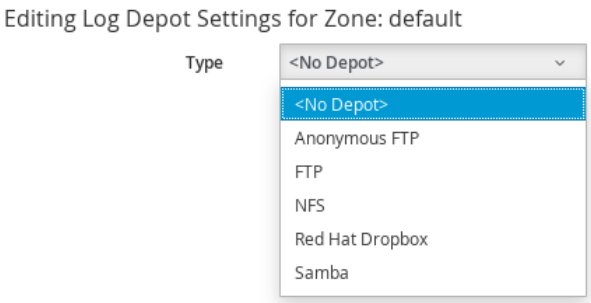
1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to view.
4. Click on the **Workers** tab.
5. Click on the worker you want to restart.
6. Click  (**Configuration**), then  (**Restart selected worker**).
7. Click **OK**.

Server and Audit Logs

Collecting Server Logs and Configuration Files

While you can designate a central location to collect logs for all servers in a specific zone, you can override those values for a specific server. To do this, designate a log depot location to store the files.

Log depot options include:



- Anonymous File Transfer Protocol (FTP)
- File Transfer Protocol (FTP)
- Network File System (NFS)
- Red Hat Dropbox
- Samba

See your network administrator to set up one of these shares. You also need a user that has write access to that location. Settings at the server level supersede the ones at the zone level.

Setting the Location of the Log Depot for a Specific Server

To set the location of the log depot for a specific server

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to collect logs for.
4. Click on the **Collect Logs** tab.
5. Click  (**Edit Log Depot Settings for the selected Server**).
6. Select the **Type** of share.

7. Using the fully qualified domain name (**FQDN**) of the depot server, type in the appropriate settings for the **URI**.
8. Enter your user ID and password, then click **Validate** to confirm the settings.
9. Click **Save**.

Collecting the Current Log Set of a Server

To Collect the Current Log Set of a Server

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to collect logs for.
4. Click on the **Collect Logs** tab.
5. Click (**Collect**), then click (**Collect current logs**). All current log files in as well as configuration files are collected.
6. Click **OK**. The status of the log retrieval shows in the Infrastructure Automation console.

Collecting All Log Sets from a Server

To Collect All Log Sets from a Server

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to collect logs for.
4. Click **Collect Logs**.
5. Click (**Collect**), then click (**Collect all logs**). All files in the logs directory as well as configuration files are collected.
6. Click **OK**. The status of the log retrieval shows in the Infrastructure Automation console.

Viewing the Server, Audit, and Production Logs

The server and audit logs roll over daily. The previous logs are stored as zipped files in the `/var/www/miq/vmdb/log` folder. The current logs can be easily viewed and downloaded from the settings menu; select **Configuration**, then click on the **Diagnostics** accordion.

Use the server log to see all actions taken by the server including communication with the SmartProxy and tasks.

Viewing the Server Log

To view the server log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to view.
4. Click **CFME Log**.

The Infrastructure Automation server automatically retrieves the last 1000 lines of the log.

Reloading the Server Log

To reload the server log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.

3. Select the server that you want to view.
4. Click **CFME Log**.
5. Click (Reload the Log Display).

Downloading the Server Log

To download the server log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to view.
4. Click **CFME Log**.
5. Click (**Download the Entire EVM Log File**).

Note:

Use the **Audit Log** to see changes to the user interface and authentication.

Viewing the Audit Log

To view the audit log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to view.
4. Click **Audit Log**.

The server automatically retrieves the last 1000 lines of the log.

Reloading the Audit Log

To reload the audit log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to view.
4. Click **Audit Log**.
5. Click (**Reload the Audit Log Display**).

Downloading the Audit Log

To download the audit log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the Zone that you want to view.
3. Select the server that you want to view.
4. Click Audit Log.
5. Click (**Download the Entire Audit Log File**).

Viewing the Production Log

Use the production log to see all actions performed using the console.

To view the production log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to view.
4. Click **Production Log**.

The Infrastructure Automation server automatically retrieves the last 1000 lines of the log.

Reloading the Production Log

To reload the production log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the Zone that you want to view.
3. Select the server that you want to view.
4. Click **Production Log**.
5. Click  (**Reload the Product Log Display**).

Downloading the Production Log

To download the production log:

1. Browse to **Settings > Application Settings**.
2. Click on the **Diagnostics** accordion, then click the **Zone** that you want to view.
3. Select the server that you want to view.
4. Click **Production Log**.
5. Click  (**Download the Production Log File**).

Database Operations

Viewing Information on the VMDB

The **Database** accordion displays a summary of VMDB information, a list of all tables and indexes, settings for the tables, active client connection, and database utilization.

To view information on the VMDB:

1. Browse to **Settings > Application Settings**.
2. Click the **Database** accordion.
3. Click **VMDB** in the tree view on the left.
4. Click the appropriate tab to view the desired information:
   - **Summary**: displays statistics about the database.
   - **Tables**: displays a clickable list of all the tables.
   - **Indexes**: displays a clickable list of all the indexes.
   - **Settings**: displays a list of all tables, their descriptions, and other valuable Information.
   - **Client Connections**: displays all current connections to the VMDB.
   - **Utilization**: displays usage charges for the disk and index nodes.

Database Regions and Replication

Regions are used to create a central database for reporting and charting. Do not use the database at the top level for operational tasks such as SmartState analysis or capacity and utilization data collection. Assign each server participating in the region a unique number during the regionalization process, then set your subordinate regions to replicate to the top region.

Important

All Infrastructure Automation databases in a multi-region deployment must use the same security key.

Creating a Region

In principle, a region is created when you set up your Infrastructure Automation environment on the first appliance for the region. However, you can also create a region on an appliance where a database has already been set up. This process involves dropping and rebuilding the existing database to accommodate the new region number, and takes several minutes to complete.

Warning

Performing this procedure destroys any existing data and cannot be undone. Back up the existing database before proceeding. By default, new appliances are assigned region 0. Do not use this number when creating a region because duplicate region numbers can compromise the integrity of the data in the database.

1. Log in to the appliance as the **root** user.
2. Enter **`appliance_console`**, and press **Enter**.
3. Press any key.
4. Select **`Stop EVM Server Processes`**.

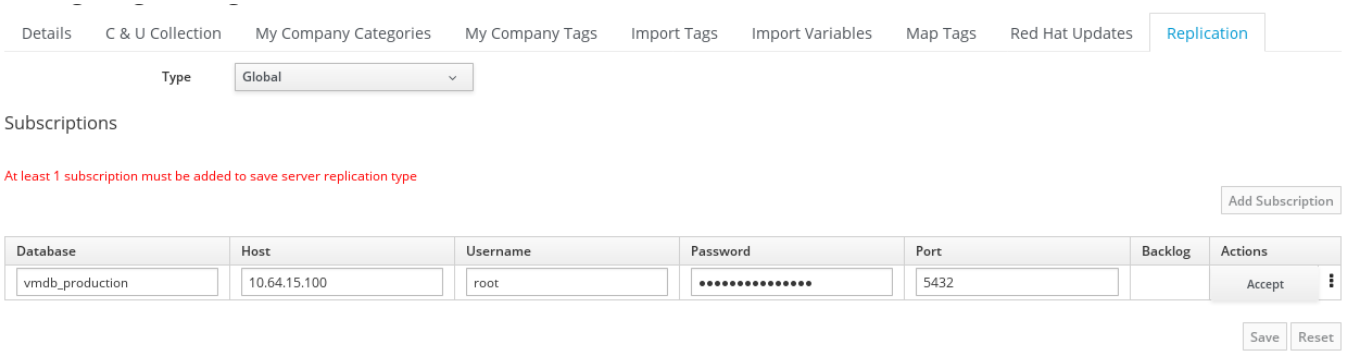
5. Enter **`Y`** to confirm.
6. Choose **`Configure Application`**.
7. Enter a database region number that has not been used in your environment. Do not enter duplicate region numbers because this can corrupt the data.
8. Enter **`Y`** to confirm.
9. The menu reappears after all processes are complete.
10. Select **`Start EVM Server Processes`**.
11. Enter **`Y`** to confirm.
12. Select **Quit** to exit the advanced settings menu.

Configuring Database Replication and Centralized Administration

To configure database replication, you must configure one Infrastructure Automation instance to act as a global copy, and one or more other instances to act as remote copies. This database replication relationship can only be configured on Infrastructure Automation instances that are of the same version. Configuring database replication in this version of Infrastructure Automation automatically enables centralized administration, eliminating the need for further configuration. Centralized administration in Infrastructure Automation supports life cycle management operations that can be initiated from the global copy and processed and executed on the remote copy.

Important

- You must configure at least one remote copy before you can configure the global copy. Changes to the role of a Infrastructure Automation instance take several minutes to take effect.
- The region number must be unique on each Infrastructure Automation instance where replication is configured. See Creating a Region for instructions on how to create a region.
- Enabling the **`EvmRole-user_global_region`** role will only provide access to specific operations that can be performed on a global region.



Configuring a Remote Copy

Configure a Infrastructure Automation instance to act as a remote copy from which data will be replicated to the global copy.

1. Browse to **Settings > Application Settings**.
2. Click the **Settings** accordion.
3. Click the region where the instance is located.
4. Click **Replication**.
5. Select **Remote** from the **Type** list.
6. Click **Save**.

Configuring the Global Copy

Configure a Infrastructure Automation instance to act as the global copy to which data is replicated from the remote copies.

1. Click **Configuration**.
2. Click the **Settings** accordion.
3. Click the region where the instance is located.
4. Click **Replication**.
5. Select **Global** from the **Type** list.
6. Click **Add Subscription**.
    1. Enter the name of the database on the remote copy in the **Database** field.

2. Enter the IP address or fully qualified domain name of the remote copy in the **Host** field.
3. Enter the name of a database user able to access the database in the **Username** field.
4. Enter the password of the database user in the **Password** field.
5. Enter the port by which the database is accessed in the **Port** field.
6. In **Actions**, click **Accept**. You can also **Update** your subscription if required, or click the menu on the right in order to **Validate** or **Discard**.

7. Click **Save**.

Note:

Once you configure a Infrastructure Automation instance to act as a global copy, and one or more other instances to act as remote copies: * centralized administration is automatically enabled after the initial data sync is complete. * you will see the type of region you are logging into (global or remote) on the Infrastructure Automation user interface login screen.

Database replication and centralized administration are now enabled on your instances. To open virtual machines of a remote region from the global region and perform required operations:

1. Browse to menu: **Compute < Infrastructure < Virtual Machines**, then click **VMs & Templates** and select a virtual machine in the global region.
2. In the **Multi Region** table on the summary screen, click **Connect to VM in its Region** to perform required operations in a new browser tab.

Resetting Database Replication

You can reset the replication relationship between the global copy and remote copies by temporarily removing and re-enabling the subscription from the global copy.

1. Browse to **Settings > Application Settings**.
2. Click the **Settings** accordion.
3. Click the region where the instance is located.
4. Click **Replication**.
5. Remove the subscription:
    1. Click the actions button for the subscription to reset.
    2. Click **OK**.
6. Click **Save**.
7. Re-add the subscription:
    1. Click **Add Subscription**.
    2. Enter the name of the database on the remote copy in the **Database** field.
    3. Enter the IP address or fully qualified domain name of the remote copy in the **Host** field.
    4. Enter the name of a database user able to access the database in the **Username** field.
    5. Enter the password of the database user in the **Password** field.
    6. Enter the port by which the database is accessed in the **Port** field.
8. Click **Save**.

Backing Up and Restoring Infrastructure Automation in a Kubernetes Based Environment (podified)

Prerequisites:

- Velero and Restic must be installed and working in your cluster. For more information on Velero, see the Velero documentation. For more information on Restic, see the Restic documentation

Note: The operator adds labels and/or annotations to everything that needs to be backed up. You can easily and quickly backup only what is required. The operator will add annotations for restic volume backups for example, `backup.velero.io/backup-volumes: <volume-label>`.

1. The backup label key can be configured by adding the following to the CR. The default label is applied if no value is specified for `backupLabelName`.

```
...
spec:
  ...
  backupLabelName: <your label name>
```

2. Create a backup by running the command:

```
velero backup create <your backup name> --include-namespaces <your namespace> -l <your label name>=t
```

3. In order to restore a backup, first ensure the Infrastructure Automation CRD exists. Then, restore the backup by running the commands:

```
oc new-project <your namespace>
velero restore create --from-backup <your backup name>
```

Backing Up and Restoring a Database for an Appliance Based Environment

Running a Single Database Backup

Infrastructure Automation supports database backups to **Network File System (NFS)**, **Samba**, **Amazon Web Service(AWS) S3** and **OpenStack Swift** storage.

Note:

Database backups to **AWS S3** require valid AWS credentials to perform this operation.

To run a single database backup:

1. Browse to **Settings > Application Settings**.
2. Click the **Diagnostics** accordion and click the **Region** name.
3. Click the **Database** tab.
4. If you have created a backup schedule and want to use the same depot settings, select the schedule in the **Backup Schedules** box.
5. If you do not want to use the settings from a backup schedule, select a type of server for storing the backups from the Type drop-down list in the **Database Backup Settings** box. You can use **Network File System** (NFS), **Samba** or **AWS S3**.
    - If you select **Samba**, enter the **Depot Name**, **URI**, **Username**, and a valid **Password**. Click **Validate** to check the settings.
    - If you select **AWS S3**, enter the **Depot Name**, **URI**, and select the **AWS Region** from the drop-down list. Enter the **Username**, and a valid **Password**. Click **Validate** to check the settings.
    - If you select **OpenStack Swift**, enter the **Depot Name**, **URI**, **Security Protocol** and **API Port**. Enter the **Username**, and a valid **Password**. Click **Validate** to check the settings.
    - If you select **Network File System**, enter the **URI**.
6. Click **Submit** to run the database backup.

Restoring a Database from a Backup

If a database is corrupt or fails, restore it from a backup. You can restore a backup from a local file, NFS, or Samba.

To restore a database from a backup:

1. Save the database backup file as **`/tmp/evm_db.backup`**. Infrastructure Automation looks specifically for this file when restoring a database from a local backup.
2. If you are restoring a database backup on a high availability environment, stop the replication manager service (**`repmgr13.service`**). This is not required in other Infrastructure Automation configurations.

   ```
   # systemctl stop repmgr13.service
   ```
3. Log in to the appliance as the **root** user.
4. Enter **`appliance_console`**, and press **Enter**.
5. Select **`Stop EVM Server Processes`** to stop processes on all servers that connect to this VMDB.
6. Enter **`Y`** to confirm.
7. After all processes are stopped, press **Enter** to return to the menu.
8. Press **Enter** again to manually configure settings.
9. Select **`Restore Database From Backup`**, then specify the location to restore the backup from in the **`Restore Database File`** menu:
    1. If you saved the database backup file locally as **`/tmp/evm_db.backup`**, select **`Local file`**. You can also restore from a **`Network File System (nfs)`** or **`Samba (smb)`**.
    2. Specify the location of the backup file.

       Note:

       The appliance console menu may respond slowly if connections are open and the server is still shutting down. If this occurs, wait a minute and try again.
10. Enter **`Y`** to keep the database backup after restoring from it. Enter **`N`** to delete it.
11. Press **`Y`** to confirm.
12. After the backup completes, press **Enter** to return to the menu.
13. Press **Enter** again to manually configure settings.
14. Select **`Start EVM Server Processes`** to restart all processes on servers that connect to this VMDB.
15. Enter **`Y`** to confirm.

16. If you are restoring a database backup on a high availability environment, start the replication manager service (**repmgr13.service**). This is not required in other Infrastructure Automation configurations.

    ```
    # systemctl start repmgr13.service
    ```

Performing a Binary Backup and Restoring the Database

Preserve data at the file system level by performing a binary backup. This includes all databases, users and roles, and other objects.

Note:

This procedure uses the **pg_basebackup** utility to perform a remote database backup and create a full replacement of the PostgreSQL data directory, capturing the exact state of the database when the backup finishes. For more information on the **pg_basebackup** utility, see the PostgreSQL documentation.

Performing a Binary Backup

Create a binary backup and store it as a **gzip** tar file inside the Infrastructure Automation backup directory.

A PostgreSQL superuser or user with *Replication* permissions are required to perform this procedure.

1. SSH into the database server as the **root** user or provide PostgreSQL superuser credentials.
2. Run the **pg_basebackup** command to create the backup:

   ```
   # pg_basebackup -X fetch -h hostname -U root -Ft -z -D filename
   ```

   Note:

   -h *hostname* specifies the IP address of the database server.

   -D *filename* specifies the name of the directory created to contain the backup.

Restoring a Database from the Binary Backup

Restore your PostgreSQL binary backup using the following steps. This process will require stopping both EVM and PostgreSQL services before restoring data.

1. Copy the existing backup to the target VM:

   ```
   # scp filename/base.tar.gz root@hostname:/var/www/miq
   ```

2. SSH to the target VM:

   ```
   # ssh root@hostname
   ```

3. Stop both the EVM and PostgreSQL servers:

   ```
   # systemctl stop evmserverd
   # systemctl stop $APPLIANCE_PG_SERVICE
   ```

4. Rename the existing data directory:

   ```
   # mv /var/lib/pgsql/data /var/lib/pgsql/data.backup
   ```

5. Create a clean data directory:

   ```
   # mkdir /var/lib/pgsql/data
   ```

6. Unzip the tar file to the new directory:

   ```
   # tar -xzf /var/www/miq/base.tar.gz -C /var/lib/pgsql/data
   ```

7. Correct permissions:

   ```
   # chown postgres:postgres /var/lib/pgsql/data
   # chmod 700 /var/lib/pgsql/data
   ```

8. Restart the PostgreSQL and EVM servers:

   ```
   # systemctl start $APPLIANCE_PG_SERVICE
   # systemctl start evmserverd
   ```

Running Database Garbage Collection

The database server collects garbage automatically, but Red Hat may occasionally direct you to run database garbage collection manually in order to reclaim unused space in your VMDB.

To run database garbage collection:

1. Browse to **Settings > Application Settings**.
2. Click the **Diagnostics** accordion and click the **Region** name.
3. Click the **Database** tab.
4. In the **Run Database Garbage Collection Now** box, click **Submit**.

Changing the Database Password

Use the following procedures to change the password on appliances containing an internal database, and on worker appliances.

To change the password for an external database, use the procedure in Changing the Password on the Worker Appliances.

Note:

See Appliance Types in the *Deployment Planning Guide* for a summary of different types of appliances.

Changing the Password on the Database Appliance

Infrastructure Automation provides a default database password for the internal PostgreSQL database.

To change the password, you need to stop the Infrastructure Automation service, change the password for the PostgreSQL database, run a command to change the password in the configuration file that **evmserverd** uses to access the server, and restart the Infrastructure Automation appliance.

1. Stop the Infrastructure Automation service:
    1. SSH into the appliance.
    2. To stop the Infrastructure Automation service, run the following command:

       ```
       service evmserverd stop
       ```
2. Use **pgadmin** to change the password for your Infrastructure Automation database (default is **vmdb_production**). If you do not have **pgadmin**, you can change the password by running:

   ```
   psql -U root -d vmdb_production
   ```
    1. At the vmdb# prompt, type:

       ```
       ALTER USER root WITH PASSWORD 'newpassword';
       ```
    2. To exit **psql**, type:

       ```
       \q
       ```
3. Change the password in the configuration file that **evmserverd** uses to access the server:

   ```
   /var/www/miq/vmdb/tools/fix_auth.rb --databaseyml --password newpassword
   ```
4. Restart the Infrastructure Automation service:

   ```
   service evmserverd start
   ```
5. Verify that you can log in to the Infrastructure Automation console.

Changing the Password on the Worker Appliances

1. Stop the Infrastructure Automation service:
    1. SSH into the appliance.
    2. To stop the Infrastructure Automation service, run the following command:

       ```
       service evmserverd stop
       ```
2. Change the password in the configuration file that **evmserverd** uses to access the server:

   ```
   /var/www/miq/vmdb/tools/fix_auth.rb --databaseyml --password newpassword
   ```
3. Restart the Infrastructure Automation service:

   ```
   service evmserverd start
   ```

   In a high availability environment, if using the same PostgreSQL user for replication, you must also change the password in the `/var/lib/pgsql/.pgpass` file on every database node. Additionally, if the password for the user being used for region-to-region replication is changing, users must also change the password in the replication subscription screen. See [Configuring the Global Copy](#configuring-the-global-copy).

Adding a New Appliance to an Existing Region with a Non-default Password

1. Create the new appliance.
2. Start the appliance, but do not go into any of the configuration options, instead **SSH** into the new appliance.
3. In the **/var/www/miq/vmdb** directory, create a file called **REGION**. Its only contents should be the number of the Region that it is joining. (You could also just copy the **REGION** file from the VMDB appliance.)
4. Edit the **database.yml** file in the **/var/www/miq/vmdb** directory. (You may want to save from the original.)
    1. Replace the contents of the **“production”** section with the contents of the **“base”** section.
    2. Edit the **“host”** parameter to match the IP of the appliance hosting the VMDB.
    3. Save the new **database.yml**.

5. Run the following command to change the password in the configuration file that **evmserverd** uses to access the server:

   ```
   /var/www/miq/vmdb/tools/fix_auth.rb --databaseyml --password newpassword
   ```

6. Restart the new worker appliance:

   ```
   service evmserverd restart
   ```

Creating a Database Dump

Creating a database dump from the appliance console can be used to provide additional information when raising a support case. Options exist to generate a database dump excluding specified tables and to split the database dump into multiple parts.

Database dumps require name or location information based on the **Dump Output File Name** selection:

Local File	Location
Network File System (NFS)	Location
Samba (SMB)	Location
Amazon S3	Name
File Transfer Protocol (FTP)	Location
ftp to dropbox.redhat.com	Name

To create a database dump:

1. SSH into the appliance console as **root**.
2. Press any key to continue.
3. Type **appliance_console** and press **Enter**.
4. From the Advanced Settings, select option 5, **Create a Database Dump**.
5. Select a **Dump Output File Name** from the list.
6. Enter the location or name to save the dump file to.
7. (Optional) Select tables to exclude from the dump:
   1. Enter **Y** to exclude tables. Select **N** to skip the operation.
   2. Enter the table names in a space-separated list:

      ```
      metrics_* vim_performance_states event_streams
      ```

8. (Optional) Split the database dump output into multiple parts:
   1. Enter **Y** to split the database dump output. Select **N** to skip the operation.
   2. Enter the size to split by, ex **250M** or **1G**.

The database dump is created and sent to the specified location.

Enabling Events Syndication

You can enable events syndication in the **Advanced** settings:

1. From the menu, go to **Settings > Application Settings**.
2. Expand the **Settings** accordian. When you select the **Settings** accordion, you are automatically taken to the server list under **Zones**.
3. Select the zone where the EVM server is located, and select the EVM server.
4. Click the **Advanced** tab.

   You can click the **Advanced** tab at the zone level to set advanced configuration settings for the entire zone. Or, you can click on the server, and then click the **Advanced** tab to set advanced configuration settings at the server (appliance) level, which overrides zone-level settings.

5. Find the following configuration:

   ```
   :event_streams:
     :history:
       :keep_events: 6.months
       :purge_window_size: 1000
     :syndicate_events: false
   ```

6. Set the value for `:syndicate_events:` to **true**.
7. Click **Save**.

Enabling Inventory Syndication

You can enable inventory syndication in the **Advanced** settings:

1. From the menu, go to **Settings** > **Application Settings**.
2. Expand the **Settings** accordion. When you select the **Settings** accordion, you are automatically taken to the server list under **Zones**.
3. Select the zone where the EVM server is located and select the EVM server.
4. Click the **Advanced** tab.

   You can click the **Advanced** tab at the zone level to set advanced configuration settings for the entire zone. Or, you can click on the server, and then click the **Advanced** tab to set advanced configuration settings at the server (appliance) level, which overrides zone-level settings.
5. Find the following configuration:

```
:ems_refresh:
 :full_refresh_threshold: 100
 :syndicate_inventory: false
 :raise_vm_snapshot_complete_if_created_within: 15.minutes
 :refresh_interval: 24.hours
```

6. Set the value for `syndicate_inventory` to `true`.

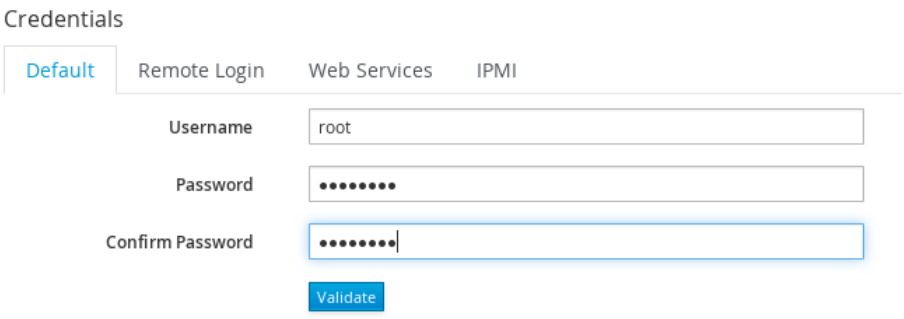
SmartProxies

The embedded SmartProxy can analyze virtual machines that are registered to a host and templates that are associated with a provider.

Installing the SmartProxy from the Console

The server comes with one SmartProxy version already available. It can also be installed on an ESX Server version 3.0.2, 3.5 or 4.

Contact Red Hat before installing a new SmartProxy on an ESX Server.
Requirements:



- On ESX, SSH (Secure Shell) must be enabled. This is usually port 22.
- 300 MB free disk space to install and run the SmartProxy.
- Administrator or root credentials.
- The host must already be in the VMDB either by discovery or manually.

Entering Credentials and Operating System for the Target Host

Set the credentials and operating system for the target host to prepare for the installation of SmartProxy.

To Enter Credentials and Operating System for the Target Host:

1. Browse to menu: **Compute > Infrastructure > Hosts**.
2. Select the host you want to edit.
3. Click **Configuration**, then  **Edit Selected items**.
4. In **Credentials**, click the **Default** tab and enter your login credentials. If you are using domain credentials, the format for User ID must be in the format of `<domainname>\<username>`. For ESX hosts, if SSH login is disabled for the default user, click the **Remote Login** tab and enter a user with remote login access.

   If the target is a Windows host, disconnect all network connections between the Windows proxy and the target. If an existing connection uses a different set of credentials than those set in the console, the installation may fail.
5. Click **Validate** to verify the credentials.
6. If you added the host manually instead of **Host Discovery** or **Provider Refresh** finding it, select the host's operating system from the **Host Platform** drop-down box to ensure the host platform is available.
7. Click **Save**.

When remotely installing on Windows hosts, the SmartProxy file is first copied to a Windows proxy. That computer then installs the file to the target host. The Windows proxy is the same as when you select the Default Repository SmartProxy box. You can locate this by navigating to the settings menu and selecting

Configuration, then clicking on the desired server, then the **Server** tab, and exploring the **Server Control** area.

About

Click the question mark icon () at the top right of the Infrastructure Automation user interface to open a dropdown menu with links to Infrastructure Automation documentation and the Red Hat Customer Portal, and for information about the current Infrastructure Automation session.

- Click **Documentation** to open a list of guides. Click the title of a document to view it as a PDF in a new web browser tab.
- Click **Red Hat Customer Portal** to open the Red Hat Customer Portal in a new web browser tab.
- Click **About** to open a pop-up window showing information about the Infrastructure Automation version and the session of the logged-in user.

Default Roles

This section outlines the default roles provided in Infrastructure Automation and the product features to which they are granted access.

Self Service User Interface Guide

Infrastructure Automation Self Service

Infrastructure Automation Self Service is a web-based graphical user interface for ordering and managing IT service requests. You can enable self-service tenant end users, who can easily access their services, track requests, and manage their accounts using the Self Service user interface (SSUI), which has widgets, dashboard controls and feedback. The Self Service user interface supports role-based access control (RBAC) of menus and features, similar to in the full administrative user interface.

Note:

All catalog items, dialogs, buttons, icons among other items must be configured in the full administrative user interface before they are available to users in the Self Service user interface.

Accessing the Self Service User Interface

The Self Service user interface is running by default and does not need to be started or configured. To access the Self Service user interface, you must know the host name (or IP address) of the appliance, and the login credentials.

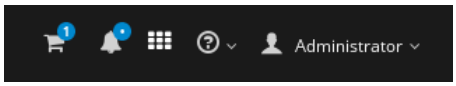
Self Service URL:

`https://HOSTNAME/ui/service/`

You can choose your preferred language for the Self Service user interface from the options in the **Language** list available on the login screen. The following languages are supported:

- English
- Español (Spanish)
- Français (French)
- 日本語 (Japanese)
- 한국어 (Korean)
- Nederlands (Dutch)
- Português (Portuguese)

- Português do Brasil (Brazilian Portuguese)
- 简体中文 (Simplified Chinese)
- Traditional Chinese



Additionally, the *User Default* and *Browser Default* options default to the language already set by the user or browser respectively.

Navigating the Self Service User Interface

The Self Service user interface has a slideout navigation menu on the left that can be minimized by clicking the menu icon (≡), like in the full administrative user interface. The slideout navigation menu comprises of the following tabs:

- **Dashboard**
- **My Services**
- **My Orders**
- **Service Catalogs**

The menu bar that runs along the top of the user interface contains several options including a shopping cart, notifications feature, full administrative user interface option, and a help option. Besides that, you can see the current logged in LDAP user, for example, **Administrator**.

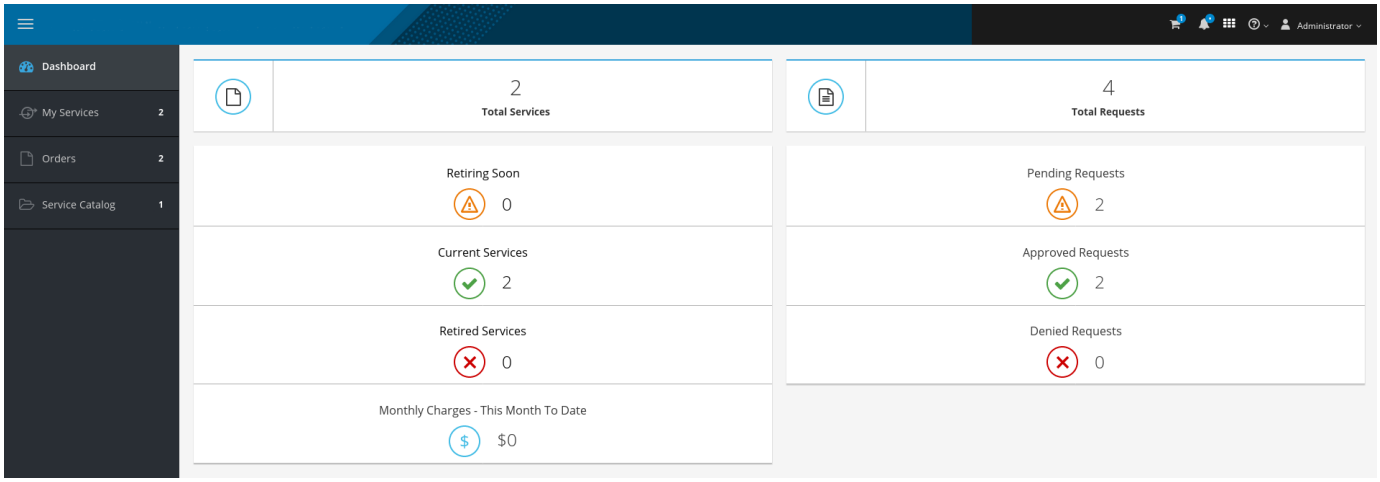
- Shopping Cart Click the shopping cart icon to view services that are available to order, manage your cart as required, and order all services at one time. You can read more about the shopping cart model adopted in the Self Service user interface under ???.
- Notifications The Self Service user interface has introduced a new notifications feature that displays messages generated by the system for various events, such adding services to the shopping cart, ordering services, provisioning, service power operations, and so on. Click the bell icon to open or close the **Notifications** drawer, which shows various notification events. You can click the double arrows («) located on the upper-left of the **Notifications** drawer to expand or contract the size of the **Notifications** screen as required.
- Administration User Interface Link Clicking the menu icon ( ) shows the **Administration UI** link, which when clicked, takes you to the full administrative user interface login page in a new window or tab of your web browser.
- Help Click the help icon to access the options to open **Documentation**, **Red Hat Customer Portal**, and **About**. Click **About** to see information about your Self Service environment, such as the logged in user name and role, the browser details, and importantly, the Self Service user interface version number, which can be useful for support purposes.

Note:

The resources linked to in the help icon will be, by default, the ones listed above. System administrators can change them to other resources as required for the logged in user.

- Role-Based Access Control The Self Service user interface supports role-based access control of menus and features. If you are a member of multiple user groups, you can change the acting group by navigating to ***Administrator***

  Change Group, then select the new group from the available options in the list.



- Switch Language Although you can set your preferred language for the user interface from the login screen itself, you can switch to a different language than what is currently set also by navigating to ***Administrator***

  Switch Language within the Self Service user interface.

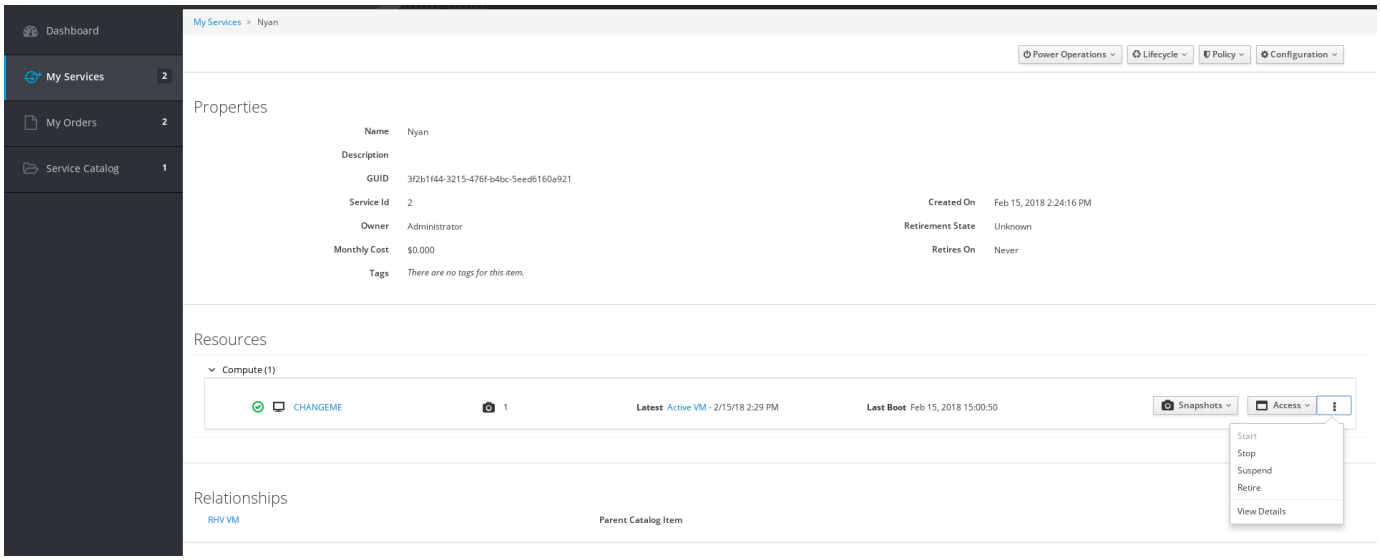
Dashboard Tab

Once you log in to the Self Service user interface, you will see the dashboard screen by default. The **Dashboard** tab provides a quick summary of the services available, requests made, and their statuses as below:

- Total Services
- Current Services
- Services Retiring Soon
- Retired Services
- Total Requests
- Pending Requests
- Approved Requests
- Denied Requests

- Monthly Charges - This Month To Date The Self Service user interface has added basic support for displaying monthly chargeback data of the computing and storage cost for the use of resources, in the currencies supported by the full administrative user interface. This provides a quick summary of where you are from cost standpoint to that point in the month. For more information about configuring chargeback rates in the full administrative user interface and how Infrastructure Automation calculates chargeback costs, see Chargeback in the *Monitoring, Alerts, and Reporting* guide.

Note:



If you are on the first day of the month, there can be no data yet therefore resulting in zero dollar amount. Also, if you have a lot of data, it might not have rolled into the new month yet, resulting in no data and dollar amount for month to date.

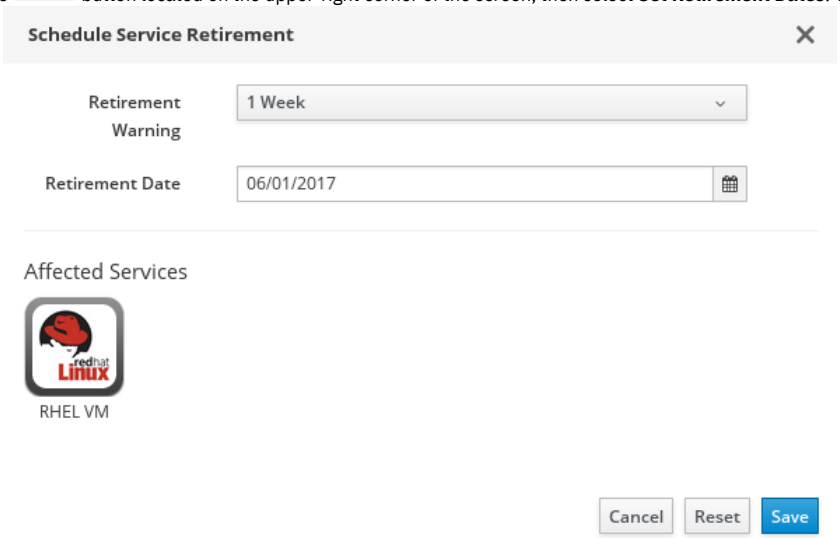
My Services Tab

The **My Services** tab lists all service requests individually with a summary of information associated with each service, including the **Service Name**, its current **Power State** represented by an icon, **Number of VMs**, **Owner**, date **Created**, and **Retires** date. Additionally, you can see the chargeback cost per service for a virtual machine's month-to-date usage. You can filter or sort services by those entities, and by **Relative Cost**.

On the same screen, you have the option to edit the service name and description, edit tags, set ownership, retire the service now or at a later date, or remove the service by clicking more options *(represented by three dots)* next to the service. You also have options to perform power operations, that is start, stop, or suspend, at the service level. You can choose to click on a service where you can perform all of these actions at the service level using the designated buttons located at the top of the screen, as well as access the virtual machine dashboard, manage snapshots, and open the virtual machine and web console from under the **Resources** section. You can also control power operations and life cycle of virtual machine resources via more options *(represented by three dots)*.

Virtual Machine Dashboard:.

From the **My Services** screen, click on a service and then on the virtual machine name or **View Details** under more options *(represented by three dots)* to access the virtual machine dashboard. The dashboard displays the following information about the virtual machine resource:



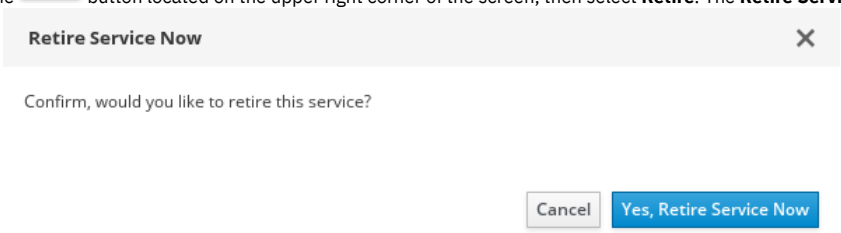
- Compliance
- Retirement
- Snapshots
- Timeline of power events
- Utilization of CPU, Memory, and Storage
- Smart State analysis
- Tags
- Custom attributes
- Disk usage

Additionally, you can also control the virtual machine power operations, and manage snapshots from the dashboard. A snapshot is a copy of the virtual machine's disk file (VMDK) that captures the entire state of the virtual machine at a point in time.

Setting a Retirement Date for a Service

Follow this procedure to schedule retirement for a service at a later date. For retiring a service immediately, see Retiring a Service.

1. From the **Services** screen, click on the required service you want to schedule retirement for.
2. Click the  button located on the upper-right corner of the screen, then select **Set Retirement Dates**. The **Schedule Service Retirement** window will appear.

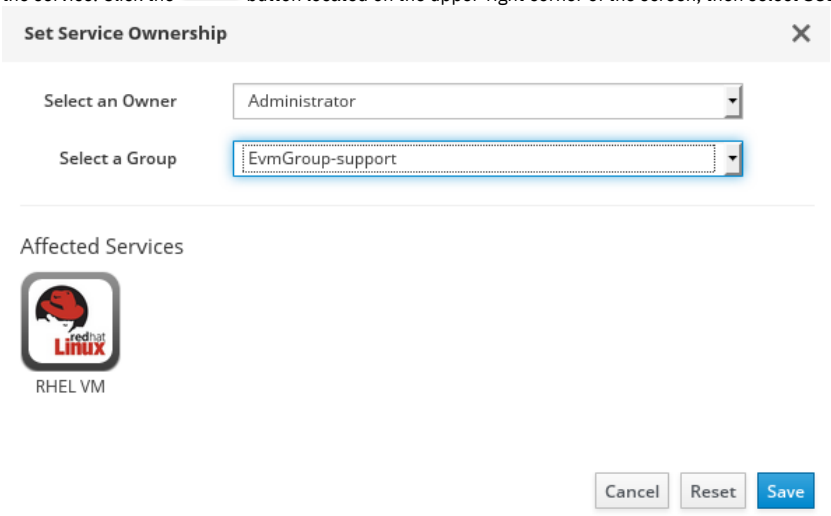


3. Set the **Retirement Date**.
4. Select the **Retirement Warning** from the list.
5. Click **Save**.

Retiring a Service

Follow this procedure to retire a service immediately. For retiring a service at a later date, see Setting a Retirement Date for a Service.

1. From the **Services** screen, click on the service you want to retire now.
2. Click the  button located on the upper right corner of the screen, then select **Retire**. The **Retire Service Now** window will appear to confirm your

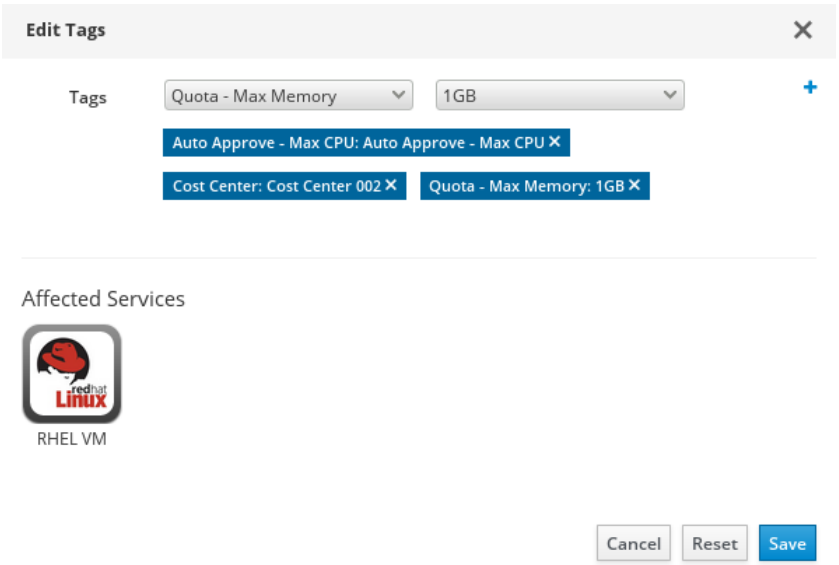


action.
3. Click **Yes, Retire Service Now**.

Setting Ownership of a Service

Follow this procedure to set ownership of a service.

1. From the **Services** screen, click on the more options button next to the service you want set ownership for, then click **Set Ownership**. Alternatively, click on the service. Click the  button located on the upper-right corner of the screen, then select **Set Ownership**.



2. Select an owner from the list.
3. Select a group from the list.
4. Click **Save**.

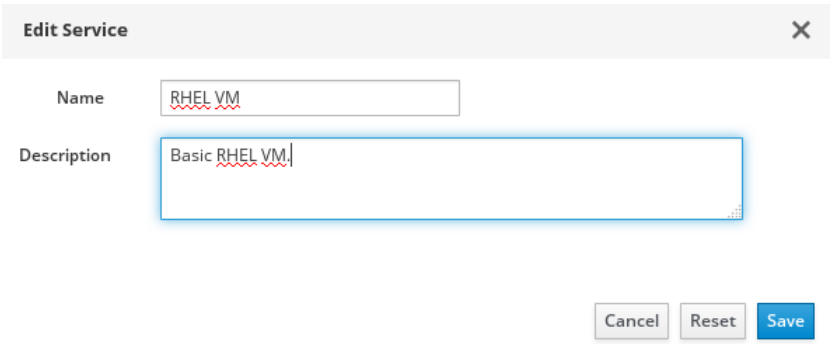
Adding and Editing Tags

Follow this procedure to add or edit tags for a service.

1. From the **Services** screen, click on more options next to the service you want add or edit tags for, then click **Edit Tags**. Alternatively, click on the service. Click the  button located on the upper-right corner of the screen, then select **Edit Tags**.

2. To add a tag, select the tag category and value from the lists, then click the blue plus (+) sign as shown in the screen capture.
3. To edit tags, simply change the value assigned to a category, or click on the cross sign in the tag to delete an existing tag.
4. Click **Save**.

Removing a Service



Follow this procedure to remove a service.

1. From the **Services** screen, click on more options next to the service you want to remove, then click **Remove**. Alternatively, click on the service. Click the button located on the upper-right corner of the screen, then select **Remove**. A confirmation window appears.
2. Click **Yes, Remove Service**.

Editing a Service

Follow this procedure to edit the name and description of a service.

1. From the **My Services** screen, click on more options next to the service you want to edit, then click **Edit**. Alternatively, click on the service. Click the button located on the upper-right corner of the screen, then select **Edit**. An **Edit Service** screen appears.

2. Edit the name and description of the service as required.
3. Click **Save**.

Controlling Virtual Machine Power States

Follow this procedure to perform power operations on virtual machines, such as start, stop, or suspend, depending on the current state of the virtual machine.

1. From the **My Services** screen, click on the required service.
2. Under **Resources**, click more options *(represented by three dots)* where you have the option to start, stop, or suspend the virtual machine. Alternatively, click on the virtual machine name to see more details about the resource, including the **Power Operations** button.

Creating Virtual Machine Snapshots

To create a snapshot from the Services screen:

1. From the **My Services** screen, click on the service associated with the virtual machine you want to create a snapshot for.

2. In **Resources**, click **Snapshots** next to the virtual machine you want to create a snapshot for, then select **Create** to create a snapshot. The **Create Snapshot** window appears.
3. Enter a name for the snapshot.
4. Optional: Select **Memory** if you want to capture the state of the virtual machine's memory.
5. Optional: Enter a **Description**.
6. Click **Create**.

To create a snapshot from the Resources screen:

1. From the **My Services** screen, click on the service associated with the virtual machine you want to create a snapshot for.
2. In **Resources**, click on the virtual machine you want to create a snapshot for.
3. On the virtual machine dashboard, click the **Snapshots** button, then select **Create**. The **Create Snapshot** window appears.
4. Enter a name for the snapshot.
5. Optional: Select **Memory** if you want to capture the state of the virtual machine's memory.
6. Optional: Enter a **Description**.
7. Click **Create**.

Viewing Virtual Machine Snapshots

1. From the **My Services** screen, click on the service associated with the virtual machine you want to view snapshots for.
2. In **Resources**, click **Snapshots** next to the virtual machine and select **View** to view available snapshots. Alternatively, click on the virtual machine, then click **Snapshots** to view available snapshots.

Note:

You can revert or delete a snapshot only from the snapshot summary screen. To do so, navigate to **Snapshots > View**, click more options *(represented by three dots)* next to the snapshot you want to revert or delete, and then click **Revert** or **Delete** as required. Revert returns a virtual machine to a previous state when you took the snapshot.

Accessing the Virtual Machine Console

Follow this procedure to open a console window to the virtual machine. The console is the remote control system that enables you to interact directly with your virtual machines.

1. From the **Services** screen, click on the required service.
2. In **Resources**, click the 

button next to the virtual machine and select **VM Console**.

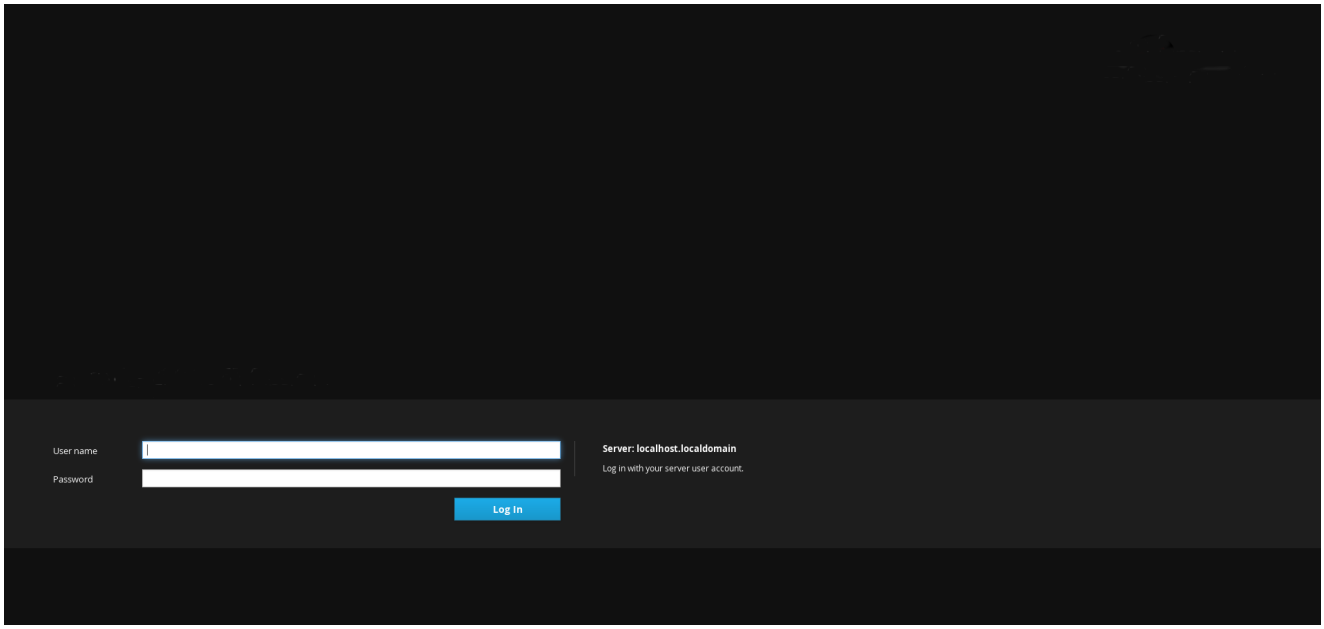
The virtual machine console will open in a new window of your web browser. Note that you may have to enable the pop-up settings in your browser to access the console.

Web Console (Cockpit) Integration

The Web console (Cockpit) is an interactive Linux server administrative interface. You can perform simple administration tasks such as starting containers, storage administration, network configuration, and inspecting logs. While Cockpit allows you to monitor and administer several servers at the same time, your browser connects to a primary server that runs the Cockpit web service through which connections to additional servers can be established.

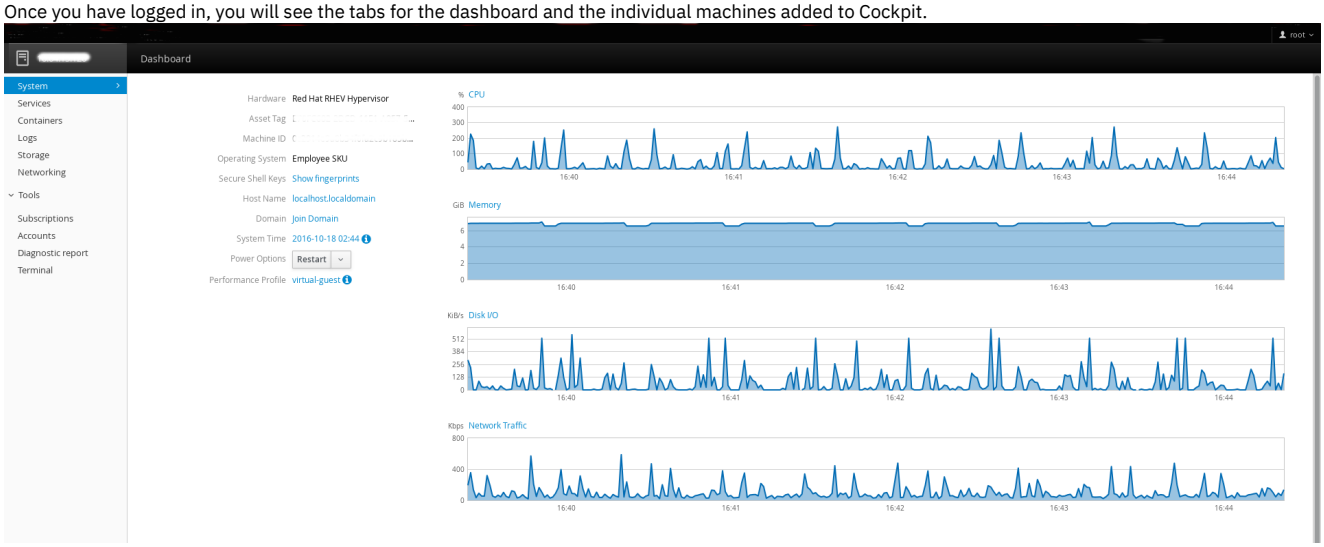
The Infrastructure Automation full administrative user interface and the Self Service user interface have enabled for users to access the Web console (Cockpit interface) for a given virtual machine.

Accessing the Web Console



Note:

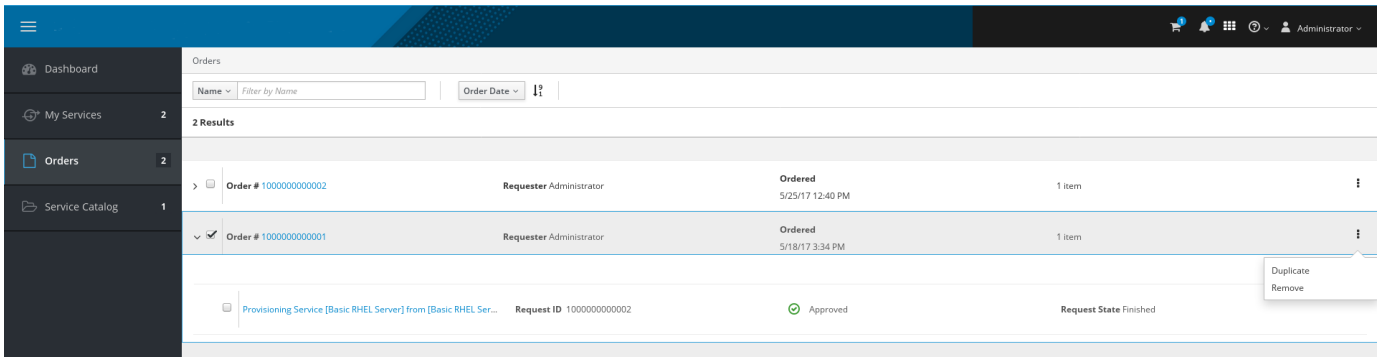
Launching of Cockpit requires as IP address for the virtual machine. It must be pre-configured and running on the virtual machine.



You can open the Web console (Cockpit) for a virtual machine from the 

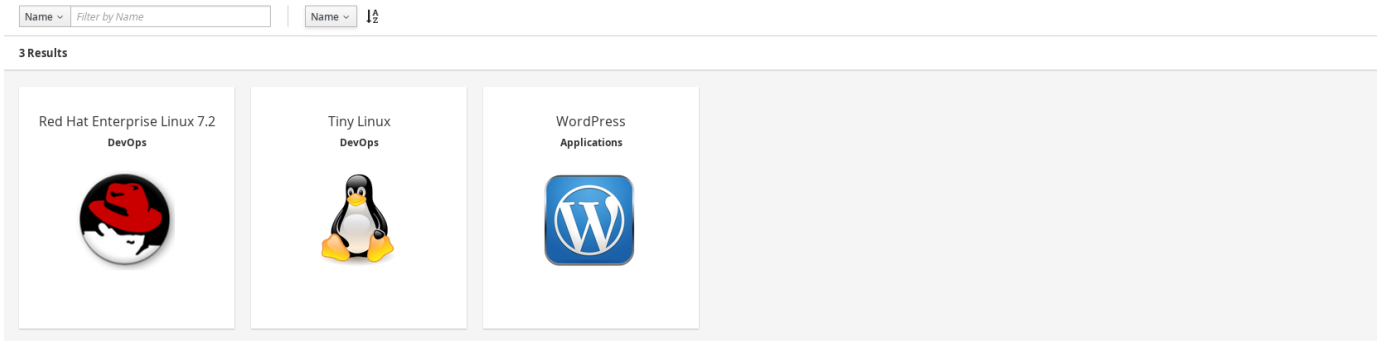
button.

1. From the **My Services** screen, click on the service associated with the virtual machine you want to open the Web console for.
2. In **Resources**, click **Access** next to the virtual machine and select **Web Console**. A notification will appear to show the Cockpit interface is loading.
3. The Cockpit interface for the virtual machine will open in a new browser window. If you get a security warning by the browser, you will need to add this connection to the security exceptions. Click **Advanced → Add Exception → Confirm Security Exception**. After that, you will see the login screen.



4. Once you have logged in, you will see the tabs for the dashboard and the individual machines added to Cockpit.

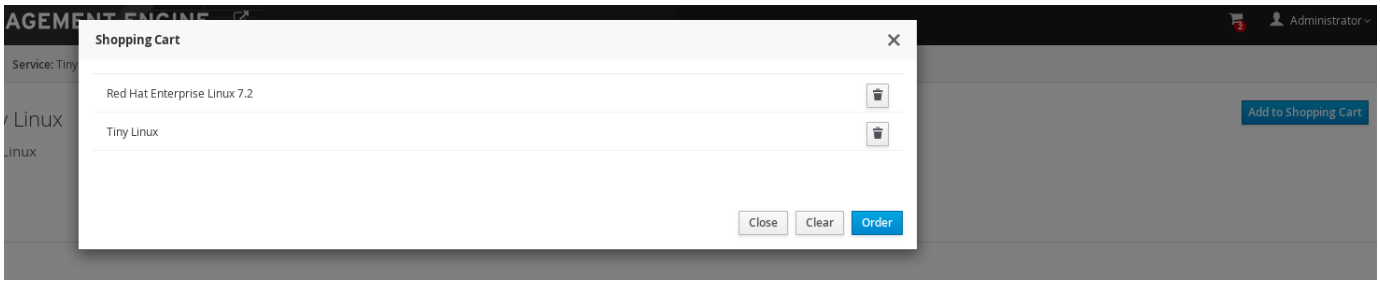
My Orders Tab



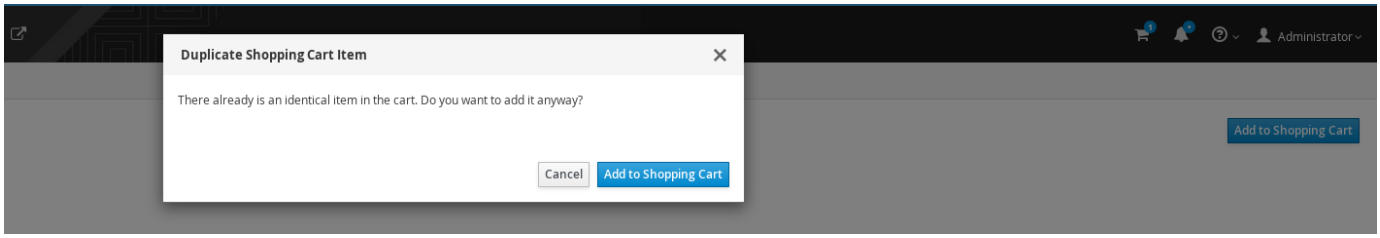
The **My Orders** tab lists all shopping cart orders which contain service requests added from the **Service Catalog**.

Click on the tab to see a summary of each order, including the order number, requester, order date, and the number of items. Click the arrow next to an order number to see more details such as the requests associated with the order, request ID, whether it is approved or denied, and the current state of the request. You can reorder a request by clicking the **Reorder** button, then enter the options associated with the order, and add to shopping cart. You can click on more options *(represented by three dots)* next to an order to **Remove** the order.

Service Catalog Tab



The **Service Catalog** tab lists all service catalog items, displayed as tiles. These items must be configured on the administrative user interface before they will be accessible to the user here. You can filter or sort the service catalog items by **Name**, **Description** and **Catalog Name**.



Click on a service to go to the page where you can enter the requested information in the dialog fields under **Service and VM Name** and **VM Characteristics** associated with the service. Note that there is now an ability to add dynamic dialog elements within the Self Service user interface, meaning you can include a particular dialog field where Infrastructure Automation will communicate to the instance and method, obtain the required information, and enter the value in the field dynamically. After you have entered all information in the dialog fields, click **Add to Shopping Cart**.

Shopping Cart:

The Self Service user interface has adopted a shopping cart model for ordering services, instead of ordering them individually. Click on the shopping cart icon at the top to view all services added to the shopping cart that are available to order. You can delete a particular service from the cart if required, and order the services in the cart all at one time. Or, you can even choose to clear all the services in the cart and exit.

If you click **Add to Shopping Cart** for the same item, you will see a pop up window alerting you that there is an identical item in the cart but if you want to add it anyway.

Reference

Go through the reference topics when you work with Managed services.

- Password migration of Managed services
- Managing the usage of virtual machines
- Managed services pods
- SSH Keys and related input required while deploying content runtime
- Control the version of a Terraform provider
- Terraform CAMC provider
- Shipped Terraform providers
- Supported Terraform templates

Password migration of Managed services

You can change the database passwords and encryption secrets of Managed services by using a password migration script.

Before you begin

- If you are planning to change the mariadb password, back up the mariadb as well.
- Download **passwordMigration.sh** from GitHub repository.

About the task

If you want to move to a different encryption password or change your bundled MongoDB password or mariadb password, use the **passwordMigration** tool. To change the encryption password, you reencrypt encrypted data in the database with the new encryption password.

Procedure

Run the following script:

```
./passwordMigration.sh [ -e ] [ -d ] [ -m ] [ -s ] [ -n ] [ -r ] [ -c ]
```

Flags to run the password migration: Usage:

- **-e** = new encryption password for Managed services. The flag changes the encryption password. Back up your MongoDB before using this).
- **-d** = new MongoDB password for Managed services. The flag changes the bundled MongoDB password. Back up your MongoDB before using this flag. It applies only for bundled MongoDB.
- **-m** = new mariadb password. This flag changes the bundled mariadb password. Back up your mariadb before using this flag. It applies only for bundled mariadb.
- **-s** = name of Managed services secret. The default is **cam-secure-values-secret**.
- **-n** = namespace for Managed services. The default is services.
- **-r** = Helm release name for Cloud Automation Manager
- **-c** = migration loop count to override the default timeout. The count is 300 by default.

Other flags can be left as default unless you changed values, such as cam secret name or namespace Managed services is installed into.

Here is an example usage to change encryption password, bundled MongoDB password, and bundled mariadb password:

```
./changePassword.sh -e newencpass -d newmongopass -m newmariapass 2>&1 | tee changePassword.log
```

When they run the password migration script, it stops Managed services. If Managed services is already running, it restarts Managed services after the script is successful. If password migration fails, you must restore your database(s).

Managing the usage of virtual machines in Managed services

You can keep a track of all virtual machines that are deployed on a system to arrive at the charges. The **Usage** page shows the highest number of virtual machines managed by Managed services each month. An average number of virtual Process Cores (VPC) per virtual machine can be entered to show the maximum and average VPCs managed each month.

About the task

You can see this option only if you log in as a cluster administrator.

The page fetches usage data only for the last 13 months.

To retrieve the currently deployed virtual machines, maximum number of virtual machines for each month, or to download the managed virtual machines report by using APIs, see Usage specific APIs.

Procedure

1. Click **Manage>Usage**.
2. View the **Current usage** section to get the number of currently actively deployed virtual machines.
3. In the **Usage** page, select your average VPCs per virtual machine. Based on the value entered, the VPCs managed is calculated. The formula used for the calculation is VMs managed * Average VPCs per VM. The monthly usage report table is populated based on your selection.
4. Go through the monthly usage table to get information about the month of usage, peak usage (maximum VMs and VPCs managed) for that month, and average usage (Average VMs managed and Average VPCs managed) for that month.
5. You can use the pagination drop-down to select the number of records you want to display in a page at a time. Use the **>** or **<** to go through the next or previous set of records.
6. You can click the **Download** link option on table to download the report in a spreadsheet format. The downloaded report includes the following information - ID, iaas resource id, name, id from provider, type from provider, provider, tenant id, namespace, action, and timestamp.

Managed services pods

List of Managed services pods and their functions.

- **cam-bpd-cds** - Cloud discovery service for dynamic parameter support in the service composer.
- **cam-iaas** - IaaS API server for cloud connections, template management, deploying instances, and more.
- **cam-mongo** - MongoDB for storing all Managed services data.

- `cam-orchestration` - Orchestration of services.
- `cam-portal-ui` - User interface for catalog of services.
- `cam-provider-helm` - Provider for deploying Helm charts from a service.
- `cam-provider-terraform` - Provider for deploying Terraform templates.
- `cam-proxy` - Proxies all requests from port 30000 to different microservices in Managed services.
- `cam-service-composer-api` - API server for composing services.
- `cam-service-composer-ui` - User interface for composing services.
- `cam-tenant-api` - API for tenant.
- `cam-ui-basic` - User interface for header (top bar), navigation, Templates, Connections, Email Configurations, Instances, Content runtimes, and getting started page.
- `cam-provider-bpm` - Provider for deploying IBM Business Process Manager processes from a service.
- `cam-provider-ansible` - Provider for managing and deploying Ansible artifacts like credential, inventory, and job templates.
- `cam-controller-manager` - Managed services Kubernetes resource controller.

SSH Keys and related input required while deploying content runtime

Content runtime deployment requires you to input public and private keys. This section provides the purpose of these keys and how they are used by the content runtime.

User's Public Key

This is an SSH public key of the private-public key pair that you can generate using ssh-keygen tool. If you enter a value for User's Public Key while you deploy the content runtime, then it is set in the `~/.ssh/authorized_keys` file of the content runtime virtual machine. After the virtual machine is up, you can use the private key part of the public key to log in to the content runtime virtual machine.

For `ssh-keygen` tool, see the "Input Parameter" section of Provisioning and managing your Content Runtime infrastructure topic.

Private Key for Pattern Manager - Base 64 encoded, Public Key for Pattern Manager and Key Name for Pattern Manager key set

This is an SSH private-public key pair that you can generate by using the ssh-keygen tool. You must encode the private part of the key pair as a base 64 encoded value and provide this encoded value as input for `Private Key for Pattern Manager - Base 64 encoded`. The public part of this key pair must be the value for `Public Key for Pattern Manager`. The private key is used to communicate with the virtual machine on which middleware is installed. The public part of this key is set on this virtual machine while installing the middleware using the middleware content Terraform template.

In case of IBM Cloud and Amazon Cloud, the public key that needs to be set on the content virtual machine must be provided as SSH Key resource. For more information on SSH Key resource, see https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/ec2-key-pairs.html and https://cloud.ibm.com/docs/ssh-keys?topic=ssh-keys-adding-an-ssh-key. This SSH Key resource must exist in the cloud prior to the deployment of the content runtime. The name of the SSH Key resource must be the value of content runtime input `Key Name for Pattern Manager key set`. When the content Terraform template is deployed, the key name is used to fetch the public key and the public key is set in the middleware content virtual machine.

Note: In case of VMWare and other clouds, the `Key Name for Pattern Manager key set` is just a name associated with the key pair.

Controlling the version of Terraform provider

In order to make use of certain functions and features of a Terraform provider, you might want to use a particular version of a Terraform provider. To do this, add version argument in the provider block of Terraform. This prevents the Terraform engine from using the latest version of the provider and instead uses the version that you need.

The value of the version can be a single version or a range of versions. You can use the following formats to specify a range of versions:

- `>= 1.0.0` - Versions greater than or equal to the 1.0.0.
- `<= 1.0.0` - Versions lesser than or equal to 1.0.0.
- `>= 1.0.0, <= 2.0.0` - This includes all versions between 1.0.0 and version number 2.0.0
- `~> 1.0.0` - Any non-beta version greater than or equal to 1.0.0 and lesser than or equal to 1.1.0.
- `~> 1.1` - Any non-beta version greater than equal to 1.1.0 and lesser than 2.0

Example:

```
provider "aws" {
  version = "~> 1.0"
  access_key = "${var.aws_access_key}"
  secret_key = "${var.aws_secret_key}"
  region     = "${var.aws_region}"
}
```

Terraform CAMC provider

Describes the Terraform CAMC providers

CAMC bootstrap

Description

The camc_bootstrap function performs a Chef bootstrap operation on the target node defined by the host_ip parameter. This function relies on a viable SSH connection between the pattern manager and the target node using SSH certificate-based security. The following steps are taken:

1. Install chef-client on the target node.
2. Register the Chef client with the Chef server. The Chef server will be bound to a single pattern manager as a parameter. If a Chef client already exists with the specified node_name parameter, then the target node is assumed to be a part of a previous deployment and is removed prior to registration.
3. Install the chef-vault gem.
4. Create a chef-vault entry based on the stack_id parameter of the node if it does not already exist. Chef nodes in a multi-node deploy will have the same stack_id and will share vault entries.

Example Usage

```
resource "camc_bootstrap" "resource1" {
    name = "resource1"
    camc_endpoint = "http://${var.endpoint}:5443/v1/bootstrap/"
    access_token = "${var.pm_access_token}"
    trace = "true"
    data = <<EOT
    {
        "os_username": "${var.referenced-image-os_username}",
        "stack_id": "${random_id.stack_id.hex}",
        "environment_name": "_default",
        "host_ip": "${vsphere_virtual_machine.referenced-image.network_interface.0.ipv4_address}",
        "node_name": "${var.referenced-image-name}",
        "node_attributes": {
            "ibm_internal": {
                "stack_id": "${random_id.stack_id.hex}",
                "stack_name": "${var.stack_name}",
                "vault": {
                    "item": "secrets",
                    "name": "${random_id.stack_id.hex}"
                }
            }
        }
    }
EOT
}
```

Argument Reference

Table 1. Parameters used with the camc_bootstrap provider

Type	Name	Description	Schema	Default	Required
Body	access_token	The pattern manager access token that was provided during Content Runtime provisioning	String		Yes
Body	camc_endpoint	The IP address or FQDN of the pattern manager	String		Yes
Body	data	A valid JSON structure. See *Data type* for more information	JSON		Yes
Body	name	A label to aid in identifying the resource	String		No
Body	trace	If true, writes more data to TF_LOG	Boolean	False	No
Data	os_username	The operating system user name used by the pattern manager to remote SSH to the target node	String		Yes
Data	stack_id	The stack ID shared across nodes in this deployment	String		Yes
Data	environment_name	The environment name for this deployment	String		Yes
Data	host_ip	The IP address of the host being bootstrapped	String		Yes
Data	node_name	The unique name to give the node on your chef server	String		Yes
Data	node_attributes	Chef attributes to be added to the node object during the bootstrap process.	String		Yes

CAMC software deploy

Description

Deploys one or more Chef cookbooks and Chef roles on the target node specified by the node_name parameter.

This node_name should match the value specified in the camc_bootstrap resource. The attributes specified by the node_attributes parameter will be applied to the node prior to executing the software deployment. Additionally, the vault may also be updated with the attributes defined in the vault_content parameter. The runlist parameter specifies an ordered list of roles and/or recipes to be run against the node. These cookbooks and roles need to be registered with the Chef server prior to executing this resource.

Example Usage

```
resource "camc_softwaredeploy" "resource2" {
    name = "resource2"
    camc_endpoint = "http://${var.endpoint}:5443/v1/softwaredeploy/chef"
    access_token = "${var.pm_private_b64}"
```

```
    data = <<EOT
    {
        "os_username": "${var.referenced-image-os_username}",
        "stack_id": "${random_id.stack_id.hex}",
        "environment_name": "_default",
        "host_ip": "${vsphere_virtual_machine.referenced-image.network_interface.0.ipv4_address}",
        "node_name": "${var.referenced-image-name}",
        "runlist": "role[ihs-wasmode-admin]",
        "node_attributes": {
            "host_ip": "${vsphere_virtual_machine.referenced-image.network_interface.0.ipv4_address}",
            "ibm": {
                "im_repo": "${var.ibm_im_repo}",
                "im_repo_user": "${var.ibm_im_repo_user}",
                "sw_repo": "${var.ibm_sw_repo}",
                "sw_repo_user": "${var.ibm_sw_repo_user}"
            },
            "ibm_internal": {
            "roles": "[ihs-wasmode-admin]"
            },
            "ihs": {
                "admin_server": {
                    "enabled": "true",
                    "port": "8008",
                    "username": "${var.referenced-image_ihs_admin_server_username}"
                },
                "install_dir": "/opt/IBM/HTTPServer",
                "install_mode": "admin",
                "plugin": {

Data	host_ip	The IP address of the host	String		Yes
Data	node_name	The unique name to give the node on your chef server	String		Yes
Data	node_attributes	Chef attributes to be added to the node object prior to the software deployment process.	String		Yes

CAMC script package

The camc_scriptpackage resource executes scripts and stores the output for use by other resources in your Terraform template. For example, use it to retrieve hostname and IP address information from an IPAM server and use the results in the virtual machine description.

The camc_scriptpackage resource allows you to store scripts locally on the cam-provider-terraform microservice or on an HTTP(s) server, execute scripts or commands locally from the cam-provider-terraform microservice or remotely on a deployed virtual machine, and control when the scripts should be run.

Passing parameters

There are two ways to pass parameters to the script: through the program array and the query JSON object. Parameters specified in the program array are passed to the script as command line parameters. The query JSON object contains name/value pairs of strings and are passed to the script through stdin.

Script response values

Responses from the script are collected and available in the Terraform template. Scripts returning multiple values must return them in a JSON object containing name/value pairs of strings. If the response is not a JSON object, it will be available to the Terraform template in a property called stdout.

Local scripts

Local scripts are run as a non-privileged user within the terraform-provider container in Managed services. This container has a limited number of installed packages, including:

```
awk
base64
bash
curl
gpg
jq
md5sum
Python 2.7.9 - no pip
sed
ssh
tr
wget
xargs
```

If the package that you are looking for does not exist locally, the recommendation is to use the remote script capabilities of the script provider to run scripts on a remote virtual machine that has those packages available.

Example usage

Local script

Example 1

```
resource "camc_scriptpackage" "LocalIp" {
  program = ["/bin/bash", "/var/scripts/get_ip.sh"]
  query = {
    prop1 = "prop1_value"
  }
  on_create = true
}
```

Example 2:

```
resource "camc_scriptpackage" "delete_test_resource" {
depends_on = ["camc_scriptpackage.create_test_resource"]
program = ["/bin/bash", "${path.module}/scripts/delete_ucd_resource.sh", "-h", "${var.ucd_host}", "-u", "${var.ucd_user}",
"-i", "${lookup(camc_scriptpackage.create_test_resource.result, "resource_id")}"]
program_sensitive = ["-p", "${var.ucd_password}"]
on_delete = true
}
```

Local script from HTTPS server

```
resource "camc_scriptpackage" "LocalHttpsScript" {
  program = ["/bin/bash", "/var/scripts/get_ip.sh"]
  source = "https://172.95.34.11/scripts/cam/get_ip.sh"
  source_user = "${var.src_user}"
  source_password = "${var.src_pass}"
  source_no_check_cert = true
  destination = "/var/scripts/get_ip.sh"
  on_create = true
}
```

Remote script

```
resource "camc_scriptpackage" "RemoteScript" {
  program = ["/bin/bash", "/var/scripts/deregister_node.sh"]
  remote_host = "172.13.205.41"
  remote_user = "${var.referenced-image-os_username}"
  remote_password = "${var.referenced-image-os_password}"
  destination = "/var/deregister_node.sh"
  on_delete = true
}
```

Referencing script output

```
output "local_script" {
  value = "${camc_scriptpackage.LocalIp.result}"
}

output "local_script_ip" {
  value = "${lookup(camc_scriptpackage.LocalIp.result, var.ip)}"
}
```

```
output "remote_script_stdout" {
  value = "${camc_scriptpackage.CreateScript.result}"
}
```

Argument Reference

Table 3. Parameters used with the camc_scriptpackage provider

Type	Name	Description	Schema	Default	Required
Body	destination	Destination file for the script. This can be the location to download the script from an HTTP server or the remote location to copy your local script	String		Yes, if specifying source
Body	on_create	Execute this script when this resource is created	Boolean	false	No
Body	on_delete	Execute this script when this resource is deleted	Boolean	false	No
Body	on_update	Execute this script when this resource is updated	Boolean	false	No
Body	depends_on	It is a Terraform metadata argument. For more information, see Terraform Resources.	Boolean	false	No
Body	program_sensitive	It is an array that contains a list of sensitive program arguments like passwords or other secret fields. Having them in this list ensures that the value of the attribute is not displayed in logs or regular output. Example: If you want to pass a sensitive field like password to a command in "program" parameter, then you can provide a program_sensitive parameter as `program_sensitive = ["${var.ucd_password}"]`.	Array		No
Body	program	Array containing the command to run	Array		Yes
Body	query	Name/value pairs of parameters passed to your script through stdin	JSON Object		No
Body	remote_host	The hostname or IP address of the remote system to execute this script	String		No
Body	remote_key	The base64-encoded private key to access the host specified by the remote_host parameter. One of remote_key or remote_password are required when specifying remote_host	String		No
Body	remote_password	The password to access the host specified by the remote_host parameter. One of remote_key or remote_password are required when specifying remote_host	String		No
Body	remote_user	The user to access the host specified by the remote_host parameter	String		Yes, if remote_host is specified
Body	source	The location of the script. This can be a local path on the cam-provider-terraform microservice or an HTTP(s) URL	String		No
Body	source_no_check_cert	Ignore the certificate when downloading the script from the HTTPS server	Boolean	false	No
Body	source_password	The password for the HTTPS server used to host the script	String		Yes, if source is an HTTPS server
Body	source_user	The user for the HTTPS server used to host the script	String		Yes, if source is an HTTPS server
Body	trace	If true, writes more data to TF_LOG	Boolean	False	No

CAMC vault item

Description

IBM Chef-based patterns use the chef-vault gem to store secrets such as passwords and user names to be defined by and used by cookbooks during the software deployment process. The camc_vaultitem resource will specify the items to be created.

It is important to note that nodes are logically arranged into a stack. A stack is a set of nodes belonging to the same pattern and is defined by the stack_id parameter. There is a single chef-vault entry for each stack so that nodes in a stack can share secrets between themselves, but not with other nodes deployed in the environment.

Example Usage

```
resource "camc_vaultitem" "vault1" {
    name = "vault1"
    trace = "true"
    camc_endpoint = "http://${var.endpoint}:5443/v1/vaultitem"
    access_token = "${var.pm_private_b64}"
    data = <<EOT
    {
        "vault_content": {
            "item": "secrets",
            "values": {},
            "vault": "${random_id.stack_id.hex}"
        }
    }
EOT
}
```

Argument Reference

Table 4. Parameters used with the camc_vaultitem provider

Type	Name	Description	Schema	Default	Required
Body	access_token	The pattern manager access token that was provided during Content Runtime provisioning	String		Yes
Body	camc_endpoint	The IP address or FQDN of the pattern manager	String		Yes
Body	data	A valid JSON structure	JSON		Yes
Body	name	A label to aid in identifying the resource	String		No
Data	vault_content	The content to add to the vault	String		Yes
Body	trace	If true, writes more data to TF_LOG	Boolean	False	No

Supported Terraform Templates

This page lists all the Terraform templates that are supported by IBM and pre-loaded into the product. The rest of the templates are provided as-is and you can import them into the product using these Import instructions or fork the repository and change the template to suit your needs.

- Starterlibrary Terraform Templates
- Starterlibrary Cluster Creation Terraform Templates
- Integration Templates
- Middleware Templates

These templates can be found in the following GitHub File

Starterlibrary Terraform Templates

Repository Location	Template Name
starterlibrary/AWS/terraform1XX/hcl/lamp/	LAMP stack deployment on AWS for Terraform 1.x.x
starterlibrary/AWS/terraform1XX/hcl/meanstack/	MEAN stack deployment on AWS for Terraform 1.x.x
starterlibrary/AWS/terraform1XX/hcl/rdssnap/	Amazon Relational Database Service Snapshot for Terraform 1.x.x
starterlibrary/AWS/terraform1XX/hcl/storage/	Amazon S3 Storage for Terraform 1.x.x
starterlibrary/AWS/terraform1XX/hcl/rds/	Amazon Relational Database Service for Terraform 1.x.x
starterlibrary/AWS/terraform1XX/hcl/lampinfra/	LAMP infrastructure deployment on AWS for Terraform 1.x.x
starterlibrary/AWS/terraform1XX/singlefile/hcl/	Amazon EC2 Virtual Server with SSH key for Terraform 1.x.x
starterlibrary/Google/terraform1XX/hcl/singleVM/	Google Cloud Single Virtual Machine Example for Terraform 1.x.x
starterlibrary/Google/terraform1XX/hcl/lamp/	Google Cloud LAMP stack deployment for Terraform 1.x.x
starterlibrary/BlueMix/terraform1XX/hcl/scenario1/	Virtual Server with SSH key for Terraform 1.x.x
starterlibrary/BlueMix/terraform1XX/hcl/scenario2/	2 Virtual Servers with SSH keys for Terraform 1.x.x
starterlibrary/BlueMix/terraform1XX/hcl/lamp-hybrid/	LAMP stack deployment (hybrid-cloud) for Terraform 1.x.x
starterlibrary/BlueMix/terraform1XX/hcl/meanstack-hybrid/	MEAN stack deployment (hybrid-cloud) for Terraform 1.x.x
starterlibrary/BlueMix/terraform1XX/hcl/scenario3/	2 Virtual Servers with SSH keys with one on a private network for Terraform 1.x.x
starterlibrary/VRA/terraform1XX/hcl/single-catalog-vm-deploy/	VMware vRealize Automation single node catalog deployment for Terraform 1.x.x
starterlibrary/OpenStack/terraform1XX/hcl/single-vm-deploy/	OpenStack Single Virtual Machine for Terraform 1.x.x
starterlibrary/Tencent/terraform1XX/hcl/singleVM/	Tencent cloud Virtual Server with SSH key for Terraform 1.x.x
starterlibrary/VMwareNSX-T/terraform1XX/hcl/switch/	VMware NSX-T Sample to create a logical switch for Terraform 1.x.x
starterlibrary/Other/Approval-1XX/InfrastructureManagement/	Poll Infrastructure Management for Approval for Terraform 1.x.x
starterlibrary/IBM_Cloud/database-service-1XX/	IBM Database Service for Terraform 1.x.x
starterlibrary/Alicloud/terraform1XX/hcl/singleVM/	Alibaba cloud ECS Virtual Server with SSH key for Terraform 1.x.x
starterlibrary/VMware/terraform1XX/hcl/singleVM/	SingleVirtualMachine for Terraform 1.x.x
starterlibrary/VMware/terraform1XX/hcl/lamp/	LAMP stack deployment on VMware for Terraform 1.x.x
starterlibrary/VMware/terraform1XX/hcl/singleWinVM/	SingleWindowsVirtualMachine for Terraform 1.x.x
starterlibrary/VMware/terraform1XX/hcl/meanstack/	MEAN stack deployment on VMware for Terraform 1.x.x
starterlibrary/VMware/terraform1XX/hcl/singleVMWithPrivateSSHKey/	Single Virtual Machine with Private SSH Key for Terraform 1.x.x
starterlibrary/Azure/terraform1XX/hcl/lamp/	LAMP stack deployment on Microsoft Azure for Terraform 1.x.x
starterlibrary/Azure/terraform1XX/hcl/meanstack/	MEAN stack deployment on Microsoft Azure for Terraform 1.x.x
starterlibrary/Azure/terraform1XX/hcl/singlevirtualmachine/	Virtual Machine with SSH key on Microsoft Azure for Terraform 1.x.x

Starterlibrary Cluster Creation Terraform Templates

Repository Location	Template Name
template_ibm_roks/terraform/	Red Hat OpenShift Single Zone Cluster on IBM Cloud for Terraform 1.x.x
template_kubernetes_iks/terraform1XX/	IBM Cloud Kubernetes Service for Terraform 1.x.x
template_kubernetes_eks/terraform1XX/	Amazon Web Services EKS for Terraform 1.x.x
template_kubernetes_aks/terraform1XX/	Microsoft Azure Kubernetes Service for Terraform 1.x.x
template_kubernetes_gke/terraform1XX/	Google Kubernetes Engine for Terraform 1.x.x

Integration Templates

Repository Location	Template Name
template_integration_servicenow/other/terraform1XX/	ServiceNow CMDB Configuration Template for Terraform 1.x.x

IBM Cloud Pak for AIOps troubleshooting

Learn how to isolate and resolve problems with IBM Cloud Pak® for AIOps.

Verify that your issues are not related to operating system requirements, such as disk, memory, and CPU capacities. For more information, see Planning.

Additionally, you can see whether the problem is documented in Known issues and limitations.

To potentially avoid problems, run routine health checks to analyze your system for potential issues. For more information about health check options for IBM Cloud Pak for AIOps, see Health checks and monitoring.

If you need direct help from IBM Support, see the Support.

Troubleshooting topics

- Install and upgrade
- Clusters and nodes
- Integrations
- AI model management
- ChatOps
- Topology
- Troubleshooting Identity Management (IM) issues
- Troubleshooting certificates
- Secure Tunnel
- Alert management
- Runbook Automation
- Infrastructure Automation

Troubleshooting installation and upgrade

Learn how to isolate and resolve problems with installing and upgrading IBM Cloud Pak for AIOps.

Known issues and limitations

In addition to the common problems and solutions that are listed, review the installation related known issues for potential issues that you might encounter during installation. For more information, see Known issues and limitations.

Troubleshooting tips

- General troubleshooting tips (Console)
- General troubleshooting tips (CLI)
- Troubleshooting storage
- Recovering IBM Cloud Pak for AIOps after a cluster restart

Note: If you have an aborted or stalled installation, uninstall any installed or partially installed components and restart the installation. For more information about uninstalling, see Uninstalling.

Installation issues

- Installation fails to proceed when creating the IBM Cloud Pak for AIOps custom resource
- The AI manager operator does not progress past `Reconciling`, and the Cassandra setup pod is stuck
- "Application is not available" message is displayed intermittently
- Installation on Linux fails with network connectivity errors when using `aiopsctl` to install on vSphere VMs
- Deployment on Linux is unstable after cluster restart

Upgrade issues

- After upgrade, policies do not process alerts due to problem with the `aiops-ir-lifecycle-create-policies-job`
- After upgrade, a metric integration goes into a failed state
- After upgrade, alerts are not visible in the UI
- Upgrade hangs due to residual Kong resources
- Navigation menu items disappear after an upgrade

Issues common to installation and upgrade

- Offline install or upgrade throws 'invalid character' error
- Offline install or upgrade stuck because the 'oc ibm-pak generate mirror-manifests' command fails with 'no space left on device'

General troubleshooting

General troubleshooting tips (Console)

1. From the Red Hat® OpenShift® console, go to **Workloads** > **Pods**.

2. Select the project that IBM Cloud Pak for AIOps is installed in from the drop-down menu to view the status of all the pods in this project.
3. If you want to see the status and details for one of the pods, click the pod that you want to investigate.
4. If you want to see the logs for the pod, click **Logs**.

General troubleshooting tips (CLI)

- To find out the status of all the pods in a project, run the following command:

  ```
  oc get pods -n <project>
  ```

  Where **<project>** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.

- To see the status of a particular pod, run the following command:

  ```
  oc get pods | grep <pod_name>
  ```

  Where **<pod_name>** is the pod that you want to see status for.

- To see a pod's logs, run the following command:

  ```
  oc logs -f <pod_name> -n <project>
  ```

  Where

  - **<pod_name>** is the pod that you want to see status for.
  - **<project>** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.

Troubleshooting storage

Storage that is associated with persistent volumes claims (PVCs) reaches capacity. This issue can occur as storage requests and resources fluctuate over time.

Solution: If storage fills up, increase the size of the PVC. For more information about increasing the size of a PVC, see Storage class requirements.

Recovering IBM Cloud Pak for AIOps after a cluster restart

After a Red Hat® OpenShift® Container Platform cluster restart, your IBM Cloud Pak for AIOps deployment has not come up successfully.

Use the following steps to help you to identify any problems.

1. Run the following command and then check that all of the OpenShift nodes come back up, and that they all report a *STATUS* of **Ready**.

   ```
   oc get nodes
   ```

   If all of the OpenShift nodes have not come back up, then see the *Updating clusters* and *Troubleshooting* sections in the OpenShift documentation for guidance.

2. Run the following command and then check that the IBM Cloud Pak for AIOps pods all have a *STATUS* OF **Running** or **Completed**.

   ```
   oc get pods -n <project>
   ```

   Where **<project>** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.

3. Check the logs of any pods that did not report a *STATUS* of **Running** or **Completed** in steps 2 and 3 to see whether you can identify a cause.

   ```
   oc logs -f <failed_pod_name> -n <project>
   ```

   Where

   - **<project>** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.
   - **<failed_pod_name>** is a failed pod name, as returned in steps 2 and 3.

Solution: Restart any failed pods with the following command:

```
oc delete pod <failed_pod_name> -n <project>
```

Where

- **<project>** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.
- **<failed_pod_name>** is the pod name as returned in steps 2 and 3.

Troubleshooting installation

Installation not proceeding after creating the IBM Cloud Pak for AIOps custom resource

When you are installing, the installation is not proceeding as expected after you create an instance of the IBM Cloud Pak for AIOps custom resource. For instance, after you create the instance, the installation process appears to be stalled, however no pods in the namespace and cluster display show errors.

This stalling of the installation process can be due to an issue with the Operator Lifecycle Manager (OLM), which causes the expected ClusterServiceVersion (CSV) for some operator subscriptions to not be found. For example, installPlan instances for the **aimanager-operator**, **connector-utilities-operator**, and other operators can be found, but without a reference to the required ClusterServiceVersion (CSV) YAML. While the operators can be created within your defined namespace, if the ClusterServiceVersion (CSV) cannot be found, the operators cannot be managed. If this issue occurs, the overall installation cannot proceed correctly.

Solution: Delete any operator subscription that does not have an associated ClusterServiceVersion (CSV) YAML and has an unresolved subscription. The installation process should re-create the associated operator and generate a new installPlan. If a new installPlan is not generated, repeat the process to delete the operator subscription and try again.

The AI manager operator does not progress past `Reconciling`, and the Cassandra setup pod is stuck

When installing, the AI Manager operator remains in **Phase: Reconciling**. The **aiops-ir-analytics-cassandra-setup** pod is in Crashloopbackoff state, and its log has the following error:

```
ERROR [2023-06-13 09:57:44,010] com.ibm.itsm.analytics.metric.service.cassandra.SessionManager: Cassandra not available.
```

Solution: Use the following steps to reset the Cassandra admin password, and delete the **aiops-ir-analytics-cassandra-setup** and **aiops-ir-core-archiving-setup** jobs.

1. Run the following command to switch to your IBM Cloud Pak for AIOps project.

   ```
   oc project <project>
   ```

   Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deploying in.

2. Reset the Cassandra admin password.

   ```
   oc rsh aiops-topology-cassandra-0 bash -c 'python3 -u /opt/ibm/change-superuser.pyc --initial --user admin --password
   $(cat /opt/ibm/cassandra_auth/password) --replication-factor $CASSANDRA_AUTH_REPLICATION_FACTOR'
   ```

3. Delete the **aiops-ir-analytics-cassandra-setup** job, if it does not own any pods.

   1. Check if there are any pods belonging to the **aiops-ir-analytics-cassandra-setup** job.

      ```
      oc get pod -l app.kubernetes.io/managed-by=aiops-analytics-operator,app.kubernetes.io/component=cassandra-setup
      ```

   2. If no pods are returned, then delete the **aiops-ir-analytics-cassandra-setup** job.

      ```
      oc delete job -l app.kubernetes.io/managed-by=aiops-analytics-operator,app.kubernetes.io/component=cassandra-
      setup
      ```

4. Delete the **aiops-ir-core-archiving-setup** job, if it does not own any pods.

   1. Check if there are any pods belonging to the **aiops-ir-core-archiving-setup** job.

      ```
      oc get pod -l app.kubernetes.io/managed-by=ir-core-operator,app.kubernetes.io/component=archiving-setup
      ```

   2. If no pods are returned, then delete the **aiops-ir-core-archiving-setup** job.

      ```
      oc delete job -l app.kubernetes.io/managed-by=ir-core-operator,app.kubernetes.io/component=archiving-setup
      ```

"Application is not available" message is displayed intermittently.

This is caused by a defect in some versions of Red Hat OpenShift. For more information, see OpenShift 4 - Intermittent 503 from all routes or timeouts when calling to backends directly when **allow-from-openshift-ingress** network policy is applied in the Red Hat OpenShift documentation.

Solution: Upgrade to a supported version of Red Hat OpenShift. For more information, see Supported Red Hat OpenShift versions.

Troubleshooting upgrade

After upgrade, policies do not process alerts due to problem with the `aiops-ir-lifecycle-create-policies-job`

This issue can occur if there is a problem connecting to Cassandra during upgrade. The **aiops-ir-lifecycle-create-policies-job** reports successful completion even it was unable to connect to Cassandra and run some of its policy-related queries. After upgrade policies do not process alerts, and error messages similar to the following are present in the **aiops-ir-lifecycle-create-policies-job's** log:

```
"name":"installdefaultpolicies","hostname":"aiops-ir-lifecycle-create-policies-job-c8k7t","pid":42,"level":40,"err":
{"message":"All host(s) tried for query failed.

"name":"installdefaultpolicies","hostname":"aiops-ir-lifecycle-create-policies-job-
c8k7t","pid":42,"level":50,"msg":"Failed to update policy with content
```

Solution: Restart the **aiops-ir-lifecycle-create-policies-job** by running the following command:

```
oc delete job aiops-ir-lifecycle-create-policies-job
```

After upgrade, a metric integration goes into a failed state

After upgrade a metric integration pod goes into a failed state waiting for a missing secret volume, because the secret **aiopsedge-postgres-edb-secret** does not yet exist. The upgrade process should create this secret after a few hours, or you can use the following solution to create it immediately and restore functionality.

Solution: Run the following command to update the **aiopsedge** custom resource with the postgres access secret if it is not set.

```
# Set environment variables
NAMESPACE=<project>
AIOPS_INSTALL_NAME=$(oc get install -n $NAMESPACE -o jsonpath='{.items[*].metadata.name}')
AIOPSEDGE_NAME=$(oc get aiopsedge -n $NAMESPACE -o jsonpath='{.items[*].metadata.name}')
```

```
EDB_POSTGRESS_SECRET=$AIOPS_INSTALL_NAME-edb-secret

# Check if spec.postgres.accessSecret is set
CURRENT_SECRET=$(oc get aiopsedge $AIOPSEDGE_NAME -n $NAMESPACE -o jsonpath='{.spec.postgres.accessSecret}')

# Patch the aiopsedge custom resource
if [[ "${CURRENT_SECRET}" != "${EDB_POSTGRESS_SECRET}" ]]; then
    oc patch aiopsedge $AIOPSEDGE_NAME -n $NAMESPACE --type='json' -p="[{'op': 'replace', 'path':
'/spec/postgres/accessSecret', 'value': '$EDB_POSTGRESS_SECRET'}]"
else
    echo "Postgres access secret name already set to $CURRENT_SECRET in $AIOPSEDGE_NAME resource."
fi

# Restart the Edge operator manager pod to force a reconcile:
oc scale deployment/aiopsedge-operator-controller-manager -n $NAMESPACE --replicas=0
oc scale deployment/aiopsedge-operator-controller-manager -n $NAMESPACE --replicas=2
```

Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in, usually **cp4aiops**.

After upgrade, alerts are not visible in the UI

1. Run the following command to view the LifecycleTrigger job.

   ```
   oc get LifecycleTrigger aiops -o yaml
   ```

2. Check the **status** section of the returned YAML.

   Example **status** section:

   ```
   status:
     conditions:
     - lastTransitionTime: "2024-04-15T10:12:44Z"
       message: Job '5e569b68014d9a669574096001ce51e6' in state 'RESTARTING'
       observedGeneration: 2
       reason: NotReady
       status: "False"
       type: LifecycleTriggerReady
     jobs:
     - jid: 5e569b68014d9a669574096001ce51e6
       startTime: "2024-04-13T20:22:17Z"
       state: RESTARTING
     savepoints:
     - path: s3://aiops-ir-lifecycle/savepoints/savepoint-d9c1a5-95d27a6574b4
       time: "2024-04-13T20:10:56Z"
     - lifecycleVersion: 4.5.1
       namespace: aiops
       path: s3://aiops-ir-lifecycle/savepoints/savepoint-d9c1a5-40e97c1c5bdd
       time: "2024-04-13T20:15:22Z"
     - lifecycleVersion: 4.5.1
       namespace: aiops
       path: s3://aiops-ir-lifecycle/savepoints/savepoint-d9c1a5-40e97c1c5bdd-upgraded
       time: "2024-04-13T20:21:53Z"
     - lifecycleVersion: 4.5.1
       namespace: aiops
       path: s3://aiops-ir-lifecycle/savepoints/savepoint-5e569b-6d60d2f35ca8
       time: "2024-04-13T20:23:20Z"
   ```

   Check to see if:

   - the **conditions** section has **Job <...> in state 'RESTARTING'**.
   - the **savepoints** section has an entry with a path that ends with **-upgraded**, which follows an entry with the same path without this suffix.
   - the two entries that are described above are followed by at least one more entry. This check is important.

Solution: If all of the above checks are true, then you can remediate this problem with the following steps.

1. Note the value of **jid** in the status block (**5e569b68014d9a669574096001ce51e6** in the example above) and export it as an environment variable.

   ```
   export JOB_ID=<jid>
   ```

2. Run the following command to cancel the LifecycleTrigger job that is restarting.

   ```
   oc patch LifecycleTrigger aiops --type json --patch '[{"op":"add","path":"/spec/cancelJobs","value":
   ["'${JOB_ID}'"]}]'
   ```

3. Check the LifecycleTrigger YAML again.

   ```
   oc get LifecycleTrigger aiops -o yaml
   ```

   After about a minute the **status.jobs** section should have two entries:

   - The first entry has the old job ID and the state will change to CANCELLED.
   - the second entry has a new job ID and the state should eventually settle at RUNNING.

Upgrade hangs due to residual Kong resources

You might notice an issue where the Kong zen extension does not get cleaned up properly while upgrading from version 4.5.x to 4.6.x. Zen operator is stuck while trying to reconcile the nginx configurations. This issue hangs the whole upgrade process until the Kong resources are manually cleaned up.

Run the following command to verify if the following solution steps are applicable:

```
oc get zenextensions kong-gateway-extension
```

Example output for a deployment experiencing this problem:

```
NAME                          STATUS      AGE
kong-gateway-extension        Completed   14h
```

Solution: If you see the preceding output, use the following steps to resolve the Kong resources issue:

1. Delete the extension:

```
oc delete zenextensions kong-gateway-extension
```

Example output:

```
zenextension.zen.cpd.ibm.com "kong-gateway-extension" deleted
```

After the deletion of the extension, the zen operator can take a few minutes to reconcile all of the existing zen extensions.

2. Monitor the extensions:

```
oc get zenextensions -w
```

All the extensions need to be in `completed` phase. Example output for a successful resolution:

```
NAME                                STATUS              AGE
ai-model-ui-ext                     Completed           14h
aiops-akora-ui-ext                  Completed           14h
aiops-baseui-frontdoor-ext          Completed           14h
common-web-ui-zen-extension         Completed           14h
connections-ui-ext                  Completed           14h
insights-ui-ext                     Completed           14h
sre-tunnel-tunnel-ui-zen-extension  Completed           14h
```

Navigation menu items disappear after an upgrade

You might notice an issue where navigation menu items in IBM Cloud Pak for AIOps console disappear when you upgrade Cloud Pak for AIOps from version 4.5.x to 4.6.x.

To determine if you are encountering this issue, run the following command:

```
oc logs -l component=zen-core-api
```

The output can resemble the following example:

```
time="2024-07-18 13:46:00" level=error msg=GetNavExtensions func=zen-core-
api/source/apis/internal_extensions/nav.GetNavItemsWrapper file="/go/src/zen-core-
api/source/apis/internal_extensions/nav/get_nav_items.go:124" exception="circular dependency or dangling node found in
aiops-nav-menuitem-alerts_page,aiops-connectors-nav,aiops-nav-menuitem-metric_search,aiops-insights-nav,aiops-nav-
menuitem-incidents_page,aiops-aimodel-nav,aiops-nav-menuitem-resource_management,aiops-nav-menuitem-automations"
```

Solution: If you see the preceding error, then use the following step to resolve the menu items disappear issue:

1. Delete the `aiops-baseui-frontdoor-ext` resource:

   ```
   oc delete zenextension aiops-baseui-frontdoor-ext
   ```

   The output can resemble the following example:

   ```
   zenextension.zen.cpd.ibm.com "aiops-baseui-frontdoor-ext" deleted
   ```

Issues that are common to installation and upgrade

Offline install or upgrade throws 'invalid character' error

When doing an offline install or upgrade, running the `oc ibm-pak generate mirror-manifests <..>` command throws an error similar to the following:

```
Error: failed to load the catalog FBC at cp.stg.icr.io/cp/ <...> invalid character '<' in string escape code
```

Solution: You must have `IBM Catalog Management Plug-in for IBM Cloud Pak` (`ibm-pak-plugin`) v1.10 or higher installed. Run the following commands to ensure that `ibm-pak-plugin` is at the required level.

1. Check which version of `ibm-pak-plugin` you have installed.

   Run the following command on your bastion host, portable compute device, or connected compute device if you are using a portable storage device.

   ```
   oc ibm-pak --version
   ```

   Example output:

   ```
   oc ibm-pak --version
   v1.11.0
   ```

2. If the `ibm-pak-plugin` version is lower than v1.10.0, then you must download and install the most recent version.

Follow the steps for your installation approach:

- Bastion host: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.
- Portable device: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.

Offline install or upgrade stuck because the 'oc ibm-pak generate mirror-manifests' command fails with 'no space left on device'

The `oc ibm-pak generate mirror-manifests $CASE_NAME $TARGET_REGISTRY --version $CASE_VERSION` command fails with a message similar to the following in `$IBMPAK_HOME/.ibm-pak/logs/oc-ibm_pak.log`:

```
write /tmp/render-unpack-4002583241/var/lib/rpm/Packages: no space left on device
```

Solution: The default temporary directory does not have enough space to run the `ibm-pak` tool. You must set the `TMPDIR` environment variable to a different directory with more space before running the `oc ibm-pak generate mirror-manifests` command.

```
TMPDIR=<new_temp_dir> oc ibm-pak generate mirror-manifests ${CASE_NAME} ${TARGET_REGISTRY} --version ${CASE_VERSION}
```

Where `<new_temp_dir>` is the path for a directory with more space.

Installation on Linux fails with network connectivity errors when using `aiopsctl` to install on vSphere VMs

The `aiopsctl` script installs the Kubernetes distribution `k3s`. When `k3s` is installed on a VMWare vSphere virtual machine (VM), routing across ClusterIPs does not work. The creation of the subscriptions for `Cert Manager` and the `Licensing Service` fail with errors similar to the following because they cannot reach the catalog:

```
- message: 'failed to populate resolver cache from source ibm-aiops-catalog/olm:
      failed to list bundles: rpc error: code = Unavailable desc = connection error:
      desc = "transport: Error while dialing: dial tcp: lookup ibm-aiops-catalog.olm.svc
      on 10.43.0.10:53: read udp 10.42.1.2:41727->10.43.0.10:53: i/o timeout"'
```

This problem is caused by a known kernel issue with Red Hat® Enterprise Linux® on vSphere. To fix the problem, run the following command on each of your nodes:

```
ethtool -K flannel.1 tx-checksum-ip-generic off
```

For more information, see k3s support

Deployment on Linux is unstable after cluster restart

After a cluster restart, one of IBM Cloud Pak for AIOps's components, `zookeeper`, cannot start due to issues around DNS resolution causing it to misidentify its assigned cluster IP address.

Running the following command shows that `iaf-system-kafka-0` and some other pods failed:

```
kubectl get pods
```

Running the following command shows errors in the `zookeeper` logs:

```
kubectl logs -l app.kubernetes.io/name=zookeeper --tail -1
```

Example errors:

```
2024-06-17 20:57:26,674 ERROR Couldn't bind to iaf-system-zookeeper-0.iaf-system-zookeeper-nodes.aiops.svc/10.42.1.53:2888
(org.apache.zookeeper.server.quorum.Leader) [QuorumPeer[myid=1](plain=127.0.0.1:12181)(secure=[0:0:0:0:0:0:0:0]:2181)]
java.net.BindException: Cannot assign requested address
java.net.SocketException: Unresolved address
```

Solution: Run the following command to restart the `zookeeper` pods, and then wait a few minutes for the system to recover:

```
kubectl delete pods -l app.kubernetes.io/name=zookeeper
```

Troubleshooting clusters and nodes

Learn how to isolate and resolve problems that involve cluster and node failures.

- Temporal grouping policies not created after training historic events
- Illegal reflective access operation in Jobmanager pod log
- Kafka pods fail to restart
- Cloud Pak for AIOps console not accessible after shutdown of backup cluster
- Log anomaly detection Kafka intermittent Issue, as Log anomaly detector abruptly stops making predictions
- Some integrations reported in error or integration dataflow disable toggle fails to save with internal server error
- EDB Postgres cluster failure
- An EDB Postgres replica is in CrashLoopBackOff
- CouchDB pod reports a permission error when draining a node

Temporal grouping policies not created after training historic events

Groups of related alerts that occur together (temporal groups) are not correlated automatically by the system. This issue can occur when temporal grouping policies are not created automatically due to communication issues between the aiops-ir-core-archiving pod and some Kafka topics.

Solution: Complete the following steps:

1. Run the following command, while logged in as an admin user in the project (namespace) where IBM Cloud Pak® for AIOps is running:

   ```
   kubectl logs $(kubectl get pods|grep aiops-ir-core-archiving|grep -v setup|awk '{print $1}') | grep "lib-rdkafka
   status"| tail -1
   ```

   Example command output:

   ```
   {
   "name": "client.kafka",
   "hostname": "aiops-ir-core-archiving-5dfd8fdcc5-l52g8",
   "pid": 20,
   "level": 30,
   "brokerStates": {
      "0": "UP",
      "-1": "UP"
   },
   "partitionStates": {
      "cp4waiops-cartridge.irdatalayer.replay.alerts.0": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.1": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.2": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.3": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.4": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.5": "UP"
   },
   "msg": "lib-rdkafka status",
   "time": "2021-10-19T11:00:49.852Z",
   "v": 0
   }
   ```

2. If any of the broker or partition states are not up, restart the aiops-ir-core-archiving pod with the following command:

   ```
   kubectl delete pod $(kubectl get pods|grep aiops-ir-core-archiving|grep -v setup|awk '{print $1}')
   ```

Illegal reflective access operation in Jobmanager pod log

Reports of illegal reflective access operation.

```
WARNING: An illegal reflective access operation has occurred
WARNING: Illegal reflective access by org.apache.flink.shaded.akka.org.jboss.netty.util.internal.ByteBufferUtil
(file:/opt/flink/lib/flink-dist_2.11-1.13.2.jar) to method java.nio.DirectByteBuffer.cleaner()
WARNING: Please consider reporting this to the maintainers of
org.apache.flink.shaded.akka.org.jboss.netty.util.internal.ByteBufferUtil
WARNING: Use --illegal-access=warn to enable warnings of further illegal reflective access operations
WARNING: All illegal access operations will be denied in a future release
```

This warning is reported when the Flink library is run by Java 11. For more information, see https://issues.apache.org/jira/browse/FLINK-17524

Solution: No action required. This warning message can be ignored and does not impact functionality.

Kafka pods fail to restart

Kafka pods fail to start when a worker node goes down, as in the following example:

```
evtmanager-kafka-0                                    1/2     Running            55          15h
evtmanager-kafka-1                                    2/2     Running            0           16h
evtmanager-kafka-2                                    1/2     Running            0           15h
evtmanager-kafka-3                                    1/2     Running            0           15h
evtmanager-kafka-4                                    1/2     Running            0           15h
evtmanager-kafka-5                                    2/2     Running            0           15h
evtmanager-zookeeper-0                                1/1     Running            0           16h
evtmanager-zookeeper-1                                1/1     Running            0           15h
evtmanager-zookeeper-2                                1/1     Running            0           15h
```

If the worker node where the Kafka pods are located goes down, the Kafka pods might fail to restart on another node.

Solution: Restart all zookeeper and Kafka pods:

```
oc delete pod {evtmanager-zookeeper-0} {evtmanager-zookeeper-1} {evtmanager-zookeeper-n} {evtmanager-kafka-0} {evtmanager-
kafka-1} {evtmanager-kafka-n}
```

Cloud Pak for AIOps console not accessible after shutdown of backup cluster

Unable to access the IBM Cloud Pak for AIOps console on the backup cluster after a systematic shut down and start up of the backup cluster. The following error message is displayed:

```
"Document was encrypted with unknown key '<namespace>-<release name>-<timestamp>'"
```

Solution: Find and then delete the required databases through the API.

1. First, run the following command to retrieve the hostname:

```
oc get route couchdb-georedundancy
```

For this scenario, use the hostname **couchdb-georedundancy-geonoi.apps.geo01primary.myibm.com**.

2. Run the two **SECRET_NAME** commands to retrieve the **username** and **password** that are required to retrieve the database names.

   For Username:

   ```
   SECRET_NAME=$(oc get secret | grep couchdb-secret | awk '{ print $1 }'); kubectl get secret ${SECRET_NAME} -o json |
   grep "username" | cut -d : -f2 | cut -d '"' -f2 | base64 -d
   username
   ```

   For Password:

   ```
   SECRET_NAME=$(oc get secret | grep couchdb-secret | awk '{ print $1 }'); kubectl get secret ${SECRET_NAME} -o json |
   grep "password" | cut -d : -f2 | cut -d '"' -f2 | base64 -d
   password
   ```

3. Use the **hostname**, **username**, and **password** obtained in the previous steps to run the command to retrieve the database names:

   ```
   curl -sk -u "username:password" https://couchdb-georedundancy-geonoi.apps.geo01primary.myibm.com/_all_dbs | jq "."
   ```

   Example output:

   ```
   [
   "_global_changes",
   "_replicator",
   "_users",
   "collabopsuser",
   "emailrecipients",
   "genericproperties",
   "icp-63666439356237652d336263372d343030362d613461382d6137336137396633731323535-rba-as",
   "icp-63666439356237652d336263372d343030362d613461382d6137336137396633731323535-rba-rbs",
   "integration",
   "noi-drdb",
   "noi-osregdb",
   "normalizercfd95b7e-3bc7-4006-a4a8-a73a79c71255",
   "osb-map",
   "otc_omaas_broker",
   "rba-pdoc",
   "schedule",
   "tenant",
   "trainingjob"
   ]
   ```

   The relevant database name here is **collabopsuser**.

4. Run the following command to delete the database:

   ```
   curl -sk -u "root:netcool" -X DELETE "https://couchdb-georedundancy-
   geonoi.apps.geo01primary.myibm.com/${DATABASE_NAME}"
   ```

   Where **DATABASE_NAME** = **collabopsuser**

5. Restart the **cem-users** pod to recreate the database:

   ```
   oc get pods |grep cem-users
   <cem_users_pod_name>

   oc delete pod <cem_users_pod_name>
   ```

6. You can confirm the database is created by running the curl command from step 3:

   ```
   curl -sk -u "username:password" https://couchdb-georedundancy-geonoi.apps.geo01primary.myibm.com/_all_dbs | jq "."
   ```

LAD Kafka intermittent Issue, as Log anomaly detector abruptly stops making predictions

The log anomaly detector abruptly stops making predictions.

On checking the anomaly pod logs, you see error messages related to Kafka, and due to these intermittent issues, log anomaly stops consuming data from the windowed logs topic, even when there are continuous windows generated from the data preprocessing component.

An example of such an error in the logs is as follows:

```
[2022-03-19 14:28:34,233] [logprophet.logs.watson_aiops] [ERROR] An error has occurred while processing message in batch
mode. Error: 'NoneType' object is not iterable
[2022-03-19 14:28:34,234] [app.anomaly_detector.service_controller] [ERROR] Consumer failed with unhandled exception :
'NoneType' object is not iterable
```

Solution: There is a two-step process to resume the flow:

1. Clear the windowed logs topic content. This step is required to clear any old data that is not yet consumed by the log anomaly detector. If you do not clear this data, when LAD is ready to make predictions, it will try to generate events for old data showing a lag. So, you need to disable the data flow, and clear data from windowed logs.

   - Disable data flow from data integration
   - Clear the windowed logs topic using following command

```
oc edit kt cp4waiops-cartridge-windowed-logs-1000-1000
```

- Set `retention.ms` to `1`.
- Wait for a few minutes, and once the data is cleared and no more windows are generated, reset the 'retention.ms' to the original value
- Enable the data flow in the data integration

2. Once the data is cleared using the above steps, restart the anomaly pod logs with the following command:

```
oc get po | grep anomaly
oc delete pod <anomaly-pod>
```

Some integrations reported in error or integration dataflow disable toggle fails to save with internal server error

The symptoms sometime differ, but the most common symptom is that several integrations are reported in error in the UI. Also it can be that the integration dataflow disable toggle fails to save with internal server error, which is due to a Flink problem in the HA topology.

Several integrations are reported in error in the UI, or the integration dataflow disable toggle fails to save with internal server error, which is due to a Flink problem in HA topology. The following command shows the logs:

```
oc logs cp4waiops-eventprocessor-eve-29ee-ep-jobmanager-0 jobmanager
```

A sample of the root cause as taken from the cp4waiops-eventprocessor-eve-29ee-ep-jobmanager pods log is shown below:

```
2022-02-25 08:57:24,288 ERROR io.fabric8.kubernetes.client.extended.leaderelection.LeaderElector [] - Exception occurred
while acquiring lock 'ConfigMapLock: cp4waiops - cp4waiops-eventprocessor-eve-29ee-ep-resourcemanager-leader (a1de269d-
3fb9-49e0-96ab-0b4248ba046a)'
io.fabric8.kubernetes.client.KubernetesClientException: Operation: [get]  for kind: [ConfigMap]  with name: [cp4waiops-
eventprocessor-eve-29ee-ep-resourcemanager-leader]  in namespace: [cp4waiops]  failed.
```

Solution: The workaround is to restart all eventprocessor-eve pods.

```
oc project <project>
for n in $(oc get cm |grep job |awk '{print $1}')
do
  oc delete cm $n
done
oc delete pod cp4waiops-eventprocessor-eve-29ee-ep-jobmanager-0 cp4waiops-eventprocessor-eve-29ee-ep-jobmanager-1
```

Where `<project>` is the project (namespace) where IBM Cloud Pak for AIOps is deployed.

EDB Postgres cluster failure

Run the following command on your cluster:

```
oc get clusters.postgresql.k8s.enterprisedb.io <installation_name>-edb-postgres -n <namespace>
```

Where:

- `<installation_name>` is the name of your IBM Cloud Pak for AIOps instance, for example `ibm-cp-aiops`.
- `<namespace>` is the namespace that IBM Cloud Pak for AIOps is deployed in.

If the cluster *STATUS* does not show `Cluster in healthy state` and the *READY* count is 0, then the EDB Postgres cluster has failed.

EDB Postgres is a component that is used by IBM Cloud Pak for AIOps. A defect in EDB Postgres 1.18.6 and lower can cause the EDB Postgres cluster to fail. If the pod that hosts the primary instance of EDB Postgres is deleted and there is not a healthy EDB Postgres replica instance available to promote, then the EDB Postgres operator may not reschedule the pod hosting the primary instance.

Solution: If you encounter this problem, then you must contact IBM Support who can help you to determine and bring up the primary EDB Postgres node.

An EDB Postgres replica is in CrashLoopBackOff

One of the EDB Postgres instances in the EDB Postgres cluster has a state of `CrashLoopBackOff`, as in the following example where the second instance has failed.

```
oc get pod -n <namespace> |grep <installation_name>-edb-postgres
```

Where:

- `<installation_name>` is the name of your IBM Cloud Pak for AIOps instance, for example `ibm-cp-aiops`.
- `<project>` is the project (namespace) where IBM Cloud Pak for AIOps is deployed.

Example output:

```
# oc get pod -n cp4aiops |grep ibm-cp-aiops-edb-postgres
ibm-cp-aiops-edb-postgres-1                                  1/1     Running             1                 5d15h
ibm-cp-aiops-edb-postgres-2                                  0/1     CrashLoopBackOff    198 (3m34s ago)   16h
ibm-cp-aiops-edb-postgres-3                                  1/1     Running             1                 5d15h
```

Entries similar to the following example can be seen in the Postgres pods' logs:

```
{"level":"info","ts":1677595436.8679705,"logger":"postgres","msg":"record","logging_pod":"ibm-cp-aiops-edb-postgres-
1","record":{"log_time":"2023-02-28 14:43:56.867
UTC","user_name":"streaming_replica","process_id":"90988","connection_from":"10.254.24.22:32852","session_id":"63fe132c.16
36c","session_line_num":"1","command_tag":"idle","session_start_time":"2023-02-28 14:43:56
UTC","virtual_transaction_id":"13/0","transaction_id":"0","error_severity":"ERROR","sql_state_code":"58P01","message":"req
uested WAL segment 000000030000000200000A0 has already been removed","query":"START_REPLICATION 2/A0000000 TIMELINE
2","application_name":"ibm-cp-aiops-edb-postgres-2","backend_type":"walsender"}}
```

A Postgres instance falls behind or is disconnected from the primary Postgres instance, and the primary instance removes or recycles the data that it requires. When the Postgres instance tries to restart, it fails because the data it requires is no longer available.

Solution: The failed Postgres replica is out of sync with the other replicas, and cannot recover on its own. Use the following commands to remove the failing Postgres instance and its associated PVCs, and cause a new replica to be created.

1. Install version 1.18.1 or higher of the `cnp` plugin. This is the EDB Postgres for Kubernetes plug-in. For more information about available EDB Postgres releases, see the EnterpriseDB documentation.

   Run the following command:

   ```
   curl -sSfL https://github.com/EnterpriseDB/kubectl-cnp/raw/main/install.sh | sudo sh -s -- -b /usr/local/bin
   v<version>
   ```

   Where `<version>` is the version of the plugin that you want to install, and is version 1.18.1 or higher.

   For example:

   ```
   curl -sSfL https://github.com/EnterpriseDB/kubectl-cnp/raw/main/install.sh | sudo sh -s -- -b /usr/local/bin v1.18.1
   ```

2. Find your installation name and set an environment variable for it.

   1. Find the name of your IBM Cloud Pak for AIOps installation.

      ```
      oc get installation -n <project>
      ```

      Where `<project>` is the project that your IBM Cloud Pak for AIOps installation is deployed in.

      Example output, where `ibm-cp-aiops` is the name of the IBM Cloud Pak for AIOps installation:

      ```
      NAME          PHASE    LICENSE   STORAGECLASS STORAGECLASSLARGEBLOCK AGE
      ibm-cp-aiops  Running  Accepted  rook-cephfs  rook-ceph-rbd          34h
      ```

   2. Export environment variables.

      ```
      export INSTALLATION_NAME=<name>
      export PROJECT_CP4AIOPS=<project>
      ```

      Where:

      - `<name>` is the name returned by the previous command, for example `ibm-cp-aiops`.
      - `<project>` is the project that your IBM Cloud Pak for AIOps installation is deployed in.

3. Find which of the Postgres replicas in your cluster is the primary.

   Run the following command:

   ```
   oc get clusters.postgresql.k8s.enterprisedb.io ${INSTALLATION_NAME}-edb-postgres -n ${PROJECT_CP4AIOPS}
   ```

   Example output:

   ```
   oc get clusters.postgresql.k8s.enterprisedb.io ibm-cp-aiops-edb-postgres -n cp4aiops
   NAME                              AGE     INSTANCES   READY   STATUS              PRIMARY
   ibm-cp-aiops-edb-postgres   7d17h   3           2       Upgrading cluster   ibm-cp-aiops-edb-postgres-1
   ```

   In the example output, `ibm-cp-aiops-edb-postgres-1` is listed under *PRIMARY*, and is the primary Postgres instance.

4. Find the number of the failed Postgres replica, which is in `CrashLoopBackOff`.

   Run the following command:

   ```
   oc get pod -n ${PROJECT_CP4AIOPS} |grep ${INSTALLATION_NAME}-edb-postgres
   ```

   Example output:

   ```
   oc get pod -n cp4aiops |grep ibm-cp-aiops-edb-postgres
   ibm-cp-aiops-edb-postgres-1                              1/1     Running            1                 5d15h
   ibm-cp-aiops-edb-postgres-2                              0/1     CrashLoopBackOff   198 (3m34s ago)   16h
   ibm-cp-aiops-edb-postgres-3                              1/1     Running            1                 5d15h
   ```

   In the example output, `ibm-cp-aiops-edb-postgres-2` is in `CrashLoopBackOff`, so the failed replica number is `2`.

5. Remove the failed Postgres pod and its associated PVC.

   Warning: Do not run the `oc cnp destroy` command against the primary Postgres replica, which you identified in step 3.

Run the following command:

```
oc cnp destroy ibm-cp-aiops-edb-postgres <instance_id>
```

Where **<instance_id>** is the failed Postgres replica number, which you identified in step 3.

Example command:

```
oc cnp destroy ibm-cp-aiops-edb-postgres 2
```

The **cnp** operator creates a new replica instance, and adds it to the EDB Postgres cluster.

6. After twenty minutes, verify that the Postgres cluster is fully functional again.

   1. Check that all of the Postgres pods are running.

      ```
      oc get pod -n ${PROJECT_CP4AIOPS} |grep ${INSTALLATION_NAME}-edb-postgres
      ```

      Example output:

      ```
      ibm-cp-aiops-edb-postgres-1 1/1 Running 1 5d15h
      ibm-cp-aiops-edb-postgres-3 1/1 Running 1 5d15h
      ibm-cp-aiops-edb-postgres-4 1/1 Running 1 20m
      ```

   2. Run the following command, and verify that the output shows that all of the replicas are running and that the *STATUS* is **"Cluster in healthy state"**.

      ```
      oc get clusters.postgresql.k8s.enterprisedb.io ${INSTALLATION_NAME}-edb-postgres -n ${PROJECT_CP4AIOPS}
      ```

      Example output:

      ```
      NAME                              AGE INSTANCES READY STATUS                  PRIMARY
      ibm-cp-aiops-edb-postgres 14d 3         3     Cluster in healthy state  ibm-cp-aiops-edb-postgres-1
      ```

CouchDB pod reports a permission error when draining a node

The **CouchDB** pod's log reports a permission error similar to the following example:

```
[error] 2022-12-02T01:24:20.726024Z couchdb@c-example-couchdbcluster-m-0.c-example-couchdbcluster-m <0.13913.7> --------
Could not open file /data/db/shards/00000000-7fffffff/_users.1669801403.couch: permission denied
```

Note: After a restore into a new namespace, similar symptoms can be seen. For more information about the solution for this scenario, see Restore fails with CouchDB pod in CrashLoopBackOff.

The way that Kubernetes mounts persistent volumes can cause this problem.

Solution: Delete the **CouchDB** pods that are not ready. When the replacement pods are created, the persistent volumes are mounted correctly.

1. Find the names of your **couchdb** pods.

   ```
   oc get pods -l app.kubernetes.io/name=IssueResolutionCoreCouchDB -n <namespace>
   ```

   Where **<namespace>** is the namespace that IBM Cloud Pak for AIOps is deployed in.

2. Delete all the **couchdb** pods that the previous step showed as not ready.

   ```
   oc delete pod <couchdb-pod> -n <namespace>
   ```

   Where:

   - **<namespace>** is the namespace that IBM Cloud Pak for AIOps is deployed in.
   - **<couchdb-pod>** is a couchdb pod that is not ready.

Troubleshooting integrations

Review frequently encountered issues with creating and managing outgoing and incoming integrations.

- Multiple integrations
- Integrations page
- Metrics integrations
- Instana
- Kafka
- Netcool
- ServiceNow
- Splunk
- IBM Tivoli Netcool/Impact

Multiple integrations

- Integrations do not initialize

Integrations do not initialize

If an integration gets stuck in a state that is not running, there may be an issue with the secrets being created.

To check this log in to openshift and check the pods. For example, the netcool integration has the following issue:

```
NAME                                                              READY   STATUS              RESTARTS        AGE
netcool-conn-cfe182e0-d7eb-42f6-9677-fb86b180bd0f-8bd546cbvv5km   0/1     ContainerCreating   0               27m
```

If you describe the pod `oc describe pod netcool-conn-cfe182e0-d7eb-42f6-9677-fb86b180bd0f-8bd546cbvv5km` and you see a mount error in the events log such as the following:

```
34s (x20 over 25m)          Warning   FailedMount                       Pod/netcool-conn-cfe182e0-d7eb-42f6-9677-
fb86b180bd0f-8bd546cbvv5km             MountVolume.SetUp failed for volume "grpc-bridge-service-binding" : secret
"connector-cfe182e0-d7eb-42f6-9677-fb86b180bd0f" not found
```

you can conclude that the secrets failed to create. The way to fix this is to use the following command:

```
oc get pods | grep connector-manager
```

Then delete the connector-manager pods and restart it. On restarting it, the secrets are re-created for all integrations.

Integrations page

On viewing the Integrations page, you might encounter the following issues:

- Deleting an integration does not remove the PVC for the integration
- Error displays when you activate Kafka, Humio, Splunk, Mezmo, ELK, PagerDuty, ServiceNow integrations
- Integrations on the Integrations page show a red 'Unknown' status
- Integrations UI pod in CrashLoopBackOff for the Integrations page
- Integrations page becomes unresponsive after some time or shows an error
- Incorrect integration status on the Integrations page
- The integration keeps showing *Error* or *Retrying* and integration pod is stuck in *Pending*
- Ansible Automation Controller integration not running due to prohibited egress

Deleting an integration does not remove the PVC for the integration

For StatefulSet type integrations, when the integration is deleted the Persistent Volume Claim (PVC) resource for the integration is not automatically deleted. You must manually delete the resource with the Red Hat OpenShift **oc** CLI or with the Red Hat OpenShift UI.

This behavior occurs because the StatefulSet PVC is created by specifying the **volumeClaimTemplate**, but the created PVC is not automatically deleted by Red Hat OpenShift when the StatefulSet resource is deleted.

To delete a PVC resource with the Red Hat OpenShift **oc** CLI, complete the following steps:

1. Get the list of PVC resources for your current integrations:

   ```
   oc get pvc | grep 'conn'
   ```

2. Select the PVC resource that you want to delete and record the name.

3. Delete the PVC resource:

   ```
   oc delete pvc <pvc-name>
   ```

   Where **<pvc-name>** is the name of the PVC resource that you want to delete.

Error displays when you activate Kafka, Humio, Splunk, Mezmo, ELK, PagerDuty, ServiceNow integrations

When you activate a Kafka, Falcon LogScale, Splunk, Mezmo, ELK, PagerDuty, ServiceNow integration in the console, an error can occur when the required Flink task slots to run the integration are not available. When this error occurs, the following message is displayed:

```
Failure: Not enough task slots to activate the connection.
```

This error occurs as there is a finite number of Flink task slots to use for creating integrations to remote resources. The error message displays the number of slots that are needed to support the current active integration set, along with the total number of slots available.

Solution: To activate the integration, you must either reduce the number of slots that are needed by this (or another) integration, or allocate more slots. To decrease the number of slots needed by a integration, consider reducing the "base parallelism" or "logs per second" value for the integration. This reduced value decreases the rate at which data flows through the integration, making more slots available to other integrations. To allocate more slots, see Increasing data streaming capacity.

Integrations on the Integrations page show a red 'Unknown' status

All integrations are showing red 'Unknown' integration status and data is not flowing after creating a new integration, such as a Mezmo integration. For the new integration if you enable 'Data collection', you can see that the data is not flowing, and the integration shows the same red 'Unknown' status in the Data collection status field instead of the expected 'Running' status. The common cause for this is unstable Kafka in the background.

Solution: If this issue occurs, restart the bridge and operator pod.

Integrations UI pod in CrashLoopBackOff for the Integrations page

You can encounter an intermittent issue that causes the Integrations page to fail and become unavailable for viewing.

Solution: If the page does not automatically recover, you can increase the timeout setting for the **aimanager-aio-controller** deployment to help prevent the issue. To increase this setting, edit the **aimanager-aio-controller** deployment (**liveliness** and **healthcheck** probe) and set it to a longer timeout of say 15 seconds, up from the default 5 seconds. This change can stop the **Connections-ui** pod from going into CrashLoopBackOff.

1. Check the **aimanager-aio-controller**

```
oc get pods | grep aio-controller
aimanager-aio-controller-6d9f68d5f5-8dkk9                         1/1     Running     0               27h
```

2. Edit the **aimanager-aio-controller**'s deployment

```
oc edit deployment aimanager-aio-controller
```

3. Edit these 2 variables (**timeoutSeconds**) for both the **livenessProbe** and the **readinessProbe** to 15 seconds:

```
livenessProbe
- timeoutSeconds
readinessProbe
- timeoutSeconds
```

Integrations page becomes unresponsive after some time or shows an error

If you are using IBM Cloud Pak for AIOps, you might encounter an unresponsive Integrations page around 24 hours after you install your cluster. The integrations page might take a long time to load and then display no integrations despite configuring them earlier. Another symptom of this problem is that you might fail to create an integration and see the following error:

```
Failed submitting creating request
```

Solution: To ensure the Integrations page works normally, delete the **aimanager-aio-controller** pod:

```
for n in $(oc get pods |grep aimanager-aio-controller |awk '{print $1}')
do
oc delete pod $n
done
```

Within one to two minutes of running the script, the pod will automatically restart and the Integrations page will work as usual.

Incorrect integration status on the Integrations page

You might encounter an incorrect integration status for all gRPC integrations (Instana, Netcool, AppDynamics, Dynatrace, AWS CloudWatch, Splunk, Zabbix, and New Relic) on the Integrations page. The integration status might appear as *Unknown* when it must be *Running*. The incorrect status might be the result of the pod connector-bridge being in CrashLoopBackOff state and restarting multiple times due to an unstable Kafka integration.

Solution: If this issue occurs, check the Kafka and zookeeper pods for any restarts. Kafka integration becomes unstable and restarts when the PVC used for Kafka is full. Review the current capacity of the PVC and increase the capacity as needed to resolve the issue. For more information about adjusting the size of the PVC, see Increasing Kafka PVC.

The integration keeps showing *Error* or *Retrying* and integration pod is stuck in *Pending*

On the Integrations UI page, an integration keeps showing *Error* or *Retrying* and the integration pod is stuck in *Pending*. This issue occurs because the Persistent Volume Claim (PVC) is requesting a volume from a storage provider that does not support the **ReadWriteOnce** (RWO) access mode.

Solution: You can use either one of the following methods to unblock the stuck integration pod:

- Change the default storage class

Or

- Re-create the Persistent Volume Claim with a different storage class

Method 1: Change the default storage class. Review the default storage class in the cluster and change to a storage class that supports **ReadWriteOnce** (RWO) access mode, such as file storage types.

Note: This method should resolve integration PVC issues but since it changes the global default storage class type in the cluster, it might also affect other workloads that rely on the default storage class settings when requesting a volume.

1. Run the following command to determine which is the current default storage class.

```
oc get storageclass
```

2. Note the name of the default storage class **(default)**.

3. Change the default storage class to one that supports the **ReadWriteOnce** (RWO) access mode like file storages. The following command sets the **storageclass.kubernetes.io/is-default-class** annotation to **true** on the new storage class and sets the annotation to **false** on the old storage class. (Change the **<new-default-storageclass-name>** and **<old-default-storageclass-name>** with the actual storage class names in your cluster.)

```
oc patch storageclass <old-default-storageclass-name> -p '{"metadata": {"annotations":
{"storageclass.kubernetes.io/is-default-class":"false"}}}'
oc patch storageclass <new-default-storageclass-name> -p '{"metadata": {"annotations":
{"storageclass.kubernetes.io/is-default-class":"true"}}}'
```

4. Verify that the default storage class is updated by running

```
oc get storageclass
```

5. Log in to the Cloud Pak for AIOps console and navigate to the **Integrations** page.
6. Delete the existing integration, then reinstall it.
7. Verify that the integration enters a *Running* state.

Method 2: Re-create the Persistent Volume Claim with a different storage class. Delete the existing PVC and re-create a new one with the same name that uses a storage class that supports the **`ReadWriteOnce`** (RWO) access mode.

Note: This method updates only a single integration instance. Repeat this step for all integrations unable to request a persistent volume, due to the incorrect storage class type.

1. Get the PVC name of the integration. You can list all PVCs by using **`oc get pvc`**. Look for the one that is still in *Pending* state with your integration name.
2. Delete the existing PVC and re-create a new one with the same name. Review the following sample command as reference. Update the **`<connector-pvc-name>`** with the PVC name from the previous step and set **`<storage-class-name>`** with the storage class that supports the required **`ReadWriteMan`** (RWX) access mode.

```
# Set the PVC name
CONNECTOR_PVC_NAME=<connector-pvc-name>

# Set new storage class
STORAGE_CLASS=<new-storage-class>

CONNECTOR_APP=$(oc get pvc $CONNECTOR_PVC_NAME -o jsonpath='{.metadata.labels.app}')
CONNECTOR_ID=$(oc get pvc $CONNECTOR_PVC_NAME -o jsonpath='{.metadata.labels.instance}')
PVC_SIZE=$(oc get pvc $CONNECTOR_PVC_NAME -o jsonpath='{.spec.resources.requests.storage}')

oc delete pvc $CONNECTOR_PVC_NAME && \
cat << EOF | tee >(oc apply -f -) | cat
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
    name: $CONNECTOR_PVC_NAME
    labels:
        app: $CONNECTOR_APP
        app.kubernetes.io/instance: aiopsedge
        app.kubernetes.io/managed-by: aiopsedge-operator
        app.kubernetes.io/name: ibm-aiops-edge
        app.kubernetes.io/part-of: ibm-aiops-edge
        instance: $CONNECTOR_ID

spec:
    accessModes:
    - ReadWriteOnce
    resources:
        requests:
            storage: $PVC_SIZE
    storageClassName: $STORAGE_CLASS
    volumeMode: Filesystem
EOF
```

For example,

```
# Set the PVC name
CONNECTOR_PVC_NAME=netcool-vct-netcool-conn-325fba02-440f-4135-bd00-8560bcf5eda1-0

# Set new storage class
STORAGE_CLASS=rook-cephfs

CONNECTOR_APP=$(oc get pvc CONNECTOR_PVC_NAME -o jsonpath='{.metadata.labels.app}')
CONNECTOR_ID=$(oc get pvc CONNECTOR_PVC_NAME -o jsonpath='{.metadata.labels.instance}')

oc delete pvc $CONNECTOR_PVC_NAME && \
cat << EOF | tee >(oc apply -f -) | cat
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
    name: $CONNECTOR_PVC_NAME
    labels:
        app: $CONNECTOR_APP
        app.kubernetes.io/instance: aiopsedge
        app.kubernetes.io/managed-by: aiopsedge-operator
        app.kubernetes.io/name: ibm-aiops-edge
        app.kubernetes.io/part-of: ibm-aiops-edge
        instance: $CONNECTOR_ID

spec:
    accessModes:
    - ReadWriteOnce
    resources:
        requests:
            storage: 50Mi
    storageClassName: $STORAGE_CLASS
    volumeMode: Filesystem
EOF
```

3. Verify that the integration pod transitions to **`Running`** state.

4. If necessary, repeat the steps above on any other integration that is producing the same problem.

Metrics integrations

If you are creating, or have, a metrics integration, you might encounter the following issue:

Metrics connection is unable to pull further historical data when historical mode is completed

When a metrics integration (for example Dynatrace, Appdynamics, Zabbix, New Relic, Splunk, or AWS) has completed its historical data pulling, historical mode can never be restarted again even if the connection configuration is edited or updated from the UI to specify a different start date, end date or a different set of metrics.

Solution: If you need to pull historical data again for another set of metrics or different dates, you can create a new connection.

Instana integrations

If you are creating, or have, an Instana integration, you might encounter the following issues:

- integration is unable to update the metric list in the UI
- IBM Cloud Pak for AIOps cannot close some alerts when an Instana integration exists
- After a repair of Instana, alerts in the Instana application do not associate with the corresponding IBM Cloud Pak for AIOps application
- Due to an out-of-memory error the Instana integration pod keeps restarting when retrieving data from Instana

integration is unable to update the metric list in the UI

The Instana integration UI page displays a list of metrics from Instana that are updated when the Instana integration pod runs. Some Instana hosts can have many technology plug-ins installed, which collect many built-in and custom metrics. These metrics can cause the Instana integration to exceed the allowed message limit when the integration sends an update to the UI. If this limit is exceeded, the Instana integration pod logs the following message:

```
0000004d Connector     I   UI configuration patch exceeds the safe message limit, skip sending configuration patch. The metrics list in the UI could not be updated with the actual list of technologies and metrics. Please configure more filter patterns to reduce the number of metrics to query.
```

The integration logs each technology plug-in and the number of metrics that are included or filtered.

Solution: Apply additional filter patterns in the Instana configmap for the integration to exclude when querying the metric list from Instana.

1. Get the Instana pod logs to determine which technology plug-in contains many metrics

   ```
   oc logs $(oc get pod | grep 'instana-conn' | awk '{print $1}') | grep -e "Plugin \'.*\' \(.*\)"
   ```

   The following example log indicates that a **aceMessageFlow** technology plug-in that contains a large list of metrics, and that is a candidate to filter.

   Tip: Look for any technology plug-ins that contain more than 100 metrics.

   ```
   0000004d InstanaInstan I Plugin 'ACE Message Flow' (aceMessageFlow) metrics: 2,666 included, 0 filtered.
   ```

2. Determine the available metrics names by technology from the Instana API or from your Instana administrator. To use the Instana API, you can use a command similar to the following sample command, which queries **aceMessageFlow** metrics:

   ```
   INSTANA_ENDPOINT=<your Instana host>
   INSTANA_TOKEN=<your Instana API token>
   curl --request GET -s  --url ${INSTANA_ENDPOINT}/api/infrastructure-monitoring/catalog/metrics/aceMessageFlow \
   --header "authorization: apiToken ${INSTANA_TOKEN}" \
   | jq 'group_by(.pluginId)[]|  {(.[0].pluginId): [.[] | .metricId] | sort}'
   ```

3. Create a pattern to filter metrics from the output of the previous command. For example, **flowNodes\\..*** to filter all metrics with **flowNodes.** prefix.

4. Get the Instana integration configmap name to add the filter pattern from the previous step.

   Note: If multiple Instana integrations exist, select the configmap with the UID that matches the pod name.

   ```
   oc get configmap | grep instana-connector
   ```

5. Extract the **exclude-filter-patterns** from the configmap. This command saves the content of the configmap into the local file:

   ```
   oc extract configmap/ibm-grpc-instana-connector-d59eea9f-501d-4bd1-b3a3-6f98b49b0930 --keys=exclude-filter-patterns --to=.
   ```

6. Edit the local **exclude-filter-patterns** file to add the metric pattern in addition to the default ones that are defined in the **filters** array.

   Note: To escape a slash **** character, you must use double ****. For example:

   ```
   {"filters":["fs\\./dev/.*","fs_mount\\./.*","metrics\\.counters\\..*\\..*\\..*","(.*\\.)?
   metrics\\.gauges\\..*\\..*\\..*","metrics\\.meters\\..*","(.*\\.)?
   metrics\\.timers\\..*","prometheus\\.metrics.*","flowNodes\\..*"]}
   ```

7. Apply the change to the configmap:

   ```
   oc set data configmap/ibm-grpc-instana-connector-d59eea9f-501d-4bd1-b3a3-6f98b49b0930 --from-file=exclude-filter-patterns
   ```

8. Verify that the new filter pattern is loaded by the pod, and that the number of metrics that are filtered for the technology plug-in is changed.

   ```
   oc logs $(oc get pod | grep 'instana-conn' | awk '{print $1}') | grep 'Loaded filter patterns from ConfigMap'
   ```

9. Verify that the Instana integration can send an update to the UI successfully:

```
oc logs $(oc get pod | grep 'instana-conn' | awk '{print $1}') | grep -e 'Status message .* write with configuration patch .* successful.'
```

10. In the *Edit Instana integration* UI page, the list of technologies and metrics list is now updated.

IBM Cloud Pak for AIOps cannot close some alerts when an Instana integration exists

When an integration with Instana exists, IBM Cloud Pak for AIOps might not be able to close some alerts. Instead, you might need to check the status for the associated event within the Instana UI and clear the alert manually.

Solution: To find the alert URL for clearing the alert, complete the following actions:

1. From the IBM Cloud Pak for AIOps console, open the *Incidents and alerts* tool.
2. Select the alert in the table to display the Alert details side panel for that alert. The Information section is open by default in the side panel.
3. Copy the URL from links and Paste the URL into your browser.
4. If you are an Instana authorized user, you see the associated event in the Instana UI.

If the event is not active and has "end-time" for the event in the Instana UI, clear the alert:

1. Click *Alert* to see the alert details.
2. Click *Clear Alert* to clear the alert.

After a repair of Instana, alerts in the Instana application do not associate with the corresponding IBM Cloud Pak for AIOps application

When you restart Instana post repair, alerts in the Instana application do not map with the corresponding application in IBM Cloud Pak for AIOps. The reason is that Instana creates new identifiers for the resources on its application on restarting, without updating the topology in IBM Cloud Pak for AIOps. As a result, the IDs of the resources do not match leading to the disassociation of alerts.

Solution: To map the alerts, you must complete the following steps:

1. Clean up the application in Instana.
2. Re-create the application after a few minutes.

To clean up and recreate applications in Instana, see Getting started with Instana.

Due to an out-of-memory error the Instana integration pod keeps restarting when retrieving data from Instana

When the Instana integration receives a large amount of data from one or more Instana APIs while the integration is observing many resources, and there is insufficient memory to process this large amount of data, an out of memory error can occur.

Solution: If this error occurs, you can apply custom memory settings to allocate more memory to the Instana integration pod by increasing the memory limit setting. This allocation can only be done post-installation as the integration must exist before applying the custom setting. To apply custom resource settings, follow the steps to patch the Instana integration:

Prerequisite: Ensure you have the `yq` and `jq` packages installed on your system before running the commands below. To get installation instructions for these packages, refer to the documentation or website for `yq` and `jq`.

1. From a command line, change to your IBM Cloud Pak for AIOps project (namespace):

```
namespace=<aiops-namespace>
oc project $namespace
```

2. Get the display name for the Instana integration you would like to increase resources for from the command line:

```
oc get connectorconfiguration
```

3. Set the required variables:

```
connectionname=<instana-connection-name>
connconfig=$(oc get connectorconfiguration --no-headers | grep $connectionname | awk '{print $1}')
connconfiguid=$(oc get connectorconfiguration $connconfig -o jsonpath='{.metadata.uid}')
gitappname=$(oc get gitapp -l connectors.aiops.ibm.com/connection-id==$connconfiguid --no-headers | awk '{print $1}')
```

Note: Update the `connectionname` variable with your Instana display name from the command above.

4. Run this command to create a variable with a patch specification for the Instana integration. This will apply only to one Instana integration at a time. This command should not have an output. Copy this command directly from the documentation and do not paste it into a text editor because this can affect the format.

```
jsonpatch=$(yq -o json <<EOF
    patch: |-
      apiVersion: apps/v1
      kind: Deployment
      metadata:
        name: ibm-grpc-instana-connector
      spec:
        template:
          spec:
            containers:
            - name: ibm-grpc-instana-connector
              resources:
```

```
                requests:
                  memory: 1536Mi
                  ephemeral-storage: 2Gi
                limits:
                  memory: 8Gi
                  ephemeral-storage: 4Gi
    target:
      group: apps
      kind: Deployment
      name: ibm-grpc-instana-connector
      version: v1
EOF
)
```

5. Run the following command to apply the custom resource setting that you created in the previous step:

   ```
   oc get gitapp $gitappname  -n $namespace -o json | jq ".spec.components[0].kustomization.patches += [$jsonpatch]" |
   oc apply -f -
   ```

   Note: If you see an error message when running this command that states there was a configuration conflict, try running the command a second time.

6. It takes a moment for the changes to show in the integration pod.

Note: If the memory limit is not updated for the Instana integration pod after a few minutes, run **`oc get gitapp $gitappname`** and check to see if there are any errors. If there is an error stating that the YAML is invalid, run the command below to revert the patch and go through all steps again. The cause of this error is that the format of the commands may have been altered by a text editor and should be copied directly from the documentation and run directly in the terminal.

Revert the custom resource settings to default resource settings:

To revert from custom to default resource settings, run the following command:

```
oc patch gitapp $gitappname -n $namespace --type='json' -p="[{'op': 'remove', 'path':
'/spec/components/0/kustomization/patches'}]"
```

Kafka integrations

If you are creating, or have, a Kafka integration, you might encounter the following issues:

- Kafka events not displayed in IBM Cloud Pak for AIOps
- After copying log data into a Kafka cluster, verify that the data is imported into Elasticsearch

Kafka events not displayed in IBM Cloud Pak for AIOps

You cannot see Kafka events in IBM Cloud Pak for AIOps after successfully creating a Kafka integration. This failure occurs when the Kafka key or message violates the format requirements. The **`MismatchedInputException`** error in the task manager pod log indicates this formatting error.

Solution: To ensure that the Kafka events display in IBM Cloud Pak for AIOps, check whether the following conditions are met:

1. The key in Kafka payload is null.

   Note: The key is determined by Kafka producer. Most producer tools use null object as key unless the producer is programmed to assign value.

2. The message in Kafka payload is a JSON message that satisfies the following requirements:

   - Exists in the format of the selected data source.
   - Contains sufficient data for the mapping.

After copying log data into a Kafka cluster, verify that the data is imported into Elasticsearch

To publish log data, you can copy it into a Kafka cluster. For more information, see Copying log data into the Kafka cluster. Then, you can check whether the log data is imported into Elasticsearch.

Solution: Verify that the log data is imported into Elasticsearch by getting shell access to the **`ai-platform-api-server`** pod. Run the following commands from the namespace where IBM Cloud Pak for AIOps is installed:

```
oc exec -it $(oc get pods | grep ai-platform-api-server | awk '{print $1}') -- /bin/bash
```

Example:

```
curl -X GET -u $ES_USERNAME:$ES_PASSWORD $ES_URL/_cat/indices -k | sort
```

Example output:

```
% Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100  4710  100  4710    0     0  28373      0 --:--:-- --:--:-- --:--:-- 28373

Netcool integrations

If you are creating, or have, a Netcool integration, you might encounter the following issues:

- Runbook automation pod "rba-rbs" crashes during an alert burst, for example, while connecting to Netcool
- ObjectServer alerts missing in IBM Cloud Pak for AIOps due to `No object found with id` error in the data layer
- Setting values for mandatory fields for events sent to the embedded ObjectServer
- Events from IBM Tivoli Netcool/OMNIbus are not updated in Alert Viewer
- Test connection fails in the Netcool connector UI configuration page
- Fresh alerts are missing in Alert Viewer

Runbook automation pod "rba-rbs" crashes during an alert burst, for example, while connecting to Netcool

The "rba-rbs" pod crashes and gets restarted automatically, and most of the fully automated runbooks that are associated with the new alerts are not run. This restart behavior might be observed multiple times until all the events from the event burst have been ingested, and the system reaches its regular state of operation again.

Solution: During an event burst like the one that occurs when connecting to a Netcool server, all enabled policies are evaluated, and for the matching events, the associated fully automated runbooks are started. If many matching events exist, these events might result in a high load of concurrent runbook invocations that the runbook service rba-rbs is not able to handle. The system recovers automatically. However, some runbooks will not be run during the burst.

ObjectServer alerts missing in IBM Cloud Pak for AIOps due to a `No object found with id` error in the data layer

If a new alert is rejected by the data layer, subsequent update alerts may be rejected by the data layer with the error: **`No object found with id`** being found in the **`cp4waiops-cartridge.irdatalayer.errors`** Kafka topic.

Solution: The **`AIOpsAlertId`** column must be cleared so that when its updates reach the connector, the data will be perceived as a fresh alert by IBM Cloud Pak for AIOps.

To do this, use the following steps:

1. Disable the connector's data collection (this will trigger the gateway to shut down).
2. Go to the connector pod, remove the gateway cache file and SAF file under the following directory:

   `/bindings/netcool-connector/omnibus/var/G_CONNECTOR`

3. In the ObjectServer:
   1. Rectify the data columns that had resulted in wrongly mapped values.
   2. Clear the **`AIOpsAlertId`** column of the alert.
4. Enable the connector's data collection.

When processing the next update event to that alert, the connector will see an empty **`AIOpsAlertId`** and will generate **`"type": "update"`** in the northbound CloudEvent payload.

Setting values for mandatory fields for events sent to the embedded ObjectServer

If you are manually inserting events into the embedded ObjectServer using **`nco_sql`**, you must set values for the following fields so that the events can be processed correctly:

- **`Node`**
- **`AlertKey`**
- **`AlertGroup`**
- **`Manager`**

Note: This is only a concern if you are creating an event manually using an insert statement. All IBM Netcool Operations Insight probes will set all required columns.

Events from IBM Tivoli Netcool/OMNIbus are not updated in Alert Viewer

You might notice an issue where events from IBM Tivoli Netcool/OMNIbus reach Cloud Pak for AIOps, but the updates are not reflected in the Alert Viewer. The reason for this issue is that the Netcool connector might have restarted. The connector restart causes existing alerts in Cloud Pak for AIOps to dissociate from the origin alerts in the ObjectServer.

Solution: Upgrade Cloud Pak for AIOps to version 4.5.1. After the upgrade, the new alerts are not impacted by the Netcool connector restart.

Test connection fails in the Netcool connector UI configuration page

You might notice that the test connection fails in the Netcool connector UI configuration page.

Solution: Use the following steps to diagnose and resolve the connection failure.

1. Set the IBM Netcool Operations Insight ObjectServer log message level to **debug**. This can be done by updating the **MessageLevel** property in the **$OMNIHOME/etc/{ObjectServer_name}.props** file on the Netcool host. **ObjectServer_name** is the name of IBM Netcool Operations Insight ObjectServer.
2. Click **test connection** in the Netcool UI. Check if the IBM Netcool Operations Insight ObjectServer login attempt is received.
    - If no log in attempt is seen in the IBM Netcool Operations Insight ObjectServer log, check whether the IBM Netcool Operations Insight ObjectServer host IP that is resolved on Cloud Pak for AIOps matches the IBM Netcool Operations Insight ObjectServer host IP.
    - If a log in attempt is seen but rejected by the OS authentication, check the Transport Layer Security (TLS) certificate, especially the Common Name (CN) value, which must match the fully qualified domain name (FDQN) of the server.
3. If the Connection manager is down or not responsive to the request to connect to the IBM Netcool Operations Insight ObjectServer, then restart the Connection manager pod.
4. For an on-premises IBM Netcool Operations Insight ObjectServer integration, you might notice these issues:
    - If the CN value in the TLS certificate does not match the host server FQDN, create a TLS certificate that contains the host FQDN.
    - If a firewall restriction exists on the IBM Netcool Operations Insight ObjectServer port, then update the firewall rules to unblock the port.

Fresh alerts are missing in Alert Viewer

You might notice an issue where the most recent alerts are not showing in Alert Viewer. You need to inspect the data in different stages of the pipeline to diagnose the problem.

When an alert is missing, you can scan the north-bound Kafka topics for the alert message. The following example shows the direction of the north-bound data flow:

Netcool connector -> **cp4waiops-cartridge.lifecycle.input.alerts** [topic] -> **cp4waiops-cartridge.irdatalayer.requests.alerts** [topic] -> Alert Viewer

Where:

- **[topic]** refers to a Kafka topic.
- **cp4waiops-cartridge.lifecycle.input.alerts** is a Kafka topic where all the new alerts are collected.
- **cp4waiops-cartridge.irdatalayer.requests.alerts** is a Kafka topic. **cp4waiops-cartridge.irdatalayer.requests.alerts** is one of the outcomes by the lifecycle.

Solution: Use the following steps to diagnose and resolve the missing alerts issue.

Note: Download and extract the **Ext_IAFKafkaTools.tar.gz** file located in Download Ext_IAFKafkaTools.tar.gz. After you extract the **Ext_IAFKafkaTools.tar.gz** file, follow the steps in the **README.txt** file.

1. Check whether an alert message appears in the **cp4waiops-cartridge.irdatalayer.errors** topic. Look for the alert message and run the following command.

    ```
    consumer.sh | grep <pattern>
    ```

    Inspect the cause of the error in the message.

2. Check whether the alert message appears in the **cp4waiops-cartridge.lifecycle.input.alerts** topic.

    The following example shows an alert message with **type: update**.

    ```
    {"tenantid":"cfd95b7e-3bc7-4006-a4a8-a73a79c71255","requestid":"b6079c67-8b2c-4a84-ae1d-
    9e50df05bfa1","requestTime":"2024-04-16T03:23:37.443484418Z","type":"update","entityType":"alert","entity":
    {"insights":[{"details":{"lastProcessedEventOccurrenceTime":"2024-04-16T03:23:33Z"},"id":"event-occurrence","type":"
    [aiops.ibm.com/insight-type/deduplication-details](https://aiops.ibm.com/insight-type/deduplication-
    details)"}],"deduplicationKey":"{hostname=null, name=null}-UserLogoutSessionEvent-
    ","eventCount":84341,"state":"open","id":"9e96637d-15cf-4618-bdf7-ef97e6016128","type":
    {"classification":"UserLogoutSessionEvent","eventType":"problem"},"lastOccurrenceTime":"2024-04-16T03:23:33.000Z"}}
    ```

3. If a new alert message appears in **cp4waiops-cartridge.lifecycle.input.alerts** and fulfills the positive criteria of **type: create**, check whether the message is delivered to **cp4waiops-cartridge.irdatalayer.requests.alerts**.

    If the message is not found in the **requests.alerts** topic, the message is either blocked or rejected by the lifecycle process or not yet consumed from the **input.alerts** topic.

4. If the message passes through **cp4waiops-cartridge.irdatalayer.requests.alerts**, and is not reflected in the Alert Viewer, check the data layer process.
5. Restart the pod of the processes that are not working based on the error in the message. The pods that might need a restart depending on the error can be **Grpc server**, **Life cycle processor**, and **Kafka broker**.
6. If Kafka topics storage limitation is an issue, update the Kafka storage size.

ServiceNow integrations

Incidents aren't created

Incidents might not be created for various reasons.

Solution: Complete the following checks to help ensure that incidents can be created.

1. Validate the ServiceNow URL and credentials. Go to the ServiceNow integration page, select the integration, and select **Test connection**. If the test fails, check that the URL and credentials are correct.
2. Make sure that the versions of Cloud Pak for AIOps and the IBM ServiceNow marketplace applications are compatible. For more information about which version of Cloud Pak for AIOps is in use, see Prerequisites in Creating a ServiceNow integration.
3. Make sure that a policy is configured to use the existing ServiceNow connection. For more information about creating policies, see Promote alerts to an incident.
4. Make sure that the ServiceNow integration user has the correct permissions. For more information, see Managing roles.
5. Incident tables can have business rules that prevent incident creation. Check business rules and change them so that they don't affect incident tables.

Splunk integrations

If you are creating, or have, a Splunk integration, you might encounter the following issues while creating or editing the integration:

- All fields in the Splunk form reset if edited while loading metrics
- Splunk integrations that are created before upgrade fail to update after upgrade

All fields in the Splunk form reset if edited while loading metrics

If you edit the fields in the Splunk form while the metrics are loading in the integration console, then you cannot save the changes made to the form.

Solution: To avoid this issue, do not modify the fields in the Splunk form while metrics are loading. If you do so, then redo the changes after the metrics are loaded to save the edits.

Splunk integrations that are created before upgrade fail to update after upgrade

On upgrading from 3.5.0, you might not be able to enable or disable log or metric data flows on Splunk integrations that were created before upgrade. This issue can occur intermittently.

Solution: When this issue occurs, you can refresh the console and try again after some time. Alternatively, you can create a new integration and later delete the Splunk integration that was defined before upgrade.

IBM Tivoli Netcool/Impact integrations

If you are creating, or have, a IBM Tivoli Netcool/Impact integration, you might encounter the following issues:

- IBM Tivoli Netcool/Impact integration status shows "Retrying"
- IBM Tivoli Netcool/Impact stops sending data to widgets in a JazzSM dashboard
- AIOps data source in IBM Tivoli Netcool/Impact is missing required headers

IBM Tivoli Netcool/Impact integration status shows "Retrying"

After Creating IBM Tivoli Netcool/Impact integrations, you might see a **Connection Orchestration** status of "Done", but the **IBM Tivoli Netcool/Impact integration** shows an error with a status of "Retrying".

The reason for this error might be a locked IBM Tivoli Netcool/Impact file that is preventing the creation of the IBM Cloud Pak for AIOps data model in IBM Tivoli Netcool/Impact. If this is the issue, the **impactserver-errors** logs in IBM Tivoli Netcool/Impact will display an error similar to the following:

```
30 Jun 2023 03:27:21,137 ERROR [DataModelUIResource] File etc/NCIP_datasourcelist is locked by user: root.
```

Solution: Locate and delete a file called **<servername>_versioncontrol.locks** in IBM Tivoli Netcool/Impact and restart the IBM Tivoli Netcool/Impact server and GUI.

1. Log in to the IBM Tivoli Netcool/Impact host and navigate to the **$IMPACT_HOME/etc** directory. Locate a file called **<servername>_versioncontrol.locks**. For example, **NCIP_versioncontrol.locks**.
2. Delete the file.
3. Restart the Impact server and GUI:

```
$IMPACT_HOME/bin/stopImpactServer.sh
$IMPACT_HOME/bin/stopGUIServer.sh

$IMPACT_HOME/bin/startImpactServer.sh
$IMPACT_HOME/bin/startGUIServer.sh
```

The status of the **IBM Tivoli Netcool/Impact integration** should switch to **Running** in Cloud Pak for AIOps.

IBM Tivoli Netcool/Impact stops sending data to widgets in a JazzSM dashboard

After Creating IBM Tivoli Netcool/Impact integrations, the IBM Tivoli Netcool/Impact server stops sending data to widgets in a JazzSM dashboard. The widget will report an **ATKRST132E** or **404** error code.

Solution: Re-create the parameter files for the AIOPS_HandleAction and AIOPS_ExecJS Impact policies.

For more information, refer to the troubleshooting article Netcool/Impact datasets for DASH stop working after deploying the AIOps to Impact integration.

AIOps data source in IBM Tivoli Netcool/Impact is missing required headers

When an integration is made to IBM Tivoli Netcool/Impact, a RESTful data source is created in Netcool/Impact during the initialization stage.

However, the data source may be missing one or more fields including required headers. Attempting to edit or delete such a data source will fail with an error message:

```
Error : Version Control System failed. Check system error logs for further details
```

Solution:

To remedy this, you can add the required connection details and header values using the Netcool/Impact GUI.

1. Log into the Netcool/Impact GUI. Open the **Data Model** tab and make a note of the data source name. For example, **`AIOps-impact-e92b7669-8809-4cc2-ab3c-5cbdf0db1534`**
2. Open an SSH terminal to the primary Netcool/Impact server.
3. Change to the **`etc`** directory of the application:

   ```
   cd /opt/IBM/tivoli/impact/etc
   ```

4. Locate the data source file with the .ds extension. For example, **`NCI_AIOps-impact-e92b7669-8809-4cc2-ab3c-5cbdf0db1534.ds`**

   Note: If the file does not exist, create an empty file with the name of the missing data source.

5. Use the **`svn add`** command to manually add the file to version control:

   ```
   /opt/IBM/tivoli/impact/platform/linux/svn/bin/svn add NCI_AIOps-impact-e92b7669-8809-4cc2-ab3c-5cbdf0db1534.ds
   ```

6. Use the **`svn commit`** command to check in the file:

   ```
   /opt/IBM/tivoli/impact/platform/linux/svn/bin/svn commit -m "manual commit" NCI_AIOps-impact-e92b7669-8809-4cc2-ab3c-5cbdf0db1534.ds
   ```

7. Log in to the Impact GUI **Data Model** tab. Open the AIOPs data source.
8. Enter the following values in the connection details fields:

Field Name	Value
Host Name	**`<HOSTNAME>`**
Resource Path	/aiops
Port	443
Use HTTTPS	Enabled

   Replace **`<HOSTNAME>`** with the Cloud Pak for AIOps hostname. For example, **`cpd-aiops.apps.clustername.cp.ibm.com`**.
9. In **Request Headers**, add the following headers:

Header	Value
x-tenant-id	**`cfd95b7e-3bc7-4006-a4a8-a73a79c71255`**
Content-Type	**`application/json;charset=utf-8`**
Authorization	**`ZenApiKey <KEY>`**

   In the **Authorization** field, replace **`<KEY>`** with the API key. Follow the procedure from Configuring a connection in IBM Tivoli Netcool/Impact for IBM Cloud Pak for AIOps to retrieve the key.

   Note: In Netcool/Impact 7.1.0.32, you can hide the values by declaring the request headers as a protected header instead.

10. In the **Proxy Settings** tab, set the **Proxy Port** to **`8080`** and select **`No Authentication`** as the **Authentication Method**.

    Note: The **Password** field is ignored.

11. Save the data source. Click **Test Connection** to confirm the connection works.

Ansible Automation Controller integration not running due to prohibited egress

After configuring an Ansible Automation Controller integration, the integration reports *Not running*, and no Ansible templates are shown in the *Automation Actions* table.

Use the following steps to check whether the failure is due to prohibited egress:

1. Run the following commands to view the RBA Automation Service pod logs, and check whether responses are being received from Ansible:

   ```
   export AIOPS_NAMESPACE=<AIOps installation namespace>
   oc logs -l app.kubernetes.io/component=rba-as -n ${AIOPS_NAMESPACE}
   ```

   Example output if responses are not being received from Ansible:

   ```
   Error: awxp/requestAwx.requestAwx: Request to Ansible failed... Request was not responded after 5 seconds
   ```

2. Run the following commands to attempt to connect to the Ansible instance from the RBA Automation Service pod:

   ```
   export AIOPS_NAMESPACE=<AIOps installation namespace>
   oc exec $(oc get pod -l app.kubernetes.io/component=rba-as -n ${AIOPS_NAMESPACE} -o
   jsonpath='{.items[0].metadata.name}') -c rba-as -n ${AIOPS_NAMESPACE} -it -- /bin/bash
   ```

```
# An interactive shell inside the container will open
curl -k -vvv <Your Ansible host>
```

Solution: If responses are not received from Ansible and you cannot connect to Ansible, then create a NetworkPolicy that allows egress from the RBA service pods. Run the following commands:

```
export AIOPS_NAMESPACE=<AIOps installation namespace>

cat << EOF | oc apply -f -
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: aiops-rba-rbs-egress
  namespace: ${AIOPS_NAMESPACE}
spec:
  egress:

Troubleshooting Secure Tunnel

Learn how to isolate and resolve problems with Secure Tunnel.

- Secure Tunnel connector is not running after restart with Podman
- fuser hangs when Secure Tunnel install script is launched
- When creating a Secure Tunnel connection, the status remains in pending for a long time
- Slack is unable to verify the secure tunnel URL
- Secure Tunnel connector pod in crash loop state after installation on OpenShift Container Platform cluster

Secure Tunnel connector is not running after a restart with Podman

This issue can occur when you install the Secure Tunnel connector to a host machine on which Podman is installed. When the host machine is rebooted and the Secure Tunnel connector is checked by using the **`podman ps -a`** command, the Secure Tunnel connector container does not display **`running`** status.

If this issue occurs, the **`podman-restart`** service must be activated by using the **`systemctl`** command:

```
systemctl start podman-restart
systemctl enable podman-restart
```

After entering the command, check **`podman-restart`** worked by using the following command:

```
systemctl status podman-restart
```

If the Connector is still not running, try restarting the host machine.

fuser hangs when Secure Tunnel install script is launched

After launching the Secure Tunnel install script, fuser hangs and you see something that resembles this

```
Checking whether docker or podman is installed ...
docker found.
Starting docker engine...
fuser found.
```

This issue can occur when fuser is having trouble finding a specific available port and so the execution stalls.

Solution: This issue rarely happens but should you encounter it edit the **`install-connector.sh`** and add a timeout in the fuser command.

Change **`PortCheck=$(fuser $HEALTHY_PORT/tcp 2>/dev/null)`** to **`PortCheck=$(timeout 2 fuser $HEALTHY_PORT/tcp 2>/dev/null)`**. This change can resolve the issue.

When creating a Secure Tunnel connection, the status remains in pending for a long time

When you use the **Custom** method to create a Secure Tunnel connection, the **Status** of the connection is stuck in **Pending** for a long time. This also occurs when you create a secure tunnel connection that uses a shortcut (for example, ChatOps, VMware or OpenStack).

This issue can occur when the `tls secret` was not created by the CertManager but the tunnel connection is waiting for it.

Solution: In most cases, re-creating the connection resolves the problem. If that does not work, you need to run the following command to restart the **IBM Cert Manager** and re-create the certificate CR to resolve this problem. Replace the namespace used here, `cp4aiops`, with your own namespace.

1. Find the namespace that IBM Cert Manager is deployed in.

   ```
   oc get pod -A | grep cert-manager-controller | awk '{print $1}'
   ```

2. Export environment variables:

   ```
   export CERT_MGR_NAMESPACE=<cert_namespace>
   export CONNECTION_NAME=<conn_name>
   ```

   Where:

   - `<cert_namespace>` is the namespace that IBM Cert Manager is deployed in.
   - `<conn_name>` is the name of the tunnel connection

3. Run the following commandL:

   ```
   for NAME in $(oc -n ${CERT_MGR_NAMESPACE} get pod --no-headers | grep cert-manager | awk '{print $1}')
   do
       oc -n ${CERT_MGR_NAMESPACE} delete pod ${NAME}
   done
   CONNECTION_ID=`oc -n cp4aiops get TunnelConnection ${CONNECTION_NAME} -o=jsonpath={.status.id}`
   oc -n cp4aiops delete certificates.certmanager.k8s.io sre-tunnel-${CONNECTION_ID}-server-cert
   oc -n cp4aiops delete certificates.certmanager.k8s.io sre-tunnel-${CONNECTION_ID}-connector-cert
   oc -n cp4aiops delete certificates.certmanager.k8s.io sre-tunnel-${CONNECTION_ID}-api-cert
   ```

Slack is unable to verify the secure tunnel URL

You can encounter an issue with Slack being unable to verify the secure tunnel URL after you set up a ChatOps secure tunnel connection. This issue can occur even when the Secure Tunnel UI shows that the installation was successful.

This issue can occur if you enabled the Egress Network policy with the `enableEgressNetworkPolicy: true` when you install the Secure Tunnel.

You can use the following command to check whether the egress network policy is enabled. If the egress network policy is enabled the output should be `true`.

```
oc -n <the namespace of the aiops> get Tunnel sre-tunnel -o=jsonpath='{.spec.enableEgressNetworkPolicy}'
```

Solution: Use the following YAML code to help you create an egress network policy in your IBM Cloud Pak for AIOps project (namespace) to allow Secure Tunnel access to the `ibm-nginx` gateway.

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: chatopstunnel-egress-ibm-nginx
  namespace: <the namespace of the aiops>
spec:
  podSelector:
    matchLabels:
      app.kubernetes.io/instance: sre-tunnel
      app.kubernetes.io/managed-by: tunnel
      app.kubernetes.io/name: sre-tunnel-chatopstunnel.app
      tunnel_connection_name: chatopstunnel
  egress:
    - to:
        - podSelector:
            matchLabels:
              app.kubernetes.io/component: ibm-nginx
              icpdsupport/app: gateway
              component: ibm-nginx
  policyTypes:
    - Egress
```

Secure Tunnel connector pod in crash loop state after installation on OpenShift Container Platform cluster

You might notice an issue where the Secure Tunnel connector pods stay in a crash loop state. The pod logs might show proxy related errors.

This issue can occur when the Secure Tunnel connector is installed on a cluster within an air-gapped (offline) environment that does not have outbound network access.

Solution: For the Secure Tunnel connector that is installed within the air-gapped (offline) environment, create a network connection with the Secure Tunnel server by using an HTTP proxy. You can create the connection by completing the following steps:

1. From a command line, go to the `tunnel-connector-install-scripts` directory.

2. Open the `tunnel-connector.yaml` file by using the following command:

   ```
   vi tunnel-connector.yaml
   ```

   When you open the YAML file, it can resemble the following example YAML file:

   ```
   apiVersion: v1
   kind: Secret
   metadata:
     labels:
       app.kubernetes.io/name: sre-tunnel-df012501eede4b02.secret
       app.kubernetes.io/managed-by: tunnel
       app.kubernetes.io/instance: sre-tunnel
       tunnel-network-name: woprod-test
       tunnel_connection_name: woprod-test
       tunnel_connection_id: "df012501eede4b02"
     name: sre-tunnel-df012501eede4b02-config
   data:
     config_connector.yaml: |
       <base64 encoded data>
   type: Opaque
   ```

3. Decode the `<base64 encoded data>` of the YAML file by using the following command:

   ```
   echo <base64 encoded data> | base64 -d
   ```

   Where `<base64 encoded data>` is the encoded data from the YAML file.

4. Update the `websocket_http_proxy` and `websocket_https_proxy` properties that are found in the decoded data.

   ```
   websocket_http_proxy: <http proxy endpoint>
   websocket_https_proxy: <https proxy endpoint>
   ```

   Where

   - `<http proxy endpoint>` is the HTTP proxy endpoint. This proxy is used by the tunnel connector to create a nonencrypted network web socket connection with the tunnel server. For example, the value can be `proxy.example.ibm.com:3128`.
   - `<https proxy endpoint>` is the HTTPS proxy endpoint. This proxy is used by the tunnel connector to create an encrypted network web socket connection with the tunnel server. For example, the value can be `proxysecure.example.ibm.com:3128`.

5. Encode the data by using the following command.

   ```
   echo '<decoded data>' | base64
   ```

   Where `<decoded data>` is the decoded data with the two modified properties.

6. Add the Base64 encoded data to the `<base64 encoded data>`.

   ```
   cat <<EOF | oc -n <namespace> apply -f -
   apiVersion: v1
   kind: Secret
   metadata:
     labels:
       app.kubernetes.io/name: sre-tunnel-df012501eede4b02.secret
       app.kubernetes.io/managed-by: tunnel
       app.kubernetes.io/instance: sre-tunnel
       tunnel-network-name: woprod-test
       tunnel_connection_name: woprod-test
       tunnel_connection_id: "df012501eede4b02"
     name: sre-tunnel-df012501eede4b02-config
   data:
     config_connector.yaml: |
       <base64 encoded data>

   type: Opaque
   EOF
   ```

   Where

   - `<base64 encoded data>` is the Base64 encoded data.
   - `<namespace>` is the namespace where Secure Tunnel connector is installed.

7. Restart the Secure Tunnel connector pods by using the following command:

   ```
   oc delete pod <secure-tunnel-connector-pod> -n <namespace>
   ```

   Where

   - `<secure-tunnel-connector-pod>` is the name of the Secure Tunnel connector pod.
   - `<namespace>` is the namespace where Secure Tunnel connector is installed.

Troubleshooting AI model management

Learn how to isolate and resolve problems with AI model training.

- Larger data sets are taking a long time to train
- Log anomaly detection training is taking longer than expected

- Network issues with Elasticsearch
- Network issues with Spark
- Training encounters insufficient resources
- Training reports failure but process completes
- Log anomaly detection model deployment fails with error undefined
- Ingested raw logs are not available
- Statistical baseline reference can require manual reset
- How to stop a precheck job
- Evaluation of historical metric data gives inconsistent results
- Model training considers less historical data in a data quality check
- Deployed model status in a metric anomaly or temporal grouping training algorithm is changed to pending
- Model version deployment reports failure despite being successfully deployed
- The Alert suppression XinY policies tile does not appear in AI model management
- Related events training can fail when when you are processing a high alert count
- Ticketing integration missing from list of integrations

Larger data sets are taking a long time to train

If your data sets are large, it can take a long time for AI training to complete. For example, when you run log anomaly training a large log data set might take a full day to train.

By default, two training pods are assigned to handle training jobs. This number of pods is sufficient to complete training within acceptable time periods if your data sets are not too large. However, larger data sets can take a considerable amount of time to train based on two training pods that are running in parallel.

Solution: To speed up training, you must increase the number of training pods that are dedicated to training. The default value is two pods, regardless of the type of training definition that you are running.

A limit applies to the number of training pods that can be dedicated to training. Before you increase the number of training pods that are dedicated to training, it is important for you to be aware of these limits.

Each additional training pod requires approximately the following extra resources:

- 2.5 CPU cores
- 2 - 16 GBytes of memory, depending on the AI type that is trained.

Complete the following steps:

1. Log in to your cluster.
2. Go to the target IBM Cloud Pak for AIOps namespace.
3. Find the training resource quota by running the following command:

   ```
   oc get resourcequota | grep training
   ```

4. Edit the resource quota by running `oc edit resourcequota <name of resource quota found in step 3>`. Also, edit the `spec.hard.pods` field with the number of pods you want to dedicate to training simultaneously. Ensure that you have the needed resources as described in the Before you begin section.
5. Save the edit by typing `:wq` or `:x`. After a few minutes, the changes are automatically applied to your cluster, and you can start training.

Log anomaly detection training is taking longer than expected

Log anomaly detection training is taking longer than expected. Currently, log training times are on the order of 860 log records per second. This number is significantly slower than the 25,000 log records per second that is expected in enterprise environments. Log training time is proportional to the volume of log data passed through the training system.

This issue can occur as the training rate is constrained by the current system architecture.

Solution: This issue has no simple resolution. Depending on the data you are training, the following actions might have some impact on training times:

- Increase the number of training pods that are dedicated to training, as described in the **Solution** section of Larger data sets are taking a long time to train.
- Decrease the sampling size used for the training.

Network issues with Elasticsearch

The IBM Cloud Pak for AIOps IBM Cloud Pak for AIOps console is generating lots of network errors.

This issue occurs when Elasticsearch is in an unhealthy state. It occurs most likely due to issues with Elasticsearch connectivity.

Solution: Try to get more information on potential Elasticsearch issues by examining the AI Platform pod logs. Check to see whether any error logs associated with Elasticsearch connectivity exists.

1. Log in to your cluster by running the `oc login` command. You must be an administrator user within the project (namespace) where IBM Cloud Pak for AIOps is installed.

   ```
   oc login -u <username> -p <password>
   ```

   For more information, see Logging in to the OpenShift CLI.

2. Display the logs and look for error logs associated with Elasticsearch connectivity.

```
oc logs $(oc get pods | grep ai-platform-api-server| awk '{print $1}')
```

Network issues with Spark

The AI platform has problems either launching training jobs, or reporting ongoing training status for the temporal grouping AI algorithm. As a result, you encounter errors on the Manage AI algorithms page.

This issue can occur as training jobs for the temporal grouping AI algorithm are orchestrated by the internal component Spark. When there are issues with launching training jobs or training status is not being displayed, it indicates that Spark is in an unhealthy state.

Solution: Try to get more information on potential Spark issues by examining the AI Platform pod logs.

Proceed as follows:

1. Log in to your cluster by running the **`oc login`** command. You must be an administrator user within the project (namespace) where IBM Cloud Pak for AIOps is installed.

   ```
   oc login -u <username> -p <password>
   ```

   For more information, see Logging in to the OpenShift CLI.

2. Display the logs and look for error logs associated with Spark.

   ```
   oc logs $(oc get pods | grep ai-platform-api-server| awk '{print $1}')
   ```

Training encounters insufficient resources

Training an AI algorithm returns an insufficient resources exception. The reason for this exception is that internal components within the training process were unable to locate a node with sufficient CPU or memory requirements to satisfy the training run.

Solution: The solution is to reduce the number of CPU and memory requests. Usually memory is the bottleneck so if you are unsure of what to do, a good option is to initially reduce memory by half.

1. Find the custom resource of the algorithm for which you want to alter the default resource requirements by running the following command:

   ```
   oc get algorithms
   ```

2. On running the command, custom resources containing all the algorithm specifications are displayed as follows:

   ```
   oc get algorithms
   ```

   ```
   NAME                AGE
   change-risk         46h
   log-anomaly         46h
   similar-incidents   46h
   ```

3. Edit the specific algorithm by running the following command:

   ```
   oc edit algorithm <name>
   ```

4. Decode the *spec.manifestBase64* field. Once decoded, you see a *resources* field that is defined as follows:

   ```
   resources:
       requests:
           cpu: 2
           memory: 4Gi
       limits:
           cpu: 2
           memory: 4Gi
   ```

   Note: You can edit requests and limits (make sure that **limits=requests** for training algorithms), re-encode to base64, and then replace the *manifestBase64* field in the CR with this newly encoded manifest.

5. Save the changes, and proceed with your training.

Training reports failure but process completes

An AI algorithm training run has completed, but the IBM Cloud Pak for AIOps console shows that the training has failed. No concrete model was generated during the training run.

The reason for this failure might be insufficient data or a misconfiguration in the range of the data set. Failure does not mean that the training failed; it just means that no value was obtained from the training run and consequently no model was produced.

Solution: Examine the data sources for the training, examine the training configuration, make any necessary changes, and launch the training again.

Log anomaly detection model deployment fails with error undefined

When you are training the log anomaly detection algorithm with historical data and you attempt to deploy the AI model, you might encounter an issue where the model deployment fails with an **`Error: undefined`** error in the UI.

Solution: As a workaround when this issue occurs, restart all **cp4waiops-eventprocessor** pods, which can cause the model deployment to complete successfully. To restart the pods, run the following command, which deletes the current instance of the pods and creates and starts a new instance of the pods.

```
oc delete po cp4waiops-eventprocessor-eve-29ee-ep-jobmanager-0 cp4waiops-eventprocessor-eve-29ee-ep-jobmanager-1
cp4waiops-eventprocessor-eve-29ee-ep-taskmanager-0 cp4waiops-eventprocessor-eve-29ee-ep-taskmanager-1
```

Note: If you installed IBM Cloud Pak for AIOps with a larger production deployment sizing, you need to specify any additional **cp4waiops-eventprocessor** pods that exist when you run the preceding command.

Ingested raw logs are not available immediately

Ingested raw logs are not available immediately for "Log anomaly detection - natural language" model training after the import is complete. Raw logs are not available for review in the "Preview log" section of the ChatOps Alert Viewer.

This issue can occur as additional time is required to store normalized logs in Elasticsearch after they are ingested. The amount of time can be reduced by allocating more Flink tasks to the Flink job that stores the normalized logs.

Solution: To resolve this issue, complete the following steps:

1. The environment variables that control the number of Flink tasks that are used to move logs to Elasticsearch are located in the Kubernetes deployment for aimanager-aio-controller. Edit this deployment: oc edit deployment aimanager-aio-controller
2. Find the environment variables by searching for "LOGS_JOB2_BASE_PARALLELISM". Change the value of LOGS_JOB2_BASE_PARALLELISM and LOGS_JOB2_NUM_PARTITIONS from their default values of 2 to something higher. Consider doubling the value to see whether it has the wanted effect.
3. Save the yaml and wait for the pods to restart. You can verify that the pods have restarted by monitoring the output of: oc get pods | grep aimanager-aio-controller
4. Stop the data flow for all logs integrations. It is important that there are no active logs integrations, as this is how the controller knows that it is OK to stop the Flink job, which copies the logs to Elasticsearch.
5. Restart the data flow for all logs integrations.

The Flink job restarts by using a higher number of tasks. It copies the logs to Elasticsearch more quickly.

Be careful not to allocate a higher parallelism than you have Flink task slots available. The number of tasks that you need can be calculated by adding the following values:

- sum of base_parallelism from all defined integrations, as defined in the Integration UI
- value of LOGS_JOB3_BASE_PARALLELISM multiplied by the number of logs type defined integrations (for example, Mezmo, Falcon Logscale, Splunk, and so on)
- value of LOGS_JOB2_BASE_PARALLELISM
- value of LOGS_JOB4_BASE_PARALLELISM

If you need additional task manager slots, you can add a task manager by Increasing data streaming capacity.

Statistical baseline reference can require manual reset

There is a chance that infrequently occurring anomalies are learned as normal behavior and they might not be detected anymore. For instance, if interval for the infrequently occurring anomalies do not exceed the predefined threshold of 0.15, the interval is not tagged as biased and the reference values are updated and the anomaly is learned as normal behavior. If this occurs, you need to reset the learning by resetting the reference of the statistical baseline with the following steps:

1. Open a terminal and log in to your cluster:

   ```
   oc login <server> -u <cluster username> -p <cluster pass>
   ```

2. Open another terminal and run port-forwarding for Elasticsearch

   ```
   while true; do oc port-forward $(oc get po | grep iaf-system-elasticsearch-es-aiops-0 | awk '{print $1}') 9200; done
   ```

3. Get the Elasticsearch credentials:

   ```
   export username=$(oc get secret iaf-system-elasticsearch-es-default-user -o jsonpath="{.data.username}"|base64 -d);
   export password=$(oc get secret iaf-system-elasticsearch-es-default-user -o jsonpath="{.data.password}"|base64 -d);
   ```

4. Reset the statistical baseline reference:

   ```
   curl -u $username:$password -XDELETE https://localhost:9200/1000-1000-reference_oob --insecure | sort
   ```

How to stop a precheck job

The workaround is to stop the precheck job manually using Openshift CLI commands, delete the training definition, recreate the training definition, and relaunch the training configuration with the correct details.

There are two methods to do this. The first is recommended as it limits mistakes and there is less risk of making training off sync with data in the Elasticsearch database, but the models are deleted if you use this method, whereas with the second method that is listed they will not, so it's preferable to use the second method if you want to conserve the models in question.

Method 1: Stop the precheck job and delete the training definition to start afresh

1. Retrieve the precheck job in the IBM Cloud Pak for AIOps namespace, or a different namespace that it is installed under:

   ```
   oc get jobs | grep precheck
   ```

2. Delete the precheck job in order to stop the precheck run:

   ```
   oc delete job <job-name>
   ```

3. Delete the training definition using the delete button on the console.
4. Re-create the training definition with the correct configurations required for the training algorithm, for example date range or scheduling.
5. Run the training as usual.

Method 2: Stop precheck job and clean up Elasticsearch data

1. Retrieve the precheck job in the IBM Cloud Pak for AIOps namespace, or a different namespace that it is installed under:

   ```
   oc get jobs | grep precheck
   ```

2. Delete the precheck job in order to stop the precheck run:

   ```
   oc delete job <job-name>
   ```

3. Retrieve the AI Platform pod name in the IBM Cloud Pak for AIOps namespace or different namespace that it is installed under:

   ```
   oc get pod | grep api-server
   ```

4. Enter inside the pod:

   ```
   oc rsh <pod-name> # Example: oc rsh aimanager-aio-ai-platform-api-server-55d5b59bd4-jk7nz
   ```

5. Verify the latest precheck run and retrieve the '_id' required for cleanup:

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/precheckrun/_search?pretty=true" -H 'Content-Type: application/json'
   -d '{"query": {"match_all": {}},"size": 1,"sort": [{"timestamp": {"order": "desc"}}]}'
   ```

   Example:

   ```
   "_id":
   "log_anomaly_detection_configurationv3"
   ```

6. Use the '_id' and version specified in the ID to delete the precheck respective run entries in elasticsearch:

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/precheckrun/_delete_by_query" -H 'Content-Type: application/json' -d
   '{"query": {"term": {"_id": <ID retrieved from previous step>}}}'
   ```

   Example:

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/precheckrun/_delete_by_query" -H 'Content-Type: application/json' -d
   '{"query": {"term": {"_id": "log_anomaly_detection_configurationv3"}}}'
   ```

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/precheckstatus/_delete_by_query" -H 'Content-Type: application/json'
   -d '{"query": {"term": {"precheckRunVersion": <version retrieved from previous step>}}}'
   ```

   Example:

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/precheckstatus/_delete_by_query" -H 'Content-Type: application/json'
   -d '{"query": {"term": {"precheckRunVersion": "v3"}}}'
   ```

7. Update the training definition document to decrement the precheck run version:

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/trainingdefinition/_update/log_anomaly_detection_configuration" -H
   'Content-Type: application/json' -d '{"doc": {"precheckRunVersion": <decremented version>}}'
   ```

   Example:

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/trainingdefinition/_update/log_anomaly_detection_configuration" -H
   'Content-Type: application/json' -d '{"doc": {"precheckRunVersion": "v2"}}'
   ```

8. Make your changes to the training configuration, for example to the date range or scheduling.
9. Run the training as usual.

Evaluation of historical metric data gives inconsistent results

Sending historical metric data for training – such as in a product demonstration – you see inconsistent outcomes in the IBM Cloud Pak for AIOps console metric anomaly results.

At inference (metric evaluation) time, it takes a short amount of time to load analytics models into memory. This delay might lead to some metric data being left out of an evaluation.

Solution: Send in one datapoint, for each individual metric, to allow the model to be loaded. Then, send remaining data after a short interval, 30 - 60 seconds later.

Model training considers less historical data in a data quality check

Less data is included in a data quality check if you select **Training** first instead of running a precheck and training separately.

If you select **Training** to run both a data quality check and training sequentially, you might notice this problem. This situation occurs only when some integrations are moved into live data after the training completes, and the training dates are changed to check historical data from another integration source.

Solution: Run the precheck and training separately. Start the data quality precheck, and after the precheck is complete, run the training after.

Deployed model status in a metric anomaly or temporal grouping training algorithm is changed to pending

A temporal grouping or a metric anomaly detection algorithm is in a pending state although the model was previously trained and deployed with success.

Solution: To resolve this issue, complete the following steps:

1. Run the `oc -n <namespace> rsh <aimanager-aio-ai-platform-api-server-*>` command.
2. Delete all versions of the `metric_anomaly_detection_configuration` or `temporal_grouping_configuration` training algorithms in the `trainingrun` index. Search the index by running the following command:

   ```
   ./elastic.sh -X GET -E trainingrun/_search\?pretty=true&size=1000
   ```

3. Identify all the documents that are related to your `metric_anomaly_detection_configuration` or `temporal_grouping_configuration` training algorithms. The `_id` field of the documents is `metric_anomaly_detection_configurationv<version>` or `temporal_grouping_configurationv<version>`, where `<version>` is the version of the training run.
4. Delete the training run documents:

   ```
   ./elastic.sh -X DELETE -E trainingrun/_doc/metric_anomaly_detection_configurationv1
   ./elastic.sh -X DELETE -E trainingrun/_doc/metric_anomaly_detection_configurationv2
   [..]
   ```

   or

   ```
   ./elastic.sh -X DELETE -E trainingrun/_doc/temporal_grouping_configurationv1
   ./elastic.sh -X DELETE -E trainingrun/_doc/temporal_grouping_configurationv2
   [..]
   ```

5. Delete the training definition to clean the UI:

   ```
   ./elastic.sh -X DELETE -E trainingdefinition/_doc/metric_anomaly_detection_configuration
   ```

   or

   ```
   ./elastic.sh -X DELETE -E trainingdefinition/_doc/temporal_grouping_configuration
   ```

6. Now, you can train a new model.

Model version deployment reports failure despite being successfully deployed

When you deploy LAD model version manually, you might encounter an error message on your console that reports deployment failure. The error message reads that the failure occurs due to the version being already deployed.

This error arises due to the successful deployment of the model version in the background despite getting timed out.

Solution: Restart the data flow for all the integrations. To do so, first disable and then re-enable the data flow for all integrations.

The Alert suppression XinY policies tile does not appear in AI Model Management

In the IBM Cloud Pak for AIOps console, click **AI model management** and find the *Alert suppression XinY policies* tile. If this tile does not appear, an administrator or developer user needs to restart the `aimanager-aio-ai-platform-api-server` pod.

To restart the target pod, delete the pod so that a new pod automatically starts up:

1. Connect to your cluster with the `oc login` command.
2. Restart the `aimanager-aio-ai-platform-api-server` pod.

   ```
   oc delete pod/"$(oc get pod|grep aimanager-aio-ai-platform-api-server|awk '{print$1; exit}')"
   ```

   Successfully running this command produces output similar to the following example:

   ```
   pod "aimanager-aio-ai-platform-api-server-55c5d975c4-6qpwk" deleted
   ```

Related events training can fail when when you are processing a high alert count

When you are running related events training on a data set that includes a high number of alerts (approximately 11.5M or more alerts), the training can fail. When this failure occurs the Spark log includes thrown exceptions.

The spark log exceptions can resemble the following output:

```
24/02/23 10:16:01 ERROR TaskSetManager: Task 0 in stage 3215.0 failed 4 times; aborting job
24/02/23 10:16:01 INFO TaskSchedulerImpl: Removed TaskSet 3215.0, whose tasks have all completed, from pool
24/02/23 10:16:01 INFO DAGScheduler: Job 326 failed: $anonfun$withThreadLocalCaptured$1 at <unknown>:0, took 0.996638 s
24/02/23 10:16:01 INFO TaskSchedulerImpl: Cancelling stage 3215
24/02/23 10:16:01 INFO TaskSchedulerImpl: Killing all running tasks in stage 3215: Stage cancelled: Job aborted due to
stage failure: Task 0 in stage 3215.0 failed 4 times, most recent failure: Lost task 0.3 in stage 3215.0 (TID 2975)
(10.254.75.83 executor 0): org.apache.spark.SparkException: Checkpoint block rdd_680_0 not found! Either the executor
```

```
that originally checkpointed this partition is no longer alive, or the original RDD is
unpersisted. If this problem persists, you may consider using `rdd.checkpoint()`
instead, which is slower than local checkpointing but more fault-tolerant.

        at org.apache.spark.rdd.RDD.iterator(RDD.scala:328)
```

Solution: As a workaround if this failure occurs, increase the spark worker memory limit and run the training again.

The spark worker memory limit can be modified by using the following command:

```
oc edit sts aiops-ir-analytics-spark-worker
```

The field that needs modification is the **memory** field as shown in the following example output:

```
resources:
  limits:
    memory: 8000Mi
```

Ticketing integration missing from list of integrations

If a ticketing integration is missing from the list of integrations in a training module such as Similar tickets or Change risk, you should update that integration. To do this, edit the integration and either update the existing description or add a new one, then save your changes. This action will trigger a resynchronization of the connector schema for that integration. After a few minutes, the updated integration should appear in the trainer **Integrations** table.

Troubleshooting alert management

Learn how to isolate and resolve problems with alert management.

- No alert or incident created when an event is sent
- No alert ranking with large installations
- Closed alerts are not being removed from Alert Viewer
- No alerts shown in Alert Viewer and "Unknown error" message is displayed
- Alert list ignores saved view sort order
- "Unknown error" message in Alert Viewer when you click the alert view without selecting the ID and Summary columns

No alert or incident created when an event is sent

Symptom A: An event is sent, but no alert is received by IBM Cloud Pak® for AIOps and no incident is created.

Running **waiops-mustgather.sh -V flink-jobs** using the must-gather tool, returns **"RESTARTING"** or **"FAILED"** under the entry **[FLINK = aiops-ir-lifecycle]**. For example:

```
[FLINK = cp4aiops]
{
  "jobs": []
}

[FLINK = aiops-ir-lifecycle]
{
  "jobs": [
    {
      "id": "4e442c7880239bede340e953e6b920b3",
      "status": "RESTARTING"
    }
  ]
}
```

This issue might be caused by a volume of event data that is too large for the given installation size and configured policy set. This can cause the policy engine to run out of available memory.

Solution: To resolve this issue, complete the following steps:

1. Evaluate the sizing of the installation compared to the current event load. If there is a miss-match, change the installed sizing, or the configured event sources.

2. Ensure that incident creation policies are only configured to raise incidents for alerts which require immediate resolution. Incidents are more resource intensive to process than alerts, so creating incidents for all alerts will require a larger sized installation.

3. After re-configuring the system, the policy engine may still be in a failure state as it tries to re-process the already-inserted events. It is possible to reset the policy engine so that it only processes new events using the must-gather tool:

   ```
   waiops-mustgather.sh -DR -C clear-lifecycle-state.sh
   ```

   NOTE: Resetting the policy engine will cause all policy state to be lost. This may result in events creating new alerts and incidents rather than being deduplicated into existing ones. It will also mean that any events inserted in the time between the failure and running this command will not be processed by the system.

4. Restart the **flink** pods:

   1. Search for the pods that match the string `aiops-ir-lifecycle-eventprocessor-ep`
      This should return four pods.
   2. Right-click and **Delete** the pods.
      The pods should restart immediately.

Symptom B: An event is sent, but no alert is received by IBM Cloud Pak® for AIOps and no incident is created. The log of the lifecycle task manager pod contains the following error:

```
WARNING: Exception thrown during asynchronous load
java.util.concurrent.CompletionException: io.grpc.StatusRuntimeException: UNAVAILABLE: ssl exception
```

The issue might be a certificate mismatch between the lifecycle operator and the policy GRPC server, causing the connection to fail with SSL exceptions.

Solution: To resolve this issue, complete the following steps:

1. Run the following command to delete the certificate:

   ```
   oc delete secret aiops-ir-lifecycle-policy-grpc-clt-svc aiops-ir-lifecycle-policy-grpc-svc
   ```

2. Get the lifecycle-operator pod name:

   ```
   oc get pods |grep ir-lifecycle-operator-controller-manager
   ```

3. Restart the lifecycle operator:

   ```
   oc delete pod ir-lifecycle-operator-controller-manager-<lifecycle-operator-pod-name>
   ```

No alert ranking with large installations

On larger production scale installations of IBM Cloud Pak® for AIOps, no ranking of alerts is displayed in the Alert Viewer.

Solution: To resolve this issue, complete the following steps:

1. Run the following command to find the **classifier** and **probablecause** pods:

   ```
   oc get pods | egrep -i "classifier|probablecause"
   ```

   For example:

   ```
   oc get pods | egrep -i "classifier|probablecause"

   aiops-ir-analytics-classifier-6477fd7788-4rzwx                    1/1     Running     0
   aiops-ir-analytics-classifier-6477fd7788-8jd55                    1/1     Running     0
   aiops-ir-analytics-probablecause-5b89d56c44-b752h                 1/1     Running     1
   aiops-ir-analytics-probablecause-5b89d56c44-kpqcb                 1/1     Running     1
   ```

2. Restart the pods:

   ```
   oc delete pods aiops-ir-analytics-classifier-6477fd7788-4rzwx aiops-ir-analytics-classifier-6477fd7788-8jd55 aiops-
   ir-analytics-probablecause-5b89d56c44-b752h aiops-ir-analytics-probablecause-5b89d56c44-kpqcb
   ```

Closed alerts are not being removed from Alert Viewer

You might notice an issue where closed alerts are not being removed from the Alert Viewer.

If this issue occurs, you might see an error that is related to timeouts for requests to Postgres. This error can be similar to the following example:

```
[2023-12-12T17:30:30.022Z] ERROR: datalayer.postgres/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz: Error detected on
streaming query
    Error: Query timed out
        at Timeout._onTimeout (/app/lib/helpers/dbservice/lib/helpers/dbservice/postgres.js:178:20)
        at listOnTimeout (node:internal/timers:559:17)
        at processTimers (node:internal/timers:502:7)
[2023-12-12T17:30:30.022Z] ERROR: datalayer.postgres/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz: Error detected on
client connection. Ending query stream (reqid=13778660-9914-11ee-844d-e573891ebc4b)
    Error: Query timed out
        at Timeout._onTimeout (/app/lib/helpers/dbservice/lib/helpers/dbservice/postgres.js:178:20)
        at listOnTimeout (node:internal/timers:559:17)
        at processTimers (node:internal/timers:502:7)
[2023-12-12T17:30:30.024Z] ERROR: datalayer.postgres/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz: Error detected on
streaming query cursor
    Error: Connection terminated
```

```
    at Connection.<anonymous> (/app/node_modules/pg/lib/client.js:132:36)
    at Object.onceWrapper (node:events:627:28)
    at Connection.emit (node:events:525:35)
    at Socket.<anonymous> (/app/node_modules/pg/lib/connection.js:63:12)
    at Socket.emit (node:events:525:35)
    at TCP.<anonymous> (node:net:301:12)
```

This issue might be caused by the failure of the datalayer job manager. Since the job is not running, there is no automated process for clearing the closed alerts.

Solution: Use the following steps to resolve the closed alerts issue:

1. Determine the name of the datalayer job manager pod.

   ```
   oc get pod -l "app.kubernetes.io/component=ncodl-jobmgr"
   ```

   The output from the preceding command can look like the following example::

   ```
   [root@6c025b05c0a7 /]# oc get pod -l "app.kubernetes.io/component=ncodl-jobmgr"
   NAME                                          READY   STATUS    RESTARTS   AGE
   aiops-ir-core-ncodl-jobmgr-85458b4979-gqgj8   1/1     Running   0          5h11m
   ```

2. Use the pod name to describe the job manager pod. If the pod is in a crash loop or not scheduled status, use the following command to see the failure:

   ```
   oc describe pod <pod name>
   ```

   Where **<pod name>** is the name of the datalayer job manager pod.

   If the failure reason from describe command is not clear or the pod appears to be running fine then check the pod logs for potential run failure conditions. Use the following command to check the logs:

   ```
   oc logs <pod name>
   ```

   Where **<pod name>** is the name of the datalayer job manager pod.

   You can, for example, search for "Alert delete job" in the logs. "Alert delete job" must be running. The logs for delete job are shown in the following example.

   ```
   [2023-12-12T17:38:00.002Z]  INFO: datalayer.jobmgr/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz: Running: Alert
   delete job [2023-12-12T17:38:30.120Z]  INFO: datalayer.jobmgr/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz:
   Complete: Alert delete job
    metrics: {
      "fetched": 0,
      "deleted": 0,
      "failed": 0
    }
    --
    psql: [
      {
        "name": "deletes",
        "mean": 0,
        "min": 0,
        "max": 0
      },
      {
        "name": "relatedDeletes",
        "mean": 0,
        "min": 0,
        "max": 0
      }
    ]
   ```

3. Use the following command to check whether the postgres instance is **Running**:

   ```
   oc get pods | grep postgres
   ```

   The postgres pod name might be similar to **ibm-cp-watson-aiops-edb-postgres-***. The asterisk (*) represents multiple pods that might be running for postgres.

4. If the Postgres instance is running fine, then it is possible that the instance might be busy and overloaded. If you see the preceding error such as "timeouts on request Postgres" or if the Postgres instance is running fine, in both cases use the following script to manually purge and recover the system.

   ```
   #!/bin/bash

   EDBPOD=ibm-cp-watson-aiops-edb-postgres-1
   EBDSECRET=aiops-ir-core-postgresql

   # Get the credentials from required sec
   USERNAME=$(oc get secret ${EBDSECRET} -o=jsonpath='{.data.username}' | base64 -d)
   PASSWORD=$(oc get secret ${EBDSECRET} -o=jsonpath='{.data.password}' | base64 -d)
   DBNAME=$(oc get secret ${EBDSECRET} -o=jsonpath='{.data.dbname}' | base64 -d)
   SCHEMA=$(oc get secret ${EBDSECRET} -o=jsonpath='{.data.schema}' | base64 -d)

   # RSH into EDB container.
   oc rsh ${EDBPOD} psql -h localhost -p 5432 -U ${USERNAME} "dbname=${DBNAME} sslmode=require" -- <<EOF
   ${PASSWORD}

   DELETE FROM aiops_irb.alerts WHERE state=2;
   DELETE FROM aiops_irb.insights insight WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE insight.parentid =
   alert.alertid) AND NOT EXISTS(SELECT 1 FROM aiops_irb.stories story WHERE insight.parentid = story.storyid);
   ```

```
DELETE FROM aiops_irb.links link WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE link.parentid =
alert.alertid) AND NOT EXISTS(SELECT 1 FROM aiops_irb.stories story WHERE link.parentid = story.storyid);
DELETE FROM aiops_irb.timeline timeline WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE timeline.parentid
= alert.alertid) AND NOT EXISTS(SELECT 1 FROM aiops_irb.stories story WHERE timeline.parentid = story.storyid);
DELETE FROM relationships relation WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE relation.childid =
alert.alertid) AND NOT EXISTS(SELECT 1 FROM aiops_irb.stories story WHERE relation.parentid = story.storyid);
DELETE FROM aiops_irb.alerts_details detail WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE
detail.identifier = alert.identifier);
EOF
```

Where **EDBPOD** is the Postgres pod name that you obtained previously.

The script deletes all closed alerts from the Alert Viewer. The job manager will also be able to remove the future closed alerts automatically.

A sample output from successful execution of the script:

```
Defaulted container "postgres" out of: postgres, bootstrap-controller (init)
Password for user aiops_irb:
DELETE 0
DELETE 0
DELETE 0
DELETE 0
DELETE 0
DELETE 0
```

The number after the **DELETE** keyword is the number of rows that are deleted.

"Unknown error" message in Alert Viewer and no alerts displayed

Symptom: No alerts are shown in the Cloud Pak for AIOps Alert Viewer and "Unknown error" message is displayed on the UI.

Cause: The problem might be that the number of alerts exceeds what the Alert Viewer can process. A production deployment of Cloud Pak for AIOps can process a standing alert count of up to 200,000 alerts, with a chosen subset displayed in the Alert Viewer. The precise number of alerts that can be shown depends on different permutations of variables that affect the performance of the Alert Viewer. For example, standing alert count, filtered alert count, and view used (such as simple columns with alert data, or complex columns with insights and custom user enriched columns).

Solution: At first (during deployment or creation of a new view), try excluding columns with insights or columns based on custom properties. You can then add these columns sequentially to better gauge how many alerts a view can handle. For more information, see Creating views.

You can also restrict the number of alerts that are returned by the data layer to the Alert Viewer. This can improve performance issues on the backend. For more information, see Restricting the number of alerts returned by the data layer to the Alert Viewer.

Alert list ignores saved view sort order

Symptom: The alerts table sort order you wanted to apply to it does not save as expected.

Cause: It might be related to a similar issue, which deals with editing the alert view and how it then does not show the correct configuration when launched for the first time. This is due to having to fetch users and groups before being able to show the right view configuration. This is being fixed now also, so should no longer be an issue in future releases.

Solution: If the original alert table sort order didn't save as expected, you have to apply the sort order again after the alerts table is loaded.

"Unknown error" message in Alert Viewer when you click the alert view without selecting the ID and Summary columns

Symptom: You may get the unknown error when you click the alert view without having selected the ID and SUMMARY columns.

Cause: This problem is because the view requires the ID and SUMMARY columns to be part of the view. If these columns are not included in the view then it will be unusable and the only way to delete that view will be by using the API.

Solution: Include the ID and SUMMARY columns in the alert view. If you do not and cannot then delete the unusable view that results, you will have to delete the view using the API.

Troubleshooting Runbook Automation

Learn how to isolate and resolve problems with Runbook Automation.

- SSH action output shows "Permission denied" error
- SSH automation action output for PowerShell shows garbled multi-byte characters
- Exported runbook includes password from referenced action in clear text (if any)
- Runbook approval request not visible

SSH action output shows "Permission denied" error

Symptom: When attempting to run an SSH action script on some Linux target system, an error such as `bash: /tmp/tmp.gXO9WCs7Zy: Permission denied` is displayed in the script output area.

Cause: In order to run an SSH script on a Linux target system, Runbook Automation writes a temporary script file to the `/tmp` directory of the target system, and executes it from there. So the user on the target system that is configured to run the SSH script remotely does not only need to have write access to the `/tmp` directory , but also the `/tmp` directory itself must not be mounted with the `noexec` property.

Solution: Mount the `/tmp` directory without the `noexec` property, and verify that scripts can be run from within `/tmp`. Then retry running the SSH action.

If using the `/tmp` directory with write and execute access is prohibited in your organization then you can configure `mktemp` to use a different directory, for example, by generally setting the target system user's `TMPDIR` environment variable to an alternative directory path. See Creating an SSH integration for more details on the requirements for target systems of SSH connections.

SSH automation action output for PowerShell shows garbled multi-byte characters

Symptom: When running a PowerShell script on a Windows target system that is expected to print multi-byte or other non-ASCII characters, these characters are not properly displayed. Instead, these characters are replaced with question marks.

Cause: Runbook Automation expects the script output to be returned in UTF-8 format, but PowerShell is not configured to use UTF-8 as the default console output encoding.

Solution: Add an instruction to your PowerShell script code to set the console output encoding to UTF-8. For example, start your script with the following command:

```
$OutputEncoding = [Console]::OutputEncoding = [Text.UTF8Encoding]::UTF8
```

See the Microsoft documentation for more details on character encoding in PowerShell.

Exported runbook includes password from referenced action in clear text (if any)

Symptom: If an HTTP action has parameters for basic authentication configured, and the action is referenced by a runbook, then exporting the runbook using the RBA API includes the password in clear text.

Cause: The exported runbook is intended to be self-contained, so when imported to the same or a different deployment, the runbook is usable again (which includes having the password available). However, there is no password encryption/decryption mechanism in place for this scenario.

Solution:

- Avoid specifying passwords within actions.
- Store the exported runbook file in a place that only persons with a need-to-know for the password(s) have access to.
- Encrypt the exported file manually.

Runbook approval request not visible

Symptom: When the approval flow is enabled, and a runbook has been previously published, then a new request for approval for an updated draft of the runbook is not visible in the runbook library table. The expected approval status is "Approval pending". Instead, the runbook continues to be marked as "Approved".

Cause: The runbook library table displays the data from the last published version of the runbook, or from the draft runbook if it has never been published before. Therefore, approval requests for new draft runbooks are visible, but not for runbooks that have been previously published.

Solution: As author of the change, notify the approver which runbook needs to be reviewed and approved. As approver, open the runbook in "edit" or "preview" mode to see the latest changes. Directly communicate with the author if changes are needed. Once the runbook is ready to be published, disable the approval flow temporarily, and publish the runbook.

Troubleshooting ChatOps

Learn how to isolate and resolve problems with ChatOps IBM Cloud Pak® for AIOps.

- Slack buttons are unresponsive
- Log preview dialog or View alerts dialog hangs intermittently in an incident in Slack or Microsoft Teams
- Alert and incidents do not appear in Slack
- Slack ChatOps integration is not working within an air-gapped (offline) environment
- Microsoft Teams ChatOps integration shows no response in the console
- During a ChatOps secure tunnel creation an 'installation failed' message displays
- Show more button does not work in Slack after an upgrade
- Links in ChatOps incident messages are invalid

Slack buttons are unresponsive

Unresponsive buttons might be caused by a number of issues. If you encounter this issue, try completing the following steps to find the cause of the problem:

1. **Ensure two-way communication is established:**
    1. **Test two-way communication:** Incoming incidents are proof that one-way communication from IBM Cloud Pak for AIOps to Slack is successful. To check two-way communication, tag the IBM Cloud Pak for AIOps bot in the Slack channel. It responds with "Hey there I'm up and running." If it doesn't, IBM Cloud Pak for AIOps might not be receiving any communication from Slack.

2. **Verify endpoints:** If the IBM Cloud Pak for AIOps bot did not respond, it might be that Slack is trying to communicate with the wrong endpoints, or the endpoints are not publicly accessible. To make sure that the endpoints are correct, open up the slack api for the app and navigate to the app manifest. The `event_subscriptions` and `interactivity` urls should match the ones that are produced by the IBM Cloud Pak for AIOps slack configuration and should be verified by Slack. If they do match but Slack has not verified them, that means Slack cannot access the endpoints likely because they are private. Slack needs some kind of proxy to access the private endpoints. A secure tunnel can be used in scenarios like this. For more information, see Secure Tunnel.

2. **Check communication speed:** If there are no problems with the steps that are outlined above, then it is possible the communication between Slack and IBM Cloud Pak for AIOps is taking too long. If a button is clicked, Slack waits 3 seconds to receive a response. If it doesn't get one, the communication is rejected and the button click fails. This is a rare occurrence, but can happen if the network communication is too slow, or if something else is preventing communication from happening in a timely manner. Try reconnecting and reconfiguring the Slack integration. For more information, see Creating a Slack integration. Then, verify that the issue is resolved.

3. **Look for errors in the ChatOps pods:** If 2-way comms are successful, and network communication seems to be fine, try logging in to the cluster to look at the logs. Look at the `aimanager-aio-chatops-slack-integrator` and `aimanager-aio-chatops-orchestrator` pods for any unusual errors and then contact the L2 support team.

Log preview modal or View alerts modal hangs intermittently in an incident in Slack or Microsoft Teams

This issue might happen when the Log Anomaly detection is in a high load, and takes longer time than normal to respond. When it occurs, you might encounter the following :

- When you select **View alerts** in an incident in Slack or Microsoft Teams, it hangs with the `Loading ...` message.

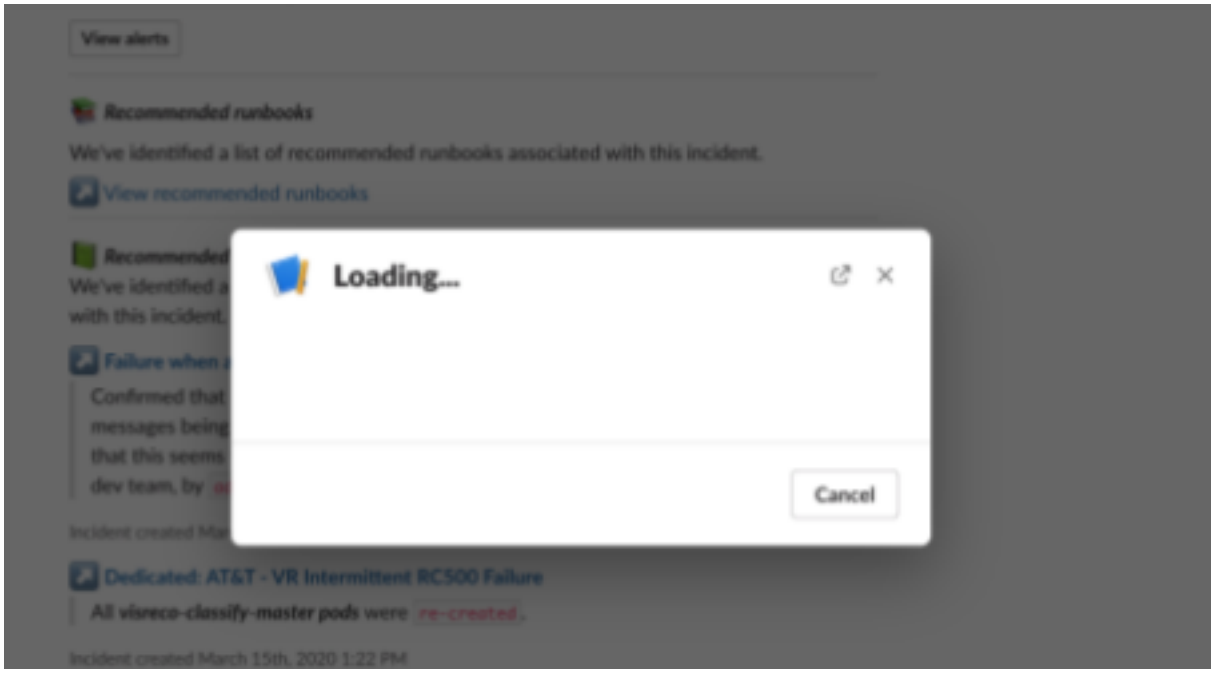

Figure. View alerts

- The **Log preview** dialog in Slack or Microsoft Teams hangs with the `Loading log data..` message.

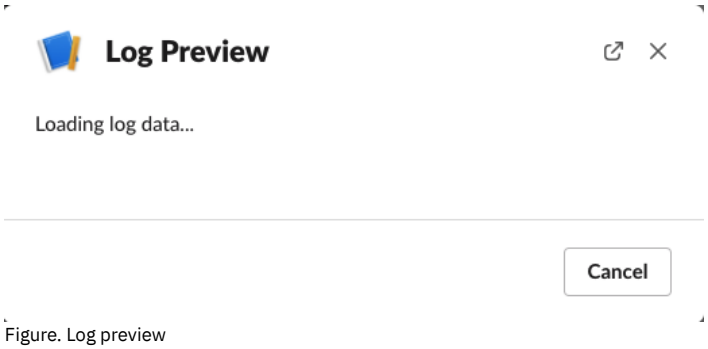

Figure. Log preview

- Checking the log results in something similar to this:

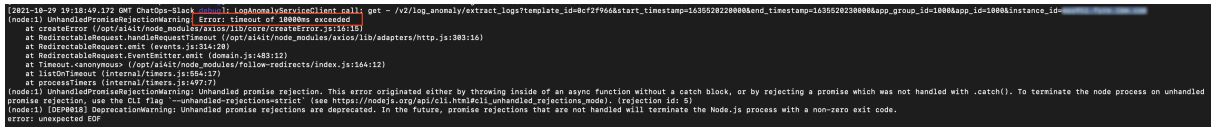

Figure. View log

Solution: close the **View alerts** dialog or the **Log preview** dialog in Slack or Microsoft Teams, and retry the operation.

Alerts and incidents not appearing in Slack

Alerts and incidents are showing up on IBM Cloud Pak for AIOps console but not in Slack ChatOps.

A number of causes can be considered when alerts are not showing up in Slack. Try one or more of the following to help resolve the problem.

1. Make sure that alerts and incidents are being created from events: alerts and incidents can be seen in the *Incidents and alerts* page in the IBM Cloud Pak for AIOps console. If events are flowing but no alerts or incidents are being created, review Troubleshooting alert management.
2. Double check channel IDs: if alerts and incidents are visible in the IBM Cloud Pak for AIOps console, make sure the channel IDs are correctly pasted in the ChatOps data integration form. Ensure the channel ID rather than the channel name is being used and make sure that no extra blank spaces are in the form field. Instructions for retrieving channel IDs can be found in the Configuring Slack applications for integration page.
3. Ensure that the Slack app is a channel member: to post incident messages, the IBM Cloud Pak for AIOps Slack app must be a channel member of the channel IDs being used. To add an application to a channel, tag the bot with the "@" symbol followed by the bot name.
4. Look for any visible errors in the **`chatops-slack-integrator`** logs. If the IDs are correct and the app is a channel member, look for error messages in the pod and contact the L2 support team.

Note: If the Slack app is not properly configured when an incident is initially created, that incident is not posted to Slack. Only when the app is successfully configured do new incidents, and updates to those incidents, get posted.

Slack ChatOps integration is not working within an air-gapped (offline) environment

If you create a Slack integration within an air-gapped (offline) environment, the integration might not work as expected. When you first create the Slack integration, the test of the integration (by clicking **Test connection to Slack.com.**) must be successful. If the test was successful, but the Slack integration is still not working, restart the Slack integrator pod to retrieve the latest integration information.

To restart the pod, complete the following steps:

1. From a command line, use the OpenShift CLI **`oc login`** command to log in to your cluster.
2. Switch to the project (namespace) where IBM Cloud Pak for AIOps is installed:

   ```
   oc project <project>
   ```

   Where **`<project>`** is the project (namespace) where IBM Cloud Pak for AIOps is installed.
3. Retrieve Slack integrator pod name:

   ```
   oc get pods | grep slack
   ```

   Record the name of the Slack integrator pod.
4. Delete the pod to cause the pod to restart:

   ```
   oc delete pod <slack integrator pod>
   ```

   Where **`<slack integrator pod>`** is the name of the pod name.

Microsoft Teams ChatOps integration shows no response in the console

If you have a Microsoft Teams ChatOps integration, you can encounter an issue the Microsoft Teams console shows no response through the integration. This issue can occur when you install and configure a Secure Tunnel for IBM Cloud Pak for AIOps on an on-premises Red Hat OpenShift Container Platform and configure a corresponding Secure Tunnel connecter for Microsoft Teams on a virtual machine (VM) that is accessible from a public network.

If you encounter this issue, complete the following steps:

1. Verify that the Secure Tunnel is working.

   1. Log in to the IBM Cloud Pak for AIOps console.
   2. Go to **Administration** > **Secure Tunnel**.
   3. Verify that the Secure Tunnel connection is configured and that the status is **`Ready`**.
   4. Click into the **Application mappings** column of your Secure Tunnel connection. Verify the URLs list in the **Application mapping address** column.

   Notes:

   - If the status is not **`ready`**, then check whether the Secure Tunnel Connector is installed and running. For more information about setting up the connector, see Install the Secure Tunnel Connector.
   - If your Secure Tunnel Connector is running, but you do not see the status as **`Ready`** for the connection, check the log messages from the Secure Tunnel Connector container.
     - If the log message indicates TLS errors, you might not have the correct Secure Tunnel Connector package. Verify that the installed package is correct. If necessary, download and install the correct package. For more information about installing the connector, see Install the Secure Tunnel Connector.
     - If the log message indicates a connecting error, check whether you can access the virtual machine (VM) where the Secure Tunnel Connector is installed from the Secure Tunnel pod.
2. Verify that the network between the Secure Tunnel and the VM on which Secure Tunnel Connector is installed is accessible.

1. Log in to the Red Hat OpenShift Container Platform console where IBM Cloud Pak for AIOps is installed.
2. Go to **Workloads** > **Pods**.
3. Switch to the project (namespace) for IBM Cloud Pak for AIOps.
4. Filter the pods to find the secure tunnel pod. For instance filter by **`sre-tunnel-network`**.
5. Click listed pod. Then, click **Terminal**.
6. Access the IP address of your VM by running a command similar to the following **`curl`** command on port **`50443`**:

   ```
   curl -k https://your.vm.external.host.com:50443
   ```

   - If you get any SSL error from the command, the error indicates that the network connection is working.
   - If you a message tht indicates **`Connection refused`** from the command, the message indicates that the network connection is not reachable. Contact your network administrator to fix the network connection.

3. Verify that the configuration of the Microsoft Azure Bot for the ChatOps integration is correct.
   1. Log in to the Microsoft Azure portal, and click **Bot services**. Then, click your Azure bot.
   2. Click **Configuration** under **Settings**.
   3. Check the **`messaging endpoint`** setting. Replace the **`request URL`** value with the **`application mapping URL`** from the Secure Tunnel connection. For more information about the settings for the connection, see Creating a Microsoft Teams connection.
   4. Attempt to send the message **`@<bot_name> /waiops_welcome`** in Microsoft Teams. If the connection still does not work, other issues might exist. contact your network administrator for assistance with investigating and fixing the network connection.
4. Verify that the network between the Microsoft Azure Bot and the VM on which the Secure Tunnel connector is installed is accessible:
   1. Log in to the terminal of the VM on which you installed the Secure Tunnel connector.
   2. Find the network interface (NIC) that is accessible from public network. You can use a command like **`ip address`** to find this interface. For example, if your network interface is **`eth1`**, listen to the port **`12443`** on that network interface by using the command **`tcpdump -i eth1 port 12443`**.
   3. Test the access to the **`application mapping URL`** of your Secure Tunnel connection from your device or from another device outside of your on-premise netowork. For example, run the following command, where **`your.vm.external.host.com`** is your VM host.

      ```
      curl -k -X POST
      https://your.vm.external.host.com:12443/aiops/aimanager/instances/1683613041902750/teams/api/messages
      ```

   4. Verify that there are outputs from the **`tcpdump`** command while you run the **`curl`** command.

      If you do not find any output from the **`tcpdump`** command, you might have firewalls or ACL restrictions that are blocking inbound traffic to the VM. Contact your network administrator to grant inbound traffic on port **`12443`** for the VM and retest the command.

During a ChatOps secure tunnel creation an 'installation failed' message displays

When you create a ChatOps integration and it fails, wait for a few minutes to see if the installation retries, and if it does not simply create the integration again.

Show more button does not work in Slack after an upgrade

You might notice an issue where the **Show more** button does not work in Slack after an IBM Cloud Pak for AIOps upgrade.

The reason for this issue is that the TLS certificate CA for ChatOps is updated through the upgrade, and the tunnel **`ApplicationMapping`** is still using the previous TLS certificate CA.

If you encounter this issue, use the following steps to restart the pod **`sre-tunnel-controller-a-`**. This restart causes the Secure tunnel controller pod to update the TLS certificate CA:

1. Get the name of the Secure tunnel controller pod:

   ```
   oc get pod | grep sre-tunnel-controller-a-
   ```

2. Restart the pod **`sre-tunnel-controller-a-*`**:

   ```
   oc delete pod <Secure tunnel controller pod>
   ```

   Where **`Secure tunnel controller pod`** is the name you extracted in the preceding step.

Links in ChatOps incident messages are invalid

In ChatOps incident messages for IBM Cloud Pak for AIOps 4.6.0, the following incident message links are invalid:

- On the *Associated automations* message, the **View associated automations** link is invalid.
- On the *Incident resources* message, the **View incident resource topology** link is invalid.

For IBM Cloud Pak for AIOps 4.6.0, go to the incident page to view the associated runbooks and resources.

Troubleshooting topology

Learn how to isolate and resolve problems with the Topology viewer and topology service.

To help you with troubleshooting topology issues, review the topology service logs. For more information, see Viewing the topology logs.

Common issues:

- Chrome extension display issues on Incident Topology page
- Error connecting topology services to Cassandra database
- Observer schedule toggle becomes disabled after saving the job
- File Observer fails due to hidden characters
- Kubernetes Observer job fails to restart after OOM
- Halt a Cassandra node for maintenance
- Topology observer job failure due to prohibited egress
- Topology viewer user interface crashes after the update manager is displayed

Chrome extension display issues on Incident Topology page

When displaying the details for a listed event in the Resolution Hub by using the Chrome browser, the resizing of the page might cause screen errors. This is caused by the MEGA Secure Cloud Storage and Chat Chrome browser extension.

Solution: Remove the MEGA Secure Cloud Storage and Chat extension.

Error connecting topology services to Cassandra database

During startup, the topology service can attempt to connect to the Cassandra database before it is fully started, which causes an error, followed by a warning message similar to the following message:

```
WARN   [2022-02-28 11:01:36,748] [main] c.i.i.t.g.ConnectionManager -  failed to connect to storage back end sleeping before retrying.
```

This issue can occur when the topology service has started before the Cassandra database is fully ready.

Solution: You do not need to complete any workaround. The topology service tries to connect to the Cassandra database repeatedly. When the Cassandra database is up and running, the service can successfully connect.

Observer schedule toggle becomes disabled after saving the job

After editing and saving an observer job that includes scheduled jobs, the **Schedule request** toggle becomes disabled. However, the job remains scheduled and continues to run in the background.

This issue can occur when the **Schedule request** toggle fails to read the existing job schedule and erroneously reverts to its default setting of **Off**.

Solution: The job scheduling remains active and no workaround is required. To confirm the existing observer job schedule:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. On the *Add integration** page, click **Topology** in the *Category* list that is next to the list of all integrations.
5. Click the **configure, schedule, and manage other observer jobs** link in the description for the topology integration.
6. Select the observer.
7. Confirm that the job schedule remains active.

File Observer fails due to hidden characters

An error can occur when your File Observer input file contains hidden characters that interfere with the processing of the content.

```
The following lines numbers had problems, check the logs for details: 1
```

This issue can occur when a file appears compliant in content and format, but is in a UTF-8 Unicode (with BOM) file format (instead of the regular UTF-8 file format).

Solution: Change the file format. For example, you can create a new file from the source file by using the following command:

```
sed '1s/^\xEF\xBB\xBF//' < topology.txt > new.txt
```

Kubernetes Observer job fails to restart after OOM

Kubernetes Observer jobs with very large payloads can encounter an OOM (out-of-memory) error, after which they may fail to restart. The observer appears offline, but a health check fails to flag any errors.

Solution: Restart the observer if it appears as offline in the UI.

Halt a Cassandra node for maintenance

Sometimes you need to manually maintain the Cassandra server nodes. For example, you might need to halt one node for long enough to allow you to complete the required maintenance work or debug a problem.

The following steps suspend (halt) one Cassandra node while the other nodes still serve queries, which allows you to perform maintenance tasks without shutting down your production environment.

Note: To reduce the impact of pausing a Cassandra node on the performance of your remaining system resources, keep such maintenance periods to a minimum.

Halt the node

1. Edit the bootstrap configMap.

```
oc edit configmaps aiops-topology-cassandra-bootstrap-config
```

For example, if you want to halt node 0, you can set the following columns.

```
hostname_filter: aiops-topology-cassandra-0
running_mode: maintenance
```

2. Save and exit.

3. To restart the target node pod, you delete the pod so that the statefulSet will restart the pod automatically. Then it should be halted.

```
oc delete pod aiops-topology-cassandra-0
```

Debug the Cassandra server

After the node is restarted and halted, you should see that its state stays as `0/1 Running`. When the pod is in this mode, the Cassandra server is not automatically started in it. The `liveness` probe and `readiness` probe will not be activated for many days in this pod, allowing you to perform any maintenance that is required.

There are two methods to start the Cassandra server for debug purposes.

- You can go into the pod container to manually start the server.

  ```
  oc exec -it aiops-topology-cassandra-0 -- bash
  bash-4.4$ /opt/ibm/cassandra/bin/cassandra -fR > /tmp/server.log 2>&1 &
  ```

  The server process will be started in the background and the log messages can be found in file `/tmp/server.log`.

- You can reuse the entry point script.

  ```
  oc exec -it aiops-topology-cassandra-0 -- bash
  bash-4.4$ export RUNNING_MODE=normal
  bash-4.4$ /opt/ibm/start-cassandra.sh > /tmp/server.log 2>&1 &
  ```

Example maintenance task: Remove corrupt commit logs that are causing Cassandra to not start.

```
$ oc exec -it aiops-topology-cassandra-0 -- bash
bash-4.4$ rm -rf /opt/ibm/cassandra/data/commitlog/CommitLog-6-1682019553495.log
```

After performing the required maintenance, you can stop the manually started Cassandra server.

```
oc exec -it aiops-topology-cassandra-0 -- bash
bash-4.4$ nodetool stopdaemon
```

Note: You can also perform other actions, like fixing volumes or transforming the data files. Every time you restart the pod, it will be halted.

Return the node to normal

After you complete your manual work, you can edit the configMap and restart the pod to return it back to normal.

```
oc edit configmaps aiops-topology-cassandra-bootstrap-config
```

Set the running mode to normal.

```
hostname_filter: aiops-topology-cassandra-0
running_mode: normal
```

Restart normal operations

Finally, you can delete the pod again so it will revert to the normal node and continue to work in the cluster.

Topology observer job failure

When you attempt to run a topology observer, the job fails because no response is returned for the request to the corresponding external service.

Solution: Run the following commands to create a NetworkPolicy that allows egress from the topology observer pods:

```
export AIOPS_NAMESPACE=<AIOps installation namespace>

cat << EOF | oc apply -f -
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: aiops-observer-egress
  namespace: ${AIOPS_NAMESPACE}
spec:
  egress:
  - {}
  podSelector:
    matchLabels:
```

```
      app.kubernetes.io/instance: aiops-topology
  policyTypes:
  - Egress
EOF
```

Topology viewer user interface crashes after the update manager is displayed

The issue is that you cannot use the update manager feature in topology viewer.

The solution is to change your topology viewer user preferences to auto render changes on refresh, which prevents the update manager from appearing.

Viewing the topology logs

You can see all topology and observer logs by using the **oc logs** command.

About this task

All observers are deployed in pods. You can identify logs either by their names or their labels.

To increase or decrease the log levels for a specific observer to help investigate issues, you first use the **oc get deployments** command to display a list of all deployments. Then, use the **oc edit deployment** command to change the logging levels to, in this example, 'debug'. A log level of 'debug' logs all request or response operations to provide detailed diagnostic data.

Viewing logs

1. To list all pods and the labels that are applied to the pods, run the **oc get pod --show-labels** command.

   ```
   oc get pod --show-labels
   ```

   Sample output:

   ```
   deploy-test-ciscoaci-observer-8755fcc94-7cp7h      1/1       Running   0          2d        app=ciscoaci-
   observer,chart=ciscoaci-observer,heritage=Tiller,pod-template-hash=431197750,release=deploy
   deploy-test-file-observer-76c5869d8b-tm7xj         1/1       Running   0          2d        app=file-
   observer,chart=file-observer,heritage=Tiller,pod-template-hash=3271425846,release=deploy-test
   deploy-test-rest-observer-789cd8699d-zb8vx         1/1       Running   0          2d        app=rest-
   observer,chart=rest-observer,heritage=Tiller,pod-template-hash=3457842558,release=deploy-test
   deploy-test-vmvcenter-observer-675bd88f5c-8kgnk    1/1       Running   0          2d        app=vmvcenter-
   observer,chart=vmvcenter-observer,heritage=Tiller,pod-template-hash=2316844917,release=deploy-test
   ```

2. Display the logs by using either the pod names or labels. When you run the **oc** logs command, you must also specify the project (namespace).

   1. View logs for a specific pod:

      ```
      oc logs asm-layout-88bd88bdb-htjfp --namespace=netcool
      ```

   2. View logs by using the label:

      ```
      oc logs -l app=layout --namespace=netcool
      ```

Changing log levels to `debug`

Run the following command to change the debug level to **DEBUG**:

```
oc exec -it deploy-test-file-observer-76c5869d8b -- /opt/ibm/netcool/asm/bin/log-level.pyc --level DEBUG
```

Sample system output

```
Configured logging level for com.ibm to DEBUG
Response code: 200
```

Defining classifier log settings

When viewing incidents on the Incident page, the topology can be viewed on the Overview tab, but is not available on the Topology tab.

About this task

Top alerts are displayed on the Overview tab, while more detailed information is used to render the information on the Topology tab.

To display the topology for an incident on the Topology tab, it uses the classifier for event classification for probable cause calculation. If these are not being recorded due to the level of log settings, the information is unavailable and the topology is not displayed. You must set additional properties to control the classifier logging.

You add (or edit) the following properties for the classifier deployment in both AI Manager and Event Manager

Note: Only the LOGGING_LEVEL property exists with a default setting of `INFO`. You must add the other settings to the classifier deployment manually.

- `0` = no logging set
- `10` = `debug`
- `20` = `information`
- `30` = `warning`
- `40` = `error`
- `50` = `critical`

Changing classifier log settings

1. Change the settings for the following log levels.

   a. For kafka:

   ```
   `KAFKA_LOGGING_LEVEL` = ???
   ```

   b. For file and console for other mime utils file:

   ```
   `LOGGING_LEVEL` = ???
   ```

2. Change the settings to define rotation and backup settings for the log files.

   a. For file rotation:

   ```
   `DEFAULT_LOGGING_FILE_SIZE` = ???
   ```

   b. For the number of history backups:

   ```
   `DEFAULT_LOGGING_FILE_BK_COUNT` = ???
   ```

   c. For the output format to console:

   ```
   `%(asctime)s.%(msecs)03d %(levelname)s %(module)s - %(funcName)s: %(message)s`
   ```

IM issues

Troubleshoot Identity Management (IM) issues.

- Login
- LDAP
- Pod issues
- OIDC
- API calls
- MongoDB to EDB PostgreSQL database migration

- EDB PostgreSQL cluster is down and the pod is in `Completed` status
- Enable debugging for user authentication issues

Login

Review frequently encountered login issues.

- Internal server error while login Platform UI by using SAML with LDAP dependency
- Cannot log in to the console by using the admin username
- Docker login results in unencrypted password warning
- Login too slow or times out, or invalid username or password error
- Cannot log in to the console by using OpenShift authentication
- Cannot log in to the console after reinstallation of foundational services
- Default admin cannot log in due to LDAP server issues
- Username shows as Undefined Undefined after login to CloudPak dashboard through SAML login
- Cannot login Platform UI with CloudPak administrator username
- Gateway timeout error while you log in to the console
- CWWKS1406E: Unable to load the login page and an invalid client error is displayed

Internal server error while login Platform UI by using SAML with LDAP dependency

Login error appears when you try to access the Platform UI by using SAML that is registered with LDAP.

Symptoms

When you use LDAP dependency with SAML authentication and try to access the Platform UI by using SAML, the login error appears and displays a message, **500 internal server error**.

If you access the Common UI console, the following errors are displayed in the **common-ui** container logs:

```
[2022-03-04T11:58:45.375] [ERROR] [webui-nav] [platform-auth-service] SAML enabled, but unable to get idsource
registrations to determine if ldap is enabled for the saml config - default to true Error:
    at Request.<anonymous> (/opt/ibm/platform-header/lib/server/request.js:115:34)
    at Request._callback (/opt/ibm/platform-header/node_modules/lodash/lodash.js:10118:25)
    at Request.requestRetryReply [as reply] (/opt/ibm/platform-header/node_modules/requestretry/index.js:105:19)

    at Request.emit (events.js:400:28)
    at Request.emit (domain.js:475:12)
    at Request.<anonymous> (/opt/ibm/platform-header/node_modules/request/request.js:1154:10)
    at Request.emit (events.js:400:28)
    at Request.emit (domain.js:475:12) {
  statusCode: 403,
  details: 'Unexpected response code 403 from request:\n' +
    'GET https://platform-identity-provider:4300/v2/auth/idsource/registration?protocol=saml HTTP/1.1\n' +
    'Accept: application/json\n' +
    'Authorization: Bearer ***\n' +
    'Accept: application/json\n' +
    '\n' +
    'HTTP/1.1 403\n' +
    'X-Dns-Prefetch-Control: off\n' +
    'X-Frame-Options: SAMEORIGIN\n' +
    'Strict-Transport-Security: max-age=15552000; includeSubDomains\n' +
    'X-Download-Options: noopen\n' +
    'X-Content-Type-Options: nosniff\n' +
    'X-Xss-Protection: 1; mode=block\n' +
    'Content-Type: application/json; charset=utf-8\n' +
    'Content-Length: 57\n' +
    'Etag: W/"39-Iup4jU4k5A0rUB2wIQCJV1dX4gw"\n' +
    'Date: Fri, 04 Mar 2022 11:58:45 GMT\n' +
    'Connection: close\n' +
    '\n' +
    '{"error":"Insufficient user permission for role :Viewer"}\n'
}
```

Causes

Service-id permission returns **Viewer** role access.

Resolving the problem

Upgrade your current foundational services version to 3.16.0 version or later.

Cannot authenticate Kubeadmin user as CloudPakAdministrator by default

The **Kubeadmin** user does not get **CloudPakAdministrator** role by default after login.

Symptoms

After you log in as a **Kubeadmin** user in the Administration panel, it assigns you the **Viewer** role.

Causes

Bootstrap process is not successful during the IM service installation.

Resolving the problem

Restart the **platform-identity-management** pod by using the following command:

```
oc -n <your-foundational-services-namespace> delete pod -l app=platform-identity-management
```

Cannot log in to the console by using the admin username

After you set up an LDAP connection, you cannot log in to IBM Cloud Pak® for AIOps cluster console by using the default cluster administrator **admin** username.

Causes

There might be a user by the name **admin** in the LDAP directory that you configured in your cluster.

Resolving the problem

To resolve the problem, see Default admin cannot log in due to LDAP server issues.

If you still want to use the admin user from the LDAP, you can change the user name in IBM Cloud Pak for AIOps cluster. To change the username in IBM Cloud Pak for AIOps cluster, see Changing the cluster administrator username.

Docker login results in unencrypted password warning

After you log in to your private image registry with the Docker login command, a warning is displayed that indicates that your password is stored unencrypted.

Symptoms

A warning message is displayed when you log in to your private image registry with the following command:

```
docker login <cluster_CA_domain>:8500
```

In this command, **<cluster_CA_domain>** is the certificate authority (CA) domain that was set during installation.

The command output includes the following warning:

```
WARNING! Your password will be stored unencrypted in /root/.docker/config.json.
Configure a credential helper to remove this warning. See
https://docs.docker.com/engine/reference/commandline/login/#credentials-store
```

Causes

By default, Docker stores the login password unencrypted within the **/root/.docker/config.json** Docker configuration file. This is the default Docker behavior.

Resolving the problem

You can store your user credentials in an external credentials store instead of within the Docker configuration file. Storing your credentials in a credentials store is more secure than storing the credentials in the Docker configuration file. For more information, see the Docker community credentials store documentation.

Login too slow or times out, or invalid username or password error

After you set up an LDAP connection, you cannot log in to IBM Cloud Pak® for AIOps cluster console.

Symptoms

There are two symptoms for the same cause.

- When you try to log in, the login process might take a long time, or might time out.
- You might see the following error:

  ```
  Invalid user name or password
  ```

Cause

The login failure is due to an LDAP error when Liberty looks up groups for the user. By default, Liberty searches which groups the user is a member of. It then searches which groups these groups are a member of. The message log shows the following error:

```
An FFDC Incident has been created: "com.ibm.wsspi.security.wim.exception.WIMSystemException: CWIML4520E: The LDAP
operation could not be completed. The LDAP naming exception
javax.naming.NameNotFoundException: [LDAP: error code 32 - 0000208D: NameErr: DSID-03152973, problem 2001 (NO_OBJECT),
data 0, best match of:
"
```

Resolving the problem

To resolve the issue, disable the **recursiveSearch** parameter in the LDAP **server.xml** file.

1. Log in to your boot node with the **oc login** command.
2. Edit the **platform-auth-idp** configmap.

   ```
   oc edit cm platform-auth-idp -n <your-foundational-services-namespace>
   ```

3. Change the **LDAP_RECURSIVE_SEARCH: "true"** parameter value to **LDAP_RECURSIVE_SEARCH: "false"**.
4. Save the changes.
5. Restart the **platform-auth-service** pods by deleting the pods.
    1. Get the **platform-auth-service** pod names.

       ```
       oc get pods -n <your-foundational-services-namespace> | grep platform-auth-service
       ```

    2. Delete the **platform-auth-service** pod.

       ```
       oc delete pods <pod-name> -n <your-foundational-services-namespace>
       ```

Cannot log in to the console by using OpenShift authentication

If you are using OpenShift authentication, you cannot log in to the console after you install IBM Cloud Pak foundational services on an OpenShift cluster that is in any cloud environment.

Symptom

You see a **400: Bad request - The request or response is invalid** error.

Cause

The rolebinding collection failed due to identity-provider:4300 connection time-out in the **oidclient-watcher** pod.

Resolving the problem

To resolve the issue, restart the **oidclient-watcher** pod.

1. Log in to your infrastructure node with the **oc login** command.
2. Get the **oidcclient-watcher** pod name.

   ```
   oc get pods -n <your-foundational-services-namespace> | grep oidcclient
   ```

3. Delete the **oidcclient-watcher** pod

   ```
   oc delete pod -n <your-foundational-services-namespace> <oidcclient-watcher-pod-name>
   ```

Wait for the pod to restart.

You can log in after the **oidclient-watcher** pod restarts.

Cannot log in to the console after reinstallation of foundational services

After you uninstall IBM Cloud Pak foundational services and reinstall them on the same cluster, you cannot log in to the console with the default admin credentials.

Symptoms

You might see the following error:

```
CWOAU0038E: The client could not be verified. Either the client ID: t19ph7yimexir00h517actss98zbrg0m or client secret is incorrect.
```

Cause

After you uninstall the foundational services, if all the resources are not properly cleaned, reinstallation on the same cluster fails.

The cause of the failure might be either or both of the following reasons:

- There is a mismatch of the **client_id** and **client_secret** values in the cluster, which causes the console login to fail.
- The IM jobs are not completed or are completed with errors.

Resolving the problem

To resolve the issue, correct the **client_id** and **client_secret** values and restart all IM jobs.

1. Log in to your boot node with the **oc login** command.
2. Check whether the **ibm-im-operator** pod is running.

```
oc -n <your-foundational-services-namespace> get pods | grep ibm-iam-operator
```

3. Check whether all the auth pods are running without any errors. If you see errors, check the logs and resolve the issue.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep auth
   ```

4. Check the `client_id` and `client_secret` values in the `platform-oidc-credentials` secret and in the `registration-json` configmap.

   - Check the values in the `platform-oidc-credentials` secret:

     ```
     oc -n <your-foundational-services-namespace> get secret platform-oidc-credentials -o "jsonpath=
     {.data.WLP_CLIENT_ID}" | base64 --decode
     oc -n <your-foundational-services-namespace> get secret platform-oidc-credentials -o "jsonpath=
     {.data.WLP_CLIENT_SECRET}" | base64 --decode
     ```

   - Check the values in the `registration-json` configmap:

     ```
     oc -n <your-foundational-services-namespace> get cm registration-json -o "jsonpath={.data['platform-oidc-
     registration\.json']}" > platform-oidc-registration.json
     cat platform-oidc-registration.json
     ```

5. If the values in the secret and configmap do not match, update the values in the `registration-json` configmap with the values from the `platform-oidc-credentials` secret. To edit the configmap, run the following command:

   ```
   oc -n <your-foundational-services-namespace> edit cm registration-json
   ```

   Replace the `client_id` and `client_secret` values, and save and exit the configmap.

6. Restart the following IM job.

   ```
   oc -n <your-foundational-services-namespace> delete job oidc-client-registration
   ```

7. Wait for some time and check the job status.

   ```
   oc -n <your-foundational-services-namespace> get jobs
   ```

   The status should show as `Completed`.

8. Restart the `common-web-ui` pods so that the `client_id` and `client_secret` get the correct values from the `platform-oidc-credentials` secret.

   1. Get the `common-web-ui` pod name.

      ```
      oc -n <your-foundational-services-namespace> get pods | grep common-web-ui
      ```

   2. Delete the pod.

      ```
      oc -n <your-foundational-services-namespace> delete <common-web-ui-pod-name>
      ```

9. Wait for sometime until the `common-web-ui` and `management-ingress` pods show the `Running` status. You can check the status by running the following command:

   ```
   oc -n <your-foundational-services-namespace> get pods | grep -e common-web-ui
   ```

After the pods are running, you can log in to the console with the default cpadmin credentials.

Default admin cannot log in due to LDAP server issues

The default admin user can no longer log in to your product cluster console.

You might see the following error in the `platform-auth-service` container of the `platform-auth-service` pod.

```
[ERROR   ] CWIML4537E: The login operation could not be completed. The specified principal name admin is not found in the
back-end repository.

com.ibm.wsspi.security.wim.exception.PasswordCheckFailedException: CWIML4537E: The login operation could not be completed.
The specified principal name admin is not found in the back-end repository.
        at com.ibm.ws.security.wim.ProfileManager.loginImpl(ProfileManager.java:1820)
        at [internal classes]
```
```## Causes

This issue can occur because of the following reasons:

- The LDAP parameters that you specified when you configured the LDAP connection might not be correct.
- LDAP server is inaccessible for some reason.
- LDAP configuration file is corrupted.
- A user who is named `admin` might exist in the LDAP directory. For this case, try this resolution, [Cannot log in to the
management console by using the admin username](../troubleshoot/ldap_admin.html).

## Resolving the problem {: #resolve}

As a temporary measure, you can remove the LDAP configuration file that is in the `platform-auth-service` container of the
`platform-auth-service` pod so that the default admin user can log in to the cluster.

The LDAP configuration is stored in the `/config/configDropins/defaults/ldap-<LDAP_connection_name>.xml` and
`federated.xml` files in the `platform-auth-service` container. To remove the incorrect LDAP configuration, you must
delete the files or move them to another location. You can then log in to the console and set up the LDAP connection again
```

with the correct parameters.

Removing the LDAP configuration file in the `platform-auth-service` container has no impact on the LDAP connection configuration. The users, groups, roles, and other resources are retained.

Complete the following steps to remove the LDAP configuration files.

1. SSH to your boot node and log in to cluster with `oc login` command.

2. Get the `platform-auth-service` pod names.

   ```cmd {: codeblock}
   oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
   ```

3. Access the shell inside the **platform-auth-service** container.

   ```
   oc -n <your-foundational-services-namespace> exec -it platform-auth--service-xxxxxx-yyyy -c platform-auth-service -- /bin/bash
   ```

4. Make a note of the LDAP settings file name that is located in the **/config/configDropins/defaults/** directory. For example, the file name is **ldap-openLDAP.xml** if your LDAP connection name is **openLDAP**.

5. Move the LDAP settings file **ldap-<LDAP_connection_name>.xml** and the **federated.xml** files out of the **/config/configDropins/defaults/** directory. For example, you can move the files to the **/config/configDropins/** directory.

   ```
   mv /config/configDropins/defaults/ldap-<LDAP_connection_name>.xml /config/configDropins/
   mv /config/configDropins/defaults/federated.xml /config/configDropins/
   ```

   Note: Instead of moving the files, you can delete the LDAP settings file, and **federated.xml** files from the **/config/configDropins/defaults/** directory. However, when you move the files, ensure that you have a backup of the configuration files, which can be used for troubleshooting.
   You can also correct the settings in the files and reuse it to set up the LDAP connection. If you are reusing the files, you must move the corrected files back into the **/config/configDropins/defaults/** directory.

   Exit from the container.

6. Perform steps 3 - 5 for all **platform-auth-service** pods.

7. Wait for a minute and then try log in as the default admin user.

8. Set up your LDAP connection with proper configuration parameters. For more information about setting up an LDAP connection, see Configuring LDAP connection.

   Note: You must identify the root cause of the issue and take the necessary actions to resolve it. After you resolve the issue, you can restart the **platform-auth-service** pod and then log in to the console as the admin user.

   You can also enable debugging for Liberty and collect logs. For more information, see Enable debugging for user authentication issues.

Username shows `Undefined Undefined` after login to CloudPak dashboard using SAML login option

Symptoms

When you use SAML login as option to login to the Cloudpak console, you might notice that the username is showing **Undefined Undefined** in the CloudPak dashboard page. You can observe this issue if you are using the foundational services version 3.20 and 3.21.

Causes

Migration from the IdP V2 to V3.

Resolving the problem

As per the SAML V3 schema, **given_name** and **family_name** are mapped to the **givenname** and **familyname** of IdP. You can update the V3 registration call to resolve this issue.

Steps

Get the V3 registration data

Note:

- The SAML UID that is supported is **defaultSP**. For more information, see Getting SAML registration by UID.
- Replace **base64-encoded-idp-xml** with actual base64 encoded **idp-metadata** that you have received in the GET call.
- Get the **cp-console-url** by using the command, **oc get routes**.

To get the existing SAML registration:

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster Master Host

Port number

Cluster Master API Port

Path

idprovider/v3/auth/idsource/defaultSP

Command

GET

Command output format

application/json

```
curl -k -X GET 'https://cp-console.apps.mycluster.mydomain.com/idprovider/v3/auth/idsource/defaultSP' --header
"Authorization: Bearer $ACCESS_TOKEN"
```

Update the V3 registration data by adding first_name and last_name under token_attribute_mappings

1. Copy the response that you get by using the curl command in Get the V3 registration data.
2. Remove the **uid** entry from the response, **"uid":"defaultSP"**.
3. Add the following attributes, **first_name** and **last_name** under the **token_attribute_mappings**.

```
"token_attribute_mappings": {
    "sub": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/name",
    "given_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
    "family_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname",
    "groups": "http://schemas.microsoft.com/ws/2008/06/identity/claims/groups",
    "email": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress",
    "first_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
    "last_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname"
}
```

4. Update the IdP V3 registration by adding the **token_attribute_mappings** payload as described in Step 3.

Note:

- Replace **base64-encoded-idp-xml** with actual base64 encoded **idp-metadata** that you have received in the GET call.
- Get the **cp-console-url** by using the command, **oc get routes**.

For example:

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster Master Host

Port number

Cluster Master API Port

Path

idprovider/v3/auth/idsource

Command

PUT

Command output format

application/json

```
curl -k -X PUT 'https://cp-console.apps.mycluster.mydomain.com/idprovider/v3/auth/idsource/defaultSP' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

```
--data-raw
'{
  "name": "w3id-sample-saml",
  "description": " this is plain saml testing",
  "protocol": "saml",
  "type": "default",
  "idp_config": {
    "token_attribute_mappings": {
    "sub": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/name",
    "given_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
    "family_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname",
    "groups": "http://schemas.microsoft.com/ws/2008/06/identity/claims/groups",
    "email": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress",
    "first_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
    "last_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname"
    },
    "idp_metadata": "<base64-encoded-idp-xml>"
  },
  "jit": true
}'
```

Gateway timeout or blank page error while you log in to the console

Cannot log in to your IBM Cloud Pak foundational services or IBM Cloud Pak® console.

Symptoms

You might see a **`504 Gateway timeout`** error or blank page when you log in to the console.

Cause

IBM WebSphere Liberty has a limitation in their federated user registry mechanism where a problem in one registry affects all other registries in the cluster.

The foundational services Identity Management (IM) service uses Liberty federated registry. Hence, if you have multiple LDAP (Lightweight Directory Access Protocol) registries in your cluster, if any registry server is down, it impacts all other registries. You can't log in to your cluster. The issue might happen even if you have only one LDAP connection in your cluster.

Resolving the problem

If you find that all the IM pods are up and running, then follow these steps as a workaround to the issue:

1. Verify whether your LDAP registries are healthy and that you are able to reach the servers.
2. If there is a problem in any LDAP registry, disconnect the LDAP registry from your cluster by using either of the following ways:
   - If other identity providers are configured in your cluster, a user with admin access can log in to the console and delete the connection from the navigation menu > **Identity and access** > **Identity providers** page.
   - If you have the foundational services default **`cpadmin`** token, you can use the Deleting an LDAP connection by using IdP V3 API to remove the connection.
3. Restart the **`platform-auth-service`** pod.

```
oc get pod -n <your-foundational-services-namespace> | grep platform-auth
oc delete pod $platform-auth-pod
```

If the problem still persists, contact IBM Support.

LDAP

Review frequently encountered LDAP (Lightweight Directory Access Protocol) configuration issues.

- Enable debugging for user authentication issues
- Troubleshooting LDAP configuration
- Configuring LDAP over SSL
- Troubleshooting users and user groups search issues
- Timeout error while setting up an LDAP connection
- LDAP nested search for Microsoft Active Directory does not work correctly
- SAML with LDAP dependency using V2 API does not work correctly

Enable debugging for user authentication issues

Enable debugging for **`platform-auth-service`** Liberty to get trace logs for debugging user authentication issues.

Enable debug logs by using oc commands

Complete these steps to enable debug logging of platform-auth-service container pods by using the command-line interface:

1. Update the **platform-auth-idp** configmap. Then, save it.

   ```
   oc edit cm platform-auth-idp -n <your-foundational-services-namespace>

   LIBERTY_DEBUG_ENABLED: "false"   << true
   LOG_LEVEL_AUTHSVC: info    << debug
   LOG_LEVEL_IDMGMT: info     << debug
   LOG_LEVEL_IDPROVIDER: info  << debug
   ```

   See the following notes:

   - **<your-foundational-service-namespace>** is the namespace where the platform-auth-service pods are deployed.
   - **LIBERTY_DEBUG_ENABLED** when set to **"true"**, enables the liberty container trace string to traceSpecification="com.ibm.ws.webcontainer*=all:com.ibm.wsspi.webcontainer*=all:HTTPChannel=all:GenericBNF=all:HTTPDispatcher=all".
   - **LOG_LEVEL** for the pods can be changed from **"info"** to **"debug"**
     - **LOG_LEVEL_AUTHSVC** is for the **platform-auth-service** pod
     - **LOG_LEVEL_IDMGMT** is for the **platform-identity-management** pod
     - **LOG_LEVEL_IDPROVIDER** is for the **platform-identity-provider** pod
2. Restart the **platform-auth-service**, **platform-identity-management**, and **platform-identity-provider** pod one at a time by deleting the pod. Wait for the pod to restart before you delete the next pod.

   1. Delete the pod.

      ```
      oc delete pod -l component=<pod-name> -n <your-foundational-services-namespace>
      ```   2. Check the pod status.
      ```cmd {: codeblock}
      oc get pods -A | grep platform
      ```

3. Wait for all containers and pods to start.

   ```
   watch "oc get pods -n <your-foundational-services-namespace> | grep platform"
   ```

Enable debug logs by using the Red Hat® OpenShift® Container Platform console

Complete these steps to enable debug logging of identity management pods by using the Red Hat® OpenShift® Container Platform console:

1. Log in to the Red Hat® OpenShift® Container Platform console as a user with cluster administrator access.
2. From the navigation menu, click **Configuration** > **ConfigMaps.**
3. Search for **platform-auth-idp**, and select the configmap.
4. Click the YAML edit tab to open the configmap for editing.
5. Search for **LIBERTY_DEBUG** and update **LIBERTY_DEBUG_ENABLED: "false"** to **LIBERTY_DEBUG_ENABLED: "true"**.
6. Change the log levels of LOG_LEVEL_IDPROVIDER, LOG_LEVEL_AUTHSVC, LOG_LEVEL_IDMGMT**from**"info"**to**"debug"`.

   ```
   LIBERTY_DEBUG_ENABLED: "false"     << true
   LOG_LEVEL_AUTHSVC: info            << debug
   LOG_LEVEL_IDMGMT: info             << debug
   LOG_LEVEL_IDPROVIDER: info         << debug
   ```

7. Click **Save**.
8. From the navigation menu, click **Workloads** > **Pods**.
9. Delete the **platform-auth-service**, **platform-identity-management**, and **platform-identity-provider** pods to restart them. Delete the pods by clicking **...** > **Actions** > **Delete pod**.
10. Wait for some time. Then, check the status of the pods on the **Pods** pane. The status of all the pods must show as **4/4** under the **Ready** field name.

Collect identity management pod and liberty container logs, and foundational services configuration information

After you enable debugging, re-create the issue and collect debug logs. Then, share all the **platform-auth-service** pod logs with the support team.

The following **MG-IAM-CSv4.sh** script helps to collect the container and liberty logs, and foundational services configuration information.

Note: Before you run the script, define the **NAMESPACE** environment variable with the namespace where you deployed foundational services.

```
#!/bin/bash
################################################################################################
#Replace the NAMESPACE where platform-auth-service pods are running
#Collects description and container logs for all pods under the namespace
#Collect the liberty FFDC, logs, and default LDAP configuration from platform-auth-service container
#For the latest script Source  https://www.ibm.com/docs/en/cloud-paks/foundational-services/4.2?topic=ldap-enable-
debugging-user-authentication-issues
################################################################################################
```

```
# export LOGLIMIT="--tail=10000" # uncomment if you experience problems collecting large files
export NAMESPACE=<common-services-instance-Namesapce>
export AUTHMGDIR=AuthidpLogs-$(date '+%y%b%dT%H-%M-%S')
mkdir -p $AUTHMGDIR/$NAMESPACE

for pod in $(oc -n $NAMESPACE get pods -l component=platform-auth-service --no-headers -o custom-
columns=name:.metadata.name); do
  echo "===== $pod ====="
  LIBDIR="$AUTHMGDIR/$NAMESPACE/$pod-liberty"
  mkdir -p $LIBDIR
  echo "$pod collect liberty logs "
  oc -n $NAMESPACE cp $pod:/logs -c platform-auth-service $LIBDIR/logs
  echo "$pod collect liberty configuration  ====="
  oc -n $NAMESPACE cp $pod:/opt/ibm/wlp/usr/servers/defaultServer/ -c platform-auth-service $LIBDIR/defaultserver
done

echo gathering info from namespace $NAMESPACE
oc get all,secrets,cm,events -n $NAMESPACE -o wide &> $AUTHMGDIR/$NAMESPACE/all-list.txt
oc get pods -n $NAMESPACE | awk 'NR>1{print "oc -n $NAMESPACE describe pod "$1" > $AUTHMGDIR/$NAMESPACE/"$1"-describe.txt
&& echo described "$1"' | bash
oc get pods -n $NAMESPACE -o go-template='{{range $i := .items}}{{range $c := $i.spec.containers}}{{println
$i.metadata.name $c.name}}{{end}}{{end}}' > $AUTHMGDIR/$NAMESPACE/container-list.txt
awk '{print "oc -n $NAMESPACE logs "$1" -c "$2" $LOGLIMIT -p > $AUTHMGDIR/$NAMESPACE/"$1"_"$2"_previous.log && echo
gathered previous logs of "$1"_"$2"' $AUTHMGDIR/$NAMESPACE/container-list.txt | bash
awk '{print "oc -n $NAMESPACE logs "$1" -c "$2" $LOGLIMIT > $AUTHMGDIR/$NAMESPACE/"$1"_"$2".log && echo gathered logs of
"$1"_"$2"' $AUTHMGDIR/$NAMESPACE/container-list.txt | bash
echo;echo
echo Replace case number TS123456
tar czf CaseTS123456-$AUTHMGDIR.tgz $AUTHMGDIR/
```

Send the logs to the support team

Complete these tasks after you collect the logs:

- Compress the logs and send them to support for analysis.

  ```
  tar czf $AUTHMGDIR.tgz $AUTHMGDIR
  ```

Note: When debug logging is enabled, excess logs are generated, which might affect the container resources. After you collect the debug logs, revert the log level values by editing the settings in the **platform-auth-idp** configmap. For the previous log level values, see parameter values.

Troubleshooting LDAP configuration

Use the **ldapsearch** command line tool to troubleshoot your LDAP (Lightweight Directory Access Protocol) configuration.

Install ldapsearch

Install the **ldapsearch** program.

On Ubuntu, run the following command:

```
sudo apt-get install ldap-utils
```

On Red Hat Enterprise Linux (RHEL), run the following command:

```
sudo yum install openldap-clients
```

Test LDAP connection

To test your LDAP connection, run the following command:

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" -w "<LDAP_BINDPASSWORD>" -s sub
```

Following are the parameter descriptions:

- **<LDAP_URL>** is the URL of the LDAP server. For example, **ldap://<LDAP server domain name or IP address>:<port>** or **ldaps://<LDAP server domain name>:<port>**. The default port number is 389 for LDAP protocol and 636 for LDAP over Secure Sockets Layer (LDAPS) protocol.
- **<LDAP_BASEDN>** is the LDAP distinguished name (DN) of the search base. For example, **dc=abc,dc=com**.
- **<LDAP_BINDDN>** is the LDAP user who is allowed to search the base DN. For example, **cn=admin,dc=abc,dc=com**.
- **<LDAP_BINDPASSWORD>** is the password of the user who is mentioned in the bind DN.

Example commands

```
ldapsearch -x -H "ldap://<hostname or IP address>:389" -b "o=abc.com" -s sub
```

```
ldapsearch -x -H "ldap://<hostname or IP address>:389" -b "dc=abc,dc=com" -D "cn=admin,dc=abc,dc=com" -w "password" -s sub
```

Validate LDAP filters

Create a search string based on the LDAP filters to retrieve data from your LDAP server. If the search results show one or more LDAP entries, then the LDAP filter configuration is correct. If the search results do not show any entry, then the LDAP filter is not correct or is not compatible with your LDAP server type.

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" -w "<LDAP_BINDPASSWORD>" -s sub "<Search string>"
```

Following are the parameter descriptions:

- **<LDAP_URL>** is the URL of the LDAP server. For example, **ldap://<LDAP server domain name or IP address>:<port>** or **ldaps://<LDAP server domain name>:<port>**. The default port number is 389 for LDAP protocol and 636 for LDAPS protocol.
- **<LDAP_BASEDN>** is the LDAP DN of the search base. For example, **dc=abc,dc=com**.
- **<LDAP_BINDDN>** is the LDAP user who is allowed to search the base DN. For example, **cn=admin,dc=abc,dc=com**.
- **<LDAP_BINDPASSWORD>** is the password of the user who is mentioned in the bind DN.
- **<search string>** is the search string that is used to search your LDAP server.

IBM Tivoli Directory Server LDAP filters

Table 1. IBM Tivoli Directory Server LDAP filters

Attribute name	Default value
Group filter	(&(cn=%v)(objectclass=groupOfUniqueNames))
Group ID map	*:cn
Group Member ID map	groupOfUniqueNames:uniqueMember
User filter	(&(emailAddress=%v)(objectclass=person))
User ID map	*:emailAddress

- Example command to validate group filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(cn=*)(objectclass=groupOfUniqueNames))"
```

- Example command to validate group ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=*)(cn=*))"
```

- Example command to validate group member ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=groupOfUniqueNames)(uniqueMember=*))"
```

- Example command to validate user filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(emailAddress=*)(objectclass=person))"
```

- Example command to validate user ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=*)(emailAddress=*))"
```

Microsoft Active Directory LDAP filters

Table 2. Microsoft Active Directory LDAP filters

Attribute name	Default value
Group filter	(&(cn=%v)(objectcategory=group))
Group ID map	*:cn
Group Member ID map	memberOf:member
User filter	(&(sAMAccountName=%v)(objectcategory=user))
User ID map	user:sAMAccountName

- Example command to validate group filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(cn=*)(objectcategory=group))"
```

- Example command to validate group ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectcategory=*)(cn=*))"
```

- Example command to validate group member ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectcategory=*)(member=*))"
```

- Example command to validate user filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(sAMAccountName=*)(objectcategory=user))"
```

- Example command to validate user ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectcategory=user)(sAMAccountName=*))"
```

Custom (OpenLDAP) server LDAP filters

Table 3. Custom (OpenLDAP) server LDAP filters

Attribute name	Default value
Group filter	(&(cn=%v)(objectclass=groupOfUniqueNames))
Group ID map	*:cn
Group Member ID map	groupOfUniqueNames:uniqueMember
User filter	(&(uid=%v)(objectclass=person))
User ID map	*:uid

- Example command to validate group filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(cn=*)(objectclass=groupOfUniqueNames))"
```

- Example command to validate group ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=*)(cn=*))"
```

- Example command to validate group member ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=groupOfUniqueNames)(uniqueMember=*))"
```

- Example command to validate user filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(uid=*)(objectclass=person))"
```

- Example command to validate user ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=*)(uid=*))"
```

Resolve common login issues

Unable to login to `cp-console` or `cpd` using LDAP authentication

The **`ClassCastException`** error is displayed if the **`ObjectClass`** or **`ObjectCategory`** attribute is not defined in the Liberty XML file. The following error is displayed in the logs of the **`auth-service`** pods:

```
Exception = java.lang.ClassCastException
Source = com.ibm.ws.security.oauth20.plugins.jose4j.OidcUserClaims
probeid = 178
Stack Dump = java.lang.ClassCastException: com.ibm.wsspi.security.wim.model.Entity incompatible with
com.ibm.wsspi.security.wim.model.PersonAccount
        at com.ibm.ws.security.oauth20.plugins.jose4j.OidcUserClaims.getUserinfoFromRegistryMap(OidcUserClaims.java:136)
        at com.ibm.ws.security.oauth20.plugins.jose4j.OidcUserClaims.getUserinfoFromRegistry(OidcUserClaims.java:177)
        at
com.ibm.ws.security.openidconnect.web.OidcEndpointServices.getUserinfoFromRegistry(OidcEndpointServices.java:1001)
        at com.ibm.ws.security.openidconnect.web.OidcEndpointServices.userinfo(OidcEndpointServices.java:922)
        at com.ibm.ws.security.openidconnect.web.OidcEndpointServices.handleOidcRequest(OidcEndpointServices.java:281)
        at com.ibm.ws.security.openidconnect.web.OidcEndpointServlet.handleRequest(OidcEndpointServlet.java:111)
        at com.ibm.ws.security.openidconnect.web.OidcEndpointServlet.doPost(OidcEndpointServlet.java:69)
        at javax.servlet.http.HttpServlet.service(HttpServlet.java:707)
```

Resolving the issue

IM supports the LDAP Entity type configuration for LDAP User and Group entities to define the **`ObjectClass`** or **`ObjectCategory`** attributes automatically in the Liberty XML file.

For the existing LDAP connection, you need to restart the **`platform-auth-service`** pods to enable the **`LDAPEntityType`** configuration.

1. Get the **`platform-auth-service`** pod name.

   ```
   oc get pods -n <your-foundational-services-namespace> | grep platform-auth-service
   ```

2. Delete the **`platform-auth-service`** pod.

   ```
   oc delete pod <platform-auth-service-pod-name> -n <your-foundational-services-namespace>
   ```

The following is the sample Liberty XML file with the LDAP configuration:

```
<server>
    <featureManager>
        <feature>ldapRegistry-3.0</feature>
    </featureManager>
    <ldapRegistry id="SunOneLDAP" realm="REALM" host="[dd103bgpvip1165.virginia.ms.com]
(https://dd103bgpvip1165.virginia.ms.com/)" port="389"
            ignoreCase="false" baseDN="o=Morgan Stanley" bindDN="msfwid=2053167,ou=prodids,o=Morgan Stanley"
            bindPassword="{xor}OQ9mHBIlFQVoaGk4NSgK" ldapType="Sun Java System Directory Server" recursiveSearch="true"
sslEnabled="false"
            certificateMapMode="CERTIFICATE_FILTER" certificateFilter="uid=${SubjectCN}">
         <ldapEntityType name="PersonAccount">
               <objectClass>msperson</objectClass>
         </ldapEntityType>
         <!-- For Groups -->
        <ldapEntityType name="Group">
                 <objectClass>msaclgroup</objectClass>
```

```
      </ldapEntityType>
       <iplanetFilters
           userFilter="(&amp;(objectClass=msperson)(uid=%v))"
           groupFilter="(&amp;(cn=%v)(objectclass=msaclgroup)(mseonid=24507))"
           userIdMap="*:uid"
           groupIdMap="*:cn"
           groupMemberIdMap="groupofuniquenames:uniquemember" />
           <ldapCache>
             <attributesCache size="2000" timeout="1200s" enabled="true" sizeLimit="2000"/>
             <searchResultsCache size="2000" timeout="1200s" enabled="true" resultsSizeLimit="2000"/>
           </ldapCache>
    </ldapRegistry>
</server>
```

Unable to log in as LDAP user after you configure an LDAP connection

You might not be able to log in as an LDAP user even when the connection test and the LDAP configuration are successful.

You see an error that indicates an **invalid username or password**.

You might see the following error in the log files of the **platform-auth-service** container:

```
CWIML4537E: The login operation could not be completed. The specified principal name XXXXXX is not found in the back-end repository.
```

To identify the error, enable trace for Liberty service to know the exact error in First failure data capture (FFDC) logs. For more information, see Enable debugging for user authentication issues.

Following are the possible causes. A resolution is provided for each cause.

Cause 1 - Invalid `username` value is used when you logged in

The user name value is not the same as the **userIdMap** filter attribute value.

Resolution for cause 1

Ensure that you enter the correct user name. The user name must be the same as the **userIdMap** filter attribute value. The user name is case-sensitive.

Consider the following example:

LDAP user details on an LDAP server:

```
dn: uid=testuser,ou=people,dc=abc,dc=com
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: person
objectClass: top
cn: TestUser
givenName: TestUser
sn: SN
uid: testuser
userPassword: testuser
mail: testuser@abc.com
```

LDAP configuration:

```
User filter: (&(uid=%v)(objectclass=person))
User ID map: *:uid
```

If you use ***:uid** as the **userIdMap** filter, then you must use the **uid** value **testuser** as the user name when you log in.

Cause 2 - LDAP login user or Bind DN user is disabled or locked at the LDAP server

- The LDAP login user is disabled or locked at the LDAP server due to many unsuccessful login attempts.
- The **Bind DN** user is disabled or locked at LDAP server due to many unsuccessful login attempts.

Resolution for cause 2

- Use the **ldapsearch** tool to test the LDAP connection.
- Enable or unlock the LDAP login user or **Bind DN** user at the LDAP server.

Cause 3 - Invalid Password value is used to log in

- The LDAP user password might be wrong.
- The **Bind DN password** might contain some unsupported special characters.

Resolution for cause 3

- Enter the correct password and try logging in.
- If the **Bind DN password** has special characters, change the password and do not use special characters in the changed password.

Cause 4 - LDAP configuration might not be synchronized across all the pods in a high availability (HA) cluster

The login request might be going to a pod in an HA cluster that does not have the LDAP configuration.

Resolution for cause 4

Restart the **platform-auth-service** pod. If the issue is still not resolved, restart the **platform-auth-service**, **platform-identity-provider**, and **platform-identity-management** pods.

Cause 5 - LDAP connection issues due to various reasons

- The LDAP server is not reachable.
- You used the LDAP server hostname in the LDAP server URL, and the hostname is not reachable. This issue might be because the correct DNS server entries were not added during cluster installation.
- If LDAPS is used to configure the LDAP connection, following might be the possible causes:
  - An IP address is used instead of the LDAP server hostname in the LDAP server URL.
  - The LDAP server certificate is not imported into your cluster.
  - The LDAP server certificate does not match with the LDAP server hostname (or certificate SANs (Subject Alternative Names)).

Resolution for cause 5

- Test the LDAP connection by using the **ldapsearch** tool.
- Add the LDAP server hostname in the **/etc/hosts** file either on the master node or in the **platform-auth-service** container.
- For configuring an LDAPS connection, use the LDAP server hostname in the LDAP server URL and the LDAP server certificate is imported into your cluster. Followed all the required steps for Configuring LDAP over SSL.
- Change the hostname, or get a new certificate that matches with the LDAP server hostname or any one of the certificate SANs.

Cause 6 - External database connection failed in the platform-auth-service container

You can see external database connection failure errors in the logs of the **platform-auth-service** container.

Resolution for cause 6

Restart the **platform-auth-service** pod that is configured with the external database.

Resolve common issues with search users or groups

Unable to search users or groups while you create a team.

Cause

You used an invalid search string.

Resolution

You must use the value of the **cn** attribute or the user or group attribute such as **uid** or **emailaddress** that you used in the LDAP configuration.

Consider the following example:

LDAP user details on an LDAP server

```
dn: uid=testuser,ou=people,dc=abc,dc=com
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: person
objectClass: top
cn: TestUser
givenName: TestUser
sn: SN
uid: testuser
userPassword: testuser
mail: testuser@abc.com
```

Following filters are used in the LDAP configuration:

- User filter: (&(uid=%v)(objectclass=person))
- User ID map: *:uid

The **userIdMap** that is used is ***:uid**.

The valid values that you can use to search for a user are as follows:

- TestUser (**cn** value)
- testuser (**uid** value)

Configuring LDAP over SSL

You can secure your Lightweight Directory Access Protocol (LDAP) connection by using SSL (Secure Sockets Layer).

If LDAP over SSL (LDAPS) is not automatically configured in your cluster, complete these steps to manually configure the LDAPS connection.

You must prepare your product cluster for connecting with your LDAPS directory.

Before you begin, you must import the public or private SSL certificate that you used for setting up your LDAPS directory.

Retrieving the SSL certificate

If you have the SSL certificate of your LDAP server, proceed with Encoding the SSL certificate.

If you do not have the SSL certificate of your LDAP server, use one of the following approaches to retrieve the SSL certificate:

Option 1: Using the `ldapsearch` command

Note: You need the **`ldapsearch`** program to run these commands. You can install it by running **`apt install ldap-utils`** on Ubuntu and **`yum install openldap-clients`** on Red Hat Enterprise Linux (RHEL).

1. Ensure that no SSL certificates are in the **`/etc/openldap/cacerts`** directory.
2. Run the following **`ldapsearch`** command to retrieve the certificate name:

   ```
   ldapsearch -H <LDAP server URL> -d 1  -b <searchbase> -D "" -s base "(<filter>)"
   ```

   Where,

   - **LDAP server URL** is your LDAP directory domain name, and port. Format: **`ldaps://<LDAP server domain name or IP address>:<port>`**.
   - **-d** is the debugging level.
   - **-b** is the search base.
   - **-D** is the bind DN. This parameter is optional.
   - **-s** is the scope of search.
   - **filter** is the LDAP filter. Default filter: **`(objectClass=*)`**.

   Sample command:

   ```
   ldapsearch -H ldaps://corp.example.com:636 -d 1  -b o=example.com -D "" -s base "(objectclass=*)"
   ```

   Sample output:

   ```
   ldap_url_parse_ext(ldaps://corp.example.com:636)
   ldap_create
   ldap_url_parse_ext(ldaps://corp.example.com:636/??base)
   ldap_sasl_bind
   ldap_send_initial_request
   ldap_new_connection 1 1 0
   ldap_int_open_connection
   ldap_connect_to_host: TCP corp.example.com:636
   ldap_new_socket: 3
   ldap_prepare_socket: 3
   ldap_connect_to_host: Trying 9.17.186.253:636
   ldap_pvt_connect: fd: 3 tm: -1 async: 0
   attempting to connect:
   connect success
   TLS: certdb config: configDir='/etc/openldap' tokenDescription='ldap(0)' certPrefix='cacerts' keyPrefix='cacerts'
   flags=readOnly
   TLS: cannot open certdb '/etc/openldap', error -8018:Unknown PKCS #11 error.
   TLS: could not get info about the CA certificate directory /etc/openldap/cacerts - error -5950:File not found.
   TLS: certificate [CN=DigiCert Global Root G2,OU=www.digicert.com,O=DigiCert Inc,C=US] is not valid - error
   -8172:Peer's certificate issuer has been marked as not trusted by the user..
   TLS: error: connect - force handshake failure: errno 2 - moznss error -8172
   TLS: can't connect: TLS error -8172:Peer's certificate issuer has been marked as not trusted by the user..
   ldap_err2string
   ldap_sasl_bind(SIMPLE): Can't contact LDAP server (-1)
   ```

   The certificate information is in the **`TLS: certificate [CN=DigiCert Global Root G2,OU=www.digicert.com,O=DigiCert Inc,C=US] is not valid - error -8172:Peer's certificate issuer has been marked as not trusted by the user..`** section of the output.
3. Locate the certificate in your web browser, export it to a file in a PEM format, and save the PEM file with a **`.crt`** extension.

   Note: If you have multiple certificates, export each certificate to a file in a PEM format and save the PEM file with a **`.crt`** extension.
4. Copy the **`.crt`** file to the infrastructure node of your cluster.

Option 2: Using the `openssl` tool

1. Run the following command:

   ```
   openssl s_client -connect <ldap-server-host>:636 -showcerts > ldap_server_certs.pem
   ```
2. Edit the **`ldap_server_certs.pem`** file:
   1. Remove the unwanted lines.
   2. Retain the content between **`-----BEGIN CERTIFICATE-----`** and **`-----END CERTIFICATE-----`** lines.

   Note: Ensure that final **`ldap_server_certs.pem`** certificate file is a valid PEM format and no empty lines are there in-between.

Preparing for a single LDAPS connection

If you are configuring a single LDAPS connection, complete the steps in the Encoding the SSL certificate section.

Encoding the SSL certificate

Complete the following steps to encode the certificate in base64:

1. Log on to the infrastructure node of your cluster.
2. Convert the certificate into PEM format.

   ```
   openssl x509 -in <cert>.cer -outform PEM -out <convertedCert>.pem
   ```

   If your LDAP server uses chain certificates (root CA and intermediate certificates), convert each certificate into PEM format. Then, combine them into one file. Use the following command to combine the converted certificates.

   ```
   cat <convertedFirstCert.pem> <convertedSecondCert.pem> ..<converted_n_Cert.pem> > <convertedCombinedCert>.pem
   ```

3. Encode your certificate in base64.

   ```
   cat <LDAPS SSL certificate name>.pem | base64 -w 0
   ```

   The output resembles the following code:

   ```
   LS0tLS1CRUdJTiBDRVJUSUZJQ0FURS0tLS0tCk1JSUdDRENDQS9DZ
   0F3SUJBZ0lRS3k1dTZ0bDFObXdVaW03Ym8zeU1CekFOQmdrcWhraUc5
   ...
   lDOHg0OU9oZ1E9Ci0tLS0tRU5EIENFUlRJRklDQVRFLS0tLS0KDQo=
   ```

Next, proceed with Preparing your cluster.

Preparing for multiple LDAPS connections

If you are configuring multiple LDAPS connections, first check if you already have a certificate in the "data" > "certificate" section of **platform-auth-ldaps-ca-cert**. If you have a certificate, then complete the steps in the following sections:

- Retrieve the current certificate
- Encode the SSL certificate

If no certificate exists, then complete the steps in Encoding the SSL certificate.

Retrieve the current certificate

You can retrieve the certificate by using the Red Hat® OpenShift® Container Platform console or command line interface (CLI).

Option 1: Using the console

1. Log on to the Red Hat® OpenShift® Container Platform console as a cluster administrator.
2. From the navigation menu, click **Workloads** > **Secrets**.
3. Locate **platform-auth-ldaps-ca-cert** and click **...** > **Edit Secret**. A window for editing displays.
4. Copy the base64 encoded certificate value from "data" > "certificate" section.

   ```
   "data": {
    "certificate": "LS0tLS1...ASDFASDo="
   },
   ```

5. Convert the existing encoded certificate and save to a file.

   ```
   echo "<copied_cert_value>" | base64 --decode > existing_cert.pem
   ```

Option 2: using the CLI

1. Access the CLI of your infrastructure node. Install the Kubernetes CLI (kubectl). You need this tool to complete the following tasks.
2. Get the base64 certificate.

   ```
   kubectl -n <your-foundational-services-namespace> get secret platform-auth-ldaps-ca-cert -o "jsonpath=
   {.data['certificate']}" | base64 --decode > existing_cert.pem
   ```

Next, proceed with Encode the SSL certificate.

Encode the SSL certificate

Complete the following steps to encode the certificate in base64:

1. Log on to the infrastructure node of your cluster.
2. Convert the new certificate into PEM format.

   ```
   openssl x509 -in <cert>.cer -outform PEM -out <convertedCert>.pem
   ```

   If your LDAP server uses chain certificates (root CA and intermediate certificates), convert each certificate into PEM format. Then, combine them into one file. Use the following command to combine the converted certificates.

   ```
   cat <convertedFirstCert.pem> <convertedSecondCert.pem> ..<converted_n_Cert.pem> > <convertedCombinedCert>.pem
   ```

3. Add the existing certificate to the new certificate, or to the combined certificate if you use chain certificates.

   ```
   cat existing_cert.pem <new_cert.pem or convertedCombinedCert.pem> > final_combined_cert.pem
   ```

4. Encode your certificate in base64.

   ```
   cat <LDAPS SSL certificate name>.pem | base64 -w 0
   ```

   The output resembles the following code:

   ```
   LS0tLS1CRUdJTiBDRVJUSUZJQ0FURS0tLS0tCk1JSUdDRENDQS9DZ
   0F3SUJBZ0lRS3k1dTZ0bDFObXdVaW03Ym8zeU1CekFOQmdrcWhraUc5
   ...
   lDOHg0OU9oZ1E9Ci0tLS0tRU5EIENFUlRJRklDQVRFLS0tLS0KDQo=
   ```

Next, complete the steps in the Preparing your cluster section.

Preparing your cluster

You can prepare your cluster by using the Red Hat® OpenShift® Container Platform console or CLI.

Option 1: Using the console

1. Log on to the Red Hat® OpenShift® Container Platform console as a cluster administrator.
2. From the navigation menu, click **Workloads** > **Secrets**.
3. Locate `platform-auth-ldaps-ca-cert` and click **...** > **Edit Secret**. A window for editing displays.
4. Paste the base64 certificate in the following section:

   ```
   "data": {
    "certificate": ""
   },
   ```

   The updated section resembles the following text:

   ```
   "data": {
    "certificate": "LS0tLS1<very_long_base64_string>ASDFASDo="
   },
   ```

5. Click **Save**.
6. From the navigation menu, click **Workloads > Deployments**.
7. Locate `platform-auth-service`.
8. Click **...** > **Edit Deployment**. A window for editing displays.
9. Click **Save** without making any change. This step is to reload the `platform-auth-service` pods with the latest ConfigMap values.
10. Wait for a minute or two and then check whether the certificate is mounted on the pod.
    1. Get the `platform-auth-service` pods.

       ```
       kubectl -n <your-foundational-services-namespace> get pods | grep platform-auth-service
       ```

    2. Check whether the certificate is mounted on the pod.

       ```
       kubectl -n <your-foundational-services-namespace> exec -it platform-auth-service-<pod-id> -c platform-auth-service cat /opt/ibm/ldaps/ldaps-ca.crt
       ```

Option 2: Using the CLI

1. Access the CLI of your infrastructure node. You need `kubectl`, the Kubernetes command line tool to complete the following tasks. For more information about installing `kubectl`, see Install tools.
2. Copy the LDAPS CA certificate secret to a file:

   ```
   kubectl get secret platform-auth-ldaps-ca-cert -o yaml -n <your-foundational-services-namespace> > platform-auth-ldaps-ca-cert-secret.yaml
   ```

3. Copy and paste the base64 certificate to the `platform-auth-ldaps-ca-cert-secret.yaml` file.
4. Get the security service Deployment YAML file:

   ```
   kubectl -n <your-foundational-services-namespace> get deploy platform-auth-service -o yaml > platform-auth-service.yaml
   ```

5. Apply the changes:
   1. Run the following command to apply the `platform-auth-ldaps-ca-cert-secret.yaml` file:

      ```
      kubectl apply -f platform-auth-ldaps-ca-cert-secret.yaml
      ```

   2. Run the following command to apply the `platform-auth-service.yaml` file:

```
kubectl apply -f platform-auth-service.yaml
```

Next, complete the steps in the Connecting to your LDAP directory section.

Troubleshooting users and user groups search issues

Verify or test search users and groups by using the **ldapsearch** command tool.

Search users

Use the following **ldapsearch** command:

```
ldapsearch -x -l <TIME_LIMIT> -z <SIZE_LIMIT> -H <LDAP_URL> -b <LDAP_BASEDN> -D <LDAP_BINDDN> -w <LDAP_BINDPASSWORD> -s
sub "<search query>"
```

See the following definitions:

- **<LDAP_URL>** is the Lightweight Directory Access Protocol (LDAP) server URL.
- **<LDAP_BASEDN>** is the LDAP Base DN.
- **<LDAP_BINDDN>** is the LDAP Bind DN.
- **<LDAP_BINDPASSWORD>** is the LDAP Bind DN password.
- **<TIME_LIMIT>** is the time limit in seconds for the search. Default value is 5 seconds.
- **<SIZE_LIMIT>** is the size limit for search. Default value is 50 entries.

In IBM Cloud Pak® for AIOps, the search string is based on the **cn** and **User ID map** attributes that are configured in the LDAP connection user filters.

For example, consider the following LDAP user filters configuration:

```
User filter: (&(uid=%v)(objectclass=person))
User ID map: *:uid
```

For the example configuration, following is the search query:

```
(|(&(cn=*<searchstring>*)(objectclass=person))(&(uid=*<searchstring>*)(objectclass=person)))
```

In the search query, user name or user ID value is the **<searchstring>**. For example, **John** or **robbie**.

Following is an example **ldapsearch** command:

```
ldapsearch -x -l 5 -z 50 -H "ldap://X.X.X.X:389" -b "dc=abc,dc=com" -D "cn=admin,dc=abc,dc=com" -w 'password' -s sub "(|(&
(cn=*user*)(objectclass=person))(&(uid=*user*)(objectclass=person)))"
```

Here, the **<searchstring>** is **user**.

Following is a sample output:

```
# extended LDIF
#
# LDAPv3
# base <dc=abc,dc=com> with scope subtree
# filter: (|(&(cn=*user*)(objectclass=person))(&(uid=*user*)(objectclass=person)))
# requesting: ALL
#

# user1, Users, abc.com
dn: uid=user1,ou=Users,dc=abc,dc=com
cn: User One
objectClass: inetOrgPerson
objectClass: person
objectClass: top
sn: One
uid: user1
userPassword:: dXNlcjE=

# user2, Users, abc.com
dn: uid=user2,ou=Users,dc=abc,dc=com
cn: User Two
objectClass: inetOrgPerson
objectClass: person
objectClass: top
sn: Two
uid: user2
userPassword:: dXNlcjI=

# search result
search: 2
result: 0 Success

# numResponses: 3
# numEntries: 2
```

Search groups

Use the following `ldapsearch` command:

```
ldapsearch -x -l <TIME_LIMIT> -z <SIZE_LIMIT> -H <LDAP_URL> -b <LDAP_BASEDN> -D <LDAP_BINDDN> -w <LDAP_BINDPASSWORD> -s
sub "<search query>"
```

See the following list of definitions:

- `<LDAP_URL>` is the LDAP server URL.
- `<LDAP_BASEDN>` is the LDAP Base DN.
- `<LDAP_BINDDN>` is the LDAP Bind DN.
- `<LDAP_BINDPASSWORD>` is the LDAP Bind DN password.
- `<TIME_LIMIT>` is the time limit in seconds for the search. Default value is 5 seconds.
- `<SIZE_LIMIT>` is the size limit for search. Default value is 50 entries.

In IBM Cloud Pak for AIOps, the search string is based on the `cn` and `Group ID map` attributes that are configured in the LDAP connection group filters.

For example, consider the following LDAP group filters configuration:

```
Group filter: (&(cn=%v)(objectclass=groupOfUniqueNames))
Group ID map: *:cn
```

For the example configuration, following is the search query:

```
(&(cn=*<searchstring>*)(objectclass=groupOfUniqueNames))
```

In the search query, group name value is the `<searchstring>`. For example, `security` or `administrators`.

If the `Group ID map` attribute is different than `cn`, for example `gid`, then the following search query can be used:

```
(|(&(cn=*<searchstring>*)(objectclass=groupOfUniqueNames))(&(gid=*<searchstring>*)(objectclass=groupOfUniqueNames)))
```

Here, the group name or `gid` value is the `<searchstring>`.

Following is an example `ldapsearch` command:

```
ldapsearch -x -l 50 -z 100 -H "ldap://X.X.X.X:389" -b "dc=abc,dc=com" -D "cn=admin,dc=abc,dc=com" -w 'password' -s sub "(&
(cn=*gr*)(objectclass=groupOfUniqueNames))"
```

Here, the `<searchstring>` is `gr`.

Following is a sample output:

```
# extended LDIF
#
# LDAPv3
# base <dc=abc,dc=com> with scope subtree
# filter: (&(cn=*gr*)(objectclass=groupOfUniqueNames))
# requesting: ALL
#

# group1, Groups, abc.com
dn: cn=group1,ou=Groups,dc=abc,dc=com
cn: group1
objectClass: groupOfUniqueNames
objectClass: top
uniqueMember: cn=group2,ou=Groups,dc=abc,dc=com
uniqueMember: uid=user1,ou=Users,dc=abc,dc=com

# group2, Groups, abc.com
dn: cn=group2,ou=Groups,dc=abc,dc=com
cn: group2
objectClass: groupOfUniqueNames
objectClass: top
uniqueMember: uid=user2,ou=Users,dc=abc,dc=com

# search result
search: 2
result: 0 Success

# numResponses: 3
# numEntries: 2
```

Retrieve users from an LDAP group

Use the following `ldapsearch` command:

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" -w "<LDAP_BINDPASSWORD>" -s sub "(cn=<GROUP_NAME>)"
```

See the following list of definition:

- `<LDAP_URL>` is the LDAP server URL.
- `<LDAP_BASEDN>` is the LDAP Base DN.
- `<LDAP_BINDDN>` is the LDAP Bind DN.
- `<LDAP_BINDPASSWORD>` is the LDAP Bind DN password.
- `<GROUP_NAME>` is the group name.

Consider the following example command:

```
ldapsearch -x -H "ldap://X.X.X.X:389" -b "dc=abc,dc=com" -D "cn=admin,dc=abc,dc=com" -w 'password' -s sub "(cn=group2)"
```

Following is a sample output:

```
# extended LDIF
#
# LDAPv3
# base <dc=abc,dc=com> with scope subtree
# filter: (cn=group2)
# requesting: ALL
#

# group2, Groups, abc.com
dn: cn=group2,ou=Groups,dc=abc,dc=com
cn: group2
objectClass: groupOfUniqueNames
objectClass: top
uniqueMember: uid=user2,ou=Users,dc=abc,dc=com

# search result
search: 2
result: 0 Success

# numResponses: 2
# numEntries: 1
```

Timeout error while setting up an LDAP connection

Cannot set up a connection with your LDAP server.

Symptoms

While setting up an LDAP connection, you might see a **`504 Gateway timeout`** error.

Cause

The connection needs more time than usual to be established.

Resolving the problem

To resolve the issue, increase the LDAP configuration timeout value in the **`platform-auth-idp`** configmap to a value in the range 25-60 seconds.

1. Log in to your infrastructure node by using the **`oc login`** command.
2. Edit the **`platform-auth-idp`** configmap.

   ```
   oc -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

3. Change the **`AUTH_SVC_LDAP_CONFIG_TIMEOUT: "25"`** parameter value to a higher value. For example, **`"45"`**. The value is in seconds.
4. Save the changes.
5. Restart the **`platform-auth-service`** pods by deleting the pods.
   1. Get the **`platform-auth-service`** pod names.

      ```
      oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
      ```

   2. Delete the **`platform-auth-service`** pod.

      ```
      oc -n <your-foundational-services-namespace> delete pods <pod-name>
      ```

Wait for some time and then check the status of the **`platform-auth-service`** pods. The status of all **`platform-auth-service`** pods must show as **`Running`**.

```
oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
```

Timeout error after enabling LDAP Nested search for Microsoft Active Directory

Once you enable Nested search option while searching the SCIM users or groups, the time taken for the SCIM API to response might be increased. As a result, sometimes you might see that the SCIM search returns empty or **`504 Gateway timeout`** error in the logs.

Symptoms

- **`504 Gateway timeout`** error is displayed.
- Or, you get no response.

Cause

- The connection needs more time than usual to search SCIM users or groups.
- You might be searching many SCIM users or groups in a single query after enabling the Nested search option.
- The underlying LDAP server has many nesting levels.

Resolving the problem

1. Increase the OCP (OpenShift Container Platform) route timeout by using the following code:

   ```
   oc -n <your-foundational-services-namespace> annotate route cp-console --overwrite
   haproxy.router.openshift.io/timeout=60s
   ```

2. Disable the Nested search if it is not required. LDAP Nested Search can be a very expensive operation and it can go worse if the nesting level increases.

Client registration failure in Platform UI console

Client registration fails in Platform UI console When you upgrade the foundational services version 3.22 or version 3.23 to foundational services version 4.x.x.

Symptoms

You might fail to register the client in Platform UI console in the following scenarios:

- When you upgrade the foundational services version 3.22 or version 3.23 to foundational services version 4.x.x and migrate more than one LDAP.
- When you have more than one LDAP before upgrading foundational services version 3.22 or version 3.23 to foundational services version 4.x.x.

Workaround

- Check the **platform-auth-service** pod configuration. You might see that some files have wrong entries. To check the pod configuration, run the following command:

  ```
  for i in $(oc get pod -l app.kubernetes.io/instance=platform-auth-service --no-headers|awk '{print $1}');do oc exec -
  it $i -- ls /config/configDropins/defaults/;done
  ```

  The sample output:

  ```
  Defaulted container "platform-auth-service" out of: platform-auth-service, init-mongodb (init)
  federated.xml  keystore.xml  ldap-cp4ba-prod-default-4776.xml
  ```

- Restart **platform-auth-service** pods.

  ```
  oc delete pod $(oc get pod -l name=platform-auth-service --no-headers|awk '{print $1}')
  ```

  Once the pod is deleted, wait for some time and then restart the **platform-auth-service** pods.

- Then, restart **platform-identity-provider** pods.

  ```
  oc delete pod $(oc get pod -l name=platform-identity-provider --no-headers|awk '{print $1}')
  ```

Once the pod is deleted, wait for some time and then restart the **platform-identity-provider** pods.

Intermittent login failure in Platform UI console

You might fail to login Platform UI console when you upgrade the foundational services version 3.22 or version 3.23 to foundational services version 4.x.x.

Symptoms

There might be intermittent login failure in Platform UI console when you upgrade the foundational services version 3.22 or version 3.23 to foundational services version 4.x.x and then configure the multiple LDAPs.

Workaround

- If you check the **platform-auth-service** pod configuration, you might see that only the **keystore.xml** file is in the pod. Also, some files might be missing in the pod. To check the pod configuration, run the following command:

  ```
  for i in $(oc get pod -l app.kubernetes.io/instance=platform-auth-service --no-headers|awk '{print $1}');do oc exec -
  it $i -- ls /config/configDropins/defaults/;done
  ```

- Restart **platform-auth-service** pods.

  ```
  oc delete pod $(oc get pod -l name=platform-auth-service --no-headers|awk '{print $1}')
  ```

Once the pod is deleted, wait for some time and then restart the **platform-auth-service** pods.

LDAP nested search for Microsoft Active Directory does not work correctly

SCIM LDAP Nested search for Microsoft Active Directory is not working properly.

Symptoms

Not all users that match the search query are returned in the search result.

Run these queries to verify whether the nested search is returning correct results.

LDAP queries

- Run an LDAP query to search all nested users that belong to a group: **memberOf:1.2.840.113556.1.4.1941:=<group dn>**.
  - Use the following syntax:

    ```
    ldapsearch -x -H ldap://ip:389 -b <LDAP_BASEDN> -D <LDAP_BINDDN> -w <LDAP_BINDPASSWORD> -s sub "(&
    (memberOf:1.2.840.113556.1.4.1941:=<group dn>)(objectcategory=user))"
    ```

  - Following is a sample output:

    ```
    ldapsearch -x -H ldap://1.2.3.4:389 -b dc=ibm,dc=com -D cn=root -w password -s sub "(&
    (memberOf:1.2.840.113556.1.4.1941:=cn=Icpgroup1,cn=platform,ou=cloud,ou=isl,ou=groups,dc=ibm,dc=com)
    (objectcategory=user))"
    ```

- Run an LDAP query to search all nested groups that a user belongs to: **(member:1.2.840.113556.1.4.1941:<user dn>)**.
  - Use the following syntax:

    ```
    ldapsearch -x -H ldap://ip:389 -b <LDAP_BASEDN> -D <LDAP_BINDDN> -w <LDAP_BINDPASSWORD> -s sub "(&
    (member:1.2.840.113556.1.4.1941:<user dn>)(objectcategory=group))"
    ```

  - Here is a sample output:

    ```
    ldapsearch -x -H ldap://1.2.3.4:389 -b dc=ibm,dc=com -D cn=root -w password -s sub "(&
    (member:1.2.840.113556.1.4.1941:uid=icpuser1,ou=people,dc=ibm,dc=com)(objectcategory=group))"
    ```

SCIM queries

- Run a SCIM query to get all nested users that belong to a group.
  - Use the following API:

    ```
    curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Accept: application/json"
    "$BCS_URL/idmgmt/identity/api/v1/scim/groups/$GROUP_ID" | jq -r '.members'
    ```

  - See the following example result:

    ```
    curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Accept: application/json"
    "$BCS_URL/idmgmt/identity/api/v1/scim/groups/cn=Icpgroup1,cn=platform,ou=cloud,ou=isl,ou=groups,dc=ibm,dc=com" |
    jq -r '.members'
    ```

- Run a SCIM query to get all nested groups that a user belongs to.
  - Use the following API:

    ```
    curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Accept: application/json"
    "$BCS_URL/idmgmt/identity/api/v1/scim/users/$USER_ID" | jq -r '.groups'
    ```

  - See the following example result:

    ```
    curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Accept: application/json"
    "$BCS_URL/idmgmt/identity/api/v1/scim/groups/uid=icpuser1,ou=people,dc=ibm,dc=com"  | jq -r '.groups'
    ```

Cause

Your LDAP directory setup might have problems, or your SCIM configuration might be wrong.

Resolving the problem

For LDAP query issues, check you LDAP directory data setup.

For SCIM query issues, see the available troubleshooting documents.

Pod issues

Troubleshoot security pod issues.

- platform-auth-service pod restarts multiple times
- Pods are not scheduled
- secret-watcher and security-onboarding pods fail to start
- Secret watcher pod shows CrashLoopBackOff status
- IM pods cannot be deployed when foundational services is configured with external EDB PostgreSQL
- The ibm-iam-operator pod fails because of cache sync failures

platform-auth-service pod restarts multiple times

The **platform-auth-service** pod restarts multiple times.

Symptoms

The **platform-auth-service** pod restarts multiple times. The **platform-auth-service** shows the following logs:

```
oc logs platform-auth-service -n <your-foundational-services-namespace> -c platform-auth-service
```

```
2019-02-12 18:18:12,170 WARN received SIGTERM indicating exit request
2019-02-12 18:18:12,170 INFO waiting for 01-wlp-platform-auth-service, 02-directory-service to die
2019-02-12 18:18:12,183 INFO stopped: 02-directory-service (terminated by SIGTERM)
[AUDIT   ] CWWKE0085I: The server defaultServer is stopping because the JVM is exiting.
[AUDIT   ] CWWKE1100I: Waiting for up to 30 seconds for the server to quiesce.
[AUDIT   ] CWWKT0017I: Web application removed (default_host): http://platform-auth-service-v9h8q:9080/oidc/
[AUDIT   ] CWWKT0017I: Web application removed (default_host): http://platform-auth-service-v9h8q:9080/oauth2/
2019-02-12 18:18:15,385 INFO waiting for 01-wlp-platform-auth-service to die
2019-02-12 18:18:18,387 INFO waiting for 01-wlp-platform-auth-service to die
2019-02-12 18:18:21,390 INFO waiting for 01-wlp-platform-auth-service to die
2019-02-12 18:18:22,391 WARN killing '01-wlp-platform-auth-service' (9) with SIGKILL
2019-02-12 18:18:22,514 INFO stopped: 01-wlp-platform-auth-service (terminated by SIGKILL)
```

Causes

The **platform-auth-service** is using more resources than the configured limit. This issue is seen more often on Linux on IBM Z and LinuxONE platforms.

Resolving the problem

To resolve the issue, remove the resource limits.

1. Install the Kubernetes CLI (kubectl).
2. Edit the **platform-auth-service** daemonset.

   ```
   kubectl edit ds platform-auth-service -n <your-foundational-services-namespace>
   ```

3. Locate the following section:

   ```
       name: platform-auth-service
       ports:
       - containerPort: 8443
         hostPort: 8443
         name: http
         protocol: TCP
       readinessProbe:
         failureThreshold: 3
         httpGet:
           path: /
           port: 8443
           scheme: HTTPS
         periodSeconds: 10
         successThreshold: 1
         timeoutSeconds: 1
       resources:
         limits:
           cpu: "1"
           memory: 1Gi
         requests:
           cpu: 100m
           memory: 256Mi
   ```

4. Remove the **limits** section under the **resources** section. The **resources** section must look like the following piece of code after the change:

   ```
         resources:
           requests:
             cpu: 100m
             memory: 256Mi
   ```

5. Save the file and wait until all the **platform-auth-service** pods restart. The pods might take a few minutes to restart.

Pods are not scheduled

Security pods are not scheduled since the master nodes do not meet the required memory or CPU requirements.

If you are unable to log in to the console, check whether the following pods are scheduled:

```
platform-identity-provider-xxx
platform-identity-management-xxx
platform-auth-service-xxx
auth-apikeys-xxx
secret-watcher-xxx
security-onboarding-xxx
```

If any of these pods are not scheduled, get information about the pod's controller (daemonset, statefulset, deployment, and other components) and check whether the pod is not getting scheduled due to resource unavailability. Use the following command to get the information:

```
kubectl describe daemonset platform-auth-service -n <your-foundational-services-namespace>
```

The output has the information about memory and CPU requirements. If the resource requirement is not met, increase the master node's memory or CPU.

After you increase the resources, the pods are automatically scheduled.

secret-watcher and security-onboarding pods fail to start

During IBM Cloud Pak foundational services installation, the **secret-watcher** and **security-onboarding** pods fail to start.

Causes

The identity management (IM) pods are not ready.

To get the status of **secret-watcher** and **security-onboarding** pods, run the following command:

```
oc get pod -A | grep -e secret-watcher -e security-onboarding
```

After you run the command, you might get the following output. The **STATUS** in the sample output shows that the **secret-watcher** pod is running successfully and the **security-onboarding** pod is completed.

```
NAMESPACE                        NAME                                  READY   STATUS      RESTARTS   AGE
<your-foundational-services-namespace>           secret-watcher-5c79cb8969-7w4nw   1/1     Running     0          19h
<your-foundational-services-namespace>           security-onboarding-8kh81         0/1     Completed   0          20h
```

For an instance, the **STATUS** of the pods can also display the error:

```
NAMESPACE              NAME                                READY     STATUS                       RESTARTS    AGE
<your-foundational-services-namespace>   secret-watcher-cccd54d9f-vdnn2   0/1       CreateContainerConfigError   0
20m
<your-foundational-services-namespace>   security-onboarding-btlhh        0/1       CreateContainerConfigError   0
20m
```

If you observe the error in the pod's status, you can run the following command to know the cause of the **CreateContainerConfigError** error. The following command display the list of events for the **security-onboarding** pod:

```
oc get event --namespace <your-foundational-services-namespace> --field-selector involvedObject.name=security-onboarding-
xxxx
```

After you run the command, you might get the following status that indicates that the "icp-serviceid-apikey-secret" key is missing due to which the pod is showing **CreateContainerConfigError** error. It indicates the issue with the **iam-onboarding** job.

```
108m    Warning  Failed      pod/security-onboarding-8kh81  Error: secret "icp-serviceid-apikey-secret" not found
```

Resolving the problem

Restart the **iam-onboarding** job to resolve the issue.

1. Log in to your boot node by running the **oc login** command.
2. Restart the **iam-onboarding** job.
    - Get the **iam-onboarding** job.

oc get job iam-onboarding

```
  * If the `iam-onboarding` doesn't exist, restart the IM operator.

  ``` {: codeblock}
 oc delete po -l name=ibm-iam-operator

* If the `iam-onboarding` job exists, restart the iam-onboarding job.

``` {: codeblock}
```

oc get job iam-onboarding -o json | jq 'del(.spec.selector)' | jq 'del(.spec.template.metadata.labels)' | kubectl replace --force -f -

Secret watcher pod shows CrashLoopBackOff status

The **secret-watcher** pod keeps crashing and shows a **CrashLoopBackOff** status.

Cause

There might be many Kubernetes secrets that are configured in the cluster. The current memory limit that is configured in the **secret-watcher** pod is not sufficient to manage the Kubernetes secrets. Kubernetes killed the pod due to less memory.

Resolving the problem

To resolve the issue, increase the resource memory limit to a value that is sufficient for the pod to manage all the Kubernetes secrets.

1. Log in to your boot node with the **oc login** command.
2. Check the number of Kubernetes secrets that are in the cluster.

   ```
   oc get secrets --all-namespaces | wc -l
   ```

3. Edit the **CommonService** custom resource.

   ```
   oc -n <your-foundational-services-namespace> edit CommonService common-service
   ```

4. Add the following piece of configuration under the **spec.services** section. Add the required memory limit in the **resources.limits.memory** section.

   ```
   spec:
     services:
     - name: ibm-im-operator
       spec:
         secretwatcher:
           resources:
             limits:
               memory: 220Mi
   ```

5. Save and exit the custom resource.

   Wait for some time and then check the **secret-watcher** pod status. The status must show as **1/1 Running** and the updated memory must show in the pod description.

6. Get the **secret-watcher** pod status and name.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep secret-watcher
   ```

7. Check the pod description.

   ```
   oc -n <your-foundational-services-namespace> describe pod <secret-watcher-pod-name>
   ```

OIDC issues

Troubleshoot OIDC related issues.

- OIDC client creation is not successful
- OIDC registration fails to update

OIDC client creation is not successful

There can be many reasons that why the OIDC client creation is not successful, however, the few obvious reasons are listed following:

- Invalid client CR
- Associated pod is not running properly
- Issue with the dependent services, such as **platform-auth-service** pod, etc.
- OIDC client watcher pod is not Out Of Memory (OOM) or not in the **crashloopback** state.

If you have verified that the client CR is valid, associated pods are running properly or dependent services are also running properly and still the OIDC client creation is still not successful then the possible reason might be that the **oidc-client-watcher** is not able to connect with **auth-service** endpoint properly. This might be because of not having the correct certificate entry at the **auth-service** end.

Confirming the certificate import issue if oidc-client-watcher pod is not able to connect with auth-service endpoint properly

The following symptoms might confirm whether there is certificate import issue:

- If no status is available in the client CR after the client CR is created
- Also, the **oidc-client-watcher** container might show the similar error:

  ```
  oc logs $oidcclient-watcher-xxx -f
  ```

Replace **oidcclient-watcher-xxx** with actual pod and instance names.

```
{"level":"error","ts":1669062335.0758603,"logger":"controller-runtime.controller","msg":"Reconciler
error","controller":"controller_oidc_client","request":"cap4ba-ns3/ibm-bts-oidc-client","error":"Error occurred during
create oidc client regstration".
```

Where, **request** name might vary.

In case you see this error, you can verify whether you are observing the error due to the certificate issue. If there are multiple **platform-auth-service** instances, you need to verify for all the instances by using the following command:

```
oc login
oc project $namespace
oc exec -it $platform-auth-service-xxx /bin/bash
cd /opt/ibm/wlp/output/defaultServer/resources/security
keytool -v -list -keystore key.jks -alias default -storepass insecurePass
```

Replace the **platform-auth-service-xxx** with the **platform-auth-service** instance names. And, provide the namespace where **common-services** are installed.

If you find the default alias entry that contains the following information as **Issuer** and **Owner**, it means that the certificate import is an issue.

```
Owner: OU=ISL, O=IBM India, L=BANGALORE, ST=KARNATAKA, C=IN
Issuer: EMAILADDRESS=test@test.local, CN=CFSSL TEST Root CA, O=CFSSL TEST, L=San Francisco, ST=California, C=US
```

Note: If certificate import is the issue, see Steps to follow if certificate import is an issue. If certificate import is not the issue then there might be different reason that why the client creation is not happening and that needs to be checked.

Steps to follow if certificate import is an issue

1. Login to the cluster by using **oc** CLI.
2. Save the content of shell as **updateJKS.sh**.
3. Run the shell script as **updateJKS.sh $namespace**. Provide the namespace where **common-services** are installed.

```
oc project $1
for pod in $(oc get pod -o name | grep platform-auth-service);
do
  echo "Going to update jks for pod Name: ${pod}"
  oc exec -it ${pod} /bin/bash -c 'platform-auth-service' -- keytool -importkeystore -destkeystore
/opt/ibm/wlp/output/defaultServer/resources/security/key.jks -srckeystore /certs/generated/platformauth-ks.p12 -
srcstoretype pkcs12 -alias default -storepass insecurePass -srcstorepass insecurePass -noprompt
  echo  "Done"
done
```

Note: It is possible that after restart you might see the same issue so it is recommended to re-run the script.

OIDC registration fails to update

Symptoms

Before you register the OIDC clients by using IdP V3 API, you need to login into third party ID provider. And, then you can register the OIDC clients in the application. While registering, you use application url as cp-console url and redirect URL as **https://<cp-console-url>/ibm/api/social-login/redirect/<name of the oidc>**. However, you might face issue while opening the cp-console browser. When you click the configured ID provider name, you might not be redirected to the authentication page of that IdP.

Causes

Issue with configuring the OIDC XML files in multi-cluster environment.

Troubleshooting the issue

Restart all the replicas of **platform-auth-service** pod.

To restart the **platform-auth-service** pod:

1. Get the platform-auth-service pod ID.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
   ```

   Following is a sample output of the command:

```
platform-auth-service-t6sfm          4/4     Running      0     1d
```

2. Delete the **platform-auth-service** pod.

   ```
   oc -n <your-foundational-services-namespace> delete pod pod-name
   ```

   Where, **pod-name** specifies the name of the **platform-auth-service** pod that you want to delete.

3. Once the pod is deleted, you might see a similar message:

   ```
   pod "pod-name" deleted
   ```

   Where, **pod-name** specifies the name of the **platform-auth-service** pod that has been deleted.

4. Verify the status of the **platform-auth-service** pod that has been deleted.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep pod-name
   ```

   Where, **pod-name** specifies the name of the **platform-auth-service** pod that you want to verify whether the pod is deleted or not.

5. The **platform-auth-service** pod will restart. The pod gets new ID after the restart.

API call issues

Troubleshoot OIDC related issues.

- Cannot generate IAM access token through API for external OIDC and SAML users
- Unable to find and add the IDP users or user groups using the console

Error 403 as a response while calling `/iam-token/serviceids/` APIs

While calling **/iam-token/serviceids/** APIs, you get **403** as a response.

Causes

The deployment of the old version of the Cloud Pak might not be properly cleaned up while you upgrading the Cloud Pak version. To know the reason for getting **403** as a response while calling **/iam-token/serviceids/** APIs, enable **platform-auth-service** pod debug level traces and liberty traces by using the following steps:

1. Open **platform-auth-idp** configmap to edit it by using the following command:

   ```
   oc edit cm platform-auth-idp
   ```

   After you run this command, the editor view of the configmap is displayed.

2. In **platform-auth-service** container log:

   - Change the value of **LOG_LEVEL_AUTHSVC** parameter to **debug**.

   Note: By default, the value of **LOG_LEVEL_AUTHSVC** parameter is **warning** or **info**. Changing its value to **debug** provides you the exact cause of error **403** that you get while calling **/iam-token/serviceids/** APIs.

   - Change the value of **LIBERTY_DEBUG_ENABLED** parameter to **true** to view liberty debug traces.

You might see the following trace sample. The sample displays the error, **Authorization failed. User is not authorized**.

```
[12/8/22 17:29:46:580 UTC] 00000099 id=00000000 com.ibm.cloud.iam.core.ServiceIdCore                    I

```

IMPORTANT: After performing the steps, restore the value of **LOG_LEVEL_AUTHSVC** and **LIBERTY_DEBUG_ENABLED** parameters value to its default values to prevent unintended adverse effects, including degraded performance and system instability.

Troubleshooting the issue

To troubleshoot the issue, restore the old namespace where Cloud Pak was deployed.

Cannot generate IAM access tokens through API for external OIDC and SAML users

An LDAP user can generate an IAM access token with API. You cannot generate the IAM access token through APIs for external OIDC and SAML users in the Platform UI.

For example:

Curl command to generate access token:

```
curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" -
d "grant_type=password&username=alfredo.cappariello@ie.ibm.com&password=*********&scope=openid" https://cp-
console.roks.ibm-stratus.com/idprovider/v1/auth/identitytoken
```

The sample output:

```
Failed to get access token, invalid token request parameters server_error
```

Causes

By default, IAM checks for the username in the LDAP backend repository to validate the user. The following error is displayed in the liberty logs if an LDAP identity provider is not configured in the Cloud Pak console.

```
com.ibm.wsspi.security.wim.exception.PasswordCheckFailedException: CWIML4537E: The login operation could not be
completed. The specified principal name 270001635h is not found in the back-end repository.
```

To enable debugging for **platform-auth-service** liberty, see Enable debugging for user authentication issues.

Workaround

Follow these steps to obtain an access token from Platform UI:

1. Login to the Platform UI. For more information, see Accessing your cluster by using the console.
2. Open Developer tools in your web browser and click **Application** tab.
3. Go to the **Cookies** section and obtain the access token in the **ibm-private-cloud-session** cookie.
4. Use the obtained token to make an API call.

Troubleshooting certificates

Learn how to isolate and resolve problems with certificates.

- Expired certificate secrets fail to rotate

Expired certificate secrets fail to rotate

When a cluster is restored from a snapshot or rebooted after a long period of shutdown, the certificate manager might need to rotate many certificates at the same time. When the IBM Cert Manager is used, this can lead to the Cert Manager failing to rotate some secrets associated with the certificates.

Solution: Use the following commands to identify if any certificate secrets contain expired certificate data:

1. Set the project (namespace):

   ```
   oc project <namespace>
   ```

   Where **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.

2. Run the following script to check for expired certificate secrets:

   Note: The script requires version 4 of bash.

   ```
   convert_date () {
   local months=( Jan Feb Mar Apr May Jun Jul Aug Sep Oct Nov Dec )
   local i
   for (( i=0; i<11; i++ )); do
      [[ $2 = ${months[$i]} ]] && break
   done
   printf "%4d-%02d-%02d\n" $3 $(( i+1 )) $1
   }
   ```

```
declare -A CERT_TO_EXPIRY

for secret in $(oc get certificate -o jsonpath='{.items[*].spec.secretName}'); do CERT_TO_EXPIRY["$(oc get secret
$secret -o jsonpath='{.metadata.name}')"]="$(oc get secret $secret -o go-template='{{index .data "ca.crt" |
base64decode}}' | openssl x509 -text -noout | grep "Not After" | awk '{print $5 " " $4 " " $7}')"; done

NOW=$(date +%s)

for secret in ${!CERT_TO_EXPIRY[@]}; do
CERT_DATE=${CERT_TO_EXPIRY[$secret]}
if [[ "$OSTYPE" == "linux-gnu"* ]]; then
   CERT_DATE_SEC=$(date -d "$(convert_date $CERT_DATE)" +%s)
elif [[ "$OSTYPE" == "darwin"* ]]; then
   CERT_DATE_SEC=$(date -j -f "%Y-%m-%d" "$(convert_date $CERT_DATE)" +%s)
fi
if [ $CERT_DATE_SEC -lt $NOW ]; then echo "$secret expired on $CERT_DATE"; fi
done
```

3. If no secret names are printed from running the preceding script, no action is required. If secret names are printed, check the state of the owning certificates using the following command:

   ```
   oc get certificates.cert-manager.io
   ```

   The output can resemble the following sample output:

   ```
   NAME                                          READY   SECRET                                        AGE
   aiops-ibm-elasticsearch-tls-secret            True    aiops-ibm-elasticsearch-tls-secret            4h2m
   aiops-installation-redis-client-cert          True    aiops-installation-redis-client-cert          4h7m
   aiops-installation-redis-server-cert          True    aiops-installation-redis-server-cert          4h7m
   ```

   If any certificates show as `False` in the **READY** column, contact IBM Support to resolve the Cert Manager failure. If all certificates show as `True` in the **READY** column, continue with the resolution steps.

4. Use the following script to force the certificate secrets to be rotated.

   Note: The script requires version 4 of bash.

```
convert_date () {
   local months=( Jan Feb Mar Apr May Jun Jul Aug Sep Oct Nov Dec )
   local i
   for (( i=0; i<11; i++ )); do
      [[ $2 = ${months[$i]} ]] && break
   done
   printf "%4d-%02d-%02d\n" $3 $(( i+1 )) $1
}

declare -A CERT_TO_EXPIRY

for secret in $(oc get certificate -o jsonpath='{.items[*].spec.secretName}'); do CERT_TO_EXPIRY["$(oc get secret $secret
-o jsonpath='{.metadata.name}')"]="$(oc get secret $secret -o go-template='{{index .data "ca.crt" | base64decode}}' |
openssl x509 -text -noout | grep "Not After" | awk '{print $5 " " $4 " " $7}')"; done

NOW=$(date +%s)

for secret in ${!CERT_TO_EXPIRY[@]}; do
  CERT_DATE=${CERT_TO_EXPIRY[$secret]}
  if [[ "$OSTYPE" == "linux-gnu"* ]]; then
    CERT_DATE_SEC=$(date -d "$(convert_date $CERT_DATE)" +%s)
  elif [[ "$OSTYPE" == "darwin"* ]]; then
    CERT_DATE_SEC=$(date -j -f "%Y-%m-%d" "$(convert_date $CERT_DATE)" +%s)
  fi
  if [ $CERT_DATE_SEC -lt $NOW ]; then oc delete secret $secret; fi
done
```

Troubleshooting Infrastructure Automation install and uninstall

Review frequently encountered issues related to installing and uninstalling Infrastructure Automation.

- Troubleshooting installing and uninstalling Infrastructure Automation
- Troubleshooting Infrastructure Management
- Troubleshooting Managed services

Troubleshooting installing and uninstalling Infrastructure Automation

Review frequently encountered issues related to installing, upgrading and uninstalling Infrastructure Automation.

Installation issues

- Database is stuck on retrying on Infrastructure Automation IMInstall Power Environment
- The `cam-tenant-api` pod is not in a ready state after installing the IAConfig CR
- Offline install or upgrade throws 'invalid character' error
- Offline install or upgrade stuck because the 'oc ibm-pak generate mirror-manifests' command fails with 'no space left on device'

Uninstall issues

- Uninstall fails to remove Infrastructure Management cleanly after deleting IAConfig instance
- Uninstall hangs when uninstalling Managed services

Troubleshooting installation

Database is stuck on retrying on Infrastructure Management IMInstall Power Environment

Sometimes when Infrastructure Management is deployed, the orchestrator pod fails to start properly with the following in the oc logs:

```
Cannot connect to the database!
Deployment status is
```

Check the postgresql pod to ensure it's running and listening. Then, verify the **vmdb_production** database was created by rushing into the postresql pod:

```
sh-4.4$ psql -U postgres
psql (10.19)
Type "help" for help.

postgres=# \l
                                  List of databases
      Name       |  Owner   | Encoding |  Collate   |   Ctype    |   Access privileges
-----------------+----------+----------+------------+------------+
 postgres        | postgres | UTF8     | en_US.utf8 | en_US.utf8 |
 template0       | postgres | UTF8     | en_US.utf8 | en_US.utf8 | =c/postgres          +
                 |          |          |            |            | postgres=CTc/postgres
 template1       | postgres | UTF8     | en_US.utf8 | en_US.utf8 | =c/postgres          +
                 |          |          |            |            | postgres=CTc/postgres
(3 rows)
```

Solution: If the **vmdb_production** database doesn't exist, like above, it is possible that a remnant postgresql.conf in the DATA directory is preventing the postgresql image from initializing the new database on boot.

You will need to check the DATA directory and either clean it manually or recreate the PVC/PV and check that it is empty.

You can always find the location of the DATA directory using the psql command below:

```
postgres=# show data_directory;
        data_directory
------------------------------
 /var/lib/pgsql/data/userdata
(1 row)
```

Ensure that the data directory is empty before the postgresql pod is restarted.

The `cam-tenant-api` pod is not in a ready state after installing the IAConfig CR

After you install Infrastructure Automation, you can encounter an error where the **cam-tenant-api** pod displays as running, but not in a ready state. When this error occurs, you can see the following message:

```
[ERROR] init-platform-security - >>>>>>>>>> Failed to configure Platform Security. Will retry in 60 seconds <<<<<<<<<<<<
OperationalError: [object Object]
```

If this error occurs, delete the **cam-tenant-api** pod to cause the pod to restart and attempt to enter a ready state.

Offline install or upgrade throws 'invalid character' error.

When doing an offline install or upgrade, running the **oc ibm-pak generate mirror-manifests <..>** command throws an error similar to the following:

```
Error: failed to load the catalog FBC at cp.stg.icr.io/cp/ <...> invalid character '<' in string escape code
```

Solution: You must have **IBM Catalog Management Plug-in for IBM Cloud Pak** (**ibm-pak-plugin**) v1.10 or higher installed. Run the following commands to ensure that **ibm-pak-plugin** is at the required level.

1. Check which version of **ibm-pak-plugin** you have installed.

   Run the following command on your bastion host, portable compute device, or connected compute device if you are using a portable storage device.

   ```
   oc ibm-pak --version
   ```

   Example output:

```
oc ibm-pak --version
v1.11.0
```

2. If the **ibm-pak-plugin** version is lower than v1.10.0, then you must download and install the most recent version.

   Follow the steps for your installation approach:

   - Bastion host: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.
   - Portable device: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.

Offline install or upgrade stuck because the 'oc ibm-pak generate mirror-manifests' command fails with 'no space left on device'

The **oc ibm-pak generate mirror-manifests $IA_CASE_NAME $TARGET_REGISTRY --version $IA_CASE_VERSION** command fails with a message similar to the following in **$IBMPAK_HOME/.ibm-pak/logs/oc-ibm_pak.log**:

```
write /tmp/render-unpack-4002583241/var/lib/rpm/Packages: no space left on device
```

Solution: The default temporary directory does not have enough space to run the **ibm-pak** tool. You must set the **TMPDIR** environment variable to a different directory with more space before running the **oc ibm-pak generate mirror-manifests** command.

```
TMPDIR=<new_temp_dir> oc ibm-pak generate mirror-manifests $IA_CASE_NAME $TARGET_REGISTRY --version $IA_CASE_VERSION
```

Where **<new_temp_dir>** is the path for a directory with more space.

Troubleshooting uninstall

Uninstall fails to remove Infrastructure Management cleanly after deleting IAConfig instance

After deleting Infrastructure Management IAConfig CR in the namespace to uninstall Infrastructure Management from Red Hat OpenShift Container Platform console, some of the Infrastructure Management pods were still there in the namespace. You can workaround the problem by deleting IMInstall custom resource from the Red Hat OpenShift Container Platform console. This will remove the pods from the namespace.

You should also delete the **clients.oidc.security.ibm.com** customer resource that was used by Infrastructure Management if it still exists. Then, You can uninstall the operators remaining on the namespace.

To delete IMInstall Custom Resource (CR), you need to edit the CR to remove the Finalizer. Save the CR. Then delete the IMInstall Custom Resource (CR). Run the following commands or perform the same from the Red Hat OpenShift Container Platform console.

1. Identify the CR name, for example, **im-iminstall**

   ```
   oc -n <project> get iminstall
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed.

2. Edit the statement "finalizers:" and the one below it. Save and exit.

   ```
   oc -n <project> edit iminstall im-iminstall
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

3. Delete the CR.

   ```
   oc -n <project> delete iminstall im-iminstall
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

After a few minutes, the Infrastructure Management pods should no longer exist. The clients.oidc.security.ibm.com Custom Resource (CR) could still exist, and to delete the CR, do the following steps,

1. Check if the CR exist.

   ```
   oc -n <project> get clients.oidc.security.ibm.com
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

2. If the CR exists, edit the CR. Delete the statement "finalizers:" and the one below. Save and exit.

   ```
   oc -n <project> edit clients.oidc.security.ibm.com ibm-infra-management-application-client
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

3. Delete the CR.

   ```
   oc -n <project> delete clients.oidc.security.ibm.com ibm-infra-management-application-client
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

Uninstall hangs when uninstalling Managed services

The Infrastructure Automation uninstallation sometimes hangs when trying to delete the manageservice instance.

Describing the Managed services instance shows output similar to the following:

```
# oc describe manageservice cam
Name:         cam
Namespace:    cp4aiops
Labels:       operator.ibm.com/opreq-control=true
Annotations:  operator-sdk/primary-resource: /cam-services-sa-csb-patch-rb-pod
              operator-sdk/primary-resource-type: ClusterRoleBinding.rbac.authorization.k8s.io
API Version:  cam.management.ibm.com/v1alpha1
Kind:         ManageService
Metadata:
  Creation Timestamp:              2024-03-05T21:46:56Z
  Deletion Grace Period Seconds:  0
  Deletion Timestamp:              2024-04-15T01:11:29Z
  Finalizers:
    helm.sdk.operatorframework.io/uninstall-release
  Generation:        2
  Resource Version:  55077252
  UID:               87e6b8cf-3123-4914-bf64-a2b209cbe22d
```

Solution: Edit the Managed services instance to remove the finalizer entry.

1. Run the following command:

   ```
   oc edit ManageService cam
   ```

2. Delete the following lines, and then save your changes.

   ```
   Finalizers:
       helm.sdk.operatorframework.io/uninstall-release
   ```

Troubleshooting for Infrastructure Management

Learn how to isolate and resolve problems with Infrastructure Management.

To get support, see Support in the product documentation.

- After upgrading to IBM Cloud Pak for AIOps users cannot access Infrastructure Management
- Error when using multiple tabs in the same browser
- Non-LDAP users cannot access Infrastructure Management
- The vmware-infra-* pods in CrashLoopBackOff error states
- Infrastructure Management vm operator encounters an error creating CRD
- Infrastructure Management vm operator encounters an error when upgrading on OpenShift
- Error when deleting cloud volumes in Infrastructure Management
- Error when logging out of Infrastructure Management
- No new data coming in to IBM Cloud Pak® for AIOps from Infrastructure Management
- **infrastructure-management-zookeeper-0** pod is not Ready on the Red Hat OpenShift on IBM Cloud cluster

After upgrading users cannot access Infrastructure Management

After upgrading, an OIDC provider error can be seen when you access Infrastructure Management.

This error can result in the following error message:

```
OpenID Connect Provider error: Error in handling response type.
```

Solution: To resolve this issue, complete the following steps:

1. Log in to your Red Hat OpenShift cluster:

   ```
   oc login
   ```

2. Change to the Infrastructure Management project:

   ```
   oc project management-infrastructure-management
   ```

3. Save the secret encoded string to a file and use the **base64** command to decode the data and direct the output to another text file.

   ```
   oc get secret -o jsonpath='{.data.oidc\.conf}' ibm-infra-management-application-connection | base64 -d | sed -e
   's#oidc/endpoint/OP/jwk#idprovider/v1/auth/jwk#g'> oidc_new.conf
   ```

   ```
   cat oidc_new.conf | base64 | tr -d '\n'
   ```

4. Replace the value above in the secret **ibm-infra-management-application-connection** in the **oidc.conf**

   ```
   oc edit secret ibm-infra-management-application-connection
   ```

   - Replace oidc.conf with the new value in step 3.
   - Save the secret.

5. Restart the **httpd** pod in the **management-infrastructure-management** namespace to pick up the changes by deleting the **<httpd_pod_instance_name>**. For example,

```
oc delete pod `oc get pod | grep httpd | cut -f1 -d" "`
```

Error with multiple tabs in the same browser by using Infrastructure Management

When you are using Infrastructure Management, you can encounter an error starting multiple tabs in the same browser.

You can encounter the following error when you attempt to access Infrastructure Management using multiple tabs in the same browser.

```
Edit aborted! Infrastructure Management does not support the browser's back button or access from multiple tabs or windows of the same browser. Close any duplicate sessions before proceeding.
```

This error occurs when Infrastructure Management does not support the browser's back button or access from multiple tabs or windows of the same browser.

Solution: Closing the other Infrastructure Management browser tab can resolve the issue.

Non-LDAP users cannot access Infrastructure Management but can see the data in IBM Cloud Pak for AIOps

While you are logged in to IBM Cloud Pak® for AIOps with a non-LDAP user, attempting to start Infrastructure Management can fail with an error.

When this error occurs, an error message can resemble the following example:

```
OpenID Connect Provider error: Error in handling response type.
```

When you attempt to access the Infrastructure Management. console through the side panel, you are sent to **inframgmtinstall.apps.<cluster_name>.<customer_domain>.com** as expected. This link brings you to a login page.

If you log in with an LDAP user, the **initialAdminGroupName** must exist as an LDAP group. Non-LDAP users cannot be used with Single Sign On for Infrastructure Management.

Solution: The initialAdminGroupName that was provided in the IMConfig was not a valid group in the enterprise LDAP directory, instead it was a group manually setup in the Identity and Access Management (IAM) panel. The user that attempted to access Infrastructure Management. using this group was manually added to the group, giving the illusion of a successful integration with the LDAP directory.

The initialAdminGroupName must be a valid group within the enterprise LDAP directory and the designated user must be added to this group. Once the user logs into the IBM Cloud Pak for AIOps console, they will be automatically added to the Identity and Access Management panel.

The vmware-infra-* pods in CrashLoopBackOff error states

You can encounter an error where several pods are crashing, and restarting constantly. These pods can appear to be failing with an authentication error.

When this error occurs, your output when checking the pod status can resemble the following example:

```
NAMESPACE                                                NAME
READY   STATUS              RESTARTS   AGE
management-infrastructure-management                     1-vmware-infra-event-catcher-30-65d7bfd967-tcsrg
0/1     CrashLoopBackOff    399        44h
management-infrastructure-management                     1-vmware-infra-operations-30-6dc9f87b75-mqfpz
0/1     CrashLoopBackOff    402        44h
management-infrastructure-management                     1-vmware-infra-refresh-30-84fcd6cbd4-fc68w
0/1     Error               412        44h
```

When you check the logs, these pods appear to be failing with an authentication error:

```
{"@timestamp":"2020-08-02T21:13:00.050303 ","hostname":"1-vmware-infra-refresh-30-84fcd6cbd4-fc68w","pid":7,"tid":"2ae9ee5f997c","level":"err","message":"MIQ(ManageIQ::Providers::Vmware::InfraManager::RefreshWorker::Runner) ID [2241] PID [7] GUID [403658a2-96a2-4823-b996-94cd6472dffd] EMS id [30] failed authentication check. Worker exiting."}
```

This error can happen when VMWare is unable to be accessed, which can be due to an authentication issue, network issue, or some other reason. When this connection issue occurs, the pods enter into this state.

Solution: To resolve this error, complete the following steps:

1. Fix the credentials or network issue, allowing the pods to recover.
2. Delete the provider to stop the CrashLoopBackOff.

Infrastructure Management vm operator encounters an error when creating CRD

After you install Infrastructure Management, you can encounter an error where no **deployers** are in the **management-infrastructure-management** namespace.

```
oc get deployers.core.hybridapp.io --all-namespaces
```

Output:

```
No resources found
```

This error can occur when the operator attempts to create the CR before the CRD is installed. To check whether this issue is occurring, run the following command:

```
oc logs -n management-infrastructure-management -f infra-management-vm-operator-764ff5fff9-zm81f
```

Output:

```
I0729 23:17:27.105548       1 deployer.go:81] Create Deployer: error creating CRD, the server could not find the requested
resource
```

Solution: Restart the **infra-management-vm-operator** pod. When the pod is restarted run the following command to view the result:

```
oc get deployers.core.hybridapp.io --all-namespaces
```

Output:

```
NAMESPACE                                 NAME        AGE
management-infrastructure-management   ibminfra   12s
```

Infrastructure Management vm operator encounters an error when upgrading on OpenShift

When you are upgrading Infrastructure Management, you can encounter an error where the operator fails to install correctly.

Checking the OpenShift console InstalledOperators for project: **management-infrastructure-management** shows the operator in "Failed" state. Checking **oc describe** shows a message "conflicting CRD owner in namespace". For example,

```
oc describe operator ibm-management-infra-vm.management-infrastructure-management
```

```
Name:         ibm-management-infra-vm.management-infrastructure-management
Namespace:
Labels:       <none>
Annotations:  <none>

      Name:                    ibm-management-infra-vm.v2.2.3-202011230408
      Namespace:               management-infrastructure-management
      API Version:             operators.coreos.com/v1alpha1
      Conditions:
        Last Transition Time:  2020-11-23T23:19:44Z
        Last Update Time:      2020-11-23T23:19:44Z
        Message:               conflicting CRD owner in namespace
        Reason:                OwnerConflict
        Status:                True
        Type:                  Failed
      Kind:                    ClusterServiceVersion
      Name:                    ibm-management-infra-vm.v2.2.3-202011231858
      Namespace:               management-infrastructure-management
Events:                        <none>
```

This error CAN be seen when conflicting CSVs exist:

```
oc get csv -n management-infrastructure-management
```

Output:

```
NAME                                                DISPLAY                                                VERSION
REPLACES                                            PHASE
ibm-management-infra-vm.v2.2.3-202011231109         IBM Management Infrastructure for virtual machines   2.2.3-
202011231109   ibm-management-infra-vm.v2.2.3-202011230859          Replacing
ibm-management-infra-vm.v2.2.5-202012021409         IBM Management Infrastructure for virtual machines   2.2.5-
202012021409   ibm-management-infra-vm.v2.2.3-202011231109          Succeeded
```

Solution: Delete any older CSVs and this will allow the operator to install.

```
oc delete csv -n management-infrastructure-management ibm-management-infra-vm.v2.2.3-202011231109

oc delete csv -n management-infrastructure-management ibm-management-infra-vm.v2.2.3-202011230859
```

Error when deleting cloud volumes in Infrastructure Management

After you create a cloud volume, you might be unable to detach the volume from an instance. When this issue occurs, you can view an error if you then try to delete the volume. The error can resemble the following message:

```
Unable to detach Cloud Volume "volume_name" from "instance_name" Instance "instance_ID" is not attached to volume
"volume_ID".
```

This error can occur when the refresh (EmsRefresh) has not run or completed. to resolve this issue, manually run a refresh by browsing to **Configuration** > **Refresh Relationships and Power States**. Then, wait for the refresh to complete. When the refresh is completed, delete or detach the volume again.

Errors logging out of or re-logging in to Infrastructure Management

While logged in to IBM Cloud Pak® for AIOps and the IBM Cloud Pak for AIOps console you log out of Infrastructure Management instance and you receive an error. The error states:

```
This page isn't working right now.  HTTP ERROR 400
```

Logging out of Infrastructure Management takes you back to the login for IBM Cloud Pak for AIOps. When attempting to start the IBM Cloud Pak for AIOps console it fails to log you back in through SSO and you are prompted to enter login credentials.

You can log out of IBM Cloud Pak for AIOps, then log back in to IBM Cloud Pak for AIOps and start the IBM Cloud Pak for AIOps console.

No new data coming in to IBM Cloud Pak® for AIOps from Infrastructure Management

You can encounter an issue where providers are added within Infrastructure Management, but are not showing IBM Cloud Pak for AIOps.

This issue can occur when the access token that provides authorization into Infrastructure Management from IBM Cloud Pak for AIOps is expired.

To confirm this cause, check the BypassAuth annotation in the **`imconnection connections.infra.management.ibm.com`** CR in the **`management-infrastructure-management`** project or namespace.

```
metadata:
  annotations:
    BypassAuth: 'false'
```

If the BypassAuth annotation is not defined or is set to "false" then:

- check if spec.cfHost is defined with the correct Infrastructure Management url.
- check for the definition of spec.secrets.accessToken.

```
spec:
  cfHost: 'inframgmtinstall.apps.cp4mcm-23.company.com'
  secrets:
    accessToken:
      secretKeyRef:
        key: accesstoken
        name: ibmconnectionsecret
```

If accessToken is defined then check the log of the VM operator and look for entries with "TokenRefresh Token has expired" similar to the following:

```
I0401 13:59:35.553292       1 update.go:34] TokenRefresh Starting update of token.
I0401 13:59:35.555424       1 secret.go:166] TokenRefresh Getting secrets from management-infrastructure-management using
name imconnectionsecret
I0401 13:59:35.571513       1 secret.go:173] TokenRefresh got token secret 131462371
I0401 13:59:35.571540       1 update.go:94] TokenRefresh checking if expired.
W0401 13:59:35.571553       1 secret.go:266] TokenRefresh Token has expired. Current time: 2021-04-01 13:59:35.571549714
+0000 UTC m=+29212.072337265, End time: 2021-03-26 18:52:49 +0000 UTC
E0401 13:59:35.571570       1 update.go:65] refresh token has elapsed not attempting refresh
E0401 13:59:35.571615       1 update.go:27] error getting token using refresh token
I0401 13:59:35.571622       1 configs.go:92] Sleeping for 300.000000 seconds.
```

Solution

If the accessToken has expired then update the secret referenced in **`accessToken.secretKeyRef.name`**.

Note: For version 2.3 upgraded from 2.2, the default secret name is **`imconnectionsecret`**. For a new install of version 2.3 the default secret name is **`ibm-infra-management-application-connection`**.

To fix the problem the oauth username and password can be added to the **<secret_name>** in order for the tokenrefresh process to request a new accesstoken from IAM. Once the accesstoken is obtained the oauth username and password are removed from the secret.

Edit the secret using the command:

```
oc edit secret <secret_name> -n management-infrastructure-management -o YAML
```

Add after the line **type: Opaque**

```
type: Opaque
stringData:
  oauth_username: <user_name>
  oauth_password: <password>
```

Where **<secret_name>** is **ibm-infra-management-application-connection**

If the BypassAuth annotation is set to "true" then check to make sure spec.cfHost in the **imconnection** CR is set to the following:

```
spec:
  cfHost: 'web-service.management-infrastructure-management.svc.cluster.local:3000'
```

Verifying the solution

Check the log for the **sre-inventory-inventory-cfcollector** pod in the **kube-system** project for entries similar to the following:

```
I0425 00:13:35.835415       7 main.go:41] ============Do synchronization from CloudForm http://web-service.management-

```

infrastructure-management-zookeeper-0 pod is not Ready on the Red Hat OpenShift on IBM Cloud cluster

You might notice that the **infrastructure-management-zookeeper** pod is not in *Ready* status on Red Hat OpenShift on IBM Cloud cluster.

The issue might happen because **infrastructure-management-zookeeper** pod requires more cpu and memory to start on a Red Hat OpenShift on IBM Cloud cluster.

Solution: Use the following steps to fix the failed pod issue:

1. Change to the Infrastructure Automation namespace.

   ```
   oc project <IANamespace>
   ```

   Where **IANamespace**is the namespace where Infrastructure Automation is installed.

   Note: If IBM Cloud Pak for AIOps is also installed, then use the IBM Cloud Pak for AIOps namespace in the command.

2. Get the name of iminstall custom resource:

   ```
   oc get iminstall --no-headers | awk '{print $2}'
   ```

3. Make a copy of the existing iminstall custom resource by using the command:

```
oc get iminstall <iminstall CR name> -o yaml > <iminstall CR name>.orig
```

Where **<iminstall CR name>** is the name of iminstall custom resource.

4. Delete the iminstall custom resource:

```
oc delete iminstall <iminstall CR name>
```

Where **<iminstall CR name>** is the name of iminstall custom resource.

5. Edit the iminstall custom resource file by using the command:

```
vi <iminstall CR name>.orig
```

Where **<iminstall CR name>** is the name of iminstall custom resource.

6. Remove the following lines from iminstall custom resource:

```
finalizers:
   - infra.management.install.finalizer.infra.management.ibm.com
resourceVersion: "3023054"
uid: c790e781-07a3-46d7-bf20-5e1acc1ba2ad
```

Note: You might have different values for the mentioned properties.

7. Add the following variables to the iminstall custom resource:

```
spec:
  zookeeperCpuRequest: 400m
  zookeeperCpulimit: 500m
  zookeeperMemoryRequest: 400Mi
```

Note:if you are using IAConfig to create the iminstall custom resource then, you can add the following environment variables to the IAConfig custom resource.

```
name: ibm-management-im-install
spec:
  iminstall:
    applicationDomain: inframgmtinstall.<your_env_domain>
    imagePullPolicy: Always
    imagePullSecret: ibm-entitlement-key
    initialAdminGroupName: <your_admin_group>
    zookeeperCpuRequest: 400m
    zookeeperCpulimit: 500m
    zookeeperMemoryRequest: 400Mi
    license:
      accept: true
```

8. Apply the iminstall custom resource by using the command:

```
oc apply -f <iminstall CR name>.orig
```

Where **<iminstall CR name>** is the name of iminstall custom resource.

Troubleshooting and support

Troubleshooting known issues and support information for Managed services.

- Getting help and support
- Troubleshooting

Getting help and support

- If you need help using Managed services, visit the IBM Support page. Additionally, you can see if the problem is documented in corresponding Troubleshooting topics.
- For Managed services blogs and tutorials, see Managed services Content Development Community.
- For information about opening an IBM Support ticket or about IBM Support levels and ticket severities, see Contacting IBM Support and Ask the community.
- Learn more about support from the following topics:
  - Open source support in Managed services
  - Collecting data for Managed services

Troubleshooting

- Open-source support in Managed services

- Troubleshooting issues in Service library
- Troubleshooting general issues
- Troubleshooting content related issues and useful links
- Troubleshooting Terrafom related issues
- Collecting data for Managed services
- Refreshing internal certificates
- Updating the resource limits for Managed services containers

Troubleshooting general issues

Some generally known issues with Managed services are documented.

- Sometimes, Managed services may fail to retrieve the power state of a resource from the remote provider. The cause of the error may be due to the missing underlying cloud resource. As a resolution, check the cloud provider console to ensure that the underlying resource is still present. If it has been deleted from outside of Managed services, then this error message may occur.
- Managed services might face issues whenever a microservice becomes inactive. To find and restart all the inactive microservices, run the following command from the directory where you extracted the content of the Managed services compressed file on the master node:

  ```
  bash MS-remedies.sh
  ```

  Note: The script does not restart base microservices like MongoDB, Auth, and Identity.
- For information about collecting Managed services Logs, see Collecting logs using camCollector script.

Troubleshooting issues in installation

Known issues in the installation of Managed services.

- If you face issues while accessing the Managed services user interface post the installation, check your firewall settings and turn it off.
- If the Managed services entry is missing from the navigation menu **Automate infrastructure**, this might be caused by a problem during Managed services installation.

  To resolve this issue:

  - Delete the Managed services installation instance and install it again.
  - After successful installation and creation of the Managed services entry in the navigation menu **Automate infrastructure**, delete the Service library pods to restart them.
- There will be instances where the **cam-tenant-api pod** does not start even after 45 minutes and an error 'Failed to get IAM access token' is displayed. Restart the pod to resolve the issue.
- Sometimes, even after the successful deployment of Managed services, the "cam-mongo" microservice might go down unexpectedly.

  Run the following command to check the pod log:

  ```
  kubectl describe pods -n cp4aiops
  ```

  If this command does not provide you the necessary details to understand the issue, run the kubectl command to get logs from previously running container. For example, this **kubectl -n cp4aiops logs cam-mongo-5c89fcccbd-r2hv4** command results in the following output:

  ```
  exception in initAndListen: 98 Unable to lock file: /data/db/mongod.lock Resource temporarily unavailable. Is a mongod  instance already running?, terminatingConclusion: While starting the container inside "cam-mongo" pod it was unable to use the existing /data/db/mongod.lock file and hence your pod will be not up and running and you cannot acces CAM URL.Solution:
  ```

  To resolve the issue, do the following steps:

  1. Use the following pod creation yaml to spin up a container and mount the cam-mongo volume within it. It mounts the concerned pv's, that is, **cam-mongo-pv** where /data/db/ is present.

     ```
     apiVersion: v1
     kind: Pod
     metadata:
       name: mongo-troubleshoot-pod
     spec:
       volumes:
         - name: cam-mongo-pv
           persistentVolumeClaim:
           claimName: cam-mongo-pv
       containers:
         - name: mongo-troubleshoot
           image: nginx
           ports:
             - containerPort: 80
     ```

```
          name: "http-server"
      volumeMounts:
        - mountPath: "/data/db"
          name: cam-mongo-pv
```

2. Use **podman exec -it /bin/bash** to keep stdin open and to allocate a terminal. Run the following commands:

```
cd /data/db
rm mongod.lock
rm WiredTiger.lock
```

3. Kill the pod that you created for troubleshooting.

4. Run the following command to kill the corrupted cam-mongo pod:

```
kubectl delete pods -n cp4aiops
```

- Managed services Container Debugging (kubectl)

  When a container is not in running state, run the following kubect1 commands to describe pods and look for errors:

```
kubectl -n cp4aiops get pod
kubectl -n cp4aiops describe pod <podname>
kubectl -n cp4aiops get pv
kubectl -n cp4aiops describe pv <pvname>
```

  Look for events or error messages when describing the pods or persistent volumes that are not in health states. For example, **CrashLoopBackoff, Pending (for a while), Init (for a while)**.

- Run the following commands to ensure PVs are created successfully:

```
kubectl -n cp4aiops describe pv cam-mongo-pv
```

  If PVs are not set up, follow PV setup steps before you install Managed services:

  Note: PVs must be deleted and re-created everytime Managed services is installed.

- Managed services installation fails due to an incorrect **Worker node architecture** value.

  The installation fails with the following error message:

```
Events:
Type     Reason        Age                            From               Message
 ----     ------        ----       ---      -------
Warning  FailedScheduling 71s (x2 over 71s)  default-scheduler  0/1 nodes are available: 1 node(s) didn't match node
selector.
```

  To resolve this issue, review the input parameter for the 'Worker node architecture' and check if the supported architecture is selected/entered correctly: **amd64**

- Managed services reinstall fails due to an existing **cam-api-secret-gen-job** left from prior Managed services installations and the job hangs indefinitely with the following error:

```
Internal service error : rpc error: code = Unknown desc = jobs.batch "cam-api-secret-gen-job" already exists

root@csz25087:~# kubectl -n cp4aiops get pods
NAME                          READY   STATUS      RESTARTS   AGE
cam-api-secret-gen-job-n5d87   0/1     Completed   0          24m
```

  To resolve this issue:

  1. Run the following command:

```
kubectl -n cp4aiops delete job cam-api-secret-gen-job
```

  2. Install Managed services.

- Managed services installation fails due to an existing **template-crd-gen-job**. In the prior installations, you might see the job hang for ten minutes and then time out.

```
Internal service error : rpc error: code = Unknown desc = jobs.batch "template-crd-gen-job" already exists

root@csz25087:~# kubectl -n cp4aiops get pods
NAME                          READY   STATUS             RESTARTS   AGE
template-crd-gen-job-wm7mj   0/1     ImagePullBackOff   0          8m27s
```

  To resolve this issue:

  1. Run the following command:

```
kubectl -n cp4aiops delete job template-crd-gen-job
```

  2. Install Managed services.

- Encountered an error **3.6.0.0 (20220113_2156) x86_64** while accessing the library page after you uninstall and reinstall Managed services.

  To resolve this issue, increase the **icpdata_addon_version** to a higher value in the configmap **cam-proxy-zen-extension**.

```
oc -n cp4aiops edit configmap cam-proxy-zen-extension
```

- A Bad Gateway error appears on some Managed Services pages following the installation of Infrastructure Automation.

  In order to resolve this issue, restart the **cam-tenant-api** pod as follows:

  ```
  oc delete pod $(oc get pod|grep cam-tenant-api|awk '{print $1}')
  ```

Troubleshooting issues in installation of Managed services on Red Hat® OpenShift® on IBM Cloud® service

- After installing the Managed services, few pods get into an error state due to permission issue caused by using the built-in storage of IBM Cloud.

The **cam-provider-terraform-api**, **cam-proxy**, and **cam-mongo** pods get into an error state.

As a resolution, do the following steps to install Managed services successfully:

1. Update the Managed services configuration parameters for **ibm-management-cam-install** and make sure to change the custom resource **roks** to **true**.

   ```
   spec:
     manageservice:
       license:
         accept: true
       arch: amd64
       roks: true
   ```

2. Ensure that all Managed services pods are in ready/running state, for example, 1/1.

- After installing the Managed services, **cam-provider-terraform-api** container fails to init.

The error **chown: /home/terraform: No such file or directory** is logged in the initContainer logs.

As a resolution, perform the following steps to install Managed services successfully:

1. Save the existing deployment in a file:

   ```
   oc -n cp4aiops get deploy cam-provider-terraform-api -o yaml > cam-provider-terraform-api-orig.yaml
   ```

2. Copy the saved deployment file to a new file:

   ```
   cp cam-provider-terraform-api-orig.yaml cam-provider-terraform-api-fix.yaml
   ```

3. Edit the **cam-provider-terraform-api-fix.yaml**

   - Remove **initContainers** section:

   ```
   initContainers:
      - args:
         - chown 1111:1111 /home/terraform && chmod 775 /var/camlog
         command:
         - /bin/sh
         - -c
         image: alpine:latest
         imagePullPolicy: IfNotPresent
         name: initcontainer
         resources: {}
         securityContext:
            allowPrivilegeEscalation: false
            capabilities:
               add:
               - CHOWN
               - FOWNER
               - DAC_OVERRIDE
               drop:
               - ALL
            privileged: false
            readOnlyRootFilesystem: false
            runAsNonRoot: false
            runAsUser: 0
            seLinuxOptions:
               type: spc_t
         terminationMessagePath: /dev/termination-log
         terminationMessagePolicy: File
         volumeMounts:
         - mountPath: /var/camlog
            name: cam-logs
   ```

   - Update the deployment name to **cam-provider-terraform-fix**:

   ```
   apiVersion: apps/v1
   kind: Deployment
   metadata:
    annotations:
       deployment.kubernetes.io/revision: "2"
     name: cam-provider-terraform-api
   ```

4. Create the new deployment using **cam-provider-terraform-api-fix.yaml**:

   ```
   oc -n cp4aiops create -f cam-provider-terraform-api-fix.yaml
   ```

5. Restart IaaS pod after new cam-provider-terraform-api is ready:

   ```
   oc -n cp4aiops delete pod <cam-iaas-pod-instance>
   ```

6. Scale down the original **cam-provider-terraform-api deployment**:

   ```
   oc -n cp4aiops edit manageservice cam
   ```

7. Change the replicaCount to 0:

Note: Add the replicaCount under camProviderTerraform if the replicaCount is not added by default.

```
camProviderTerraform:
 isolateRuntime: false
 replicaCount: 0
 runtime:
  replicaCount: 0
```

Troubleshooting issues in CLI tool

Known issues with Managed services CLI tool (camctl).

- If Managed services is installed on an OpenShift environment, the port value <CAM_PORT> defaults to 443. But the CLI login command in the **Configure the client** step shows the **cam_port** as **undefined**. The workaround is to replace **--cam_port undefined** with **--cam_port 443** and execute the **camctl login** command again. For example:

  ```
  camctl login --cam_host <CAM_HOST> --cam_port 443 --username admin
  ```

Troubleshooting deployment issues

Some common issues, limitations, and logs related to deployment.

Common issues and solutions in IBM Cloud Kubernetes Service

The deployment of IBM Cloud Kubernetes Service template sometimes fails with a **404 page not found** error. It can occur when the cluster endpoints become temporarily unavailable in IBM Cloud during the deployment. Performing a plan and apply resolves the error.

Common issues and solutions in vSphere

- The following error might occur because of Self-Signed certificates:

  ```
  provider.vsphere: Error setting up client: Post https://192.168.64.140/sdk: x509: cannot validate certificate for
  192.168.64.140 because it doesn't contain any IP SANs
  ```

  As a resolution, set the parameter "allow_selfsigned_cert" to "true".

- The following error occurs whenever vSphere virtual machine is in powered on state:

  ```
  vsphere_virtual_machine.vm_1: The attempted operation cannot be performed in the current state (Powered on).
  ```

  A virtual machine with same hostname/IP already present.

  - To create folder, use create_vm_folder=1.

    Use integer 1 to create a virtual machine only if it is not already available.

  - IPv4 Prefix: ipv4_prefix_length="24"

    This is a number string for prefix length.

Common issues in Amazon WebServiced Cloud (AWS)

- The following error message might occur whenever the virtual private cloud (VPC) is not found:

  ```
  VPC not found
  ```

  As a resolution, provide a "Name" for VPC and refer to the name in the template as opposed the VPC ID.

- Errors occur whenever you do not specify unique public keys.

- The following error might occur when using an older images for deployment:

  Error: Your query returned no results. You must change your search criteria and try again with **data.aws_ami.aws_ami**.

The deployment using Ubuntu14 fails as AWS has removed support for older versions of operating system.

The solution is to replace prefilled **AMI** with the available **AMI** in AWS. For example: replace **ubuntu/images/hvm-ssd/ubuntu-trusty-14.04-amd64-server-*** with **ubuntu/images/hvm-ssd/ubuntu-focal-20.04-amd64-server-***.

The sample templates are also updated to use the latest **AMI**. To pull the latest updated templates, delete the existing **templates/services** and restart **cam-iaas*** and **cam-service-composer-api*** pods. Alternatively, import the updated sample templates/services, see Importing a template.

Common issues in IBM Cloud

- The following error message might occur because of SSH keys:

  ibm_compute_ssh_key.orpheus_public_key: Error deleting SSH key: SoftLayer_Exception_Public: SSH key cannot be deleted because it is currently being used in an active transaction. (HTTP 500)Keys

  IBM Cloud does not allow you to upload two identical pub keys having the same fingerprints. However, the IBM Cloud Terraform provider does not throw an error instead reuses that key. Issues occur whenever you try to destroy the key resource that is now associated with another running virtual machine.

  The solution is to use different keys for each deployment, reference an existing key or retry the destroy/delete to get past the error.

- The following error might occur when using an older image for deployment:

  [ERROR] Error ordering virtual guest: SoftLayer_Exception_Order_Item_Unavailable: Debian GNU/Linux 9.x Stretch/Stable - Minimal Install (64 bit)

  The deployment using Debian9 fails as IBM Cloud has removed support for older versions of the operating system.

  The solution is to replace prefilled Operating System ID with the available ID in IBM Cloud. For example: replace **DEBIAN_9_64** with **DEBIAN_10_64**.

  The sample templates are also updated to use the latest Operating System ID. To pull the latest updated templates, delete the existing templates/services and restart **cam-iaas*** and **cam-service-composer-api* pods**. Alternatively, import the updated sample templates/services, see Importing a template.

Common issues using older terraform engines or terraform templates

- The following error might occur when using deprecated terraform engine or terraform templates:

  NoCompatibleProviderEngineVersionError

  Terraform engine is removed and terraform templates are updated to use the Terraform 1.x.x version as Terraform engine 0.11.x is out of support.

  The solution is to use the latest terraform engine and terraform templates based on latest terraform version. For more information, see Managing Terraform Versions to use an older terraform version and see, Importing a template to import an older terraform template.

General issues

- Set a custom maximum number of Terraform jobs to process in parallel per cam-provider-terraform pod:

  1. Run the following command to edit the deployment for cam-provider-terraform.

     - If isolateRuntime = false, then run the following command:

       ```
       kubectl -n management-infrastructure-management edit deployment cam-provider-terraform-api
       ```

     - If isolateRuntime = true, then run the following command:

       ```
       kubectl -n management-infrastructure-management edit deployment cam-provider-terraform-runtime
       ```

  2. Update the value of MAX_LOCAL_TERRAFORM_JOBS.

     ```
     containers:
     - env:
       - name: MAX_LOCAL_TERRAFORM_JOBS
         value: "10"
     ```

     In this example, it is set to 10.

- The IP address might change after you restart a virtual machine, but it might not get reflected on the Managed services user interface. To refresh the resource state including the IP address, either run a plan/apply or use the refresh API to refresh the resource.

- Failures might occur in the deployment of a Terraform template that executes actions on a Windows image by using a WinRM connection type. As a resolution, check whether "AllowUnencrypted" parameter of WinRM configuration is set to true in the Windows image that is used in the Terraform template. For more information, see Terraform documentation.

- You might observe a failure whenever you do back-to-back interdependent VMware operations. For example, a "Start" followed by "Shutdown OS" causes a failure because the second action requires VMware Tools that has not got started yet.

- Managed services on IBM Cloud Pak for AIOps has a predefined 6 hours deployment window. Do the following steps to add **TERRAFORM_JOB_TIMEOUT_MS** environment variable to the deployment:

  1. Run the following command to open the deployment in edit mode.

     - If isolateRuntime = false, then run the following command:

```
kubectl -n management-infrastructure-management edit deployment cam-provider-terraform-api
```

- If isolateRuntime = true, then run the following command:

```
kubectl -n management-infrastructure-management edit deployment cam-provider-terraform-runtime
```

2. Add the **TERRAFORM_JOB_TIMEOUT_MS** variable with value.

   For example, the value of **TERRAFORM_JOB_TIMEOUT_MS** is updated to 10 hours in millisecond:

```
name:TERRAFORM_JOB_TIMEOUT_MS
value: "36000000"
```

- During template deployment, you must specify user credentials based on the operating system.
  - For IBM Cloud with Red Hat Enterprise Edition operating system, specify "root" as the user.
  - For AWS with Red Hat Enterprise Edition operating system, specify "ec2-user" as the user.
  - For AWS with Ubuntu operating system, specify "ubuntu" as the user name.

  If the appropriate user is not provided for the corresponding operating system, then the deployment fails with an error message.

  For example, If you do not provide "root" as the user while deploying a VMware template and the passwordless sudo is also not enabled, then the following error message is displayed:

```
Error: Response from pattern manager:
StatusCode:500
Message:
{
 "message": "Bootstrap command failed. See the pattern manager logs for more details.",
 "rc": 1,
 "request_id": "1c844be316b74601853d2ddde595d94d",
 "stderr": "Creating new client for cam-apache-1\nCreating new node for cam-apache-1\nConnecting to 0.0.0.0\nstty:
'standard     input': Inappropriate ioctl for device\nstty: 'standard input': Inappropriate ioctl for device\nstty:
'standard input': Inappropriate   ioctl for device",
 "stdout": "0.0.0.0 knife sudo password: \nEnter your password: \r\n0.0.0.0 \r\n0.0.0.0 Sorry, try again.\r \n0.0.0.0
knife sudo password: \n0.0.0.0 \r\n0.0.0.0 Sorry, try again.\r\n0.0.0.0 knife sudo password: \n0.0.0.0 \r\n0.0.0.0
sudo: 3 incorrect password attempts"
}
```

- You can import templates from GitHub or GitLab and deploy them. However, if you remove or change access token in GitHub or GitLab and then try to destroy instance, the operation fails with the following error message:

```
GithubClientError: vmware/terraform: failed to retrieve content list from github.; caused by {"message":"Not Found",
"documentation_url":"https://developer.github.com/v3"}
```

  Ensure that the Managed services has a connection to GitHub/Gitlab when you destroy the instance.

- **CAM deployment stays in Progress - Log File repeating null_resource.clone_git: Still creating..."**

  The log file can record the template deployment status as in progress for a very long time. To identify the reason for the issue, do the following analysis on the deployed virtual machine wherein the problem occurred:
  - Run the following command to check whether your user has passwordless sudo:

```
sudo cat /etc/sudoers
```

    When it prompts for a password, enable passwordless sudo for the specific user.
  - If the user does not have sudo privileges, add that user to **/etc/sudoers**.
  - Run the following command to check if name server is set up in your machine:

```
ping github.com
```

  - Check if the curl or Git commands are installed on the virtual machine. It might be an issue with the apt mirror.

- SSL Certificate error while deploying a template.

  To setup Git client locally:
  - Create **.gitconfig** file in the same Git repository as the template. The file should point to the correct CA certificates.

```
[http]
    sslCAInfo = /home/terraform/certs/ca-bundle.crt
```

  - When the provider Terraform deploys the template, it downloads the template and all its files from the Git repository, which includes the **.gitconfig**. When the Terraform init is executed, the Git client looks up in the current folder (user's home folder for the current process) and it uses the appropriate CA certificates to download the modules from Git.

- To debug Terraform template deployment, set **TF_LOG** environment variable in **cam-provider-terraform** pod. You can set **TF_LOG** to one of these log levels **TRACE**, **DEBUG**, **INFO**, **WARN**, or **ERROR** to change the verbosity of the logs. **TRACE** is the most verbose log level. This results in the detailed logs to appear on **stderr**.

1. Run the following command to open the deployment in edit mode:
   - If isolateRuntime = false, then run the following command:

```
kubectl -n management-infrastructure-management edit deployment cam-provider-terraform-api
```

- If isolateRuntime = true, then run the following command:

```
kubectl -n management-infrastructure-management edit deployment cam-provider-terraform-runtime
```

2. Add the **TF_LOG** variable with value.

```
name: TF_LOG
value: "TRACE"
```

Logs

The logs that you can examine are as follows:

- Check the template instance Terraform logs on the UI for Terraform or template errors.
- Check logs in containers for internal Managed services errors wherein the **CAM_logs** is in the **cam-logs-pv** path:
  - **/CAM_logs/cam-iaas**
  - **/CAM_logs/provider-terraform-local**

Troubleshooting security related issues

Some known security related issues in Managed services.

- If you deploy multiple template instances with the same SSH key content to the IBM Cloud environment, an issue occurs when trying to delete the instances.
- You can only view the deployments (template instances and service instances) that are allowed for the specified namespace. **Namespace** dropdown allows you to switch between the available namespaces and to see the deployments of those namespaces.

  Note: If your user role is not authorized to perform a certain action, a 401 (unauthorized) error occurs in the API. However, the error is not displayed in the user interface. Symptoms may include buttons that do not respond to clicks or the page redirects in the user interface. For example, When you click deploy, the page gets redirected back to the list of instances without performing deployment. If you are logged in as an LDAP user, then go to IBM Cloud Pak for AIOps user interface and ensure that the user is assigned to a team that has access to one or more namespaces.
- Examine the following logs for security related issues:
  - cam-iaas
  - cam-orchestration
  - cam-portal-api

  Note: LDAP is configured in the IBM Cloud Pak for AIOps user interface. You can use roles in Managed services only if the LDAP is configured.

Open source support in Managed services

Because Managed services contains open source software, IBM offers some support for the open source software that it uses.

IBM uses open source software in three ways:

- To help its valued customers avoid vendor lock-in
- To ensure compatibility with the broadest ecosystem of software
- To accelerate development of its products

The mature, enterprise-level open source components that are used in Managed services was carefully selected, integrated, and tested to work as described in the product documentation and licenses. The components include integral open source components like Terraform, Kubernetes, Docker Engine, Helm, and ELK stack.

The IBM Support Guide is the definitive reference for IBM's open source support statement. To review IBM's open source support statement, see Third party software and Open Source software in the {{site.data.keyword.support_}guide}}. The IBM Support team uses the information in this statement to scope its interactions with you.

The main goal of the IBM Support team is to help paying customers get their supported product functional again as quickly as possible. Although the community support options are available for all Managed services users, contacting IBM Support is the best support option for users of the different bundled enterprise editions of Managed services. The community support channels are the only support options forManaged services Community Edition users.

When you contact IBM Support, there are two phases of open source support:

1. The problem determination phase. During this phase, IBM Support engineers determine whether the root cause of an issue is due to open source code or IBM code.
2. The open source support phase. If the root cause is due to open source code, IBM Support engineers identify which open source project contains the issue and work with you to identify next steps.

If a critical defect is found in the open source software within Managed services, IBM engineers use open source community resources to deliver a fix to the problem. The resulting fix is integrated, tested, and released to customers as an emergency update and in the next product release. If no fix is available from the community for a critical defect, IBM might use reasonable commercial efforts to provide a test fix to customers and then work with the specific open source community to create an official fix. The final arbiter over whether a supported fix can be provided belongs to the open source community.

Note that if any enterprise-level open source project has a critical defect, many clients are affected, and the community works as fast as possible to resolve it. It is unusual for only one customer to encounter a critical open source defect.

IBM cannot support any open source software that is not packaged with Managed services. In addition, if a client chooses to make any additions, subtractions, or upgrades to the Managed services open source code outside of product updates, that code is not supported. For Cloud Foundry, IBM might assist you with reporting defects in community buildpacks and runtimes to the appropriate open source community. IBM cannot provide fixes for these Cloud Foundry community buildpacks and runtimes.

Note: Managed services will support new versions of supported operating systems, Kubernetes, Docker, and other dependent infrastructure after new releases happen and when they are fully tested by the Managed services team.

Importing custom CA Certificate into Terraform provider pod

Your Terraform template might include Terraform modules whose source might be in a source control management system that is secured by your organization's internal certificate. To avoid certificate errors while making calls to Terraform modules follow these steps to add your own CA certificate chain to the existing list of pre-configured certificates.

1. Run the following command to get the name of the pod that runs the Terraform engine:

   ```
   kubectl -n cp4aiops get pods | grep cam-provider-terraform
   ```

   If this command returns pods that are prefixed with **cam-provider-terraform-runtime** and **cam-provider-terraform-api**, then you are running Terraform engine in isolation mode. In this mode, the Terraform runtime runs in separate pod. If this command returns pods that are prefixed only with **cam-provider-terraform-api**, then you are running the Terraform engine in non-isolation mode.

   If Terraform engine is deployed in an isolation mode, then you must apply the rest of the steps to **cam-provider-terraform-runtime** pod and deployment else apply the steps to **cam-provider-terraform-api** pod and deployment.

2. Run the following command to copy the existing CA bundle file from a Terraform engine pod.

   ```
   kubectl -n cp4aiops cp <terraform-engine-pod-name>:/etc/pki/ca-trust/extracted/pem/tls-ca-bundle.pem ca-bundle.crt
   ```

   Where **<terraform-engine-pod-name>** is:

   - For **Isolation mode**: A pod name prefixed with `cam-provider-terraform-runtime`
   - For **Non-isolation mode**: A pod name prefixed with `cam-provider-terraform-api`

   You might see the following error, ignore it and check whether the file got copied.

   ```
   tar: Removing leading `/' from member names
   ```

3. Add your CA certificate to the copied CA bundle file **ca-bundle.crt**.

   1. Back up the original CA bundle file **ca-bundle.crt**.

      ```
      cp ca-bundle.crt ca-bundle-original.crt
      ```

   2. Add your CA certificates (root and any intermediary) to the **ca-bundle.crt** file.

      ca-bundle.crt file has number of certificates as follows:

      ```
      -----BEGIN CERTIFICATE-----
      <certificate_content>
      -----END CERTIFICATE-----

      -----BEGIN CERTIFICATE-----
      <certificate_content>
      -----END CERTIFICATE-----
      ```

      Append your certificates at the end of the file as follows:

      ```
      -----BEGIN CERTIFICATE-----
      <certificate_content>
      -----END CERTIFICATE-----

      -----BEGIN CERTIFICATE-----
      <certificate_content>
      -----END CERTIFICATE-----

      -----BEGIN CERTIFICATE-----
      <my_custom_certificate_content>
      -----END CERTIFICATE-----
      ```

      If you have your certificate in a file, then you can execute the following command to append your certificate to **ca-bundle.crt**

      ```
      cat <your-ca-cert-file> >> ca-bundle.crt
      ```

4. Create a secret from a modified **ca-bundle.crt** file.

   ```
   kubectl create secret generic cam-custom-cert-file --from-file=./ca-bundle.crt -n cp4aiops
   ```

5. Patch the Terraform engine pod deployment file to mount a new volume that contains the created secret file.

   a. Create a file **cam-provider-terraform-patch.json** with the following contents:

```
{"spec": {"template": {"spec": {"containers": [{"name": "< terraform-engine-deployment>","volumeMounts":
[{"mountPath": "/etc/pki/tls/certs","name": "cam-custom-cert-bundle","readOnly": true}]}],"volumes": [{"name": "cam-
custom-cert-bundle","secret": {"defaultMode": 420,"secretName": "cam-custom-cert-file"}}]}}}}
```

Where **<terraform-engine-deployment>** is:

- For **Isolation mode**: `cam-provider-terraform-runtime`
- For **Non-isolation mode**: `cam-provider-terraform-api`

b. Run the following command to patch the deployment to mount the new CA bundle to Terraform engine pods.

```
kubectl -n cp4aiops patch deployment <terraform-engine-deployment> --patch "$(cat cam-provider-terraform-patch.json)"
```

Where **<terraform-engine-deployment>**:

- For **Isolation mode**: `cam-provider-terraform-runtime`
- For **Non-isolation mode**: `cam-provider-terraform-api`

Troubleshooting user interface

Known issues in the Managed services user interface.

- When all Managed services pods are running, but you cannot still log in to the user interface, then it might be an issue with oauthcache.
- The plan functionality fails to work whenever you do the following steps:

  1. Return to the **modify** tab of a deployed instance wherein a plan is already run.
  2. Click **Back** or **Edit parameters**.

  As a workaround, do the following steps:

  1. Click select version step.
  2. Edit parameters page.
  3. Click **Plan** again to start the plan process
- The following error might occur when you start the console in spite of Managed services services running in IBM Cloud Pak for AIOps:

  ```
  CWOAU0061E: The OAuth service provider could not find the client because the client name is not valid.
  ```

  To resolve the problem, run the following commands to restart the cam-iaas pod and wait for the pod to start:

  ```
  kubectl get pods -n cp4aiops | grep iaas
  kubectl delete po/<pod_name> -n cp4aiops
  ```

  Wait for the pod to start. Run the following command to confirm whether it is in running state:

  ```
  kubectl get pods -n cp4aiops | grep iaas
  ```

- If you are redirected to the getting started page in Managed services user interface after the restart of IBM Cloud Pak for AIOps or you encounter other user interface related issues, then restart the user interface microservices. Run the following command to restart the user interface pods:

  ```
  kubectl delete -n cp4aiops -l 'name in (cam-portal-ui,cam-service-composer-ui,cam-ui-basic,cam-ui-connections,cam-ui-
  instances,cam-ui-templates)' pods
  ```

- As an LDAP user you might get redirected to the getting started page. To avoid such erroneous redirection, go to IBM Cloud Pak for AIOps user interface and ensure that the user is assigned to a team that has access to one or more namespaces.
- There might be performance issues in Managed services user interface whenever you use Mozilla Firefox browser. If this issue affects all websites wherein you use self-signed certificates, then the problem might be because of SSL certificates. If a service generates a new certificate for a particular website every time it is restarted, then Mozilla Firefox stores all these certificates in its local database and verifies whether the path is valid. Multiple self-signed certificates of the same name can slow down the turn around time of your browser. In addition, the TLS handshake operation ceases to respond. To identify the root cause of the problem and resolve it temporarily, open the profile folder of your Mozilla Firefox browser and locate the **cert8.db** file. Replace the file with a different name and revisit the same site that had problems. If the page displays properly, then the issue is because of local certificate database having too many self-signed certificates of the same name. Do the workaround often to avoid problem recurrence.
- Turn on the inspect for the browser and look for any errors returned on the API. For example, an API call might return a 401 (unauthorized), or might return a 400 (bad input) with an error message in the response, which is not displayed on the API. Page redirects, looping/refreshing pages might indicate a bad API call being returned to the user interface.

  To debug such errors, examine the following logs:

  - cam-ui-basic
  - cam-ui-connections
  - cam-ui-instances
  - cam-ui-templates
  - cam-portal-ui
  - cam-service-composer-ui
- The logout button might not be visible with some screen resolutions or if you zoom in the Managed services user interface. To solve the problem zoom out the user interface or access directly the logout page at **https://<CAM_IP_address>:30000/logout**.
- The Internet Explorer browser is not supported.
- Managed services UI shows one of the following errors:

- Topology destroyed error while deployment
  - To resolve this issue, check the logs of **cam-orchestration** and if there are any errors, restart the pod.
- Pool destroyed error on UI while accessing Managed services
  - To resolve this issue, check the logs of **cam-ui-basic** and if there are any errors, restart the pod.
- Internal server error on UI while accessing Managed services
  - To resolve this issue, check the logs of **cam-portal-ui** and if there are any errors, restart the pod.

Check whether all the pods are up and running for namespace **cp4aiops**.

Troubleshooting Service Composer issues

Some known issues that are related to Service Composer or Portal-related issues in Managed services.

- If the logged in user is not able to import services from GitLab and the following error occurs, then it indicates that the user does not have access to Helm repositories:

  ```
  "Activity_id: ibmchartc7e3fb29, The template ibm-nodejs-sample does not exist."
  ```

  As a resolution, grant access to Helm repository for the logged in user and then import service from GitHub/Gitlab/Bitbucket Server.

- When you use special characters in JSON values that are used as an input parameter for a template, the provisioning fails with an error from IaaS.

  For example,

  ```
  "amis": { "today": "\"Thursday, January 24, 2019 11:01 AM\"" }
  ```

  As a resolution, remove the special characters and retry provisioning. The following example is cleared off special characters:

  ```
  "amis": { "today": "Thursday, January 24, 2019 11:01 AM" }
  ```

- For some reason, if a service instance is stuck in IN_PROGRESS state for a long time without any backend activity, then delete the service instance entry from the database. This situation might arise because of an unplanned restart of any of the Managed services pods or any other related issues. Use Cleanup Service Instance in inprogress state API to delete the service instance. The API section provides you information about any **ResourceLockError** that might occur during the cleanup process.

- If you do not see any content on the palette of the composer tab, then it is because of the connectivity issue between service composer and Business Process Manager or IBM Cloud Orchestrator or Helm plug-ins.

  IaaS sample error message:

  ```
  Bad return code from provider: { statusCode: 500, body: '{"error":{"statusCode":500,"message":"Internal Server Error"}}' }
  ```

  Business Process Manager Plugin/Provider Error

  ```
  [2019-05-08T06:29:47.422] [ERROR] http_utils - { Error: connect ETIMEDOUT <IP_ADDRESS>:9443 at TCPConnectWrap.afterConnect [as oncomplete] (net.js:1191:14) errno: 'ETIMEDOUT', code: 'ETIMEDOUT', syscall: 'connect', address: '<IP_ADDRESS>', port: 9443 } Error: Error stack Logged at: at Logger.(anonymous function) [as error]
  ```

  As a workaround, disable Business Process Manager plug-in that is causing the failure. For the actual procedure to disable a plug-in, see Enabling and disabling Business Process Manager and IBM Cloud Orchestrator.

- Even after the service is deployed and is in a running state, the IBM Cloud Pak for AIOps or IBM Kubernetes Services cluster does not show up in the controller's cluster list.

  It is possible that the service deployment had taken long enough that the controller token that is passed as a parameter on service deployment has been refreshed since the service deploy action. In this case, the IBM Cloud Pak for AIOps cluster is unable to register to the controller. To verify that this is the issue, check that the token on the controller instance has the same value as the one you have used when you deployed the Managed services. As a workaround for this issue, try any of the following methods:

  - Method 1:

    1. Redeploy the service.
    2. Ensure that the controller token stays unchanged for the time it takes for the service to deploy the new cluster.
    3. Attach the token to the controller.
    4. Estimate the duration of service deployment.
    5. Set the refresh of the controller token beyond that time interval.
  - Method 2

    1. Deploy the new cluster by using the Managed services templates.
    2. Use **Loads_Images_and_Deploys_Chart_on_ICP** service to install the chart.
    3. Register the cluster with the controller. Use **Services/MCM/MCM_on_ICP/MCM_Klusterlet-Loads_Images_and_Deploys_Chart_on_ICP/MCM_Klusterlet-Loads_Images_and_Deploys_Chart_on_ICP.json** from Git repository.

    Using this two-step cluster registration has the benefit that the long running step, which is the deployment of the cluster, gets separated from the chart install and connect operation. As the controller token is passed through during the service deploy, and this service deploy takes only minutes to deploy and run, it is unlikely for the token to be invalidated during the service deployment. If the issue still persists, redeploy just the chart service using the new token, rather than redeploying the entire cluster again.

- When you keep multiple browser instances open for the same deployed instance (instance details or associated instance) that is in "wait" state, manually refresh the browser to see the latest updates.
- Service may fail with unexpected EOF or may fail with both connection timeout and unexpected EOF. As a workaround, do the following steps:

  Set the **`TERRAFORM_PARALLELISM_COUNT`** environment variable on the running cam-orchestration deployment of Managed services:

  - Using the user interface:

    1. Login to IBM Cloud Pak for AIOps user interface and go to **Workloads** > **Deployments**.
    2. Search for **`cam-orchestration`** deployment.
    3. Select edit from the overflow menu.
    4. Edit the deployment by adding the following element to the **`env:`** array and then click **Submit**.

       ```
       {
        "name": "TERRAFORM_PARALLELISM_COUNT",
        "value": "1"
       }
       ```

    5. To verify whether your deployment is successful, double-click **`cam-orchestration`** deployment link.
    6. In the **Overview** tab > **Pods** section, check whether the **`cam-orchestration`** pod has restarted successfully.

  - Using the command line:

    1. SSH to the Managed services deployment machine.
    2. Run the following command to edit the **`cam-orchestration`** deployment:

       ```
       kubectl edit deployment cam-orchestration -n cp4aiops
       ```

    3. Under the **`- env:`** section, add the following lines.

       Note: Make sure you maintain the indentation same as other name-value pairs in this section.

       ```
       name: TERRAFORM_PARALLELISM_COUNT
       value: "1"
       ```

    4. Run the following command to ensure that the cam-orchestration pod has come up successfully after the change:

       ```
       kubectl get pods -n cp4aiops | grep cam-orch
       ```

    5. Save these changes.
- When you deploy a service that has non-permissible special characters in the value of any of its parameters, then the service instance creation fails with an error. For example, a service deployment fails because of a period (.) in the key value of a MongoDB parameter.
- Mongo does not allow you to create a map with a key value having dot in the name. To resolve this Mongo limitation, use a list with key names that have hardcoded text without a dot.
- If you use the same bind secret across multiple provisioned instances, the first bind instance is created correctly. From the second instance onwards, though a bind instance gets created, the following error occurs in IBM Cloud Pak for AIOps user interface:

  ```
  ServiceBroker returned failure; bind operation will not be retried: Status: 400;
  ErrorMessage: <nil>;
  Description: <nil>;
  ResponseError: <nil>;
  ```

- When you create a service instance with bind action in IBM Cloud Pak for AIOps user interface, you cannot terminate the instance from IBM Cloud Pak for AIOps user interface without removing associated bind instances. Though you can terminate it from Managed services user interface, the bind action remains in active state.
- For IBM Cloud Kubernetes Service template in Service Composition, do not select or enter values for datacenter and other networking attributes whenever the value of the **`machine_type`** is "free". This selection is not supported because the datacenter parameter along with other networking attributes are ignored by the Terraform provider for free clusters.
- If you are logged into Managed services for a very long time, then its Access-Token on the browser expires. If you try to deploy a Service Instance after the Access-Token expires, the deployment fails with a 401 error. As a resolution, do the following steps:

  1. Logout of Managed services.
  2. Relogin to Managed services.
  3. Retry service instance deployment.
- When you drag-drop Helm charts in the composer, parameter details are not fetched properly. To resolve this error, synchronize the IBM Cloud Pak for AIOps Helm repositories in IBM Cloud Pak for AIOps user interface. For more information, see Managing Helm repositories.
- Whenever an email notification is sent, the SMTP user name value is also used as the sender email address value. However, sometimes when you use services like sendgrid, the SMTP user name is not a valid email address. Though send a test email results in a message that says **`Test email sent successfully.`**, no email is actually sent or received.
- Terminate service instance may go to error state wherever the service instance has more than one Terraform template /Helm chart or is a combination of Terraform and Helm chart. A deployment failure in a template or helm chart can cause the entire terminate service instance to fail. However, the success of the destroy action of individual template or helm charts is based on their sequence in the composition.

For example, consider the following behavior whenever a Helm chart and Terraform template are placed in sequence and a failure occurs in Helm chart deployment:

  - If Terraform template is positioned after the Helm chart in the sequence, it gets destroyed but the termination fails at the Helm chart. The rest of the sequence is not tried and the service instance termination fails.
  - If the Helm chart is positioned after the Terraform template in the sequence, it is never attempted as the Helm failure occurs before the destroy action of Terraform template.

To resolve this issue, clean up Helm charts from backend. For the Terraform template, you can clean from backend or from the template tab.

- Helm chart limitations:

  - If you observe the following error message in the activity logs, then ensure the helm tiller has been configured on your IBM Kubernetes Service cluster:

    ```
    Error: could not find tiller
    ```

  - Helm deployments assume that you have precreated the required persistent volumes, otherwise it uses dynamic provisioning (for example GlusterFS).
  - When you click the link for helm release in the **View a deployed service instance** page, you are forwarded to the IBM Cloud Pak for AIOps management console, and not to the **Deployed templates** page in Managed services.
  - Helm release deployments are not visible from the deployed templates list view in Managed services. They are only visible from the **Service instance details** page and IBM Cloud Pak for AIOps Helm releases page.

- When you rectify an invalid primary email server and redeploy a service that is already deployed, email notification may fail with an error message.

  An example error message is as follows:

  ```
  serviceblueprint_email.emailnot379ed899: Creating...
  connection_used: "" => ""
  fail_quietly: "" => "true"
  message: "" => "Test"
  sender_name: "" => "CAMadmin"
  sequence_no: "" => ""
  status: "" => ""
  status_error_message: "" => ""
  status_message: "" => ""
  subject: "" => "Test"
  to.#: "" => "1"
  to.0: "" => "abc@in.ibm.com"
  Error applying plan:

  1 error(s) occurred:

  serviceblueprint_email.emailnot379ed899: 1 error(s) occurred:
  serviceblueprint_email.emailnot379ed899: unexpected EOF
  Terraform does not automatically rollback in the face of errors
  ....
  ....
  ```

  Do the following steps to resolve the error:

  1. Go to IBM Cloud Pak for AIOps console and click **Automate infrastructure>Managed services**.
  2. Delete primary and secondary SMTP connection.
  3. Open new tab in same browser without closing the browser.
  4. Open any REST Client extension in the browser and call the following API:

     ```
     URL : https://<TSA_HOSTNAME>/cam/connections/call_proxy?
     service=composer&httpmethod=POST&relative_url=smtpconnections
     Header: Content-Type : application/json
     Method: POST
     Payload:
     ```

     Payload For Primary connection:

     ```
     {
       "name": "PRIMARY",
       "description": "Primary SMTP Connection",
       "connection_parameters": [
         {
           "name": "username",
           "value": "<primary@somesmtpserver.com>"
         },
         {
           "name": "password",
           "value": "<password>"
         },
         {
           "name": "hostname",
           "value": "<smtp.somesmtpserver.com>"
         },
         {
           "name": "port",
           "value": "<587>"
         }
       ]
     }
     ```

Payload For Secondary connection:

```
{
  "name": "SECONDARY",
  "description": "Secondary SMTP Connection",
  "connection_parameters": [
    {
      "name": "username",
      "value": "<secondary@somesmtpserver.com>"
    },
    {
      "name": "password",
      "value": "<password>"
    },
    {
      "name": "hostname",
      "value": "<smtp.somesmtpserver.com>"
    },
    {
      "name": "port",
      "value": "<587>"
    }
  ]
}
```

- If you remove the mapping of service parameters in the **Composition** tab > **Parameters** tab of the template activity, it does not delete it from the main **Parameters** tab > **Service Parameters** section of the service and is also available while you create a service instance. If you do not want to see it while you create a service instance, you must delete it exclusively from the main **Parameters** tab > **Service Parameters** section.
- There might be failures in the termination of a template instance in spite of a "Terminated" message in the user interface. After you terminate a service instance, check the template instance logs to reconfirm.
- Whenever an error occurs during category creation, check for API-related errors in the log file.
- When you order a service, do not map the same parameter to two different decisions in the Additional Parameters page. This causes both decisions to follow the same path.
- If you do not provide the instance name in the composition tab for a template, then an error message is displayed in the **Source Code** tab during publish. To avoid such errors, whenever you add a template in the composition tab, provide a value for the instance name.
- Examine the following logs for Service Composer or Portal-related issues:
  - cam-orchestration
  - cam-portal-api
  - cam-iaas
- If Managed services orchestration has multiple templates and a template fails in the workflow, then all subsequent templates are also not considered for deployment.

Troubleshooting Service library issues

Some known issues that are related to the Service library.

- When Managed services is reinstalled, the following error is seen when Service library is accessed:

  `Error Connection failed to fetch deployable services.`

  To resolve this issue, restart `service-library-ui-api` pod by using the following command:

  `oc delete pod <service-library-ui-api-xxx> -n cp4aiops`

- When default services do not show up in Service library, delete the `cam-service-composer-api` pod to reinitiate the call to pull the services from GitHub. Delete the pod by using the following command:

  `oc delete pod <cam-service-composer-api> -n cp4aiops`

- If the **Service library** menu entry is missing from the navigation menu **Automate infrastructure** for the first time, try accessing the Service library by using the following URL: `https://<cp4mcm-console>/servicelibrary`. Then, the Service library entry is visible in the navigation menu.

Troubleshooting middleware content

Common issues in middleware content.

For more information about common issues or errors that may occur in middleware content, see the following troubleshooting references:

- For common issues while deploying the Content Runtime, see Troubleshooting and known issues.
- For issues while populating the Software Repository, see Populating the software repository.
- For issues while deploying Middleware Templates, see Troubleshooting issues and useful links.
- For issues while deploying customizing Middleware Content, see Customizing a predefined template.

In addition to these references, you can also refer to the following logs:

- Content Runtime - Pattern Manager logs, go to `/var/log/ibm/docker/pattern-manager/flask.log`.
- Content Runtime - Software Repository logs, go to `/var/log/ibm/docker/software-repo/var/nginx/log`.
- Content Runtime - Chef Server logs, go to `/var/log/opscode/*`
- Deployed Virtual machine, go to `/var/log/chef-client.log` that are displayed in the UI logging.

Troubleshooting content related issues and useful links

Learn how to isolate and resolve problems with the Managed services Middleware Content Runtime.

The following logs are useful in determining deployment failures:

- Middleware product logs for installation and configuration issues
- Template deployment instance logs
- Chef client logs
  - `/var/log/chef-client.log`
- Chef server logs
  - `/var/log/opscode`
- Content Runtime Pattern Manager log (on Content Runtime Instance)
  - `/var/log/ibm/docker/pattern-manager/flask.log`

If you have a question about Managed services content Middleware templates, check the dedicated Stack Overflow channel to see whether it is already answered. If not, post your question and it will be answered by a member of the middleware template development team or the wider community.

Known restrictions

- When you correct a public key of content runtime and redeploy the middleware template, the template deployment might still fail due to key pair mismatch. As middleware deployments do not update content runtime variables on plan and apply, deployment fails even if you destroy (not delete) the middleware template and use plan and apply to recreate it.
- Managed services content does not configure yum repos. Ensure that a correct configuration is set in the image template.

Template deployment failures

- Starter Library templates are not loaded
- SSH handshake failure
- Terraform provider does not support resource
- SSH key not found
- Node already registered with the Chef server
- Failure cleanup does not occur
- Known issues with VMware vSphere
- Recovering the Content Runtime
- Bootstrap fails with knife sudo password error
- Troubleshooting issues in IBM Cloud Pak for AIOps or Red Hat® OpenShift® Container Platform template deployments

Starter Library templates are not loaded

Some of the Starter Library templates may not load properly in Managed services because of invalid git token.

To fix this issue, run the steps mentioned in the Configuring Managed services to import out of box templates and services by using your github.com token.

SSH handshake failure

SSH handshake failure occurs when the credentials supplied don't match the operating system credentials when creating the virtual machine.

Symptoms

When the virtual machine image is started, the bootstrap mechanism for the Terraform cloud provider needs the ability to log in to the virtual machine, but the operating system credentials were not correct.

```
Error applying plan:
1 error(s) occurred:
* ibmcloud_infra_virtual_guest.referenced-image: 1 error(s) occurred:
* ssh: handshake failed: ssh: unable to authenticate, attempted methods [none publickey], no supported methods remain
```

Resolving the problem

- For IBM Cloud and AWS:

When deploying an IBM Cloud or AWS template, you specify the advanced content runtime to use for the deployment. The VM is created using the AWS key pair and private key for pattern manager that was specified for that advanced content runtime. If you are seeing the SSH handshake failed error message, it is likely that the private key for pattern manager is not the correct private key for the key pair defined in IBM Cloud or AWS.

Using the process described on Content Runtime plan and apply, modify the advanced content runtime by updating either the Key Name for Pattern Manager key set field or the private and public keys for pattern manager fields. Once the apply completes, you will be able to deploy your template to the advanced content runtime.

- For VMware:

Verify that the correct operating system user name is provided in the Terraform template. To determine the default user name, see the cloud provider documentation.

Terraform provider does not support resource

The Terraform provider cannot find a resource that is defined in the Middleware Terraform template.

Symptoms

The following error is displayed:

```
1 error(s) occurred:
* camc_notaresource.referenced-image_db2_v111_install: Provider doesn't support resource: camc_notaresource
```

Resolving the problem

Edit your Terraform template and find the resource. Verify that it is one of the following values and correct the misspelled name:

- `camc_softwaredeploy`
- `camc_bootstrap`
- `camc_vault`

SSH key not found

During provisioning of the middleware template, data lookups are being performed to retrieve information from the IBM Cloud or Amazon Web Services (AWS) accounts. When this error is encountered, the Pattern Manager public SSH key cannot be found in the appropriate vendor SSH key list.

Symptoms

If this key cannot be located, the Pattern Manager is not able to install the public SSH key on the virtual machine.

```
* data.ibmcloud_infra_ssh_key.camc_public_key: data.ibmcloud_infra_ssh_key.camc_public_key:
No ssh key found with name [camc_public_ssh_key_name]
```

Resolving the problem

The **camc_public_ssh_key** must be recreated in the appropriate Cloud account that is being used by the Managed services Automation Content runtime.

The **camc_public_ssh_key** was provided during the deployment of the Managed services Automation Content template deployment.

- For IBM Cloud:
  1. Log in to the IBM Cloud Console.
  2. Select **Classic Infrastructure** > **Manage** > **SSH Keys**.
  3. Click **Add**.
  4. Cut and paste the contents of the **camc_public_ssh_key** into the **Key Contents** section.
  5. Enter the name of the key in the **Label** section.
  6. Click **Add**.
- For AWS:
  1. Log in to the Amazon Web Services console.
  2. Click **All services > Compute > EC2**.
  3. Under the **NETWORK & SECURITY** section, click **Key Pairs**.

4. Recreate the `camc_public_ssh_key` by clicking **Create Key Pair** or **Import Key Pair**.

Node already registered with the Chef server

During the provisioning of each virtual machine resource in the middleware template, the Managed services Pattern Manager registers the virtual machines short host name with the Chef server. This registration adds the host name as a Chef node.

Symptoms

The pattern manager throws the following error when the Chef node already exists:

```
1 error(s) occurred:
* camc_bootstrap.referenced-image_chef_bootstrap_comp: 1 error(s) occurred:
* camc_bootstrap.referenced-image_chef_bootstrap_comp:
**********
Error: Response from pattern manager:
StatusCode:400
Message:
{
  "message": "Node huhnHostName is already registered with the chef server"
}
**********
```

Causes

This issue can occur in the following scenarios:

- If the same host name was specified more than once during the deployment of the template.
- If you deploy an instance of the template and specify a host name that is already registered with the Chef server.

Resolving the problem

The solution for the issue depends on the cause of the duplicate Chef node names. Perform one of the following actions that corresponds to the cause of the issue:

- Make sure that the middleware template that is being deployed has unique host names for each virtual machine (node) that is being provisioned. If it does not, delete the deployed instance, correct the template, and deploy again.
- Pick a unique host name that is not being used by an already deployed middleware template instance. If you have access to the Chef server, you can run the following command to list all nodes that are registered:

  ```
  knife node list
  ```

- If you are sure that you are using a unique host name for all middleware template deployed instances, you can delete the Chef node from the server. This action should only be done if you are certain that the Chef node is no longer being used by another middleware template deployed instance.

  Log in to the Chef server and delete the node:

  ```
  knife node delete [Node_Name]
  ```

Failure cleanup does not occur

Pattern Manager does not do the failure cleanup after a software deployment failure.

Symptoms

The software deploy process involves the following steps:

1. Update vault.
2. Update runlist.
3. Update node attributes.
4. Do software deployment.

If the software deployment fails, the items created during the previous three steps are not removed.

Resolving the problem

If you have access to a Chef server, you can run the following commands:

1. Update or delete vault:

   ```
   knife vault update [vault] [item] '[value]'
   ```

   or

```
knife vault delete [vault] [item]
```

2. Update runlist:

   ```
   knife node run_list set [node_name] [runlist]
   ```

3. Update node attributes:

   Use **knife exec** to remove node attributes.

   Note: **knife exec** is a powerful tool and it should be used carefully.

Known issues with Managed services and VMware vSphere

Read the following list of known issues with Managed services deploying to VMware vSphere.

Incorrect credentials for the operating system template

The credentials specified in the operating system user name and operating system password during a deployment need to be set to valid credentials for the operating system template that you are using for the deployment. If they do not match, the deployment request fails with the following error:

```
Error applying plan:

1 error(s) occurred:

* vsphere_virtual_machine.DB2Node01: 1 error(s) occurred:

* ssh: handshake failed: ssh: unable to authenticate, attempted methods [none password], no supported methods remain
```

Enter the correct credentials for the operating system template and redeploy your instance.

Multiple virtual machines with the same IP address

When deploying a virtual machine, there is no checking that the specified IP address is already in use by a different virtual machine on your vSphere instance, so an IP address conflict within your network might occur. IP address management should be handled outside of Infrastructure Automation - Managed services.

Virtual machines can be reused

Terraform reuses an existing VM in your VMware vSphere environment if the following conditions are met:

- The short hostname matches an existing virtual machine in vSphere.
- The existing virtual machine in vSphere is stopped.

If the existing virtual machine was deployed to the same Content Runtime as your current deployment, the deployment fails with the error that the node is already registered with the Chef server. For more information, see Node already registered with the Chef server.

If the existing virtual machine was deployed to a different Content Runtime as your current deployment, the deployment may declare that it completed successfully. However, the virtual machine is now deployed to the new Content Runtime Chef server and is no longer registered to the old Content Runtime Chef server. Any recipes or roles from the old Chef server is no longer applied to this virtual machine. It is recommended to always deploy to a new virtual machine.

The attempted operation cannot be performed in the current state (Powered on)

This issue occurs when you have specified a short host name that matches an existing virtual machine in vSphere. The following error is displayed, for example:

```
Error applying plan:

1 error(s) occurred:

* vsphere_virtual_machine.MQV9Node01: 1 error(s) occurred:

* vsphere_virtual_machine.MQV9Node01: The attempted operation cannot be performed in the current state (Powered on).
```

Choose a different short hostname and redeploy your instance.

Virtual machine not found

Terraform raises the following issue if it cannot find the expected virtual machine in your VMware vSphere environment. This issue typically happens if vSphere had a problem creating the VM but did not report the failure in an expected fashion.

```
Error applying plan:

1 error(s) occurred:

* vsphere_virtual_machine.HTTPNode01: 1 error(s) occurred:

* vsphere_virtual_machine.HTTPNode01: vm 'managed_services/content/content-dev63' not found
```

In the previous error, **`Content`** is the vSphere folder name and **`content-dev63`** is the short hostname specified during deployment. Check the vSphere task log files to see why the virtual machine creation failed.

Recovering the Content Runtime

Learn how to recover your Managed services environment after losing the Content Runtime instance.

If the Content Runtime virtual machine is lost with no backup, there is a path to create a new Content Runtime and register any deployed instances to that Chef server again.

It is highly recommended that the Content Runtime virtual machine be backed up so that if it were ever destroyed, it could be restored without needing the following procedure.

Requirements

Get the following information:

- The Content Runtime host name
- The Content Runtime IP address
- The private and public keys from the original Content Runtime
- The network routing information from the original Content Runtime
- The deploy logs from any instances that had been deployed to the Content Runtime

AWS and IBM Cloud

To perform a recovery on any of these two cloud providers, a portable IP address had to be initially associated with the Content Runtime virtual machine. If that's the case, then the following information will be required in addition when creating the new Content Runtime:

AWS

- Private IP address

IBM Cloud

- Private subnet
- Private VLAN name
- Portable IP address
- Portable private netmask
- Portable private gateway

It'll also be required to backup the Pattern Manager's configuration file. This file is base64 encoded and can be found at **`/opt/ibm/docker/pattern-manager/config/config.json`**

Recovery actions

The following steps are required to recover your Content Runtime and register your existing deployed instances to the new Chef server on the Content Runtime:

1. **Deploy new Content Runtime**

   The first step in recovering your Chef server is to deploy a new Content Runtime instance. The new Content Runtime virtual machine must have the same host name and IP address as the old Content Runtime.

   Save the value used for the pattern manager access passphrase field. It is needed for making requests against the pattern manager.

   For more information on provisioning your Content Runtime, see Provisioning and managing your Content Runtime infrastructure.

2. **Populate software repositories**

   Repopulate your software repository as described in:

   - Populating the software repository
   - Populating the Installation Manager repository

3. **Optional: Restore your previous Chef server configuration**

   If a previous Chef server configuration was backed up from the previous Content Runtime virtual machine, it can be restored at this point by using the **`chef-server-ctl restore`** command. For more information visit Backup and Restore Chef.

4. **AWS and IBM only: Restore the Pattern Manager configuration file**

   Before copying the Pattern Manager's configuration back to the newly created Content Runtime virtual machine, there are some changes required.

   1. Open a terminal window on the location of the backed up **`config.json`**

   2. Run the following command replacing **`<previous_content_runtime_public_IP>`** with the previous Content Runtime's public IP address and **`<portable_or_private_IP>`** with the portable IP address (IBM) or the private IP address (AWS)

      ```
      base64 -d ./config.json | sed -e 's/<previous_content_runtime_public_IP>/<portable_or_private_IP>/g' | base64 > config.json.new
      ```

This command will decode the **config.json** file, replace the previous VM's IP address with the portable IP address (which will match with the newly create Content Runtime) and encoded the resulting change into a file named **config.json.new**

3. Establish an SSH connection with the new Content Runtime virtual machine.

4. Replace the contents of the current Pattern Manager configuration file, located at **/opt/ibm/docker/pattern-manager/config/config.json** with the ones from the generated **config.json.new**.

5. Restart the Pattern Manager docker image by navigating to the **advanced-content-runtime** folder and running **podman-compose stop** followed by **podman-compose start**.

5. **Re-register your virtual machines**

This step requires the Pattern Manager access passphrase that was specified when the Content Runtime was deployed.

For each deployed instance:

1. Log in to the Managed services web interface.
2. Click **Menu** and click **Deployed Instances > Terraform templates**.
3. Find your deployed instance in the list and click it.
4. Click the **Log File** tab to bring up the log.

There are three REST requests made to the pattern manager in this log that you must reissue to re-register your virtual machine. The REST requests can be made from any environment that has network access to the Content Runtime. Some values have been removed from the log file and must be re-entered. The following examples use the **curl** command to make these requests, but they can also be made with any standard HTTP request tool.

1. **Create vault entry**

The first request creates an empty vault entry for the stack ID of the previous deploy request. Search in the log file for a URL ending in **/v1/vault_item/chef**.

Figure. Vault entry

Copy the **camc_endpoint** and **data** properties and form a **curl** request. **Note**: If using IBM Cloud or AWS, instead of using the IP address provided in the **camc_endpoint**, use the "portable IP address" (IBM Cloud) or "private IP address" (AWS).

```
curl -i -H "Authorization: Bearer <pattern_manager_access_token>" -d '{"vault_content":
{"item":"secrets","values":{},"vault":"<vault-id>"}}' https://<camc_endpoint_ip>:5443/v1/vault_item/chef
```

Note: If there is no **VaultItem** in the deployment's logs, the vault id and **camc_endpoint_ip** can be obtained from the **bootstrap** section in the logs, as:

```
camc_bootstrap.LAMPNode01_chef_bootstrap_comp: Creating...
access_token:     "" => "******"
camc_endpoint:    "" => "https://<camc_endpoint_ip>:5443/v1/bootstrap/chef"
data:             "" => "{\"environment_name\":\"_default\",\"host_ip\":\"host_ip_addr\",\"node_attributes\":
{\"ibm_internal\":{\"stack_id\":\"stack_id\",\"stack_name\":\"\",\"vault\":{\"item\":\"secrets\",\"name\":\"
<vault-id>\"}}},\"node_name\":\"node_name\",\"os_admin_user\":\"root\",\"stack_id\":\"stack\"}"
```

The request should return a 200 response code and the **vault_item** is added to the pattern manager.

2. **Bootstrap virtual machine**

The next step is to bootstrap the virtual machine. A node on the Chef server for the virtual machine is created. Search in the log file for a URL ending in **/v1/boostrap/chef**.

Figure. Bootstrap virtual machine

Copy the **camc_endpoint** and **data** properties and form a **curl** request. **Note**: If using IBM Cloud or AWS, instead of using the IP address provided in the **camc_endpoint**, use the "portable IP address" (IBM Cloud) or "private IP address" (AWS).

```
curl -i -H "Authorization: Bearer <pattern_manager_access_token>" -d
'{"environment_name":"_default","host_ip":"9.5.38.18","node_attributes":{"ibm_internal":
{"stack_id":"77757fd10ef26711542b34f6ae5c368e","stack_name":"nschambu-mysql-01","vault":
{"item":"secrets","name":"77757fd10ef26711542b34f6ae5c368e"}}},"node_name":"wild-nschambu-
vm01","os_admin_user":"root","stack_id":"77757fd10ef26711542b34f6ae5c368e"}'
https://9.5.38.16:5443/v1/bootstrap/chef
```

This request should return a 200 response code and a message confirming that the bootstrap request was successful.

3. **Assign software**

   The final step reassignes software to the endpoint. Search in the log file for a URL ending in **`/v1/software_deployment/chef`**.

Figure. Software deployment

   Copy the **`camc_endpoint`** and **`data`** properties and form a **`curl`** request, adding a new property called **`recovery_request`** to the JSON data. **Note**: If using IBM Cloud or AWS, instead of using the IP address provided in the **`camc_endpoint`**, use the "portable IP address" (IBM Cloud) or "private IP address" (AWS).

```
curl -i -H "Authorization: Bearer <pattern_manager_access_token>" -d
'{"environment_name":"_default","host_ip":"9.5.38.18","node_attributes":{"ibm":
{"sw_repo":"https://9.5.38.16:9999","sw_repo_user":"repouser"},"ibm_internal":{"roles":"
[oracle_mysql_base]"},"mysql":{"config":{"data_dir":"/var/lib/mysql","databases":{"database_1":
{"database_name":"default_database","users":{"user_1":{"name":"defaultUser"},"user_2":
{"name":"defaultUser2"}}}},"log_file":"/var/log/mysqld.log","port":"3306"},"install_from_repo":"true","os_users"
:{"daemon":
{"gid":"mysql","home":"/home/mysql","ldap_user":"false","name":"mysql","shell":"/bin/bash"}},"version":"5.7.17"}
},"node_name":"wild-nschambu-
vm01","os_admin_user":"root","runlist":"role[oracle_mysql_base]","stack_id":"77757fd10ef26711542b34f6ae5c368e","
vault_content":{"item":"secrets","values":{"ibm":{"sw_repo_password":"r3P0?@5s"},"mysql":{"config":{"databases":
{"database_1":{"users":{"user_1":{"password":"aew2#4trNB"},"user_2":
{"password":"dwr3%%nGKMd"}}}}},"root_password":"fqt@9dbeft"}},"vault":"77757fd10ef26711542b34f6ae5c368e"},
"recovery_request" : "True"}'
```

   This request should return a 200 response code and a message confirming that your Chef runlist is updated to the previous cookbooks and roles.

Your deployed instances are now registered with the new Chef server. You are be able to interact with them in the Managed services web interface.

Troubleshooting

When executing the curl commands to re-register your virtual machine, a JSON object will be returned once the request has been executed. The following are examples of issues that might be found in this JSON message

```
HTTP/1.1 400 BAD REQUEST
Date: Mon, 11 Dec 2017 19:23:51 GMT
Server: Apache
x-pm-request-id: a5ba0df88f264cbaa940a0503a440b73
Cache-Control: no-cache, no-store, must-revalidate
Pragma: no-cache
Content-Length: 86
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Access-Control-Allow-Origin: *
Access-Control-Allow-Headers: accept, authorization, content-type
Access-Control-Allow-Methods: GET, POST, PUT, DELETE
X-Frame-Options: SAMEORIGIN
Connection: close
Content-Type: application/json

{
  "message": "Vault e781c96d6a6b0f069b7e823877e045f3 item secrets already exists"
}
```

This error message indicates that the vault has already been created (step 1 on the **Re-register your virtual machines** has already been performed).

```
HTTP/1.1 400 BAD REQUEST
Date: Mon, 11 Dec 2017 19:19:58 GMT
Server: Apache
x-pm-request-id: a66f497afa8f4fe883eae340518ee2f5
Cache-Control: no-cache, no-store, must-revalidate
Pragma: no-cache
Content-Length: 80
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Access-Control-Allow-Origin: *
Access-Control-Allow-Headers: accept, authorization, content-type
Access-Control-Allow-Methods: GET, POST, PUT, DELETE
```

```
X-Frame-Options: SAMEORIGIN
Connection: close
Content-Type: application/json

{
  "message": "vault_content was specified for a vault that does not exist."
}
```

The provided `vault-id` is either misspelled, or hasn't been created yet. Make sure that step 1 on the **Re-register your virtual machine** has been executed.

Bootstrap Fails With Knife Sudo Password Error

How to troubleshoot the bootstrap error when knife sudo fails.

The IBM middleware cookbooks that are packages with Managed services require a user with password-less sudo capabilities. For most templates this user is root. However, if root is not available, then the operating system template that is used to deploy must include a user with the ability to use sudo without requiring a password.

If the deploy fails with this message, it means that the user did not have the ability to use sudo without requiring a password:

```
Error: Response from pattern manager:
StatusCode:500
Message:
{
 "message": "Bootstrap command failed. See the pattern manager logs for more details.",
 "rc": 1,
 "request_id": "1c844be316b74601853d2ddde595d94d",
 "stderr": "Creating new client for cam-apache-1\nCreating new node for cam-apache-1\nConnecting to 172.16.9.71\nstty:
'standard input': Inappropriate ioctl for device\nstty: 'standard input': Inappropriate ioctl for device\nstty: 'standard
input': Inappropriate ioctl for device",
 "stdout": "172.16.9.71 knife sudo password: \nEnter your password: \r\n172.16.9.71 \r\n172.16.9.71 Sorry, try
again.\r\n172.16.9.71 knife sudo password: \n172.16.9.71 \r\n172.16.9.71 Sorry, try again.\r\n172.16.9.71 knife sudo
password: \n172.16.9.71 \r\n172.16.9.71 sudo: 3 incorrect password attempts"
}
```

Troubleshooting issues in IBM Cloud Pak for AIOps or Red Hat® OpenShift® Container Platform template deployments

Known issues and workaround related to IBM Cloud Pak for AIOps or Red Hat® OpenShift® Container Platform template deployment.

- When you destroy a failed IBM Cloud Pak for AIOps or Red Hat® OpenShift® Container Platform template deployment, your destroy operation may fail with the following error:

  ```
  Error applying plan:2 error(s) occurred:

    - module.gather_output.output.icp_install_dir: variable "get_cluster_config" is nil, but no error was reported
    - module.gather_output.output.registry_ca_cert: variable "get_cluster_config" is nil, but no error was reported
      Terraform does not automatically rollback in the face of errors.

      Instead, your Terraform state file has been partially updated with any resources that successfully completed.
      Please address the error above and apply again to incrementally change your infrastructure.
  ```

  This error is a warning that is thrown even if resources are destroyed. This is a known issue in Terraform v0.11.xx.

  For more information on this issue, see Link to issue reported by Terraform.

Troubleshooting Terraform related issues

Review the following known issues with Terraform.

- When you deploy a Terraform template that contains plug-in provider version that is not packaged with IBM Cloud Pak for AIOps, using Terraform engine 0.13.x or higher, you see the following error. The error is due to the changes made by Terraform on how Terraform manages the provider versions in Terraform 0.13.x or higher. For more information, see Terraform Provider Requirements.

  ```
  Failed to query available provider packages
  Could not retrieve the list of available versions for provider <provider_name>: no available releases match the given
  constraints <provider_version>
  ```

  To resolve this issue, you have to add the new provider version to the local provider registry. For more information, see Custom Terraform providers.

  For the list of shipped provider versions, see Shipped Terraform providers.

- After you install, you may see the following error when you deploy services.

  ```
  SubmitJobProviderResponseError: Failed to submit task for stack <stack_id> on the remote provider (API:
  /stack/create).  Caused by: The terraform binary for version <version_number> does not exist.
  ```

The reason for this error is that the service definition in default provided services is using the older version of Terraform engine. The following versions of Terraform engine are packaged: 0.12.31, 0.13.7, and 0.14.11.

To resolve this issue, edit the failed service in the service composer, open the source code tab and change the value for **`provider_engine_version`** attribute. If **`provider_engine_version`** is 0.12.21, then use 0.12.31.

Collecting data for Managed services

This section explains how and which data you must collect when you encounter problems in the Managed services. If you gather this information before contacting the IBM Support, it expedites the troubleshooting process and saves time.

Self-diagnose

Before contacting IBM Support, you can try to find a resolution to the problem on your own. First, check Stack Overflow or the Troubleshooting sections to see whether your problem has been reported already.

If you are looking for examples, tutorials or more detailed information regarding specific Managed services topics, review the following links:

- Go through the other topics in this IBM Documentation.
- IBM Cloud Automation Manager Developer Community

If you see problems during the installation of Managed services, ensure that you have completed all the requirements correctly. That should solve most of your installation problems.

General troubleshooting information

If problem persists after self-diagnose, collect the following troubleshooting data:

- A detailed description of the problem. Be as precise as possible, include information where you see the issue, which steps you followed and if this can be reproduced every time or only happens intermittently.
- The error message (if any) and the timestamp of the error.
- Examples of the environment data that you can collect:
  - Production/test/staging environment
  - Managed services version
  - IBM Cloud Pak for AIOps version
  - Online or Offline installation
  - Topology
  - Proxy or network restrictions
  - Cloud provider
  - GlusterFS/NFS
  - Available disk space
- Screen captures that can help to understand the issue
- Did this work previously? If yes, what has changed? Any recent modifications to the system/configuration/version?
- Have any corrective actions been tried already?
- Did you apply any fixes from Fix Central or any other patches?
- Did you customize Kubernetes or any third-party component?
- Provide the business impact this issue is having on your company, including any upcoming deadlines as well as any realized or potential effect on customers.

Automatically collecting troubleshooting data

Use the **`camCollector`** script, which can be downloaded from GitHub or find it included in the Helm Chart.

For more information, see Collecting logs using camCollector script.

What to do next

After you collect the troubleshooting data, either review it on your own or send it to IBM Support. If you have already opened a case for the issue, you can upload the data to that case directly by using the IBM Support Portal. If the data is too large or any other problems occur, see Enhanced Customer Data Repository to check alternative ways to exchange data.

For more complex issues, the recommendation is to open a case by using the IBM Support Portal.

Note: Do not send any confidential information from your company.

Refreshing internal certificates

Refresh internal certificates as follows if error with certificate expiry.

1. Switch to the cp4aiops namespace.

   ```
   oc project cp4aiops
   ```

2. Edit the certificate.

   ```
   oc edit certificate.certmanager.k8s.io cert
   ```

3. Add duration and renewBefore after `secretName: cert`.

   ```
   secretName: cert
   duration: 17520h
   renewBefore: 240h
   ```

4. After you save the changes, verify the output by using the command as follows:

   ```
   oc get certificate.certmanager.k8s.io cert -o yaml | grep -i duration -A4
   ```

   Output:

   ```
   duration: 17520h0m0s
   issuerRef:
     kind: Issuer
     name: cs-ca-issuer-for-cam
   renewBefore: 240h0m0s
   ```

5. Delete the secret certificate.

   ```
   oc delete secret cert
   ```

The Managed services (CAM) pods are restarted.

Collecting logs using camCollector script

The **camCollector** script is used to collect diagnostic information for Managed services and the underlying platform.

About the task

The script collects the following information:

- About Managed services Helm chart, such as the persistent volumes and its claims, secrets, config maps and deployments.
- OpenShift information for Managed services, such as namespaces/persistent volumes/pvc/secrets/config maps and status of each pod.
- Status of IBM Cloud Pak for AIOps pods.
- Logs for each of the Managed services pods.

Before you begin

To run the **camCollector** script, you must have configured OpenShift Client(oc).

Procedure

1. Ensure that you are logged in to your OpenShift Cluster with this command:

   ```
   oc login -n cp4aiops
   ```

   Note: If you use a namespace other than **cp4aiops**, you need to edit the **infrastructure_management_ns** variable in the script.

2. Download the **camCollector** script from GitHub using the following commands:

   ```
   curl https://raw.githubusercontent.com/IBM-CAMHub-Open/cam-support/release-2.0/scripts/camCollector.sh --output camCollector.sh
   ```

   ```
   chmod +x camCollector.sh
   ```

3. Run **camCollector.sh** script using the following command:

   ```
   ./camCollector.sh
   ```

Updating the resource limits for Managed services containers

To begin you need to install the correct version of the container in question, for example "ibm-management-cam-install.vx.xxxxxxx" and then specify the resource limit.

Steps involved in updating the resource limits for the container

1. Run the command:

```
oc project cp4aiops
```

2. Followed by:

```
oc edit iaconfig `oc get iaconfig --no-headers | awk '{print $1}'`
```

3. Next, update the content under the `ibm-management-cam-install` enablement section.

```
  - enabled: true
    name: ibm-management-cam-install
    spec:
      manageservice:
        camAPI:
          camMongo:
            resources:
              limits:
                cpu: 500m
                memory: 4Gi
              requests:
                cpu: 100m
                memory: 4Gi
```

4. Then, crosscheck the updates using the following command:

```
oc edit manageservice cam
```

5. The results should look like the following:

```
  camAPI:
    camMongo:
      resources:
        limits:
          cpu: 500m
          memory: 4Gi
        requests:
          cpu: 100m
          memory: 4Gi
```

6. Finally, run the command:

```
oc edit deploy cam-mongo
```

7. The results should match the resources you specified in the IAConfig and appear similar to the following:

```
containers:
        resources:
          limits:
            cpu: 500m
            memory: 4Gi
          requests:
            cpu: 100m
            memory: 4Gi
```

Support

If you need help with using IBM Cloud Pak® for AIOps, visit the IBM Support page.

Additionally, you can see whether the problem is documented in Known issues or in Troubleshooting.

Learn more about IBM Support from the following topics:

- Opening an IBM Support case
- Installing the MustGather tool
- Running the MustGather tool

Collecting support information for IBM Cloud Pak for AIOps

Learn how to gather information that is needed and relevant to a problem before you open a case with IBM® Support. Additionally, learn how to open a meaningful support case with IBM Support for IBM Cloud Pak® for AIOps.

Before you open an IBM Support case

Check the troubleshooting and known issues sections

Before you contact IBM Support, review the following topics to check whether your problem is already reported and a workaround or solution exists:

- Troubleshooting and support
- Known issues

Collect support information with MustGather tools

If you cannot find a solution for your problem in the documentation, complete the following steps to use the MustGather tool and gather information from the cluster for opening an IBM Support case. The collected data facilitates more effective support.

- Data collection for IBM Support cases
- Infrastructure Automation data collection for IBM Support cases

Data collection for IBM Support cases

1. Ensure that you meet the prerequisites for running the MustGather tool for collecting data
   - Access to the cluster as a user with a cluster-admin role.
   - The Red Hat® OpenShift® Container Platform CLI (oc) installed. For more information, see Installing the Red Hat OpenShift CLI.
2. Download and install the MustGather tool
3. Run the MustGather tool

Infrastructure Automation data collection for IBM Support cases

1. Ensure that you meet the prerequisites for running the MustGather tool for collecting data
   - Access to the cluster as a user with a cluster-admin role.
   - The Red Hat® OpenShift® Container Platform CLI (oc) installed. For more information, see Installing the Red Hat OpenShift CLI.
2. Run the MustGather to collect data and logs

   Follow the instructions on the following IBM Support page to run the MustGather tool to collect the data and logs for IBM Cloud Pak for AIOps: Collecting Data: MustGather for IBM Cloud Pak for AIOps - Infrastructure Automation

Opening an IBM Support case

If you cannot find a solution to your problem in product documentation, open a support case with IBM Support. Complete the following steps

1. Go to the IBM Support site and click **Open a case**.
2. Log in with your IBM ID and password, and consent to the IBM Privacy Statement.
3. Enter the case details. Enter the meaningful title that summarizes your problem. Then, select the Product Manufacturer, Product, and Severity.

   Note: The case severity is based on the business impact of the problem. If you set the case severity as 1, you need to have 24x7 availability to work with IBM Support on this issue.
4. Provide the detailed description of your problem. A detailed description can help IBM Support understand your problem more accurately and thus provide solutions or answers more quickly. The following information is crucial:
   - Product version
   - Platform
   - Red Hat OpenShift Container Platform version
   - Virtualization platform (VMWARE, Azure, AWS, IBM Cloud)
   - High Availability (HA)
   - Steps to reproduce the issue
5. Optional: Upload the **`.tar.gz`** file with the results of the diagnostic scan. For more information, see Collecting support information.

   Note: If you encounter problems with uploading the file, see Uploading a file during case creation.
6. Select the language preferences and click **Submit a case**.

Installing the IBM Cloud Pak for AIOps MustGather tool

You must download and install the MustGather tool before you can run any commands for the tool. You must download the installation package for the MustGather tool from IBM Support. You can download the package to any machine that has valid access to the target cluster for running **`oc`** commands.

Important: This MustGather tool gathers data for IBM Cloud Pak® for AIOps deployments. For gathering data for Infrastructure Automation, see Infrastructure Automation data collection for IBM Support cases.

Procedure

Complete either of the following steps to download the tool:

- Download the (**`waiops-mustgather-<version>.tar.gz`**) package at the end of the following IBM Support page:

  Collecting Data: MustGather for IBM Cloud Pak for AIOps
- Open a command-line terminal and use the following command to download the package:

  ```
  wget https://www.ibm.com/support/pages/system/files/inline-files/waiops-mustgather-<version>.tar.gz
  ```

  Where **`<version>`** is the version of the MustGather tool. Refer to the preceding IBM Support page to determine the latest available version. For v.1.16.6, the command is:

```
wget https://www.ibm.com/support/pages/system/files/inline-files/waiops-mustgather-v1.16.6.tar.gz
```

Important:

- Unpack the downloaded **waiops-mustgather-<version>.tar.gz** package in its own directory. Ensure that the directory is not shared with any other files or directories.
- Keep the MustGather tool up to date. By default the tool can run a **new-version-check** automatically. To disable this check, include the **-M** option when you run the MustGather tool to gather data. If you want to directly check for, and download, the latest version run the following command

  ```
  waiops-mustgather.sh -UD
  ```

MustGather tool use cases

Learn how to run the tool, and learn about the different use cases and command options that are available for use with the tool. For more information, see:

- Running the MustGather tool
- Data collection modes
- Advanced tips for using the MustGather tool

IBM Cloud Pak for AIOps MustGather tool

Learn how to use the IBM Cloud Pak® for AIOps MustGather tool to gather information that is needed and relevant to a problem before you open a case with IBM Support.

Important: This MustGather tool gathers data for IBM Cloud Pak for AIOps deployments. For gathering data for Infrastructure Automation, see Infrastructure Automation data collection for IBM Support cases.

The IBM Cloud Pak for AIOps MustGather tool is a wrapper for running **oc** commands. With this tool, you can complete data collection tasks and view analytics on the gathered data. After you run the tool to gather data, upload the output data file that is under your **/tmp** (or another directory if you used the ``-o` option) to the IBM Support website.

The tool generates a report that shows critical data about the status and health of the cluster and installation. This report allows the user view an overview of their cluster to help spot and solve multiple problems. The report can provide basic cluster analysis to identify cluster node resource utilization, warnings, and problematic resources. The report can also provide incident analysis, such as to identify whether Pod A is in CrashLoopBackOff.

The tool supports data collection for the following types of data:

Data type collection mode

Data type	Collection mode
oc get and **oc describe** (or **kubectl**) commands	This data is collected through the primary data collection modes.
Pod logs	This data is collected through the primary data collection modes.
Application logs within pods	This data collection is supported by the CPFILES secondary data collection mode.
Command output for commands that run through pods	This data collection is supported by the MANUALCOLLECT secondary data collection mode.
Command output that run on client machines (custom script)	This data collection is supported by the CMDEXEC secondary data collection mode.
Logs or command output that run on individual cluster nodes, such as journal, systemctl, iptables	This data collection is supported by the CLUSTERNODES secondary data collection mode.

Command syntax

```
waiops-mustgather.sh -[a|b|c|l] [-k resourname] [-z modules] [-d] [-L numlines] [-C cmdexec-file:cmdexec-env] [-E cmdexec-envvar] [-T timeout-value] [-m manual-collection-param] [-n manual-collection-envvar] [-j objname] [-w manual-collection-exec-timeout] [-e extra-namespaces:extra-resources] [-x product-version/path-to-config-file] [-A compliance-param] [-P plugins] [-Z plugins-envvar] [-Q plugins-timeout] [-F cpfiles-param] [-K] [-V view-only-module] [-y] [-J] [-p] [-t] [-g] [-f] [-R] [-S] [-s] [-u node-admin-username] [-i path-to-sshkey] [-o output-directory] [-G filename-regex:pattern] [-W primary-mode-var] [-N] [-I] [-X] [-Y] [-U] [-M] [-D] [-v] [-h]
```

- For details about the command options, see Data collection modes for the IBM Cloud Pak for AIOps MustGather tool.
- For details about running a custom script with the tool, see Run a custom script to complete corrective actions

Running the tool

- Primary use cases
- Additional use cases
- Miscellaneous use cases

Primary use cases

- Installation related problems
- Application related problems

- IBM Cloud Pak for AIOps related problems
- Log anomaly detection related problems
- Metric anomaly detection related problems
- Lifecycle related problems
- Datalayer related problems
- ChatOps related problems
- Healthcheck related problems

Installation related problems

To gather data for installation related problems, run the following command:

```
waiops-mustgather.sh -O install
```

The alias **`-O install`** is expanded to **`-cypDfd`** that uses the primary comprehensive (**`-c`**) mode and clusternode (**`d`**) mode to cause the tool to gather data for installation related problems.

To gather data for general non-installation related problems, run the following command:

```
waiops-mustgather.sh -O general
```

The alias **`-O general`** is expanded to **`-cypDf`** that is used to gather data for common problems.

Overall operation related problems

To gather data for overall IBM Cloud Pak for AIOps operation related problems, run the following command:

```
waiops-mustgather.sh -O aimgr
```

To gather raw data for IBM Cloud Pak for AIOps from its various data sources, such as Kafka, Flink, ElasticSearch and Postgres, run the following command:

```
waiops-mustgather.sh -O aimgr-data
```

To learn more about what aliases are available, use the command **`waiops-mustgather.sh -O .listalias`**

Important: The ALIAS mode (**`-O xxx`**) is used to expand an alias into a predefined command. If there is a need to change or add any option, you need to revert to the conventional way of running the MustGather tool by providing all the options or flags manually. For example, if a secret YAML is needed, you need to use **`-cypDfS`** (plus any other options or flags).

Log anomaly detection related problems

To gather data for log anomaly related problems, run the following command:

```
waiops-mustgather.sh -O lad
```

Metric anomaly detection related problems

To gather data for metric anomaly related problems, run the following command:

```
waiops-mustgather.sh -O mad
```

Lifecycle related problems

To gather data for Lifecycle related problems, run the following command:

```
waiops-mustgather.sh -O lifecycle
```

Datalayer related problems

To gather data for Datalayer related problems, run the following command:

```
waiops-mustgather.sh -O datalayer
```

ChatOps related problems

To gather data for ChatOps related problems, run the following command:

```
waiops-mustgather.sh -O chatops
```

Healthcheck related problems

Use the healtcheck option to gather data to check whether your installation was successful or to analyze how IBM Cloud Pak for AIOps is running.

For more information about using this option, see Running the MustGather Healthcheck.

Additional use cases

- Run script to complete corrective actions
- Run baseline data collection
- Pod specific data collection
- Product specific data collection
- Installation verification
- Copying pod files and directories

- Complex command

Run a custom script to complete corrective actions

If you want to complete a **corrective action**, such as to delete a pod to restart it, you can write a script and run the following command to run the script:

```
waiops-mustgather.sh -C <script>
waiops-mustgather.sh -R -C <script>
```

Where **<script>** is the script that contains the corrective action to run.

The preceding command will only run your script. To perform data collection before running the script, you can opt for any of the primary modes."

Notes: If needed, you can run the secondary data collection modes **MANUALCOLLECT**, **EXTRA**, **CPFILES** within your custom script.

The following examples show how to trigger the MANUALCOLLECT, EXTRA, and CPFILES modes:

- To make sure the correction actions are successful, you can trigger MANUALCOLLECT to collect some data within the script

  ```
  echo "ALL##NS4PROD=aimanager##pod##teams######" >> $CMD_EXEC_RESULT_MCCFG_FILE
  ```

- You can also trigger EXTRA mode to collect namespace data within the script

  ```
  echo "openshift-insights" > $CMD_EXEC_RESULT_EXTRANS_FILE
  ```

- If you need to copy some files from some pods to make sure your script ran successfully:

  ```
  echo "NS4PROD=aimanager##^iaf-system-kafka####/opt/kafka/config/log4j.properties" >> $CMD_EXEC_RESULT_CPFILES_FILE
  ```

For an example custom script and some of the variables and functions that you can include within it, see Example: custom script.

Run baseline data collection

To run a baseline data collection, use any of the primary data collection modes, such as **-cypDf**, for example:

```
waiops-mustgather.sh -cypf -C <script> -e <namespace> -F 'NS4PROD=<prodname>,<podname-regex>,<container-name>,<filename>'
```

With the preceding command, you can run a baseline data collection that is followed by running a corrective action through a custom script. You can also check the result of the corrective action by using the **-e** option where **<namespace>** is the namespace where the custom script runs. You can also opt to copy files from the restarted pod through the **-F** option.

Notes:

- Only **-c** is the primary data collection mode. Other options are supported, but should be used together.
- If you want to run another round of data collection after your custom script runs, use a secondary data collection mode (other than **clusternodes** or **cmdexec**).

Pod specific data collection

If you have to run commands on a specific pod, but you do not know the full name of the pod, such when you know only the UUID portion, you can use the **manualcollect** mode:

```
waiops-mustgather.sh -R -m ps-out:[configfile]
```

Example (**<configfile>**):

```
@ TAG##NAMESPACE##OBJTYPE##OBJNAME##CONTAINER##EXECPREP##EXECCMD
ps-out##NS4PROD=aimanager##pod##^cp4waiops-postgres-keeper######hostname;ps -ef
```

The podname is a regex. The tool determines the full name of the pod automatically.

```

Product specific data collection

If you need to collect product-specific data, you can run the *plugins* secondary collection mode:

```
waiops-mustgather.sh -P aimanager
```

Installation verification

If you just want to check whether an installation is successful:

```
waiops-mustgather.sh -x X -DR
```

The preceding command scans the product namespaces for missing resources or objects based on the configuration file that is specified in the **<MUSTGATHER-DIR>/missingobj/config/missingobj-waiops-<prodver>.cfg** file.

Copying pod files and directories

If you need to copy files from a pod, you can run a command similar to the following command:

```
waiops-mustgather.sh -F 'NS4PROD=aimanager##aimanager-aio-log-anomaly-detector-####/opt/ai4it/*.log*'
```

The preceding command copies files and directories that match the filename wildcard of **/opt/ai4it/*.log*** from pods that match regex **aimanager-aio-log-anomaly-detector-** in the auto-resolved IBM Cloud Pak for AIOps namespace.

Complex command

If needed, you can run a more complex command:

```
waiops-mustgather.sh -aypf -e ibm-common-services,cs-control,openshift-operators -P aimanager -G
'ALL:error|fail|exception|login' -C /tmp/test.sh -E 'TEST1=uname -a##TEST2=date' -m cqlsh:manualcollect.csv -n
'SQL="describe tables"' -F spark
```

Miscellaneous use cases

- Scale down the MustGather data collection

Scale down the MustGather data collection

If the cluster that you are working on is slow or throttles a lot, you can scale down the MustGather through the *selective* primary collection mode:

```
waiops-mustgather.sh -Xy -k deployments,sts,pods,jobs,pvc
```

The preceding command disables custom data collection (**-X**), enables YAML collection (**-y**) and runs the MustGather tool with the *selective* primary collection mode (**-k**) to collect data on resources such as **deployments**, **statefulsets**, **pods**, **jobs**, and **pvc**.

Command help

If you need help with running the MustGather tool, you can use the tool **help** command when you run the tool to view more details about the command:

```
waiops-mustgather.sh -h
```

Running the MustGather Healthcheck

You can run the IBM Cloud Pak for AIOps MustGather tool with a healthcheck option to gather data to check whether your installation was successful or to analyze how IBM Cloud Pak for AIOps is running.

Important: Ensure that your installed version of the tool is **v1.17.6** or newer. Some healthcheck data is only gathered with version **v1.17.6** and newer.

To gather data for healthcheck related problems, run the following command:

```
waiops-mustgather.sh -O healthcheck
```

This option gathers the following data for checking the current health of your IBM Cloud Pak for AIOps deployment and Red Hat OpenShift Container Platform cluster:

The healthcheck gathers the following data:

1. Node status, CPU utilization, and memory utilization
2. Red Hat OpenShift etcd status
3. Cluster service version (CSV) phase for IBM Cloud Pak for AIOps CSVs
4. CustomResourceDefinitions (CRDs) phase/status and version for IBM Cloud Pak for AIOps projects
5. Persistent volumes and persistent volume claims (PVC) status
6. Deployments, statefulsets, pods, daemonsets, and jobs statuses
7. Key missing resources
8. Basic compliance check results

After the tool finishes gathering data, review the **0-README-FIRST/SUMMARY.log** log file.

Node status, CPU utilization, and memory utilization

For the list of all nodes in the cluster with their respective status, CPU utilization, and memory utilization, review the **HEALTH REPORT OF NODES** section of the log.

This report shows the total CPU and MEMORY available in the cluster, and the CPU and memory request and limit of individual nodes. This report also indicates a warning when the CPU or memory utlization exceeds 95%.

The following log example shows a node health report for a IBM Cloud Pak for AIOps deployment:

```
================================================
HEALTH REPORT OF NODES
```

Cluster service version (CSV) phase for IBM Cloud Pak for AIOps CSVs

For a report that lists the cluster service versions (CSVs) for a IBM Cloud Pak for AIOps project (namespace), including the CSV phase, review the **STATUS REPORT OF CLUSTER SERVICE VERSION (namespace = <namespace>)** section of the log, where **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.

This report lists the version and phase for each CSV. Within the report check the **PHASE** column and value for each CSV. The value should be **Succeeded**.

The following log example shows a cluster service version status report for a IBM Cloud Pak for AIOps deployment:

```
================================================
STATUS REPORT OF CLUSTER SERVICE VERSION (namespace = cp4aiops)
================================================
NAME                                        DISPLAY                                          VERSION   REPLACES

CustomResourceDefinitions (CRDs) phase/status and version

For a report that lists all important CustomResourceDefinitions (CRDs) for a IBM Cloud Pak for AIOps project (namespace), including the CRD phase/status and version, review the **STATUS REPORT OF AIOPS PRODUCT COMPONENTS** section of the log.

This report shows the version, phase/status, and any error for each key CRD. Within the report check the **VERSION** column for each CRD:

- The string value **<none>** indicates that no version details are available. This value is not a cause for alarm.
- The string value **N/A** indicates that the MustGather tool is unable to detect the CRD. The healthcheck option for the MustGather scans for a predefined list of CRDs, if a CRD is installed, but shows as **N/A**, further investigation is required as there might be a problem with that component.

The following log example shows a product components status report for a IBM Cloud Pak for AIOps deployment:

```
================================================
STATUS REPORT OF WAIOPS PRODUCT COMPONENTS
================================================

Persistent volumes and Persistent volume claims (PVC) status

For node disk status (disk utilization details), Persistent volume status, and Persistent volume claims status, review the following sections of the log:

- `STATUS REPORT OF PERSISTENTVOLUMECLAIMS (namespace = <namespace>)`
- `PVC UTILIZATION REPORT (namespace = <namespace>)`

The PVC utilization report lists all PVCs and their respective `df -h` output. The report also shows a warning if the disk utilization is over 95% or if the `df -h` output is not available for a PVC.

Note: **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.

The following log example shows a PERSISTENTVOLUMECLAIMS report for a IBM Cloud Pak for AIOps deployment:

```
=================================================
STATUS REPORT OF PERSISTENTVOLUMECLAIMS (namespace = cp4waiops)
=================================================
[Sun Nov 12 20:54:41 PST 2023] [cp4waiops] All PVCs seem to be operating fine!
>>> [TOTAL OK] [cp4waiops] Bound (pvc) = 40
>>> [TOTAL PVC] = 40
```

The following log example shows a PVC utilization report for a IBM Cloud Pak for AIOps deployment:

```

Deployments, statefulsets, pods, daemonsets, and jobs statuses

For deployment, statefulset, pod, daemonsets, and job statuses, review the **HEALTH REPORT OF NAMESPACE = <namespace>** section of the log, where **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.

This resource analysis report includes a simple analysis of the total resources (deployments, statefulsets, daemonsetspods, pods, and jobs) that are running properly and not running properly. The report identifies any of these resources that are problematic. For problematic pods, the report shows the events for the pods.

The following log example shows a project (namespace) health report of namespace for a IBM Cloud Pak for AIOps deployment:

```
================================================
HEALTH REPORT OF NAMESPACE = cp4waiops
================================================
[Sun Nov 12 20:53:38 PST 2023] [analyzeOcAll] Analyzing 'oc get all -o wide -n cp4waiops' => /tmp/mg/waiops-modules-

[Sun Nov 12 20:53:41 PST 2023] [analyzeOcAll] Analyzing STATEFULESETS [cp4waiops]
>>> [TOTAL OK] [cp4waiops] Statefulset = 14
>>> [TOTAL STATEFULSET] = 14

[Sun Nov 12 20:53:41 PST 2023] [analyzeOcAll] Analyzing DAEMONSET [cp4waiops]
>>> [cp4waiops] There is no 'daemonset' found!
>>> [TOTAL DAEMONSET] = 0

[Sun Nov 12 20:53:41 PST 2023] [analyzeOcAll] Analyzing PODS [cp4waiops]
>>> [TOTAL OK] [cp4waiops] Running = 166 / Completed = 20
>>> [TOTAL POD] = 186

[Sun Nov 12 20:53:46 PST 2023] [analyzeOcAll] Analyzing JOBS [cp4waiops]
COUNT  JOB                                                                  READY      DURATION   STATUS
1      aimanager-aio-curator-job-28281060                                   0/1        34d        NOK
>>> [TOTAL OK] [cp4waiops] Job = 40
>>> [TOTAL NOK] [cp4waiops] Job = 1
>>> [TOTAL JOB] = 41
```

Key missing resources

For the list of missing resources, review the **REPORT OF MISSING OBJECTS (PROD_VER=<version>)** section of the log, where **<version>** is the version of IBM Cloud Pak for AIOps that is installed.

This report includes the results of a scan for the resources that are expected to exist after a successful installation. The list of resources that are scanned is configurable, and can include any resource type (deployments, statefulsets, pods, strimzipodset, and more).

When reviewing the results, review the **[SCAN RESULT]** and **[SCAN SUMMARY]** sections for details. The results list:

- Any missing resources and their expected count.
- Resources that exist, but have mismatched counts, such as when 2 are expected, but only 1 exists

For any **[Objects Not Matched]** section for a context in the report, the section lists resources that are found, but are not configured in the scan as needed or critical resources. These results are not cause for concern.

The following log example shows a missing objects report for a IBM Cloud Pak for AIOps deployment:

```
==================================================
REPORT OF MISSING OBJECTS (PROD_GROUP = cp4aiops@ibm-cp-aiops / PROD_VER = 4.4.0)
==================================================
NOTE(1): Please be as accurate as possible with the regex of OBJNAME. Otherwise, an object is considered found as long as
there is at least one instance!
NOTE(2): The algorithm is based on matching 'oc get' returned object name against AWK regular expression defined by
'OBJNAME'!
NOTE(3): For missing object with label [Count condition OK], it is likely to be either optional or deleted job pod. To
investigate further!

[INPUT FILE]

Data collection modes for the IBM Cloud Pak for AIOps MustGather tool

Learn more about the different commands that you can use with the IBM Cloud Pak® for AIOps MustGather tool to gather information for opening a case with IBM® Support.

There are 2 sets of data collection modes (primary and secondary). The MustGather tool has multiple (6) primary collection modes and multiple advanced modes for collecting specific sets of data.

Rules:

- Users can select zero or one primary mode.
- User can select zero, some or all secondary modes.
- User can combine one primary mode with zero, some or all secondary modes.
- Secondary modes can run independently without any primary mode
- The secondary modes selected (independently, or with any primary mode) are run with the following precedence: **clusternodes** > **cmdexec** > **manualcollect** > **extra** > **missingobj** > **compliance** > **plugins** > **cpfiles** > **snapshots**

Example commands:

```
waiops-mustgather.sh -aypD -C /tmp/cmdexec.input -m /tmp/manualcollect.csv -e cp4aiops
```

Since a primary mode **-a** is selected, all data collection that is configured for the *all* primary mode is run first. Then the data collection for the secondary modes are run in the sequence of **cmdexec** > **manualcollect** > **extra**.

```
waiops-mustgather.sh -C /tmp/cmdexec.input -m /tmp/manualcollect.csv -e cp4aiops
```

Since no primary mode is selected, the secondary modes are run in the sequence **cmdexec** > **manualcollect** > **extra**.

Primary modes

Primary mode options

Option	Description

Option	Description
`-a`	All mode, which gets all data (data volume is high).
`-c`	Comprehensive mode, which gets comprehensive data (data volume is moderate).
`-b`	Basic mode, which gets basic data (data volume is OK).
`-l`	Limited mode, which gets limited data (data volume is low).
`-k`	Selective mode, which gets data for selective resources (separate resources with comma), for example, pods,deployment,secrets (data volume is varied). To get cluster-wide (all-namespaces) data for namespace-scoped resource, such as a pod, you can use the special keyword `allns` (`pod/allns`,`ingress`,`cm/allns`). `allns` data is available in the `CLUSTER_DATA` directory. `namespaced` data is available in the `PROD_NAMESPACES` directory.
`-z`	Module mode, which gets data based on predefined modules separated by comma (clusterinfo productinfo storage networking installation csv pvcusage nodeinfo) (data volume is varied). To list all available modules, use `-z .listmodules`.

Secondary modes

Clusternode modes

Clusternode mode options

Option	Description
`-d`	Gets logs and data from all cluster nodes by using `oc debug` or SSH (if `-i` or `-u` is used).
`-l`	Number of lines of journal to collect from cluster nodes. The default is `2000`.

cmdexec mode

cmdexec mode options

Option	Description
`-C`	`[script file]##[environment file]` Where `[environment file]` is optional. The format of `[environment file]` is `KEY=VALUE`, which is similar to the variable definition format in shell script.
`-E`	Environment variable for the `cmdexec` script. For example, `'VAR1=VAL1##VAR2=VAL2##...'` - Enclose the entire input string with single quotation marks. For example `'VAR1=hello##VAR2=uname -a'`
`-T`	Timeout value for `cmdexec [-C]`. The default is `5m`. For example, `10s` where `s`=second; `m`=minute; `h`=hour.

Manualcollect mode

Manualcollect mode options

Option	Description
`-m`	`<manual-collection-param>` = `[TAGS]:input file` for the `getManualCollection()` function where `TAGS` is optional. The default is all config lines. - Separate multiple tags with a comma.
`-n`	Environment variables for the `manualcollect` `EXECCMD` command. For example, `TAG1~>VAR1=VAL1##VAR2=VAL2^^TAG2~>VAR1=VAL1...` - Use the symbol `^^` to separate environment variables for different tags. - Use the symbol `~>` to define an environment variable for a tag. Use the symbol `##` to separate multiple environment variables. - Enclose the entire input string with single quotation marks and each value with double quotation marks. For example, `VAR1="hello"##VAR2="uname -a"`.
`-j`	Provided string `[tag:<objname>##tag:<objname>##...]` is used to substitute the `OBJNAME` keyword under the `OBJNAME` column that is based on the `tagname` in the manual collect input configuration file, such as `tag1=pod-abc##tag2=pod-xyz`.
`-w`	Timeout value for `manualcollect [-m]`. The default is `5m`. For example, `10s` where `s`=second; `m`=minute; `h`=hour.

Extra namespace mode

Extra namespace mode options

Option	Description
`-e`	Get data for extra namespaces (`oc get all,pvc,configmap,secret,serviceaccount`, `oc describe`, `oc logs`) - Separate namespaces with a comma (,)

The `[:extra-resouces]` is optional and is a file that can be used to specify additional resource types, such as catalog sources, operand configs, and more). Specify one resource type per line in the file.

Missing object mode

Missing object mode options

Option	Description
`-x`	- Product version to use for `getMissingObj` function, such `-x 3.2.0` or `-x X` to auto-detect. Defaults to the product version that is detected by tool if a version is not provided Or - The absolute path for an input config file, such as `-x /tmp/myfile.cfg` for the `getMissingObj` function to use.

Compliance mode

Compliance mode options

Option	Description

Option	Description
`-A`	`<compliance-param> = TAGS:[input file for the getCompliance() function]` where `input file` is defaulted to `compliance/<prod-version>/compliance.cfg` (use keyword `ALL` to select all config lines. Separate multiple tags with a comma) [EXPERIMENTAL]

plugins mode

Plugins mode options

Option	Description
`-P`	Product plugin `[supported=aimanager]:action [supported=data fix]`. The default action is `data`. For example, `aimanager` or `aimanager:data` or `aimanager:fix`. - Separate plugins with a comma (`,`).
`-Z`	Environment variables for the plugins script. For example, `VAR1=VAL1##VAR2=VAL2##...` - Enclose the entire input string with single quotation marks. For example, `VAR1=hello##VAR2=uname -a`.
`-Q`	Timeout value for plugins `[-P]` The default is `15m`. For example, `10s` where `s`=second; `m`=minute; `h`=hour.

cpfiles mode

cpfiles mode options

Option	Description
`-F`	Copy files in a pod. `cpfiles-param` = `TAGS` or `NAMESPACE##PODNAME##CONTAINER##FILES` where multiple `TAGS` can be delimited by `@@`. `CONTAINER` is optional and `FILES` can be delimited by a colon. - `-F aimanager` refers to `cpfiles/cpfiles-<prodname>-<version>.cfg` and copies all the files configured as `TAG=aimanager`. `-F NS4PROD=aimanager##iaf-system-kafka-0####/tmp/abc.txt` is the manual command to copy a file.

Notes:

- You can use keyword `NS4PROD=<prodname>` to obtain namespace for those products automatically.
- You can use asterisk(`*`), square brackets(`[]`), question mark(`?`), and curly braces(`{}`) wildcards in `FILES`.
- Since the `tar` (needed by `oc cp`) command might not be available in the target pod or container, use this option only for text files (`oc exec/cat` is used as a secondary option).

Snapshots mode

Snapshots mode options

Option	Description
`-K`	Complete snapshots comparison.

View mode

View mode options

Option	Description
`-V`	`<view-only-module>` is a script that can be created under the `<mustgather-install-dir>/config/view/<PRODUCT_VERSION>` (precedence) or `<mustgather-install-dir>/view` directory. You can use `-V .listviews` to list down all available modules and their descriptions.

Supporting Options

Supporting options

Option	Description
`-Y`	Collect YAML output (`oc get -o yaml`).
`-J`	Collect JSON output (`oc get -o json`).
`-p`	Collect logs for the previous instance of the container in a pod if it exists
`-t`	Do not collect `oc describe`.
`-g`	Do not collect pod logs (`oc logs` and `oc logs -p`).
`-f`	Collect PVC usage data (`df -h`) - Available only with options `-a`, `-c`, `-b`, `-l`, `-z` (productinfo/storage/pvcusage), `-k` (pvc) and `-e`.
`-R`	Enable report-on-screen where SUMMARY.log is printed on display.
`-S`	Explicitly collect YAML output of secret objects.
`-s`	Use SSH to collect logs and data from all cluster nodes without a common admin username across the cluster.
`-u`	Provide the admin username to used to SSH to all cluster nodes for data collection purpose. A passwordless SSH is needed for this option.
`-i`	Set the path to the SSH key. This path is needed for clusters on a cloud (experimental).
`-o`	Set the output directory. The default directory is `/tmp`.
`-G`	Use a filename regex and pattern, that is delimited by a colon, to run a grep operation. This option is applicable to pod logs, events, cpfiles, and node-related data files. - Separate patterns with double asperands (`@@`). - Separate `FILENAME_REGEX:PATTERNS` key value pairs with double hashes (`##`). - Use the keyword `ALL` as the filename regex as an instruction to run `grep` for all detected files. - Use a tilde (~) to run a piping grep. For example, `grep A <file> | grep B | grep C`. - To escape, use a tilde (~) with a backward slash (\) for the literal value. There is no need to escape by using a colon (`:`). For example, `ALL:error@@failure` or `^aimanager:error~fail` or `^aimanager:error##ALL:failure` or `ALL:error\~fail##ALL:error\/fail`

Option	Description
`-W`	Set global environment variable that all primary data collection modes can use for further processing. For example, `-W 'VAR1=123##VAR2=456##VAR3=789'`; this option delimits multiple variables with the `##` characters. All variables are suffixed with the string `PRIMODE_` when used internally (`VAR1` > `PRIMODE_VAR1`).
`-N`	Turn on data collection for problematic non-product namespaces. Data collection for problematic Red Hat OpenShift namespaces is always enabled.
`-I`	Enable incident reporting (experimental).
`-X`	Turn off custom data collection.
`-Y`	Auto-answer `YES` to question prompts.
`-U`	Check for updates.
`-M`	Turn of the automatic new version check and download for the tool.
`-D`	Turn on Debug mode.
`-v`	View the version details.
`-h`	View the tool help details.

Advanced tips for using the IBM Cloud Pak for AIOps MustGather tool

Learn more about advanced techniques that you can use with the IBM Cloud Pak® for AIOps MustGather tool to gather information for opening a case with IBM® Support.

Tip: Use manual collection mode to run commands

If you need to run `oc exec` commands on pods, you can use the manual collection (`MANUALCOLLECT`) mode. This mode can be configured to complete specific tasks, such as to "get all Elasticsearch indexes".

The MustGather Tool does include some default task configurations. For more information, review the `manualcollect/<version>/mc.cfg` file within the MustGather tool installation package.

Example command:

```
# ./waiops-mustgather.sh -R -m aimgr-indices:mc.cfg
```

Example output:

```
================================================
[MANUALCOLLECT] OUTPUT OF EXECCMD
================================================

[CFGLINE = lifecycle-policy##cp4waiops##pod##^aiops-ir-lifecycle-policy-registry-svc-######curl -u$(cat
$SYSTEMAUTH_BINDING_DIR/username):$(cat $SYSTEMAUTH_BINDING_DIR/password) http://localhost:$PORT/policyregistry.ibm-
netcool-prod.aiops.io/v1alpha/system/cfd95b7e-3bc7-4006-a4a8-a73a79c71255]

```

Tip: Use `CPFILES` to copy files from pods

If you need to copy specific files from pods, you can use the **`CPFILES`** option.

For example, the following command uses the MustGather tool to pull the **`/conf/redis/redis.conf`** file from all pods that match regex expression **`^c-example-redis-m-`**. This example uses the following parameters:

- **`NS4PROD=`** is a special keyword that instructs the tool to auto-resolve the namespace for product **`aimanager`**.
- **`keyword`** and **`regex`** (avoid hardcoding) are used to allow the configuration to be used across different environments without the need to reconfigure.

Example command:

```
[file cpfiles/cpfiles-waiops-320.cfg in the package]
test##NS4PROD=aimanager##^c-example-redis-m-####/conf/redis/redis.conf
```

Example output:

```
# pwd
/tmp/waiops-cpfiles-01042022-173635/8-CPFILES/waiops32
# ls -l c-example-redis-m-0/
total 56
-rw-r--r-- 1 root root 51281 Apr  1 17:36 '^conf^redis^redis.conf'
-rw-r--r-- 1 root root    78 Apr  1 17:36 '^conf^redis^redis.conf.ls'
# ls -l c-example-redis-m-1
total 56
-rw-r--r-- 1 root root 51306 Apr  1 17:36 '^conf^redis^redis.conf'
-rw-r--r-- 1 root root    78 Apr  1 17:36 '^conf^redis^redis.conf.ls'
# ls -l c-example-redis-m-2
total 56
-rw-r--r-- 1 root root 51306 Apr  1 17:36 '^conf^redis^redis.conf'
-rw-r--r-- 1 root root    78 Apr  1 17:36 '^conf^redis^redis.conf.ls'
```

Tip: Run custom scripts with the MustGather tool

You can run your own script with the MustGather Tool, such as for completing corrective actions before the tool collects data. After completing the custom script actions, the tool then proceeds with the data collection.

- Custom script variable
- Custom script functions
- Example Command
- Example script
- Example script functions
- Example script results

Custom script variable

The following tables list some of the variables that you can include within a custom script:

Custom script variables

Variable	Description
`$OC_CMD`	The system command used to collect data. You can use either an **`oc`** or **`kubectl`** command.
`$OC_WHOAMI`	The current user.
`$AWK`	The **`AWK`** used in the tool, which can be either **`awk`** or **`gawk`** (preferred).
`$OLDIFS`	The original IFS.
`$PRODUCT_VERSION`	The product version detected during runtime (on site).
`$MUSTGATHER_DIRNAME`	The directory name where the MustGather tool is installed.
`$OUTDIR`	The directory where the output data is written.
`$PROD_NAMESPACES_REFFILE`	The product-to-namespace mapping reference file (Do not change).
`$PROD_NAMESPACES_UNIQUE_REFFILE`	The unique product namespaces reference file (Do not change).
`$PROD_NAMESPACES_INVALID_STR`	A constant string value that represents the failed **`getNamespaceToProdMapping()`** function.
`$CMD_EXEC_OUTPUT_DIR`	The directory where the output of **`CMDEXEC`** is written to.
`$CMD_EXEC_PRODUCT_NSFILE`	A copy of the original product namespaces reference file that needs to be used by the inherited **`getNamespaceToProdMapping()`** function.
`$CMD_EXEC_RESULT_MCCFG_FILE`	A file that the custom script can write to for running the *MANUALCOLLECT* secondary mode.
`$CMD_EXEC_RESULT_EXTRANS_FILE`	A file that the custom script can write to for running the *EXTRA* (namespace) secondary mode.
`$CMD_EXEC_RESULT_CPFILES_FILE`	A file that the custom script can write to for running the *CPFILES* secondary mode.

Custom script functions

The following tables list some of the functions that you can include within a custom script:

Custom script functions

Functions	Description
`getProdToNamespacesMapping()`	A function to retrieve product namespace through provided product name. **Syntax:** `getProdToNamespacesMapping <product-name> $CMD_EXEC_PRODUCT_NSFILE` **Returns:** - Product namespaces of the given product name or `PROD_NAMESPACES_INVALID_STR`. - Return status `0` for successful execution and `1` for a failed execution. Product namespaces: - `aimanager` = IBM Cloud Pak for AIOps - `noihybrid` = IBM Netcool Operations Insight (hybrid) - `ics` = IBM Cloud Pak foundational services
`getNamespaceToProdMapping()`	A function to retrieve product name through provided product namespace. **Syntax:** `getNamespaceToProdMapping <product-namespace> $CMD_EXEC_PRODUCT_NSFILE` **Returns:** Product name of the given product namespace.
`getResourceInstances()`	A function to retrieve a list of resource instances. **Syntax:** `getResourceInstances <resource type> <resource name regex> <resource namespace>` Where `<resource namespace>` is optional and defaults to `-all-namespaces`. **Returns:** - A list of resources that match the provided details or a blank string if the command fails or no resource is detected. - Return status `0` for successful execution and `1` for a failed execution.
`getUniqueProdNamespaces()`	A function to retrieve a list of unique product namespaces. **Syntax:** `getUniqueProdNamespaces $CMD_EXEC_PRODUCT_NSFILE` **Returns:** A list of unique product namespaces or blank string if failed.
`checkUserPriv()`	A function to check whether the current user has privilege to complete specific actions (verb) on a specific resource in a specific namespace. **Syntax** `checkUserPriv <verb> <resource type> <resource namespace>` **Returns:** `0` to indicate the user has the required privileges and `1` to indicate that user does not have the required privilege. `<verb>` reference: Kubernetes API Concepts.
`isPodOk()`	A function to determine whether a pod is in `RUNNING` state and all its containers are up. **Syntax:** `isPodOk <namespace> <podname>` **Returns:** `0` for an OK pod and `1` for a pod that is not OK.
`isPodLineOk()`	A function to determine whether a pod is in RUNNING state and all its containers are up. **Syntax:** `isPodLineOk <'oc get –no-headers' output of the pod>` **Returns:** `0` for an OK pod and `1` for an pod that is not OK.

Example Command

```
waiops-mustgather.sh -R -C /tmp/elite.sh##/tmp/env.in -Y
```

The previous command uses an environment variable file `/tmp/env.in` to pass in variables into the script.

```
POD=teams
CMD=date > /tmp/date.out
```

Example script

The following code shows an example custom script:

```
NOI_NAMESPACE=$(getProdToNamespacesMapping noi $CMD_EXEC_PRODUCT_NSFILE)

if [ ${#NOI_NAMESPACE} -gt 0 ]
then
  echo "[$(date)] Detected namespace = [$NOI_NAMESPACE]"

  IMPACTGUI_POD=$(getResourceInstances pod impactgui $NOI_NAMESPACE)

  if [ ${#IMPACTGUI_POD} -gt 0 ]
  then
    echo "[$(date)] Detected IMPACT GUI pod = [$IMPACTGUI_POD]"
    oc delete pod -n $NOI_NAMESPACE $IMPACTGUI_POD

    WAITFORPOD=0

    while [ $WAITFORPOD -eq 0 ]
    do
      if isPodOk "$NOI_NAMESPACE" "$IMPACTGUI_POD"
      then
        OUTFILE=$($OC_CMD exec -n $NOI_NAMESPACE $IMPACTGUI_POD -- /opt/IBM/tivoli/impact/bin/nci_collect_logs | grep
'Netcool/Impact log file is' | $AWK '{ print $7 }')

        if [ ${#OUTFILE} -gt 0 ]
        then
          echo "[$(date)] Creating COLLECTLOG timestamp file..."
          echo "ALL##$NOI_NAMESPACE##pod##$(getResourceInstances pod impactgui $NOI_NAMESPACE)####touch /tmp/collectlog" >
$CMD_EXEC_RESULT_MCCFG_FILE

          echo "[$(date)] Detected IMPACT GUI logfile = [$OUTFILE]"
          echo "$NOI_NAMESPACE##$IMPACTGUI_POD####$OUTFILE" > $CMD_EXEC_RESULT_CPFILES_FILE

          WAITFORPOD=1
        else
```

```
          echo "[$(date)] Unable to locate IMPACT GUI logfiles!"
          exit 1
        fi
      else
        echo "[$(date)] IMPACT GUI pod is not running!"
        sleep 5
      fi
    done
  else
    echo "[$(date)] Unable to locate IMPACT GUI pod!"
    exit 1
  fi
else
  echo "[$(date)] Unable to determine NOI namespace!"
  exit 1
fi
```

Example script functions

When you are creating your custom script, you can use the following functions:

- The function **getProdToNamespacesMapping** can be used in any **CMDEXEC** script to obtain product namespaces:

  ```
  NS=$(getProdToNamespacesMapping aimanager $CMD_EXEC_PRODUCT_NSFILE)
  echo "NAMESPACE=$NS"
  ```

- The Function **getResourceInstances** can be used in any **CMDEXEC** script to obtain resource instances based on a provided regex expression such to complete a corrective action:

  ```
  for MYPOD in $(getResourceInstances pod $POD $NS)
  do
  MYCMD="oc exec $MYPOD -n $NS -- bash -c '$CMD'"
  echo $MYCMD
  eval $MYCMD
  done
  ```

- The **MANUALCOLLECT** mode can be used to collect data within the script, such as to ensure that the correction actions are successful:

  ```
  echo "ALL##NS4PROD=aimanager##pod##teams####" >> $CMD_EXEC_RESULT_MCCFG_FILE
  ```

- The **EXTRA** mode can be used to collect namespace data within the script:

  ```
  echo "openshift-insights" > $CMD_EXEC_RESULT_EXTRANS_FILE
  ```

- The **CPFILES** option can be used to copy files from pods to verify that your script ran successfully:

  ```
  echo "NS4PROD=aimanager##^iaf-system-kafka####/opt/kafka/config/log4j.properties" >> $CMD_EXEC_RESULT_CPFILES_FILE
  ```

Example script results

- When the command **date > /tmp/date.out** runs in the pod:

  ```
  oc exec -it
  ```

  Output:

  ```
  aimanager-aio-chatops-teams-integrator-545bc7d4d-9w8fp -- bash -c 'ls -l /tmp; cat /tmp/date.out'
  Defaulted container "chatops-teams-integrator" out of: chatops-teams-integrator, controller-is-ready (init)
  total 12
  -rw-r--r--. 1 default root  29 Apr  2 01:00 date.out
  -rwx------. 1 root    root 701 Sep 14  2021 ks-script-vzv5jj6c
  -rwx------. 1 root    root 291 Sep 14  2021 ks-script-y5xeen0d
  Sat Apr  2 01:00:25 UTC 2022
  ```

- Through **MANUALCOLLECT**, the data of the pod that matched the regex **teams** is collected. You can verify this by running the following commands:

  1. Print the working directory:

     ```
     # pwd
     ```

     Output:

     ```
     /tmp/waiops-cmdexec-01042022-175950/4-MANUALCOLLECT/TAG=ALL/waiops32
     ```

  2. List the directory files:

     ```
     # ls -l
     ```

     Output:

     ```
     total 4
     -rw-r--r-- 1 root root 180 Apr  1 18:00 oc_pod-aimanager-aio-chatops-teams-integrator-545bc7d4d-9w8fp.out
     drwxr-xr-x 2 root root 164 Apr  1 18:00 pod
     ```

  3. List the pods files:

     ```
     total 12
     -rw-r--r-- 1 root root 1551 Apr  1 18:00 aimanager-aio-chatops-teams-integrator-545bc7d4d-9w8fp~chatops-teams-
     integrator.log
     -rw-r--r-- 1 root root 7315 Apr  1 18:00 aimanager-aio-chatops-teams-integrator-545bc7d4d-9w8fp.desc
     ```

- Through the **EXTRA** mode, data about the namespace **openshift-insights** is collected. You can verify this by running the following commands:

  1. Print the working directory:

     ```
     # pwd
     ```

     Output:

     ```
     /tmp/waiops-cmdexec-01042022-175950/5-EXTRA/openshift-insights
     ```

  2. List the directory files:

     ```
     # ls -l
     ```

     Output:

     ```
     total 28
     drwxr-xr-x 2 root root  132 Apr  1 18:00 configmaps
     drwxr-xr-x 2 root root   36 Apr  1 18:00 deployment.apps
     -rw-r--r-- 1 root root 1738 Apr  1 18:00 oc_all.out
     -rw-r--r-- 1 root root  194 Apr  1 18:00 oc_configmaps.out
     -rw-r--r-- 1 root root  328 Apr  1 18:00 oc_pod_scc.out
     -rw-r--r-- 1 root root   52 Apr  1 18:00 oc_pvc.out
     -rw-r--r-- 1 root root 1427 Apr  1 18:00 oc_secrets.out
     -rw-r--r-- 1 root root  155 Apr  1 18:00 oc_serviceaccounts.out
     drwxr-xr-x 2 root root  117 Apr  1 18:00 pod
     drwxr-xr-x 2 root root   35 Apr  1 18:00 pvc
     drwxr-xr-x 2 root root   86 Apr  1 18:00 replicaset.apps
     drwxr-xr-x 2 root root 4096 Apr  1 18:00 secrets
     drwxr-xr-x 2 root root   26 Apr  1 18:00 service
     drwxr-xr-x 2 root root  107 Apr  1 18:00 serviceaccounts
     ```

- Through CPFILES, the file **/opt/kafka/config/log4j.properties** is copied from the pods that matches the regex expression **^iaf-system-kafka**. You can verify this by running the following commands:

  1. Print the working directory:

     ```
     # pwd
     ```

     Output:

     ```
     /tmp/waiops-cmdexec-01042022-175950/8-CPFILES/waiops32/iaf-system-kafka-0
     ```

  2. List the directory files:

     ```
     # ls -l
     ```

     Output:

     ```
     total 12
     -rw-r--r-- 1 root root 4674 Apr  1 18:00 '^opt^kafka^config^log4j.properties'
     -rw-r--r-- 1 root root   77 Apr  1 18:00 '^opt^kafka^config^log4j.properties.ls'
     ```

  3. View the first lines of the file to verify the file contents:

     ```
     # head ^opt^kafka^config^log4j.properties
     ```

     Output:

     ```
     # Licensed to the Apache Software Foundation (ASF) under one or more
     # contributor license agreements.  See the NOTICE file distributed with
     # this work for additional information regarding copyright ownership.

Security bulletins and fixes

Stay informed about known security vulnerabilities and fixes for IBM Cloud Pak® for AIOps by subscribing to the security bulletins and by reviewing the list of fixed security-related vulnerabilities.

- Security bulletins
- Fixed security-related vulnerabilities in version 4.6.0
- Fixed security-related vulnerabilities in previous versions

Security bulletins

Subscribe to IBM Cloud Pak for AIOps notifications by following these steps:

1. Go to the IBM Support site.

2. Scroll to the **Support basics** section. Then, click the **Notification settings** card.
3. Log in to IBM with your IBM ID and password to continue.
4. Enter **IBM Cloud Pak for AIOps** in the **Product lookup** field. Click **Subscribe**.
5. In the **Select document types** page, select **Security bulletin** and **Fixes** > **Security Vulnerability (Sec/Int)**. You can also select any other document types that you need to keep informed about.
6. Click **Submit**.
7. To configure how you receive notifications, click **Delivery preferences** in the banner at the beginning of the page. Edit your settings as needed.

Fixed security-related vulnerabilities in version 4.6.0

Review the following tables, which lists the fixed reported security-related vulnerabilities with IBM Cloud Pak for AIOps, and any included IBM or third-party software.

Table. Fixed Common Vulnerabilities and Exposures in Version 4.6.0

CVE-ID	Issue	Description
CVE-2019-13631	Linux Kernel parse_hid_report_descriptor function code execution	Linux Kernel could allow a physical attacker to execute arbitrary code on the system, caused by an an out-of-bounds write flaw in the parse_hid_report_descriptor function in drivers/input/tablet/gtco.c. By using a specially-crafted USB device to send an HID report, an attacker could exploit this vulnerability to execute arbitrary code or cause a denial of service condition on the system.
CVE-2019-15505	Linux Kernel technisat-usb2.c information disclosure	Linux Kernel could allow a physical attacker to obtain sensitive information, caused by an out-of-bounds read flaw in technisat-usb2.c. By using a specially-crafted USB device, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition on the system.
CVE-2019-25162	Linux Kernel denial of service	Linux Kernel s vulnerable to a denial of service, caused by a use-after-free flaw in the i2c driver module. By sending a specially crafted request, a local attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2020-15778	OpenSSH scp.c command execution	OpenSSH could allow a remote attacker to execute arbitrary commands on the system, caused by improper input validation in the remote function in scp.c. By opening a specially crafted file containing backtick characters in the destination argument, an attacker could exploit this vulnerability to execute arbitrary commands on the system.
CVE-2020-25656	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free in the vt_do_kdgkb_ioctl function. By executing a specially-crafted program, a local authenticated attacker could exploit this vulnerability to cause the system to crash.
CVE-2020-36777	Linux Kernel denial of service	Linux Kernel s vulnerable to a denial of service, caused by a memory leak flaw in the dvb_media_device_free() function. By sending a specially crafted request, a local attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2021-3753	Linux Kernel information disclosure	Linux Kernel could allow a local attacker to obtain sensitive information, caused by an out-of-bounds read flaw in VT. By using a specially-crafted vc_visible_origin setting, an attacker could exploit this vulnerability to obtain sensitive information, or cause a denial of service condition.
CVE-2021-4204	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by improper input validation in the handling of eBPF programs. By executing a specially-crafted eBPF program, an authenticated attacker could exploit this vulnerability to gain elevated privileges and execute code in the context of the kernel.
CVE-2021-31684	netplex JSON Smart denial of service	netplex JSON Smart is vulnerable to a denial of service, caused by a flaw in the indexOf function of JSONParserByteArray. By sending a specially-crafted web request, a remote attacker could exploit this vulnerability to cause the application to crash.
CVE-2021-34538	Apache Hive security bypass	Apache Hive could allow a remote attacker to bypass security restrictions, caused by improper authorization validation by the CREATE and DROP function operations. By sending a specially-crafted request, an attacker could exploit this vulnerability to drop and recreate UDFs and pointing them to malicious jars.
CVE-2021-37533	Apache Commons Net information disclosure	Apache Commons Net could allow a remote attacker to obtain sensitive information, caused by an issue with the FTP client trusts the host from PASV response by default. By persuading a victim to connect to specially-crafted server, an attacker could exploit this vulnerability to obtain information about services running on the private network, and use this information to launch further attacks against the affected system.
CVE-2021-43565	Golang x/crypto/ssh package denial of service	Golang x/crypto/ssh package is vulnerable to a denial of service, caused by an unspecified flaw. By sending a specially-crafted request, a remote attacker could exploit this vulnerability to cause a panic in the SSH server, and results in a denial of service condition.
CVE-2021-46934	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by improper validating user data in compat ioctl. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2021-47013	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by a use-after-free flaw in the emac_mac_tx_buf_send function. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2021-47118	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free flaw when initializing cad_pid. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2021-47153	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds read flaw in the interrupt handler (i801_isr). By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2021-47171	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a memory leak in smsc75xx_bind. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2021-47185	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a softlockup issue in flush_to_ldisc. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.

CVE-ID	Issue	Description
CVE-2022-0500	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by an out-of-bounds write flaw in the BPF_BTF_LOAD function in the BPF subsystem. By executing a specially-crafted eBPF program, an authenticated attacker could exploit this vulnerability to gain elevated privileges or crash the system.
CVE-2022-2047	Eclipse Jetty security bypass	Eclipse Jetty could allow a remote authenticated attacker to bypass security restrictions, caused by a flaw in the HttpURI class. By sending a specially-crafted request, an attacker could exploit this vulnerability to the HttpClient and ProxyServlet/AsyncProxyServlet/AsyncMiddleManServlet wrongly interpreting an authority with no host as one with a host.
CVE-2022-2048	Eclipse Jetty denial of service	Eclipse Jetty is vulnerable to a denial of service, caused by a flaw in the error handling of an invalid HTTP/2 request. By sending specially-crafted HTTP/2 requests, a remote attacker could exploit this vulnerability to cause the server to become unresponsive, and results in a denial of service condition.
CVE-2022-3565		
CVE-2022-23222	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by improper input validation by the bpf verifier in kernel/bpf/verifier.c. By executing a specially-crafted eBPF program with certain *_OR_NULL pointer types, an authenticated attacker could exploit this vulnerability to gain elevated privileges and execute code in the context of the kernel.
CVE-2022-25857	Java package org.yaml:snakeyam denial of service	Java package org.yaml:snakeyam is vulnerable to a denial of service, caused by missing to nested depth limitation for collections. By sending a specially-crafted request, a remote attacker could exploit this vulnerability to cause a denial of service.
CVE-2022-38749	SnakeYAML denial of service	SnakeYAML is vulnerable to a denial of service, caused by a stack-overflow in parsing YAML files. By persuading a victim to open a specially crafted file, a remote attacker could exploit this vulnerability to cause the application to crash.
CVE-2022-38750	SnakeYAML denial of service	SnakeYAML is vulnerable to a denial of service, caused by a stack-overflow in parsing YAML files. By persuading a victim to open a specially crafted file, a remote attacker could exploit this vulnerability to cause the application to crash.
CVE-2022-38751	SnakeYAML denial of service	SnakeYAML is vulnerable to a denial of service, caused by a stack-overflow in parsing YAML files. By persuading a victim to open a specially crafted file, a remote attacker could exploit this vulnerability to cause the application to crash.
CVE-2022-38752	SnakeYAML denial of service	SnakeYAML is vulnerable to a denial of service, caused by a stack-overflow in parsing YAML files. By persuading a victim to open a specially crafted file, a remote attacker could exploit this vulnerability to cause the application to crash.
CVE-2022-40152	XStream denial of service	XStream is vulnerable to a denial of service, caused by a stack-based buffer overflow. By sending a specially-crafted XML data, a remote authenticated attacker could exploit this vulnerability to causes the parser to crash, and results in a denial of service condition.
CVE-2022-41723	Golang Go denial of service	Golang Go is vulnerable to a denial of service, caused by a flaw in the HPACK decoder. By sending a specially-crafted HTTP/2 stream, a remote attacker could exploit this vulnerability to cause excessive CPU consumption, and results in a denial of service condition.
CVE-2022-41854	snakeYAML denial of service	snakeYAML is vulnerable to a denial of service, caused by improper input validation. By persuading a victim to open a specially-crafted YAML content, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2022-42003	FasterXML jackson-databind denial of service	FasterXML jackson-databind is vulnerable to a denial of service, caused by a lack of a check in the primitive value deserializers when the UNWRAP_SINGLE_VALUE_ARRAYS feature is enabled. By sending a specially-crafted request using deep wrapper array nesting, a local attacker could exploit this vulnerability to exhaust all available resources.
CVE-2022-42004	FasterXML jackson-databind denial of service	FasterXML jackson-databind is vulnerable to a denial of service, caused by a lack of a check in in the BeanDeserializer._deserializeFromArray function. By sending a specially-crafted request using deeply nested arrays, a local attacker could exploit this vulnerability to exhaust all available resources.
CVE-2022-45934	Linux Kernel unspecified	An integer wraparound in the function l2cap_config_req in net/bluetooth/l2cap_core.c in Linux Kernel could allow a remote authenticated attacker from within the local network using L2CAP_CONF_REQ packets to cause an unknown impact.
CVE-2022-48624	less command execution	less could allow a local attacker to execute arbitrary commands on the system, caused by a flaw with omitting shell_quote calls for LESSCLOSE in the close_altfile() function in filename.c. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary commands on the host operating system.
CVE-2022-48627	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by a memory overlapping flaw when deleting chars in the buffer. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2022-48669	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a memory leak flaw in the papr_get_attr() function. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-0475	HashiCorp go-getter denial of service	HashiCorp go-getter is vulnerable to a denial of service, caused by improper handling of highly compressed data. By using a specially-crafted compressed archive, a local authenticated attacker could exploit this vulnerability to crash the go-getter library.
CVE-2023-1370	netplex json-smart-v2 denial of service	netplex json-smart-v2 is vulnerable to a denial of service, caused by not limiting the nesting of arrays or objects. By sending a specially crafted input, a remote attacker could exploit this vulnerability to cause a stack exhaustion and crash the software.
CVE-2023-1513	Linux Kernel information disclosure	Linux Kernel could allow a local attacker to obtain sensitive information, caused by a flaw when calling the KVM_GET_DEBUGREGS ioctl in the KVM module. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2023-3138	X.Org libX11 denial of service	X.Org libX11 is vulnerable to a denial of service, caused by a buffer overflow in the functions in src/InitExt.c. By sending a specially crafted request, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-3567	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by a use-after-free flaw in the vcs_read function in drivers/tty/vt/vc_screen.c in vc_screen. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain internal kernel information or cause the system to crash.

CVE-ID	Issue	Description
CVE-2023-4043	Eclipse Parsson denial of service	Eclipse Parsson is vulnerable to a denial of service, caused by a flaw when processing a large value in BigDecimal. By sending a specially crafted input using Json.createArrayBuilder().add(data), a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-4133	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free flaw in the cxgb4 driver. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause the system to crash.
CVE-2023-4244	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by a use-after-free flaw in the netfilter: nf_tables component. By sending a specially crafted request, an authenticated attacker could exploit this vulnerability to gain elevated privileges.
CVE-2023-4408	ISC BIND denial of service	ISC BIND is vulnerable to a denial of service, caused by an error when parsing large DNS messages. By flooding the target server with queries, a remote attacker could exploit this vulnerability to cause excessive CPU load.
CVE-2023-5517	ISC BIND denial of service	ISC BIND is vulnerable to a denial of service, caused by a flaw in query-handling code. By querying RFC 1918 reverse zones, a remote attacker could exploit this vulnerability to trigger an assertion failure.
CVE-2023-5679	ISC BIND denial of service	ISC BIND is vulnerable to a denial of service, caused by an error when enabling both DNS64 and serve-stale. By querying a DNS64-enabled resolver for domain names triggering serve-stale, a remote attacker could exploit this vulnerability to trigger an assertion failure.
CVE-2023-5954	HashiCorp Vault and Vault Enterprise denial of service	HashiCorp Vault and Vault Enterprise are vulnerable to a denial of service, caused by an unbounded consumption of memory flaw when triggering a policy check. By sending specially crafted inbound client requests, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-6121	Linux Kernel information disclosure	Linux Kernel could allow a remote authenticated attacker to obtain sensitive information, caused by an out-of-bounds read flaw in the NVMe-oF/TCP subsystem. By sending a specially crafted TCP packet, an attacker could exploit this vulnerability to obtain kmalloc data information, and use this information to launch further attacks against the affected system.
CVE-2023-6176	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw in the API for the cryptographic algorithm scatterwalk function. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause the system to crash or gain elevated privileges.
CVE-2023-6240	Linux Kernel information disclosure	Linux Kernel could allow a remote attacker to obtain sensitive information, caused by a Marvin vulnerability side-channel leakage in the RSA decryption operation. By exploiting the side-channel leakage, an attacker could exploit this vulnerability to decrypt ciphertexts or forge signatures, limiting the services that use that private key.
CVE-2023-6337	HashiCorp Vault and Vault Enterprise denial of service	HashiCorp Vault and Vault Enterprise are vulnerable to a denial of service, caused by improper input validation. By sending specially crafted unauthenticated and authenticated HTTP requests, a remote attacker could exploit this vulnerability to cause a memory exhaustion, and results in a denial of service condition.
CVE-2023-6516	ISC BIND denial of service	ISC BIND is vulnerable to a denial of service, caused by an out-of-memory condition. By using specific recursive query patterns, a remote attacker could exploit this vulnerability to cause the amount of memory used by a named resolver to go well beyond the configured max-cache-size limit, leading to a denial of service.
CVE-2023-6622	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw in the nft_dynset_init() function in net/netfilter/nft_dynset.c. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-6915	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw in the ida_free function in lib/idr.c. By sending a specially crafted request, a remote authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-6932	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by a use-after-free flaw in the ipv4: igmp component. By sending a specially crafted request, an authenticated attacker could exploit this vulnerability to gain elevated privileges.
CVE-2023-24023	Bluetooth Core Specification machine-in-the-middle	Bluetooth BR/EDR devices with Secure Simple Pairing and Secure Connections pairing in Bluetooth Core Specification is vulnerable to a machine-in-the-middle attack. By sniffing the network traffic, a network adjacent attacker could exploit this vulnerability to launch a man-in-the-middle attack and force a short key length, leading to the discovery of the encryption key and potentially live injection.
CVE-2023-25193	Harfbuzz denial of service	Harfbuzz is vulnerable to a denial of service, caused by an error in hb-ot-layout-gsubgpos.hh. By using consecutive marks during the process of looking back for base glyphs when attaching marks, a remote attacker could exploit this vulnerability to trigger O(n^2) growth and cause a denial of service.
CVE-2023-25775	Intel Ethernet Controller Remote Direct Memory Access (RDMA) driver for Linux escalation	Intel Ethernet Controller Remote Direct Memory Access (RDMA) driver for Linux could allow a remote attacker to gain elevated privileges on the system, caused by improper access control. An attacker could exploit this vulnerability to gain elevated privileges.
CVE-2023-28464	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by a double free flaw in the hci_conn_cleanup function in the Bluetooth subsystem. By sending a specially-crafted request, an authenticated attacker could exploit this vulnerability to gain elevated privileges or cause a denial of service condition.
CVE-2023-31083	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a race condition between HCIUARTSETPROTO and HCIUARTGETPROTO in the hci_uart_tty_ioctl function in drivers/bluetooth/hci_ldisc.c. By sending a specially crafted request, a local attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-31484	CPAN.pm man-in-the-middle	CPAN.pm is vulnerable to a man-in-the-middle attack, caused by improper validation of TLS certificates when downloading distributions over HTTPS. An attacker could exploit this vulnerability to launch a man-in-the-middle attack and gain access to the communication channel between endpoints to obtain sensitive information or further compromise the system.
CVE-2023-37453	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an out-of-bounds flaw in the read_descriptors function in drivers/usb/core/sysfs.c in the USB subsystem. By using a specially crafted USB device, a physical attacker could exploit this vulnerability to cause the system to crash.
CVE-2023-38409	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in the set_con2fb_map function in drivers/video/fbdev/core/fbcon.c. By sending a specially crafted request, a local attacker could exploit this vulnerability to cause a denial of service condition.

CVE-ID	Issue	Description
CVE-2023-39189	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds read flaw in the nfnl_osf_add_callback function in the Netfilter subsystem. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2023-39192	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds read flaw in the u32_match_it function in Netfilter Xtables. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2023-39193	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds read flaw in the match_flags function in Netfilter Xtables. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2023-39194	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds read flaw in the processing of state filters in XFRM. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2023-39198	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by a race condition in the QXL driver. By sending a specially crafted request, an authenticated attacker could exploit this vulnerability to gain elevated privileges or cause a denial of service condition.
CVE-2023-42754	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw in the ipv4_send_dest_unreach function in net/ipv4/route.c. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-42755	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an out-of-bounds read in the rsvp traffic classifier. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause the kernel to crash.
CVE-2023-43785	X.Org libX11 information disclosure	X.Org libX11 could allow a remote attacker to obtain sensitive information, caused by an out-of-bounds memory access flaw in the _XkbReadKeySyms() function. By persuading a victim to connect to a specially crafted server, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2023-43786	X.Org libX11 denial of service	X.Org libX11 is vulnerable to a denial of service, caused by a stack exhaustion from infinite recursion in the PutSubImage() function. By persuading a victim to open a specially crafted content, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-43787	X.Org libX11 buffer overflow	X.Org libX11 is vulnerable to a heap-based buffer overflow, caused by improper bounds checking by the XCreateImage() function. By persuading a victim to open a specially crafted file, a remote attacker could overflow a buffer and execute arbitrary code or cause a denial of service condition.
CVE-2023-43788	X.Org libXpm information disclosure	X.Org libXpm could allow a remote attacker to obtain sensitive information, caused by an out-of-bounds memory read flaw in the XpmCreateXpmImageFromBuffer() function. By persuading a victim to open a specially crafted content, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2023-43789	X.Org libXpm information disclosure	X.Org libXpm could allow a remote attacker to obtain sensitive information, caused by an out-of-bounds memory read flaw in the XPM. By persuading a victim to open a specially crafted content, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2023-45863	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by a race condition that results in a fill_kobj_path out-of-bounds write in lib/kobject.c. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code or cause a denial of service condition.
CVE-2023-46809	Node.js information disclosure	Node.js could allow a remote attacker to obtain sensitive information, caused by a vulnerability in the privateDecrypt() API of the crypto library. An attacker could exploit this vulnerability to conduct a covert timing side-channel during PKCS#1 v1.5 padding error handling and obtain significant timing differences in decryption for valid and invalid ciphertexts.
CVE-2023-50387	ISC BIND denial of service	ISC BIND is vulnerable to a denial of service, caused by an error when processing responses coming from specially crafted DNSSEC-signed zones. By flooding the target server with queries, a remote attacker could exploit this vulnerability to cause CPU exhaustion on a DNSSEC-validating resolver.
CVE-2023-50868	ISC BIND denial of service	ISC BIND is vulnerable to a denial of service, caused by an error when preparing an NSEC3 closest encloser proof. By flooding the target resolver with queries, a remote attacker could exploit this vulnerability to cause CPU exhaustion on a DNSSEC-validating resolver.
CVE-2023-51714	Qt integer overflow	Qt could allow a remote attacker to execute arbitrary code on the system, caused by an integer overflow in the HTTP2 implementation. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2023-51779	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by a use-after-free flaw in the bt_sock_recvmsg function in net/bluetooth/af_bluetooth.c. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code or cause a denial of service on the system.
CVE-2023-51780	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by a use-after-free flaw in the do_vcc_ioctl function in net/atm/ioctl.c. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code or cause a denial of service. on the system.
CVE-2023-52340	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an uncontrolled resource consumption flaw in the ICMPv6 handling of "Packet Too Big". By sending a specially crafted IPV6 request, a remote attacker could exploit this vulnerability to consume available CPU resources.
CVE-2023-52425	libexpat denial of service	libexpat is vulnerable to a denial of service, caused by improper system resource allocation. By sending a specially crafted request using an overly large token, a remote attacker could exploit this vulnerability to cause a denial of service.

CVE-ID	Issue	Description
CVE-2023-52434	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds error in the smb2_parse_contexts() function. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2023-52439	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by a use-after-free memory flaw in the uio_open function. By sending a specially crafted request, an authenticated attacker could exploit this vulnerability to gain elevated privileges or cause the system to crash.
CVE-2023-52445	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free on context disconnection. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52448	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference in gfs2_rgrp_dump. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52477	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw when usb_get_bos_descriptor() fails. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-52489	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a race condition in accessing memory_section->usage. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-52513	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to the handling of a connection failure. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52520	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a reference leak. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52528	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to uninit-value access in __smsc75xx_read_reg. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52565	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds read. By sending a specially crafted request, n attacker could exploit this vulnerability to obtain sensitive information.
CVE-2023-52574	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw when team device type is changed. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-52578	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to using DEV_STATS_INC(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52580	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an incorrect calculation of buffer size in ETH_P_1588 flow dissector. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-52581	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by a memory leak when more than 255 elements expired. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code or cause the system to crash.
CVE-2023-52594	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an array-index-out-of-bounds read in ath9k_htc_txstatus(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52595	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to the restart beacon queue when hardware reset. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52598	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by the incorrect handling of setting of fpc register. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52606	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to size for vector operations. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52607	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference in pgtable_cache_add. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52610	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an skb leak and crash on ooo frags. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52620	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a resource injection flaw in timeout parameter in nf_tables. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-0340	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by a flaw in the vhost_new_msg function in drivers/vhost/vhost.c. By reading the /dev/vhost-net device file, an attacker could exploit this vulnerability to obtain kernel memory information, and use this information to launch further attacks against the affected system.
CVE-2024-0841	Linux Kernel privilege escalation	Linux Kernel could allow a local authenticated attacker to gain elevated privileges on the system, caused by a NULL pointer dereference flaw in the hugetlbfs_fill_super function in the hugetlbfs (HugeTLB pages) functionality. By sending a specially crafted request, an authenticated attacker could exploit this vulnerability to gain elevated privileges or cause the system to crash.
CVE-2024-2048	HashiCorp Vault and Vault Enterprise security bypass	HashiCorp Vault and Vault Enterprise could allow a remote attacker to bypass security restrictions, caused by improper validating the client certificates when configured with a non-CA certificate as trusted certificate. By using a specially crafted certificate, an attacker could exploit this vulnerability to bypass authentication.
CVE-2024-2660	HashiCorp Vault and Vault Enterprise security bypass	HashiCorp Vault and Vault Enterprise could allow a remote authenticated attacker to bypass security restrictions, caused by improper validation of OCSP responses when one or more OCSP sources were configured. By sending a specially crafted request, an attacker could exploit this vulnerability to bypass authentication validation.

CVE-ID	Issue	Description
CVE-2024-3817	HashiCorp go-getter code execution	HashiCorp go-getter could allow a remote attacker to execute arbitrary code on the system, caused by an argument injection flaw. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-5798	Hashicorp Vault and Vault Enterprise information disclosure	Hashicorp Vault and Vault Enterprise could allow a remote authenticated attacker to obtain sensitive information, caused by improper validating the JSON Web Token (JWT) role-bound audience claim when using the Vault JWT auth method. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.
CVE-2024-20918	Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition unspecified	An unspecified vulnerability in Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition related to the Hotspot component could allow a remote attacker to cause high confidentiality impact and high integrity impact.
CVE-2024-20926	Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition unspecified	An unspecified vulnerability in Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition related to the Scripting component could allow a remote attacker to cause high confidentiality impact.
CVE-2024-20952	Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition unspecified	An unspecified vulnerability in Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition related to the Security component could allow a remote attacker to cause high confidentiality impact and high integrity impact.
CVE-2024-21011	Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition unspecified	An unspecified vulnerability in Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition related to the Hotspot component could allow a remote attacker to cause low availability impact.
CVE-2024-21012	Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition unspecified	An unspecified vulnerability in Oracle Java SE, Oracle GraalVM for JDK, Oracle GraalVM Enterprise Edition related to the Networking component could allow a remote attacker to cause high integrity impact.
CVE-2024-21068	Oracle Java SE, GraalVM for JDK and GraalVM unspecified	An unspecified vulnerability in the Oracle Java SE, GraalVM for JDK and GraalVM related to Hotspot component could allow a remote authenticated attacker to cause low integrity impacts.
CVE-2024-21085	Oracle Java SE, GraalVM for JDK and GraalVM unspecified	An unspecified vulnerability in Oracle Java SE, GraalVM for JDK and GraalVM related to the Hotspot component could allow a remote attacker to cause low availability impacts.
CVE-2024-21094	Oracle Java SE, GraalVM for JDK and GraalVM unspecified	An unspecified vulnerability in Oracle Java SE, GraalVM for JDK and GraalVM related to the Hotspot component could allow a remote attacker to cause no confidentiality impact, low integrity impact, and no availability impact.
CVE-2024-21503	Python Software Foundation Black denial of service	Python Software Foundation Black is vulnerable to a denial of service, caused by a regular expression denial of service (ReDoS) flaw in the lines_with_leading_tabs_expanded function in the strings.py. By sending a specially crafted regex input, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-21892	Node.js privilege escalation	Node.js could allow a local authenticated attacker to gain elevated privileges on the system, caused by a bug in the implementation of the exception of CAP_NET_BIND_SERVICE. An attacker could exploit this vulnerability to inject code that inherits the process's elevated privileges.
CVE-2024-22025	Node.js denial of service	Node.js is vulnerable to a denial of service, caused by a resource exhaustion flaw in fetch() brotli decoding . By sending a specially crafted request, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-22190	GitPython code execution	GitPython could allow a remote attacker to execute arbitrary code on the system, caused by an untrusted search path flaw. By persuading a victim to open a specially crafted file, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-22262	VMware Tanzu Spring Framework open redirect	VMware Tanzu Spring Framework could allow a remote attacker to conduct phishing attacks, caused by an open redirect vulnerability in UriComponentsBuilder. An attacker could exploit this vulnerability using a specially-crafted URL to redirect a victim to arbitrary Web sites.
CVE-2024-23307	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an integer overflow in the md, raid, raid5 modules. By sending a specially crafted request, a remote authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-23944	Apache ZooKeeper information disclosure	Apache ZooKeeper could allow a remote authenticated attacker to obtain sensitive information, caused by a flaw in persistent watchers handling. By attaching a persistent watcher to a parent, an attacker could exploit this vulnerability to obtain information of the full path of znodes, and use this information to launch further attacks against the affected system.
CVE-2024-25580	Qt denial of service	Qt is vulnerable to a denial of service, caused by a buffer overflow in gui/util/qktxhandler.cpp. By using a crafted KTX image file, a remote attacker could exploit this vulnerability to cause the application to crash.
CVE-2024-25629	C-ares denial of service	C-ares is vulnerable to a denial of service, caused by an out-of-bounds read in ares__read_line(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause the application to crash.
CVE-2024-25742	Linux Kernel security bypass	Linux Kernel could allow a local authenticated attacker to bypass security restrictions, caused by improper input validation. By injecting a specially crafted virtual interrupt 29 (#VC), an attacker could exploit this vulnerability to make arbitrarily change the value stored in EAX while a SEV VM is running.

CVE-ID	Issue	Description
CVE-2024-25743	Linux Kernel security bypass	Linux Kernel could allow a local authenticated attacker to bypass security restrictions, caused by improper input validation. By injecting a specially crafted virtual interrupts 0 and 14, an attacker could exploit this vulnerability to make arbitrarily change the value stored in EAX while a SEV VM is running.
CVE-2024-25744	Linux Kernel security bypass	Linux Kernel could allow a local authenticated attacker to bypass security restrictions, caused by a flaw in rch/x86/coco/tdx/tdx.c and arch/x86/mm/mem_encrypt_amd.c. By sending a specially crafted request, an attacker could exploit this vulnerability to trigger int80 syscall handling at any given point.
CVE-2024-26593	Kernel information disclLinuxosure	Linux Kernel could allow a remote attacker to obtain sensitive information, caused by an out-of-bounds read within i2c: i801. An attacker could exploit this vulnerability to obtain sensitive information and execute arbitrary code on the system.
CVE-2024-26602	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to sched/membarrier: reducing the ability to hammer on sys_membarrier. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26603	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by the reliance of userspace for info to fault in xsave buffer. A local attacker could exploit this vulnerability to cause a segmentation fault.
CVE-2024-26609		
CVE-2024-26610	Linux Kernel denial of service	Linux Kernel could allow a local attacker to execute arbitrary code on the system, caused by a memory corruption error. A local attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-26615	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by illegal rmb_desc access in SMC-D connection dump. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26642	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to anonymous set with timeout flag. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26643	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to page fault dead lock on mmap-ed hwrng. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26659	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by the improper handling of isoc Babble and Buffer Overrun events. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26664	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an out-of-bounds memory access. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26671	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a race condition in the blk_mq_mark_tag_wait() function. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-26693	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a crash when we run out of stations. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26694	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a double-free error. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26743	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to qedr_create_user_qp error flow. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26744	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to supporting specifying the srpt_service_guid parameter. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26779	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a race condition on enabling fast-xmit. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26872	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to registering event handler when srpt device is not fully setup. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26892	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free in free_irq(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26897	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by the failure to delay all of ath9k_wmi_event_tasklet() until init is complete. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26901	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by the failure to use kzalloc() to fix kernel-infoleak. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26919	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a debugfs directory leak. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26933	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a deadlock in port "disable" sysfs attribute. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26934	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a deadlock in usb_deauthorize_interface(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26964	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error handling in xhci_map_urb_for_dma. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26973	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an uninitialized field in nostale filehandles. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26993	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a reference leak in sysfs_break_active_protection(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-27014	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a deadlock issue while disabling aRFS. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.

CVE-ID	Issue	Description
CVE-2024-27048	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw when handle pmk_op allocation failure. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-27052	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free flaw due to workqueue might still be running, when the driver is stopped. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-27056	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw when no packets have been send on TID 0. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-27059	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a divide by zero flaw in the isd200_ata_command function. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-27280	Ruby StringIO gem information disclosure	Ruby StringIO gem could allow a remote attacker to obtain sensitive information, caused by a buffer over-read flaw in the ungetbyte and ungetc methods. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain memory value information, and use this information to launch further attacks against the affected system.
CVE-2024-27281	Ruby RDoc gem code execution	Ruby RDoc gem could allow a remote attacker to execute arbitrary code on the system, caused by an object injection flaw when parsing .rdoc_options as a YAML file. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-27304	pgx SQL injection	pgx is vulnerable to SQL injection. A remote attacker could send specially-crafted SQL statements, which could allow the attacker to view, add, modify or delete information in the back-end database.
CVE-2024-27306	aio-libs aiohttp cross-site scripting	aio-libs aiohttp is vulnerable to cross-site scripting, caused by improper validation of user-supplied input. A remote attacker could exploit this vulnerability using a specially crafted URL to execute script in a victim's Web browser within the security context of the hosting Web site, once the URL is clicked. An attacker could use this vulnerability to steal the victim's cookie-based authentication credentials.
CVE-2024-27982	Node.js request smuggling	Node.js is vulnerable to HTTP request smuggling, caused by the use of content length obfuscation in the http server. By sending specially crafted HTTP request headers, an attacker could exploit this vulnerability to poison the web cache, bypass web application firewall protection, and conduct XSS attacks.
CVE-2024-27983	Node.js denial of service	Node.js is vulnerable to a denial of service, caused by an assertion failure in node::http2::Http2Session::~Http2Session(). By sending a small amount of HTTP/2 frames packets with a few HTTP/2 frames inside, an attacker could exploit this vulnerability to cause the HTTP/2 server to crash.
CVE-2024-28176	Node.js jose module denial of service	Node.js jose module is vulnerable to a denial of service, caused by a flaw during JWE Decryption operations. By sending a specially crafted request, a remote attacker could exploit this vulnerability to consume unreasonable amount of CPU time or memory, and results in a denial of service condition.
CVE-2024-30251	aio-libs aiohttp denial of service	aio-libs aiohttp is vulnerable to a denial of service, caused by an infinite loop flaw. By sending specially crafted POST requests, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-34062	tqdm code execution	tqdm could allow a local authenticated attacker to execute arbitrary code on the system, caused by a CLI arguments injection . By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-34069	Pallets Werkzeug code execution	Pallets Werkzeug could allow a remote attacker to execute arbitrary code on the system, caused by improper usage of a pathname and improper CSRF protection in the debugger. By persuading a victim to interact with a domain and subdomain they control, enter the debugger PIN and guess a URL in the developer's application that will trigger the debugger, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-34447	The Bouncy Castle Crypto Package For Java security bypass	The Bouncy Castle Crypto Package For Java could allow a remote attacker to bypass security restrictions, caused by a flaw when endpoint identification is enabled in the BCJSSE and an SSL socket is created without an explicit hostname. By sending a specially crafted request, an attacker could exploit this vulnerability to perform DNS poisoning attack.

Fixed security-related vulnerabilities in previous versions

Review the following documentation, which includes the list of fixed reported security-related vulnerabilities in previous versions of IBM Cloud Pak for AIOps:

- Fixed security-related vulnerabilities in version 4.5.1
- Fixed security-related vulnerabilities in version 4.5.0
- Fixed security-related vulnerabilities in version 4.4.1
- Fixed security-related vulnerabilities in version 4.4.0
- Fixed security-related vulnerabilities in version 4.3.0
- Fixed security-related vulnerabilities in version 4.2.1
- Fixed security-related vulnerabilities in version 4.2.0
- Fixed security-related vulnerabilities in version 4.1.2
- Fixed security-related vulnerabilities in version 4.1.1
- Fixed security-related vulnerabilities in version 4.1.0

Fixed Support originated issues in IBM Cloud Pak for AIOps 4.6.0

Review the following list of fixed issues that were reported through IBM Support cases.

Fixed Support originated issues

Fixed install and upgrade issues

Fixed issue	Problem description
IBM Cloud Pak for AIOps is missing alerts through the Netcool connector	After integrating IBM Cloud Pak for AIOps with IBM Tivoli Netcool/OMNIbus, some events that appeared on the Netcool DASH alert viewer did not appear on the IBM Cloud Pak for AIOps Alert viewer.
Events stop processing through Netcool integration with IBM Tivoli Netcool/OMNIbus	Netcool events stopped processing due to a high load. Connector pods were also in CrashLoopBackOff and not pushing events from ObjectServers to IBM Cloud Pak for AIOps.
IBM Cloud Pak for AIOps is not receiving alerts through an Instana integration	New data that was coming through an Instana integration was not displaying in IBM Cloud Pak for AIOps. This could happen when a large payload was received from an Instana API.
IBM Cloud Pak for AIOps instance failure after an event storm	When an event storm was encountered, the IBM Cloud Pak for AIOps instance failed. When this issue occurred, events initially were visible by administrative users before not displaying at all. In addition, pods failed.
Mismatch in Alert count on topology resource view and resource alert details tabs	The status service was not broadcasting the status message of alert states being closed to the inventory service. This missing state change caused the variation in the resource status values on the resource management page and the alert viewer.
Policies are missing in the UI	Policies were missing in the UI when the Elasticsearch indices maximum index count was reached. This occurred due to AIOps not pruning some Elasticsearch indices which led to the maximum index count being reached. When this limit was reached, new indices were no longer created causing issues, such as the policy queries failing.
`edges_labels_weights_mapping.csv` includes an error	The mime configuration file `edges_labels_weights_mapping.csv` included an error as `data flow` should have been `dataflow`.
(Infrastructure Automation) In the Overview screen for schedules, the value for the **Message** field was shown for the **Request** field.	When this issue occurred, the **Message** and **Request** field were both displaying the value for the **Message** field. This issue occurred when creating a new schedule on the **Settings** > **Application Settings** > **schedules** > **Configuration** > **Add a new schedule** screen with the object details request and creating a message and request with different values. The UI then showed the message value for both the **Message** and **Request** on the summary page.
(Infrastructure Automation) Additional messaging appliances fail to start the `evmserverd` service	When this issue occurred, a messaging (server and database) appliance would run normally, but additional appliances that were configured as a messaging client failed to start the `evmserverd` service and the `manageiq-messaging-ready` service was hanging.

Fixed security vulnerabilities

For the list of fixed security-related vulnerabilities, see Security bulletins and fixes.

Known issues and limitations

For more information about current known issues in IBM Cloud Pak® for AIOps, see Known issues and limitations.

Notices

These legal notices pertain to the IBM Cloud Pak® for AIOps product and its documentation.

This information was developed for products and services offered in the US. This material might be available from IBM in other languages. However, you may be required to own a copy of the product or product version in that language in order to access it.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any third party product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing IBM Corporation North Castle Drive, MD-NC119 Armonk, NY 10504-1785 US

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing Legal and Intellectual Property Law IBM Japan Ltd. 19-21, Nihonbashi-Hakozakicho, Chuo-ku Tokyo 103-8510, Japan

Glossary

This glossary provides terms and definitions for IBM Cloud Pak® for AIOps.

The following cross-references are used in this glossary:

- *See* refers you from a nonpreferred term to the preferred term or from an abbreviation to the spelled-out form.
- *See also* refers you to a related or contrasting term.

While IBM values the use of inclusive language, terms that are outside of IBM's direct influence are sometimes required for the sake of maintaining user understanding. As other industry leaders join IBM in embracing the use of inclusive language, IBM will continue to update the documentation to reflect those changes.

A

accelerator

A set of assets that enable customers to understand core concepts and implement solutions.

AI model

In a machine learning context, a set of functions and algorithms that are trained and tested on a data set to provide predictions or decisions. See also training definition training definition.

alert

A record of an event indicating a fault in the managed environment.

anomaly

A deviation from the expected baseline behaviors.

application

One or more computer programs or software components that provide a function in direct support of a specific business process or processes.

application mapping

Used to expose the on-premises IBM Cloud Pak for AIOps instance to the public cloud. After the application mapping is created, IBM Cloud Pak for AIOps can be accessed from Slack.

auto-remediation

The process of resolving an issue with minimal or no human intervention.

B

boot node

The OpenShift cluster node that is used for running installation, configuration, node scaling, and cluster updates.

C

capability

The core functions of a service. For example, the XYZ service provides "monitoring" capability.

CD

See continuous delivery.

change risk

The risk associated with implementing any type of change, whether it is to code, configurations, or data. See also risk score.

CI

See continuous integration.

connector

The means by which a data source is connected to a product or service. See also integration.

continuous delivery (CD)

A software development practice that employs techniques such as continuous testing, continuous integration, and continuous deployment so that new features and fixes are packaged and deployed rapidly and at low risk to test environments and then to customers.

continuous integration (CI)

A software development practice where members of a team integrate their work frequently so that there are multiple integrations each day. Integrations are verified by an automated build to detect integration errors as quickly as possible.

coverage

A qualitative determination of the AI's ability to produce insights from your incoming data flow as a result of it's training. See also training definition.

CRD

See custom resource definition.

custom resource

An instance of a custom resource definition. See also custom resource definition.

custom resource definition (CRD)

A customizable YAML file that defines a logically related group of objects in a cluster. Custom resource definitions enable a custom resource to be used like any native Kubernetes object in the cluster. See also custom resource.

D

data set

Data that is extracted and organized from data streams. Data sets serve as inputs for pipelines to train, retrain, or tune models.

data stream

A set of processes that convert extracted data into a normalized data set.

E

edge

The relationship, or link, between resources. See also hop, seed.

error

The fault in an event that causes a failure.

event

A change in state of a service or system.

F

failure

The surfacing of an error to the user.

fault

An error in the internal state of a component in a system.

field mapping

The assignment of values from one integration type to a standard set of values. When one maps source fields, one replaces or supplements those values with new or different values.

H

hop

A step along a single edge from one resource to another. See also edge, seed.

I

incident

An unplanned interruption that causes, may cause, or reduces the quality of an IT service. See also incident.

integration

Any independent application that provides additional capabilities to an IBM service or base product. See also connector.

issue

A cause or potential cause of one or more recurring or similar tickets or incidents.

L

log

Data output from an application or service that describes a transaction or state occurring in that application or service.

M

mean time between failures (MTBF)

The average time between failures.

mean time to failure (MTTF)

The average amount of time before a system lapses into a failed state.

mean time to detect (MTTD)

The average amount of time it takes to identify a failure.

mean time to resolve (MTTR)

The total time period from the start of a failure to when the failure resolves and operations resume.

O

observer

A service that extracts resource information and provides topology data for integrations and localization and blast radius information for events published to ChatOps integrations.

observer job

An automated scheduled task that retrieves topological details for a target system.

operand

The service component used by an operator to perform actions.

operator

A system design that simulates user behavior by linking a controller to custom resources, simulating the act of observing differences in states then acting on them.

P

pipeline

A set of iterative processes that transforms data into insights. For example, retraining pipelines take additional training data sets and improves existing models based on new insights.

proactive channel

A ChatOps channel that is used for change risk notifications. See also reactive channel.

probable cause

A rank-based indicator of causal likelihood that is based on the analysis of alerts and associated topology within the context of an incident.

problem

See issue.

R

reactive channel

A ChatOps channel that is used for outgoing incidents and alerts. See also proactive channel.

resource

A physical or logical component that can be provisioned or reserved for an application or service instance. Examples of resources can include storage, processors, memory, clusters, and VMs.

risk score

A value derived to describe risk across several dimensions associated with change. See also change risk.

RPO (Recovery point objective)

The application loss tolerance, such as the amount of data that can be lost before significant harm to the application occurs.

RTA (Recovery Time Actual)

The actual time that is required for an application to recover completely.

RTO (Recovery Time Objective)

The time that an application can be down without causing significant damage. RTA should be less than RTO.

S

secure tunnel

A feature to package TCP requests and responses, encrypt them with HTTPS, and transport the payloads between IBM Cloud Pak for AIOps and Slack. With Secure Tunnel, you can integrate IBM Cloud Pak for AIOps with Slack without creating firewall rules and policies.

seed

A single resource that serves as the starting point of a topology. Once defined, the topology view is expanded one hop at a time. See also edge, hop.

service

In IBM Cloud Pak solutions, a set of capabilities that provide functionality to a product.

service catalog

A curated repository of services that users can discover and instantiate for use within their organization's applications.

incident

A collection of insights derived from different data sources (logs, events, and alerts) that represent the products' determination of an incident. Incidents build understanding and drive remediation.

T

ticket

A formal record of identified issues or requests that are created against an item and assigned to appropriate users to resolve those issues or complete the requests.

topology

An arrangement of specific, interconnected assets and resources within a network or application.

topology template

A defined topology pattern that is used to dynamically generate topologies based on matching conditions from previously established topologies in the topology database.

training definition

The established model that serves as the baseline for your data to be measured against. For example, your AI model for log anomalies acts as the training definition for all of your log anomaly integrations. See also AI model, coverage.

tunnel worker

Server side of a TCP-over-HTTPS tunnel. It is developed based on OSS project, and is installed in the IBM Cloud Pak for AIOps cluster.

tunnel connection

Used to manage IBM Cloud Pak for AIOps instance that you want to expose. If you want to expose on-premises IBM Cloud Pak for AIOps for Slack integration, first you need to create a tunnel connection.

tunnel connector

Client side of a TCP-over-HTTPS tunnel. It is developed based on OSS project, and can be installed in an OpenShift cluster. Ensure that the OpenShift cluster can be accessed from the public network, and the cluster domain certificate is signed.
