Attention: The ALM observer supports the discovery of Cloud Pak for Network Automation (CP4NA) and has been tested against versions 2.3.x and 2.4.x. The ALM observer was first developed to integrate with the legacy Telco Network Cloud Manager (TNCM) Orchestrator (TNCO/ALM). A re-branding from ALM (Agile Lifecycle Manager) to CP4NA happened, while the observer retained its ALM name. The observer has some level of backward compatibility with the legacy ALM.

Ensure you have the Agile LifeCycle Manager Kafka server host and topics to hand, such as the Agile Lifecycle Manager server, the Kafka port, and the topics used for lifecycle events.

Important: To access Agile LifeCycle Manager remotely, you must ensure that the Agile LifeCycle Manager installation is configured with the KAFKA_ADVERTISED_HOST_NAME so as to allow remote connections. For more information, see the Configuration reference topic in the Agile LifeCycle Manager documentation: Configuration reference

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The Agile LifeCycle Manager Observer jobs listen to the Kafka 'state change' topics of Agile Lifecycle Manager, as well as the Agile Lifecycle Manager Resource Manager. Information is extracted from Agile Lifecycle Manager about Assemblies and Resources and a topology is created.

After installation, you define and start the following two jobs.

Listen for Agile Lifecycle Manager events ('alm' job)

The **alm** job is a long-running job that monitors its source for updates and runs until it is explicitly stopped, or until the observer is stopped.

Listen for Resource Manager events ('rm' job)

The **rm** job is a long-running job that monitors its source for updates and runs until it is explicitly stopped, or until the observer is stopped.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Important: The value of the IBM Agile Lifecycle Manager instance name parameter needs to be the same for both jobs to allow the topology to be combined.

Listen for lifecycle events ('alm' job) parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
IBM Agile LifeCycle Manager instance name	Use this to identify the Agile LifeCycle Manager installation and any associated Resource Managers	Required
Group ID	Use this to identify the Kafka group ID to be used	Required
Connection	Use this to specify the Kafka Host and Port to be used	Required
ALM State Change Topic	Use this to identify the Agile LifeCycle Manager Kafka topic name to be consumed.	Required
ALM Service State Transition Topic	Use this to identify the Agile LifeCycle Manager State Transition Kafka topic name to be consumed.	Required
Secured or unsecured Kafka connection	Select false or true to make secured or unsecured connection to the CP4NA server. The default is 'false'.	Required. When set to 'true', you must also provide the credentials and target system certificate parameters. See the following topic for more information on obtaining connection and credential details: IBM Cloud Pak for Network Automation: Configuring Kafka connections
Kafka username	Enter the username of the secured Kafka cluster.	Required only if the parameter for secured connection has been set to 'true'.
Kafka password	Enter the password of the secured Kafka cluster.	Required only if the parameter for secured connection has been set to 'true'.
Certificate	Enter the certificate of the secured Kafka cluster.	Required only if the parameter for secured connection has been set to 'true'. For more information, see Configuring observer jobs security
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Listen for Resource Manager events ('rm' job) parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
IBM Agile Lifecycle Manager instance name	Use this to identify the Agile LifeCycle Manager installation and any associated Resource Managers	Required
Group ID	Use this to identify the Kafka group ID to be used	Required
Connection	Use this to specify the Kafka Host and Port to be used	Required

Parameter	Action	Details
Topic	Use this to identify the Agile Lifecycle Manager **Resource Manager** Kafka topic	Required
Secured or unsecured Kafka connection	Select false or true to make secured or unsecured connection to the CP4NA server. The default is 'false'.	Required. When set to 'true', you must also provide the credentials and target system certificate parameters. See the following topic for more information on obtaining connection and credential details: IBM Cloud Pak for Network Automation: Configuring Kafka connections
Kafka username	Enter the username of the secured Kafka cluster.	Required only if the parameter for secured connection has been set to 'true'.
Kafka password	Enter the password of the secured Kafka cluster.	Required only if the parameter for secured connection has been set to 'true'.
Certificate	Enter the certificate of the secured Kafka cluster.	Required only if the parameter for secured connection has been set to 'true'. For more information, see Configuring observer jobs security
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Ansible AWX Observer jobs

Using the Ansible AWX Observer, you can define load jobs that will gather and read data from a defined Ansible AWX instance. When a load job is run, it will load a baseline topology data view from Ansible AWX through its REST APIs.

Before you begin

Important: The Ansible AWX Observer supports the on-premises Ansible AWX version 21.14.0 and Tower API version 3.8.6.

Ensure you have the Ansible AWX details to hand, such as the host, port, user and token before defining and running the observer job.

Required: Before defining the observer load job, you must obtain a personal access token (PAT) from AWX. The token authentication is recommended for the usage of Tower's API.

1. Access the AWX UI.
2. From the menu bar, navigate to the **Users** page that is under the **Access** section.
3. Select a username, then click the **Token** option.
4. Click the **+** (plus) icon.
5. Leave the application field blank, and choose **read** for the token’s access.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

You define and start the following job.

Full Topology Upload job (through restapi)

By default, Load jobs are one-off, transient jobs that upload all of the requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job.	Required
Ansible AWX hostname	Specify the Ansible AWX hostname	Required
Ansible AWX host port	Specify the Ansible AWX host port	Required
Username (owner) of the personal access token (PAT)	Specify the username (owner) of the personal access token (PAT)	Required
Personal access token (PAT)	Specify the personal access token (PAT)	Required.
HTTPS truststore file name	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `Ansible.jks`.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.
truststore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
Target system certificate	Specify a certificate by name to automatically create and load into the truststore	Required
SSL verification	Choose whether SSL validation is true or false. Turning SSL validation to `false` will use HTTPS without host verification.	Optional
Number of jobs to display for each template	Specify the number of recent jobs that will be modeled on the topology for each of the job template. Max value is 50. Larger value might result in the topology being less perceptible	Optional
Connection timeout (milliseconds)	Enter a connection timeout in milliseconds	Optional. Must be a value greater than 0 (zero), and the default is `5000` (5 seconds).
Read timeout (milliseconds)	Enter a read timeout in milliseconds	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring AppDynamics Observer jobs

Using the AppDynamics Observer, you can define a full load job that will read data from the AppDynamics Controller through the REST API. This job can provide, for example, business applications, nodes, and tiers.

Before you start

Important: The AppDynamics Observer supports the cloud and SaaS AppDynamics version 4.5.12 and API version 4.5.x.

Ensure you have the AppDynamics details to hand, such as the instance, account, username and password before running the observer job.

Tip: Before defining the observer load job, you must create an AppDynamics user with the correct permissions. This is required for REST API authentication.

1. On the AppDynamics Administration page, click the gear icon (upper right).
2. Under the Admin group, select **Administration**, then select the **Users** tab.
3. Select the **AppDynamics** option from the **Display users** drop-down list.
4. Assign all available roles to the user by selecting **Add from Roles** > **Select All** > **Done**, then click **Save**.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The AppDynamics Observer imports ITSM Resource Topology Service data.

You define and start the following job.

Full Topology Upload job

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
AppDynamics Controller instance	Specify the AppDynamics Controller instance	Required
Tenant account name	Specify the Tenant account name	Required
Username	Specify the name of the user of the specified tenant account	Required
Password	Specify the password for the specified user	Required
HTTPS instance target system	Set to `true` to discover HTTPS instance, and to `false` for HTTP instance.	Optional
SSL Verification	Choose to use SSL validation or not. The options are `true` or `false`.	Optional. The default is 'false', which uses HTTPS validation without hostname validation.
Connection timeout	Specify the connection timeout in milliseconds.	Optional. Default is 5000 (5 seconds).
Read timeout	Specify the read timeout in milliseconds.	Optional. Default is 5000 (5 seconds).
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional

Parameter	Action	Details
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring AWS Observer jobs

Using the AWS Observer, you can define jobs that read services data from the Amazon Web Services (AWS) through AWS SDK and generate a topology. The AWS Observer supports multiple Amazon web services such as EC2 for its 'elastic compute' services.

Before you begin

Important: The AWS Observer supports the cloud and SaaS AWS version 1.11.

The AWS Observer supports EC2 service and currently processes EC2 resources in the following order. When the account in use has insufficient privileges to access a resource, the observer skips the resource(s) and proceed to the next one.

- Instance
- AvailabilityZones
- NetworkInterfaces
- Volumes
- SecurityGroups
- VPCs
- Subnets
- RouteTables

Important: As a minimum, the account in use must have the DescribeInstances policy, or the observer job fails. For more information, see Identity and access management for Amazon EC2.

About this task

You define and start the following job.

Full Topology Upload job

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Job data tenant	Specify the unique data tenant name to track the discovered data for each job.	Required
AWS Access Key ID	Specify the AWS access key. **Tip:** You can find your access key ID using AWS's IAM console, the AWS CLI, or the AWS API. See the AWS Managing access keys for IAM users website for more information.	Required
AWS Secret Access Key	Specify the AWS secret key. For more information, see the AWS Managing access keys for IAM users website	Required
AWS Region	Specify the AWS region or multiple regions to discover	Required
Proxy	Specify the proxy (`true` or `false`)	Required. If set to `true`, you must supply the proxy host, port and protocol.
Proxy Host	Specify the proxy host	Optional (unless proxy is set to `true`)

Parameter	Action	Details
Proxy Port	Specify the proxy port	Optional (unless proxy is set to `true`)
Proxy Protocol	Specify the proxy protocol	Optional (unless proxy is set to `true`)
Property to exclude	Single or multiple properties to exclude	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Azure Observer jobs

Using the Azure Observer, you can define a full load job that will read data from Azure cloud services through its REST APIs and generate a topology.

Before you begin

Important: The Azure Observer supports the cloud and SaaS Azure version.

Ensure you have the Azure details to hand, such as the Tenant ID, Client ID, and client password before running the observer job.

Tip: To configure access to Azure resources, see the following information: Create an Azure Active Directory application and service principal that can access resources

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The Azure Observer retrieves topology data from Azure cloud services through REST APIs exposed by the Azure API server.

In addition to the standard resources, the following resources are now also supported:

- Load Balancers
- Virtual Machine Scale Set
- Virtual Network Gateway (including VPN Gateway and Express Route Gateway)
- ExpressRoute

You define and start the following job.

Full Topology Upload job

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Data center	Enter the data center of the Azure service	Required
Tenant ID	Specify the Azure account tenant ID	Required
Client ID	Specify the client ID to access the registered app	Required
Client password	Enter the client password to access the registered app	Required
Subscriptions to be discovered	Specify the subscription Ids to be discovered in comma-separated lists. To discover all subscriptions, use `*`	Optional
Connection timeout (milliseconds)	Define the Azure connection timeout in milliseconds. The default value is 5000.	Optional
Read timeout (milliseconds)	Specify the read timeout in milliseconds. The default value is 5000.	Optional
Proxy Host	Specify the proxy host	Optional
Proxy Port	Specify the proxy port; defaults to 8080	Optional
Proxy Username	Specify the proxy username.	Optional
Trust all certificates by bypassing certificate verification	Set to true to allow connection to target environment without verification.	Optional. The default is 'false'.
Proxy Password	Specify the proxy password.	Optional
Proxy Secure	Specify whether the proxy server is secure.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Big Cloud Fabric Observer jobs

You configure Big Cloud Fabric Observer jobs to dynamically load data from the Big Cloud Fabric REST interface.

Before you begin

Ensure you have the Big Cloud Fabric service details to hand, such as username, password, hostname and port.

About this task

The Big Cloud Fabric Observer job extracts Big Cloud Fabric resource information through REST and loads and updates the resources and their relationships within the topology service.

You define and start the following job:

LDAP job

Run this job whenever you need Big Cloud Fabric topology data refreshed.

By default, these jobs are one-off, transient jobs that perform a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them.

The Big Cloud Fabric Observer loads the following resources and their relationship:

Big Cloud Fabric resources and relationships loaded by the Big Cloud Fabric Observer LDAP job

Vertex	Description
Access Leaf	Access Leaf Switch part of DC fabric
Access Port	Access Leaf Switch port connected to Compute Node and Spine Switch port
Spine Switch	Spine Switch part of DC fabric
Spine Switch Port	Spine Switch port connected to Access Leaf Switch and L3 Router Port

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

LDAP job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Proxy hostname	Specify the proxy server name	Required
Proxy Port	Specify the proxy port number for the REST API	Required
Proxy username	Specify the proxy username	Required
Proxy password	Specify the proxy password	Required. Plain text password can be entered.
BCF authentication URL	Specify the BCF authentication URL.	Required
BCF Controller Host Name	Specify the BCF controller hostname in string format. The hostname is taken from the job parameter.	Required. **Note:** The BCF controller hostname value (together with the proxy hostname and username) identifies the source of data for a Big Cloud Fabric Observer job instance. If your BCF controller hostname changes after a job is created, you must create more than one job instance for each BCF controller hostname. If the BCF controller hostname **does not** change after the job is created, then create a single job instance with all BCF controller hostnames specified.
HTTPS or HTTP connection to the BCF authentication server	Specify whether the connection to the BCF authentication server should be HTTPS (secured) or HTTP.	Required
HTTPS or HTTP connection to the BCF proxy server	Specify whether the connection to the BCF proxy server should be HTTPS (secured) or HTTP.	Required
Trust all certificates Verification	Choose whether Trust all certificates Verification is true or false.	Required. When set to true, the observer will trust all certificates.
Delay between two api calls (in seconds)	Specify the delay between retries	Optional
Concurrency Level	Specify the Concurrency Level, with a minimum of 3 and a maximum of 5.	Optional
Authentication system certificate	Specify the BCF Authentication system certificate to be used (if any).	Optional. Required if the HTTPS or HTTP connection to the BCF authentication server parameter is true. To obtain authentication certificates using OpenSSL and store them as secrets, see the Configuring observer jobs security topic.
Proxy system certificate	Specify the BCF proxy system certificate to be used (if any)	Optional. Required if the HTTPS or HTTP connection to the BCF proxy server parameter is true. To obtain proxy certificates using OpenSSL and store them as secrets, see the Configuring observer jobs security topic.
SSL Host Name Verification	Choose whether SSL validation is true or false.	Optional. When SSL validation is set to false, the observer will make HTTPS connections without validating the proxy hostname of the provided certificate.

Parameter	Action	Details
Connection timeout (milliseconds)	Enter the time at which the connection actions time out.	Optional. Must be a value greater than 0 (zero), and the default is 5000 (5 seconds).
Read timeout (milliseconds)	Enter the time at which the read actions time out.	Optional. Must be a value greater than 0 (zero), and the default is 5000 (5 seconds).
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring BigFix Inventory Observer jobs

You configure BigFix Inventory Observer jobs to read data from a BigFix Inventory instance through its REST APIs, and generate a topology.

Before you begin

Important: The BigFix Inventory Observer supports BigFix Inventory 9.5.0.

Before configuring a BigFix Inventory job, ensure you have the BigFix Inventory details to hand such as the BigFix Inventory URL, API token and SSL truststore.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

You define and start the following job.

BigFix Inventory Observer job (full topology load)

Run this job whenever you need BigFix Inventory topology data refreshed.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Data Center	Specify the data centers in which the BigFix Inventory instance runs	Required.
BigFix Inventory instance URL	Specify the API URL of the BigFix Inventory endpoint (including port)	Required. Usually in the following format: https://<hostname or IP address>:<port>
BigFix Inventory API token	Enter the BigFix token for authentication	Required. Must be encrypted.

Parameter	Action	Details
HTTPS truststore file name	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `BigFixInventory.jks`.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.
Truststore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
BigFix Inventory resources	Specify the resources to be discovered	Optional. Lists supported values such as software, hardware or `*`. If left blank, all available resources are discovered.
BigFix Inventory certificate	Specify the name of the certificate to be loaded into the trust store	Required
SSL Validation	Choose whether SSL validation is on or off. Turning off SSL validation will use HTTPS without host verification.	Optional
BigFix Inventory connection timeout (ms)	Enter the time at which the connection times out	Optional. Must be a value greater than 0 (zero), and the default is 5000 (5 seconds).
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Troubleshooting: If you configure a BigFix Inventory Observer job, the pod for the job might not start. After you configure the job, if you view the list of all observers you might not see the BigFix Inventory Observer job (`bigfixinventory-observer`) pod listed with a status of running.

If you encounter this issue, you can manually enable the job by changing the value of `asm.bigfixinventoryObserver.enabled` to true:

```
helmValuesASM:
  asm.bigfixinventoryObserver.enabled: true
```

To change this value, you can run the following command:

```
oc patch asm.asm.ibm.com/aiops-topology --type=json -p
'[{"op":"add","path":"/spec/helmValuesASM/asm.bigfixinventoryObserver.enabled","value":true}]'
```

To verify that the pod is now running, run the following command:

```
oc get pods | grep -i big
aiops-topology-bigfixinventory-observer-7f8c465698-gtm5p          1/1     Running             0          5m
```

Configuring Ciena Blue Planet Observer jobs

Using the Ciena Blue Planet Observer, you can define jobs that will gather and read all topology data from the Blue Planet MCP instance by REST API and generate a topology.

Before you begin

Important: The Ciena Blue Planet Observer supports MCP 4.0.

Ensure you have the Ciena Blue Planet details to hand, such as API username, API password, MCP URL, MCP certificate, truststore file and truststore password.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The Ciena Blue Planet Observer has two jobs, the restapi load and WebSocket listen jobs.

- When a **load** job is run, it loads baseline topology data through Blue Planet MCP APIs: Network Elements (constructs), EquipmentHolder, Equipment, TPE (Terminating Point Encapsulation), and FRE (Forwarding Relationship Encapsulation).
- When a **listening** job is run, the observer listens to changes in resource's status from the BluePlanet MCP instance through a WebSocket connection.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Full Topology Upload job (through restapi)

By default, Load jobs are one-off, transient jobs that upload all of the requested topology data as soon as they are triggered.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
SSL truststore file name	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `VMVCenter.jks`.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.
SSL truststore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
Data Center	The data center the MCP instance is running in	Required
Tenant Name	The tenant to use	Required
Blue Planet MCP server URL	Specify the MCP server endpoint including port and version (such as `AUTH_URL`)	Required
Username	MCP API username	Required
Password	MCP API password.	Required
Blue Planet MCP certificate	Certificate name to load into the truststore	Optional
SSL Validation	Choose whether SSL validation is on or off. Turning off SSL validation will use HTTPS without host verification.	Optional
Connection timeout	Sets the connection and read timeout in milliseconds	Optional. Must be a value greater than 0 (zero), and the default is 5000 (5 seconds).
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

WebSocket Listen job parameters

A long-running job that monitors its source for updates and runs until it is explicitly stopped, or until the observer is stopped.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
SSL truststore file name	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `CienaBluePlanet.jks`.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.
SSL truststore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
Data Center	The data center the MCP instance is running in	Required
Tenant Name	The tenant to use	Required
Blue Planet MCP server URL	The URL of the MCP server instance	Required
Username	MCP API username	Required
Password	MCP API password	Required
WebSocket URL	The MCP WebSocket URL to connect to	Required
WebSocket Topics Subscriptions	The MCP topics to subscribe to	Required
Blue Planet MCP Certificate	Certificate name to load into the truststore	Optional
SSL Validation	Choose whether SSL validation is on or off. Turning SSL validation off will use HTTPS without host verification.	Optional
Connection timeout	Sets the connection and read timeout in milliseconds	Optional. Must be a value greater than 0 (zero), and the default is 5000 (5 seconds).
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Cisco ACI Observer jobs

You use the Cisco ACI Observer when you have a Cisco ACI environment with Cisco Application Policy Infrastructure Controller (APIC) in your environment. The Observer interfaces with Cisco APIC and makes active REST calls to Cisco APIC in the Cisco ACI environment.

Before you begin

Important: The Cisco ACI Observer supports the on-premises Cisco ACI version 4.1.

Ensure you have the Cisco ACI service details to hand, such as the Cisco APIC username, Cisco APIC password, Cisco APIC SSL truststore and Cisco APIC URL.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

Optional: Install and configure a proxy

The Cisco ACI Observer can (optionally) connect to Cisco ACI through a proxy. See the Proxy Host and Proxy Port parameters listed in the table. A proxy can be used to create a tunnel to the target system.

Example: Squid proxy

1. Install the squid proxy:

   ```
   sudo yum install squid
   ```

2. Edit the /etc/squid/squid.conf file to add ACL for the source and target system. Example of a line added:

   ```
   acl localnet src 1.2.3.0/19 # ASM Host
   ```

3. Initialize the squid directories:

   ```
   sudo squid -z
   ```

4. Configure the squid proxy for auto-start:

   ```
   sudo systemctl start squid
   sudo systemctl enable squid
   ```

For more information about the squid proxy, see http://www.squid-cache.org.

About this task

A Cisco ACI Observer job extracts Cisco ACI resources from Cisco APIC through REST, and then the observer loads and updates the resources and their relationships within the topology view.

You define and start the following jobs.

Restapi Load job

A transient (one-off) job that loads all requested topology data using Cisco APIC REST APIs to build a tenant logical construct topology or a fabric topology, and then exits.

A 'restapi' job loads initial topology data, and can resynchronize topology data from Cisco ACI when required.

You assign 'restapi' as the job type for /jobs/restapi observer endpoint.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

WebSocket Listen job

A long-running job that listens for notifications from Cisco APIC to build the topology and runs until it is explicitly stopped, or until the observer is stopped.

A 'websocket' job monitors changes from Cisco APIC object notification and updates the topology.

You always run a 'websocket' job **after** running a 'restapi' job type.

You assign 'websocket' as the job type for /jobs/websocket observer endpoint.

Cisco ACI objects and relationships loaded

The Cisco ACI Observer loads the following Cisco ACI objects and their relationships into the topology service:

Tenant Logical construct

- fvTenant
- fvAp - A policy owner in the virtual fabric
- fvAEPg - A set of requirements for the application-level EPG instance
- fvAEpP - Abstract representation of an endpoint profile
- fvEpP - An endpoint profile
- fvBD - A bridge domain is a unique layer 2 forwarding domain that contains one or more subnets
- fvCtx - The private layer 3 network context that belongs to a specific tenant or is shared
- vzBrCP - A contract is a logical container for the subjects, which relate to the filters that govern the rules for communication between endpoint groups (EPGs)
- vzOOBBrCP - An out-of-band binary contract profile can only be provided by an out-of-band endpoint group and can only be used by the external prefix set
- vzSubj - A subject is a subapplication running behind an endpoint group (for example, an Exchange server). A subject is parented by the contract, which can encapsulate multiple subjects

- vzFilter - A filter policy is a group of resolvable filter entries
- fvSubnet - A subnet defines the IP address range that can be used within the bridge domain
- fvRsCons -The Consumer contract profile information and on Cisco ACI console the option to create this object is through Consumed Contract. Used to build relationship between fvAEPg and vzBrCP
- fvRsBd - A source relation to the bridge domain associated to this endpoint group. Used to build relationship between fvBD and fvAEPg
- fvRsCtx - A source relation to a private layer 3 network context that either belongs to a specific tenant or is shared. Used to build relationship between fvBD and fvCtx
- vzRsSubjFiltAtt - The filter for the subject of a service contract. Used to build relationship between vzSubj and vzFilter

Fabric Topology

- fabricInst - A container object for fabric policies
- fabricNode - The root node for the APIC
- polUni - Represents policy definition or resolution universe
- firmwareRunning - Information about leaf or spine switch firmware running on a node
- firmwareCtrlrRunning - Information about each controller firmware that is running
- eqptLCSlot - The slot for the module card
- eqptLC - A line card (IO card) contains IO ports
- eqptPsuSlot - The power supply slot
- eqptPsu - The power supply unit
- eqptFtSlot - A fan tray slot
- eqptFan - The fan in a fan tray
- topSystem - Used to retrieve fabric node Operational State
- cnwPhysIf - The physical interface that is assigned to the node cluster
- l1PhysIf - The object that represents the Layer 1 physical Ethernet interface information object
- mgmtMgmtIf - The management interface
- lldpAdjEp - The LLDP neighbors, which contains the information regarding the neighbors
- eqptRsIoPhysConf - A source relation to an L1 Ethernet interface. Used to build relationship between l1PhysIf and eqptLC
- mgmtRsOoBStNode - An object that contains management ip address of fabric spine switches and fabric leaf switches

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: For more information, see the Configuring observer jobs security topic.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Tenant name	Use this to identify the tenant	Required. Set to **`admin`** if no specific tenant is referenced. Set to '' to load Fabric Topology resources.
Cisco APIC endpoint	Specify the API URL of the Cisco APIC endpoint	Required. Usually in the following format: https://[hostname or IP address]/api
Cisco APIC username	Specify the username to connect as, or listen to	Required
Cisco APIC password	Enter the password for Cisco APIC authentication	Required
HTTPS truststore file name	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (**`<observer>.jks`**), for example **`CiscoACI.jks`**.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.
Truststore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
Cisco APIC certificate	Specify a certificate by name to load into the truststore	Optional.
Read timeout	Specify the read timeout in ms (default is 2000)	Optional
SSL certificate validation	Choose whether SSL validation is on or off. Turning SSL validation off will use HTTPS without host verification.	Optional

Parameter	Action	Details
Connection timeout	Specify the connection timeout in ms (default is 5000)	Optional
Proxy Host	Specify the proxy host through which to connect	Optional
Proxy Port	Specify the proxy port, defaults to 8080	Optional
Trust all certificates by bypassing certificate verification	Set to true to allow connection to target environment without verification.	Optional. The default is 'false'.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Contrail Observer jobs

Using the Contrail Observer, you can retrieve topology data from Juniper Network Contrail Release 4.1 through REST APIs exposed by the Contrail apiserver. This observer is developed against Juniper Network Contrail that integrates with OpenStack orchestration platform (Ubuntu 18.04 + Contrail Cloud - Ocata).

Before you begin

Important: The Contrail Observer supports the on-premises Contrail version 4.1.0.

Ensure you have the Contrail API Server and OpenStack credentials details to hand. For rabbitmq jobs, you must also specify the location of the RabbitMQ queue and its authentication details.

About this task

You define and start the following jobs.

Rabbitmq Listen job

A long-running job that monitors its source for updates and runs until it is explicitly stopped, or until the Observer is stopped.

This job loads all supported resources during startup, and listens to RabbitMQ messages from 'vnc_config.object-update' fanout exchange.

The restapi job does not have to be run before running the rabbitmq job because the rabbitmq job performs a restapi job during initialization.

Restapi Load job

This job loads all supported resources.

Run this job whenever you need the Contrail topology data refreshed.

By default, Load jobs are one-off, transient jobs that upload all of the requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Rabbitmq Listen job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Contrail API URL	Specify the URL for the Contrail apiserver	Required
OpenStack Authentication URL	Enter the authentication URL for the identity service	Required
OpenStack username	Specify the OpenStack username to connect as (or to)	Required
OpenStack password	Specify the OpenStack password with which to authenticate	Required
RabbitMQ hostname or IP address	Enter a hostname or IP address for the RabbitMQ server	Required
RabbitMQ port	Specify the port for connection	Required
RabbitMQ username	Specify the username for authentication with RabbitMQ	Required
RabbitMQ password	Enter the password for authentication with RabbitMQ	Required
Authentication type	Specify the authentication type used.	Optional. The default is **Keystone**. The other option is **None**.
OpenStack project domain name	Specify the OpenStack project domain name	Optional
OpenStack user domain name	Specify the OpenStack project user domain name	Optional
OpenStack project name	Enter the OpenStack project name for version 3 authentication	Optional
OpenStack tenant name	Enter the OpenStack tenant name for version 2 authentication	Optional
OpenStack identity API version	Select an option from the drop-down list. Defaults to 3.	Optional
Connection and read timeout (milliseconds)	Choose the time at which the connection and read action times out	Optional. Must be a value greater than 0 (zero). The default is 5000 (5 seconds).
RabbitMQ virtual host	Enter the RabbitMQ virtual hostname	Optional. Default is /.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Restapi Load job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Contrail API URL	Specify the URL for the Contrail API server	Required
OpenStack Authentication URL	Enter the authentication URL for the identity service	Required
OpenStack username	Specify the OpenStack username to connect as (or to)	Required
OpenStack password	Specify the OpenStack password with which to authenticate	Required
Authentication type	Specify the authentication type used	Optional. The default is **Keystone**, the other option is **None**.
OpenStack project domain name	Specify the OpenStack project domain name	Optional
OpenStack user domain name	Specify the OpenStack project user domain name	Optional
OpenStack project name	Enter the OpenStack project name for version 3 authentication	Optional
OpenStack tenant name	Enter the OpenStack tenant name for version 2 authentication	Optional
OpenStack identity API version	Select an option from the drop-down list	Optional
Connection and read timeout (milliseconds)	Choose the time at which the connection and read action times out	Optional. Must be a value greater than 0 (zero). The default is 5000 (5 seconds).
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Datadog Observer jobs

Using the Datadog Observer functionality, you can load monitored hosts and their associated processes, and then visualize this data as a topology view in the IBM Cloud Pak for AIOps UI.

Before you start

Important: The Datadog Observer supports the cloud/SaaS Datadog version.

Ensure you have the Datadog server details to hand, such as the data tenant, API server URL, Auth API key and App key.

About this task

A Datadog Observer job extracts host and its associated processes from Datadog via REST API. The Observer loads and updates the resources and their relationships within the IBM Cloud Pak for AIOps core topology service.

You define and start the following job.

Full Topology Upload job

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Table. Parameter details

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Data Tenant	Enter the data tenant to track the Datadog topology	Required
API server URL	Enter the Datadog API base URL	Required
Auth API key	Specify the authorized API key to authorize with Datadog	Required
App key	Specify the application key to access the Datadog resources	Required
Configure Host API query	Specify the host API query. Each query parameters needs to be separated by ";" and its value needs to be inside "()". For parameters that support list, the values need to be separated by "," and API will treat them as AND operation	Optional
Configure Process API query	Specify the process API query. Each query parameters needs to be separated by ";" and its value needs to be inside "()". For parameters that support list, the values need to be separated by "," and API will treat them as AND operation	Optional
Datadog certificate	Specify the Datadog certificate to enable secure connection to the target system	Optional. For more information, see Configuring observer jobs security.
Certificate validation	Choose whether to use SSL validation ('true' or 'false'). Turning SSL validation off will use HTTPS without host verification.	Optional
Connection and read timeout (milliseconds)	Set the connection and read timeout value.	Optional
Trust all certificates	Trust all certificates without validating the certificate's contents. Choose 'true' or 'false'.	Optional
Number of connection retries	Set the number of times a connection should try again. The default value is 3.	Optional
Delay before a connection retry (milliseconds)	Specify the period of time in milliseconds to delay before a connection tries again.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring DNS Observer jobs

Using the DNS Observer, you can query internal DNS server performance, and use the returned information on response times and service addresses to create topologies within the topology service. The DNS Observer supports forward and reverse job types, with 'recurse' or 'no recurse' options.

Before you begin

Ensure you have the DNS access details to hand, such as DNS server, address types and port numbers.

Tip: The relationship types can be customized with line color, width and pattern functions. For more information, see the Creating custom relationship type styles topic.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The DNS Observer provides DNS query services and topological insight into how a specified DNS server is performing forward (name-to-IP address) or reverse (IP address-to-name) lookups. Query results include a list of addresses, information on how long it takes the DNS server to resolve a lookup, and, optionally (with the maximum number of recursive calls set at 200) how the DNS server is recursively resolving a given name or IP address.

Note: The DNS observer models the resources based on the DNS lookup record. A separate set of resources will be created for IPv4 and IPv6 discovery of the same domain name.

You define and start the following jobs.

Reverse lookup job

A transient (one-off) Load job that loads all requested DNS reverse (IP address-to-name) lookup topology data.

By default, Load jobs are one-off, transient jobs that upload all of the requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Forward lookup job

A transient (one-off) Load job that loads all requested DNS forward (name-to-IP address) lookup topology data.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: For more information, see the Configuring observer jobs security topic.

Reverse lookup job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
IP address	Enter the host or internet name to look up	Required
Server	Specify the DNS server	Required
Port	Specify the UDP DNS port	Optional
Address type	Specify either `IPV4` or `IPV6`.	Optional
Recursive query	Toggle **True** or **False**	Optional. If set to True, the maximum number of calls is set at 200.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.

Parameter	Action	Details
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Forward lookup job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Domain name	Specify a domain	Required
Address Types	Specify the address types to be observed	Required. Select either IPv4 or IPv6.
Server	Specify the DNS server	Required
Port	Specify the UDP DNS port	Optional
Address type	Specify either `IPV4` or `IPV6`.	Optional
Recursive query	Toggle **True** or **False**	Optional. If set to True, the maximum number of calls is set at 200.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Docker Observer jobs

Using the Docker Observer, you can discover Docker network resources, including Docker Swarm clusters, and then visualize (or model) this data as a topology view.

Before you begin

Important: The Docker Observer supports Docker 3.1.0.

Note: Docker UCP 3.1.0 supports only TLS 1.2 for SSL negotiation and no longer supports TLS 1 and TLS 1.1.

Ensure you have the details for your Docker job to hand, specifically your Docker system's Unix socket, and or host and port number.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

Using the Observer Configuration UI you configure observer jobs that query the Docker REST API to retrieve data and display it as a topology in the Topology Viewer. The Docker Observer can model external Docker systems, and it can also provide a System health view of the Docker

system on which IBM Cloud Pak® for AIOps runs.

The job parameters connect to a remote Docker using the host and port parameters.

Remote Docker

The 'host' and 'port' parameters of the job can be used to identify the TCP port that Docker can be reached on. The **unix_socket** parameter must not be supplied.

Docker is not accessible through TCP by default. To enable it, edit the 'docker.service' file. On Red Hat® OpenShift® Container Platform, this is available in `/usr/lib/systemd/system`. Amend the **ExecStart** option under the **Service** section to include a `-H` option. For example, to make it available externally on port 2375, you might add `-H tcp://0.0.0.0:2375`.

Note: If you want to continue to be able to access Docker through the default socket, for example if the Docker Observer container needs access, or if you want to be able to perform `docker ps -a` rather than `docker -H tcp://0.0.0.0:2375 ps -a`, then you need to also list it in the same line, as on the following example:

```
-H tcp://0.0.0.0:2375 -H unix:///var/run/docker.sockCopy
```

You must reload the configuration:

```
sudo systemctl daemon-reload
sudo systemctl restart docker
```

Tip: If this fails to start Docker, and a Unix socket (or no socket at all) was specified, check that no directory with that name exists. If you start Docker with just a TCP socket and no Unix socket, this creates a `/var/run/docker.sock` directory, which you must delete after Docker is stopped, so that you can restart with access through that Unix socket.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Host	Use this to identify the TCP host socket (HTTP or HTTPS) on which to access the remote Docker system	Required for **remote** Docker access only
Port	Use this to identify the TCP port (HTTP or HTTPS) on which to access the remote Docker system	Required for **remote** Docker access only
Unix Socket	Use this to access local docker environments using the complete path	Required for **local** Docker access only. Host and port parameters **must** be empty.
Username	Specify the username of the remote Docker environment with HTTPS	Required for remote Docker with HTTPS access only
Docker password	Specify the password of the remote Docker environment with HTTPS	Required for remote Docker with HTTPS access only.
Docker SSL Certificate	Specify the certificate file name	Optional
Docker SSL truststore File	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `Docker.jks`.	Required for remote Docker with HTTPs access only.The supported format is JKS and the file is relative to $ASM_HOME/security.
SSL truststore File Password	Specify the truststore password the observer will use to decrypt the truststore file. Use a password that conforms to your internal security requirements.	Required for remote Docker with HTTPs access only.
View	Use this to select which resources are modeled in the topology view	Optional. The Default displays running resources only. Options are **Container** (all running containers), **Image** (images used by running containers), and **Task** (running tasks only)
Containers to exclude	List container you want to exclude	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.

Parameter	Action	Details
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Dynatrace Observer jobs

Using the Dynatrace Observer, you can query a specified Dynatrace environment for information about its applications, services, process groups, and infrastructure entities.

Before you begin

Important: The Dynatrace Observer supports Dynatrace cloud, SaaS and Dynatrace onPrem v1.182.102.

Ensure you generate a Dynatrace token to access your Dynatrace environment. You also need topology access scope to access the Dynatrace resources.

Ensure you have the Dynatrace access details to hand, such as Dynatrace API URL and API token.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

You define and start the following job.

Dynatrace Load job

A transient (one-off) job that loads all requested Dynatrace resource data.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Notice: Dynatrace v1 API endpoints are no longer supported.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Dynatrace Observer job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Data tenant	Data tenant is used to track your data. It needs to be unique for each job or else it will override the previously discovered data.	Required
Base URL	Specify the API URL of the Dynatrace endpoint (including version). An example of a Dynatrace **cloud-based URL** is: `https://< your-environment-id >.live.dynatrace.com/api/v2/`, while an example of a Dynatrace managed or **onPrem URL** is: `https://< your-domain >/e/< your-environment-id >/api/v2/`	Required
Dynatrace API Token	Enter the Dynatrace token for authentication	Required
Enable/Disable Secure Connection to CSO's host	Select to either enable or disable a secure connection to the CSO's host. Set to true to secure the connection, or false to bypass it.	Required

Parameter	Action	Details
The entitySelectors for the Dynatrace v2 API	The format is `{"taskname" : "entitySelector"}`, and multiple tasks can be added to the entitySelector list. The **taskname (string, required)** is a user defined value that identifies each task uniquely. The **entitySelector** defines the scope of the query. Only entities matching the scope and criteria will be discovered. Separate each filter of entitySelector with ';' and place its value inside parentheses '( )'. For a filter that supports a list, separate the values using a comma ','. For more entitySelector information, see more details and example below this table.	Required
Edge Capture Direction	Choose to display either a one-directional or bi-directional edge topology. A (default) bi-directional direction uses both `FromRelationships` and `ToRelationships` edges when displaying the Dynatrace relationship, while a one-directional direction uses only `FromRelationships` edges. **Tip:** If the Dynatrace relationship is bi-directional, the observer will use both `FromRelationships` and `ToRelationships` between A and B, and also between B and A, and therefore both edges will be displayed in a bi-directional edge topology. If the Dynatrace relationship is one-directional, the observer will use `FromRelationships` from host A to host B, and also `FromRelationships` from host B to host A.	Optional
Number of records to be fetched per page	Number of records to be fetched per page. Maximum value is `4000` and minimum is `1`.	Optional. Default value is `4000`.
Relationship mapping for dynatrace with ASM	Observer relationship to be used for Dynatrace relationship. The user can use edge mapping values to also override the default values	Optional. Observer will use a default mapping for edges.
Entity mapping for dynatrace with ASM	Observer entity types to be used for Dynatrace entity type. Observer will use a default mapping for entity. The user can use entity mapping values to also override the default values.	Optional. If there is no default value then Dynatrace entity type will be used as ASM entity type.
Grouping vertex preference	The observer creates the defined topology for the discovered vertices based on the preference in this field.	Optional. Value can be **host** or **none**. - Default value is **none**, which indicates that no resource groups are created. - When **host** is selected, resource groups are created with the host as `seed` and its connected entities, except other hosts, as members.
Certificate validation	Option for SSL validation. Turning SSL validation off will use HTTPS without host verification.	Optional
Trust all certificates by bypassing certificate verification	Trust all certificates without validating the certificate's contents.	Required. Default value is true.
Connection timeout (milliseconds)	Set the connection timeout in milliseconds.	Optional. The default is 5000ms.
Read timeout (milliseconds)	Set the read timeout in milliseconds.	Optional. The default is 5000ms.
Proxy Host	Specify the proxy host to connect to.	Optional
Proxy Port	Specify the proxy port, defaults to 8080.	Optional

Parameter	Action	Details
Target system certificate	Specify a certificate by name to load into the trustStore.	Optional. To obtain authentication certificates using OpenSSL and store them as secrets, see Configuring observer job security.
Proxy Username	Specify the proxy user name to connect. Set for basic auth proxy.	Optional
Proxy Password	Specify the password for the proxy user (if `Proxy Username` has been specified).	Optional. Use plain text.
Proxy Secure	Specify whether to connect to the proxy in secure mode. Set to True for HTTPS proxy.	Optional. The default is 'false'.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Note: For the **Grouping vertex preference** job parameter, when **host** is selected for creating resource groups, the host unique ID is set as the seed during the processing of the host API response. Connected entities from the response (excluding connected hosts) are used as the members of the created resource group. In Dynatrace, entities like application, service, process and even custom data can be part of several hosts.

Dynatrace API entitySelector parameters and examples:

Examples:

Single task example:

```
{
"HostTask": "type(host);entityId(HOST-E9B8C2EF21BA5217,HOST-B343896535B69B84,HOST-
F4A80CBC1027416A);timeframe(now-10m);fields(properties.osType,properties.hypervisorType)"
}
```

Multiple tasks example:

```
{
"HostTask":"type(host);timeframe(now-10m);fields(properties)",
"AppTask":"type(application);timeframe(now-10m);fields(properties)",
"ServiceTask":"type(service_instance);timeframe(now-10m);fields(properties)",
"ProcessTask":"type(process_group_instance);timeframe(now-10m);fields(properties)"
}
```

Parameters:

- **!** (negation): For example `!entityName(eur01.ibm.com)`
- **type (string, required)**: Each task can only accept one type. You must set this criteria in the entitySelector. Negation is not supported by type.
- **mzName (string, list, optional)**: Management zone name of the entity
- **mzId (string, list, optional)**: Management zone id of the entity
- **entityName (string, list, optional)**: Name of the entity
- ✱ (wildcards): For example the string `"type(host);entityName(eur0*);..."` will fetch all of the hosts that start with an entityName of 'eur0', such as 'eur01.ibm.com,eur02.ibm.com', etc; while the string `"type(host);entityName(*eur0*);..."` will fetch all hosts that contain 'eur0' as part of their entityName parameters, such as `ibm.eur0.com,ibm.eur02.com`, etc.
- **entityId (string, list, optional)**: Id of the entity
- **tag (string, list, optional)**: Tags of the entity
- **state (string, list, optional, case-sensitive):** State of the entity
- **excludeRelationsWith**: Excludes the connectivity with the listed entity type. Negation is not supported.

- **timeframe (string, optional)**: Time frame of the entity. The time frame should be a minimum of 5m and a maximum of 24h. The format is timeframe-NU, where 'N' is the amount of time, and 'U' is the unit of time. The default is '(now-5m)'. Supported time units for the relative time frame are 'm' (minutes), and 'h' (hours). For a setting of `timeframe-1hr`, the observer filters out if the lastSeenTms is within one hour of the observer job's start time, and only model those resources.
- **fields (string, list, optional)**: Entity fields that will be added to the entity vertex

Configuring File Observer jobs

Using the File Observer functionality, you can write bespoke data to a file in a specific format, upload this data to the topology service, and then visualize this data as a topology view.

Before you begin

The File Observer reads topology data from specified files, and uploads it. You must create these files manually.

About this task

Topology data in a file is composed of vertices (nodes) and edges. A vertex represents an object (resource), while an edge represents the relationship between two objects.

Each line of the file you create should be in one of the following formats, loading a single resource vertex (including optional relationships in the '_references' field) or a single edge, deleting a single vertex, or pausing execution.

Lines starting with `V:` (vertex), `E:` (edge), `D:` (delete) or `W:` (wait) are treated as instruction lines to be processed. Other lines, for example lines that are empty or commented out, are ignored.

Line format

V - Load a resource vertex, with a JSON representation as documented for the body of the topology service API method: `POST /resources`

If specifying the `_status` element, acceptable state values are `open`, `closed`, or `clear`, and acceptable severity values are `clear`, `indeterminate`, `warning`, `minor`, `major`, or `critical`. The following **geolocation example** adds `point` geolocation data as a GeoJSON object inside the vertex JSON, with the coordinates being longitude first, then latitude.

```
V:{"name":"Smallbrook Junction", "uniqueId":"gb-nr-SAB", "entityTypes":["railStation"], "geolocation":
{"geometry":{"coordinates":[-1.15511,50.71141],"type":"Point"}}}
```

E - Load an edge, with a JSON representation as documented for the `_references` section of the body of the topology service API method `POST /resources`.

D - Delete a resource vertex, identified by it's `uniqueId`.

W - Pause for the duration (for testing purposes only). Takes an integer period followed by a string specifying the units.

G - To load a group via the File Observer, see the following example syntax:

```
G:{"uniqueId":"EA","entityTypes":["group"],"name":"Event Analytics"}
```

Note: When creating a group's edge, it must be based on `uniqueId`.

Important: Ensure that the file is structured correctly. For each line of the file, information included after the closing **}** that matches an opening **{** is ignored, and no error is recorded.

Mapping alerts to topologies: When using the File Observer to correlate events from Logs Anomaly, ensure you use the `matchTokens` property when creating topology templates. The `matchTokens` property is a list of values you can use to look up a resource from an alert. If a unique `matchToken` is found that matches an alert's resource fields, such as `resource.name` or `resource.sourceId`, the alert will be assigned to that resource.

File Observer syntax

When uploaded to the file observer in a file, say `example.txt`, the following small topology can be generated by running a File Observer job for that file. The figure also shows an alert matched to a resource.

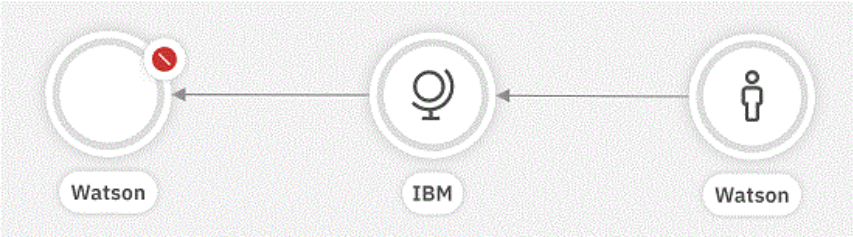

Figure. File Observer topology

```
V:{"uniqueId":"Thomas J. Watson","entityTypes":["person"],"name":"Watson"}
V:{"uniqueId":"IBM","entityTypes":["company","domain"],"name":"IBM","_references":
[{"_edgeType":"owns","_toUniqueId":"Cloud Pak for AIOps"},{"_edgeType":"contributedTo",
"_fromUniqueId":"Thomas J. Watson"}]}
V:{"uniqueId":"Cloud Pak for AIOps","entityTypes":["ai"],"name":"Watson","platform":"OCP","matchTokens":
["AIOps","Cloud Pak for AIOps"]}
```

Line 1: This line has the minimal set of properties for a resource vertex:

- `uniqueId` - Uniquely identifies the resource within the provider namespace (the provider is supplied when running the job).
- `entityTypes` - Determines the icon displayed in the UI. Some types have a pre-defined mapping to icons, as described in the Entity types topic.
- `name` - The label displayed in the UI.

Line 2: This line shows multiple entityTypes. There is no default icon mapped to type company, so the icon is determined from the domain type. In addition to the properties of the resource, this adds an edge to another resource.

- The edgeType must exist already. Either one of the default Edge types or one created by the topology service's `POST /types/edge` API (see Accessing APIs)
- The referenced uniqueId does not have to exist yet.
- Multiple edges can be added in the `_references` list.

Line 3: This line shows that more data or properties can be added. It adds a custom `platform` property (might be any additional property required). See the Properties topic for a list of existing properties. This line also illustrates that any `entityType` can be supplied, and that the `name` does not have to be unique. The UI does not show an icon for this resource because no default icon mapping has been created. You can add custom mapping through the UI as described in the Defining custom icons topic. And finally, this line also adds a `matchToken` property, which is a list of values that can be used to link a resource to an alert.

File Load job

By default, Load jobs are one-off, transient jobs that upload all of the requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Save** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required.
File mode	Select either **Upload local file**, then drag and drop (or browse) to the input file; or **Use server file**, then specify the name of the file previously uploaded through the `POST /files` API.	Required. **Note:** If the same file name is used in a second job, or the file is replaced through `PUT /files`, any resources missing from the second load will be deleted.
Provider	Enter the job's provider, that is, a namespace for the resources' uniqueIds. Resources can be loaded from multiple files with the same provider, and linked as if they were all loaded from the same file. To link to resources from another provider (for example, from another observer), the cross-provider semantics are required.	Optional. Defaults to `FILE.OBSERVER:{fileName}` if not supplied.
Include delays	Select **true** (default) to accept any delays included in the files, or **false** to skip such delays.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.

Parameter	Action	Details
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Swagger API documentation

For the Swagger API documentation, see Topology File Observer API. The documentation explains how to use the File Observer APIs.

File Observer API access

Two public APIs are available, and both APIs can be used to retrieve data.

- **API name**

  topology-file-observer

- **Public API URLs**

  `/aiops/api/application-manager/topology-file-observer/v1/*`

  `/aiops/api/app/topology-file-observer/v1/*`

For information on how to obtain route and token information, see Accessing the console.

For information on how to obtain your token, see Accessing APIs.

Example API queries

GET /health API

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}"
https://$ROUTE/aiops/api/application-manager/topology-file-observer/v1/healthcheck
{"date":"2021-02-05T19:24:00.974+00:00","jobs":0,"threads":10,"items":[{"type":"load"}]}
```

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}"
https://$ROUTE/aiops/api/app/topology-file-observer/v1/healthcheck
{"date":"2021-02-05T19:24:00.974+00:00","jobs":0,"threads":10,"items":[{"type":"load"}]}
```

GET /service/info API

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}"
"https://$ROUTE/aiops/api/application-manager/topology-file-observer/v1/service/info"
{"startDate":"2021-02-04T10:30:56.991+00:00","id":"example-noi-topology-file-observer-6f88fb6fc4-
n9xm2","name":"file-observer","version":"1.1.0.17 66dd27a","adminConnector":"https://example-noi-topology-
file-observer-6f88fb6fc4-n9xm2:9099","appConnector":"https://example-noi-topology-file-observer-6f88fb6fc4-
n9xm2:9098","uptimeMillis":118575702}
```

```
curl -k -X GET --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}"
"https://$ROUTE/aiops/api/app/topology-file-observer/v1/service/info"
{"startDate":"2021-02-04T10:30:56.991+00:00","id":"example-noi-topology-file-observer-6f88fb6fc4-
n9xm2","name":"file-observer","version":"1.1.0.17 66dd27a","adminConnector":"https://example-noi-topology-
file-observer-6f88fb6fc4-n9xm2:9099","appConnector":"https://example-noi-topology-file-observer-6f88fb6fc4-
n9xm2:9098","uptimeMillis":118575702}
```

Upload a file

```
curl -k -X POST --header 'Accept: application/json' -H "Authorization: Bearer ${TOKEN}"
https://$ROUTE/aiops/api/app/topology-file-observer/v1/files --form 'job_file=@/tmp/file.json.txt' --header
'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255'
```

Creating cross-data origin relationships

Using the File Observer functionality, you can create edges between resources from different observations or providers.

It requires both the `uniqueID` and the provider of the resources at each end of the link (so typically applies to previously observed resources).

In the following syntax examples, note the **_toProvider** and **_fromProvider** edge properties.

You can define an edge from a resource in the current observation to one owned by a different provider:

```
V:{"uniqueId":"host1.ibm.com","entityTypes":["host"],"name":"host1","_references":
[{"_edgeType":"connectedTo","_toProvider":"someOtherProvider","_toUniqueId":"host2.ibm.com"}]}
```

You can define an edge from a resource between two different providers:

```
E:{"_fromProvider":"providerOne","_fromUniqueId":"host1-
interface1","_edgeType":"connectedTo","_toProvider":"providerTwo","_toUniqueId":"host2-interface1"}
```

File Observer sample files

You can upload sample file data to the topology service on File Observer, and then view this data in the topology. To download the sample files, go to Sample files.

Configuring GoogleCloud Observer jobs

Using the GoogleCloud Observer, you can define a full load job that will read services data from the Google Cloud Platform Compute Services through Google's Compute Services SDK, and then generate a topology.

Before you begin

Important: The Google Cloud Observer supports the cloud and SaaS Google Cloud version.

The GoogleCloud Observer supports GoogleCloud's compute services. Ensure you have the GoogleCloud details in hand, such as the Project ID, Service Account Key File and Zone, before running the observer job.

The GoogleCloud Observer supports a transient (one-off) Load job that loads all requested topology data through Google's Compute Services SDK to build the topology, and then exits.

To create a service account key file

1. From the Google Cloud Platform dashboard, under your 'Project ID', go to APIs and Services and then choose **Credentials**. The Credentials page is displayed listing a number of authentication methods.
2. Select the **Service account** authentication service
3. From **Create Credentials**, choose **Service account**.
4. Complete the service account details, then click **Create** to create a new service account.
5. Select the **Compute Engine > Compute Admin** role, then click **Continue** and **Done**.
6. To download the JSON file from the Credentials page, click **Service account > Manage Service Accounts**.
7. Select the new service account, then choose **Create key** from the overflow menu (the three dots under the **Actions** column).
8. Choose a key type of JSON, then click **Create**. A JSON file will be downloaded. For more information on storing the service account key file as a secret, see the Configuring observer jobs security topic. The file name will be used in the observer parameter (service_account_key_file) for the full load job.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

You define and start the following job. You must edit the parameters in the configuration file before running this job.

Full Topology Upload job

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: For more information, see the Configuring observer jobs security topic.

Parameter	Action	Details

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Project ID	Enter the Google Cloud Platform Project ID	Required
Service Account Key File	Supply the Google Cloud Platform Service Account Key File	Required
Zones	Specify the Google Cloud Platform zones	Required.
Connection timeout	Specify the connection timeout in ms (default is 5000)	Optional
Read timeout (milliseconds)	Specify the read timeout in milliseconds. The default value is 5000.	Optional
Proxy Host	Specify the proxy host via which to connect.	Optional
Proxy Port	Specify the proxy port. Set as per HTTP/HTTPS Proxy Host.	Optional. Defaults to 8080.
Proxy Username	Specify the proxy username. Set for basic auth proxy.	Optional
Trust all certificates by bypassing certificate verification	Set to true to allow connection to target environment without verification.	Optional. The default is 'false'.
Proxy Password	Specify the proxy password. Set if Proxy Username has been specified.	Optional. Use plain text.
Proxy Secure	Specify whether the proxy server is secure. Set to 'true' for HTTPS proxy.	Optional. Default is 'false'.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Note: You must create a service account key file or use an existing one to allow the GoogleCloud Observer to discover resources from GoogleCloud.

Troubleshooting: While the job is running, the status of discovered resources may appear as 'indeterminate' in the topology until the full upload is complete.

Configuring HP NFVD Observer jobs

You configure HP NFVD Observer jobs to dynamically load data from the HP NFVD REST interface.

Before you begin

Important: The HP NFVD Observer supports the HPE NFV Director API release 6.0.3.

Ensure you have the HP NFVD service details to hand, such as username, password, hostname and port.

About this task

The HP NFVD Observer job extracts HP NFVD resource information through REST. The observer loads and updates the resources and their relationships and then displays them as a topology view.

You define and start the following jobs.

Load job

Run this job whenever you need HP NFVD topology data refreshed.

By default, these jobs are one-off, transient jobs that perform a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them.

Fileload job

Run this job to consumes topology data from a file.

The fileload job loads a baseline topology data view from a provided data file.

The fileload job is a transient (one-off) job that consumes topology data from the file, sends the data for processing, and then stops.

The fileload job provides an alternative to loading topology data through a file.

Listen job

A long-running job that reads LCM events published by HP NFVD on CGMB (Kafka) topic continually until it is explicitly stopped, or until the observer is stopped.

LCM messages in Kafka are typically encoded in Avro and are decoded by the observer using an HP NFVD LCM notification Avro schema file. Refer to the HP NFVD documentation on how to obtain the schema file. The additional steps required when using an Avro schema file are documented in the following subsection of the procedure.

The job should only be run *after* a load job has been completed.

HP NFVD resources and relationships loaded by the HP NFVD Observer job

The HP NFVD Observer loads the following resources and their relationship into the Agile Service Manager core topology service:

Vertex	Description
Organization	Organization (for example, LOB) within Domain
VDC	Tenant within Organization
VNF Group	Group of VNF / CNF
VNF	Virtual Network Function
CNF	Containerized Network Function
VNFM	Manager of VNF/CNF
VM	Virtual Machine attached to VNF
Network Interface / Port	Network Interface or Port attached to VNF
Connection Point	Internal Connection Point
VNF-C	VNF Component
CNF-C	CNF Component
Virtual Link	Virtual Network attached to VNF
Virtual Storage	Storage attached to VNF
Deployment	K8s resources attached to CNF
Statefulset	K8s resources attached to CNF

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: For more information, see the Configuring observer jobs security topic.

Load job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
HP NFVD data center name	The name of the data center on which the HP NFVD is hosted.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.
HP NFVD hostname	Specify the hostname of the HP NFVD.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.

Parameter	Action	Details
HP NFVD host port	Specify the port of the HP NFVD.	Required
HP NFVD username	Specify the username.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.
Password	Enter the password with which to authenticate.	Required. Plain text password can be entered.
HTTPS or HTTP connection to the HP NFVD server	Choose to make either a HTTPS (secured) or HTTP connection to the HP NFVD server.	Required. When set to true, provide the target system certificate to the certificate parameter.
True for a CNF job and false for a VNF job	The VNF job is expected to run with fewer threads and will take longer to complete. If this filter parameter is set to **`false`**, cnf_group_filters defines group names to exclude. If this filter parameter is set to **`true`**, cnf_group_filters defines group names to include.	Required
Target system certificate	Specify a certificate by name to load into the trustStore.	Required if the **`HTTPS connection to the HP NFVD server`** parameter is set to true. To obtain authentication certificates using OpenSSL and store them as secrets, see Configuring observer jobs security.
SSL Verification	Choose whether SSL validation is true or false. Turning SSL validation false will use HTTPS without hostname validation.	Optional
Connection timeout	Enter the time at which the connection actions time out.	Optional. Must be a value greater than 0 (zero). The default is 5000 (5 seconds).
Read timeout	Enter the time at which the read actions time out.	Optional. Must be a value greater than 0 (zero). The default is 5000 (5 seconds).
First retry after delay (milliseconds)	Set the initial delay for a retry.	Optional
Correlate	Set this to true to enable Event Analytics correlation on the topology grouping based on VNF Groups created by this job.	Optional
CNF group name for filters	If specified, this parameter selects CNF groups by partial matching on group name. For example, if **`CNF1,CNF2`** is specified, then a CNF job will only process matching groups such as 'MyCNF1Yeh' and 'YourCNF2No', and a VNF job will process groups that do not match.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Fileload job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
HP NFVD data center name	The name of the data center on which the HP NFVD is hosted.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.

Parameter	Action	Details
HP NFVD hostname	Specify the hostname of the HP NFVD.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.
HP NFVD username	Specify the username.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.
Name of the VNF or CNF data file	Specify the name of the VNF or CNF data file. Wildcards (`*`) are supported. Use separate data files for CNF and VNF resource types. **Tip:** If the filename contains the token `nfvd-cnf-data-dump/nfvd_cnf_data_dump`, it is treated as a **CNF** resource. If the filename contains the token `nfvd-vnf-data-dump/nfvd_vnf_data_dump` then it is treated as a **VNF** resource.	Required. The data file must be located in the $/opt/ibm/netcool/asm/data/hpnfvd-observer directory.
HP NFVD archive file retention days	Specify the number of days that the HP NFVD archive files are retained.	Optional. Default is 5 days.
Correlate	Set this to true to enable Event Analytics correlation on the topology grouping based on VNF Groups created by this job.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Listen job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
HP NFVD data center name	The name of the data center on which the HP NFVD is hosted.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.
HP NFVD Kafka broker host	Specify the hostname of the HP NFVD.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.
HP NFVD Kafka broker port	Specify the port number of the Kafka broker.	Required
The HP NFVD Kafka topic to listen for LCM notifications	Specify the topic name for LCM notifications.	Required
HP NFVD username	Specify the username.	Required. **Important:** To observe the complete lifecycle of resources, configure the same data center name, username and hostname across all jobs.

Parameter	Action	Details
True for a CNF job and false for a VNF job	Specify `True` for a CNF job, or `False` for a VNF job. The VNF job is expected to run with fewer threads and will take longer to complete.	Required. **Important:** To observe the complete lifecycle of resources, this must be the same as the option used in the Load job.
SSL	Choose to turn SSL on (or off) for Kafka connection. Turn this option on if the Kafka connection is secured using SSL.	Optional
Avro Decoding	Choose whether Avro decoding is on or off (True or False). Set to `True` if incoming LCM messages are Avro encoded. If so, the Avro schema file is required.	Optional. Default is false.
Avro schema file	The name of the Avro schema file to be used in decoding binary Avro Kafka messages.	Required if Avro Decoding is set to true. Complete the Avro schema file setup.
Kafka TrustStore file	Specify the truststore file used to establish a secured connection to the Kafka broker	Required if SSL has been enabled. For TrustStore and KeyStore configuration, see Avro schema file.
Kafka trustStore password	Enter the password of the Kafka truststore	Required if a Kafka TrustStore file is specified. Use plain text.
Kafka KeyStore file	Specify the keyStore file used to establish a secured connection to the Kafka broker	Required if SSL has been enabled. For TrustStore and KeyStore configuration, see Avro schema file.
Kafka keyStore password	Enter the password of the Kafka keyStore	Required if a Kafka KeyStore file has been specified. Use plain text.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

To use the Avro schema file

Avro schema file setup is required if the Avro decoding parameter is set to `True`.

To use the LCM Avro schema file, create a ConfigMap for the schema file to be mounted to the existing volume. If Kafka is in secured mode (SSL), additionally create two ConfigMaps (that is, truststore and keystore to be mounted to the existing volume).

Assumption: The Kafka keystore and truststore files are already set up together with the LCM Avro schema file.

1. Create a configMaps to mount the schema files to the existing volume.

   a. Create ConfigMaps to mount schema files to the existing volume.

   The example below creates the ConfigMap Avro schema file named 'lcm-notification-schema.avsc':

   ```
   oc create configmap hpnfvd-lcm-notification-schema --from-file=lcm-notification-schema.avsc
   ```

   If Kafka is secured (SSL), keystore/truststore is most likely required. The example below creates ConfigMaps using the keystore file named 'keystore', and the truststore file named 'truststore':

   ```
   oc create configmap hpnfvd-kafka-truststore --from-file=truststore
   ```

   ```
   oc create configmap hpnfvd-kafka-keystore --from-file=keystore
   ```

   After creating the ConfigMap, you can verify the results using one of the following commands:

   ```
   oc describe <configMap name>
   ```

   or

```
oc get <configMap name>
```

b. Map the ConfigMap to a volume in the pod's deployment.

Add to the existing volume, (asm-security), under 'volume Mounts' and 'volumes':

```
volumeMounts:
  - mountPath: /opt/ibm/netcool/asm/security          <--- existing mount
    name: asm-security

volumes:
  - name: asm-security

  - configMap:
    name: hpnfvd-lcm-notification-schema
    optional: false
    items:
    - key: lcm-notification-schema.avsc
      path: lcm-notification-schema.avsc
```

You can verify the results using the following command:

```
oc exec -it <pod-name> -- ls /opt/ibm/netcool/asm/security
```

The schema files should be listed.

Configuring IBM Cloud Observer jobs

Use the IBM Cloud Observer when you have IBM Cloud installed in your environment to run jobs that read data from an IBM cloud instance. These jobs retrieve Cloud Foundry Apps information and services, and then dynamically load the retrieved data.

Before you begin

Important: The IBM Cloud Observer supports the cloud and SaaS IBM Cloud version.

Important: The IBM Cloud Observer supports Cloud Foundry API version 2.92.

Ensure you have the IBM Cloud access details to hand to specify and access the cloud instance, such as the instance ID, credentials, and region.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

You define and start the following job.

Full Topology Upload job

The IBM Cloud Observer imports ITSM Resource Topology Service data.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Mapping IBM Cloud model objects to entity types

IBM Cloud resource object	Entity types
stacks	`operatingsystem`
apps	`application`
routes	`path`
service bindings	`hub`
service instance	`service`
user provided service instance	`service`
spaces	`group`
organization	`organization`
buildpacks	`component`

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Password	Enter the password or API key used to access the instance.	Required
Instance	Enter the name of the IBM cloud instance.	Required
IBM Cloud Region	Choose the cloud instance region from the drop-down list (US, UK, EU, AP)	Required. Each region has its own URI, and only a single region is discovered in a full load job. To discover different regions, a full load job needs to be triggered for each region.
User email	The email address used to access the instance, or enter **`apikey`** if IBM Cloud API Key is used.	Required. See Creating an API key on steps to create an IBM Cloud API key.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Jenkins Observer jobs

Using the Jenkins Observer, you can define listen jobs that receive build information generated by the Jenkins plug-in.

Before you begin

Ensure you have all required Jenkins details to hand.

Before you configure the Jenkins Observer, you must install and configure the Jenkins plug-in provided with the installation images. The plug-in sends your instrumented build data to the Jenkins Observer in order to generate the appropriate topology information: Configuring the Jenkins plug-in.

For the Jenkins plug-in to be able to communicate and send information to a Jenkins Observer job, you must enable a URL route for the Jenkins Observer, which is not exposed in your installation by default.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

You define and start the following job.

Listen job: The stand-alone listen job receives Jenkins build notification data for a specified namespace and processes it as a topology.

The listen job is long-running, and runs until it is explicitly stopped or until the observer is stopped.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Provider namespace	Specify a provider namespace with which to associate all the topology data generated by this job	Required
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring the Jenkins plug-in

The IBM Cloud Pak® for AIOps software includes the Jenkins plug-in, which you install on your Jenkins server using the Jenkins Plugin Manager Advanced installation web UI. From the Jenkins server, the plug-in gathers and sends information to the Jenkins Observer.

Ensure you have all the required administrator or management permissions to deploy the IBM Cloud Pak for AIOps Jenkins component onto the Jenkins server.

Plug-in	Version	Description
Jenkins core	2.159	Jenkins server minimum version
apache-httpcomponents-client-4-api	4.5.10-2.0	Provided by Jenkins core
workflow-step-api	2.22	
workflow-cps	1.9	
workflow-multibranch	2.17	
credentials	2.3.1	Compatible version usually provided by Jenkins core
Git	2.6.5	
artifactory	3.15.0	Optional (for using the Artifactory integration only)

Obtain the Jenkins plug-in

You can find the Jenkins plug-in included with the Jenkins Observer image. For example:

```
JENKINS_OBSERVER_POD=(oc get po -l app.kubernetes.io/name=jenkins-observer -o
jsonpath='{.items[0].metadata.name}')

echo {JENKINS_OBSERVER_POD}
evtmanager-topology-jenkins-observer-84c456f58c-jxlrj
```

To copy the plug-in from the image:

```
oc cp JENKINS_OBSERVER_POD:/opt/ibm/asm-observer-plugin-2.0.0-SNAPSHOT.hpi asm-observer-plugin-2.0.0-
SNAPSHOT.hpi

ls asm-observer-plugin-2.0.0-SNAPSHOT.hpi
asm-observer-plugin-2.0.0-SNAPSHOT.hpi
```

Obtain credentials

The credentials for the API are dynamically created. If IBM Cloud Pak for AIOps is installed with a release name of **asm**, then:

```
CREDS_USER=(oc get secret evtmanager-topology-asm-credentials -o jsonpath={.data.username} | base64 -d)
CREDS_PASS=(oc get secret evtmanager-topology-asm-credentials -o jsonpath={.data.password} | base64 -d)
```

Use the following command to print the UI API credentials:

```
echo CREDS_USER CREDS_PASS
```

Example user and password credentials returned:

```
aimanager-topology-aiops-user N8gJJGEfmmDnF6Q/1zg8NyAGKgQ9PmZQLhUSKd9/j54=
```

Obtain certificate

The following sample steps apply to the default router deployed on Red Hat OpenShift Container Platform. If more routers are used, adjust these steps. You perform these steps as **cluster administrator**.

Obtain the certificate:

```
oc get secret -n openshift-ingress router-certs-default -o jsonpath='{.data.tls\.crt}' | base64 -d > ocp-default-router.crt
```

Obtain the certificate key:

```
oc get secret -n openshift-ingress router-certs-default -o jsonpath='{.data.tls\.key}' | base64 -d > ocp-default-router.key
```

Convert to PKCS12:

```
openssl pkcs12 -export -out ocp-default-router.p12 -inkey ocp-default-router.key -in ocp-default-router.crt
Enter Export Password: enter-suitably-secure-password
Verifying - Enter Export Password: enter-suitably-secure-password
```

Ensure that the files you have extracted from Red Hat OpenShift Container Platform are securely deleted.

Obtain observer URL

Obtain the hostname as in the following example:

```
oc get routes -l app.kubernetes.io/name=jenkins-observer -o jsonpath='{.items[*].spec.host}'
```

The Jenkins plug-in defines Jenkins pipeline DSL steps that you use to instruct the Jenkins builds to generate and then send topology data to the Jenkins Observer. Use the DSL steps to send the notification to include Artifactory BuildInfo modules information, in order for the build products to be modeled. You create an observer instance, which then triggers the sending of the notification to the observer.

For information on configuring Jenkins Observer jobs, see the related tasks.

Important: You perform the following steps as **Jenkins administrator**.

Install the Jenkins plug-in

1. Log in to your Jenkins server with a user ID that has administration (management) permissions.
2. Navigate to **Manage Jenkins** > **Manage Plugins** and select the **Advanced** tab.
3. In the Upload Plugin section, upload and install the provided plug-in (asm-observer-plugin-2.0.0-SNAPSHOT.hpi)

Configure the Jenkins plug-in

1. Navigate to **Manage Jenkins** > **Configure System** and select the **Agile Service Manager plugin**.
2. Enter the Jenkins Observer URL obtained earlier in the **Observer URL** field.
3. Create credentials for IBM Cloud Pak for AIOps using the **Manage Jenkins** > **Credentials** configuration page.

   Enter the credentials and the certificate details obtained earlier from the (or as the) cluster administrator.

   Auth Credentials Enter the username and password to authenticate with the Jenkins Observer at API level.

   Click **ADD**.

   Certificate Enter the PKCS12 format certificate to secure the communication between the Jenkins plug-in and the observer using SSL.

   Click **ADD**.

   For more detailed information on using the Jenkins Credentials feature, see the Jenkins site: https://jenkins.io/doc/book/using/using-credentials/
4. Enter a **Default Tenant ID**.

The tenant to be used as default when sending information to IBM Cloud Pak for AIOps (if it is not overridden in the build).

5. Enter a **Default Job ID**.

   The default job ID to be used when sending information to IBM Cloud Pak for AIOps (if it is not overridden in the build). This represents the ID of the job the observer is running to process your information.

6. Click **TEST CONNECTION** to attempt to establish a connection with the observer using the configured credentials.

   If successful, a Connection successful! message is displayed. If unsuccessful, an error is returned.

   Note: The connection test does not verify the default job and tenant IDs.

Configuring your Jenkins build to notify IBM Cloud Pak for AIOps

After configuring the installed plug-in in Jenkins, you integrate the provided functionality into your existing Jenkins build. The following two steps describe how to use scripted pipeline syntax to send your build information to the observer.

Remember: You perform the following two steps on your Jenkins build (and **not** the Jenkins Observer).

1. Create an instance of the IBM Cloud Pak for AIOps observer communication object using the default credentials set during the configuration steps.

   ```
   def <my observer> = ASM.newObserver()
   ```

   Tip: Override credentials: to override any configured credentials (that is, the Jenkins credentials ID rather than the actual credentials themselves), you can use the following syntax:

   ```
   def <my observer> = ASM.newObserver
   authCredsId: 'auth-credentials-id', certCredsId: 'cert-credentials-id'
   ```

2. Send a build notification using the following syntax:

   ```
   ASM.notifyASM asmObserver: <my observer>
   ```

   Tip: You can override the default values for the tenant and job IDs:

   ```
   ASM.notifyASM tenantId: '<tenantId>', jobId: '<jobId>', asmObserver: <my observer>
   ```

   You can integrate the Jenkins plug-in with the Artifactory component using the modules information to model any artifacts the build has published to the repository:

   ```
   ASM.notifyASM asmObserver: <my observer>, artModules: <buildInfoObject>.getModules()
   ```

The following Jenkins file code sample shows the integration with IBM Cloud Pak for AIOps. It starts with the declaration of the observer instance, and ends with the notification to IBM Cloud Pak for AIOps. This notification should be added as a `post / always` block, so that the information is sent as the last operation of the build, and is sent regardless of the result of the build.

The optional `try / catch` around the notification to IBM Cloud Pak for AIOps is included in this sample to avoid the build failing if the notification to IBM Cloud Pak for AIOps fails.

The following sample also depicts the use of Artifactory to publish the build products, and how that information can be included in the notification to IBM Cloud Pak for AIOps using the artModules parameter.

```
**def asm = ASM.newObserver()**
def buildInfo = Artifactory.newBuildInfo()
buildInfo.env.capture = true

… your build logic here …
**
post {
    always {
      script {
            try {
                 ASM.notifyASM asmObserver: asm, artModules: buildInfo.getModules()
            } catch (err) {
                echo An error ocurred sending a notification to ASM:  {err}"
            }
          }
      }
   }
}**
```

Tip: You can further refine your integration and visualization.

After you install and configure the Jenkins plug-in, configure the Jenkins Observer listen job.

You can further refine your IBM Cloud Pak for AIOps system to take advantage of its topology and other customization functionality. For more information, see Customizing the Jenkins topologies.

You can extend your Jenkins integration with rules to merge data from different sources, custom topology display conventions, and the use of templates for the automated generation of topologies. For more information, see Additional Jenkins plug-in customization tasks.

More Jenkins plug-in customization tasks

You can extend your Jenkins integration with rules to merge data from different sources, custom topology display conventions, and the use of templates for the automated generation of topologies.

You first install and configure the Jenkins plug-in, before extending its functionality as described here.

Trouble: For useful Jenkins troubleshooting information, see troubleshooting.

Customizing the Jenkins topologies

You can customize how your Jenkins topologies are displayed in a number of ways, either by using the Jenkins customizations supplied with IBM Cloud Pak® for AIOps, or by creating your own custom display elements.

Creating Jenkins topology templates

Over time topologies generated through a specific Jenkins Observer job may grow, including the information from different Jenkins builds. You can use the IBM Cloud Pak for AIOps topology template functions to create meaningful, scoped views per build.

Example

The information obtained from Jenkins through the Red Hat OpenShift Container Platform plug-in for Jenkins and the Jenkins Observer includes URLs for several Jenkins elements. You can create topology tools that use these URLs to provide in-context navigation to Jenkins or your Git repositories from within the topologies displayed in Red Hat OpenShift Container Platform. The code snippets in this section demonstrate how to create such tools.

If required, you can customize how your Jenkins topologies are displayed further using the Configuring topology elements topics.

Opens a GitHub repository commits log

```
function url2Http(url) {
  if(url.indexOf("http") != -1) {
      return url;
  }
  var res = url.split(":");
  var ghUrl = res[0].replace("git@", "https://");
  var repoUrl = res[1].replace(".git", "");
  return ghUrl + "/" + repoUrl;
}

if (asmProperties.repositoryUrl && asmProperties.revision) {
    var normUrl = url2Http(asmProperties.repositoryUrl);
    window.open(normUrl + '/ commits/'
        + asmProperties.revision);
}
```

Relationship type is **builds**

Opens the specific commit

```
function url2Http(url) {
  if(url.indexOf("http") != -1) {
      return url;
  }
  var res = url.split(":");
  var ghUrl = res[0].replace("git@", "https://");
  var repoUrl = res[1].replace(".git", "");
  return ghUrl + "/" + repoUrl;
}

if (asmProperties.repositoryUrl && asmProperties.revision) {
    var normUrl = url2Http(asmProperties.repositoryUrl);
```

```
    window.open(normUrl + '/commit/'
        + asmProperties.revision);
}
```

Relationship type is **builds**

Opens the Jenkins resources records

```
if (asmProperties.url) {
    window.open(asmProperties.url);
}
```

Resource types are **person**, **build**, **job**

Opens a GitHub repository tree view from the commit

```
function url2Http(url) {
  if(url.indexOf("http") != -1) {
      return url;
  }
  var res = url.split(":");
  var ghUrl = res[0].replace("git@", "https://");
  var repoUrl = res[1].replace(".git", "");
  return ghUrl + "/" + repoUrl;
}

if (asmProperties.repositoryUrl && asmProperties.revision) {
    var normUrl = url2Http(asmProperties.repositoryUrl);
    window.open(normUrl + '/tree/'
        + asmProperties.revision);
}
```

Relationship type is **builds**

Opens the build log console view in Jenkins

```
if (asmProperties.buildConsoleLog) {
    window.open(asmProperties.buildConsoleLog);
}
```

Resource type is **build**

Creating Jenkins topology templates

Over time topologies generated by a specific Jenkins Observer job may grow, including the information from different Jenkins builds. You can use the IBM Cloud Pak® for AIOps group templates functionality to create meaningful, scoped groups per build. This can then be included as part of a broader application definition.

Create 'per build' topology templates

The following template generates a group for each build, which includes the build and its associated pipeline resources:

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Application management**.
3. Click the **Group templates** icon on the upper right corner of the page.
4. From the **Group templates** page, click **Create a new template**.
5. Select **Dynamic template** to ensure that all matching builds will generate topologies like this.
6. Click **Start** to begin building your template.
7. On the Preview pane, search for the build resource and select **Follow Relationship**. Repeat this for all of the connected resources in your build topology.

Important: Do not expand the 'lastRunOf' relationship.

8. Set the Group type as 'cicd'.
9. (Optional) Define tags for the template, then click **Save template & generate groups**.

Create `current pipeline status` group templates.

The following template generates a group that shows the status of your pipeline that is the latest build for which a notification was received by the observer and associated resources:

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Application management**.
3. Click the **Group templates** icon on the upper right corner of the page.
4. From the **Group templates** page, click **Create a new template**.
5. Select **Dynamic template** to ensure that all matching builds will generate topologies like this.
6. Click **Start** to begin building your template.
7. On the Preview pane, search for the job resource and select **Follow Relationship**. Then click 'lastRunOf'. The latest build resource for which a topology was generated is displayed. Expand any relationships you want to include in this template.

Important: Do not expand the 'RunOf' relationship.

6. Set the Group type as 'cicd'.
7. (Optional) Define tags for the template, then click **Save template & generate groups**.

Configuring Juniper CSO Observer jobs

Using the Juniper CSO Observer, you can define a full load job that will gather and read data about topology data from Juniper CSO.

Before you begin

Important: The Juniper CSO observer supports the on-premises Juniper CSO version 4.1.0.

Ensure you have the Juniper CSO details to hand, such as details of the Juniper CSO apiserver and its credentials.

The Juniper CSO Observer retrieves topology data from Juniper CSO Release 4.1 through REST APIs exposed by CSO API server.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

You define and start the following job.

Full Topology Upload job

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them.

Run this job whenever you need the Juniper CSO topology data refreshed.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required

Parameter	Action	Details
Juniper CSO Central MS URL	Specify the Juniper CSO Central micro-service URL	Required
CSO Keystone Authentication URL	Enter the authentication URL for the identity service	Required
CSO user domain name	Enter the CSO user domain name	Required
CSO domain or project or tenant name	Enter the CSO domain or project or tenant name	Required
CSO Authentication username	Specify the CSO authentication username	Required
CSO Authentication password	Specify the CSO authentication password	Required
Enable/Disable Secure Connection to CSO Host	Set to 'true' to secure the connection, otherwise set to 'false' to bypass	Required
Target system certificate	Specify the certificate file name.	Required if **`Enable/Disable Secure Connection to CSO Host`** is set to 'true'. To obtain authentication certificates using OpenSSL and store them as secrets, see Configuring observer jobs security.
SSL truststore File	Specify the HTTPS truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (**`<observer>.jks`**), for example **`JuniperCSO.jks`**.	Required if **`Enable/Disable Secure Connection to CSO Host`** is set to 'true'. The supported format is JKS and the file is relative to $ASM_HOME/security.
SSL truststore Password	Specify a password to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required if **`Enable/Disable Secure Connection to CSO Host`** is set to 'true'.
SSL Validation	Choose whether SSL validation is on or off. Turning SSL validation off will use HTTPS without host verification.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Kubernetes Observer jobs

Using this observer, you can configure jobs that discover the structure of your Kubernetes clusters, including pods, worker nodes and containers.

Before you begin

Important: The Kubernetes Observer has been tested against OpenShift version 4.12.53 with Kubernetes 1.25.8, and GKE version 1.27.8-gke.1067004.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The observer reads topology data from Kubernetes through its REST APIs, or Weave Scope.

You can run the following jobs:

Load

A transient (one-off) job that loads all requested topology data from a Kubernetes environment.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them.

Tip: When observing different Kubernetes clusters, make sure that the name of the data center is unique across all of the jobs.

Listen

A long-running job that monitors the Kubernetes REST API for updated resources, and loads them in the topology service.

Important: A Load job must be run before a Listen job can run.

Local

Note: The Kubernetes Observer Local job has been deprecated as of IBM Cloud Pak for AIOps 3.4.0. Use the Load job instead to performs local observations of the Kubernetes REST API for available resources.

Weave_scope Listen

Note: The Kubernetes Observer Weave Scope listen job has been deprecated as of IBM Cloud Pak for AIOps 4.5.0.

The Weave Scope listen job is a stand-alone job that listens to the Weave Scope agent and continues to stream topology and state data to IBM Cloud Pak® for AIOps.

It provides visibility of your Kubernetes services, pods, containers, deployments, stateful sets, Cron Jobs and processes for a specified namespace.

It is a long-running job that monitors its source for updates and runs until it is explicitly stopped, or until the Observer is stopped.

Kubeconfig Load

A stand-alone load job that accepts kubeconfig data in JSON format to perform a one-off discovery.

Kubernetes Observer Load job prerequisites

Before defining a Kubernetes Observer Load job, you must create a service account in the Kubernetes environment and obtain its token. The following example uses the default namespace.

1. Create either cluster role access or role access.

   For clusterole access, create a configuration file called **`asm-k8s-observer.yaml`** with the custom cluster role **`asm:kubernetes-observer`**.

   Use the following sample content:

```
kind: ClusterRole
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  annotations:
    rbac.authorization.kubernetes.io/autoupdate: "true"
  name: asm:kubernetes-observer
rules:
- apiGroups: [""]
  resources: [ "pods", "namespaces", "nodes", "services", "endpoints", "persistentvolumes",
"persistentvolumeclaims"]
  verbs: ["get", "list"]
- apiGroups: ["apps"]
  resources: ["replicasets", "deployments", "statefulsets", "daemonsets"]
  verbs: ["get", "list"]
```

   For role access:

   Use the following sample content:

```
kind: Role
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  namespace: {namespace} <-- Specify which namespace to create the Role access
```

```
  name: asm:kubernetes-observer
rules:
- apiGroups: [""]
  resources: [ "pods", "services", "endpoints"]
  verbs: ["get", "list"]
- apiGroups: ["apps"]
  resources: ["replicasets", "deployments", "statefulsets", "daemonsets"]
  verbs: ["get", "list"]
```

Observing Custom Resources:

To model custom resource definitions (CRDs) and custom resources (CRs) in the topology, identify the names of the CRDs that are present in the environment by running the **oc get crds** command. Then, update the job parameters to include the names of CRDs to be discovered. When a CRD is being included in the job, the respective CRs will also be discovered.

Example (discovering ibm.com CRDs):

```
oc get crds | grep ibm.com
```

Sample output:

```
asmformations.asm.ibm.com                                 2020-12-03T01:53:38Z
asms.asm.ibm.com                                          2020-12-03T01:53:38Z
cemformations.cem.ibm.com                                 2020-12-03T01:53:38Z
cemserviceinstances.cem.ibm.com                           2020-12-03T01:53:38Z
noiconnectionlayers.noi.ibm.com                           2020-12-03T01:47:19Z
noiformations.noi.ibm.com                                 2020-12-03T01:47:19Z
noihybrids.noi.ibm.com                                    2020-12-03T01:47:19Z
nois.noi.ibm.com                                          2020-12-03T01:47:20Z
```

Also, change the existing **ClusterRole** in the target environment, to include the following resources:

```
- apiGroups: ["apiextensions.k8s.io"]
  resources: ["customresourcedefinitions"]
  verbs: ["get", "list"]
- apiGroups: ["noi.ibm.com"]
  resources: ["nois", "noihybrids", "noiformations", "noiconnectionlayers"]
  verbs: ["get", "list"]
- apiGroups: ["asm.ibm.com"]
  resources: ["asms", "asmformations"]
  verbs: ["get", "list"]
- apiGroups: ["cem.ibm.com"]
  resources: ["cemformations"]
  verbs: ["get", "list"]
```

The **apiextensions.k8s.io** segment of the cluster role provides your permission required to access all the custom resource definitions resources.

```
- apiGroups: ["apiextensions.k8s.io"]
  resources: ["customresourcedefinitions"]
  verbs: ["get", "list"]
```

The **asm.ibm.com** segment provides access to **asms** and **asmformations** custom resources. The names of the resources listed are the plural for each of the resources. They are usually derived from the first word of the CRD.

```
- apiGroups: ["asm.ibm.com"]
  resources: ["asms", "asmformations"]
  verbs: ["get", "list"]
```

For a fresh discovery:

Create a configuration file called **asm-k8s-observer.yaml** in the target environment using the yaml resource provided in the sample content, then run the following command before moving to the next step:

```
oc create -f asm-k8s-observer.yaml
```

For an existing discovery:

Create a configuration file called asm-k8s-observer.yaml using the yaml resource provided in the sample, then run the following command to patch the clusterole:

```
oc patch clusterrole asm:kubernetes-observer --patch "$(cat asm-k8s-observer.yaml )"
```

2. Create the service account in the target environment.

```
oc create serviceaccount asm-k8s-account -n <namespace>
```

To verify that the service account exists:

```
oc get serviceaccount
```

Important: When running the following command, ensure you know the namespace in which it was created:

```
oc create serviceaccount asm-k8s-account
```

3. Bind the **asm:kubernetes-observer** ClusterRole or role to the **asm-k8s-account** service account.

   Important: The service account and the cluster role binding need to be created in the same namespace.

   Example command for clusterole binding:

   ```
   oc create clusterrolebinding asm-k8s --clusterrole=asm:kubernetes-observer --serviceaccount=
   {namespace}:asm-k8s-account
   ```

   Example command for role binding:

   ```
   oc create rolebinding asm-k8s --role=asm:kubernetes-observer --serviceaccount={namespace}:asm-k8s-
   account
   ```

   Example role binding output:

   ```
   rolebinding.rbac.authorization.k8s.io/asm-k8s created
   ```

4. Obtain the Kubernetes service account token. Complete the following substeps depending on your version of Kubernetes.

   For Kubernetes on OpenShift:

   1. Look for the mounted service account token secret from the secrets section:

      ```
      oc describe serviceaccount asm-k8s-account
      ```

      Example:

      ```
      oc describe serviceaccount asm-k8s-account
      Name: asm-k8s-account
      Namespace: default
      Labels: <none>
      Annotations: <none>
      Image pull secrets: asm-k8s-account-dockercfg-wwzx2
      Mountable secrets: asm-k8s-account-dockercfg-wwzx2
      Tokens: asm-k8s-account-token-tzl52
      Events: <none>
      ```

   2. Describe the asm-k8s-account-token-******* (which in this example is tzl52) to obtain the token's value:

      ```
      oc describe secret asm-k8s-account-token-tzl52
      ```

      Alternatively, use the following method to obtain the token's value (applicable to both OpenShift and GKE environments):

      ```
      oc describe serviceaccount asm-k8s-account | grep Tokens | awk '{ print $2} ' | xargs -I{} oc get
      secret {} --template='{{.data.token}}' | base64 -d
      ```

      For Kubernetes load jobs, ensure you have the Kubernetes service details to hand, such as the Kubernetes host IP and SSL Certificate details.

   For Kubernetes on GKE:

   1. Verify that the token has been created using the **kubectl describe serviceaccount <service-account>** command.

      Example of a missing token:

      ```
      oc kubectl describe serviceaccount asm-k8s-account
      Name:                asm-k8s-account
      Namespace:           default
      Labels:              <none>
      Annotations:         <none>
      Image pull secrets:  <none>
      Mountable secrets:   <none>
      Tokens:              <none>
      Events:              <none>
      ```

   2. If missing, create the token manually.

      Example:

      ```
      kubectl apply -f - <<EOF
      apiVersion: v1
      kind: Secret
      metadata:
         name: asm-k8s-account-secret
         annotations:
            kubernetes.io/service-account.name: asm-k8s-account
      ```

```
type: kubernetes.io/service-account-token
EOF
secret/asm-k8s-account-secret created
```

3. Verify that the token exists.

   Example of a token that is present:

```
oc kubectl describe serviceaccount asm-k8s-account
Name:                asm-k8s-account
Namespace:           default
Labels:              <none>
Annotations:         <none>
Image pull secrets:  <none>
Mountable secrets:   <none>
Tokens:              asm-k8s-account-secret
Events:              <none>
```

4. Describe the secret to obtain the token's value.

   Example:

```
oc kubectl describe secret asm-k8s-account-secret
Name:         asm-k8s-account-secret
Namespace:    default
Labels:       <none>
Annotations:  kubernetes.io/service-account.name: asm-k8s-account
              kubernetes.io/service-account.uid: d82e86c1-2258-4072-8a53-f517f776a149

Type:  kubernetes.io/service-account-token

Data
====
ca.crt:     1509 bytes
namespace:  7 bytes
token:      eyJhbGciO
```

Kubernetes Observer Listen job prerequisites

Important: Before defining a Kubernetes Observer Listen job, you must have configured and run a Load job.

Before defining a Listen job, update the ClusterRole or Role configuration.

1. Edit the **asm-k8s-observer.yaml** configuration file and add the following information:

   For clusterole access, add **watch** as in the following example.

```
kind: ClusterRole
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  annotations:
    rbac.authorization.kubernetes.io/autoupdate: "true"
  name: asm:kubernetes-observer
rules:
- apiGroups: [""]
  resources: [ "pods", "namespaces", "nodes", "services", "endpoints", "persistentvolumes",
"persistentvolumeclaims"]
  verbs: ["get", "list", "watch"]
- apiGroups: ["apps"]
  resources: ["replicasets", "deployments", "statefulsets", "daemonsets"]
  verbs: ["get", "list", "watch"]
```

   For role access, add **watch** as in the following example.

```
kind: Role
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  namespace: default
  name: asm:kubernetes-observer
rules:
- apiGroups: [""]
resources: [ "pods", "services", "endpoints"]
verbs: ["get", "list", "watch"]
- apiGroups: ["apps"]
resources: ["replicasets", "deployments", "statefulsets", "daemonsets"]
verbs: ["get", "list", "watch"]
```

2. Run the following command:

```
oc apply -f asm-k8s-observer.yaml
```

Kubernetes Observer Weave Scope listen job prerequisites

For Weave Scope listen jobs, do a Weave Scope installation, and then configure a job using the Weave Scope IP and port parameters. You must install Weave Scope and then use the Weave Scope Master IP and Node port parameters. For more information on Weave Scope, see the following location: https://www.weave.works/docs/scope/latest/introducing/

1. Create namespace 'weave' with 'ibm-privileged-psp'.

oc create namespace weave oc -n weave create rolebinding weave-clusterrole-rolebinding --clusterrole=ibm-privileged-clusterrole --group=system:serviceaccounts:weave

2. Install Weave Scope using the following command:

```
oc apply -f "https://cloud.weave.works/k8s/scope.yaml?k8s-service-type=NodePort&k8s-version=$(kubectl version | base64 | tr -d '\n')"
```

This will result in a port being opened that the observer can use.

3. You can discover the NodePort using the following command:

oc -n weave describe service weave-scope-app

4. Launch the Weave Scope UI using the following URL:

```
https://<master ip>:<NodePort>
```

5. Create a new route using the Red Hat OpenShift Container Platform console to expose the Red Hat OpenShift Container Platform Weave Scope service under the weave namespace. In the left panel of the Red Hat OpenShift Container Platform console, click **Networking** > **Routes**.
6. Click **Create Route** to create a new route.
7. Complete the required fields and then click **Create**.
8. A new route has been created. Launch the Weave Scope UI using the location link.

Kubernetes Observer kubeconfig load job prerequisites

For a kubeconfig load job, ensure your kubeconfig.yml file is in the correct format. If it is not, generate a new file.

Important: The kubeconfig should meet the following criteria:

- Single cluster
- User type of 'token'
- Base64 encoded JSON

View the kubeconfig.yml file:

```
oc config view --raw -o json
```

Important: Make sure the token and certificate are not omitted or redacted.

If it meets all required conditions, encode it using the following command:

```
oc config view --raw -o json | base64 -w 0
```

If it does not meet all conditions, generate a new kubeconfig.yml file using the following steps:

1. Create a cluster-role or role, service account, cluster-role/role binding. From the service account, get the secret, and from the secret get the token. Refer to "Kubernetes Observer Load job prerequisites" for detailed steps.
2. Get the current context details:

   ```
   oc config current-context
   ```

3. Get the current cluster, cluster ca (certificate-authority-data), and cluster server details:

   ```
   oc config view --raw -o json
   ```

4. Create a kubeconfig.yml using the obtained data. Sample kubeconfig.yml file:

   ```
   apiVersion: v1
   kind: Config
   current-context: <CURRENT_CONTEXT>
   contexts:
   ```

```
- name: <CURRENT_CONTEXT>
  context:
    cluster: <CURRENT_CONTEXT>
    user: <USER>
    namespace: <NAMESPACE>
clusters:
- name: <CURRENT_CONTEXT>
  cluster:
    certificate-authority-data: <CLUSTER_CA>
    server: <CLUSTER_SERVER>
users:
- name: <USER>
  user:
    token: <TOKEN_VALUE>
```

Where **USER** is the user-defined value, and **NAMESPACE** is the namespace of the service account.

5. Test the kubeconfig validity and access:

```
oc --kubeconfig <config>.yml get all
```

6. Run the following command to convert the file to base64 encoded json:

```
oc --kubeconfig <config>.yml config view --raw -o json | base64 -w 0
```

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Load job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job. **Note:** The name cannot be the same as any of the following observer job names: 'local', 'listen', 'weave_scope', 'load', 'kubeconfig'.	Required
data_center	Specify the name of the data center in which the Kubernetes instance is running. The data center name is treated as the provider of the data. **Note:** If you change the data center name, the observation is treated as a separate observation under the different provider, and a duplicate set of resources and groups will be created under the new provider.	Required
Kubernetes Master IP address	Enter the Kubernetes Master IP address	Required. Get the Kubernetes master IP and its API port using the 'oc cluster-info' command.
Kubernetes API port	Enter the Kubernetes API port number	Required
Kubernetes token	The service account token for Kubernetes	Required
Trust all certificate by bypassing certificate verification	Enter **true** if you want to connect to Kubernetes without certificate	Required
Exact HTTPS certificate file name	Enter the exact name of the SSL/HTTPS certificate	Optional. If 'Trust all certificate' is set to **false**, then this parameter is Required.
SSl Validation	Choose whether SSL validation is **true** or **false**. If **false**, HTTPS without hostname validation is used.	Optional
Terminated pods	Choose whether terminated pods should be hidden (**true** or **false**)	Optional. The default is false.
API query timeout (ms)	Specify the Kubernetes REST API query timeout	Optional. The default is 5000 ms (that is, 5 seconds)
Correlate	If 'true', enables the Event Analytics correlation on the namespace groups	Optional
Names of the custom resource definitions	Specify the custom resource definitions (CRDs) queryable from the Kubernetes API	Optional

Parameter	Action	Details
Role permission token	Determine whether the provided token is a role token. Defaults to `false` for cluster role permissions.	Optional
Namespace	Specify the Kubernetes namespace	Optional. Specify the Kubernetes namespace to observe, leave blank or enter `*` to observe all.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Listen job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job. **Note:** The name cannot be the same as any of the following observer job names: 'local', 'listen', 'weave_scope', 'load', 'kubeconfig'.	Required
data_center	Specify the name of the data center in which the Kubernetes instance is running. The data center name is treated as the provider of the data. **Note:** If you change the data center name, the observation is treated as a separate observation under the different provider, and a duplicate set of resources and groups will be created under the new provider.	Required
Kubernetes Master IP address	Enter the Kubernetes Master IP address	Required. Get the Kubernetes master IP and its API port using the 'oc cluster-info' command.
Kubernetes API port	Enter the Kubernetes API port number	Required
Kubernetes token	The service account token for Kubernetes	Required
Trust all certificate by bypassing certificate verification	Enter **true** if you want to connect to Kubernetes without certificate	Required
Exact HTTPS certificate file name	Enter the exact name of the SSL/HTTPS certificate	Optional. If 'Trust all certificate' is set to **false**, then this parameter is Required.
SSl Validation	Choose whether SSL validation is **true** or **false**. If **false**, HTTPS without hostname validation is used.	Optional
Terminated pods	Choose whether terminated pods should be hidden (**true** or **false**)	Optional. The default is false.
API query timeout (ms)	Specify the Kubernetes REST API query timeout	Optional. The default is 5000 ms (that is, 5 seconds)
Correlate	If 'true', enables the Event Analytics correlation on the namespace groups	Optional
Names of the custom resource definitions	A number of custom resource definitions (CRDs) that can be queried from the Kubernetes API	Optional
Role permission token	Determine whether the provided token is a role token. Default to false for cluster role permissions.	Optional

Parameter	Action	Details
Namespace	Specify the Kubernetes namespace	Optional. Specify the Kubernetes namespace to observe, leave blank or enter `*` to observe all.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Weave_scope job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job. **Note:** The name cannot be the same as any of the following observer job names: 'local', 'weave_scope', 'load', 'kubeconfig'.	Required
Host	Enter the Weave Scope hostname (or IP address) of the web socket to be observed	Required
Port	Enter the Weave Scope port number of the web socket to be observed	Required. The Port can be obtained using the 'oc -n weave describe service weave-scope-app' command.
Cluster Name	Enter the name of the cluster or data center to be observed	Required
Namespaces	Enter a list of namespaces to be observed	Optional. If left empty, all namespaces will be observed.
Resource types	Select the Weave Scope resource types to observe	Optional.
Resources to exclude	List resources to be excluded by ID, label, rank or namespace	Optional. Containers named 'pod' are excluded by default.
Refresh interval	Specify the refresh interval in seconds between updates. The minimum allowed value is 60s, and the default value is 120s.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Kubeconfig load job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job. **Note:** The name cannot be the same as any of the following observer job names: 'local', 'weave_scope', 'load', 'kubeconfig'.	Required

Parameter	Action	Details
data_center	Specify the name of the data center in which the Kubernetes instance is running. The data center name is treated as the provider of the data. **Note:** If you change the data center name, the observation is treated as a separate observation under the different provider, and a duplicate set of resources and groups will be created under the new provider.	Required
kubeconfig	Provide the contents of the kubeconfig in json format. The kubeconfig needs to be a json with a single cluster and its user needs to be of token type.	Required. The json needs to be base64 encoded.
Terminated pods	Choose whether terminated pods should be hidden (**true** or **false**)	Optional. The default is false.
API query timeout (ms)	Specify the Kubernetes REST API query timeout	Optional. The default is 5000 ms (that is, 5 seconds)
Correlate	If 'true', enables the Event Analytics correlation on the namespace groups	Optional
Names of the custom resource definitions	A number of custom resource definitions (CRDs) that can be queried from the Kubernetes API	Optional
Role permission token	Determine whether the provided token is a role token. Default to false for cluster role permissions.	Optional
Namespace	Specify the Kubernetes namespace	Optional. Specify the Kubernetes namespace to observe, or `*` to observe all. Leaving this field blank will observe the namespace in which IBM Cloud Pak for AIOps is installed. When using a role permission token, specify the single namespace where the role was created.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Network Manager Observer jobs

Using the IBM Tivoli Network Manager Observer, you can define jobs that dynamically load data discovered by Network Manager for analysis.

Before you begin

Important: The IBM Tivoli Network Manager Observer supports the on-premises IBM Tivoli Network Manager version 4.2.

Ensure you have the IBM Tivoli Network Manager service details to hand, such as the domain, host and port number.

The IBM Tivoli Network Manager Observer jobs extract Network Manager resources using an Object Query Language JDBC driver, and the observer loads and updates the resources and their relationships within the topology.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

You configure the following two jobs.

Load

A transient (one-off) job that queries Network Manager for topology data, and performs a complete upload for a single IBM Tivoli Network Manager domain.

By default, Load jobs are one-off, transient jobs that upload all of the requested topology data as soon as they are triggered.

For cross-domain connections: Each ITNM domain must read existing cross-domain connections from the topology service, which means that you may need to run two observations of all domains contributing cross-domain connections (that is, run the full load job twice) before all cross-domain edges are created.

You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them.

Listen

A long-running job that monitors the Network Manager message bus for changes and updates the topology service. When the job is started, the observer creates an OQL connection that listens for changes in the IBM Tivoli Network Manager network. Any resources added, changed or deleted are passed on by the OQL connection and the topology is updated.

The listen job runs until it is explicitly stopped, or until the observer is stopped.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
ITNM instance name	Specify the IBM Tivoli Network Manager instance name	Required. Specify the same instance name for all jobs to enable connectivity across domains.
ITNM domain port	Specify the IBM Tivoli Network Manager port for the specified domain	Required. The value of `port` will vary if multiple domains exist. To determine which port number to use for a Network Manager domain, look for the domain-specific ncp_config entry in the `$NCHOME/etc/precision/ServiceData.cfg` file.
ITNM domain	Specify the IBM Tivoli Network Manager domain	Required
Hostname or Server IP	Specify the IBM Tivoli Network Manager hostname or server IP on which the domain is running	Required
OQL connection timeout (ms)	Specify the OQL Connection timeout value	Optional. The default is 3000 (30 seconds).
Edge Type Map	Map IBM Tivoli Network Manager layers to topology relationship types	Optional. If blank, IBM Cloud Pak® for AIOps will auto-map. The value of topology type can be found in IBM Tivoli Network Manager in '$NCHOME/precision/disco/stitchers/DNCIM/PopulateDNCIMTopologies.stch'; alternatively, run the following OQL statement against the model service to list the available topology type: `select ENTITYNAME from ncimCache.entityData where METACLASS='Topology'`
Exclude resources without connections	Select whether to display disconnected resources	Optional. The choices are **true** and **false**. The default is **true**.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring a New Relic Observer job

Use the New Relic Observer when you have a New Relic account with a New Relic Infrastructure subscription. Using this observer you can configure jobs that dynamically load New Relic Infrastructure resource data through New Relic for analysis.

There is a known issue that is currently impacting the New Relic Observer job. For more information, see New Relic observer job fails with an authorization error.

Before you begin

Important: The New Relic Observer supports the cloud/SaaS New Relic version.

Ensure you have the New Relic account and New Relic Infrastructure subscription details to hand, such as the account name, account ID, and New Relic Insights API query key.

Restriction: New Relic applies a 1000 results limit on all New Relic Query Language (NRQL) queries. To accommodate this limit when retrieving data from the SystemSample, StorageSample, ProcessSample and NetworkSample event tables, the New Relic Observer uses the following NRQL query time clause:

```
"SINCE 4 hours ago LIMIT 1000"
```

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The Observer uses the New Relic Infrastructure subscription and makes active New Relic Query Language (NRQL) calls over REST to New Relic Insights to download New Relic Infrastructure resource data.

The New Relic Observer loads the following New Relic Infrastructure resources and their relationships:

- Host
- Storage
- OS
- Network Interfaces
- Processes

The New Relic Observer job extracts New Relic Infrastructure resources from New Relic using New Relic Query Language (NRQL) over REST, and the observer loads and updates the resources and their relationships.

You configure the following job.

Load: By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: For more information, see Configuring observer job security

Table. Parameter details

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
New Relic Account Name	Specify the New Relic account name or tenant name	Required
New Relic account ID in numeric	Specify the New Relic numeric account ID	Required.
New Relic Insights Query API key	Specify the New Relic Insights Query API key	Required.
New Relic Events table filter criteria	Extend the result set returned to IBM Cloud Pak® for AIOps	Optional. The default value is `SINCE 4 hours ago LIMIT 1000`. For more information, see the documentation for New Relic Query Language.

Parameter	Action	Details
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Tips:

- **New Relic account ID**: To obtain the account ID log in to New Relic and then go to the URL https://rpm.newrelic.com/accounts/%3CaccountId%3E
- **New Relic Insights Query API Key**: A New Relic user with a New Relic Infrastructure subscription is required to generate a New Relic Insights Qeury API Key. For more information, see https://docs.newrelic.com/docs/insights/insights-api/get-data/query-insights-event-data-api.

Configuring OpenStack Observer jobs

Using the OpenStack Observer, you can configure jobs that dynamically load OpenStack data for analysis.

Before you begin

Important: The OpenStack Observer supports the on-premises OpenStack up to versions Ocata, Pike, Rocky, Queens, Stein, Train, Zed and Antelope.

Ensure you have the OpenStack service details to hand, such as the parameters for its APIs or RabbitMQ message bus. If you are configuring a query job, have OpenStack location and authorization details to hand. If you are configuring a rabbitmq job, you must also identify and provide access to the RabbitMQ message bus.

OpenStack installation requirements

If you previously installed OpenStack with DevStack, you must add the configuration that is specified here to the end of the local.conf file, and reinstall it. If you previously installed OpenStack with another installation method, you must add the configuration that is specified here to the nova.conf file, and then restart the Nova (compute) service.

- If you **have already** installed OpenStack using DevStack, add the following configuration to the end of the local.conf file, and **then reinstall** OpenStack.
- If you are **planning to** install OpenStack using DevStack, add the following configuration to the end of the local.conf file **before installation**.

```
[[post-config|$NOVA_CONF]]
[DEFAULT]
notification_topics = notifications,com.ibm.asm.obs.nova.notify
notification_driver=messagingv2
notify_on_state_change=vm_and_task_state
notify_on_any_change=True
```

For standard (or any other) OpenStack installations, add the following configuration under the `[DEFAULT]` section of the nova.conf file, and then you restart the Nova (compute) service.

```
notification_topics = notifications,com.ibm.asm.obs.nova.notify
notification_driver=messagingv2
notify_on_state_change=vm_and_task_state
notify_on_any_change=True
```

Note: OpenStack uses RBAC-based protection of its API by defining policy rules based on an RBAC approach. Availability of resources retrieved by the observer is also governed by this same policy. For example, a VM created in project A by users with the admin role may be available to other users with the same admin role. This can be configured or modified according to user requirements in the OpenStack's policy configuration.

OpenStack port numbers

OpenStack assigns standard port numbers to each of its service. To communicate with the OpenStack instance, you must enable the following default ports.

Tip: Check with your OpenStack administrator if custom port numbers have been configured.

Load jobs default ports:

```
- KeyStone: 5000
- Nova: 8774
- Neutron: 9696
- Glance: 9292
- Cinder: 8776
- Heat: 8004
```

Listen jobs default port:

```
- RabbitMQ: 5672
```

Troubleshooting

A **Certificate Chaining Error** can occur when launching an OpenStack Observer job.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The OpenStack Observer jobs extract OpenStack resources through REST or RabbitMQ, and the observer loads and updates the resources and their relationships within the topology service.

You configure and run the following two jobs.

Restapi Load job

A transient (one-off) job that loads all requested topology data from the OpenStack instance by REST API.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

The job loads baseline topology data through the following OpenStack's APIs:

- Keystone (identity)
- Cinder (block storage)
- Glance (image)
- Heat (orchestration)
- Neutron (network)
- Nova (compute)

Restriction: An OpenStack environment that has a list of endpoints whereby the 'heat-cfn' service comes first (before the 'heat' service) will encounter a JSON parsing error recorded in the logs due to a known issue in the openstack4j library. When this happens, the full load for the heat service will be skipped entirely. Other services will run as normal.

Rabbitmq Listen job A long-running job that reads messages on OpenStack's RabbitMQ message bus for activity from the Cinder (block storage), Heat (orchestration), Neutron (network) and Nova (compute) components continually, until it is explicitly stopped, or until the Observer is stopped.

Note: The rabbitmq job should only be run after an initial restapi job has been completed.

Restriction: Only one rabbitmq job should be listening to one queue (or sets of queues) at any one time. If you need to listen to multiple projects, then separate queues must be set up in OpenStack, with appropriate names, before separate listening jobs are submitted for each. For example, for Nova through the rmq_nova_notify attribute, for Neutron through the rmq_neutron_notify attribute.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Restapi Load job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required

Parameter	Action	Details
Data center name	Specify the name of the data center in which the OpenStack instance is running	Required. If more than one OpenStack instance is run, and duplicate project or tenant names exist, you must disambiguate them here.
OpenStack Project/Tenant name	Specify the OpenStack project name(s) to use, for example the value of **`OS_PROJECT_NAME`**. Multi project names should be separated by comma.	Required
OpenStack authentication type	Specify the OpenStack connection authentication technique to use	Required. Choose either **`v2_Tenant`**, **`v3_Unscoped`**, v3_Project, v3_Domain**`, or`** v3_ProjectDomain`.
OpenStack identity endpoint	Specify the OpenStack Identity Endpoint to connect to inclusive of port and version, e.g. the value of **`OS_AUTH_URL`**.	Required
OpenStack username	Specify the OpenStack username to connect as (or to)	Required
OpenStack password	Specify the OpenStack password with which to authenticate	Required
OpenStack host certificate	Specify a certificate name to load into the truststore	Required
SSL truststore file name	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (**`<observer>.jks`**), for example **`OpenStack.jks`**.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.
SSL truststore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
OpenStack user domain name	Specify the user domain name to use, for example the value of **`OS_USER_DOMAIN_NAME`**.	Optional
OpenStack project domain name	Specify the project domain name to use, for example the value of **`OS_PROJECT_DOMAIN_NAME`**.	Optional
OpenStack region name	Specify the OpenStack region to use, for example the value of **`OS_REGION_NAME`** The value is case-sensitive. If it is not set, the default value is *regionOne*.	Required for v3 authentication.
OpenStack perspective	Select the URL perspective the API accesses data from	Optional. Choose from **`Admin`**, **`Public`**, and **`Internal`**.
SSL Verification	Choose whether to use SSL verification (true or false). If false, HTTPS is used, but **without** hostname validation.	Optional
Optionally load hypervisors	Choose whether to turn the loading of hypervisors on or off. **Note:** To load hypervisors, admin privileges must be assigned to the user.	Optional. The default is **`false`** (off).
Optionally load Host Aggregates	Choose whether to turn the loading of Host Aggregates on or off. **Note:** To load host aggregates data, admin privileges must be assigned to the user.	Optional. The default is **`false`** (off).
Connection timeout (ms)	Choose the timeout setting for the connection actions	Optional. The default is 5000 (5 seconds).
Read timeout (ms)	Choose the timeout setting for the read actions	Optional. The default is 5000 (5 seconds).
Proxy host	Specify the proxy host to connect via	Optional
Proxy username	Specify the proxy username.	Optional
Proxy password	Specify the proxy password	Optional
Proxy port	Specify the proxy port to connect via	Optional. Default is **`8080`**.
Trust all certificates	Set to **`true`** to connect to target environment without verification	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.

Parameter	Action	Details
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Rabbitmq Listen job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Data center name	Specify the name of the data center in which the OpenStack instance is running	Required. If more than one OpenStack instance is run, and duplicate project or tenant names exist, you must disambiguate them here.
OpenStack Project/Tenant name	Specify the project or tenant name(s) to use, such as the value of `OS_PROJECT_NAME. Multi-project or tenant names should be separated by comma.	Optional
OpenStack username	Specify the OpenStack username to connect as (or to)	Required
RabbitMQ username	Specify the AMQP username to connect to the broker	Required
RabbitMQ hosts	Enter a (comma-separated) list of hosts in the RabbitMQ cluster	Required. Add a comma-separated host, or list of hosts, (for example, **`host1:5672,host2:5672`**) to connect to in the RabbitMQ cluster. The first host connected to successfully is used. **Note:** Use IP addresses instead of hostnames.
RabbitMQ password	Specify the password to use to connect to the broker	Required
RabbitMQ virtual host name	Specify the virtual host to connect to the broker	Optional
Use SSL	Choose whether to use an SSL connection	Optional. Choose **`true`** or **`false`**. For RabbitMQ, you must choose **`true`**.
Nova v2 Oslo message queue	Specify the Nova v2 Oslo message queue	Optional
Neutron v2 Oslo message queue	Specify the Neutron v2 Oslo message queue	Optional
Cinder v2 Oslo message queue	Specify the Cinder v2 Oslo message queue	Optional
Heat v2 Oslo message queue	Specify the Heat v2 Oslo message queue	Optional
Number of consumer instances	Specify the number of consumer instances to create for each API queue type	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Important: You **must** specify the following properties consistently for both the restapi and rabbitmq jobs:

- Data center name
- OpenStack project name

- OpenStack username

Configuring Rancher Observer jobs

Using the Rancher Observer, you can define a full load job that will read data from Rancher through the REST API and generate a topology.

Before you begin

Important: The Rancher Observer supports the on-premises Rancher version 2.3.2 and API version 3.0.

Ensure you have the Rancher details to hand, such as the Rancher host IP, accessKey, secretKey and clusterId, before running the observer job.

The Rancher Observer supports a transient (one-off) Load job that loads all requested topology data through Rancher REST API to build the topology, and then exit.

You define and start the following job. You must edit the parameters in the configuration file before running this job.

Full Topology Upload job By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Rancher Host IP	Enter the Rancher host IP address	Required
Rancher Access Key ID	Supply the Rancher access key	Required
Rancher Secret Access Key	Supply the Rancher secret key	Required
Rancher Cluster ID	Enter the cluster ID to be discovered	Required
Enable/Disable Secure Host Connection to Rancher's Host	Set to 'true' to secure the connection. Alternatively, set to 'false' to bypass secure host connection.	Required
Rancher certificate	If enable_secure_host_connection is set to 'true', update the global secret with encrypted certificate information. See the relevant step here.	Optional
SSL TrustStore File	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `rancher.jks`.	Required if `enable_secure_host_connection` is set to 'true'. The supported format is JKS and the file is relative to $ASM_HOME/security. You **must** also supply the SSL truststore password to decrypt the HTTPS truststore file.
SSL TrustStore Password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required if `enable_secure_host_connection` is set to 'true'
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.

Parameter	Action	Details
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring REST Observer jobs

Use the REST Observer for obtaining topology data through REST endpoints. This observer is a counterpart to the File Observer.

Before you begin

For the Swagger API documentation, see REST Observer for Agile Service Manager.

About this task

The REST Observer passes topology data using a RESTful set of interfaces, which provide REST APIs that enable the following functionality:

- Management of Listen and bulk-replace job types.
- The insert-update (HTTP POST) of resources.
- The insert-update (HTTP POST) of relationships.
- The insert-replacement (HTTP PUT) of resources.
- The deletion (HTTP DELETE) of resources.
- A REST API that supports the deletion (HTTP DELETE) of all relationships of a particular type from a specified resource.
- A REST API that supports the deletion (HTTP DELETE) of a specific relationship.

Restriction: Resources created through REST can have a provider, but not an observer.

Benefits: Using the REST Observer rather than the File Observer or Topology Service APIs includes the following benefits:

- The ability to provide data through HTTP REST Endpoints instead of files.
- The processing performed by all observers in their framework ensures that metadata about observations from observers is managed correctly.
- A simple way of deleting all edges of a given type on a resource or a specific edge instance.

To use the REST Observer, a job request must be issued (HTTP POST) to the Observer instance job management APIs before sending data to the Resource and Relationship APIs.

Listen

A long-running listen job capable of consuming topology data over a long period. A listen job is designed to support scenarios where the input data stream is unpredictable, or little or no consistency or versioning of resources exists within the data stream.

Synchronize (bulk replace)

A long-running job with the same resource replace semantics as the File Observer. Bulk-replace jobs are designed to support scenarios where a known set of resources are subject to updates or versioning, and a prior observation about resources is to be replaced with a new one. This job provides a new set of resources and relationships and synchronizes them to the topology service, causing any previous data provided by the observer to be deleted and replaced with the new data.

Note: In both cases, a provider job parameter is required to identify the origin of the data being provided to the observer job.

Once a job request has been successfully submitted, you can start to provide data to the Resource and Relationship APIs on behalf of a particular job instance.

The Resource and Relationship APIs may respond with an HTTP 503 Service Unavailable response with a Retry-After: 10 seconds in the header. This indicates that even though the request against those APIs is valid, the observer has not been able to ascertain that metadata about the job is held in IBM Cloud Pak® for AIOps yet; this may be due to, for example, any prevailing conditions in the network that support the micro-services.

Tip: If such a response is received, try the request again later.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Important: Ensure that the body is structured correctly. When posting the body, information included in the body after the closing **}** that matches an opening **{** is ignored, and no error is recorded.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Provider	Specify the name of the program or system to provide data	Required
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

REST Observer API access

API name: topology-rest-observer

Public API URLs: `/aiops/api/application-manager/topology-rest-observer/v1/*`

For information on how to obtain route and token information, see Accessing the console.

For information on how to obtain your token, see Accessing APIs.

Swagger API documentation

For the Swagger API documentation, see Topology REST Observer API. The documentation explains how to use the REST Observer APIs.

Creating cross-data origin relationships

Using the REST Observer functionality, you can create edges between resources from different observations or providers.

It requires both the **`uniqueID`** and the provider of the resources at each end of the link (so typically applies to previously observed resources).

In the following syntax examples, note the **`_toProvider`** and **`_fromProvider`** edge properties.

You can define an edge from a resource in the current observation to one owned by a different provider. This example needs to be POSTed to the REST observer's **`/rest/resources`** endpoint:

```
{
   "uniqueId":"host1.ibm.com",
   "entityTypes":["host"],
   "name":"host1",
   "_references":
   [
       {
          "_edgeType":"connectedTo",
          "_toProvider":"someOtherProvider",
          "_toUniqueId":"host2.ibm.com"
       }
   ]
}
```

You can define an edge from a resource between two different providers. This example needs to be POSTed to the REST observer's **`/rest/references`** endpoint:

```
{
   "_fromProvider":"providerOne",
   "_fromUniqueId":"host1-interface1",
   "_edgeType":"connectedTo",
   "_toProvider":"providerTwo",
   "_toUniqueId":"host2-interface1"
}
```

Example listen job

The following examples show how to use the REST Observer listen job to create and adjust a small topology.

Start the Listen job

Use the following example as a model.

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' -d '{
  "unique_id": "my job",
  "type": "listen",
  "parameters": {
    "provider": "MyListenJob"
  }
}' 'https://localhost/1.0/rest-observer/jobs/listen'
```

Verify that the listen job is running

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X GET --header 'Accept: application/json' --header 'X-TenantID:
cfd95b7e-3bc7-4006-a4a8-a73a79c71255' 'https://localhost/1.0/rest-observer/jobs/my%20job'
```

Create a 'person' resource

This example creates a person resource called 'Thomas Watson'.

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my job' -d '{
  "name": "Thomas Watson",
  "uniqueId": "Thomas Watson",
  "entityTypes": [
    "person"
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Create an 'organization' resource

This example creates an 'organization' resource of 'IBM'.

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my job' -d '{
  "name": "IBM",
  "uniqueId": "IBM",
  "entityTypes": [
    "organization"
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Create a 'manages' relationship

This example creates a 'manages' releationship between Thomas Watson and IBM.

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my job' -d '{
  "_fromUniqueId": "Thomas Watson",
  "_edgeType": "manages",
  "_toUniqueId": "IBM"
}' 'https://localhost/1.0/rest-observer/rest/references'
```

Create a new 'location' resource

This example creates a 'location' resource of 'Campbell, New York' for Thomas Watson, and a location relationship (an edgeType of locatedAt).

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my job' -d '{
  "name": "Campbell, New York",
  "uniqueId": "Campbell, New York",
  "entityTypes": [
```

```
    "location"
  ],
  "_references": [
    {
      "_fromUniqueId": "Thomas Watson",
      "_edgeType": "locatedAt"
    }
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Replace the location resource with one having latitude and longitude properties

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X PUT --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my job' -d '{
  "name": "Campbell, New York",
  "uniqueId": "Campbell, New York",
  "entityTypes": [
    "location"
  ],
  "longitude": -77.196918,
  "latitude": 42.232909
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Delete all 'locatedAt' relationships

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X DELETE --header 'Accept: application/json' --header 'X-TenantID:
cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my job' 'https://localhost/1.0/rest-
observer/rest/resources/Thomas%20Watson/references/both/locatedAt'
```

Delete the location

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X DELETE --header 'Accept: application/json' --header 'X-TenantID:
cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my job' 'https://localhost/1.0/rest-
observer/rest/resources/Campbell%2C%20New%20York'
```

Delete the manages relationship

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X DELETE --header 'Accept: application/json' --header 'X-TenantID:
cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my job' 'https://localhost/1.0/rest-
observer/rest/resources/Thomas%20Watson/references/both/manages/IBM'
```

Example bulk-replace job

The following examples show how to use the REST Observer bulk replace job to create and adjust a small topology.

Note: These examples use a mixture of the provided scripts in $ASM_HOME/bin and the cURL command.

Submit a bulk-replace job request with the unique ID of 'my bulk replace'

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' -d '{
  "unique_id": "my bulk replace",
  "type": "bulk replace",
  "parameters": {
    "provider": "Me"
  }
}' 'https://localhost/1.0/rest-observer/jobs/bulk_replace'
```

Verify that the bulk-replace job is running

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X GET --header 'Accept: application/json' --header 'X-TenantID:
cfd95b7e-3bc7-4006-a4a8-a73a79c71255' 'https://localhost/1.0/rest-observer/jobs/my%20bulk%20replace'
```

Submit a location resource for the city of Coventry

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my bulk
replace' -d '{
  "name": "Coventry",
  "uniqueId": "Coventry",
  "entityTypes": [
    "location"
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Submit a location resource for the town of Rugby

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my bulk
replace' -d '{
  "name": "Rugby",
  "uniqueId": "Rugby",
  "entityTypes": [
    "location"
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Submit a location resource for the Town of Leamington Spa with relationships to the existing resources of Coventry and Rugby

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my bulk
replace' -d '{
  "name": "Leamington Spa",
  "uniqueId": "Leamington Spa",
  "entityTypes": [
    "location"
  ],
  "_references": [
     {
        "_toUniqueId": "Coventry",
        "_edgeType": "routesVia"
     },
     {
        "_toUniqueId": "Rugby",
        "_edgeType": "routesVia"
     }
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Check your progress by rendering the topology

Having completed this set of observations, initiate a synchronize request for 'my bulk replace' job.

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' -d ''
'https://localhost/1.0/rest-observer/jobs/my%20bulk%20replace/synchronize'
```

Provide a new topology for the 'my bulk replace' job

This example submits a location resource for the town of Leamington Spa with relationships to the towns of Warwick and Stratford-Upon-Avon (resource placeholders).

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my bulk
replace' -d '{
  "name": "Leamington Spa",
  "uniqueId": "Leamington Spa",
  "entityTypes": [
    "location"
  ],
  "_references": [
     {
        "_toUniqueId": "Warwick",
        "_edgeType": "routesVia"
     },
     {
        "_toUniqueId": "Stratford-upon-Avon",
        "_edgeType": "routesVia"
     }
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Provide the resource data for the Town of Warwick resource placeholder, thus fully creating the resource

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my bulk
replace' -d '{
  "name": "Warwick",
  "uniqueId": "Warwick",
  "entityTypes": [
    "location"
```

```
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Provide the resource data for the town of Stratford-upon-Avon resource placeholder, thus fully creating the resource

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' --header 'JobId: my bulk
replace' -d '{
  "name": "Stratford-upon-Avon",
  "uniqueId": "Stratford-upon-Avon",
  "entityTypes": [
    "location"
  ]
}' 'https://localhost/1.0/rest-observer/rest/resources'
```

Initiate a synchronize request for the 'my bulk replace' job. This signifies to the Observer that it should instruct the system to replace the previous set of observations with the new ones.

Note: The new data is available immediately as it is provided. The synchronize request simply deletes any resources previously observed that were not observed this time. In the current example, Coventry and Rugby were not observed, and therefore they are deleted.

```
curl -u PROXY_USER[:PROXY_PASSWORD] -X POST --header 'Content-Type: application/json' --header 'Accept:
application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' -d ''
'https://localhost/1.0/rest-observer/jobs/my%20bulk%20replace/synchronize'
```

Configuring SDC ONAP Observer jobs

You configure SDC (Service Design and Creation) ONAP (Open Network Automation Platform) Observer jobs to dynamically load data from the SDC REST interface.

Before you begin

Important: The SDC ONAP Observer supports the SDC release 8.0.0.

Ensure you have the SDC ONAP service details to hand, such as username, password, hostname and port.

To obtain SDC ONAP system details:

1. To get port

   ```
   kubectl describe svc --selector=app.kubernetes.io/name=sdc-be | grep NodePort
   ```

2. To get message bus port

   ```
   kubectl describe svc --selector=app.kubernetes.io/name=message-router | grep NodePort
   ```

3. To copy trust store

   ```
   kubectl cp <onap-sdc-be-*>:/var/lib/jetty/chef-solo/environments/org.onap.sdc.trust.jks
   ./org.onap.sdc.trust.jks
   ```

   Or

   ```
   kubectl cp <onap-sdc-be-*>:/app/jetty/chef-solo/environments/org.onap.sdc.trust.jks
   ./org.onap.sdc.trust.jks
   ```

4. To get trust store password

   ```
   kubectl exec -it <onap-sdc-be-*> -- sh -c "cat /var/lib/jetty/chef-solo/environments/AUTO.json | grep
   truststore_pwd"
   ```

   Or

   ```
   kubectl exec -it <onap-sdc-be-*> -- sh -c "cat /app/jetty/chef-solo/environments/AUTO.json | grep
   truststore_pwd"
   ```

About this task

The SDC ONAP Observer job retrieves the service design data from the SDC server through REST. The observer loads and updates the resources and their relationships within the Agile Service Manager core topology service.

SDC manages two levels of assets:

Resource

A fundamental capability, implemented either entirely in software, or as software that interacts with a hardware device. Each Resource is a combination of one or more Virtual Function Components (VFCs), along with all the information necessary to instantiate, update, delete, and manage the Resource. A Resource also includes license-related information.

There are three kinds of resource:

- Infrastructure: Cloud resources, such as Compute, Storage, etc
- Network: Network connectivity functions & elements, for example a Virtual Network Function (VNF)
- Application: Features and capabilities of a software application, for example a load-balancing function=

Service

A well-formed object comprising one or more resources.

Service designers create services from resources, and include all of the information about the service needed to instantiate, update, delete, and manage the service.

You define and start the following jobs:

Load job

Run this job whenever you need SDC ONAP topology data refreshed.

By default, these jobs are one-off, transient jobs that perform a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them.

Listen job

A long-running job that consumes relevant messages from the SDC DMaaP broker continually until it is explicitly stopped, or until the observer is stopped.

You should run this job after a load job has been completed.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Load job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
SDC Distribution Engine host	Specify the host name of the SDC Distribution Engine	Required
SDC Distribution Engine port	Specify the port number of the SDC Distribution Engine	Required
SDC username	Specify the user name to use when connecting to the SDC	Required
SDC password	Specify the password to use when connecting to the SDC	Required. Plain text password can be entered.
Target system Key Store file name	Specify the key store name that contains either the CA certificate or the SDC's public key	Required. For information on encrypting the contents of the key store file, see step 2 of the Configuring observer jobs security topic.
Target system Key Store password	Specify the password to access the key store file	Required. Plain text password can be entered.
Optional provider name	Auto-generated if not specified	Optional. **Warning:** Do not change to avoid resource duplication.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.

Parameter	Action	Details
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Listen job parameters

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
SDC Distribution Engine host	Specify the host name of the SDC Distribution Engine	Required
SDC Distribution Engine port	Specify the port number of the SDC Distribution Engine	Required
SDC username	Specify the user name to use when connecting to the SDC	Required
SDC password	Specify the password to use when connecting to the SDC	Required. Plain text password can be entered.
SDC environment name	Specify the environment name configured on the SDC, for example `TEST`, `PROD`, `AUTO`, etc	Required
DMaaP message-router address	Specify the DMaaP message bus addresses on which to listen for distribution events	Required
DMaaP message-router port	Specify the DMaaP message bus port on which to listen for distribution events	Required
Target system Key Store file name	Specify the key store name that contains either the CA certificate or the SDC's public key	Required. For information on encrypting the contents of the service account key file, see step 2 of the Configuring observer jobs security topic.
Target system Key Store password	Specify the password to access the key store file	Required. Plain text password can be entered.
DMaaP polling interval (in seconds)	Specify how often (in seconds) to poll the DMaaP cluster for new model events	Optional. The default is 20s.
DMaaP polling timeout (in seconds)	Specify the timeout value (in seconds) when polling DMaaP for new model events	Optional. The default is 20s.
Optional provider name	Auto-generated if not specified	Optional. **Warning:** Do not change to avoid resource duplication.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring ServiceNow Observer jobs

Using the ServiceNow Observer job, you can retrieve the configuration management database (CMDB) data from ServiceNow through REST API, using basic authentication credentials.

Important: The ServiceNow Observer supports the cloud and SaaS ServiceNow versions **`New York`**, **`Quebec`**, **`Paris`**, **`Tokyo`**.

Before you begin

- **Important**: If you have any restrictive EgressFirewall in place, ensure that they are updated to allow for this inbound connection. For more information, see Create an EgressFirewall.
- **Important**: Ensure that your ServiceNow user account has the required roles to configure this observer and to access resources from ServiceNow. You need the following roles:
  - **`rest_api_explorer`**
  - **`web_service_admin`**
- Ensure that you have the ServiceNow service details to hand to complete this observer configuration, such as username, password, and URL.

To add a role to your user account, complete the following steps:

1. Log in to your **ServiceNow** instance using an admin account.
2. Go to **User Administration** and select **Users** from the menu.
3. Select to create or edit a user:
   - To create a user, click **New**.
   - To edit an existing user, search for, and then select, the user.
4. From the user's information tab, select the **Roles** tab, then click **Edit**.
5. Assign the required roles to the user.
6. Click **Save**, then **Update**.

For more detailed descriptions of available roles, go to **User Administration** and select the **Roles** page. You can also assign other roles with similar privileges to the non-admin account. To find other roles with similar privileges, navigate to **System Security** and select **Access Control (ACL)**.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

ServiceNow jobs retrieve configuration management database (CMDB) data from ServiceNow through REST API. The Observer loads and updates the resources and their relationships within the topology service.

By default, the observer discovers the following relationship tables:

- /api/now/table/cmdb_ci_service_discovered (services data)
- /api/now/table/cmdb_rel_ci (connectivity information for inventory data)
- /api/now/table/cmdb_ci_service_calculated (calculated service data)
- /api/now/table/cmdb_ci_query_based_service (query-based service data)

The observer supports all system-created or user-created child tables of cmdb_ci, as well as the following resource:

- /api/now/table/sys_user (user data)

ServiceNow job: By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered. You can also run these jobs (again) manually from the Observer UI, or schedule them to run at set times when configuring them. Run this job whenever you want to refresh the ServiceNow topology data.

Mapping of ServiceNow object types to topology entity types

Table. ServiceNow object and entity types

ServiceNow object types	Entity types
cmdb_ci, cmdb_ci_service_discovered	based on sys_class_name attribute
sys_user	person

Tip

Important: Specify **`cmdb_ci_{name}`** tables to discover using the **`ServiceNow tables to be discovered`** parameter.

Follow these steps to run the ServiceNow glide script that lists availabe **cmdb_ci** tables.

Note: You must have admin access to run the script.

1. Login to the ServiceNow instance as the admin user.
2. Go to **System Definition > Scripts - Background**.
3. Paste the following script into the text box:

```
var g = new GlideAggregate('cmdb_ci');
g.addAggregate('COUNT', 'sys_class_name')
g.orderByAggregate('COUNT', 'sys_class_name');
g.query();
while (g.next()) {
gs.info(g.sys_class_name + ': ' + g.getAggregate('COUNT', 'sys_class_name'));
}
```

4. Run the script.
5. ServiceNow will list all **cmdb_ci** tables in the environment. Sample output:

```
*** Script: cmdb_ci_spkg: 1767
*** Script: cmdb_ci_computer: 814
*** Script: cmdb_ci_service: 41
*** Script: cmdb_ci_printer: 28
*** Script: cmdb_ci_server: 19
*** Script: cmdb_ci_win_cluster_node: 14
*** Script: cmdb_ci_database: 13
*** Script: cmdb_ci_web_server: 9
*** Script: cmdb_ci_win_server: 8
*** Script: cmdb_ci_unix_server: 7
*** Script: cmdb_ci_ups: 6
*** Script: cmdb_ci_email_server: 5
*** Script: cmdb_ci_netgear: 5
*** Script: cmdb_ci_rack: 5
*** Script: cmdb_ci_zone: 5
*** Script: cmdb_ci_linux_server: 4
*** Script: cmdb_ci_win_cluster: 4
*** Script: cmdb_ci_cluster_node: 3
*** Script: cmdb_ci_ip_router: 3
*** Script: cmdb_ci_msd: 3
*** Script: cmdb_ci_network_adapter: 3
*** Script: cmdb_ci_aix_server: 2
*** Script: cmdb_ci_computer_room: 2
*** Script: cmdb_ci_disk: 2
*** Script: cmdb_ci_peripheral: 2
*** Script: cmdb_ci: 1
*** Script: cmdb_ci_appl: 1
*** Script: cmdb_ci_app_server_java: 1
*** Script: cmdb_ci_cluster: 1
*** Script: cmdb_ci_datacenter: 1
*** Script: cmdb_ci_db_mysql_catalog: 1
*** Script: cmdb_ci_db_ora_catalog: 1
*** Script: cmdb_ci_ip_switch: 1
*** Script: cmdb_ci_service_group: 1
*** Script: cmdb_ci_storage_switch: 1
```

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Remember: To improve performance and to focus your topology, **do not** include all ServiceNow tables. Instead (**before** running an observer job) identify the ServiceNow tables that are most useful to your requirements, and exclude the ones you do not require. For example, you may want to exclude the vast number of records of SIM cards from being displayed in the topology, and include only servers, services or applications.

***Tip:** The **Device group path** parameter cannot be configured.

Table. Parameter action details

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
ServiceNow instance	Specify the ServiceNow instance, which should be **NMS**	Required
ServiceNow username	Specify the ServiceNow username	Required

Parameter	Action	Details
ServiceNow password	Specify the ServiceNow password	Required
ServiceNow tables to be discovered	The supported tables are **sys_user**, and all system-created or user-created child tables of **cmdb_ci**. Using a comma as delimiter for multiple entries, specify either **sys_user** or tables that are either system-created or user-created children of the **cmdb_ci** table, such as **cmdb_ci_database** (the system table), **u_ibm_database** (the global scope custom table), or **sn_app_ws_u_ibm_database** (the application scope custom table). **Note** that the following relationship tables are added by default: **cmdb_rel_ci**, **cmdb_ci_service_discovered**, **cmdb_ci_service_calculated**, and **cmdb_ci_query_based_service**.	Required
Number of records to fetch per API call from a table	Enter the number of records to fetch per API call from a table. The default value is 10000. The value you enter should be in the range of 100 to 10000.	Optional
Entity mapping for sysClassNames	This parameter will override the default observer mapping for the sys_class_name entity type with a user-defined entity type. Enter the class name and the new entity type name, where the values of the class and the new entity type name are separated by a colon. Example: **cmdb_ci_linux_server:node**.	Optional
Options to exclude entity edges	Select an exclude option to exclude resource edges	Optional
List of entities to exclude edge modelling	Enter the entities to exclude resource edges. The listed entities will be not have any edge connectivity to any entities	Optional
Use **include** or **exclude** filter	Specify the type of filter to use when retrieving resources. The options are **include** (default), or **exclude**. Specify whether to include or exclude an API filter in every ServiceNow API call.	Optional. If you select **include**, you specify the filter next.
Filter resources based on JSON attributes	Specify a filter using the JSON **key:value** attribute. The format used is **key=value**, where value can be more than one: **key=value1,value2,value3** For more than one key, use the vertical bar symbol (|) as delimiter: **key=value1|key2=value1,value2,value3**	Optional. Required only if the **include** option has been set.
Number of connection retry times	Set the number of connection retries.	Optional. The default is **2**.
Delay in (milliseconds) before a connection retry	Set the delay in milliseconds before a connection retry.	Optional. The default is **5000ms**.
Maximum number of tables	Enter the number of batch calls into which you want to split each API query. Defining a number greater than one (up to a maximum of 10) can avoid the query from being too long, thereby avoiding **query too long** ServiceNow API errors.	Optional. The default and maximum is 10.
Connection timeout (milliseconds)	Set the connection timeout in milliseconds.	Optional. The default is **5000ms**.
Read timeout (milliseconds)	Set the read timeout in milliseconds.	Optional. The default is **5000ms**.
Proxy Host	Specify the proxy host to connect to.	Optional
Proxy Port	Specify the proxy port; defaults to **8080**.	Optional
Proxy Username	Specify the proxy user name to connect as. Set for basic auth proxy.	Optional
Trust all certificates by bypassing certificate verification	Set to true to allow connection to target environment without verification.	Optional. The default is 'false'.
Proxy Password	Specify the password for the proxy user (if **Proxy Username** has been specified).	Optional
Proxy Secure	Specify whether to connect to the proxy in secure mode. Set to True for HTTPS proxy.	Optional. The default is **false**.

Parameter	Action	Details
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring SevOne Observer jobs

Using the SevOne Observer functionality, you can load monitored servers and their relationships, and then visualize this data as a topology view.

Before you begin

Important: The SevOne Observer supports SevOne version 6.2.0 and API version 2.20.0.

Ensure you have the SevOne server details to hand, such as the username and password.

About this task

A SevOne Observer job extracts SevOne managed servers and their relationships via REST API calls.

You define and start the following job.

SevOne Load job

Run this job whenever you need SevOne topology data refreshed.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

SevOne resources and relationships loaded by the SevOne Observer job

Vertex	Description
Server	SevOne managed server
Ipaddress	IP address associated with the server managed by SevOne

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

SevOne Observer job parameters for Load job

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Hostname	Enter the SevOne hostname	Required
Data Tenant	Specify the data tenant used for the device group or groups.	Required
Username	Specify the SevOne username	Required
Password	Specify the SevOne password	Required. Use plain text.

Parameter	Action	Details
Device group path	Specify the device group path to be discovered. To discover more than one group, enter a comma-separated list.	Required
Number of SevOne hops	Choose the number of hops to be discovered	Required. Default is 2, maximum hops is 3.
HTTPS connection to SevOne server	Select true to enable HTTPS connection. If `true`, you must also provide the target system certificate.	Required
Topology relationship type	Select one of the following topology relationship types: `host` (creates a direct host-to-host topology relationship), or `network interface` (creates a relationship between the hosts' network interfaces)	Required
Target system certificate	Specify a certificate by name to load into the trustStore.	Required
SSL certificate hostname verification	Choose whether SSL validation is on or off. Turning SSL validation off will use HTTPS without host verification.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring TADDM Observer jobs

IBM Tivoli Application Dependency Discovery Manager (TADDM) Observer jobs retrieve network topology data, including discovered applications, their components, configurations and dependencies, from the TADDM database server (running either an IBM Db2 or an Oracle database), and use this data to create topology views.

Before you begin

Important: The TADDM Observer supports the on-premise TADDM version.

To connect to a TADDM Oracle database, you must place the Oracle JDBC Driver into the $ASM_HOME/lib folder, and then restart the observer for it to take effect. You can download the driver from the Oracle website, or copy it from the Oracle server (**not** the Oracle client) from the following location: ../app/oracle/product/Oracle_version/dbhome/jdbc/lib/ojdbc6.jar

Ensure you have the TADDM Rest API login access details in hand, such as the TADDM API URL, username and password.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The TADDM Observer is built on the Observer framework:

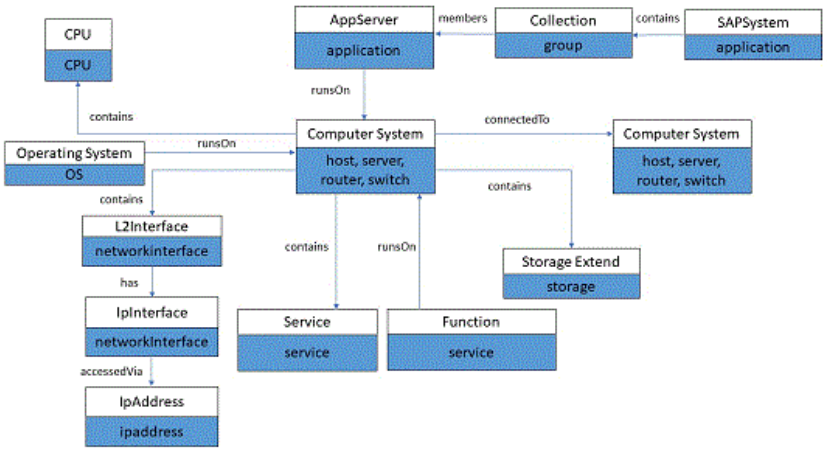

Figure. Observer framework

- A computer system can be a host, server, router, or switch
- A computer system contains CPU, L2Interface, and storage
- Operating system, application server and service run on a computer system
- A computer system can connect to another computer system
- A SAPSystem contains collection
- An application server can be a member of a collection

Mapping TADDM model objects to topology entity types

TADDM model object	Entity types
AppServer	`application`
ComputerSystem	`host`, `server`, `router`, `switch`
CPU	`cpu`
L2Interface	`networkinterface`
IpInterface	`networkinterface`
IpAddress	`ipaddress`
OperatingSystem	`os`
Service	`service`
StorageExtent	`storage`
Function	`service`
SAPSystem	`application`
Collection	`group`

TADDM Observer jobs retrieve topology data using the TADDM REST API, and the observer loads and updates the resources and their relationships within the topology service.

You define and start the following jobs.

Load job

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
TADDM password	Specify the password for the TADDM user	Required
TADDM API URL	Specify the TADDM endpoint to connect to	Required.
TADDM username	Specify the TADDM username	Required

Parameter	Action	Details
TADDM objects to observe	Select one or more options from the drop-down list	Optional. If none are selected, all supported model objects are retrieved.
TADDM certificate	Specify the certificate file name.	Optional
Certificate validation	Choose whether SSL validation is `on` or `off`. Turning SSL validation off will use HTTPS without host verification.	Optional
Connection and read timeout (ms)	Enter the time at which the connection and read actions time out	Optional. Must be a value greater than 0 (zero), and the default is 5000 (5 seconds).
Trust all certificates verification	Set to true to allow connection to target environment without verification.	Optional. The default is 'false'.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Viptela Observer jobs

You use the Viptela Observer to load managed Viptela SD-WAN control plane, vEdge and their associated network resources, and then visualize this data as a topology view.

Before you begin

Important: The Viptela Observer supports version 18.4.302 of Cisco SD-WAN.

Ensure you have the server details to hand, such as the username and password.

About this task

The Viptela Observer targets the Cisco SD-WAN (or 'Cisco Viptela') system. A Viptela Observer job extracts server information and its associated network resources from Viptela through REST API. The observer loads and updates the resources and their relationships and then displays them as a topologgy view.

You define and start the following job.

Full Topology Upload job

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Data center name	Specify the data center the vEdge runs in.	Required. If you want to discover multiple vEdge locations or sets, then provide a different data center, for example `EURDC01,USDC01`.
Cisco Viptela vManage host IP	Enter the Cisco SD-Wan Viptela vManage host IP.	Required
Cisco Viptela API port.	Specify the Cisco SD-Wan Viptela vManage API port.	Required. The default value is 8443.
Username to login to Cisco Viptela service	Specify the Cisco SD-Wan Viptela vManage username.	Required
Password for Cisco Viptela user	Specify the Cisco SD-Wan Viptela vManage password.	Required. A plain text password can be entered.
Include the control plane data	Select true to load the control plane data.	Optional
vEdge grouping preference for defined topology	Specify the vEdge grouping preference for your topology.	Optional. Supported grouping: `device-group (default)`, `site-id` `Data Tenant`
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring VMware NSX Observer jobs

You configure VMware NSX Observer jobs to dynamically load data from the VMware NSX REST interface. You can use the VMware NSX Observer when you have a VMware NSX appliance in your environment.

Before you begin

Important: The VMware NSX Observer supports the on-premises VMware NSX version 6.3.

Ensure you have the VMware NSX REST API details to hand, such as the VMware NSX URL, username, password, and SSL truststore.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The VMware NSX Observer job extracts VMware NSX resource information through REST, and the observer loads and updates the resources and their relationships within the topology service.

You define and start the following job.

VMware NSX Observer job (full topology load) This job loads a baseline of topology data from an environment, which contains a VMware NSX appliance.

Run this job whenever you need VMware NSX topology data refreshed.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

The VMware NSX Observer loads the following resources and their relationship into the IBM Cloud Pak® for AIOps core topology service:

- NSX Appliance
- vCenter Appliance
- NSX Controller
- Edge Router - Logical (Distributed) Router, Edge Service Gateway
- Virtual machines
- Host
- VNIC

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
Data center name	Specify the data center in which the VMware NSX instance runs	Required.
Network Virtualization and Security Platform API URL	Specify the API URL of the VMware NSX endpoint	Required. Usually in the following format: https://[hostname or IP address]/api
Network Virtualization and Security Platform username	Specify the username to connect as, or listen to	Required
Network Virtualization and Security Platform password	Enter the password to authenticate with	Required
Network Virtualization and Security Platform tenant name	Specify the tenant	Optional.
Network Virtualization and Security Platform certificate	Specify a certificate by name to load into the truststore	Required.
SSL Validation	Choose whether SSL validation is on or off. Turning SSL validation off will use HTTPS without host verification.	Required
SSL truststore file	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `VMWareNSX.jks`.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.
SSL truststore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
Connection and read timeout (ms)	Enter the time at which the connection and read actions time out	Optional. Must be a value greater than 0 (zero), and the default is 5000 (5 seconds).

Parameter	Action	Details
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring VMware vCenter Observer jobs

You configure VMware vCenter Observer jobs to dynamically load data from the VMware vCenter REST interface.

Before you begin

Important: The VMware vCenter Observer supports the on-premise VMware vCenter versions 6.5, 6.7 and 7.0.3.

Ensure you have the VMware vCenter service details to hand, such as username, password, SSL truststore and URL.

Important: If you have any restrictive EgressNetworkPolicies in place, ensure that they are updated to allow for this inbound connection. For more information, see Postinstallation tasks.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

The VMware vCenter Observer job extracts VMware vCenter resource information through REST, and the observer loads and updates the resources and their relationships within the topology service.

You define and start the following job.

VMware vCenter Observer job (full topology load)

Run this job whenever you need VMware vCenter topology data refreshed.

By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

The VMware vCenter Observer loads the following resources and their relationship into the topology service:

- ESXi / ESX Hosts
- Virtual machines
- VNICs
- Storage

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required

Parameter	Action	Details
Data center name	Specify the data center in which the VMware vCenter instance runs	Required. If more than one, list them (comma-separated).
vCenter API URL	Specify the API URL of the VMware vCenter endpoint (including port and version)	Required. Usually in the following format: https://[hostname or IP address]/rest
vCenter username	Specify the username to connect as, or listen to	Required
vCenter password	Enter the password to authenticate with	Required
vCenter certificate	Specify a certificate by name to load into the truststore	Required. For more information, see the Configuring observer jobs security topic.
Certificate validation	Choose whether SSL validation is on or off. Turning SSL validation off will use HTTPS without host verification.	Optional
HTTPS truststore file name	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `VMVCenter.jks`.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.
truststore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
Connection and read timeout	Enter the time at which the connection and read actions time out	Optional. Must be a value greater than 0 (zero), and the default is 5000 (5 seconds).
vCenter host's name regex to discover	Specify an exact match or a regular expression match for a host's name in order to discover all its virtual machines	Optional
Connection retry times	Set the connection retry times	Optional. The default value is 5.
Retry after delay (milliseconds)	Set the time delay before trying to reconnect (in milliseconds)	Optional. The default value is 1000.
Connection timeout	Specify the connection timeout in ms (default is 5000)	Optional
Read timeout	Specify the read timeout in ms (default is 5000)	Optional
Proxy Host	Specify the proxy host to connect to	Optional
Proxy Port	Specify the proxy port, defaults to 8080	Optional
Proxy Username	Specify the proxy user name to connect to. Set for basic auth proxy.	Optional
Trust all certificates	Select `true` to connect to target environment without verification, or 'false' to validate the certificate before connecting.	Optional. Default is `true`.
Proxy Password	Specify the password for the proxy user (if `Proxy Username` has been specified)	Optional. Use plain text.
Proxy Secure	Specify whether to connect to the proxy in secure mode. Set to True for HTTPS proxy.	Optional. The default is 'false'.
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.

Parameter	Action	Details
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring Zabbix Observer jobs

Using the Zabbix Observer functionality, you can load monitored servers and their associated network resources, and then visualize this data as a topology view.

Before you begin

The Zabbix Observer supports Zabbix 4.0.3, 6.0.3 and 6.4.11.

Ensure you have the Zabbix server details to hand, such as the username, password and SSL truststore.

Enabling access to the URL routes

To access the URL routes for the topology Swagger documentation, see the Enabling access to URL routes topic.

About this task

A Zabbix Observer job extracts server information and its associated network resources from Zabbix through REST RPC, and the observer loads and updates the resources and their relationships within the topology service.

You define and start the following job.

Full Topology Upload job By default, Load jobs are one-off, transient jobs that do a full upload of all requested topology data as soon as they are triggered.

You can also run these jobs (again) from the Observer UI, or schedule them to run at set times when configuring them.

Procedure

Define or edit the following parameters, then click **Run job** to save and run the job.

Encryption requirement: See the Configuring observer jobs security topic for more information.

Parameter	Action	Details
Unique ID	Enter a unique name for the job	Required
The datacenter of zabbix server	Specify the data center in which the Zabbix instance runs	Required. If more than one, list them (comma-separated).
Zabbix server	Enter the Zabbix virtual hostname	Required
Zabbix username	Specify the Zabbix username	Required
Zabbix password	Specify the Zabbix user password	Required
Zabbix SSL certificate	Specify a certificate file name	Required
HTTPS truststore file name	Specify the truststore file name. The observer generates the trust store file based on the file name provided. **Tip:** You can use the observer name as file name (`<observer>.jks`), for example `Zabbix.jks`.	Required. The supported format is JKS and the file is relative to $ASM_HOME/security.

Parameter	Action	Details
TrustStore file password	Specify the truststore password the observer will use to decrypt the HTTPS truststore file. Use a password that conforms to your internal security requirements.	Required
Zabbix connection timeout (milliseconds)	Timeout, in ms, when querying the Zabbix REST API	Optional. Default is 5000 (5s).
Resources to exclude	List resources by name/regex (seperated by "	"), to be excluded from the topology. By default, virtual network interfaces (veth) are not observed.
SSL Validation	Choose whether SSL validation is on or off. Turning off SSL validation will use HTTPS without host verification.	Optional
Access scope	Enter text to provide a scope for the resources. Access scope can help map alerts to resources when resources in different scopes share the same parameters, such as matchTokens.	Optional. **Tip:** You can define access scope for locations, project names, namespaces, etc.
Generate debug support file	Set this parameter to 'True' in order to capture the output of the next scheduled job run as a file. This file will be stored with an observer's log files and can be used to debug observer issues, for example at the request of your designated support team, or while using a test environment. For one-off jobs (that is, Load jobs), this parameter reverts to 'False' after the next completed run. To examine the output produced, you can load the generated debug file using the File Observer.	Optional
Observer job description	Enter additional information to describe the job	Optional
Job schedule	Specify when the job runs	Optional. Load jobs only.

Configuring observer job security

Some observers require authentication credentials such as certificates, keystores, or both. This topic describes such configuration tasks.

Note: Information on specific observers is located in the subtopics under Defining observer jobs.

To configure the security, complete the following steps:

- Obtain an authentication certificate.
- Store that certificate as a secret.

Important: Only update **`topology-custom-secrets`** with the Red Hat OpenShift Container Platform command-line interface (CLI). If you update custom secrets in the console, the crypto key is corrupted and the command to encrypt passwords does not work.

Truststore tip: The supported file format for truststore files is JKS and the file is relative to $ASM_HOME/security. You can use the observer name as file name (**`<observer>.jks`**), for example **`VMVCenter.jks`**, and use any password that conforms to your internal security requirements.

Managing authentication certificates and storing them as secrets (Red Hat OpenShift Container Platform)

1. Obtain the authentication certificate by using OpenSSL.

   ```
   echo -n | openssl s_client -connect {ipAddress}:{port} | sed -ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' | base64 -w 0 > target_system.crt
   ```

   Where **`target_system.crt`** contains the encoded certificate, and **`{ipAddress}`** is the IP address of any of the following target systems:

   - Ansible
   - Big Cloud fabric
   - BigFix Inventory
   - Ciena Blue Planet
   - Cisco ACI
   - Datadog

- Dynatrace
- Juniper CSO
- HPNFVD
- GitLab
- Kubernetes master node
- OpenStack
- Rancher
- SDC ONAP
- VMware NSX
- VMware vCenter
- Zabbix

Example `target_system.crt`:

```
[root@localhost ~]# cat target_system.crt
LS0tLS1CRUdJTiBDRVJUSUZJQ0FURS0tLS0tCk1JSUN3RENDQWFnQ0NRRGRuMENqU3BXZXhUQU5CZ2txaGtpRzl3MEJBUVVGQURBaU1

BVEUtLS0tLQo=

[root@locahost ~]#
```

2. **For the SDC ONAP Observer**, encrypt the contents of the key store file using base64.

   For example:

   ```
   cat {onap_sdc_file_name}.jks | base64 -w 0 > org.onap.sdc.trust.txt
   ```

   Where `org.onap.sdc.trust.txt` contains the encoded key store file, and `{onap_sdc_file_name}.jks` is the key store file downloaded from the target ONAP SDC system.

   Next, store the encoded file as a secret.

3. **For the GoogleCloud Observer**, encrypt the contents of the service account key file by using base64.

   For example:

   ```
   cat {project_id_file_name}.json | base64 -w 0 > googlecloud.json
   ```

   Where `googlecloud.json` contains the encoded service account key file, and `{project_id_file_name}.json` is the service account key file you downloaded from **Credentials** under **API & Services** in the Google Cloud Platform dashboard.

   Next, store the encoded service account key file as a secret.

4. Store the encoded certificate that was generated in the previous step as a secret.

   Each installed IBM Cloud Pak for AIOps release has a single special secrets file. Data added to that is made available to the appropriate observer containers.

   - Find the correct secrets file by using the following command:

     ```
     oc get secret <releasename>-custom-secrets
     ```

     Where the value of `<releasename>` and the secret can be obtained by using the following example:

     ```
     oc get asm
     ```

     Sample output:

     ```
     NAME            AGE
     aiops-topology  12d
     ```

     Find the secret for `aiops-topology`:

     ```
     oc get secret aiops-topology-custom-secrets
     ```

     Sample output:

     ```
     NAME                           TYPE     DATA   AGE
     aiops-topology-custom-secrets  Opaque   4      12d
     ```

- Edit the appropriate file for your release.

  ```
  oc edit secret <releasename>-custom-secrets
  ```

- Add a name and value pair to the data section.

  The value is the certificate generated earlier. The name is the value that you entered as the certificate file name to run the observer job.

  Example: The following sample shows the expected content in the secret file after adding **vcenter.crt**. The data section is between the **apiVersion** and **kind** sections.

  ```
  data:
  {name}:{value}
  ```

  Note: This VMware vCenter Observer example registers the **vcenter.crt** SSL certificate in Red Hat OpenShift Container Platform Secret. **vcenter.crt** is the job parameter value for the VMware vCenter Observer. Define a new **{name}** parameter in the same file for other observers that require SSL certificates. You provide the certificate in Red Hat OpenShift Container Platform Secret and the settings you provide for truststore/truststore password is used to generate a new truststore automatically.

  ```
  apiVersion: v1
  data:

  kind:Secret
  ```

  If the edit is successful, the following message will be displayed:

  ```
  secret "<release-name>-custom-secrets" edited
  ```

5. In the Red Hat OpenShift Container Platform web console, you can view the configured secret under the **Menu** > **Workload** > **Secrets** option, where the **Name** is **'<releasename>-custom-secrets'**. Within **'<releasename>-custom-secrets'**, all data configured earlier displays.

Event Manager integrations

Probes connect to an event source, detect and acquire event data, and forward the data as events. They use the logic specified in a rules file to manipulate the event elements before converting them into fields of an event in the ObjectServer alerts.status table.

If a built-in integration does not exist, you can use a probe connection from the Netcool Probe library. The Netcool Probe library contains more than 140 Probes to retrieve or receive events from many different sources. For example, any trap event sources can be consumed by an SNMP Probe. By integrating with event manager probes, you can acquire data from different data sources, including devices, databases, and log files. Some probes are uniquely designed to acquire event data from a specific source, while other more generic probes (for example, the Message Bus Probe) can be configured to integrate with a variety of sources.

Important: You can connect IBM Netcool Operations Insight probes directly to IBM Cloud Pak for AIOps without needing to install the Netcool OMNIbus ObjectServer. If you do not have an existing version of Netcool or IBM Netcool Operations Insight deployed, install the probe on either a Linux VM or Red Hat OpenShift (if supported), and follow the instructions in Installing the IBM Netcool Event Integrations Operator and common probe configuration steps to get the information of the AIOps ObjectServer and point the probe to the AIOps ObjectServer.

Note: Netcool probes are still supported in an IBM Cloud Pak for AIOps deployment. For more information, see Probes and probe integrations in the IBM Tivoli Netcool/OMNIbus documentation.

Resource requirements for running probes

This section describes the resources that each probe require per pod.

The operator controller pod resource requirements are shown below:

- CPU:
  - Requested 100m (100 millicpu)
  - Limit 200m (200 millicpu)
- Memory:
  - Requested 64Mi (~ 67 MB)
  - Limit 256Mi (~ 267 MB)

Typically each probe pod requires at least the following level of resources per pod:

- CPU Requested: 100m (100 millicpu)
- Memory Requested: 128Mi (~ 134 MB)

You can increase or decrease the resource request and limit by modifying the resources settings (resources.limits and resources.requests) in the customer resource YAML.

Cluster configuration

The minimum cluster configuration required is 1 master node and 3 worker nodes. The recommended cluster configuration is 3 master nodes and 5 worker nodes. This operator requires worker nodes that support amd64 architecture.

Connecting with on-premises probes

You can connect IBM® Netcool® Operations Insight® probes directly to IBM Cloud Pak for AIOps using an ObjectServer pair running within the Cloud Pak. By default, the ObjectServers are not started up. If you plan to connect IBM® Netcool® Operations Insight® probes, you must update the installation resource. This will change the number of replicas of the **aiops-ir-core-ncoprimary** and **aiops-ir-core-ncobackup** stateful sets and the **aiops-ir-core-ncodl-if** deployment to one.

The update that you need to make is to the **Installation** custom resource. After installing IBM Cloud Pak for AIOps, use the following steps:

1. Find your installation name and set an environment variable for it.
   1. Find the name of your IBM Cloud Pak for AIOps installation.

      ```
      oc get installation -n <project>
      ```

      Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

      Example output, where **ibm-cp-aiops** is the name of the IBM Cloud Pak for AIOps installation:

      ```
      NAME           PHASE     LICENSE    STORAGECLASS  STORAGECLASSLARGEBLOCK  AGE
      ibm-cp-aiops   Running   Accepted   rook-cephfs   rook-ceph-rbd           34h
      ```

   2. Export environment variables.

      ```
      export INSTALLATION_NAME=<name>
      export PROJECT_CP4AIOPS=<project>
      ```

      Where:

      - **<name>** is the name returned by the previous command, for example **ibm-cp-aiops**.
      - **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.
2. Run the following command to edit the installation.

   ```
   oc edit installation ${INSTALLATION_NAME} -n ${PROJECT_CP4AIOPS}
   ```

3. Set the values as follows to scale up **nocprimary** and **ncobackup**:

   ```
   spec:
     pakModules:
       - enabled: true
         name: aiManager
   ```

```
    - enabled: true
      name: aiopsFoundation
    - enabled: true
      name: applicationManager
      config:
       - name: ir-core-operator
         spec:
           issueresolutioncore:
             customSizing:
               deployments:
               - name: ncodl-if
                 replicas: 1
               statefulSets:
               - name: ncoprimary
                 replicas: 1
               - name: ncobackup
                 replicas: 1
```

These pods will start **aiops-ir-core-ncoprimary-0** and **aiops-ir-core-ncobackup-0**

Shutting down nocprimary and ncobackup

1. Find your installation name and set an environment variable for it.
    1. Find the name of your IBM Cloud Pak for AIOps installation.

       ```
       oc get installation -n <project>
       ```

       Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

       Example output, where **ibm-cp-aiops** is the name of the IBM Cloud Pak for AIOps installation:

       ```
       NAME           PHASE    LICENSE   STORAGECLASS STORAGECLASSLARGEBLOCK AGE
       ibm-cp-aiops   Running  Accepted  rook-cephfs  rook-ceph-rbd          34h
       ```

    2. Export environment variables.

       ```
       export INSTALLATION_NAME=<name>
       export PROJECT_CP4AIOPS=<project>
       ```

       Where:

       - **<name>** is the name returned by the previous command, for example **ibm-cp-aiops**.
       - **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.
2. Run the following command to edit the installation.

   ```
   oc edit installation ${INSTALLATION_NAME} -n ${PROJECT_CP4AIOPS}
   ```

3. To shut down **nocprimary** and **ncobackup**, scale them down to 0.

   ```
   spec:
     pakModules:
       - enabled: true
         name: aiManager
       - enabled: true
         name: aiopsFoundation
       - enabled: true
         name: applicationManager
         config:
          - name: ir-core-operator
            spec:
              issueresolutioncore:
                customSizing:
                  deployments:
                  - name: ncodl-if
                    replicas: 0
                  statefulSets:
                  - name: ncoprimary
                    replicas: 0
                  - name: ncobackup
                    replicas: 0
   ```

Monitoring the processes

ncoprimary and **ncobackup** are not managed by deployment. They are managed by statefulsets (sts).

If you run the following command to grep the pods for **ncoprimary** and **ncobackup**, you will not see anything:

```
oc get pod | grep aiops-ir-core-ncoprimary-0
```

If you then check the statefulset using the following command:

```
oc get sts | grep nco
```

You can see you can see that the pods are listed under the statefulset, but they are not running:

```
aiops-ir-core-ncobackup                                 0/0     49d
aiops-ir-core-ncoprimary                                0/0     49d
```

To get these pods up and running, complete the following steps:

1. Scale up the statefulsets.

   Scale up **aiops-ir-core-ncobackup**:

   ```
   oc scale --replicas=1 sts/aiops-ir-core-ncobackup
   ```

   Expected output:

   ```
   statefulset.apps/aiops-ir-core-ncobackup scaled
   ```

   Scale up **aiops-ir-core-ncoprimary**:

   ```
   oc scale --replicas=1 sts/aiops-ir-core-ncoprimary
   ```

   Expected output:

   ```
   statefulset.apps/aiops-ir-core-ncoprimary scaled
   ```

2. Check the pods for **ncoprimary** and **ncobackup**.

   Check for **ncoprimary**:

   ```
   oc get pod | grep aiops-ir-core-ncoprimary-0
   ```

   Expected output:

   ```
   aiops-ir-core-ncoprimary-0                                        1/1     Running     0
   5m24s
   ```

   Check for **ncobackup**:

   ```
   oc get pod | grep aiops-ir-core-ncobackup-0
   ```

   Expected output:

   ```
   aiops-ir-core-ncobackup-0                                         2/2     Running     0
   5m54s
   ```

3. Grep **pvc** for **nco**.

   ```
   oc get pvc | grep nco
   ```

   Expected output:

   ```
   database-aiops-ir-core-ncobackup-0                                Bound    pvc-534c0182-0ce9-47d1-a134-
   20168781965c   5Gi        RWO            ocs-storagecluster-cephfs     18m
   database-aiops-ir-core-ncoprimary-0                               Bound    pvc-4507add6-9d6f-432b-9a53-
   644c742c61cd   5Gi        RWO            ocs-storagecluster-cephfs     17m
   ```

Integrating stand-alone on-premises probes to IBM Cloud Pak for AIOps

If you want to connect stand-alone on-premises probes to IBM Cloud Pak for AIOps, you can use NodePorts to securely connect to the in-cluster ObjectServer.

These instructions can be used to connect an on-premises deployment of IBM® Netcool® Operations Insight® to IBM Cloud Pak for AIOps.

Complete the steps in both of the following topics.

- Configuring the Cloud system
- Configuring the on-premises system

Note: IBM Cloud Pak for AIOps does not support connecting with a uni-directional gateway.

Configuring the Cloud system

1. Run the following commands to expose the ObjectServer services as node ports.

   Ensure that you replace **<name>** with the name of your IBM Cloud Pak® for AIOps instance.

   For more information about the configured IBM Cloud Pak for AIOps ports, see Ports.

```
cat << EOF | oc apply -f -
apiVersion: v1
kind: Service
metadata:
  labels:
    app.kubernetes.io/component: ncoprimary
    app.kubernetes.io/instance: aiops
    app.kubernetes.io/managed-by: ir-core-operator
    app.kubernetes.io/name: IssueResolutionCore
  name: aiops-ir-core-ncoprimary-np
spec:
  ports:
  - name: tds
    port: 4100
    protocol: TCP
    targetPort: 4100
  selector:
    app.kubernetes.io/component: ncoprimary
    app.kubernetes.io/instance: aiops
    app.kubernetes.io/managed-by: ir-core-operator
    app.kubernetes.io/name: IssueResolutionCore
  sessionAffinity: None
  type: NodePort
EOF

cat << EOF | oc apply -f -
apiVersion: v1
kind: Service
metadata:
  labels:
    app.kubernetes.io/component: ncobackup
    app.kubernetes.io/instance: aiops
    app.kubernetes.io/managed-by: ir-core-operator
    app.kubernetes.io/name: IssueResolutionCore
  name: aiops-ir-core-ncobackup-np
spec:
  ports:
  - name: tds
    port: 4100
    protocol: TCP
    targetPort: 4100
  selector:
    app.kubernetes.io/component: ncobackup
    app.kubernetes.io/instance: aiops
    app.kubernetes.io/managed-by: ir-core-operator
    app.kubernetes.io/name: IssueResolutionCore
  sessionAffinity: None
  type: NodePort
EOF
```

2. Get the service node port for the primary:

```
NCOPRIMARY_NODEPORT=$(oc get svc aiops-ir-core-ncoprimary-np -o jsonpath='{.spec.ports[?
(@.port==4100)].nodePort}')
```

3. Get the service node port for the backup:

```
NCOBACKUP_NODEPORT=$(oc get svc aiops-ir-core-ncobackup-np -o jsonpath='{.spec.ports[?
(@.port==4100)].nodePort}')
```

4. Get the node internal IP addresses:

```
oc get node -o jsonpath='{.items[*].status.addresses[?(@.type=="InternalIP")].address}'
```

   The output of the command returns the master node IP addresses and worker node IP addresses. You can run the following command to confirm which IP address belongs to which node.

```
oc get nodes -o wide | grep <NAME_OF_MASTER_OR_WORKER_NODE>
```

   Where **<NAME_OF_MASTER_OR_WORKER_NODE>** is the name of the master node or worker node. For example, the name can be **master1** or **worker1**.

5. Depending on the configuration of your cluster, you might need to add network policies to allow network traffic from outside the cluster. To test this, use the commands below. If you are using a proxy such as HA proxy (see below) you should run the test on the host running the

proxy. Otherwise, run the test on the host running your on-premise system. Each of the following commands should output **CONNECTED**, followed by a **Certificate chain** with the first subject containing **ncoprimary** or **ncobackup**.

```
openssl s_client -connect <WORKER0_IP>:${NCOPRIMARY_NODEPORT} < /dev/null
openssl s_client -connect <WORKER0_IP>:${NCOBACKUP_NODEPORT} < /dev/null
```

Where

- **<WORKER0_IP>** is the value of worker IP address from the node internal IP addresses command.
- **${NCOPRIMARY_NODEPORT}** is the service node port for the primary ObjectServer.
- **${NCOBACKUP_NODEPORT}** is the service node port for the backup ObjectServer.

6. If the test in step **5** fails, you might need to add network policies. The ingress "from" rules are specific to your cluster and the clients or proxies that you want to connect to the ObjectServers. The rest of the policies should look as follows:

```
---
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: ncoprimary-external-ingress
  namespace: aiops_namespace
spec:
  ingress:
  - from:
      # Add ingress rules required for your cluster and on-premises system here
    ports:
    - port: 4100
      protocol: TCP
  podSelector:
    matchLabels:
      app.kubernetes.io/component: ncoprimary
      app.kubernetes.io/instance: aiops
  policyTypes:
  - Ingress
...
---
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: ncobackup-external-ingress
spec:
  ingress:
  - from:
      # Add ingress rules required for your cluster and on-premises system here
    ports:
    - port: 4100
      protocol: TCP
  podSelector:
    matchLabels:
      app.kubernetes.io/component: ncobackup
      app.kubernetes.io/instance: aiops
  policyTypes:
  - Ingress
...
```

7. Next, you must update any proxies and firewalls to ensure that the exposed node ports are reachable. For example, if you have a HA proxy in front of your Red Hat OpenShift Container Platform cluster, you only need to update the HA proxy configuration that is running on the main control node. This routes that port to the master and worker nodes in the cluster. When you are logged on to that cluster, perform the following steps:

    1. Run the command:

       ```
       systemctl stop haproxy.service
       ```

    2. Add the following entries to **/etc/haproxy/haproxy.cfg**:

       ```
       frontend ingress-ncoprimary
           bind *:<NCOPRIMARY_NODEPORT>
           default_backend ingress-ncoprimary
           mode tcp
           option tcplog

       backend ingress-ncoprimary
           balance source
           mode tcp
           server master0 <MASTER0_IP>:<NCOPRIMARY_NODEPORT> check
           server master1 <MASTER1_IP>:<NCOPRIMARY_NODEPORT> check
           server master2 <MASTER2_IP>:<NCOPRIMARY_NODEPORT> check
           server worker0 <WORKER0_IP>:<NCOPRIMARY_NODEPORT> check
           server worker1 <WORKER1_IP>:<NCOPRIMARY_NODEPORT> check
           server worker2 <WORKER2_IP>:<NCOPRIMARY_NODEPORT> check
       ```

```
frontend ingress-ncobackup
    bind *:<NCOBACKUP_NODEPORT>
    default_backend ingress-ncobackup
    mode tcp
    option tcplog

backend ingress-ncobackup
    balance source
    mode tcp
    server master0 <MASTER0_IP>:<NCOBACKUP_NODEPORT> check
    server master1 <MASTER1_IP>:<NCOBACKUP_NODEPORT> check
    server master2 <MASTER2_IP>:<NCOBACKUP_NODEPORT> check
    server worker0 <WORKER0_IP>:<NCOBACKUP_NODEPORT> check
    server worker1 <WORKER1_IP>:<NCOBACKUP_NODEPORT> check
    server worker2 <WORKER2_IP>:<NCOBACKUP_NODEPORT> check
```

Where

- **<MASTER0_IP>**, **<MASTER1_IP>**, and **<MASTER2_IP>** are the values of master IP addresses from node internal IP addresses command.
- **<WORKER0_IP>**, **<WORKER1_IP>**, and **<WORKER2_IP>** are the values of worker IP addresses from node internal IP addresses command.
- **<NCOPRIMARY_NODEPORT>** is the value of service node port for the primary ObjectServer.
- **<NCOBACKUP_NODEPORT>** is the value of service node port for the backup ObjectServer.

3. Run the command:

```
systemctl start haproxy.service
```

8. Run the following command to retrieve the challenge credentials for the probe:

```
oc get secret aiops-ir-core-omni-secret -o=jsonpath='{.data.OMNIBUS_PROBE_PASSWORD}' | base64 -d
```

Configuring the on-premises system

1. Get the service CA that signed the ObjectServer certificates:

   Note: You must run this step on the cloud side and copy over the **service-ca.crt** to the on-premises server.

   ```
   oc get configmap <name>-tls-ca -o jsonpath='{.data.ca\.crt}' > service-ca.crt
   ```

   Where **<name>** is the name of your installation resource.

2. Import the CA certificate into the IBM Tivoli Netcool/OMNIbus keystore:

   ```
   $NCHOME/bin/nc_gskcmd -keydb -create -db $NCHOME/etc/security/keys/omni.kdb  -pw "$KEYSTORE_PW" -stash

   $NCHOME/bin/nc_gskcmd -cert -add -db $NCHOME/etc/security/keys/omni.kdb -pw "$KEYSTORE_PW" -label "CA"
   -file service-ca.crt
   ```

   Note: The default for **$NCHOME is /opt/IBM/tivoli/netcool/**.

3. Add the local host resolution for service name that is used in the CN of certificates to the IP of the cluster control node. This is so that the client can validate the certificate chain by the hostname used.

   ```
   /etc/hosts:
   <cluster_control_node_ip> aiops-ir-core-ncoprimary.<namespace>.svc
   <cluster_control_node_ip> aiops-ir-core-ncobackup.<namespace>.svc
   ```

4. Update the **omni.dat** (**$NCHOME/etc/omni.dat**) with the necessary connection details, for example:

   ```
   [AIOPS_AGGV]
   {
           Primary: aiops-ir-core-ncoprimary.<namespace>.svc ssl ${NCOPRIMARY_NODEPORT}
           Backup: aiops-ir-core-ncobackup.<namespace>.svc ssl ${NCOBACKUP_NODEPORT}
   }
   ```

   Then, regenerate the interfaces file through **$NCHOME/bin/nco_igen**.

5. Try pinging the server by name:

   ```
   $NCHOME/omnibus/bin/nco_ping AIOPS_AGGV
   ```

6. Specify the challenge credentials in the probe property files:

```
AuthUsername: "aiopsprobe"
AuthPassword: "<password from step 6 of on cloud side>"
```

Probe for IBM SevOne Network Performance Management (NPM) integration

You can configure the Probe integration for connecting IBM SevOne Network Performance Management to IBM Cloud Pak for AIOps.

Note: Since the release of IBM Cloud Pak AIOps 4.1, you can now use a Generic Webhook integration to integrate IBM Cloud Pak for AIOps with IBM SevOne Network Performance Management (NPM) to digest events. Using a Webhook integration is preferred over installing a probe to connect with IBM SevOne as it simplifies the setup process. For details see Creating Generic Webhook integrations.

- Overview
- Deployment Scenarios
- Installation

Overview

The Probe integration for IBM SevOne NPM creates a webhook endpoint to receive policy based alerts from IBM SevOne NPM. This integration is provided by the IBM Netcool Operations Insight Event Integrations Operator 3.4. Depending on your deployment you can configure the probe integration for IBM SevOne NPM connection to the IBM Cloud Pak for AIOps. If it is the IBM Cloud Pak for AIOps, the Probe integration for IBM SevOne NPM with IBM Cloud Pak for AIOps consists of the following steps. As a prerequisite you need the following systems: IBM Cloud Pak for AIOps in openshift container platform, and IBM SevOne Network Management System (NMS) 6.1. You then need to install the IBM Netcool event integrations operator, gather IBM Cloud Pak for AIOps ObjectServer connection information, configure and install the probe for SevOne integration, obtain the probe Webhook URL, and then lastly, configure IBM SevOne Network Management System (NMS) to forward events to the probe for SevOne.

Deployment Scenarios

Depending on your deployment scenario, you can configure the Probe integration for IBM SevOne NPM connecting to the IBM Cloud Pak for AIOps.

Installation

Note: Using the Generic Webhook integration is preferred over installing a probe to integrate with IBM SevOne, so you should consider migrating to this method. See Creating Generic Webhook integrations.

The instructions to configure the probe with IBM Cloud Pak for AIOps are provided in the following link. Follow the instructions according to your deployment architecture.

IBM SevOne NPM Integration with IBM Cloud Pak for AIOps

Install the Probe integration for IBM SevOne NPM connecting to IBM Cloud Pak for AIOps.

Probe integration for IBM SevOne Network Performance Management (NPM) with IBM Cloud Pak for AIOps

You can use a probe to integrate IBM Cloud Pak for AIOps with IBM SevOne Network Performance Management (NPM).

When this integration is created, alert changes from SevOne are reported within IBM Cloud Pak for AIOps. Changes in IBM Cloud Pak for AIOps are not reported in SevOne.

The properties of the alerts include fields that are based on the IBM Netcool Operations Insight **`alert.status`** table columns (**`Identifier`**, **`AlertGroup`**, **`AlertKey`**, **`EventId`**, and more).

The following table shows comparative severity mapping:

SevOne Severity	IBM Netcool Operations Insight Severity	IBM Cloud Pak for AIOps Severity
Emergency, Alert, Critical	Critical	Critical
Error	Major	Major
Warning	Warning	Warning

SevOne Severity	IBM Netcool Operations Insight Severity	IBM Cloud Pak for AIOps Severity
Notice, Info, Debug	Informational	Informational
Indeterminate	Indeterminate	Indeterminate
Cleared (from clear condition)	(Creates a resolution event)	(Clears alert)

Prerequisites

You need to install the IBM Netcool Event Integrations Operator and gather the ObjectServer connection information before proceeding with defining the probe integration. For more information about installing the operator, see Installing the IBM Netcool Event Integrations Operator and common probe configuration steps

Configure and Install Probe For SevOne Integration

1. Set the probe namespace variable to the namespace where you want to install the probe. Usually this namespace is the same namespace as the IBM Netcool Operations Insight Event Integrations Operator.

   ```
   PROBE_NAMESPACE=<probe-namespace>
   ```

2. Create a secret with the ObjectServer credentials for the probe to authenticate with the ObjectServer.

   ```
   PROBE_OMNI_SECRET=noi-probe-secret
   oc create secret generic $PROBE_OMNI_SECRET --namespace $PROBE_NAMESPACE \
    --from-literal=AuthUserName=$IRC_OMNI_USERNAME \
    --from-literal=AuthPassword=$IRC_OMNI_PASSWORD
   ```

   (Optional) If you want to import the ObjectServer TLS Certificate, use the following command to specify the **tls.crt** file in the secret.

   ```
   PROBE_OMNI_SECRET=noi-probe-secret
   oc create secret generic $PROBE_OMNI_SECRET --namespace $PROBE_NAMESPACE \
    --from-literal=AuthUserName=$IRC_OMNI_USERNAME \
    --from-literal=AuthPassword=$IRC_OMNI_PASSWORD \
    --from-file=tls.crt=tls.crt
   ```

3. Create a secret for the probe to use for basic authentication.

   ```
   PROBE_AUTH_SECRET=sevone-probe-client-basic-auth
   oc create secret generic --namespace $PROBE_NAMESPACE $PROBE_AUTH_SECRET --from-
   literal=serverBasicAuthenticationUsername=<username>  --from-literal=serverBasicAuthenticationPassword=
   <password>
   ```

   where **<username>** is a user name and **<password>** is the password for SevOne NMS to use as basic authentication.

4. Create a Network Policy in the IBM Cloud Pak for AIOps namespace.

   Note: Review any other Network Policy that may be denying access to the ObjectServer pod and update the policy to allow ingress connection to the pods.

   ```
   cat << EOF | tee >(oc apply -f -) | cat
   apiVersion: networking.k8s.io/v1
   kind: NetworkPolicy
   metadata:
     name: probe-allow-objectserver
     namespace: ${IRC_NAMESPACE}
   spec:
     ingress:
     - from:
       - namespaceSelector:
           matchLabels:
             kubernetes.io/metadata.name: noi-integrations
       ports:
         - protocol: TCP
           port: 4100
     podSelector:
       matchLabels:
         app.kubernetes.io/instance: ${IRC_INSTANCE}
         app.kubernetes.io/managed-by: ir-core-operator
         app.kubernetes.io/name: IssueResolutionCore
     policyTypes:
     - Ingress
   EOF
   ```

5. Create a Probe for SevOne Integrations with the **WebhookProbe** custom resource by running the following commands.

   ```
   PROBE_SEVONE_INSTANCE=sevone-probe

   cat << EOF | tee >(oc apply -f -) | cat
   ```

```
apiVersion: probes.integrations.noi.ibm.com/v1
kind: WebhookProbe
metadata:
  name: ${PROBE_SEVONE_INSTANCE}
  labels:
    app.kubernetes.io/name: ${PROBE_SEVONE_INSTANCE}
    app.kubernetes.io/managed-by: netcool-integrations-operator
    app.kubernetes.io/instance: ${PROBE_SEVONE_INSTANCE}
  namespace: ${PROBE_NAMESPACE}
spec:
  helmValues:
    netcool:
      backupHost: '${IRC_BACKUP_OBJECTSERVER_SVC}.${IRC_NAMESPACE}.svc'
      backupPort: ${IRC_BACKUP_OBJECTSERVER_PORT}
      backupServer: 'AGGB'
      connectionMode: SSLAndAuth
      primaryHost: '${IRC_PRIMARY_OBJECTSERVER_SVC}.${IRC_NAMESPACE}.svc'
      primaryPort: ${IRC_PRIMARY_OBJECTSERVER_PORT}
      primaryServer: 'AGGP'
      secretName: '${PROBE_OMNI_SECRET}'
    probe:
      jsonParserConfig:
        notification:
          jsonNestedHeader: ''
          jsonNestedPayload: ''
          messageDepth: 3
          messageHeader: ''
          messagePayload: json
      integration: sevone
      enableTransportDebugLog: false
      messageLevel: debug
    ingress:
      enabled: true
      host: ''
    arch: amd64
    webhook:
      uri: /probe/sevone
      serverBasicAuthenticationCredentialsSecretName: '${PROBE_AUTH_SECRET}'
      tls:
        enabled: true
        secretName: ''
  license:
    accept: true
  version: 3.1.0
EOF
```

6. Verify that the probe pod is running.

```
oc get pods -l app.kubernetes.io/instance=$PROBE_SEVONE_INSTANCE
```

Obtain the Probe Webhook URL

Use the following command to get the probe webhook URL, which is used to configure a Webhook destination in IBM SevOne NMS.

```
PROBE_HOSTNAME=$(oc get route $PROBE_SEVONE_INSTANCE-mb-webhook -o jsonpath='{.spec.host}')
PROBE_URI=$(oc get route $PROBE_SEVONE_INSTANCE-mb-webhook -o jsonpath='{.spec.path}')
PROBE_WEBHOOK_URL=https://$PROBE_HOSTNAME$PROBE_URI
echo "$PROBE_WEBHOOK_URL"
```

Configure IBM SevOne Network Management System (NMS) to forward events to the Probe for SevOne

IBM SevOne NMS must be configured with a new webhook configuration to send alerts to the Probe for SevOne NMS.

Note: Instructions to configure the webhook with SevOne NMS can differ depending on your SevOne NMS version. For more information about using the SevOne Webhook Definition Manager and configuring alerts in SevOne NMS, see NMS 6.6 Guides and the SevOne NMS User Guide.

Note IBM SevOne requires the webhook destination to use a TLS certificate signed by a trusted Certificate Authority (CA).

1. Log in to the IBM SevOne console.
2. On the top menu, go to **Events > Configuration > Webhook Definition Manager**.
3. On the Policy Browser page, click **Configure Webhook Destination** on the Policies panel.
4. Complete the following steps from the Add Webhook Destination panel:

1. Set a Webhook Destination Name, for example: IBM Cloud Pak for AIOps Probe for SevOne
2. Set a Description, for example: IBM Cloud Pak for AIOps Probe for SevOne NMS
3. Set the URL with the **`$PROBE_WEBHOOK_URL`** value from the previous Obtaining the Probe Webhook URL section.
4. Select the **Allow insecure webhook connection** option if the probe uses a self-signed certificate.
5. Expand the Headers section and select **Use Basic Auth**. Then, set the **Username** and **Password** fields with the credentials set in the **`PROBE_AUTH_SECRET`** from the Configure and install probe for SevOne integration section.
6. Click **Test Definition** to send a test HTTP event to the probe. Test both the triggering condition and clear condition webhooks to ensure that the recieved response code is **`200`** or **`204`**.
   - A **`204`** status code indicates that no payload is included in the HTTP response, but the connection is successful.
   - If a response code of **`400 Bad request`** is received, check the JSON template that is configured. Ensure that the JSON does not contain any syntax errors.
7. Click **Save**.

5. Configure or create policies to send events to the probe by selecting the probe as the webhook destination. For each of the policies in the **Webhooks** section, select the webhook that was created in the previous step. Complete the selection for the **Trigger Conditions** and **Clear Conditions** tabs and select the **One Webhook per Alert** option.

Probe for IBM Turbonomic integration

You can configure the Probe integration for connecting IBM Turbonomic to IBM Cloud Pak for AIOps.

Note: Since the release of IBM Cloud Pak AIOps 4.1, you can now use a Generic Webhook integration to integrate IBM Cloud Pak for AIOps with IBM Turbonomic to digest events. Using a Webhook integration is preferred over installing a probe to connect with IBM Turbonomic as it simplifies the setup process. For details see Creating Generic Webhook integrations.

The Probe integration for IBM Turbonomic is provided by the IBM Netcool Operations Insight Event Integrations Operator.

- Prerequisites
- Common pre-installation tasks
- Configure and install probe For Turbonomic integration
- Obtain the probe Webhook URL
- Configure IBM Turbonomic to forward events to the probe for Turbonomic

Prerequisites

The following systems are prerequisites for this integration.

1. IBM Cloud Pak for AIOps in Openshift Container Platform
2. IBM Turbonomic (IBM Turbonomic 8.6)

Common pre-installation tasks

Follow the instructions in Installing the IBM Netcool Event Integrations Operator and common probe configuration steps to install the operator and gather the ObjectServer connection information before proceeding with the following sections.

Configure and install probe For Turbonomic integration

Note: Using the Generic Webhook integration is preferred over installing a probe to connect with IBM Turbonomic, so you should consider migrating to this method. See Creating Generic Webhook integrations.

Use the following steps to create the required secrets, configure the WebhookProbe custom resource and install the probe in the namespace.

1. Create a secret with the ObjectServer credentials for the probe to authenticate with the ObjectServer.

```
PROBE_OMNI_SECRET=noi-probe-secret
oc create secret generic $PROBE_OMNI_SECRET \
 --from-literal=AuthUserName=$IRC_OMNI_USERNAME \
 --from-literal=AuthPassword=$IRC_OMNI_PASSWORD
```

   If you want to import the ObjectServer TLS Certificate (optional), use the following command to specify the **`tls.crt`** file in the secret.

```
PROBE_OMNI_SECRET=noi-probe-secret
oc create secret generic $PROBE_OMNI_SECRET \
 --from-literal=AuthUserName=$IRC_OMNI_USERNAME \
 --from-literal=AuthPassword=$IRC_OMNI_PASSWORD \
 --from-file=tls.crt=tls.crt
```

2. Create a secret for the probe to use for basic authentication.

```
PROBE_AUTH_SECRET=turbonomic-probe-client-basic-auth
oc create secret generic $PROBE_AUTH_SECRET --from-literal=serverBasicAuthenticationUsername=<username>
--from-literal=serverBasicAuthenticationPassword=<password>
```

where **<username>** is a user name and **<password>** is the password for Turbonomic to use as basic authentication.

3. Create a Network Policy in the IBM Cloud Pak for AIOps namespace.

Note: Review any other network policy that may be denying access to the ObjectServer pod(s) and update the policy to allow ingress connection to the pods.

```
cat << EOF | tee >(oc apply -f -) | cat
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: probe-allow-objectserver
  namespace: ${IRC_NAMESPACE}
spec:
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          kubernetes.io/metadata.name: noi-integrations
    ports:
      - protocol: TCP
        port: 4100
  podSelector:
    matchLabels:
      app.kubernetes.io/instance: ${IRC_INSTANCE}
      app.kubernetes.io/managed-by: ir-core-operator
      app.kubernetes.io/name: IssueResolutionCore
  policyTypes:
  - Ingress
EOF
```

4. Create a probe for Turbonomic integrations with the **WebhookProbe** custom resource by running the following commands:

```
PROBE_TURBONOMIC_INSTANCE=turbonomic-probe

cat << EOF | tee >(oc apply -f -) | cat
apiVersion: probes.integrations.noi.ibm.com/v1
kind: WebhookProbe
metadata:
  name: ${PROBE_TURBONOMIC_INSTANCE}
  labels:
    app.kubernetes.io/name: ${PROBE_TURBONOMIC_INSTANCE}
    app.kubernetes.io/managed-by: netcool-integrations-operator
    app.kubernetes.io/instance: ${PROBE_TURBONOMIC_INSTANCE}
  namespace: ${NAMESPACE}
spec:
  helmValues:
    netcool:
      backupHost: '${IRC_BACKUP_OBJECTSERVER_SVC}.${IRC_NAMESPACE}.svc'
      backupPort: ${IRC_BACKUP_OBJECTSERVER_PORT}
      backupServer: 'AGGB'
      connectionMode: SSLAndAuth
      primaryHost: '${IRC_PRIMARY_OBJECTSERVER_SVC}.${IRC_NAMESPACE}.svc'
      primaryPort: ${IRC_PRIMARY_OBJECTSERVER_PORT}
      primaryServer: 'AGGP'
      secretName: '${PROBE_OMNI_SECRET}'
    probe:
      jsonParserConfig:
        notification:
          jsonNestedHeader: ''
          jsonNestedPayload: ''
          messageDepth: 3
          messageHeader: ''
          messagePayload: json
      integration: Turbonomic
      enableTransportDebugLog: false
      messageLevel: debug
    ingress:
      enabled: true
      host: ''
```

```
    arch: amd64
    webhook:
      uri: /probe/turbonomic
      serverBasicAuthenticationCredentialsSecretName: '${PROBE_AUTH_SECRET}'
      tls:
        enabled: true
        secretName: ''
  license:
    accept: true
  version: 3.1.0
EOF
```

5. Verify that the probe pod is running.

```
oc get pods -l app.kubernetes.io/instance=$PROBE_TURBONOMIC_INSTANCE
```

Obtain the probe Webhook URL

Use the following command to get the probe webhook URL, which is used to configure a Webhook destination in IBM Turbonomic.

```
PROBE_HOSTNAME=$(oc get route $PROBE_TURBONOMIC_INSTANCE-mb-webhook -o jsonpath='{.spec.host}')
PROBE_URI=$(oc get route $PROBE_TURBONOMIC_INSTANCE-mb-webhook -o jsonpath='{.spec.path}')
PROBE_WEBHOOK_URL=https://$PROBE_HOSTNAME$PROBE_URI
echo "$PROBE_WEBHOOK_URL"
```

Configure IBM Turbonomic to forward events to the probe for Turbonomic

IBM Turbonomic must be configured with a new webhook configuration to send alerts to the probe for Turbonomic.

Creating a workflow

1. Set the following variables:

```
TURBONOMIC_HOSTNAME=<api endpoint hostname>
TURBONOMIC_ADMIN_USER=<turbonomic username>
TURBONOMIC_ADMIN_PASSWORD=<turbonomic password>
BASIC_AUTH_USERNAME=<probe basic authentication username>
BASIC_AUTH_PASSWORD=<probe basic authentication password>
```

2. Get the JSESSIONID token

```
JSESSIONID=$(curl \
--silent \
--cookie-jar - \
--insecure \
https://${TURBONOMIC_HOSTNAME}/api/v3/login?hateoas=true \
--data "username=${TURBONOMIC_ADMIN_USER}&password=${TURBONOMIC_ADMIN_PASSWORD}" \
| awk '/JSESSIONID/{print $7}')
```

3. Create a workflow

```
curl \
"https://${TURBONOMIC_HOSTNAME}/api/v3/workflows" \
--insecure \
--compressed \
--header 'Accept: application/json' \
--header 'Content-Type: application/json' \
--header "cookie: JSESSIONID=${JSESSIONID}" \
--request POST \
-vv \
--data @- <<EOF
{
"displayName": "Event Probe",
"className": "Workflow,
"description": "Event webhook probe",
"discoveredBy": {
    "readonly": false
},
"type": "WEBHOOK",
"typeSpecificDetails": {
```

```
  "url": "${PROBE_WEBHOOK_URL}",
  "method": "POST",
  "authenticationMethod": "BASIC",
  "username": "${BASIC_AUTH_USERNAME}",
  "password": "${BASIC_AUTH_PASSWORD}",
  "template": "\$converter.toJson(\$action)",
  "trustSelfSignedCertificates": true,
  "headers": [
     {
      "name": "Content-type",
      "value": "application/json"
     }
   ],
  "type": "WebhookApiDTO"
  }
}
EOF
```

4. Get the workflow UID for later use.

```
WORKFLOW_UUID=$(curl \
"https://${TURBONOMIC_HOSTNAME}/api/v3/workflows" \
--insecure \
--compressed \
--header 'Accept: application/json' \
--header 'Content-Type: application/json' \
--header "cookie: JSESSIONID=${JSESSIONID}" \
--request GET | jq -c ".[] | select(.typeSpecificDetails .
url | contains(\"${PROBE_WEBHOOK_URL}\")) | .uuid" | tr -d '"')
```

Create a policy

1. Log in to the Turbonomic console.
2. Navigate to the *Settings* page and then choose **Policies**.
3. Click **New Automation Policy** and then select the policy type, **Virtual Machine** in this case. This sets the type of entity that your policy will affect. Refer to Working with policies for more information.

   Name the policy:

   - **Add Scope** The scope determines which entities this policy will affect. Choose one or more groups, or create new groups and add them to the policy scope. These groups match the type of entity you have set for the policy.
   - **Policy Schedule** The *Select Schedule* fly-out lists all the schedules that are currently defined for your instance of Turbonomic. Expand a schedule entry to see further details, or skip it if you don't need the schedule.
   - **Automation and Orchestration** You can define automation and orchestration settings for different action types within the same policy.
     - **Action Type** See a list of actions that are viable for the policy, and then make your selections.
     - **Action Generation and Acceptance**:
       - Do not generate actions as Turbonomic doesn't considers your selected actions in its calculations. For example, if you do not want to generate resize actions for VMs in the policy, analysis will still drive toward the desired state, but will do so without considering resizes.
       - Generate Actions Turbonomic generates your selected actions to address or prevent problems. Choose from the following *Action Acceptance* modes to indicate how you would like the actions to run:
         - **Recommend** — Recommend the action so a user can run it via the given hypervisor or by other means
         - **Manual** — Recommend the action, and provide the option to run that action through the Turbonomic user interface
         - **Automatic** — Run the action automatically For automated resize or move actions on the same entity, Turbonomic waits five minutes between each action to avoid failures associated with trying to run all actions at once. Any action awaiting execution stays in queue.
     - **Before Execution and Action Execution:** By default, generated actions run without the need for orchestration. Turbonomic gives you the ability to set up orchestration to affect the execution of actions.
     - **After Execution**: The default is to 'do nothing'. Other options include:
       - **Create Record in Orchestration** Turbonomic registers the action in the Orchestration log, showing that the given action has been run. For example: A final ActionID could be created and with the final ActionState, the Type and

Severity would be updated accordingly in IBM Cloud Pak for AIOps. Those actions would also be updated to IBM Cloud Pak for AIOps, and it would handle with the alerts with updated state: closed or cleared or keep open.

- **Use Action Script** Run an action script that is set up for the POST entrypoint. The action script name must match the entity type and action type.

4. Save the policy.
5. Action events will be sent to the probe when an action is run.

Triggering a test event

To trigger a test event to verify that the webhook integration is successful:

1. Get a list of actions by market to test out the workflow. Select an action from the list and copy the UUID, which will be used to trigger an action event manually using an API.

```
curl \
"https://${TURBONOMIC_HOSTNAME}/api/v3/markets/Market/actions?ascending=true" \
--insecure \
--compressed \
--header 'Accept: application/json' \
--header 'Content-Type: application/json' \
--header "cookie: JSESSIONID=${JSESSIONID}" \
--request GET
```

2. To test triggering an action event based on the UUID in the workflow, use one of the action UUIDs from the previous command (in the actionId attribute value) as in the following command:

```
curl --location --request POST "https://${TURBONOMIC_HOSTNAME}/api/v3/workflows/${WORKFLOW_UUID}" \
--header 'Content-Type: application/json' \
--header "Cookie: JSESSIONID=$JSESSIONID" \
--insecure \
--data-raw '{
    "operation": "TEST",
    "actionId": "637553640602793"
}'
```

Datadog integration probe

An IBM Tivoli Netcool/OMNIbus probe for integrating with Datadog is available. This probe integration sends HTTP GET requests to Datadog to retrieve events based on the time frame set by start and end mandatory query parameters in the URI.

Prerequisites

The following systems are prerequisites for this integration.

- IBM Cloud Pak for AIOps version 4.7.1
- Datadog: Cloud Monitoring as a Service

Note: This probe only supports the **`https://api.datadoghq.com/api/v1/events`** v1 API to get events from Datadog.

Note: The IBM Netcool Operations Insight Event Integrations Operator must be deployed before deploying this integration. See Installing the IBM Netcool Operations Insight Event Integrations Operator

To deploy a new instance of the Generic Webhook Probe, review the custom resource YAML template supplied with the operator package, update the parameters if required, and save the configurable parameters in a file, for example **`probes_v1_webhookprobe_datadog_integration.yaml`**.

Then deploy the custom resource using the updated file:

```
kubectl apply -f deploy/crs/probes_v1_webhookprobe_datadog_integration.yaml --namespace <NAMESPACE>
```

Note: If you are installing using the CLI, you can get the custom resource Yaml file from the **`ibm-netcool-integrations/inventory/netcoolIntegrationsOperatorSetup/files/op-cli/deploy/crs`** directory in our CASE archive. If you are installing using the Operator Lifecycle Manager Web console, the custom resource is provided in the YAML view.

Pre-installation tasks

The Probe for SevOne, Probe for Turbonomics, and Probe for Datadog have the same pre-installation requirements. See Probe Common Tasks before proceeding with the following sections.

Configuring and installing the Probe for Datadog integration

To create the required secrets, complete the following steps, which configure the **WebhookProbe** custom resource and install the probe in the namespace.

1. Create a secret with the ObjectServer credentials for the probe to authenticate with the ObjectServer.

```
PROBE_OMNI_SECRET=noi-probe-secret
kubectl create secret generic $PROBE_OMNI_SECRET --from-literal=AuthUserName=$NOI_OMNI_USERNAME --from-
literal=AuthPassword=$NOI_OMNI_PASSWORD --from-file=tls.crt=tls.crt
```

2. Create a secret for the Datadog certificate.

```
echo -n | openssl s_client -connect api.datadoghq.com:443 | sed -ne '/-BEGIN CERTIFICATE-/,/-END
CERTIFICATE-/p'  > datadog.pem
PROBE_CLIENT_TLS_SECRET=datadog-probe-client-tls-cert
kubectl create secret generic $PROBE_CLIENT_TLS_SECRET --from-file=server.crt=datadog.pem
```

3. Create a secret for the transport properties.

```
TRANSPORT_PROPS=restMultiChannelHttpTransport.json
cat << EOF | tee > $TRANSPORT_PROPS
{
  "GLOBAL":
  {
    "httpVersion":"1.1",
    "httpHeaders":"",
    "responseTimeout":"60",
    "securityProtocol":"TLSv1.2",
    "keepTokens":"",
    "autoReconnect":"OFF",
    "gatherSubsTopicInfo":"false"
  },
  "RESYNC":
  {
      "RESYNC_CHILD_BY_FDN":
      {
          "uri":"https://api.datadoghq.com:443/api/v1/events?start=++date_happened:<initial-start-
epoch-time>++&end=++now++&page=0",
          "method":"GET",
          "headers":"Accept=application/json,DD-API-KEY=<datadog-api-key>,DD-APPLICATION-KEY=<datadog-
application-key>",
          "content":"{}",
          "contentFile" : "",
          "interval":"60",
          "attempts":"0",
          "requireSSL":"true",
          "asEventStream" : "false",
          "enablePagination" : "true"
      }
  }
}
EOF

PROBE_HTTP_REQUEST=http-requests
kubectl create secret generic $PROBE_HTTP_REQUEST --from-file=httpRequests=$TRANSPORT_PROPS
```

   Where:

   - **++date_happened:<initial-start-epoch-time>++** allows the probe to assign the value of RecordData.date_happened in the probe data backup file to the start query parameter to continue from previous resynchronization if RecordData.date_happened is available. Otherwise, the probe assigns **<initial-start-epoch-time>** to the start query parameter.
   - **<datadog-api-key>** is the Datadog API key.
   - **<datadog-application-key>** is Datadog Application key.

   Note: The end query parameter can be set to an epoch time or ++now++ which represents the current epoch time.

4. Create a Network Policy in the IBM Tivoli Netcool/OMNIbus namespace to allow the probe to access the TLS Proxy service and port in IBM Tivoli Netcool/OMNIbus namespace. Note: Review any other Network Policy that may be denying access to the ObjectServer TLS Proxy pod and update the policy to allow ingress connection to the TLS Proxy pod.

```
cat << EOF | tee >(kubectl apply -f -) | cat
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
```

```
metadata:
  name: noi-allow-proxy
  namespace: ${NOI_NAMESPACE}
spec:
  podSelector:
    matchLabels:
      app.kubernetes.io/instance: ${NOI_INSTANCE}
      app.kubernetes.io/name: proxy
  ingress:
    - ports:
        - protocol: TCP
          port: ${NOI_PROXY_PRIMARY_PORT}
        - protocol: TCP
          port: ${NOI_PROXY_BACKUP_PORT}
  policyTypes:
    - Ingress
EOF
```

5. Create a Probe for Datadog Integrations with the WebhookProbe custom resource by running the following commands.

```
PROBE_DATADOG_INSTANCE=datadog-probe

cat << EOF | tee >(kubectl apply -f -) | cat
kind: WebhookProbe
apiVersion: probes.integrations.noi.ibm.com/v1
metadata:
  name: webhookprobe
  labels:
    app.kubernetes.io/name: ${PROBE_DATADOG_INSTANCE}
    app.kubernetes.io/managed-by: netcool-integrations-operator
    app.kubernetes.io/instance: ${PROBE_DATADOG_INSTANCE}
  namespace: ${NAMESPACE}
spec:
  license:
    accept: true
  version: 3.3.0
  helmValues:
    global:
      image:
        secretName: ''
      serviceAccountName: ''
      enableNetworkPolicy: true
    image:
      useDefaultOperandImages: true
      probe: >-
        cp.icr.io/cp/noi-int/netcool-probe-
messagebus@sha256:745a7dae41f1a0c8f1517a9dc2368d227e39be4798b74175f903bc5ac940b95b
      utility: >-

      limits:
        cpu: 200m
        memory: 256Mi
        ephemeral-storage: 200Mi
    arch: amd64
EOF
```

6. Verify that the probe pod is running.

   ```
   kubectl get pods -l app.kubernetes.io/instance=$PROBE_DATADOG_INSTANCE
   ```

7. If you want to store the probe data backup file in Persistent Volume Claim (PVC), follow the instructions in Providing custom Message Bus Probe configuration files in a persistent volume. Then set configPVC.name to a pre-created PVC name and configPVC.dataBackupFile to the data backup filename.

Installing the IBM Netcool Event Integrations Operator and common probe configuration steps

This topic describes how to install the IBM Netcool Event Integrations Operator which contains the probes you will need to connect to, and acquire event data from, event sources. It also describes how to gather the IBM Cloud Pak for AIOps ObjectServer connection information that the individual probe installations require.

- 1. Install the IBM Netcool Event Integrations Operator
- 2. Gather IBM Cloud Pak for AIOps ObjectServer connection information

1. Install the IBM Netcool Event Integrations Operator

Install the IBM® Netcool® Operations Insight® Event Integrations Operator.

- For more information, see Installing the IBM Netcool Operations Insight Event Integrations Operator but skip the Install Netcool Operations Insight step.
- Or see Installing the IBM Netcool Operations Insight Event Integrations Operator to a private container registry.

2. Gather IBM Cloud Pak for AIOps ObjectServer connection information

Before you configure the probe and connect to the ObjectServer, you need to gather the following information:

- Primary and backup ObjectServer service name and port
- ObjectServer client credentials
- TLS certificate used by the ObjectServer

In the IBM Cloud Pak for AIOps, the ObjectServer is deployed by the issue resolution core component. Complete the following instructions to get the ObjectServer connection details.

1. Set the IBM Cloud Pak for AIOps namespace variable to the namespace where IBM Cloud Pak for AIOps is installed.

   ```
   IRC_NAMESPACE=<namespace>
   ```

2. Determine the issue resolution core instance name.

   ```
   IRC_INSTANCE=$(oc get issueresolutioncore -n $IRC_NAMESPACE -o custom-columns=name:metadata.name --no-headers)
   ```

3. Run the following commands to gather service information and credentials.

   ```
   IRC_PRIMARY_OBJECTSERVER_SVC=$IRC_INSTANCE-ir-core-ncoprimary
   IRC_BACKUP_OBJECTSERVER_SVC=$IRC_INSTANCE-ir-core-ncobackup
   IRC_PRIMARY_OBJECTSERVER_PORT=$(oc get svc -n $IRC_NAMESPACE $IRC_PRIMARY_OBJECTSERVER_SVC -o jsonpath='{.spec.ports[?(@.name=="primary-tds-port")].port}')
   IRC_BACKUP_OBJECTSERVER_PORT=$(oc get svc -n $IRC_NAMESPACE $IRC_BACKUP_OBJECTSERVER_SVC -o jsonpath='{.spec.ports[?(@.name=="backup-tds-port")].port}')
   IRC_OMNI_USERNAME=aiopsprobe
   IRC_OMNI_PASSWORD=$(oc get secret -n $IRC_NAMESPACE $IRC_INSTANCE-ir-core-omni-secret -o jsonpath='{.data.OMNIBUS_PROBE_PASSWORD}' | base64 --decode && echo)
   ```

4. Extract the ObjectServer TLS certificate from the secret into your current directory. This file is used when creating a secret for the probe to connect with the ObjectServer in the following sections.

   ```
   oc extract secret/$IRC_INSTANCE-ir-core-ncoprimary-tls -n $IRC_NAMESPACE --to=. --keys=tls.crt
   ```

5. Proceed to install the probe.

Individual probe integration PDF documentation

To view the offline PDF documentation for individual probe integrations, download the appropriate PDF documentation.

For the full list of PDF documentation for each probe integration, view the online IBM documentation IBM Cloud Pak for AIOps offline documentation.

Managing AIOps Insights

IBM Cloud Pak® for AIOps includes an AIOps Insights dashboard in the IBM Cloud Pak for AIOps console. This dashboard provides a set of predefined interactive charts that show you, at a glance, what is going on in your environment. For more information about using the dashboard, see AIOps Insights dashboard.

Enabling AIOps Insights

During installation of IBM Cloud Pak® for AIOps, AIOps Insights is enabled by default and is accessible to all users.

Disabling AIOps Insights

Access to AIOps Insights can be restricted by changing the permissions of a user. For more information, see Roles and permissions.

Scopes and filtering

Once you enable data to flow into the AIOps Insights dashboard, you can refine your insights by using filters and scopes to segment that data. For more information, see AIOps Insights Scopes and Filter.

AIOps Insights dashboard

Use the AIOps Insights dashboard to view key insights provided by IBM Cloud Pak® for AIOps. View insights for a 24-hour, 7-day, or 30-day period. This information can show the value of using IBM Cloud Pak for AIOps for your IT operations.

The AIOps Insights dashboard can be accessed from the administration page of IBM Cloud Pak for AIOps, under **Overview** > **Quick navigation** > **AIOps insights**. Alternatively, click the navigation icon (four horizontal bars) in the upper-left corner of the screen to go to the main navigation menu. Then click **Operate** > **AIOps insights**.

Figure. AIOps Insights dashboard

Prerequisites

All relevant data integrations and activity (incident opened, active runbook, and so on) must be operational to allow live data to flow into the chart.

By default, all users have access to AIOps Insights. However, Administrators can restrict access, by changing a user's permissions. For more information, see Roles and permissions.

Note: If you have not yet setup integrations or implemented activity (or there is limited information) you can view examples of each AIOps Insights. chart, containing sample data, by taking the AIOps Insights. product tour. Click the signpost icon beside your avatar, then **Product Tours** > **Discover AIOps insights**.

Summary bar

The summary bar of the dashboard displays key indicators and shows how IBM Cloud Pak for AIOps is improving the efficiency of your IT operations teams. It summarizes the charts currently showing on the dashboard. An arrow indicates an increase or decrease in activity.

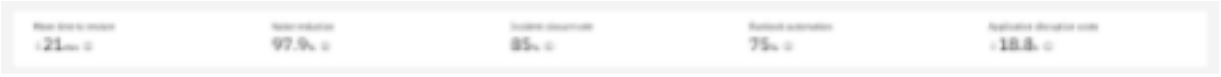

Figure. Summary bar

For more detailed information on metrics in the summary bar, view the individual charts.

- Mean time to restore
- Incident activity
- Noise reduction

- Runbook automation
- Chart tooltips

Mean time to restore

The *Mean time to restore* chart displays the average time that is needed to isolate, repair, and fully resolve IT incidents.

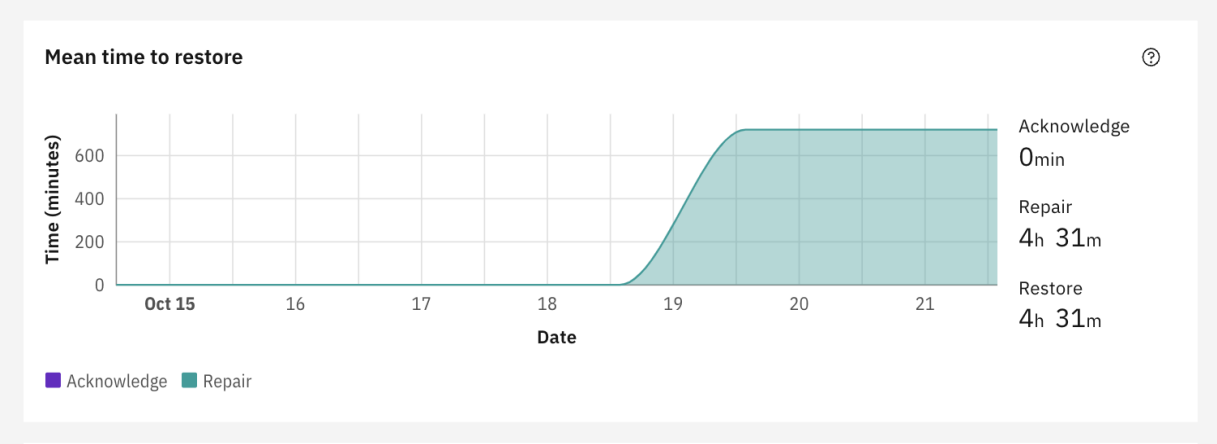

Figure. Mean time to restore chart

Chart definitions:

Acknowledge: the mean time that it takes to begin work on an incident. Toggle the purple *Acknowledge* box in the legend to display only this data on the chart.

Repair: the mean time taken to reestablish a service. Toggle the green *Repair* box in the legend to display only this data on the chart.

Restore: the total mean time (*Acknowledge* time and *Repair* time combined) taken to restore service.

Note: All mean values that are generated are based on dividing the item total by the number of data points on the chart. Because of the time intervals, this is always the selected time period +1 unit. So 24-hour totals are divided by 25, 7-day totals are divided by 8, 30-day totals are divided by 31.

Incident activity

Within IBM Cloud Pak for AIOps, an incident is a collection of alerts, insights, and potential solutions to help drive incident remediation.

By clicking the chart icon in the *Incident activity* chart, you can select to view by *Time series* (default view) or *Summary*.

- The *Time series* chart displays the number of incidents that were opened and closed during the selected time period.

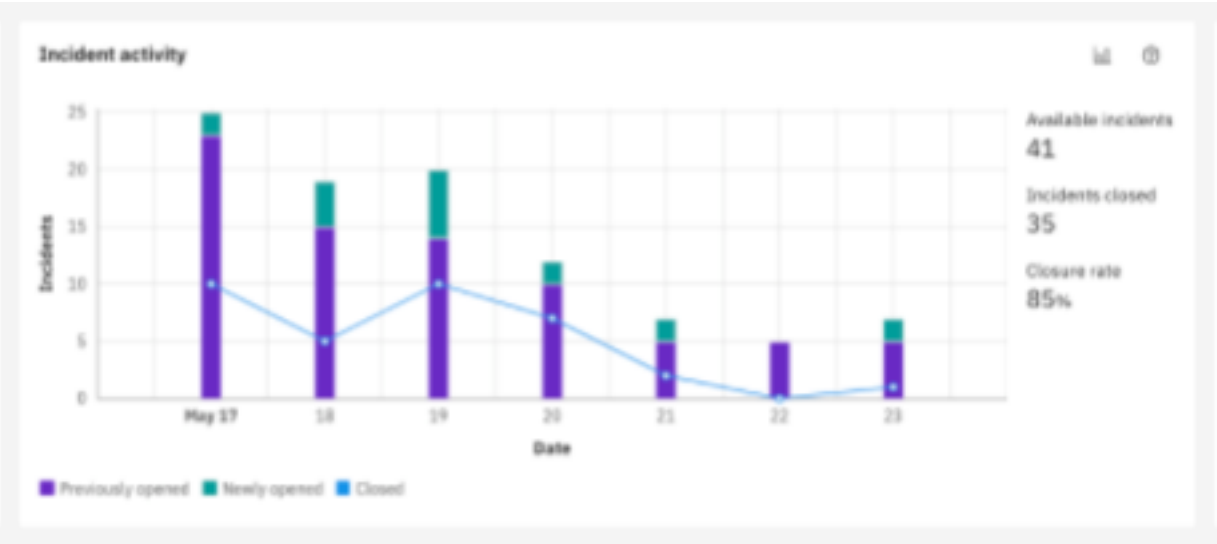

Figure. Incidents closure rate

- The *Summary* chart displays open and closed incidents according to their severity level, over the selected time period.

Figure. Summary setting

Chart definitions:

Previously opened: incidents carried over from the preceding time unit (for example, in a 7-day period, it would be incidents that are carried over from the day before), and previously opened incidents that are not yet resolved. Hover the cursor over the purple bar to see specific numbers for each day. Toggle the purple *Previously opened* box in the legend to display only this data on the chart.

Newly opened: incidents opened in the selected time period. Hover the cursor over the green bar to see specific numbers for each day. Toggle the green *Opened* box in the legend to display only this data on the chart.

Closed: the number of incidents that closed in the selected time period. Expressed as a line graph. Toggle the blue *Closed* box in the legend to display only this data on the chart.

Available incidents: the total number of incidents that were in an open state over the selected period. Combines the number of previously opened incidents – carried over when the selected time period began - with the aggregate number of new incidents (combined value of all the green bars) opened.

Incidents closed: the aggregated number of incidents closed in the selected period.

Closure rate: *Incidents closed* expressed as a percentage of the *Total incidents*.

Noise reduction

The *Noise reduction* chart displays how IBM Cloud Pak for AIOps reduces the number of IT events and alerts that your operations staff must evaluate, speeding up recovery time and reducing employee fatigue.

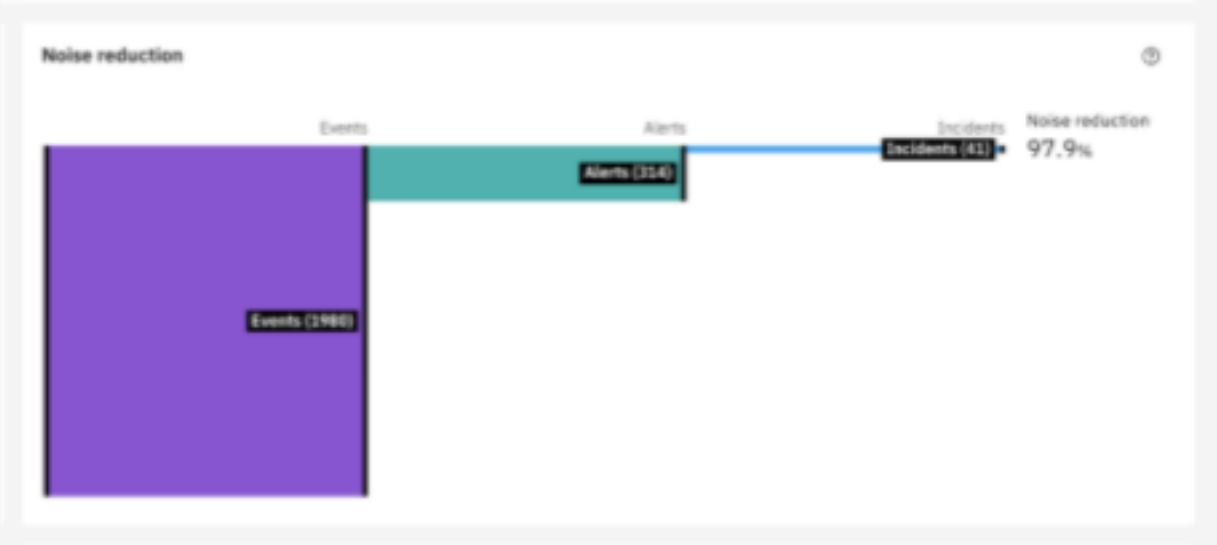

Figure. Noise reduction dashboard

Note: Updated events first created more than 30 days earlier are not incremented into the *Noise reduction* chart. For more information, see this Known issue.

Chart definitions:

Noise reduction occurs in three phases, as depicted in the chart:

1. *Events*: Duplicate or irrelevant events are removed.
2. *Alerts*: Events are correlated and grouped into alerts based on when they occurred and the relationships between the associated IT resources.
3. *Incidents*: Alerts are grouped into prioritized incidents that also include insights and potential solutions to help drive incident remediation.

The *Noise reduction* percentage is the reduction that occurs in the transition from the original number of events that are generated to the final number of incidents.

IBM Cloud Pak for AIOps includes three noise reduction algorithms, two of which require no pre-training. You can also create policies to suppress events and precisely control how alerts are grouped into incidents. For more information, see About event grouping, Deduplication, and About policies.

Incidents and noise reduction:

Leveraging **Incidents** is fundamental to deriving value from IBM Cloud Pak for AIOps. If you limit the number of policies that create incidents, by default you also limit the level of noise reduction that can be tracked and presented in the *Noise Reduction* chart.

Policies connect events and alerts to incidents. Without that connection, the value of the *Noise Reduction* chart is unnecessarily restricted. It can still display the number of *Events* and *Alerts* but not the level of *Noise Reduction*, which will instead display as empty (double dashes).

Figure. Noise reduction dashboard with incidents restricted

Note: Alerts that surface in *Resource Management* may not flow into the Noise Reduction chart. This is because they may not be part of a policy that directly ties them to an incident.

Runbook usage

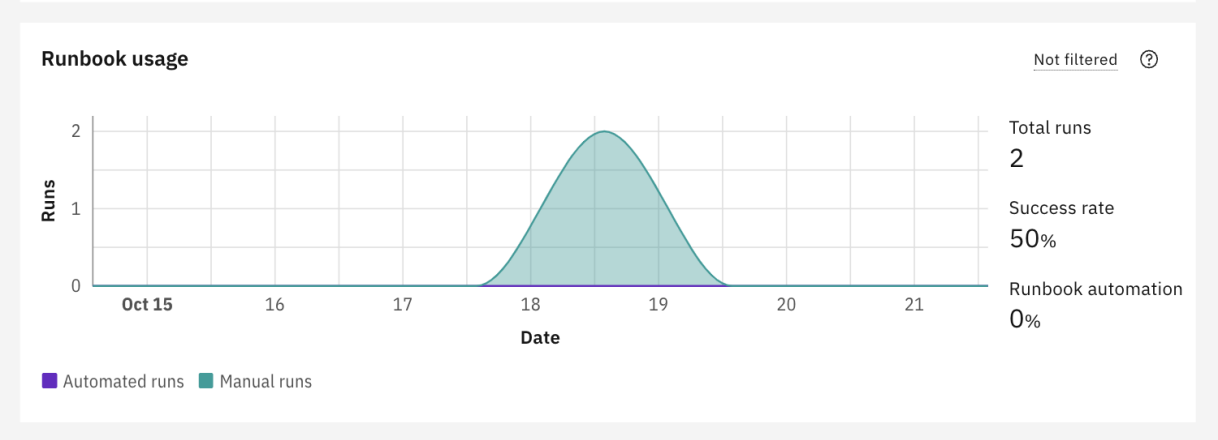

Figure. Runbook usage

Use the runbook usage chart to view the number of automated versus manual runbook runs and the success rates of them.

Chart definitions:

Automated runs: Runbooks that were run without any operator interaction, in the selected period. Toggle the purple *Automated runs* box in the legend to display only this data on the chart.

Manual runs: Runbooks that were implemented manually by an operator who followed an exact procedure, in the selected period. Toggle the green *Manual runs* box in the legend to display only this data on the chart.

Total runs: The combined number of automated and manual runs, in the selected period.

Success rate: The percentage of automated and manual runbooks successfully implemented.

Runbook automation: Percentage of total runbooks that were automated - that needed no operator interaction.

Chart tooltips

White dots highlight particular points on a chart. Clicking on a chart and then clicking one of these dots generates a tooltip data box for that particular point in time. **Note:** This is not available for Noise reduction chart as it does not use a line graph.

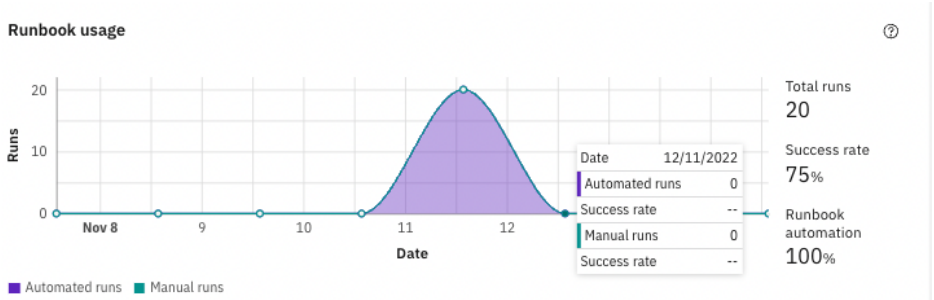

Figure. Tooltip

Tooltip information is also available for metrics in the sidebar of a chart.

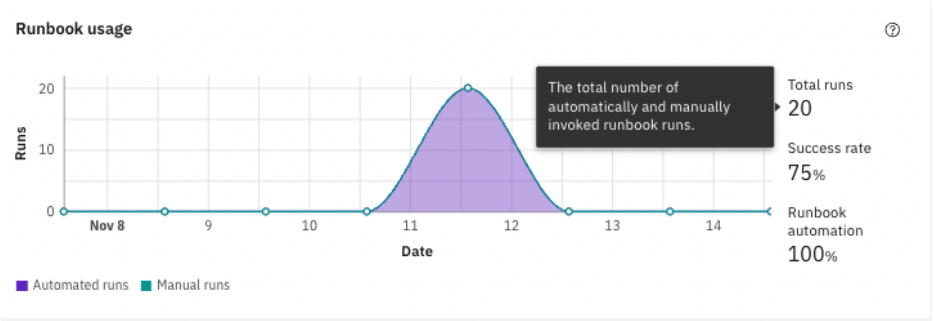

Figure. Tooltip sidebar

AIOps Insights Scopes and Filter

Use customized scopes and the filter bar in **AIOps Insights** to refine your charts, to achieve more focused insights.

Create a scope

A scope is a customized view of data. Use a scope to segment data and base your metrics on a meaningful set of IT resources.

Initially, **AIOps Insights** includes a single scope, *All resources*. When selected, metrics are scoped to all of the IT resources monitored by IBM Cloud Pak® for AIOps. Create custom scopes to display metrics for smaller, more meaningful sets of IT resources.

Prerequisites

Creating and managing scopes requires administrative privileges. For more information, see Roles and permissions.

Procedure

Do the following to create a custom scope.

1. On the toolbar, when you first open **AIOps Insights** go to the dropdown menu with the words *All resources*. This indicates that all data that is related to Cloud Pak for AIOps is included in the charts. Click the dropdown menu.

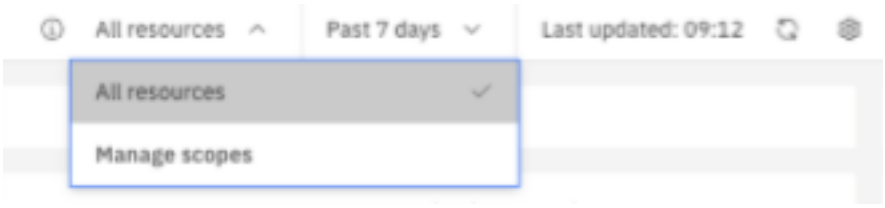

Figure. Scope dropdown

2. From the dropdown menu, select **Manage scopes**. This opens the **Scopes** panel in *AIOps insights settings*, and lists all scopes available to you. **Note**: another route to the Scopes panel is to click *AIOps Insights settings* and then click **Scopes**.

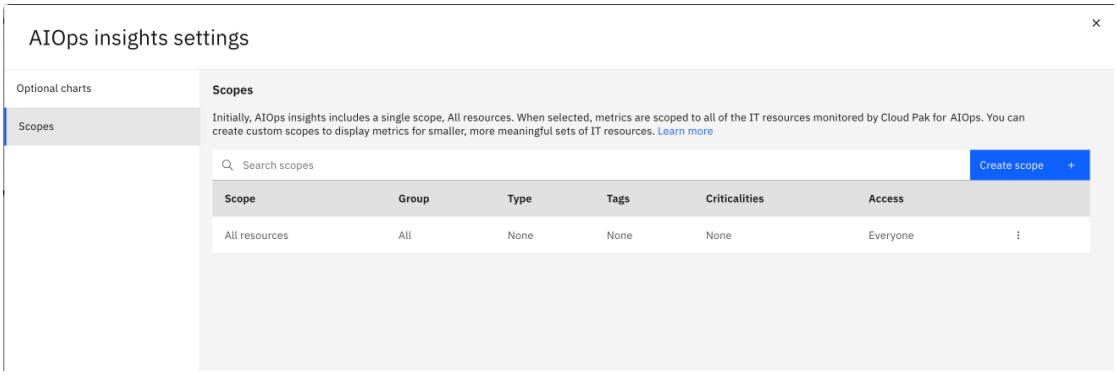

Figure. Scope panel

3. In the **Scopes** panel, click **Create scope**.
4. The *Name and description* panel opens. Enter a short title for your scope – *Banking Sales*, for example – and a description (optional), explaining what this scope shows. When completed, click **Next**.
5. In the **Resources** panel, select either *Applications* or *Resource groups*.
    - Under *Tags*, use the dropdown menu to select how to filter by selected tags:
        - For **Applications**, select either **Include applications with all of the tags selected below** or **Include applications with any of the tags selected below**.
        - For **Resource groups**, select either **Include resource groups with all of the tags selected below** or **Include resource groups with any of the tags selected below**.
    - If a tag is attached to an application or resource group, it appears under *Tag*. To find a specific tag, enter the name in the *Search tags* field.
    - Under *Tag*, select an available tag for the scope. A blue border around the tag name indicates it is selected. Click again, to deselect.
    - To scope by *Business criticalities*, click *Criticalities* and select from the criticalities you assigned to define levels of criticality, for example Tier1, Tier2, and so on. For more information on criticalities, see Defining business criticality.
6. Click **Next**.
7. Use the **Access control** panel to control who can access the scope that you are creating. You can also use this panel to enable and disable a scope, which allows you to create and store scopes for future use.

    Once the scope is enabled, use the dropdown menu to select who can access the scope. There are three choices: **Only me**, **Specified user groups** and **Everyone**.

    Use the search box to find any specified user groups who you want to allow access to this scope. Any group that is selected is displayed under *User groups*. A blue border around the user group indicates it is selected. Click again, to deselect.

    When you complete your selections, click **Create scope**.

The scope that you created is now added to the list of scopes in the main **Scopes** panel. Click the three vertical dots to edit or delete a scope. **NOTE**: You can access a description of the scope by hovering your mouse over its title. Where a number appears, hover the cursor over it, to see what this references (a tag, for example).

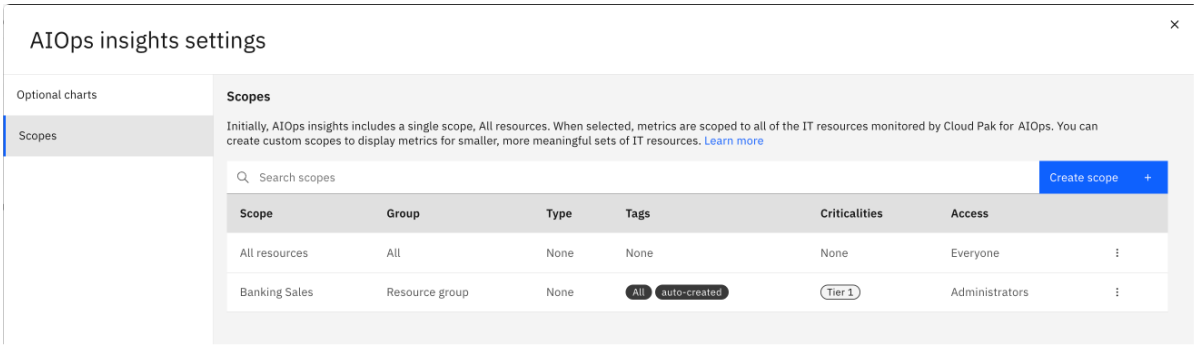

Figure. Scopes panel

On the AIOps Insights dashboard toolbar, the new scope is added to the dropdown menu. Only users who have access to this scope see it in the scopes list.

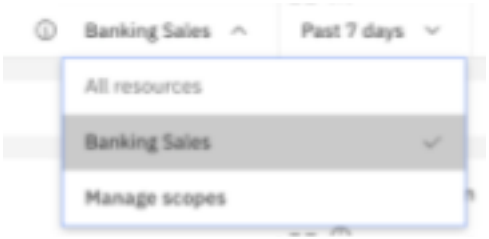

Figure. Scopes dropdown customized

Click the information button beside the scope to view a summary of the key information about the scope.

Adding a filter

Use the filter to refine by incident priority. Changes take effect immediately on the dashboard. **Note**: The filter is not applied to runbook usage metrics.

1. Click the filter icon to access the **Filter** panel.
2. Click *Incident priority* and then select one or more priority (**P**) level. A blue border around the level name indicates it is selected. To clear selections, click the level name again and the border disappears.
3. Click **Apply**.

The incident priority filters that you chose are applied to the dashboards (excluding *Runbook usage*).

Managing AI modelling

Leverage your data to build models that IBM Cloud Pak® for AIOps can use to learn patterns in your data. IBM Cloud Pak for AIOps can then apply these patterns to provide insights to your Operations and SRE teams.

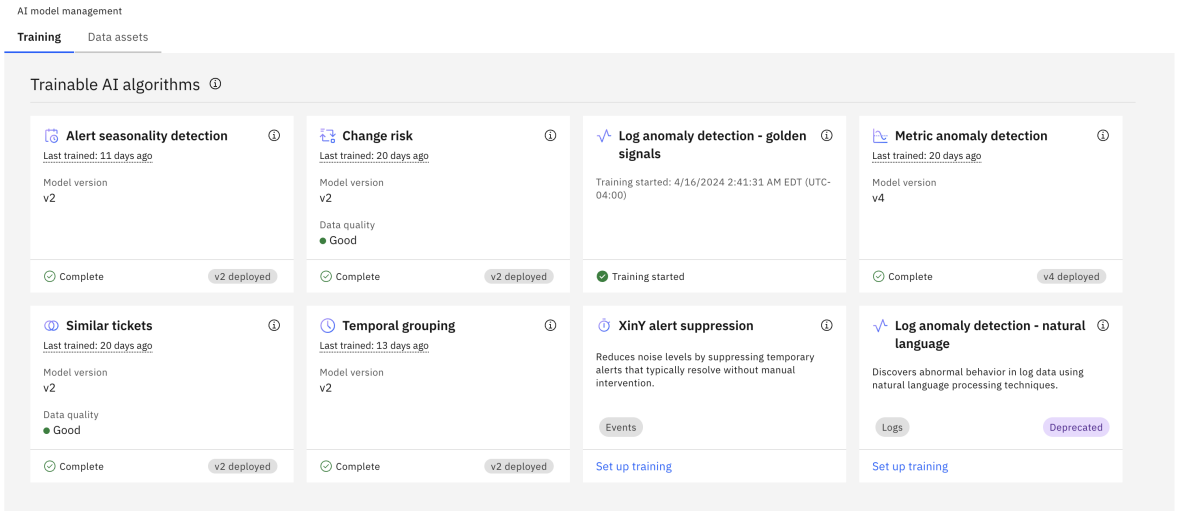

Figure. AI model management trainable AI algorithms

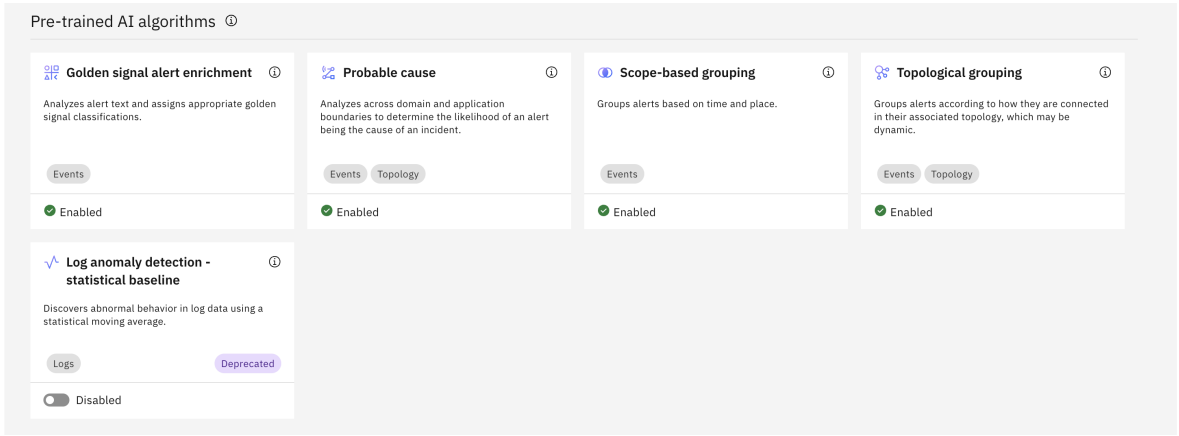

Figure. AI model management pre-trained AI algorithms

For more information about configuring AI training, see the following topics:

- Preparing the AI environment
- About AI algorithms
- Preparing AI algorithms
- Managing AI algorithms
- Displaying data assets

About AI models

IBM Cloud Pak® for AIOps provides a wide range of AI algorithms to gather data and learn from your environment, and provide insights to support resolution of health issues across your application, service, and network infrastructure.

For each of the following AI algorithms, this topic describes the algorithm, explains how it helps you, and, where configuration is necessary, points to the relevant configuration tasks.

- Alert seasonality detection
- Change risk
- Event grouping
- Log anomaly detection
- Metric anomaly detection
- Probable cause
- Similar tickets

Alert seasonality detection

This AI algorithm groups alerts that tend to occur within a seasonal time window. Periodicity of alert occurences is an indication of a common underlying cause, which might help you to diagnose the underlying cause of the alert. The model also enables you to take different actions on

alerts depending on if they are occuring within the seasonal window, or outside. If a seasonal alert is considered benign when occuring within the time window, you can also suppress seasonal alerts.

To train this algorithm, you must initially configure it using the console, as described in Configuring alert seasonality detection.

When this algorithm is successfully trained and the resulting AI model deployed, alerts that occur within a seasonal time window are grouped together. Site reliability engineers (SREs) and other users responsible for application and service availability can then view the details in the Alert Viewer, as described in Displaying alert seasonality.

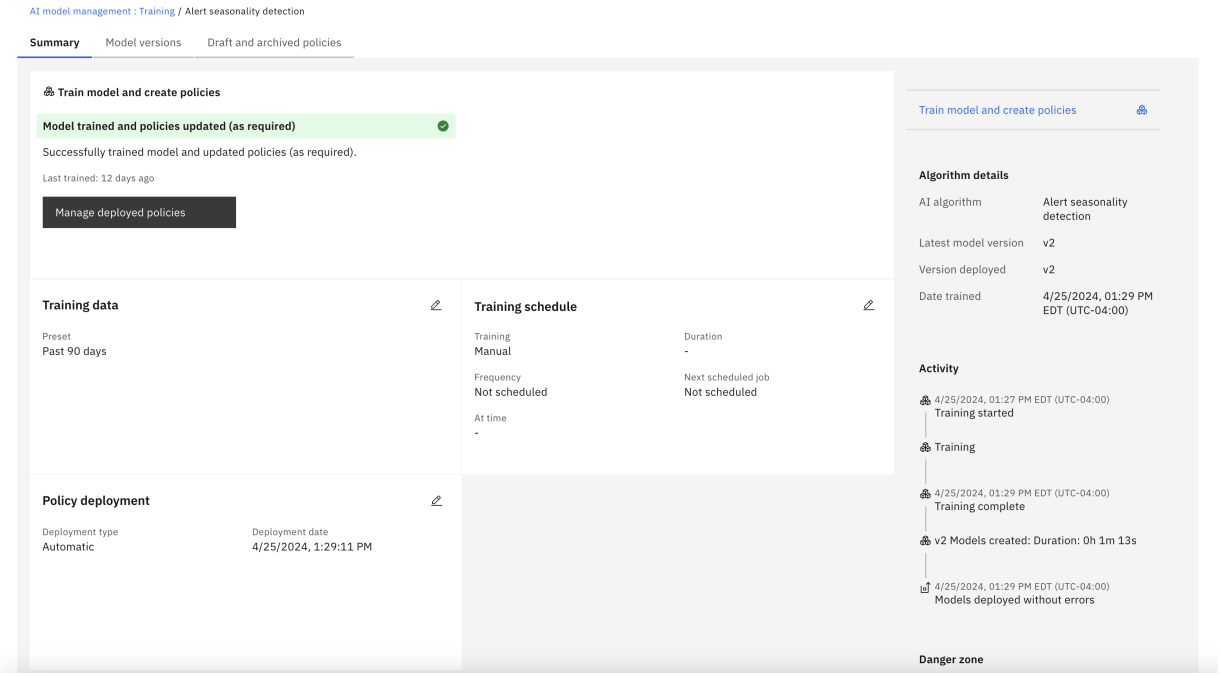

Figure. Alert seasonality detection summary

Change risk

This AI algorithm provides an assessment of the risk of implementing a proposed change; for example, a code change or a new software version.

Hundreds of changes can affect an application during its lifecycle. Change risk takes historical data about all of those changes and helps you determine how likely it is that a specific change would cause a problem, based on how successfully that similar change was deployed in the past. Using the assessment score provided by this AI model, you can determine how safe it is to proceed with the change.

Training this AI algorithm helps you ensure that risky changes for an application are assessed before deployment. To train this algorithm, you must initially configure it using the console, as described in Configuring change risk.

Once this algorithm is successfully trained and the resulting AI model deployed, then when someone opens a change request ticket, a *Change risk assessment* appears in the proactive ChatOps channel. For more details, see Change risk.

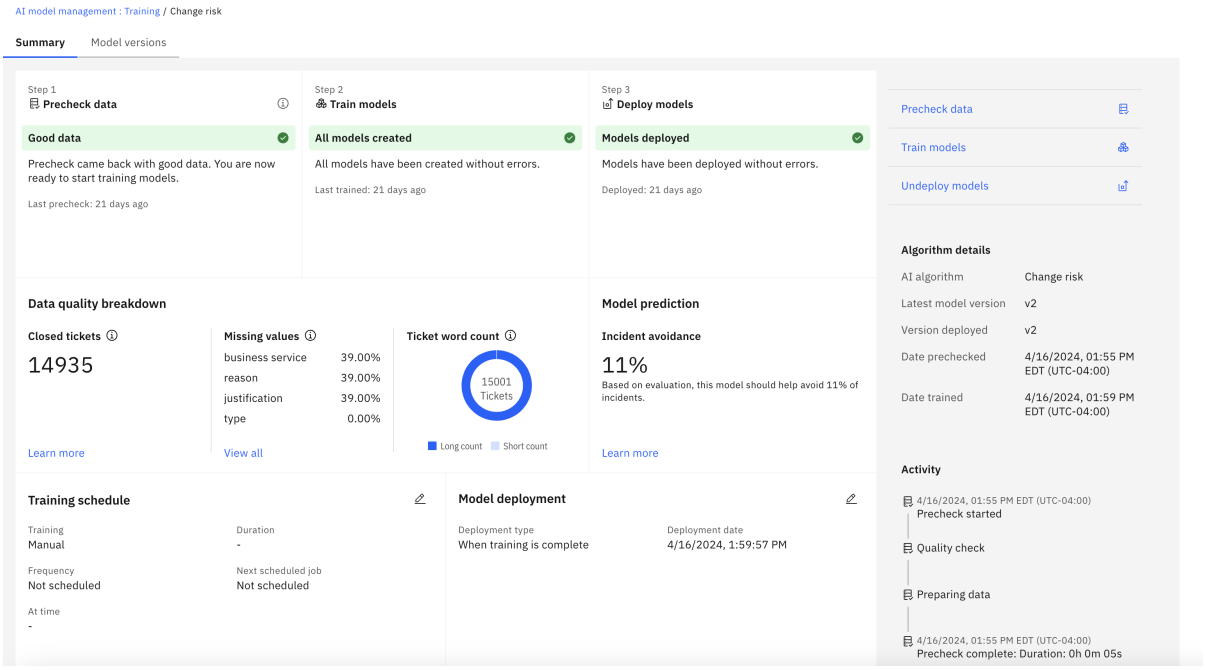

Figure. Change risk summary

Event grouping

Three AI algorithms are provided that group events together and present the groups within a single incident.

The three algorithms are the following:

- Temporal grouping
- Topological grouping
- Scope-based Grouping

Temporal grouping

This AI algorithm groups events that are discovered to co-occur over time. When a problem arises, there are typically multiple parts of a system or environment that are impacted. When events in different areas co-occur, it makes sense to look at them together and treat them as one problem to try to determine what might have happened.

Grouping co-occurring events together reduces the number of tickets and incidents opened and the number of people looking at the same problem, thereby significantly reducing noise in your monitoring systems. It helps you to understand the context of an issue so you can prioritize, triage, and resolve it more quickly.

To train this algorithm, you must initially configure it using the console, as described in Configuring temporal grouping.

When this algorithm is enabled related alerts are grouped based on when they occur, Site reliability engineers (SREs) and other users responsible for application and service availability are able to view the details in the Alert Viewer, as described in About alerts.

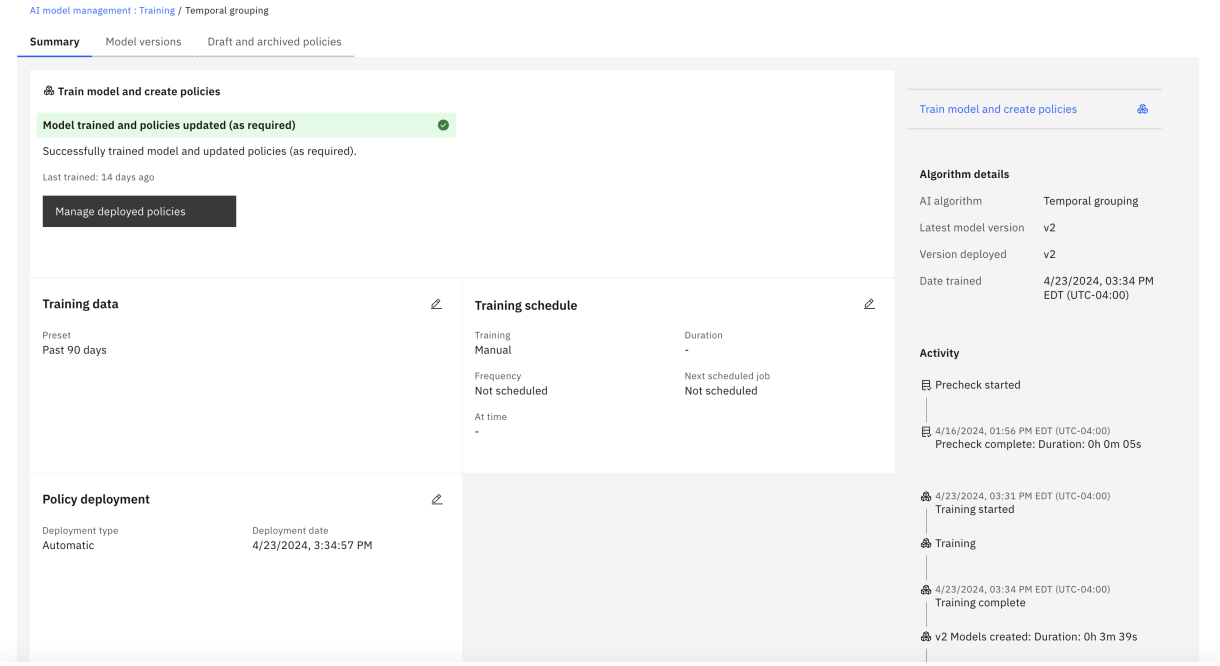

Figure. Temporal grouping summary

Topological grouping

This AI algorithm groups your events based on the resource groups in which events events occur. For example if you have a resource group made up of all the resources within a given Kubernetes namespace, then any events on pods, microservices, or other resources in that namespace will be grouped together in a single topological group.

Topological grouping helps you understand when events are connected based on their topology, providing valuable context for why related events might occur together.

This algorithm is enabled so when related events are grouped based on their topology, Site reliability engineers (SREs) and other users responsible for application and service availability will be able to view the details in the Alert Viewer, as described in About alerts.

Scope-based grouping

This AI algorithm automatically groups events relating to an incident if they have the same defined scope and occur during the same period of time. A scope can be used to identify where events originate based on a common attribute, for example, the location of a server room.

By understanding when events are related based on both time and location, you can more quickly diagnose incidents.

This algorithm is enabled so when related events are grouped based on their scope, Site reliability engineers (SREs) and other users responsible for application and service availability will be able to view the details in the Alert Viewer, as described in About alerts.

Log anomaly detection

This pair of AI algorithms gather log data from one or multiple components in the application architecture, identifies a baseline of expected log message types, and uses this baseline to discover abnormal behavior in your live log data. For more information on log anomaly detection algorithms, see About log anomaly detection algorithms.

Metric anomaly detection

Metric anomaly detection first learns normal patterns of metric behavior by analyzing metric values at regular intervals. If that behavior significantly changes, it raises anomalies or alerts.

For more information, see About metric detection algorithms.

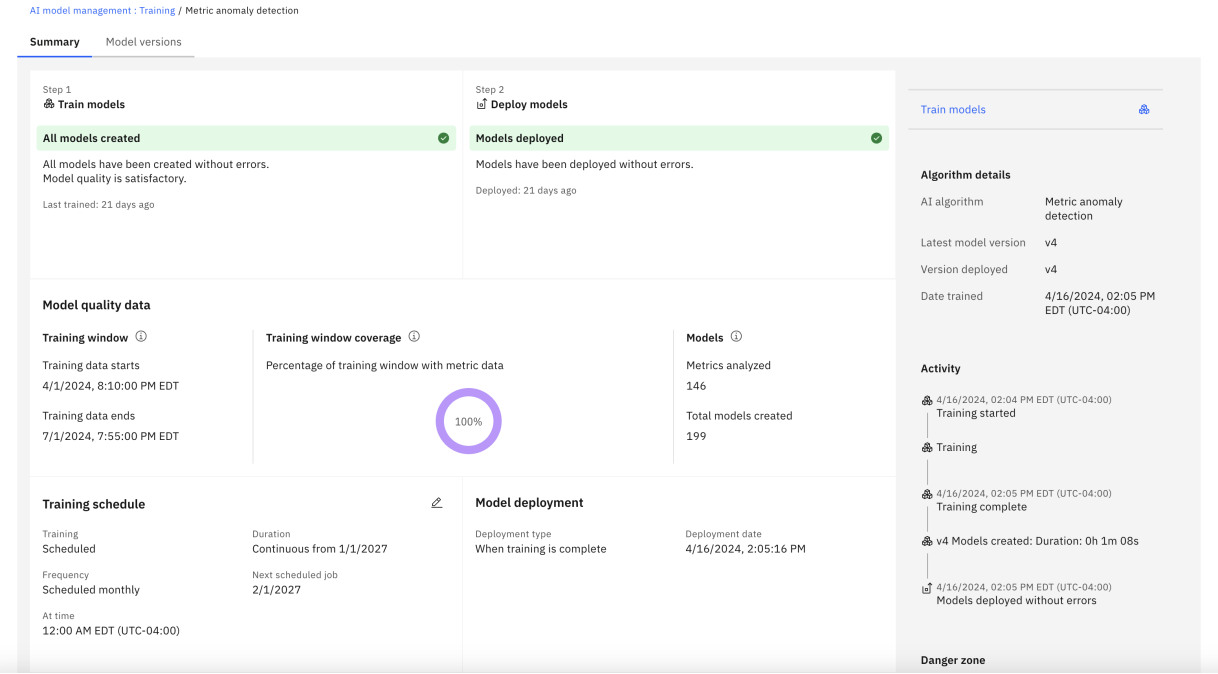

Figure. Metric anomaly detection summary

Probable cause

This AI algorithm identifies the event with the greatest probability of being the cause of an incident.

Probable cause analyzes event and topology data to understand how events are related to each other. It then uses that understanding to try to determine the root cause of a problem.

All events in an incident are given a probability score that indicates the likelihood of that event being the cause of the incident. events that occur on resource that is lower down in the topology are giving a higher probability score. events are also categorized and are scored based on the category that they fall into. This ensures that if two events occur on the same resource in the topology, the event with the more significant category will have a higher probability score.

Once the SRE has identified the probable cause event, they can take action on the resource that is generating that event and quickly resolve the incident.

The probable cause AI algorithm is enabled by default, so that information about the probable cause of a problem is automatically included in your incident details, which are surfaced in your ChatOps interface, as described in Managing incidents.

Similar tickets

This AI algorithm discovers details about similar messages, anomalies, and events within your tickets that occurred in the past and are impacting the current application.

When an incident occurs, it can be helpful to review details for similar tickets to help determine a resolution. This model aggregates information about similar messages, anomalies, and events for a component or application. This model can also extract the steps used to fix previous incidents, if documented.

Training this AI model helps you discover historical incidents to aid in the remediation of current problems. To train this algorithm, you must initially configure it using the console, as described in Setting up training for similar tickets.

Site reliability engineers (SREs) and other users responsible for application and service availability are able to access incidents in their ChatOps interface and within each incident view historical similar tickets, as described in Managing incidents.

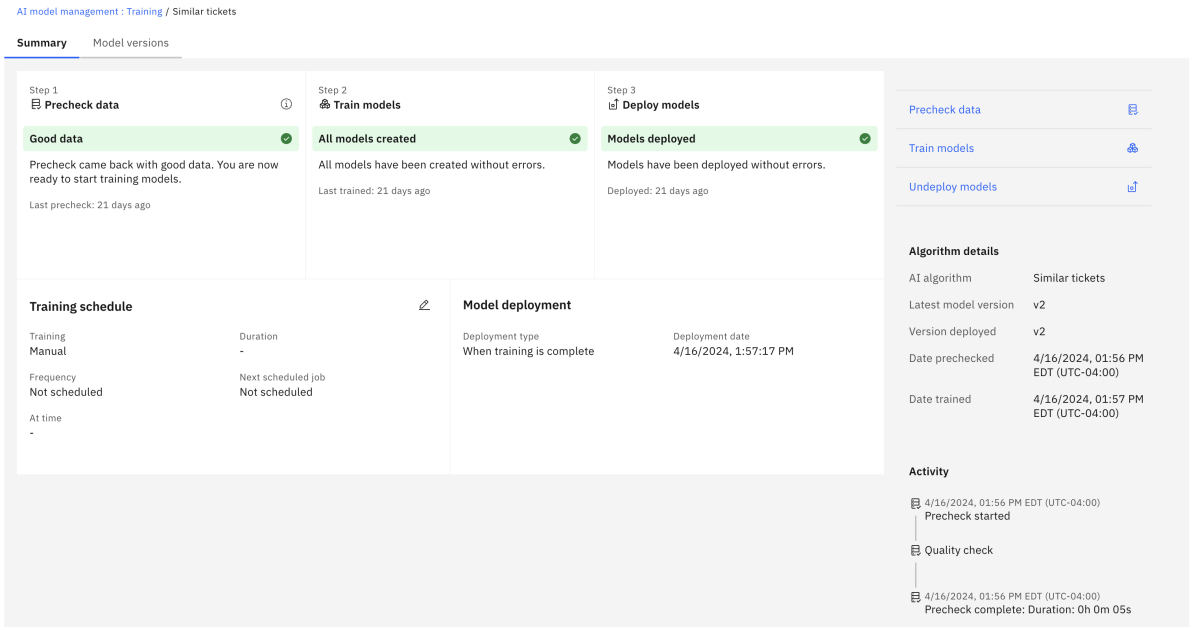

Figure. Similar tickets summary

Prerequisites for AI modelling

For each different AI algorithm, you must integrate with the right tools and gather specific types of data so the AI can begin learning.

This topic describes the prerequisites for each of the following AI algorithms.

- Change risk and Similar tickets
- Log anomaly detection
- Alert grouping, Alert seasonality detection, and Probable cause

Change risk and Similar tickets

Both the Change risk algorithm and the Similar ticket algorithm require ticket data from ServiceNow. Before attempting to configure these algorithms, ensure that you have created a functioning data integration to ServiceNow. For more information, see Creating a ServiceNow integration.

Log anomaly detection

The Log anomaly detection algorithms require log data from one or more of your log systems. Before attempting to configure these algorithms, ensure that you have created a functioning data integration to at least one of the log systems listed in the following table.

Log system	For more details, see:
Falcon LogScale	Creating Falcon LogScale integrations
Mezmo	Creating Mezmo integrations
Splunk	Creating Splunk integrations

You can also load log data into the system using one of these generic data loading methods.

Data loading method	For more details, see:
Custom	Creating custom integrations
ELK	Creating ELK integrations
Kafka	Creating Kafka integrations

Event grouping, Alert seasonality detection, and Probable cause

The three alert grouping algorithms, the Alert seasonality detection algorithm, and the Probable cause algorithm all require event data. In the case of the Topological grouping algorithm and the Probable cause algorithm, topological data is also required. This topological data must be correlated with the event data.

Event data

In some cases, your event data is loaded into IBM Cloud Pak® for AIOps from a IBM® Netcool® Operations Insight®-based data source by using the following Netcool Operations Insight integration.

Data loading method	For more details, see:
Connecting an external ObjectServer	Creating IBM® Tivoli® Netcool®/OMNIbus integrations

You can also load event data into the system by using other integration types. For more information, see Incoming integrations.

Topological data

Load topology data into IBM Cloud Pak® for AIOps by configuring observers. For more information, see Defining observer jobs.

Preparing the AI environment

Prepare the AI environment by configuring performance and other setttings for the various AI algorithms.

For more information about preparing the AI environment, see the following topics:

- Adjusting model training resources
- Configuring alert expiry time
- About Elasticsearch indices and shards
- Managing embedded JSON
- Scaling log anomaly detection pods

How to modify training resources

You can modify training resources, such as to alter requirements.

Procedure

1. Find the custom resource of the algorithm for which you wish to alter the default resource requirements by running the following command:

   ```
   oc get algorithms
   ```

2. This should return something similar to the following:

   ```
   oc get algorithms
   ```

   Output:

   ```
   NAME                AGE
   change-risk         46h
   log-anomaly         46h
   similar-incidents   46h
   ```

3. These CRs contain all the algorithm specifications. You can go ahead and edit the specific algorithm by running:

   ```
   oc edit algorithm <name>
   ```

4. Then you decode the *spec.manifestBase64* field. Once decoded you see a resources field defined as follows:

   ```
   resources:
      requests:
         cpu: 2
         memory: 4Gi
      limits:
         cpu: 2
         memory: 4Gi
   ```

   Note: You can edit requests and limits (For training algorithms, make sure that the **limits=requests**), re-encode to base64, and then replace the *manifestBase64* field in the CR with this newly encoded manifest.

5. Save the changes, and proceed with your training.

Configuring expiry time for log anomaly alerts

By default, alerts that are generated by a log anomaly expire in six hours (21,600 seconds). You can modify this value.

1. Access the IBM Cloud Pak Administration panel by following the instructions at UI console.
2. In the main navigation menu, click **Workloads** > **Deployments**.
3. Search by name, and type **log-anomaly** in the field. The **aimanager-aio-log-anomaly-detector** deployment is listed in the table.
4. Click **aimanager-aio-log-anomaly-detector** to visualize deployment details.
5. Click the **Environments** tab. A list of environment variables is displayed.
6. From the list, click **Add more** to add another environment variable.
7. Name the environment variable **EXPIRY_SECONDS**.
8. Set the value of the **EXPIRY_SECONDS** environment variable in seconds. For example, if you want to increase the expiry time to 24 hours, which is 86,400 seconds, set the value to `86400`.
9. Click **Save** to save the changes. This action triggers a restart of the **aimanager-aio-log-anomaly-detector** pod, which takes a few minutes.

After the pod restarts, the new expiry time applies to any alerts that are generated by a log anomaly.

About indices and shards

When setting up AI training, a critical factor is the number of shards available to support the creation of Elasticsearch indices. By default, a production installation provides 1000 shards for use by the various AI training types and by the AI platform itself.

Each Elasticsearch index requires a certain number of shards. If the number of Elasticsearch indices used by the various AI training components requires more than the default of 1000 available shards, then some of the AI training might fail. A training failure returns a **Needs improvement** data qualtiy level, as described in Generating an AI model. In order to avoid training failure, you can do one or more of the following:

To avoid the possibility of running out of shards, a periodic cron job utility runs every hour to delete all the logtrain elastic indices that have an index creation date older than 14 days from the current timestamp.

Determining your current shard consumption

Monitor the number of indexes and shards currently in use so that you can plan your AI training accordingly.

About this task

When log data is collected for IBM Cloud Pak® for AIOps, the data is persisted within Elasticsearch for training purposes. While the collection of historical or live data for training is occurring or after the data collection completes, you can connect to Elasticsearch to check the progress and look at the indexes.

Connect to Elasticsearch

Select the instructions for your deployment architecture.

Deployments on Red Hat® OpenShift® Container Platform:

1. Open two console sessions on your computer.
2. Log in to your Red Hat OpenShift Container Platform cluster where IBM Cloud Pak for AIOps is installed.
3. In one console session, switch to the namespace where IBM Cloud Pak for AIOps is installed.
4. Run the following command to the cluster in one console. With this command, you port forward to the Elasticsearch service to access the service for checking the indexes.

   ```
   while true;

   do oc port-forward statefulset/$(oc get statefulset | grep elasticsearch-es | awk '{print $1}')
   9200;done
   ```

5. In your second console session, run the following commands to obtain your username and password credentials for accessing Elasticsearch:

   ```
   export username=$(oc get secret $(oc get secrets | grep <installation name>-es-admin-user-connection-
   secret | awk '!/-min/' | awk '{print $1;}') -o jsonpath="{.data.username}"|base64 -d)

   export password=$(oc get secret $(oc get secrets | grep <installation name>-es-admin-user-connection-
   secret | awk '!/-min/' | awk '{print $1;}') -o jsonpath="{.data.password}"|base64 -d)
   ```

Where **<installation name>** is the name of your IBM Cloud Pak for AIOps installation, for example **ibm-cp-aiops**. To find the installation name, run the **oc get installation** command.

6. In the second console session, list the indexes that are stored in Elasticsearch. Look for index files that have a **1000-1000-<date>-logtrain** name format, such as **1000-1000-20210510-logtrain**. Use the following command to list the indexes in your cluster:

   ```
   curl -k -u $username:$password -XGET https://localhost:9200/_cat/indices | sort
   ```

   The following example illustrates a typical line of output:

   ```
   green open 1000-1000-20220302-logtrain        eEvaBufQ06yG074hmeHKG  8 1 244 6 72.7kb 72.7kb
   ```

   The following table lists the elements in this line of output:

   Table. elements

Element	Description	Example
Index health	Health of the index.	green
Index Status	Status of the index.	open
Index name	Name of the index.	1000-1000-20220302-logtrain
UUID	Universal unique identifier for this index.	eEvaBufQ06yG074hmeHKG
Number of shards	Number of shards required by default for this index. This value varies based on the type of index. For example, an index that is associated with a day of ingested log data for natural language log anomaly training requires 8 shards for both a large and a small installation.	8
Number of replicas	Number of replicas required by default for this index. This value varies based on the type of index and the size of the installation. For example, an index that is associated with a day of ingested log data for natural language log anomaly training requires 1 replica for a large installation and 0 replicas for a small installation. A replica value of 1 replicates all of the shards for that index, meaning that a shard replica setting of 8/1 assigns 16 shards to the index.	1
docs.count	Detailed statistic associated with this index.	244
docs.deleted	Detailed statistic associated with this index.	6
Store size	Detailed statistic associated with this index.	72.7 kb
Primary store size	Detailed statistic associated with this index.	72.7 kb

7. Check the count of the records for an index by using the following command:

   ```
   curl -k -u $username:$password -XGET https://localhost:9200/<indexname>/_count --insecure
   ```

   ```
   {"count":318713,"_shards":{"total":1,"successful":1,"skipped":0,"failed":0}}
   ```

8. You can also look at sample data by using the following command:

   ```
   curl -k -u $username:$password -XGET https://localhost:9200/<indexname>/_search --insecure
   ```

Deployments on Linux

1. SSH into a control plane node or the loadbalancer VM on your Linux® deployment, and then switch to the namespace where IBM Cloud Pak for AIOps is installed.

   ```
   oc project <project>
   ```

   Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

2. Run the following command to list the indices stored in Elasticsearch. Look for index files that have a **1000-1000-<date>-logtrain** name format, such as **1000-1000-20210510-logtrain**.

   ```
   export ELASTIC_SET="$(oc get statefulset -l app.kubernetes.io/managed-by=ibm-elasticsearch -o jsonpath='{.items[0].metadata.name}')"
   oc exec "statefulset/${ELASTIC_SET}" -- curl -XGET -k --fail "http://127.0.0.1:19200/_cat/indices?v" | sort
   ```

   Example output, where the index name is **1000-1000-20220302-logtrain**:

   ```
   green open 1000-1000-20220302-logtrain        eEvaBufQ06yG074hmeHKG  8 1 244 6 72.7kb 72.7kb
   ```

   The following table lists the elements in this line of output:

   Table. elements

Element	Description	Example
Index health	Health of the index.	green

Element	Description	Example
Index Status	Status of the index.	open
Index name	Name of the index.	1000-1000-20220302-logtrain
UUID	Universal unique identifier for this index.	eEvaBufQ06yG074hmeHKG
Number of shards	Number of shards required by default for this index. This value varies based on the type of index. For example, an index that is associated with a day of ingested log data for natural language log anomaly training requires 8 shards for both a large and a small installation.	8
Number of replicas	Number of replicas required by default for this index. This value varies based on the type of index and the size of the installation. For example, an index that is associated with a day of ingested log data for natural language log anomaly training requires 1 replica for a large installation and 0 replicas for a small installation. A replica value of 1 replicates all of the shards for that index, meaning that a shard replica setting of 8/1 assigns 16 shards to the index.	1
docs.count	Detailed statistic associated with this index.	244
docs.deleted	Detailed statistic associated with this index.	6
Store size	Detailed statistic associated with this index.	72.7 kb
Primary store size	Detailed statistic associated with this index.	72.7 kb

3. Check the count of the records for an index by using the following command:

```
export INDEX_NAME=<index name>
export ELASTIC_SET="$(oc get statefulset -l app.kubernetes.io/managed-by=ibm-elasticsearch -o
jsonpath='{.items[0].metadata.name}')"
oc exec "statefulset/${ELASTIC_SET}" -- curl -XGET -k --fail
"http://127.0.0.1:19200/${INDEX_NAME}/_count"
```

Where **<index_name>** is the name of an index returned by the previous step

Example output:

```
{"count":318713,"_shards":{"total":1,"successful":1,"skipped":0,"failed":0}}
```

4. You can also look at sample data by using the following command:

```
export INDEX_NAME=<index name>
export ELASTIC_SET="$(oc get statefulset -l app.kubernetes.io/managed-by=ibm-elasticsearch -o
jsonpath='{.items[0].metadata.name}')"
oc exec "statefulset/${ELASTIC_SET}" -- curl -XGET -k --fail
"http://127.0.0.1:19200/${INDEX_NAME}/_search"
```

Where **<index_name>** is the name of an index returned by the previous step.

Shard consumption in a large installation

Use the following table to help interpret the results returned. All values that are provided are for a production (large) installation.

Table. shard consumption

N.	AI component	Index name	Shard usage	Notes
	Natural language log anomaly detection (total)		Varies	
1	Each day of ingested log data	`1000-1000-`*date*`-logtrain`	16	The index for each extra day of data uses 16 shards.
2	Each model version total	`1000-1000-v_`x-contenttype	50	The index for each extra model version uses 50 shards.
3	Dedicated index for saving training data	`1000-1000-windowed_logs`	5	
4	Dedicated index for deploying models	`1000-1000-log_modles_latest`	5	
	Statistical baseline log anomaly detection (total)		20	
5	Statistical baseline log anomaly detection	`1000-1000-log_models_latest`	5	
6	Statistical baseline log anomaly detection	`1000-1000-reference_embedding`	5	
7	Statistical baseline log anomaly detection	`1000-1000-reference_oob`	5	

N.	AI component	Index name	Shard usage	Notes
8	Statistical baseline log anomaly detection	`1000-1000-si_models_latest`	5	
9	**Change risk**	`1000-1000-cr_models_latest`		
10	**Similar tickets**	`1000-1000-si_models_latest`	10	
	Lifecycle services		Varies	
11	Each service	`aiops-searchservice-v10` *datetime*	5	The index for each extra lifecycle service uses 5 shards.
	AI platform		12	
12	AI platform	`postchecktrainingdetails0`	2	
13	AI platform	`prechecktrainingdetails0`	2	
14	AI platform	`trainingdefinition`	2	
15	AI platform	`trainingrun`	2	
16	AI platform	`trainingrunning`	2	
17	AI platform	`trainingstatus`	2	

Best practices

An analysis of the table in Shard consumption in a large installation shows that the most effective way to keep shard usage down is to follow these practices:

- Train natural language log anomaly detection on a smaller number of days. As you can see from the table row that is labeled 1, the index for each extra day of data uses 16 shards. The recommended number of days for training is 14.

  Note To avoid the possibility of running out of shards, a periodic cron job utility runs every hour to delete all the logtrain elastic indexes that have an index creation date older than 14 days from the current timestamp.

- Regularly delete new versions of natural language log anomaly detection models. As you can see from the table row that is labeled 2, the index for each extra model version uses 50 shards.

- When you define a log integration, such as for Elasticsearch, Logstash, and Kibana (ELK), Humio, or Mezmo, the Log Ops UI in IBM Cloud Pak for AIOps doesn't show the start and end date time zone when you use the **Historical data for initial AI training** data flow mode. You can't use the Log Ops UI to enter the start and end times. Instead, you can specify only the start and end dates. The start and end date time zone is Greenwich mean time (GMT).

Managing embedded JSON

Log lines containing embedded JSON might not be parsed correctly by the natual language log anomaly detection algorithm. If your log lines contain embedded JSON, then apply the methods described here to convert your log lines to unstructured data.

The following snippet shows an example of a log line containing embedded JSON.

```
021-09-23T21:43:40.067+0000  I NETWORK  [conn5083706]  received client metadata from 127.0.0.1:49736
conn5083706: { name: \"PyMongo\",  version: \"3.8.0\", type: \"Linux\", architecture: \"x86_64\",  version:
\"3.10.0-1160.25.1.el7.x86_64\", platform: \"CPython3.7.3.final.0\" }
```

The braces (curly brackets) and the section between those braces is embedded JSON.

You can handle these log lines by applying one of the following options:

- **None**: The default option. The JSON is not processed or modified. This option results in the example JSON resembling the following code:

  ```
  021-09-23T21:43:40.067+0000  I NETWORK  [conn5083706]  received client metadata from 127.0.0.1:49736
  conn5083706:  { name: \"PyMongo\",  version: \"3.8.0\", type: \"Linux\", architecture: \"x86_64\",
  version: \"3.10.0-1160.25.1.el7.x86_64\", platform: \"CPython3.7.3.final.0\" }
  ```

- **Flatten**: This option flattens the JSON object by removing the opening and closing braces. This option results in the example JSON resembling the following code:

  ```
  021-09-23T21:43:40.067+0000  I NETWORK  [conn5083706]  received client metadata from 127.0.0.1:49736
  conn5083706:  name: \"PyMongo\",  version: \"3.8.0\", type: \"Linux\", architecture: \"x86_64\",
  version: \"3.10.0-1160.25.1.el7.x86_64\", platform: \"CPython3.7.3.final.0\"
  ```

- **Filter**: This option extracts the JSON object and replaces it with an empty string. This option results in the example JSON resembling the following code:

```
021-09-23T21:43:40.067+0000  I NETWORK  [conn5083706]  received client metadata from 127.0.0.1:49736
conn5083706:
```

Note: Examine your data before applying this option, especially if your log lines are complete JSON objects.

Which option to select

Perform the following steps to get an idea of which option to select:

1. Retrieve a sample of your log data of at least 30,000 lines.
2. In your sample, determine the percentage of log lines that contain either JSON objects, or lines made up of both text and JSON objects.
3. Use the following table to help you select an option.

JSON percentage in data	Suggested option
Less than 30% of log lines contain JSON objects	**none**
More than 30% of log lines contain JSON objects	**filter**
More than 80% of log lines contain JSON objects	**none** or **flatten**

Limitations

Be aware of the following limitations:

1. Neither the **flatten** nor **filter** option checks the validity of the JSON object.
2. In some cases log data can include partial JSON. In this case, the **filter** options will extract the message preceding the first opening brace of the partial JSON object.

Selecting an option

To select a JSON processing option, see Adding an integration.

Scaling log anomaly detection pods

You can scale up the number of log anomaly detection pods for your instace.

Each `log-anomaly-detection` replica supports roughly 10 components. By default, a starter deployment has 2 `log-anomaly-detection` pods, while a production deployment has 4.

To scale the replicas to handle processing for additional components, modify the `AIManagerMainProd` custom resource.

Before you begin

Clusters can be for starter or production deployments, as described in Hardware requirements. A starter deployment cluster has limited resources, so you might want to check your cluster resources before you complete the following task to ensure that you are able to allocate adequate resources.

Procedure

1. Log in to your cluster by running the `oc login` command.

   ```
   oc login -u kubeadmin -p <password>
   ```

   For more information, see Logging in to the OpenShift CLI.

2. Edit the IBM Cloud Pak for AIOps customer resource. The following command opens the file in the `vi` editor for editing.

   ```
   oc edit AIManagerMainProd aimanager
   ```

3. Search for the following configuration:

   ```
   spec:
     helmValues:
       global:
         logAnomaly:
           replicas: 2
   ```

4. Modify the replica count, such as to change the number of replicas to **4**.

```
spec:
  helmValues:
    global:
      logAnomaly:
        replicas: 4
```

Note: Each instance of the **log-anomaly-detector** pod requires an additional 0.5 CPU cores and 0.5Gi of memory.

5. Save the file.

6. Restart the **ai-platform-api-server** pod to put the changes into effect. Restart the pod by deleting the associated pod. A new pod automatically starts up and uses the new parameters that are specified in the configmap.

    1. First, determine the name of the currently running pod.

    ```
    oc get po | grep ai-platform-api-server
    ```

    Your output can resemble the following sample output:

    ```
    aimanager-aio-ai-platform-api-server-7d75768cbc-zx5dh              1/1     Running     0
    6d1h
    ```

    Where,

    - The string **aimanager-aio-ai-platform-api-server-7d75768cbc-zx5dh** is the pod ID. The character string **7d75768cbc-zx5dh** uniquely identifies the pod. This string is the value for **<unique pod reference>** in the following steps.
    - The other information indicates that the pod is running and has been running for 6 days and 1 hour.

    2. Delete the pod by running the following command:

    ```
    oc delete po aimanager-aio-ai-platform-api-server-7d75768cbc-zx5dh
    ```

    3. Wait a short time, then run the following command to check that the new pod started up, and to show the new pod ID.

    ```
    oc get po | grep ai-platform-api-server
    ```

Configuring log formats for WebSphere log anomaly detection

To access log messages for WebSphere log anomaly detection, configure the domains with the correct type of log formats.

- Configure IBM WebSphere Application Server to use High Performance Extensible Logging (HPEL).
    - HPEL provides a mechanism for storing and accessing log, trace, **System.err**, and **System.out** information that is generated by the server or generated by applications that use **java.util.logging**.
    - To render data stored by HPEL in JSON format, use the LogViewer command.
- Configure IBM WebSphere Liberty servers to output JSON to the **messages.log** file.
- Only log messages from IBM WebSphere Liberty server code have IBM message IDs, so IBM Cloud Pak for AIOps can use only those messages. IBM Cloud Pak for AIOps can't run log anomaly detection on logs from applications that run on IBM WebSphere Application Server.
    - Thus, the upstream log data source for IBM Cloud Pak for AIOps is either HPEL for IBM WebSphere Application Server or a **messages.log** file for an IBM WebSphere Liberty server.

About AI algorithms

AI algorithms analyze different kinds of data and produce AI models, which automate research, reducing the need for manual work in solving problems. These unsupervised algorithms enable the use of unlabeled data for training AI models without any human intervention. IBM Cloud Pak® for AIOps training generates models for a number of different AI algorithms. You can train the models for each of these AI algorithms independently of each other.

You use the AI Model Management to set up training for various AI algorithms.

The AI Model Management has these tabs: **Training** and **Data assets**.

1. The **Training** tab allows you to view two types of algorithms in tile format:

- **Trainable AI algorithms** These algorithms must be trained on certain data types before they can create deployable models. They include change risk, log anomaly detection-natural language, metric anomaly detection, similar tickets, and temporal grouping. These algorithms are listed as tiles. You can set up the training for each algorithm separately.
- **Pre-trained AI algorithms** These algorithms don't require models to derive insights. They are enabled by default. These algorithms include probable cause, scope-based grouping, topological grouping, and log anomaly detection-statistical baseline. Again each of these algorithms is represented by a tile.

2. The **Data assets** tab shows the data integrations that are feeding your AI training. It lists them in a table and gives details about each integration, such as Integration name, Data flow status (Running or Finished), Integration type, Data type, and Data collected (Live or Historical).

Note: It is worth noting that naming the training is an optional step in setting up training for trainable AI algorithms.

For more information about AI algorithms, see the following topics:

- About change risk
- About event grouping
- About log anomaly detection algorithms
- About metric anomaly detection
- About probable cause
- About similar tickets

About change risk

This AI algorithm provides an assessment of the risk of implementing a proposed change; for example, a code change or a new software version.

Hundreds of changes can affect an application during its lifecycle. *Change risk* is an unsupervised learning algorithm that takes historical data about all of those changes and helps you determine how likely it is that a specific change would cause a problem, based on how successfully that similar change was deployed in the past.

Using the assessment score provided by this AI model, you can determine how safe it is to proceed with a change.

To train this algorithm, you must complete some setup tasks, as described in Setting up training for change risk.

When a *Change risk* algorithm is successfully trained and the resulting AI model deploys, if someone opens a change request ticket, a *Change risk* assessment appears in the proactive ChatOps channel (for more information, see Change risk in ChatOps). When the assessment is deemed to be high risk, then an alert is generated and is displayed in the Alert Viewer.

Note: Some training features are specific to the change risk algorithm. For more information, see Managing algorithms.

Prerequisites

To train a change risk algorithm, you need change request and incident ticket data from ServiceNow. Starting with IBM Cloud Pak® for AIOps version 4.1.0, similar incidents, such as from a ServiceNow integration, are called similar tickets.

Before you set up training for this algorithm, create a functioning data integration to ServiceNow. For more information, see Creating a ServiceNow integration.

Note: If you enable collection of historical data when you integrate with ServiceNow, then data for the selected timeframe is available to train on.

To provide the best data for training, you need a mix of successful and failed change tickets. Around 10,000 change tickets, with a minimum 2% failure rate, is considered ideal. However, models can also be created with much less data.

Language support

For information about supported languages for this algorithm, see Language support.

About event grouping

Three AI algorithms are provided with IBM Cloud Pak for AIOps that group events together and present the groups within a single incident.

Event grouping AI algorithms:

- Temporal grouping
- Topological grouping

- Scope-based Grouping

Temporal grouping

This AI algorithm is an unsupervised learning algorithm that groups alerts that are discovered to co-occur over time. When a problem arises, there are typically multiple parts of a system or environment that are impacted. When alerts in different areas co-occur, it makes sense to look at them together and treat them as one problem to try to determine what might have happened.

Grouping co-occurring alerts together reduces the number of tickets and opened incidents, and the number of people looking at the same problem, thereby significantly reducing noise in your monitoring systems. It helps you to understand the context of an issue so you can prioritize, triage, and resolve it more quickly.

To train this algorithm, complete some initial setup tasks. This AI algorithm also needs at least three months of historical event data to learn alert patterns and discover groups. For more information, see Setting up training for temporal grouping.

Just like alert seasonality detection algorithm, no configuration is required to activate temporal grouping. The model training needs to be configured and run.

When the Temporal grouping algorithm is enabled related alerts are grouped based on when they occur, Site reliability engineers (SREs) and other users responsible for application and service availability are able to view the details in the event Viewer, as described in About alerts.

Topological grouping

This AI algorithm is an unsupervised learning algorithm that groups alerts based on the resource groups in which those alerts occur. For example if you have a resource group made up of all the resources within a given Kubernetes namespace, then any alerts on pods, microservices, or other resources in that namespace will be grouped together in a single topological group.

Topological grouping helps you understand when alerts are connected based on their topology, providing valuable context for why related alerts might occur together.

When this algorithm is enabled related alerts are grouped based on their topology, site reliability engineers (SREs) and other users responsible for application and service availability are able to view the details in the Alert Viewer, as described in About alerts.

Notes:

1. Topology resources in the same group do not need to be connected for alert grouping to happen.
2. Alerts that target topology resources in the same application (service) are also grouped.
3. Alerts must occur within a 15-minute time window to get correlated.

Topological grouping requires that there be a topological group creator.

Scope-based grouping

This AI algorithm is an unsupervised learning algorithm that automatically groups alerts relating to an incident if they have the same defined scope and occur during the same period of time. A scope can be used to identify where events originate based on a common attribute, for example, the location of a server room.

By understanding when alerts are related based on both time and location, you can more quickly diagnose incidents.

This algorithm is enabled so when related alerts are grouped based on their scope, Site reliability engineers (SREs) and other users responsible for application and service availability will be able to view the details in the Alert Viewer, as described in About alerts.

Prerequisites

The three event grouping algorithms require event data. In the case of the Topological grouping algorithm, topological data is also required. This topological data must be correlated with the event data.

For correlations, they must exist within the same topological group or template.

Event data

In most cases your event data will be loaded into IBM Cloud Pak® for AIOps from a IBM® Netcool® Operations Insight®-based data source, by using one of the methods listed in the following table.

Data loading method	For more details, see:
Connecting on-premises probes	Integrating on-premises probes to the in-cluster ObjectServer
Connecting an external ObjectServer	Connecting an external ObjectServer into the system by using an XML Gateway

You can also load event data into the system by using the generic custom and Kafka methods.

- For more information on the custom integration, see Creating custom integrations.
- For more information on the Kafka integration, see Creating Kafka integrations.

Topological data

Load topology data into IBM Cloud Pak® for AIOps by configuring observers. For more information, see Defining observer jobs.

Language support

For information about supported languages for this algorithm, see Language support.

About log anomaly detection algorithms

IBM Cloud Pak® for AIOps processes incoming logs as part of the log anomaly detection process.

There are two log anomaly detection AI algorithms, each of which can run independently of the other. If both algorithms are enabled, then any log anomalies discovered by both will be reconciled, so that only one alert is generated. In this case, the severity of the combined alert will be equal to the highest severity of the two alerts.

Site reliability engineers (SREs) and other users responsible for application and service availability are able to display log anomalies as alerts within the context of an incident, as described in Viewing relevant events. They will also be able to view these log anomaly alerts in the Alert Viewer, as described in About alerts.

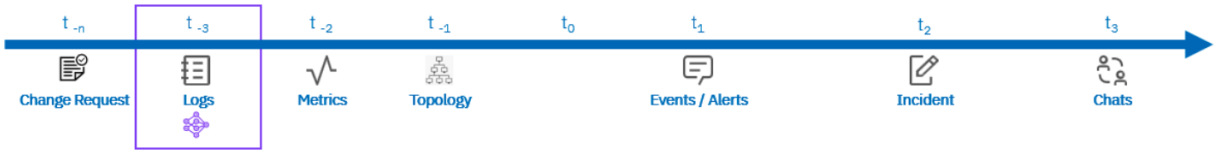

Figure. Log anomaly detection algorithm

The preceding diagram highlights the machine learning models that are used within Cloud Pak for AIOps. The models utilize advanced algorithms to analyze data from various sources, including logs, metrics, topology, and alerts. The analyzed data is used to detect anomalies, predict changes, and provide real-time insights.

The primary goal of these Cloud Pak for AIOps machine learning models is to enable IT teams to proactively identify and resolve issues before these issues impact the business. The advanced language models, deep NLP, and semantic parsing enable IT teams to extract and summarize incident information quickly and accurately. The machine learning models identification of patterns and trends enables IT teams to quickly identify the root cause of the issues, take corrective actions to prevent downtime, help ensure optimal system performance, and security, ultimately leading to improved efficiency, reliability, and security of IT operations.

With Cloud Pak for AIOps policies, IT operators can automatically assign runbooks to events based on pre-configured conditions. They can also identify the root cause and scope of affected components using blast radius and fault localization. Additionally, operators can execute assigned runbooks automatically or manually using operator-configurable policies.

Cloud Pak for AIOps policies automate routine tasks and provide real-time system performance visibility, enable teams to streamline workflows, enhance incident response, reduce downtime, and boost overall efficiency.

Prerequisites

Log data

Logs are sent from an application environment to a logging system, such as Mezmo or Splunk, through data shippers, such as Logstash. Each logging system has a mapping definition in Cloud Pak for AIOps.

The Log anomaly detection algorithms require log data from one or more of your log systems. Before attempting to set up training for these algorithms, ensure that you have created a functioning data integration to at least one of the log systems listed in the following table.

Table. Log system details

Log system	For more details, see:
Falcon LogScale	Creating Falcon LogScale integrations
Mezmo	Creating Mezmo integrations
Splunk	Creating Splunk integrations

You can also load log data into the system using one of these generic data loading methods.

Table. Data loading method details

Data loading method	For more details, see:
Custom	Creating custom integrations
ELK	Creating ELK integrations
Kafka	Creating Kafka integrations

Cloud Pak for AIOps has various integrations with log aggregators such as ELK (Elasticsearch, Logstash, Kibana), Falcon LogScale, Mezmo, Splunk, and comes with a REST service for custom integrations. These integrations connect to the source and pull the log data. If you do not have a log aggregator that is compatible with Cloud Pak for AIOps, there is an alternative option that utilizes Kafka-based integration. The Kafka-based integration also supports log processing where historic logs are fed in offline mode. Additional time needs to be allocated for planning and development in this scenario, since custom logic might be needed to parse and transform the logs in to a format that is expected by Cloud Pak for AIOps.

Performance tuning

Before training can occur, logs are pulled from a logging system, such as Mezmo or Splunk, and are stored in Elasticsearch.

Before attempting to set up training for these algorithms, review the performance tuning tasks at the following location: Setting up training for log anomaly detection.

Language support

For information about supported languages for this algorithm, see Language support.

Algorithms

The algorithms are as follows:

- Natural language
- Statistical baseline
- Golden signals

Best practices

Log anomaly detection algorithms are useful when you have logs that represent a healthy system. When Cloud Pak for AIOps is trained on a healthy system, anomalous problems can then be detected. For instance, if the infrastructure or application logs are accurate real-time representations of system health, then log anomaly alerts can help to minimize the mean time to error detection, which includes the early warning signs of potential problems that might occur later.

Log anomaly detection is resource-intensive, and each log anomaly algorithm has different data requirements. You are recommended to limit log analysis to your infrastructure and applications that are considered business critical to ensure that you do not see hardware requirements increase significantly.

About log anomaly detection - natural language

Natural language log anomaly detection is an unsupervised learning algorithm that uses Natural Language Processing (NLP) on a subset of your log data to discover abnormal behavior.

Deprecated: The natural language log anomaly detection algorithm is to be deprecated in a future release. The recommended action is to use log anomaly detection - golden signals as a replacement.

Log anomaly detection takes large amounts of log data and trains on it to learn what is normal behavior for a particular component. This model goes beyond just looking at error states or frequency of metadata around log messages. Instead, it determines when something becomes an anomaly compared to what patterns it typically exhibits.

To train this AI algorithm, you must complete some initial setup tasks, as described in Setting up training for log anomaly detection - natural language

For more information about natural language log anomaly detection, see the following topics:

- Workflow
- Examples

Workflow of natural language log anomaly detection

Find out how natural language log anomaly detection processes your log data to generate log alerts.

The workflow of natural language log anomaly detection is made up of two parts:

- Model generation
- Application of the model to the live log data stream

Model generation

The following figure shows a simplified workflow illustrating how the natural language log anomaly detection algorithm generates an AI model from log data. This part of the workflow is known as **training**.

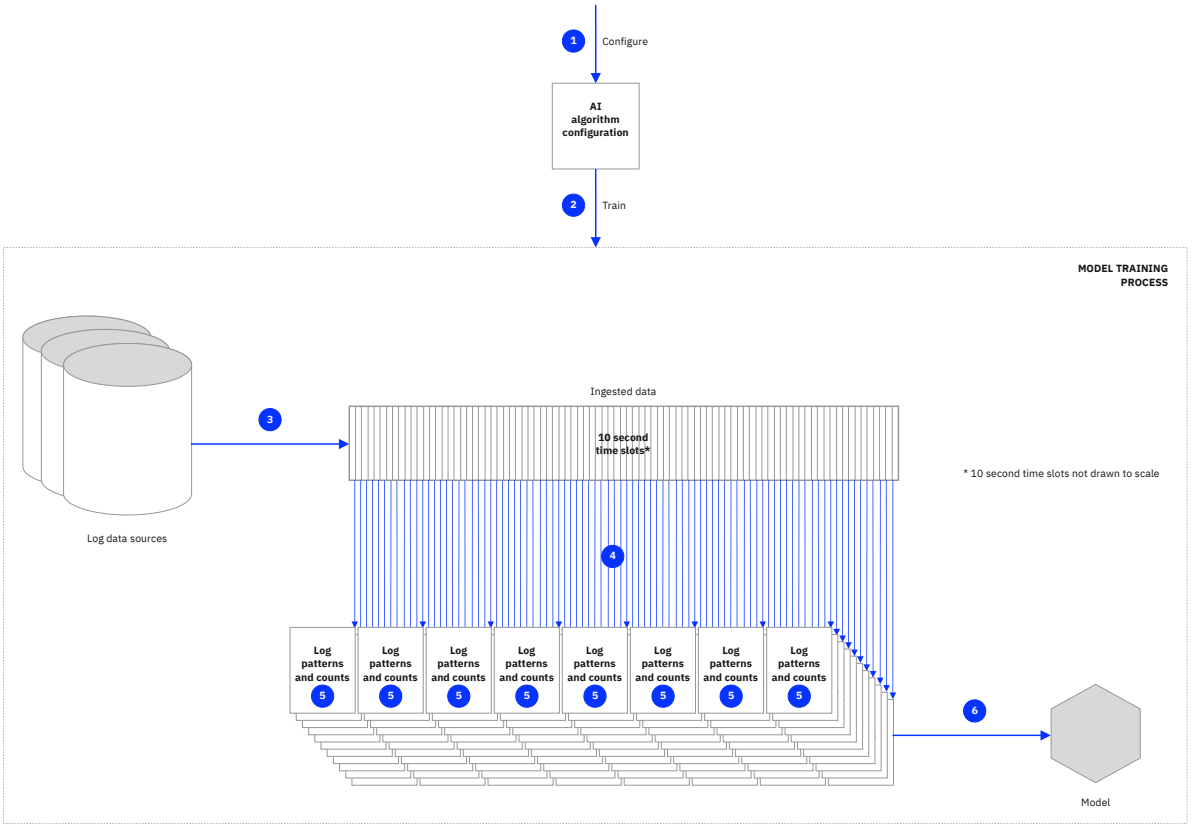

Figure. Workflow

1. **Algorithm is configured and trained**

   The algorithm configuration includes specification of log data sources, the period of data to train on, whether to run training on a schedule or on demand, and whether to deploy the training automatically or manually. Training is started and the model training process begins, as described in steps 2 to 6.

2. **Training jobs are identified**

   Assume that you have a microservice that is made up of multiple components such as orders, catalog, front-end, and more, each of these components with its own set of logs. As it is likely that each of the components has different logging behavior, the log anomaly detection algorithm creates a separate model for each component. Each of these models is trained by a separate training job.

   The logging data for the different components is differentiated by using the `instance-id` parameter that is specified during log integration mapping. For an example of log integration mapping for a Mezmo log system, see Specifying field mapping.

   The following steps 3 to 6 explain the process for training a unique model for each component. The steps are repeated for each component identified.

   Note: For more information about limits and throughput rates, see Supported resource number and throughput rates.

3. **Data is imported**

   Based on the specification of log data sources in the algorithm configuration, data is imported from log data sources for a given component.

4. **Data is divided into 10-second slots**

The imported data is divided into 10-second time slots. For example, if two weeks' worth of data was impoirted, then that data is divided into x time slots based on the following calculation.

2 weeks = 14 days = 336 hours = 20,160 minutes = 120,960 time slots

5. **Log patterns are identified and counted**

   Within each time slot, the system identifies and counts log patterns. Log patterns are identified in the following way:

   1. Each log message is separated into variant and invariant parts. For example, consider the following log messages:

```
2021-03-12T03:05:31.608355778+00:00 stdout F
{
  "name":"@instana collector",
  "__in":5,
  "hostname":"cart-846b9595c9qcqfk",
  "pid":35261,
  "module": "announceCycle/agentHostLookup",
  "level":2,
  "msg":"Agent cannot be contacted through system ABC nor through default gateway 123. Scheduling
reattempt 0
}

2021-03-12T03:05:33.608355778 +00:00 stdout F
{
  "name":"@instana collector",
   "__in":5,
   "hostname":"cart-846b9595c9qcqfk",
   "pid":89561,
   "module": "announceCycle/agentHostLookup",
   "level":2,
   "msg":"Agent cannot be contacted through system DEF nor through default gateway 456. Scheduling
reattempt 1
 }

2021-03-12T03:05:35.321654987+00:00 stdout F
{
 "name":"@instana collector",
 "__in":5,
 "hostname":"cart-846b9595c9qcqfk",
 "pid":75421,
 "module": "announceCycle/agentHostLookup",
 "level":3,
 "msg":"Agent cannot be contacted through system GHK nor through default gateway 789. Scheduling
reattempt 2
}
```

      These log messages can be expressed by using the following log pattern, where the variant parts of the log messages are expressed by using wildcards, such as **<*>** and **<NUM>**.

```
<*> stdout F
{
  "name":"@instana collector",
  "__in":<NUM>,
  "hostname":"cart-846b9595c9qcqfk",
  "pid":<NUM>,
  "module": "announceCycle/agentHostLookup",
  "level":<NUM>,
  "msg":"Agent cannot be contacted through <*> nor through default gateway <*>. Scheduling
reattempt <NUM>
}
```

   2. Log patterns are counted in each 10-second slot and means and standard deviations are stored for each log pattern.

6. **Model is created**

   On completion of training, a model is created that includes log pattern statistics.

   Note: Each time that the algorithm is run, steps 2 to 5 are repeated from scratch and a new version of the model is generated.

Application of the model to the live log data stream

The following figure shows a simplified workflow illustrating how the natural language log anomaly detection algorithm applies the AI model to the live log data stream. This part of the workflow is known as **inference**, and it involves applying the findings from the model.

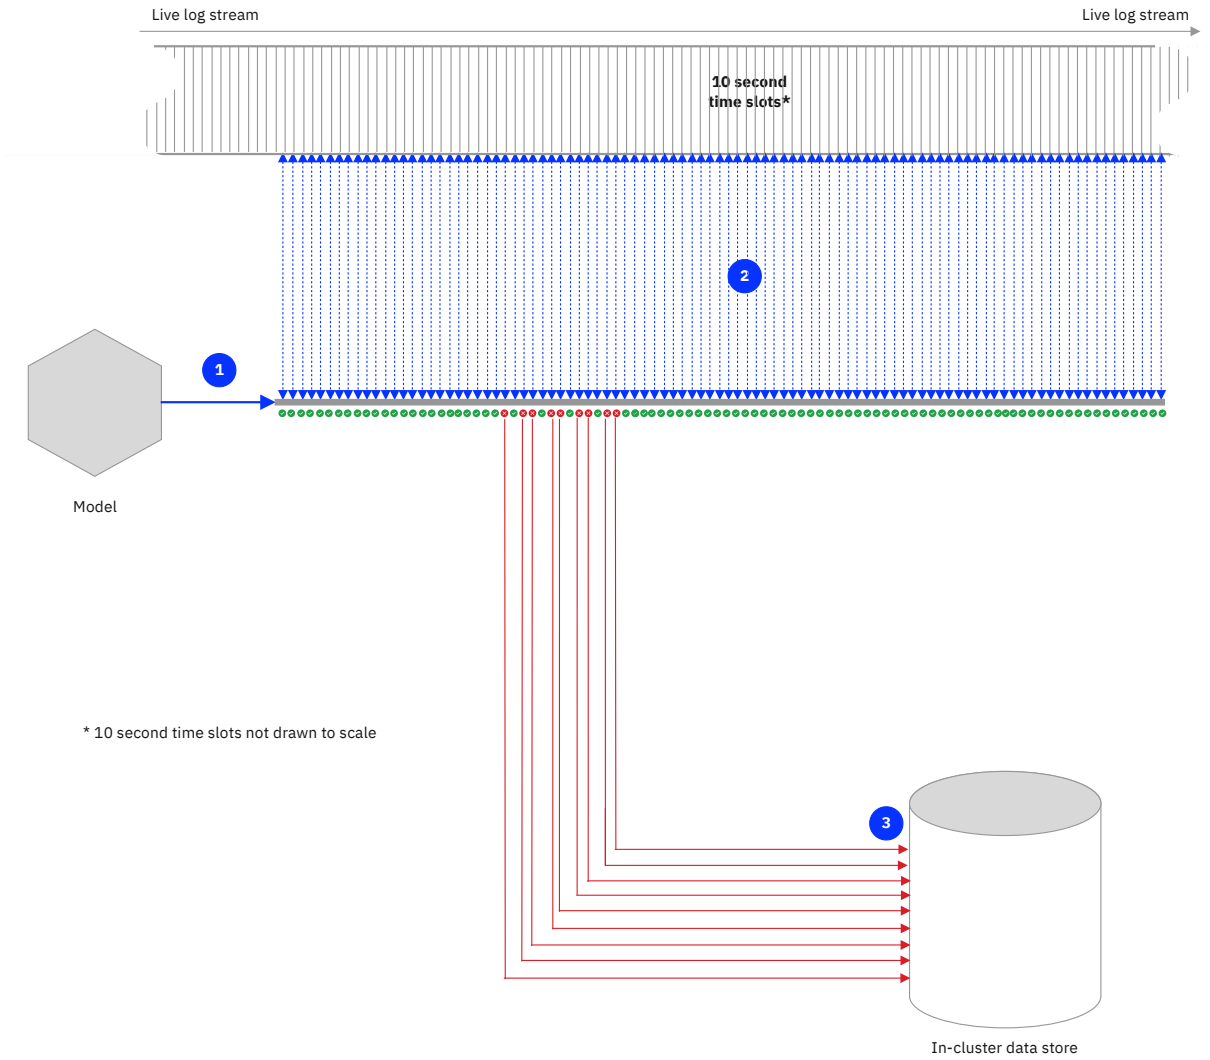

Figure. Workflow model generation

1. **Model is deployed**

   Depending on how the algorithm was configured a new version of the model is deployed automatically on completion of training, or manually.

2. **Review live stream for anomalies**

   Now that you have a deployed model, the system starts monitoring the live log stream for anomalies, which are statistically significant deviations from the baseline. It evaluates each component's logs every 10 seconds for anomalies.

3. **Log alerts are generated**

   Log anomalies are generated at the end of each 10-second interval for each log line in which there is a statistical difference between the log pattern counts and the reference values and log patterns – or both – are identified in the live log stream that does not exist in the model.

   Based on this analysis, the log anomaly detection algorithms identify one or more of the following log anomaly types:

   1. Pattern is expected but is not detected
   2. Pattern is detected but is not expected
   3. Pattern is detected but is not expected, and includes an error
   4. Pattern is detected with lower frequency than expected
   5. Pattern is detected with higher frequency than expected

   The algorithm creates a log alert for each log anomaly. The severity of the log alert is calculated based on the following considerations:

   - All alerts that are generated by this algorithm are given an intial severity of 4 (Minor)
   - If the pattern is detected but not expected (log anomaly type 2) or it is an error pattern, then the severity is increased to 5 (Major).
   - If the pattern is detected with a lower frequency than expected (log anomaly type 4), then the severity is increased to 6 (Critical).

Example of natural language log anomaly detection

This topic provides an examples of log anomalies generated by the natural language log anomaly detection algorithm and when they are likely to be found.

Example: unexpected log pattern

You recently installed an application, which is made up of multiple microservices. Most of the microservices that make up this application generate their own log files.

Note For the natural language log anomaly detection algorithm to work, the following minimum data requirements must be met. At least 75% of the component microservices must have at least 2000 data points, where a data point is usually a log line.

The example proceeds as follows:

1. Data from the microservices is trained, as described in Workflow of natural language log anomaly detection.
2. During training, log patterns statistics are gathered and stored in the initial version of the model, as described in Workflow of natural language log anomaly detection. One of the patterns identified in the model is the following pattern within the **message** keyword.

   ```
   incident euid=<NUM> epid=<NUM> dsteuid=<NUM> dstepid=<NUM> <*>type=undefined subtype=undefined level=notice
   ```

   This pattern occurs on average roughly 2.5 times in every 10 second time slot. See Clean log file lines for an example of what a log like this might look like.
3. When the model is applied to the live data stream as described in Workflow of natural language log anomaly detection, at a certain point the log pattern described in the previous step starts occurring in a number of the 10 second time slots. See Error log file lines for an example of what a log like this might look like.
4. Log anomaly alerts are generated for each log anomaly and sent to the in-cluster ObjectServer. These alerts report that a pattern has been detected with higher frequency than expected. See Log anomaly alert format for an example of what a log anomaly alert might look like.

Reference information

The following information is referenced in this task.

- Clean log file lines
- Error log file lines
- Log anomaly alert example

Clean log file lines

These example JSON log snippets display log lines for one of the microservices within the application.

Clean log file lines

The pattern of interest is:

```
incident euid=<NUM> epid=<NUM> dsteuid=<NUM> dstepid=<NUM> <*>type=undefined subtype=undefined level=notice
```

You can find this pattern in the **message** parameter within the log lines below by searching for the invariant code **type=undefined subtype=undefined level=notice**. This will show you that the pattern of interest only occurs once, in the first line.

In a real life example, the number of lines and the number of occurrences of the pattern in a 10 second time slot would be consistent with the two or three times that is expected based on the values in the model.

```

Error log file lines

These example JSON log snippets display log lines for one of the microservices within the application. You can see that the pattern of interest occurs in every line in this log snippet, in all five times.

The pattern of interest is:

incident euid=<NUM> epid=<NUM> dsteuid=<NUM> dstepid=<NUM> <*>type=undefined subtype=undefined level=notice

You can find this pattern in the **message** parameter within the log lines below by searching for the invariant code **type=undefined subtype=undefined level=notice**. This will show you which lines of code instantiate this pattern.

In a real life example, the number of lines and the number of occurrences of the pattern in a 10 second time slot would be significantly larger. You might have 100 or so log lines in 10 seconds and the pattern might occur on the order of 20 times, which is a significant deviation from the two or three times that is expected based on the values in the model. Based on this, log anomaly alerts would be generated.

Error log file lines

Log anomaly alert example

This example alert incorporates data from the identified log anomalies into an ObjectServer alert structure. Note that based on the values in the **details.log_anomaly_detector.causality.template_list** field, three different templates have been identified as occurring with significant deviations from the model and have been grouped together within this anomaly.

About log anomaly detection - statistical baseline

Statistical baseline log anomaly detection is an unsupervised learning algorithm that uses a statistical moving average on all of your log data to discover abnormal behavior. This algorithm automatically detects unusual patterns in logs and notifies you when they occur.

Deprecated: The statistical baseline log anomaly detection algorithm is to be deprecated in a future release. The recommended action is to use log anomaly detection - golden signals as a replacement.

Data that is used for analysis is updated every 30 minutes, so this algorithm provides value quickly. After it takes the first 30 minutes to establish a baseline, statistical baseline log anomaly detection uses the computed baseline to identify potential errors.

For domain-specific log anomaly detection, such as for IBM MQ or WebSphere, the statistical baseline model already has a baseline for domain-specific logs. Thus, the model can detect potential errors without waiting for 30 minutes to establish an initial baseline. Other than the means of establishing a baseline, domain-specific log anomaly detection has identical behavior to standard statistical baseline log anomaly detection. For more information about domain-specific log anomaly detection, see this video.

The algorithm for both statistical baseline log anomaly detection and domain-specific log anomaly detection supplements the natural language log anomaly detection algorithm by reporting extra log anomalies to your ChatOps interface and to the Alert Viewer.

Domain-specific log anomaly detection is available for the following products:

- WebSphere
- IBM MQ

Enabling this algorithm helps IBM Cloud Pak for AIOps understand normal behavior so when an anomalous situation arises, you are notified. Anomalies are raised to your ChatOps interface. For information on an anomaly, you can view related alerts to see the patterns and associated log messages.

By default the training of this AI algorithm is enabled and it is suggested that you leave it on. If you disable it, you won't see details about statistical baseline anomalies in either your ChatOps feed or in the Alert Viewer.

For more information about natural language log anomaly detection, see the following topics:

- Workflow

- Examples

Workflow of statistical baseline log anomaly detection

Find out how statistical baseline log anomaly detection processes your log data to generate log alerts.

This algorithm extracts specific entities from the logs, such as short text strings that indicate error codes and exceptions. Combined with other statistics, such as the number of logs for each component, the algorithm uses these statistics as a baseline to discover abnormal behavior in your live log data.

These extracted entities are not just a simple dictionary, but rather use *clue words* to interpret other data in the logs, such as numbers. For example, the number **`500`** appearing in a log message might be a count, identifier, or some other value, but if it is accompanied by clue words, such as **`http status`**, then the system knows that this number refers to an error code. When enough of these deviations are detected to be statistically significant, then the system knows it needs to report an anomaly issue.

Domain-specific log anomaly detection, such as that for IBM MQ or WebSphere, uses the same algorithm as statistical baseline log anomaly detection. However, the entities that are used in domain-specific log anomaly detection and that are included in the input logs are already provided from prior knowledge about the specific domain. After entities like the message ID and log level are detected, the workflow of a domain-specific log anomaly is similar to the workflow of a general statistical baseline log anomaly.

The following figure shows a simplified workflow of the statistical baseline log anomaly detection algorithm.

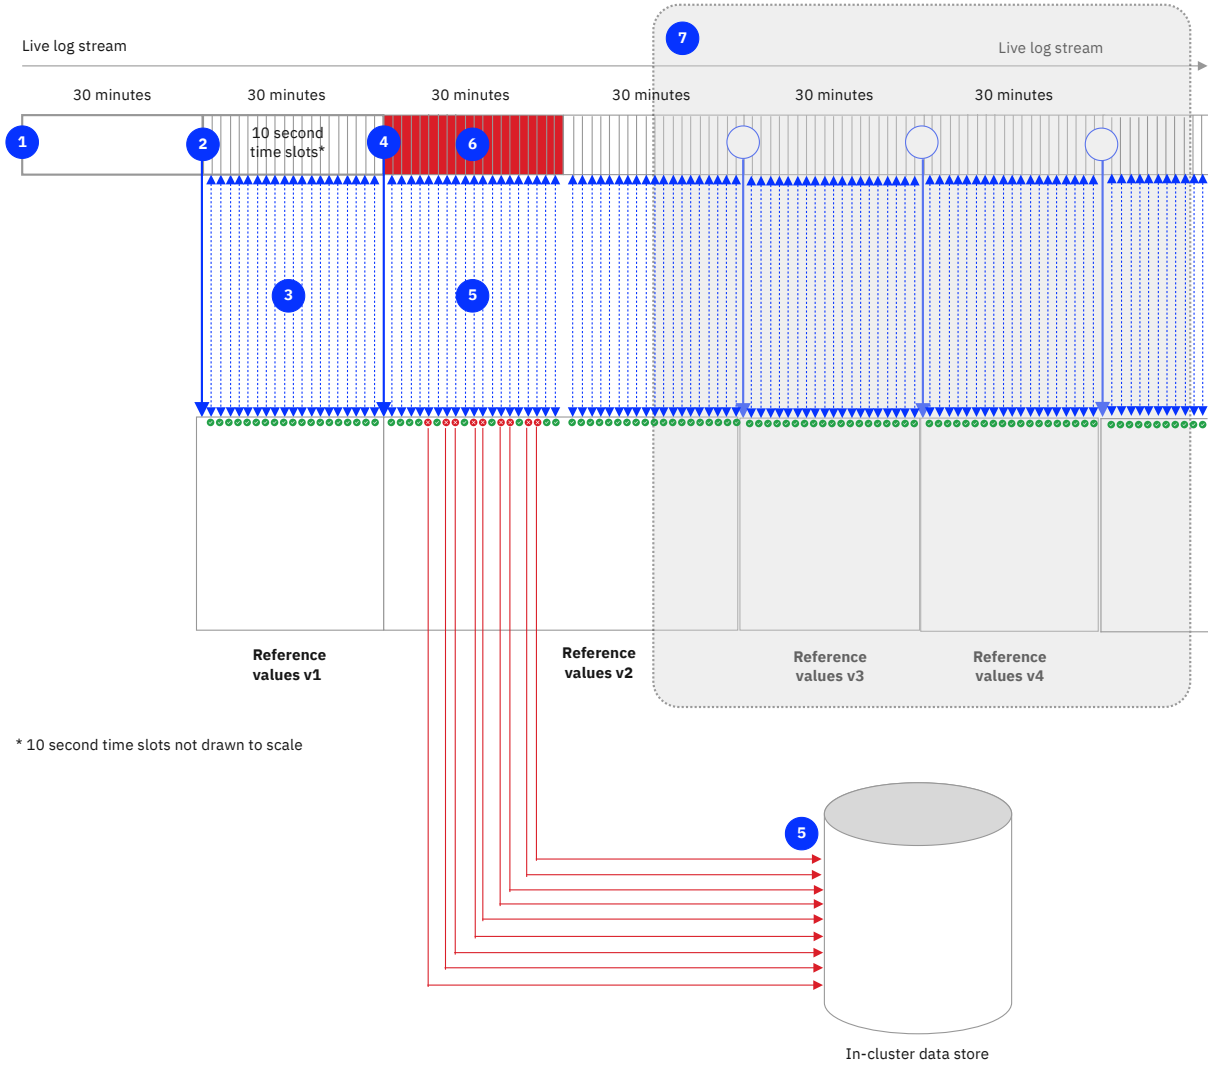

Figure. Workflow

1. **Algorithm switched on**

   The algorithm is first switched on. **Note:** See Supported resource number and throughput rates for limits on throughput rates.

2. **Extract initial reference values**

   At the end of the first 30-minute time interval, the algorithm reviews the log messages from the previous 30 minutes and extracts text entities from the logs. It saves the number of occurrences of each entity as reference values.

3. **Review live stream for anomalies**

   Now that it has the reference values, the system starts monitoring the live log stream for anomalies, which are statistically significant deviations from the baseline. It evaluates each component's logs every 10 seconds for anomalies.

4. **Extract values from next 30-minute interval and update reference values**

   At the end of the next 30-minute time interval, the algorithm again reviews the log messages from the previous 30 minutes. As before, the algorithm extracts text entities and statistics from the logs. It then combines this data with the previous baseline to compute a new baseline, which now covers 60 minutes' worth of normal behavior data.

   Note: If the live data that is being processed is not from the last 30 minutes, then the algorithm still looks for anomalies, but the reference values are not updated. One reason why the last 30-minute time interval might contain older data is when a delay in data processing occurs due to a temporary malfunction of a data processing component, such as a Flink job.

5. **Log alerts are generated**

   The system is continuously monitoring the live log stream for anomalies and evaluates each component's logs every 10 seconds for anomalies. Log anomalies are generated at the end of each 10-second interval for each log line in which a statistical difference exists between the number of entities that are identified and the reference values and numbers, or both, that are identified and accompanied by clue words.

   Based on this analysis, the log anomaly detection algorithm identifies one or more of the following log anomaly types:

   - An entity is detected but not expected and includes an error.
   - An entity is detected with lower frequency than expected.
   - An entity is detected with higher frequency than expected.

   The algorithm creates a log alert for each log anomaly and sends these alerts to the in-cluster data store. Any alerts that are generated by this algorithm are assigned severity 5 (Major).

6. **Interval is potentially tagged as biased**

   Based on the number of log anomalies detected in the previous step, a threshold calculation is performed. The number of log anomalies that are detected is divided by the number of windows. If the resulting value exceeds the predefined threshold of 0.15, then the entire interval is tagged as biased, and none of the reference values are updated based on the entity extraction values for this interval.

   Note: The predefined threshold ensures that frequently occurring anomalies do not bias the statistical baseline reference. If the anomalies are not frequently occurring, such as when the resulting value does not exceed the predefined threshold of 0.15, the interval is not tagged as biased, and the reference values are updated. It is possible that such infrequent anomalies are learned as normal behavior, and they might not be detected again. To reset the learning, you need to manually reset the reference of the statistical baseline. For more information, see Resetting the reference of the statistical baseline.

7. **Processing of the live log stream continues**

   The algorithm continues processing 30-minute time intervals in the live log stream.

Examples of statistical baseline log anomaly detection

This topic provides examples of log anomalies generated by the statistical baseline log anomaly detection algorithm and when they are likely to be found.

Examples presented in this topic

The following examples are described in this topic.

- Unexpected 500 error
- WebSphere log anomaly
- IBM MQ log anomaly

Example: unexpected 500 error

You recently installed the sock-shop application, which is made up of multiple microservices, such as **`front-end`** and **`orders`**. Most of the microservices that make up this application generate their own log files.

Note For the statistical baseline log anomaly detection algorithm to work, there is no formal minimum log line count. The main requirement is that all microservices generate a reasonable amount of log data.

The example proceeds as follows:

1. Initially the microservices are all running OK and generate clean log files, without any text entities that might indicate an error. See Clean log file lines for an example of what a log like this might look like.
2. Shortly after this, some of the pods associated with the microservices start shutting down unexpectedly; as a result of this, **`HTTP 500`** errors appear for the first time in the live log stream.
3. Live log data is analyzed in 10 second slots. Now, when the latest logs are compared to the baseline reference values, several error entities are identified: **`500`**, **`error`**, and **`illegIllegalStateException`**. The algorithm determines that the number **`500`** is an error, as it is accompanied by the entity **`status`**, which points to an HTTP 500 error, a general HTTP status code indicating that something has gone wrong on a server but the server could not be more specific about what the exact problem is. These entities have not been identified before during normal behavior and since they are statistically significant (trivially so in this example) thus point to an anomaly. See Error log file lines for an example of what a log like this might look like.

   Note If this was an error message that occurs on a regular basis, say an optional library that is not used in a given piece of code, then the statistical baseline log anomaly detection algorithm will automatically learn this, and consequently treat this error message as normal and therefore no longer alert on it.
4. Log anomaly alerts are generated for each log anomaly and sent to the in-cluster ObjectServer. See Log anomaly alert format for an example of what a log anomaly alert might look like.

Reference information

The following information is referenced in this task.

- Clean log file lines
- Error log file lines
- Log anomaly alert example

Clean log file lines

These example JSON log snippets display clean log lines for the front-end and orders microservices within the sock-shop application. The log algorithm extracts entities from the **`_line`** keyword within these log lines and then performs the analysis described in Workflow of statistical baseline log anomaly detection on these extracted entities.

Clean log file lines from the front-end microservice

The following log files lines do contain numbers but they are not accompanied by error entities. The numbers in these log message are actually part of user address data (for example **`322 Main Street`**) and credit card data, and can be seen in the **`_line`** parameter in the code snippet below. You might need to scroll to the right to see the full content of the **`_line`** parameter.

Error log file lines

The following example JSON log snippet displays error log lines for the front-end microservice within the sock-shop application. The log algorithm extracts entities from the **`_line`** keyword within these log lines and then performs the analysis described in Workflow of statistical baseline log anomaly detection on these extracted entities.

Error log file line from the front-end microservice

The following log line contains numbers accompanied by error entities; in particular, the **`_line`** parameter contains the number **`500`**, as well as the error entities **`status`**, **`exception`**, and **`IllegalStateException`**. You might need to scroll to the right to see the full content of the **`_line`** parameter.

Log anomaly alert example

This example alert incorporates data from the identified log anomalies into an ObjectServer alert structure.

- This alert has been assigned a severity of 5.
- The **summary** parameter explains that 24 errors have been found in the front-end component.
- The **details.log_anomaly_detector.text_dict.template_list** parameter lists the error entities identified.

Example: WebSphere log anomaly

The following example shows a WebSphere log. In log anomalies for a specific domain like WebSphere, entities are included in the logs. WebSphere log anomaly detection identifies which entities are error indicators. Message ID, **ibm_messageId**, and log levels, **loglevel**, are examples of WebSphere entities.

```
{
  "type": "was_message",
  "host": "abc-123.myserver.com",
  "ibm_cellName": "gsV900Cell",
  "ibm_nodeName": "node4",
  "ibm_serverName": "nodeagent",
  "ibm_sequence": "1616166373781_0000000000002",
  "message": "TRAS0017I: The startup trace state is *=info.",
  "ibm_datetime": "2021-03-19T11:06:13.781-0400",
  "ibm_messageId": "TRAS0017I",
  "ibm_threadId": "00000001",
  "module": "com.ibm.ejs.ras.ManagerAdmin",
  "loglevel": "INFO",
  "unix_ts": 1616166373781,
  "start": 1616166370000,
  "end": 1616166380000
}
```

On the **Incidents and alerts** page, the following example from the **Summary** parameter explains that two logs were found in the **qotd-qrcode** container. This parameter also says that a primary message code of **SSLC0008E** is contributing to the error. This alert is further explained by the **Alert details** panel. For more information, see Domain-specific log anomaly alert details.

```
Log Anomaly found 2 logs containing errors for container(s): qotd-qrcode with a primary message code of SSLC0008E
```

Example: IBM MQ log anomaly

The following example shows an IBM MQ log. In log anomalies for a specific domain like IBM MQ, entities are included in the logs. IBM MQ log anomaly detection identifies which entities are error indicators. Message ID, **ibm_messageId**, and log levels, **loglevel**, are examples of IBM MQ entities.

```
{
  "ibm_messageId": "AMQ6287I",
  "ibm_arithInsert1": 0,
  "ibm_arithInsert2": 0,
  "ibm_commentInsert1": "Linux 4.18.0-193.70.1.el8_2.x86_64 (Cloud Pak Linux (x86-64 platform) 64-bit)",
  "ibm_commentInsert2": "/opt/mqm (Installation1)",
  "ibm_commentInsert3": "9.3.0.0 (p930-L220526)",
  "ibm_datetime": "2022-06-01T01:13:49.673Z",
  "ibm_serverName": "QMA",
  "type": "mq_log",
  "host": "slot11-qma-ibm-mq-0",
  "loglevel": "INFO",
  "module": "amqxeida.c:6755",
  "ibm_sequence": "1654046029_673594295",
  "ibm_processId": "37",
  "ibm_threadId": "3",
  "ibm_version": "9.3.0.0",
  "ibm_processName": "amqzmuc0",
  "ibm_userName": "mqm",
  "ibm_installationName": "Installation1",
  "ibm_installationDir": "/opt/mqm",
  "message": "AMQ6287I: IBM MQ V9.3.0.0 (p930-L220526)."
}
```

On the **Incidents and alerts** page, the following example from the **Summary** parameter explains that two logs were found in the **qotd-qrcode** container. This parameter also says that a primary message code of **SSLC0008E** is contributing to the error. This alert is further explained by the **Alert details** panel. For more information, see Domain-specific log anomaly alert details.

```
Log Anomaly found 2 logs containing errors for container(s): qotd-qrcode with a primary message code of SSLC0008E
```

About log anomaly detection - golden signals

Detect log anomalies with golden signals.

Log anomaly detection - golden signals, introduced in Version 4.6.0, is an algorithm that improves signal-to-noise management of anomaly detection over previous log anomaly detection algorithms. It uses autoclassification of log templates to pre-filter logs of interest and provides administrative control to further tune the anomalies that are raised as alerts. It also improves anomaly alert explainability by providing anomaly periods, baselines, and forecasts in a chart and access to raw logs.

How do golden signals help with log anomaly detection?

Working with metric anomaly detection, **Log anomaly detection - golden signals** discovers important log message patterns and detects when they change significantly. The algorithm takes in raw log messages and converts the textual information to log patterns with both known and unknown variables and static content. These log patterns are called templates. Domain knowledge is used to assign a golden signal type to each template.

After this templatization, log data is filtered based on the golden signal type and converted to metric data. This converted metric data is passed through the metric anomaly detection algorithm to train models and infer anomalies.

IT operations teams can use the alerts that are generated to identify the log patterns that deviated from normal behavior and the time period in which the abnormalities were observed. Teams can use this information for root cause analysis to help resolve incidents.

Note: If the **Log anomaly detection - golden signals** algorithm is enabled, the **Log anomaly detection - natural language** or **Log anomaly detection - statistical baseline** algorithms cannot be active. Likewise, if **Log anomaly detection - natural language** or **Log anomaly detection - statistical baseline** is enabled, **Log anomaly detection - golden signals** cannot be active.

What is a golden signal?

Golden signals help IT operations teams to classify and organize events when they diagnose incidents.

- Seven types of golden signals exist within IBM Cloud Pak® for AIOps.
- Golden signal types can fall into the following classes:
  - Causes include latency, error, and availablity.
  - Effects include exception, traffic, saturation, and information.
  - The information type is not assigned to any class and shows up with none.

Golden signal types

- **Latency:** These events include a duration and are not related to resources.
  - Examples include transaction load, transfer, or any other metrics where the unit of measurement is time.
  - Example events include disk read/write times and I/O wait times.
- **Error:** These events are associated with a timeout, drop, failure, reset, retry, retransmission of request, packets, or a notification.
  - An error might also be understood as a limiting condition of latency. Examples include HTTP code 5xx, requests failed, crash affected user rate or count, count of errors, or any user actions with errors, error count, or rate associated with reported or requests, and event failure.
- **Availability:** These events are indicative of the availability or readiness of the resource.
  - Examples include HTTP code 4xx, host unhealthy, resource availability, readiness, and health status.
- **Exception:** These events are composed of stack trace or any indication of other errors in the log data.
  - Examples include `DSRA0010E : SQL State = 08S01`, `Error Code = 18.456: (FailedLoginException) Login error: com.ibm.security.krb5.KrbException`, and `status code: 6 message: Client not found in Kerberos database`.
- **Traffic:** These events represent the volume or rate of transactions that flow through the system.
  - Examples include HTTP code 2xx, traffic in/out, bytes received/sent/outstanding, disk/bytes read/write operations, throughput, service idle time, and HTTP 2xx/4xx/5xx success counts.
  - Events that represent idle time might also be classified as traffic because they might indicate that a service is experiencing idle time, indicating low traffic.
- **Saturation:** These events can be measured in terms of count or percentage and can be exhausted and throttled. These events are also resource-oriented, such as CPU, GPU, memory, swap, kernel thread, cache, containers, link, connection, process, queue, disk, and session.
  - At the infrastructure level, such resources might be as granular as CPU, GPU, memory, and disk space or as broad as a Kubernetes cluster, pod, and VM.
  - At the middleware level, such resources might include connection pool and thread pool.
  - At the application level, such resources might be user sessions.
- **Information:** Events that do not fall into any of the previous golden signal types are assigned as information logs, for example, `<<UNKNOWN TYPE>> on Success type = 0 data=true`.

Enabling or disabling the log anomaly golden signals pipeline

To enable the pipeline, complete the following steps:

1. Before you enable the log anomaly golden signals pipeline, disable the **Log anomaly detection - natural language** and the **Log anomaly detection - statistical baseline** algorithms from the AI Model Management UI.

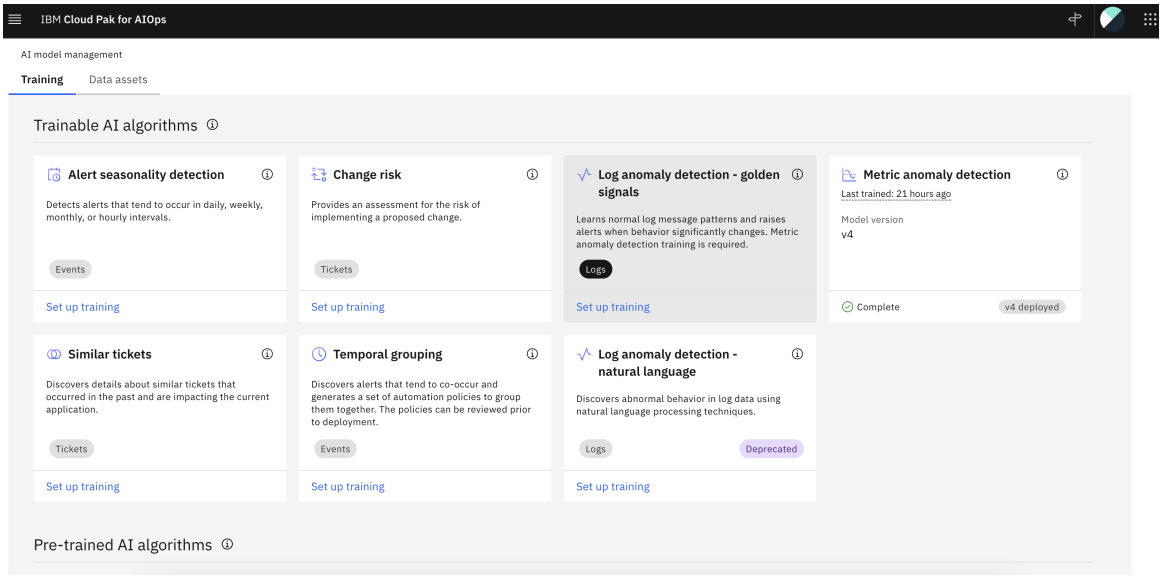

Figure. AI Model Management UI page

2. Enable the metric anomaly detection training schedule from the AI Model Management UI.
3. Click **Set up training** and complete the steps in Starting the training setup to enable the pipeline.
4. Verify that the **Log anomaly detection - golden signals** policy is enabled so the log anomaly golden signals pipeline can run as expected. The policy is enabled by default. After the pipeline runs, it produces an alert.

To disable the pipeline, complete the following steps:

1. Click the **Log anomaly detection - golden signals** tile within the AI Model Management page and delete the training definition.

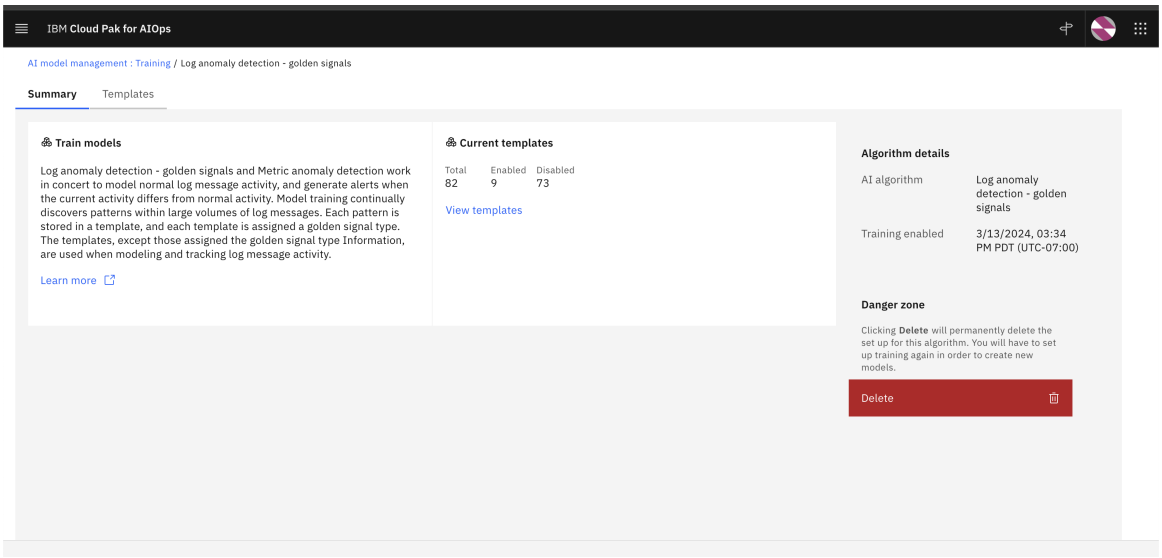

Figure. Log anomaly detection - golden signals UI page

2. Enable the **Log anomaly detection - natural language** or the **Log anomaly detection - statistical baseline** algorithms from the AI Model Management UI. Now the pipeline is configured not to use golden signals, and all incoming log lines are instead sent to the log anomaly detection pipeline.

How to set up a training definition for log anomaly detection - golden signals

For more information, see Setting up training for log anomaly detection - golden signals.

Handling large log message loads for template training

Starting with IBM Cloud Pak® for AIOps version 4.7.0, log message sampling is enabled by default. The training initially runs every 10 minutes until at least 100,000 log messages are processed. Then, the training runs once every hour. Regardless of the log message load, 450,000 logs are sampled by default for every training run.

If the log message load contains more than 10 million logs each hour, tune some parameters to override the defaults with one of the following options.

Option 1

Increase the pod resources and the **MINIMUM_SAMPLE_SIZE_PER_TRAINING_RUN** and **MAXIMUM_SAMPLE_SIZE_PER_TRAINING_RUN** values.

1. After you log in to the terminal with the **oc login** command, edit the deployment file by entering the following command:

   ```
   oc edit deployment aimanager-aio-log-anomaly-golden-signals
   ```

2. Modify the values in the **container.resources** file to the following values:

   ```
   containers:
     - resources:
         limits:
           cpu: '3'
           memory: 6Gi
         requests:
           cpu: '2'
           memory: 4Gi
   ```

3. In the **env** section, add or modify the following values:

   ```
   - name: MINIMUM_SAMPLE_SIZE_PER_TRAINING_RUN
     value: '800000'
   - name: MAXIMUM_SAMPLE_SIZE_PER_TRAINING_RUN
     value: '900000'
   ```

Option 2

Alternatively, run the training more frequently even after the initial 100,000 log messages are processed by modifying the **JOB_FREQUENCY_TIME** value.

1. After you log in to the terminal with the **oc login** command, edit the deployment file by entering the following command:

   ```
   oc edit deployment aimanager-aio-log-anomaly-golden-signals
   ```

2. In the **env** section, add or modify the following value to change the number of minutes:

   ```
   - name: JOB_FREQUENCY_TIME
     value: '10'
   ```

Viewing templates

Now the training setup is complete. The template training continuously runs in the background.

After the data integration collects the threshold number of log messages, the algorithm triggers template training on the data that is collected. The algorithm starts to process the log messages to categorize them into the required templates.

When template training gets completed, you can see a summary count of all the templates that got generated, as shown in the following example:

Figure. Summary count of all templates

Any template with a golden signal type of **Information** gets categorized as a **`disabled`** template, and all other templates with a golden signal type other than **Information** get categorized as **`enabled`**.

You can view more details about these templates by clicking the **Templates** tab.

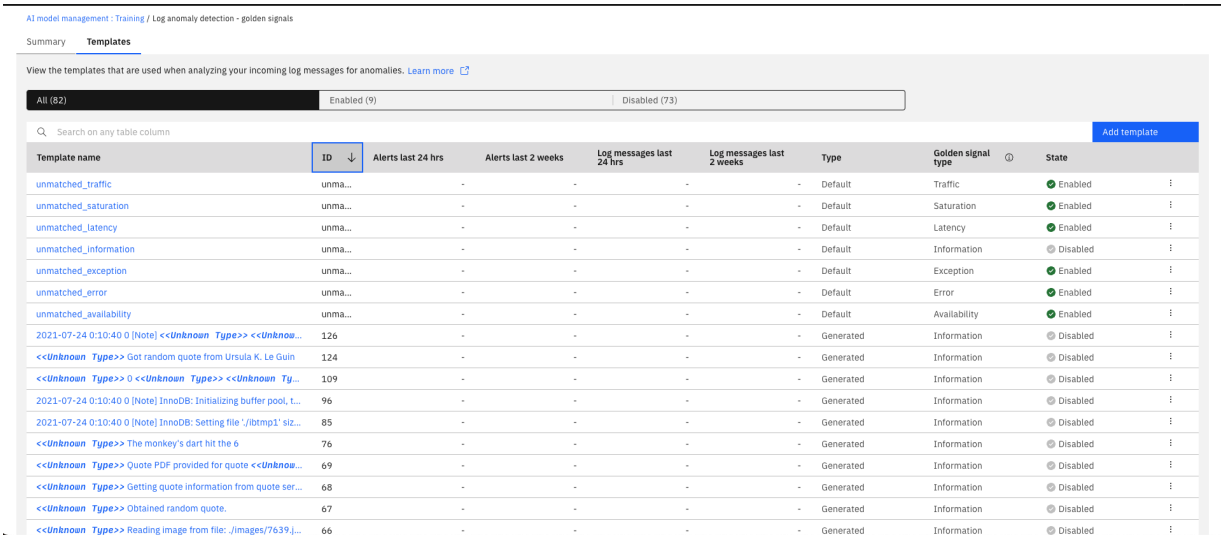

Figure. View templates

The templates are displayed in a tabular format with the following details:

- The **Template name** section shows the log pattern that matches the input log messages.
  - Logs that were not matched to any existing template are assigned to a **Template name** that includes *unmatched* in its name. A specific *unmatched* template is assigned based on the golden signal that is classified on the log content.
  - Click a **Template name** to view template **Details**.
- The **ID** numbers indicate the unique template ID value that is assigned by the training algorithm.
- The **Alerts last 24 hours** and **Alerts last 2 weeks** sections display the alert count if an alert was generated for that particular template in the last 24 hours or 2 weeks. If any log message patterns or frequencies change unexpectedly, the template triggers an alert to be generated.
- The **Log messages last 24 hours** and **Log messages last 2 weeks** sections show the count of any log messages that were collected in the last 24 hours or 2 weeks that match a specific template pattern.
- The **Type** section indicates whether the template is **Custom**, **Generated**, or **Default**.
  - You can create a **Custom** template with **Add template**.
  - A **Generated** template is created from the training algorithm.
  - All *unmatched* templates are categorized as **Default**.
- The **Golden signal type** section shows the golden signal type that is attached to a template. Open the menu for the template that you want to modify. Click **Set golden signal** to select a golden signal type, or click **Set state** to set the state.
- The **State** section shows **`enabled`** or **`disabled`** based on the golden signal type for the specific template. **`Enabled`** templates are used to track log message patterns over extended periods of time. This data is then sent to metric anomaly detection. Alerts are generated when log message patterns or their frequencies change unexpectedly.

If the counts against template patterns from the log anomaly detection - golden signals algorithm are not updated in the training UI table, enable historic alert storing in Elasticsearch to access alert counts. For more information, see Counts against template patterns are not updated in the training UI.

Viewing unmatched templates

Log messages that don't have any common pattern to them are grouped based on their golden signal type and matched to a template pattern with an `unmatched_<golden_signal_type>` format.

After enough unmatched log messages reach the threshold count, an incremental training run is triggered. The incremental training might generate new log template patterns to help match the log lines that are similar to current unmatched logs and add the logs to a template.

Click a **Template name** of an unmatched template to view template **Details**.

Viewing log messages

View up to 10,000 log messages that match a template pattern.

1. Click a **Template name**. Then, click the **Log messages** tab.
   - **Received** shows timestamps for when the messages were received.
   - **Log message** shows the log message content that matches the template pattern.
2. Click **Export to CSV file** to generate a CSV file if you want to further analyze the data.

Viewing metric anomalies in the Alert Viewer

For more information about viewing **Log anomaly detection - golden signals** metric anomalies in the Alert Viewer, see Viewing metric anomaly details.

Adding templates

If the automatically generated templates didn't capture a pattern that is important to you, click **Add template** to add your own custom template patterns.

1. From the **Templates** tab, click **Add template**. The **New custom template** page opens.
2. Enter an optional **Template name**.
3. Enter a **Sample log message** for the pattern that needs to be generated.
4. Click **Generate pattern**. Based on prior knowledge and predefined variable rules, the model generates a **Log message pattern** for the sample log message. Along with the pattern, a default **Golden signal type** is assigned based on the log message that you entered. The **State** is **Enabled** by default. However, you can modify these values.
5. To edit the generated pattern, click **Edit**. Use the menus to customize the log message pattern. For example, to change a variable type, click an **Unknown Type** menu and select the option that you want.
6. Click **Done**.
7. If the assigned category isn't correct, select a different **Golden signal type**.
8. Select the **State** as needed. If the template is **Disabled**, models aren't trained with it.
9. When your template is ready for use, click **Create template**.

Editing templates

Edit templates from the **Templates** tab or the **Details** tab.

Edit a template from the **Templates** tab:

1. Find the template that you want to edit in the table.
2. Click **Golden signal type**. A menu opens.
3. Select **Set golden signal type** to set the golden signal type of the template or select **Set state** to enable or disable the template.
4. If the template **Type** is **Custom**, you can also edit the **Template pattern**.

Edit a template from the **Details** tab:

1. In the table, find the template that you want to edit and click the **Template name**. The template **Details** tab opens.
2. Update the **Template name**, select a **Golden signal type**, or change the **State** to **Enabled** or **Disabled**.
3. If the template **Type** is **Custom**, you can also edit the **Template pattern**.
4. After your changes are complete, click **Save**.

Deleting templates

You can delete any templates except Default templates.

1. Find the template that you want to delete in the table.
2. Click **Template edit options** (the three dots at the end of the row) and select **Delete**.

About shape correlation

BETA Shape correlation is available only for technology preview, not for production usage.

Provide a metric and pattern to the shape correlation algorithm, and it can search whether another metric shows a similar metric pattern.

Enabling shape correlation

Enable the shape correlation algorithm by creating a policy.

1. In IBM Cloud Pak® for AIOps, select **Automations** and then **Create policy**.
2. In *Policy templates*, select the **Group alerts based on scope** template and click **Create**.
3. From the *Policy details* section, enter a **Policy name**.
4. From the *Condition sets* section, click **Add condition** and select **Alert property**. An alert property condition is added.
5. Select **AND** so that the alerts are grouped when all the conditions are met.
6. Enter the following values for the alert property condition:
    - Set the *Property* field to `Value of: alert.sender.name`.
    - Set the *Operator* field to **contains**.
    - Set the *Matches* field to **only**.
    - Set the *Value* field to `String: anomaly-detection`.
7. In the *Create a scope-based grouping* section, set the *ScopeID* to `Value of: alert.sender.sourceId`.
8. Click **Create policy**. The shape correlation algorithm is enabled.

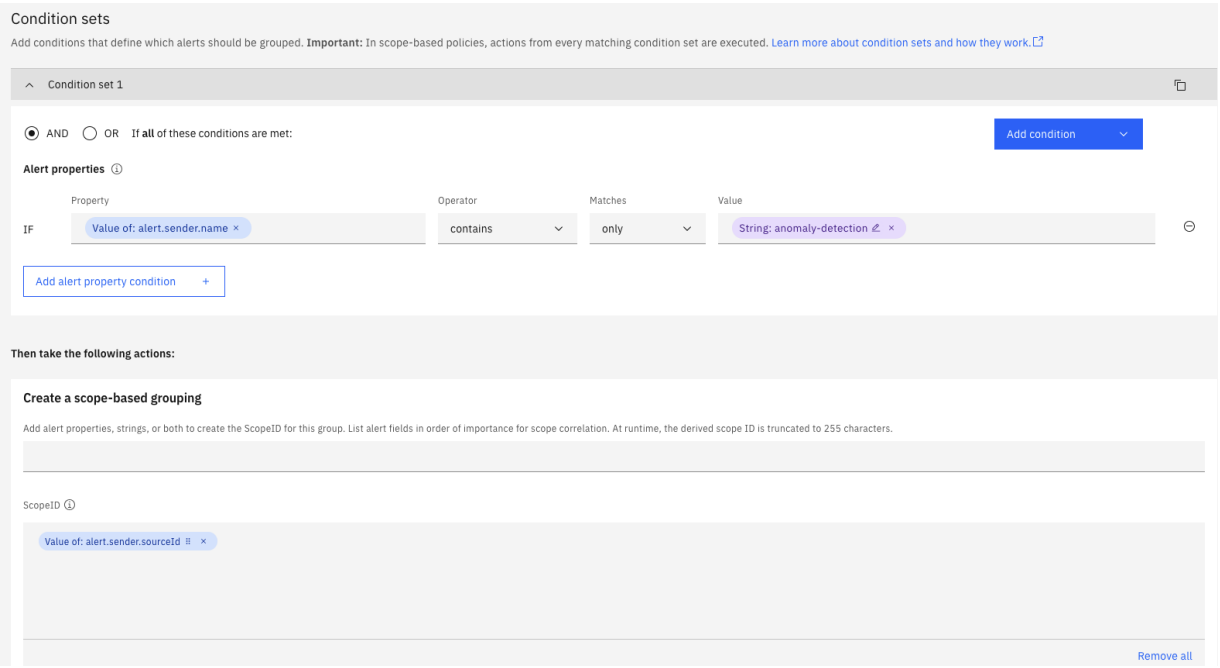

Figure. Create a policy with the appropriate values to enable shape correlation.

About metric anomaly detection

This AI algorithm generates alerts when it detects anomalous behavior in your metrics.

Description

Metric anomaly detection is composed of a set of unsupervised learning algorithms. These algorithms learn normal patterns of metric behavior by analyzing metric values at regular intervals. Then, metric anomaly detection raises anomalies or alerts when that behavior significantly changes.

Enabling metric anomaly detection helps IBM Cloud Pak® for AIOps discover metric anomalies. The first model, simple baseline, is produced after 4 data points. Simple baseline is also known as the naive baseline.

Unless otherwise stated, other models are produced when at least 7 days of data are present in the system, and training is completed. The algorithm can use up to 14 days of data to learn. After models are trained, you can be alerted to problems before services or applications are

impacted.

Metric anomalies are generated based on the following analyses:

- Dynamic calculation of baseline values for each metric. For example, a metric baseline might be within the 1 to 25 range at a particular time of day. If a metric value is returned outside of this range, then a metric anomaly alert is immediately generated.
- Simple baseline, where less than 50% of data is available for a time series when training occurs, or the analytics determines that a dynamic baseline isn't a good fit for a particular time series. This baseline starts to be produced after 4 data points. After the analytics training occurs, this algorithm might raise alerts when values exist outside the simple baseline. Before the analytics training occurs, values can fall outside the simple baseline and not raise an alert.
- Flatlining, whereby the system identifies that the metric started unexpectedly returning a constant value. Models are produced when at least 3.5 days of data are present in the system, and training is completed. The algorithm can use up to 7 days of data to learn.
- Finite Domain, whereby the system detects an anomaly when a metric value elevates to a level not reached previously.
- Predominant Range, whereby the system detects an anomaly when the variation in a metric value exceeds the range within which the metric normally varies.
- A metric with learned variance and that is later found to vary significantly is also flagged as a metric anomaly alert.

Site reliability engineers (SREs) and other users responsible for application and service availability are able to display metric anomalies as alerts within the context of an incident, as described in the following topics:

- Viewing alerts in ChatOps
- Viewing probable cause alerts in an incident

They can also view metric anomaly alerts in the Alert Viewer and associated graphs that display metrics over time, baseline values of metrics, highlighting of anomalous metrics, and forecasting of metric values, as described in the following topics:

- Viewing metric anomaly details
- Metric anomaly forecasts

Note: Individual anomolous or non-anomalous metrics can be viewed on a timeseries chart using the Metric search function located on the Cloud Pak for AIOps console.

Prerequisites

Metric anomaly detection must be trained before anomalies are generated. For more information about training metric anomaly detection based on time series from integrated data sources, see Setting up training for metric anomaly detection.

To train metric anomaly detection, you need time series data that takes measurements at regular intervals.

- Up to 14 days of the most recent timeseries data are used to build the models.
- Models require 50% of their training window to have data before they are built and used to detect anomalies. For more information, see Description.
- Models that do not satisfy the 50% data availability requirement might raise anomalies with simple baseline. Anomalies from simple baseline are always produced. Simple baseline is trained with a minimum of 4 data points.

Data ingestion

Data comes from one of the following sources

- Ingest metric data by posting data using the REST API. For more information, see Metrics API and the POST entry in the associated Swagger document.
- Check that ingested data is being ingested by retrieving metric data using the REST API. For more information, see Metrics API and the GET entry in the associated Swagger document.
- If you have a metric data integration set up (Instana, Dynatrace, New Relic, Zabbix, for example), you can ingest data using the relevant integration, as described in Integration.

Automating metric anomalies to create incidents

You can automatically create incidents from a subset of anomalies, for example, if you want to allow for better prioritization. You need to create a policy to promote alerts to an incident like you would for any other alert. For more information, see Promote alerts to an incident.

The following example shows a policy to promote alerts to an incident:

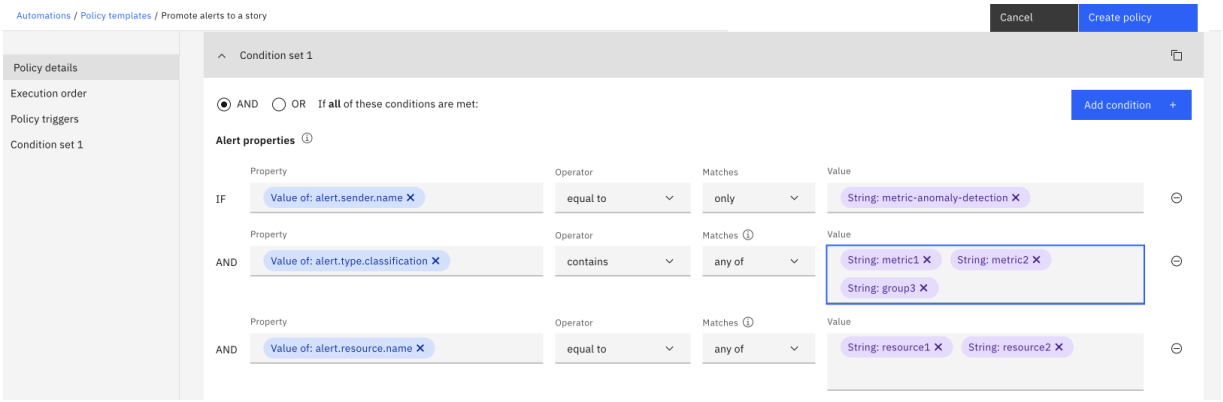

Figure. Policy template alerts

This policy means that the next time there is a new alert on **`resource1`** or **`resource2`** for **`metric1`** or **`metric2`**–or any metric in group3–then an incident is automatically created for it.

For more information, see Promote alerts to an incident.

Language support

For information about supported languages for this algorithm, see Language support.

About golden signal alert enrichment

This AI algorithm analyzes the text of an alert and assigns the golden signal that applies to it.

Enabling and disabling the golden signal alert enrichment policy

Golden signal alert enrichment is a default policy that comes with IBM Cloud Pak® for AIOps. You can enable or disable this policy.

1. From IBM Cloud Pak® for AIOps, click **Automations**. The *Policies* tab opens.
2. In the search bar, search for *story creation*. In the *Policies* table, *Golden signal and persistence story creation* appears.
3. In the *Policies* table, on the *State* column, select **Enabled** or **Disabled** to enable or disable the policy. Or click the **Golden signal and persistence story creation** table row. The *Golden signal and persistence story creation* panel opens. The panel displays details, and you can enable or disable the policy from the panel.

Viewing and editing the golden signal alert enrichment policy

The policy creates stories if specified conditions are met. View the default conditions and edit them if wanted.

1. From IBM Cloud Pak® for AIOps, click **Automations**. The *Policies* tab opens.
2. In the search bar, search for *story creation*. In the *Policies* table, *Golden signal and persistence story creation* appears.
3. Click the **Golden signal and persistence story creation** table row. The *Golden signal and persistence story creation* panel opens.
4. Click the **Specification** tab to view the conditions and the action that is taken if they are met. For more information about editing policies, see Policy editor.

Accessing the golden signal alert enrichment tile

View information about this AI algorithm from the tile.

1. From IBM Cloud Pak® for AIOps, click **AI model management**. The *Training* tab opens.
2. In the *Pre-trained AI algorithms* section, find *Golden signal alert enrichment* and confirm that it is enabled.
3. For more information about this AI algorithm, click **Golden signal alert enrichment**.

Viewing the golden signal classifications

See the golden signals that the AI algorithm assigned to the alerts.

1. From IBM Cloud Pak® for AIOps, click **Alerts**. The *Alerts* tab opens.
2. On the table row that you want more information about, click the arrow to view more details.

3. Scroll horizontally in the table until the *Golden signal* column comes into view. This column displays the golden signal that is associated with the alerts. The golden signals can fall into the following classifications:

- *Effect* golden signals indicate that users are negatively impacted because of the service.
  - *Effect- Error:* Users call the service and receive errors in the service responses, such as an HTTP status code 500. This classification might be the result of latency.
  - *Effect - Latency:* Users receive correct responses from the service, but the response is delayed beyond an acceptable time. This classification might be the result of saturation.
- *Cause* golden signals indicate situations that might eventually impact users.
  - *Cause - Saturation:* This classification indicates potential problems with system resources and might be the result of high traffic.
  - *Cause - Traffic:* This classification indicates workload. Higher traffic can lead to saturation.
- If the alert isn't significant, or the algorithm can't specify a classification, it is classified with *None*.
  - *None - Availability:* This classification indicates that the service is available.
  - *None - Information:* If the algorithm can't specify a classification for the alert, the alert is classified as *Information*.

About probable cause ranking

This AI algorithm identifies the alert with the greatest probability of being the cause of an incident.

It is enabled by default, so that information about the probable cause of a problem is automatically included in your incident details.

Description

Probable cause is a set of approaches and customizations that analyses alerts and topologies together. It then uses that understanding to try to determine the root cause of a problem. After the probable cause alert is identified, action can be taken on the resource that is generating that alert to quickly resolve the incident.

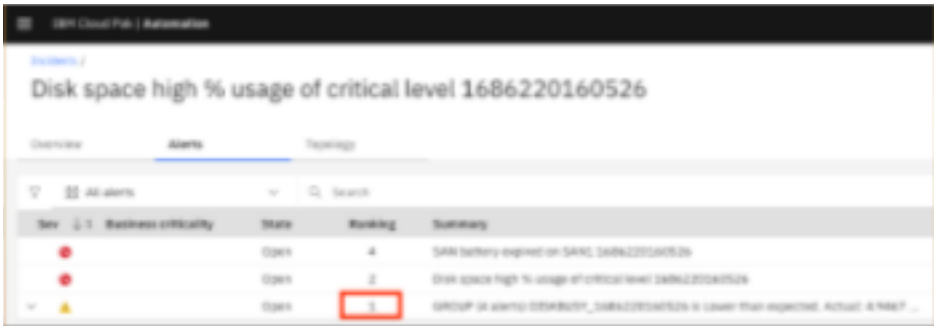
A number of techniques are used to make a probable cause determination. These are derived from topological relationships and natural language calculations. The natural language model has been built to classify the alerts in the golden signal classes, based on their summary. This information is then combined with the topological information (path calculation between the affected resources on which the alert exists). Then, the path and class are combined together to determine the rank of the alert, within the context of the other alerts in the incident.

- Keyword in the **Summary**: For example, if the word "down" appears, it might be more indicative of the root cause than the word "up".
- Severity: The highest severity normally means it's more likely to be indicative of what to look for in the root cause.
- First to occur: Set off by default. Often the first alert to arrive in a group of alerts can be seen as the root cause of the problem, but it is not always the case.
- The ability to inherit previous root causes from IBM Tivoli Network Manager (ITMN) root causes and CauseWeights that exist from scope-based alert grouping in Netcool. (For more information, see the **Event Grouping** section here.)
- Scoring config: The following options contribute to probable cause determination:
  - `PathCalculationEnabled`: This option uses topological data to calculate the path between sources. You must create the topological resource group. For the resource group, set the alert correlation to `true`. This setting allows alerts to be correlated by toplogical correlation. When a problem is encountered in the system, a path is calculated between all the alerts in the group. This path is the shortest number of hops. After the path is calculated, a path score is calculated based of the edge types in the system.
  - `wordEnabled`: You can add or remove words from the system with an API. If a specified word is in the summary field of an alert, the word score is added.
    - Another option exists for case sensitivity.
    - The higher the score, the more likely a problem is to be the root cause.
    - The word score is the sum of the score. For example, if 2 words in the summary are found, and one word has a value of 100, and the other has a value of 10, the total word score is 110.
  - `SeverityEnabled`: The problem severity is accounted for. By default, the score is the severity multiplied by 10.
  - `causeScoreEnabled`: If the field `CauseWeight` is present in the details section of an alert then the `causeScore` is added to the total score in `CauseWeight`. If this field is not present in the details section, there is no effect. This field cannot be changed.
  - `itnmproccessing`: If this option is turned on and ITMN marked an alert as the root cause(`NmosCauseType=1`), then `itnmcauseweight` is added to the score.
  - `firstBoost`: If `firstBoost` is set to true, the amount that is specified in the `firstBoostWeight` is added to the alert that has the lowest `firstoccurrence` time.

The techniques work together to determine the root cause. One technique alone does not work in an environment as an alert might, or might not, have an associated topology.

Prerequisites

For topology and natural language probable cause, the alert data must have topological data and must also be topologically co-related. For more information, see Topological grouping.



Viewing rankings

Probable cause rankings from 1 (highest) to 3 (lowest) in order of probability can be viewed in the Incident overview UI.

Figure. Probable cause Incidents Overview

They also display (showing rankings greater than 3) in the Alerts tab of the Incidents viewer.

Probable cause Alerts tab

Rankings can also appear in ChatOps notifications. (For more information, see Probable cause in ChatOps.)

Language support

For information about supported languages for this algorithm, see Language support.

Related topic

- Configuring probable cause
- Probable cause customization APIs

About similar tickets

This AI algorithm discovers details about similar tickets that occurred in the past and are impacting the current application.

Important: Starting with IBM Cloud Pak® for AIOps version 4.1.0, similar incidents, such as from a ServiceNow integration, are called similar tickets.

When an incident occurs, it can be helpful to review details for similar tickets from the past to help determine a resolution. Similar tickets is an unsupervised learning algorithm that aggregates information from past similar tickets. It can also extract the steps used to fix previous tickets, if

documented.

Training this AI algorithm will help you discover historical tickets to aid in the remediation of current problems. To train this algorithm, you must complete some initial setup tasks, as described in Setting up training for similar tickets.

Site reliability engineers (SREs) and other users responsible for application and service availability are able to access tickets in their ChatOps interface and within each ticket view historical similar tickets, as described in Managing incidents.

Prerequisites

The Similar tickets algorithm requires ticket data from ServiceNow. Before attempting to set up training for this algorithm, ensure that you have created a functioning data integration to ServiceNow. For more information, see Creating a ServiceNow integration.

After training is complete, enable the similar ticket policy in the **Policies** page. For more information, see Setting up training for similar tickets.

Language support

For information about supported languages for this algorithm, see Language support.

Language support

The AI algorithms in the AI Model Management are able to analyze and train on a limited set of non-English language data. In an operations environment, languages often occur in combination. For example, English and Spanish, or English and German. Analysis and training on the following non-English languages data are supported: German, and Spanish.

The use of mixing languages in a feed of records is supported. However, mixing languages in an individual record is not supported. For example, a feed of support tickets can contain a mixture of English and Spanish tickets, but a mixture of languages in a single support ticket is not supported.

If data in an unsupported language is detected during pre-training of any of the algorithms, **Summary** *Step 1 - Precheck data* will contain the warning message **Data needs improvement**.

Click **View recommendations** and, if unsupported langage is a problem, the following instructions appear :

```
We have detected that a portion of this data is in an unsupported language and could impact the quality of this model.

We recommend that you remove any data containing unsupported languages. Then, run training again.
```

Supported language combinations

The following table lists supported language combinations for each of the AI algorithms.

Table. Supported language combinations

Algorithm	Data used	Supported language combinations	Not supported
Alert Grouping	Events	Not language sensitive	N/A
Change risk	Tickets	English and Spanish, English and German, English and Spanish and German	N/A
Log anomaly detection (deprecated)	Logs	English and Spanish, English and German, English and French, English and Italian, English and Korean	N/A
Log anomaly detection - golden signals	Logs	English only	N/A
Metric anomaly detection	Metrics	Not language sensitive	N/A
Probable cause	Events	English only	If event data in Spanish or German is processed by this algorithm, the ranking of probable cause in an incident might be unreliable or missing.
Similar tickets	Tickets	English and Spanish, English and German, English and Spanish and German, English and French, English and Italian, English and Japanese	N/A

Preparing AI algorithms

Use this information for how to prepare AI algorithms. Some algorithms require setting up training, training, and deploying, such as trainable AI algorithms. Others simply need to be enabled, and others still are enabled by default.

For more information about preparing AI algorithms, see the following topics:

- About algorithm types
- About pre-trained AI algorithms
- Setting up training for trainable AI algorithms

About algorithm types

The AI algorithms can be categorized into two types: ones that analyze your data in real time, and ones that must first be trained to generate an AI model.

The following are the two types of AI algorithms:

- Trainable AI algorithms
- Pre-trained AI algorithms

Trainable AI algorithms

These algorithms require user interaction as they must first be trained to generate an AI model. Models are well-defined computations that are formed as a result of an algorithm that takes some value, or set of values, as input and produces some value, or set of values as output. When deployed, it is your model that acts on the data and derives insights.

You must first set up training for these AI algorithms, and then train that algorithm to generate a model. The following table lists the trainable AI algorithms in alphabetical order, along with a link to the relevant training setup task.

Algorithm	Action
Change risk	Set up training
Metric anomaly detection	Set up training
Natural language log anomaly detection	Set up training
Similar tickets	Set up training
Temporal grouping	Set up training

Pre-trained AI algorithms

These algorithms analyze your data in real time and derive insights without the need to generate a model.

You do not need to set up training for these AI algorithms. You can enable them. In some cases, these algorithms are automatically enabled for you. The following table lists the online algorithms in alphabetical order, along with their default state, and whether you can take action on them to change that state.

Algorithm	Default state	Action
Probable cause	Enabled	None
Scope-based grouping	Enabled	None
Statistical baseline log anomaly detection	Enabled	Disable or Enable
Topological grouping	Enabled	None

About pre-trained AI algorithms

These algorithms don't require models to derive insights. They are enabled by default. You do not need to set up training for these AI algorithms; they are automatically enabled for you, except for the statistical baseline log anomaly detection algorithm, which is enabled by default, but can be disabled.

Click here for more information about the pre-trained AI algorithms:

- About probable cause

- About scope-based grouping
- About statistical baseline log anomaly detection
- About topological grouping

About probable cause

The probable cause AI algorithm is enabled by default and cannot be disabled. To indicate this, the word **Enabled** appears in grayed out text at the bottom of the "Probable cause" tile in the AI Model Management.

For more information on the probable cause AI algorithm, see About probable cause ranking.

About scope-based grouping

The scope-based grouping algorithm is enabled by default and cannot be disabled. To indicate this, the word **Enabled** appears in grayed out text at the bottom of each of the event grouping tiles in the AI Model Management.

For more information on the event grouping AI algorithms, see About scope-based grouping.

About statistical baseline log anomaly detection

Leave this AI algorithm turned on to see details about statistical baseline anomalies in your ChatOps feed and in your Alert Viewer.

Statistical baseline log anomaly detection is an unsupervised learning algorithm that automatically detects unusual patterns in logs and notifies you when they occur. Data that is used for analysis is updated every 30 minutes so this algorithm provides value quickly. This algorithm supplements the natural language log anomaly detection algorithm by reporting extra log anomalies to your ChatOps interface and to the Alert Viewer.

By default, this algorithm is turned on and it is recommended that you leave it turned on. If you turn it off, you won't see details about statistical baseline anomalies in either your ChatOps feed or in your Alert Viewer.

Note: If both statistical baseline and natural language log anomaly detection algorithms are active, then any log anomalies discovered by both will be reconciled, so that only one alert is generated.

About topological grouping

The topological grouping AI algorithm is enabled by default and cannot be disabled. To indicate this, the word **Enabled** appears in grayed out text at the bottom of each of the event grouping tiles in the AI Model Management.

For more information on the event grouping AI algorithms, see About topological grouping.

Setting up training for trainable AI algorithms

AI algorithms analyze different kinds of data and produce AI models, which automate research, reducing the need for manual work in solving problems. IBM Cloud Pak® for AIOps training generates models for a number of different AI algorithms. You can train the models for each of these AI algorithms independently of each other.

For more information about setting up training for trainable AI algorithms, see the following topics:

- Setting up training for alert seasonality detection
- Setting up training for change risk
- Setting up training for log anomaly detection - golden signals
- Setting up training for natural language log anomaly detection
- Setting up training for metric anomaly detection
- Setting up training for similar tickets
- Setting up training for temporal grouping

Setting up training for alert seasonality detection

Set up alert seasonality detection to train policies. Then, choose how to deploy the policies.

For more information about alert seasonality, see Alert seasonality detection algorithm.

Before you begin

To train a definition for alert seasonality detection, you need event data. By default, this AI algorithm can load up to 90 days of historical event data. A set of data creates a set of policies. For more information, see Prerequisites.

This AI algorithm can start to discover seasonal trends after a pattern is learned, which is typically ranging between days or months. For example, if an alert instance occurs on each weekday at two PM, the seasonality algorithm will detect a daily seasonal pattern after one week. However, if this only occurs on Tuesdays at a given time, then it will take multiple weeks to detect this pattern in the alert data.

About this task

There are multiple parts to this task:

- Starting the training setup
- Scheduling the training
- Select data
- Deciding how to deploy the training
- Running the training again
- What to do next

Starting the training setup

Go to the AI Model Management and complete some setup tasks.

1. In the Cloud Pak for AIOps home page, click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **AI model management** to open the AI Model Management.
3. In the **Training** tab, click **Set up training** within the **Alert seasonality detection** tile under the Trainable AI algorithms section.

Scheduling the training

Decide whether to run the training set up on demand or to schedule it to run on an ongoing basis.

Note: When you schedule each of the trainable AI algorithms, it is strongly recommended to schedule training on quieter periods of the day, and to stagger them out. For example, schedule training runs at least one hour apart from each other. This helps to spread the analytical processing load out.

1. Proceed as follows:
   - To run the training set up on demand, ensure that **Schedule to run** is set to **Off**, and go to step 3.
   - To run the training set up on a schedule, set **Schedule to run** to **Yes**, and go to the next step.
2. Schedule the run. Click this option to specify a schedule. You can specify a start date with an optional end date, a frequency, and a time based on Coordinated Universal Time (UTC).
3. Click **Next** to move to the next panel.

Select data

Select a date range (either Preset or Custom) for the event data that will be included in the AI training. Including additional data typically improves the effectiveness of the AI models and policies that are generated by the training.

Deciding how to deploy the training

The option to review training results before deployment is disabled for this algorithm. However, you can choose when to deploy the policies that are generated by training the algorithm.

- To review and manually deploy the model, set **Deployment type** to **Manual**.
- To automatically deploy the model, set **Deployment type** to **On completion**.

Click **Done** to save the training setup for the algorithm.

Running the training again

- If you run the training again with the same data, expect to receive the same policies.
- If you run the training again with different data, you might receive new policies.

What to do next

Now that the training setup is complete, you can train the algorithm. For more details, see Launching the training.

Setting up training for change risk

Set up training for this AI algorithm to determine how likely it is that a proposed change would cause a problem.

About this task

Hundreds of changes can affect an application during its lifecycle. Change risk is an unsupervised learning algorithm that correlates historical change data with historical incident data and determines how likely it is that a specific code change would cause a problem. Using the assessment score provided, you can determine how safe it is to proceed with the change. Training this AI algorithm helps you ensure that risky changes for an application are assessed before deployment.

Training setup of the algorithm is done by completing some setup tasks. When the training setup is complete, you need to go to a different part of the AI Model Management to train the model.

Before you begin

To train this algorithm, you need change request and incident ticket data from ServiceNow. If you enable the collection of historical data when you connect to ServiceNow, then data for the selected timeframe is available to train on.

To provide the best data for change risk, you need a mix of successful and failed change tickets. Around 10,000 change tickets, with a minimum 2% failure rate, is ideal. However, models can also be created with much less.

Closed change ticket count requirements

For a closed change ticket count less or equal to 150, you need at least three problematic tickets. For a closed change ticket count greater than 150, you need at least 2% of change tickets to be problematic. A *problematic change ticket* is defined as a change ticket that can "either be associated with incident tickets or have an 'unsuccessful' value set in the change ticket close code field".

Failure rate

If you provide data with a change ticket failure rate of less than 2%, the training fails with a **Needs improvement** data quality error. For more information, see Data quality messages.

To check whether you meet these requirements, review your ServiceNow integration. For more information, see Creating a ServiceNow integration.

To resolve the issue, you can optionally configure the failure percentage. Edit the deployment yaml of the ai-platform server and reduce the value for the failure percentage to do so. The following example shows the failure percentage set to 1.9.

```
oc set env deploy/aimanager-aio-ai-platform-api-server MIN_LABEL_PERCENT="1.9"
```

Where **`MIN_LABEL_PERCENT`** is the failure percentage.

Note Model quality deteriorates with a MIN_LABEL_PERCENT less than 2.0

Running the task

There are multiple parts to this task:

- Starting the training setup
- Checking data integrations
- Deciding how to run the training
- Deciding how to deploy the training
- What to do next

Starting the training setup

Go to the AI Model Management and complete some setup tasks.

1. In the Cloud Pak for AIOps home page, click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **AI model management** to open the AI Model Management.
3. Under the Training tab, in the Trainable AI algorithms section, click the **Change risk** tile.

Note: If you want to edit configurations for algorithms after the first time set-up, you can simply click the algorithm tile.

Checking data integrations

Review the information on the page. It explains what this AI algorithm is, how it helps in your production environment, and provides a list of integrations that are needed to generate a model.

1. On the Integrations, check that at least one integration is listed.

   Note: If no integrations are listed, or you expected to see more integrations, click **Go to Integrations** to modify your integrations. For more details, see Creating a ServiceNow integration.

2. Click **Next** to move to the next section.

Deciding how to run the training

Decide whether to run the training setup on demand or to schedule it to run on an ongoing basis.

1. Proceed as follows:
   - To run the training setup on demand, ensure that **Schedule to run** is set to **Off**, and go to step 3.
   - To run the training setup on a schedule, set **Schedule to run** to **Yes**, and go to the next step.
2. Schedule the run. Click this option to specify a schedule. You can specify a start date with an optional end date, a frequency, and a time based on Coordinated Universal Time (UTC).
3. Click **Next** to move to the next section.

Deciding how to deploy the training

Decide whether to review the results of training before deploying the model, or to have the system automatically deploy the model.

1. Proceed as follows:
   - To review the results of training before deploying the model, ensure that **Deployment type** is set to **Review first**.
   - For the system to automatically deploy the model, set **Deployment type** to **On completion**.
2. Click **Save** to save the training setup for the algorithm.

What to do next

Now that the training setup is complete, you can train the algorithm. For more details, see Launching the training.

Enabling full data profiling report in Change Risk

Note: To enable this feature, a user must have administrator privilege.

The following procedure generates a JSON data profiling report. This JSON report provides information about word count and parts of speech in the tickets that are used for training, which can be helpful in understanding model behavior.

1. Obtain the change-risk algorithm of the corresponding namespace as a yaml file.

   ```
   oc -n get algorithm change-risk -o yaml >temp.yaml; cp temp.yaml backup.yaml
   ```

2. Use a text editor to extract the value of the **manifestBase64** field from **temp.yaml**, then use **base64** to decode it.

   ```
   echo <value of manifestBase64> | base64 -d > manifest.tmp
   ```

3. Edit **manifest.tmp** to add **GENERATE_FULL_PROFILING_REPORT** to the environment. Set it to **True**.

   ```
   env:
     - name: GENERATE_FULL_PROFILING_REPORT
       value: "True"
   ```

4. Encode the updated file. Update the value of **manifestBase64** in **temp.yaml** with this result.

   ```
   cat manifest.tmp | base64
   ```

5. Apply the modified **temp.yaml** on the cluster.

   ```
   oc apply -f temp.yaml
   ```

6. When enabled, the full data profiling report will be generated from the next run of the change-risk training.

Accessing full data profiling report

The report of the corresponding training is stored in Elasticsearch under the index name **change-risk-data-profiling-<Version-Number>** Access the *version-number* from the AI model management tool when you run training.

Example: if Version number is **v1** then the report is in **change-risk-data-profiling-v1**

Select the instructions for your deployment architecture.

Deployments on Red Hat® OpenShift® Container Platform:

To access Elasticsearch, obtain the Elasticsearch username and password from the Elasticsearch secret, and encode it in the request.

```
curl -k --location --request GET 'https://iaf-system-elasticsearch-es-<NAMESPACE>.apps.
<CLUSTER_NAME>.mysite.ibm.com/change-risk-data-profiling-v1/_search?pretty' \
--header 'Authorization: Basic <AUTH>
```

– where AUTH is base64 encoded value of username:password.

Deployments on Linux

Run the following command:

```
export ELASTIC_SET="$(oc get statefulset -l app.kubernetes.io/managed-by=ibm-elasticsearch -o
jsonpath='{.items[0].metadata.name}')"
oc exec "statefulset/${ELASTIC_SET}" -- curl -XGET -k --fail "http://127.0.0.1:19200/change-risk-data-
profiling-v1/_search?pretty"
```

Training a Change Risk model

Note: Make sure ServiceNow Integration is first set to *Historical* mode.

1. Go to IBM Cloud Pak for AIOps console.
2. Click **AI Model Management**.
3. Find the Change risk algorithm under the *Training* tab.
4. Click **Set up training**.
5. Verify your ServiceNow integration is listed.

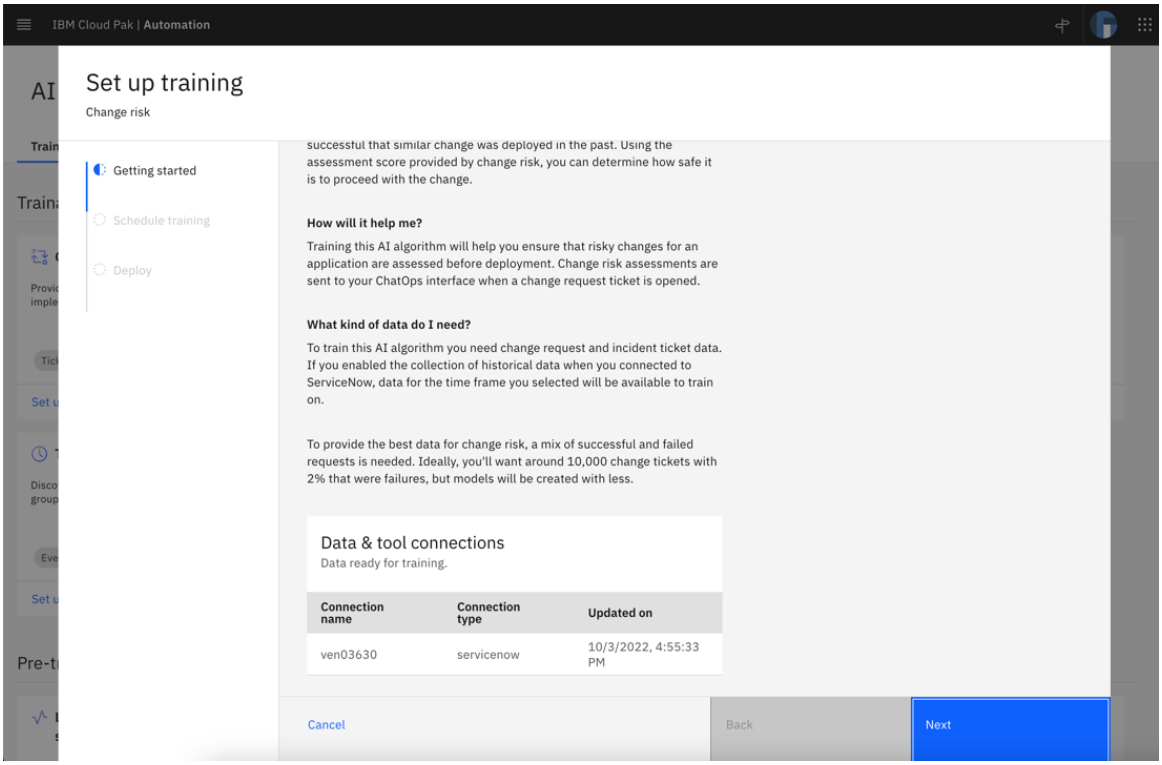


Figure. Set up training page

6. Click **Next** for **Schedule training**. No need to schedule the training. It starts training in a few moments.
7. Click **Next** for **Deploy**. Set to deploy model *On completion*.
8. Click **Done**.
9. View details on the Change risk algorithm.

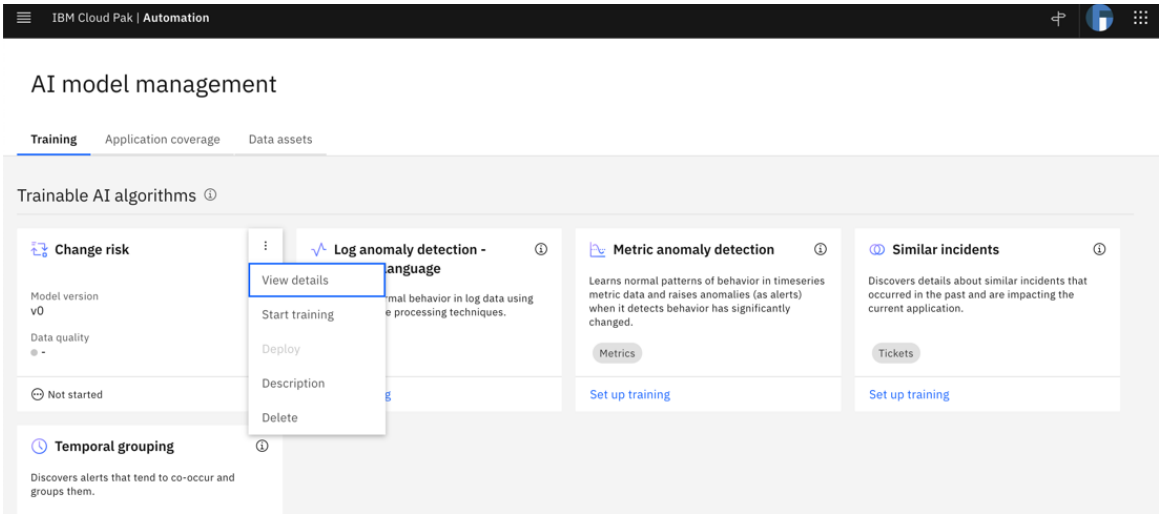

Figure. View details menu option

10. Click **Start training**. IBM Cloud Pak® for AIOps will first check data quality before training.

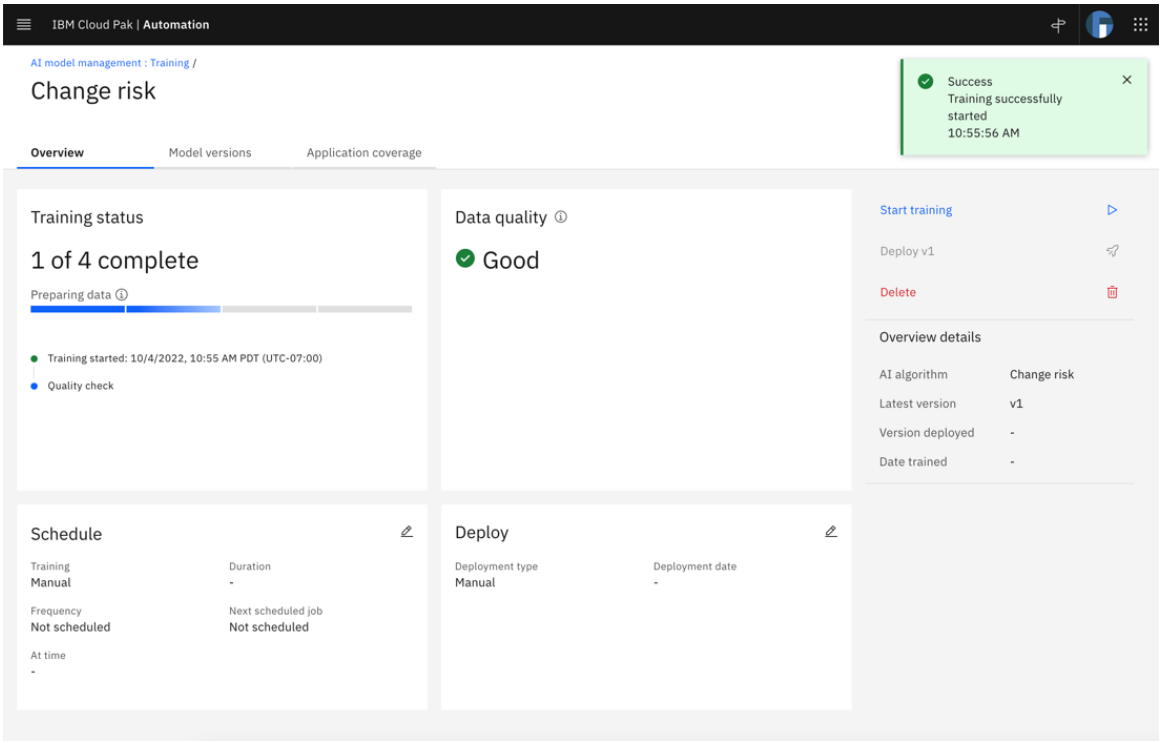

Figure. Data quality check

11. Deploy model to enable change risk assessment functionality. Remember to change ServiceNow Integration to Live data mode

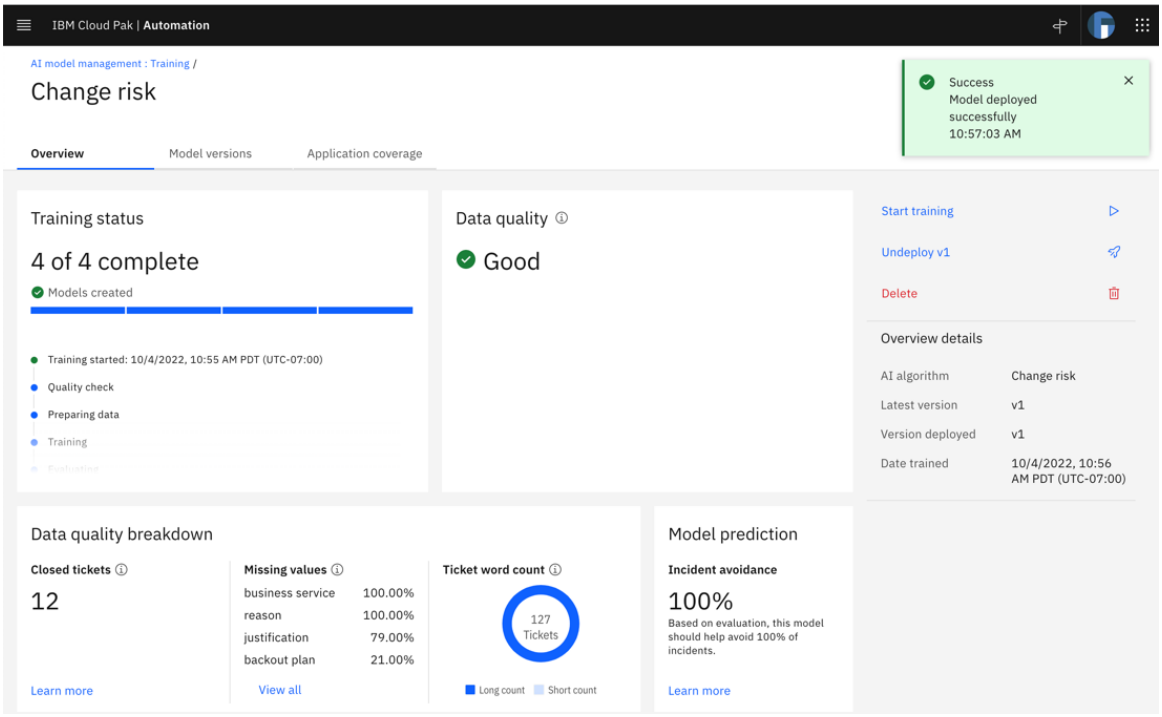

Figure. Model deployed successfully

Configuring change risk

The more data that you provide, the better the quality of your change risk analysis. At a minimum, your AI modeling requires about 2 percent of change tickets to be problematic. If you train with 20,000–50,000 tickets with a 2–5 percent failure rate, you would yield more robust results. Training does not start automatically when you reach that threshold. If you selected *Live data for initial AI training* in your ServiceNow integration, you would need to manually disable the integration when you reach the minimum threshold of the training model.

The following change ticket fields are used for training. To help produce a good model, provide various values for these change ticket fields:

- *sys_domain*
- *business_service*
- *type*
- *short_description*
- *impact*
- *reason*
- *justification*
- *description*
- *backout_plan*

For more information about training change risk AI models, see Configuring change risk.

Change risk assessment

If all of these steps are complete, when someone opens a change request ticket, a *Change risk assessment* appears in your proactive ChatOps channel. (For more information about channels, see ChatOps insight management). Depending on the risk level, you might also receive a second notification: *Most relevant change requests*.

The *Change risk assessment* includes the ticket number and a link to the change request ticket in ServiceNow and message links to the approver and creator of the ticket.

Confidence percentage

Change risk is scored on a 0–100 percent scale. The higher the percentage, the higher the confidence in the prediction. The amount of information that is provided depends on the severity of the risk.

Most relevant change requests

If the outcome is deemed as high risk change, IBM Cloud Pak® for AIOps provides links to historical relevant problematic tickets. You can view these tickets, with their accompanying explanations, to gain a better understanding as to why the perceived risk is high.

Three types of relevant change tickets can be generated. Each can be identified by a particular term:

1. *successfully completed* – provides details of successfully completed change and incident that is caused by that change. Includes timeline and closing remarks.
2. *closed as being unsuccessful* – occurs when the ticket was not resolved and includes closing remarks, which can indicate that further investigation was undertaken. Also, gives information why this ticket was deemed relevant to new change request.
3. *closed as being successful but change mentioned in incident(s)* – provides details of successfully completed change that was later mentioned in one or more incident tickets.

Setting up training for log anomaly detection - golden signals

Log anomaly detection - golden signals uses the Metric anomaly detection pipeline for log data sets. It takes in raw logs and converts the textual information to log patterns with variables (both known and unknown) and static content.

The patterns are also referred to as templates. Log data after templatization is filtered, based on golden signals, and converted to metric data.

Prerequisites

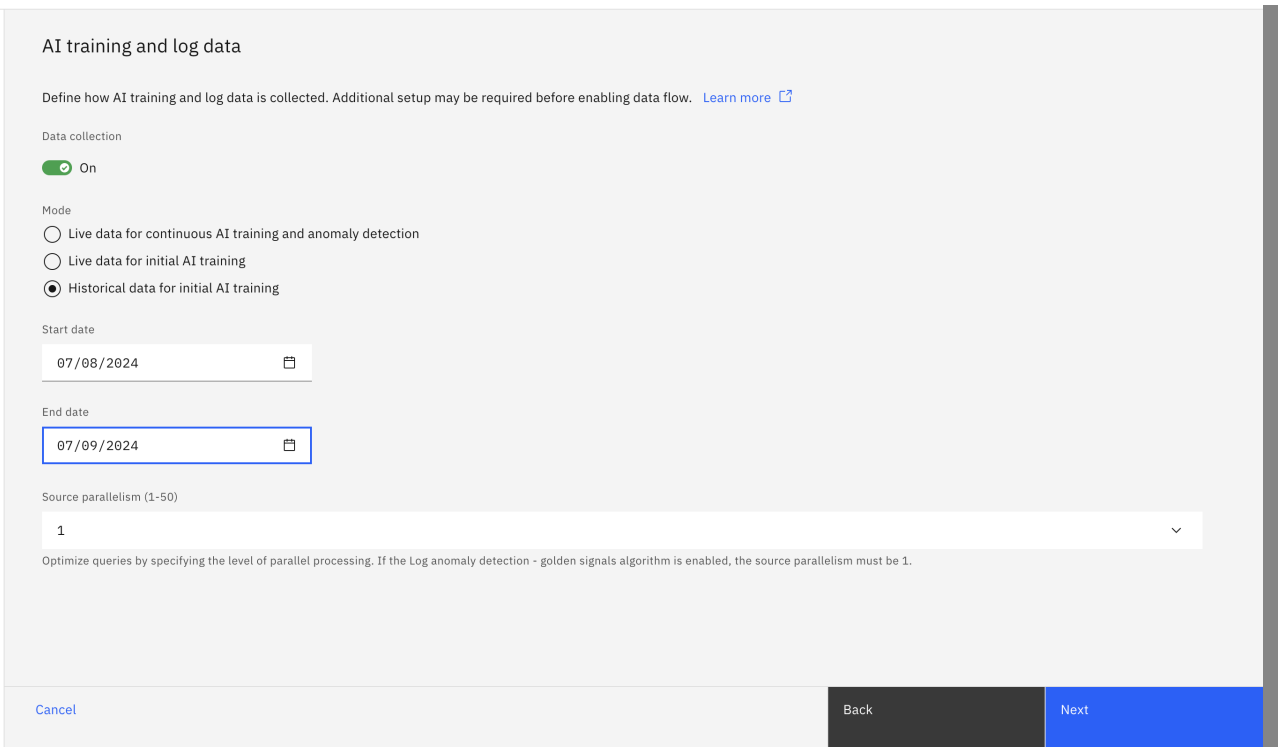
Take the following actions.

1. To set up training for this algorithm, you need log data that shows normal operational behavior. If your logs include anomalous situations, such as a critical incident or a technical glitch, filter out this anomalous data before you train the algorithm.
2. In the Cloud Pak for AIOps home page, click the navigation icon (four horizontal bars) to go to the main navigation menu.
3. In the main navigation menu, click **Operate** > **AI Model Management** to open the AI Model Management.
4. Disable the **Log anomaly detection - natural language** and **Log anomaly detection - statistical baseline** algorithms.
5. Create a training definition for *Metric anomaly detection* with a training schedule.

Starting the training setup

1. Within the **Log anomaly detection - golden signals** tile, click **Set up training**.

   Note: If this AI algorithm is already set up for training, **Set up training** is not available. For more information about changing the algorithm training setup, see Editing the training setup for an algorithm.



2. Click **Next** to open the **Getting started** panel. The panel explains this AI algorithm and how it helps in your production environment. The panel also provides a list of integrations that are available to generate a model. At least one integration must exist in this list for the model to collect data and start training.
3. If no integrations are listed or if you expected to see more integrations, click **Integrations** to modify your integrations.
4. Add at least one integration by using the Integrations area of IBM Cloud Pak for AIOps. Alerts are generated after the following conditions are true:

   - At least 100,000 log messages are processed for template quality.
   - The logs span at least 3.5 days, and metric anomaly detection training is run on that data.

   On the Integrations, check that at least one integration is listed.

   Note: If no integrations are listed, or you expected to see more integrations, click **Go to Integrations** to modify your integrations.

   Note: Make sure that all the log data integrations that are created in the **Integrations** section are in **Live data for initial training** or **Historical data for initial AI training** mode. If you choose **Historical data for initial AI training**, the source parallelism must be set to `1`. You can set up log data integration before or after you enable log anomaly golden signals.

5. Click **Next**.
6. In the **Training setup** panel, click **Done**. The training begins.

What happens next

Now the training setup is complete.

The template training continuously runs in the background and in parallel data is sent to Metric anomaly detection.

If you chose the *Historical data for initial AI training* mode, and the integration status displays as *Done*, edit your integration and select *Live data for initial AI training* mode for continuous AI training and anomaly detection.

Upon receiving sufficient data, Metric anomaly detection trains models and generates alerts if any anomalous logs are detected.

Disabling the training

You can turn off the algorithm by toggling the switch to **Disabled** in the *Log anomaly detection - golden signals* tile in the AI model management UI.

To restart, toggle the switch to **Enabled**.

The training pipeline sets `la_golden_signals_enabled_flag` to `True` in **Elasticsearch**. **Flink jobs** is now enabled to start with log anomaly golden signal components.

To initiate the change, the training pipeline restarts all the **Flink jobs**.

Setting up training for log anomaly detection - natural language

Set up training for this AI algorithm to detect unusual patterns in your logs and notify you by generating an alert when they occur.

About this task

For more information on the how the different types of log anomaly detection work, see About log anomaly detection algorithms.

To set up training for this algorithm, you need log data that shows normal operational behavior. If your logs include anomalous situations, such as a critical incident, technical glitch, or some other change that deviates from the norm, you can filter that data out before training the algorithm.

Training setup of the algorithm is done by completing some setup tasks. When the training setup is complete, you need to go to a different part of the AI Model Management to train the model.

Note If both natural language and statistical baseline log anomaly detection algorithms are active, then any log anomalies that are discovered by both will be reconciled, so that only one alert is generated.

Before you begin

When providing log data, select a date range that includes at least 10,000 lines of messages for each resource that you want insights from. An ideal amount would be around 100,000 lines. When selecting longer date ranges, consider that it might take more time to process the data and might have system impacts.

To check that you have met these requirements, review the prerequisites for this AI algorithm. For more details, see the rows that are associated with Log anomaly detection in the prerequisites table on this page: Prerequisites.

In addition, you must perform the following tasks:

- Configure resources such as CPU and memory to ensure good training performance. For more details, see Configuring resources for log anomaly detection

Running the task

There are multiple parts to this task:

- Starting the training setup
- Checking data integrations
- Specifying which data to train on
- Excluding irregular data
- Deciding how to run the training
- Deciding how to deploy the training
- What to do next
- Viewing the running jobs

Starting the training setup

Go to the AI Model Management and complete some setup tasks.

1. In the Cloud Pak for AIOps home page, click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **AI model management** to open the AI Model Management.
3. In the AI algorithms tab, click **Set up Training** within the **Log anomaly detection - natural language** tile.

Note: If this AI algorithm has already been set up for training, then the word Set up appears in grayed out text at the bottom of the tile. In this case, you can edit the algorithm training setup, as described in Editing the training setup for an algorithm.

Checking data integrations

Review the information on this page. It explains what this AI algorithm is, how it helps in your production environment, and provides a list of integrations that are needed to generate a model.

1. On the Integrations, check that at least one integration is listed.

   Note: If no integrations are listed, or you expected to see more integrations, click **Go to Integrations** to modify your integrations. For more details, see this page: Prerequisites.

2. Click **Next** to move to the next panel.

Specifying which data to train on

Review and modify your data integrations, if necessary.

1. Review the Data assets table.

   This table lists the data integrations from the **Getting started** panel, and provides the following information for each data integration:

   - How is the data being collected? Options are Live or Historical.
   - Is the data flow on?

   To make any changes, click **Go to Integrations** to modify your integrations. For more details, see this page: Prerequisites.

   Optionally remove a data integration by clicking the checkbox to the left of the data integration name, and clicking the Delete icon that appears.

2. Specify a date range to train on. Select **Preset** for a preset option or **Custom** for a range of dates.

Tip If you are planning to schedule the execution of the training for this algorithm then you must select one of the preset options that retrieves a fixed window of data relative to the current time.

- **Preset**: Click this option and select one of the following time ranges. Note that 14 days of log data is the maximum amount that is supported with the default values.
    - Past day
    - Past 3 days
    - Past 7 days
    - Past 10 days
    - Past 14 days

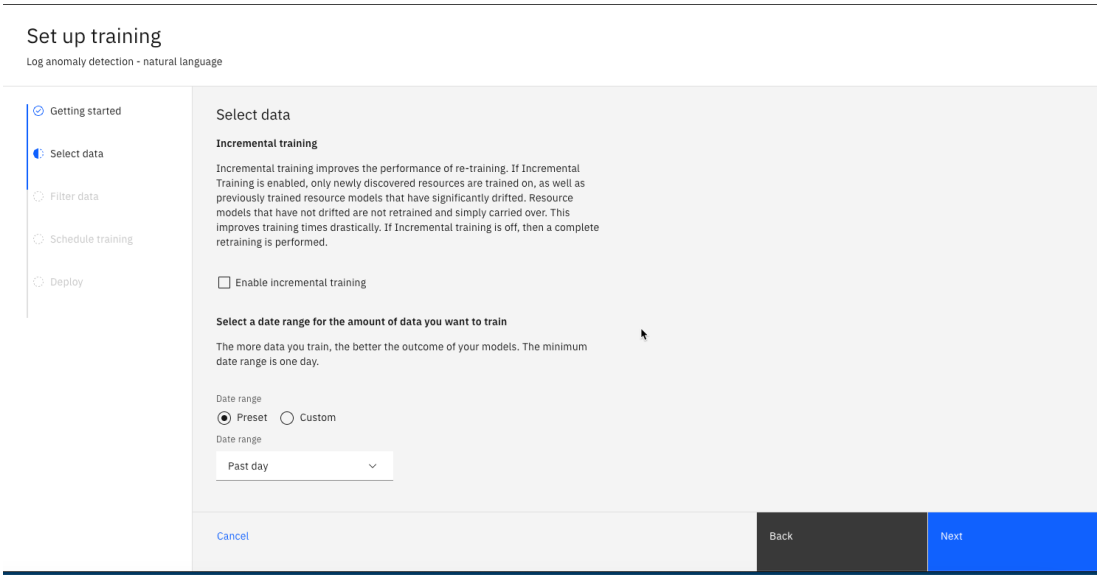


Figure. Schedule training

- **Custom**: This is an easy and quick option to use if you are not concerned with training models on data from a very specific window of time. Click this option and specify a fixed date range.

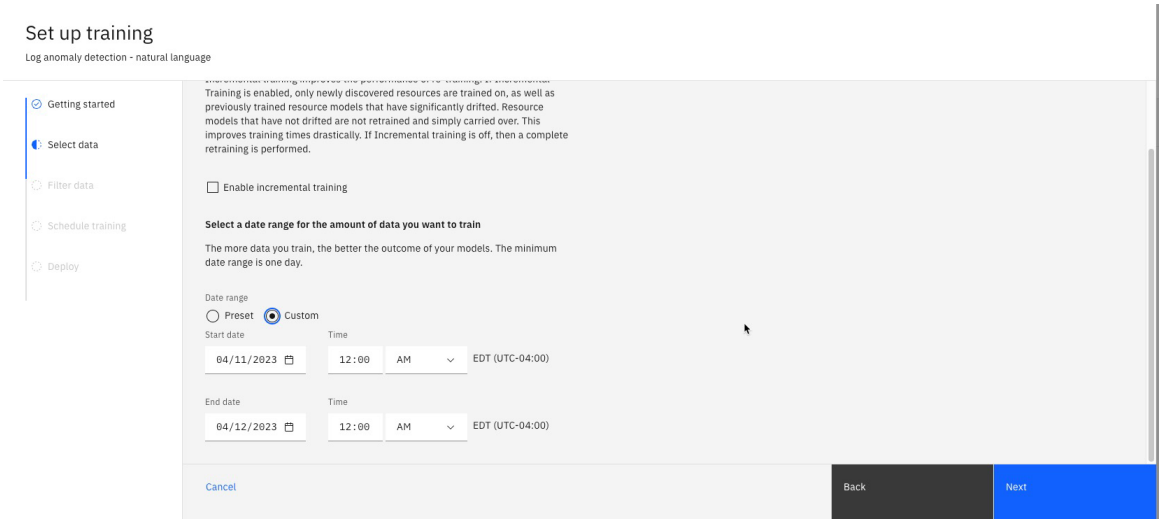

Figure. Custom

Note When you set custom dates and times, you must be aware of the following:

- You have the option to specify start and end times in local time or UTC. By default, the time is in local time.
- Ingested log data is stored in Elasticsearch in UTC.
- To ensure that you select the correct data intervals, specify both the start and end times in this panel in UTC.

For example, if you select November 15 12:00 AM through December 15 11:59 PM UTC time, the training window includes data from the start day of November 15 through to the end of the day on December 15. If you instead select December 15 12:00 AM, then the training window includes data from November 15 through December 14 11:59 PM.

- If you choose to use local time, you need to adjust the start and end date and time to match the period for which log data is available in ES.

3. Click **Next** to move to the next panel.

Filter data

Filter data from the training. This includes data associated with event storms, maintenance windows, major events, and other unusual outages. This will enable the Log anomaly detection algorithm to baseline normal behavior and record expected log messages.

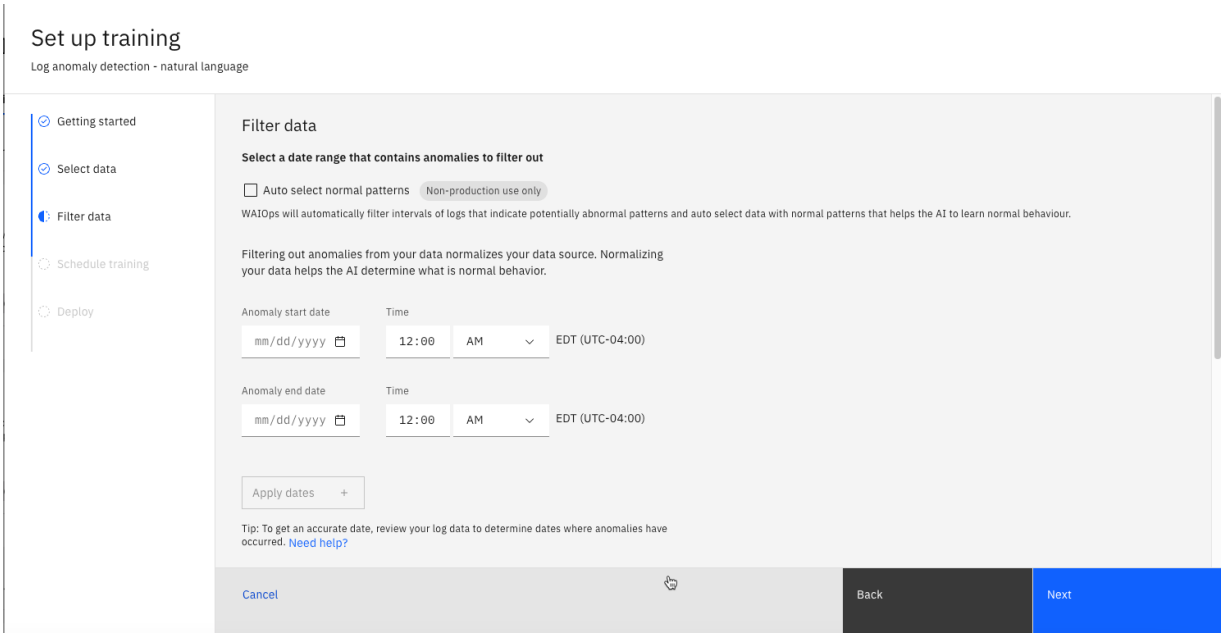

Figure. Log anomaly

1. (Optional) Select date range of irregular data to filter out. Then click **Apply dates**. Your selection appears in the **Applied dates** table below.

   Tip Go to your data source to view your log data. This will help you determine when there were incidences of irregular data.

   Note When you set custom dates and times, you must be aware of the following:

   - You have the option to specify start and end times in local time or UTC. By default, the time is in local time.
   - Ingested log data is stored in Elasticsearch in UTC.
   - To ensure that you select the correct data intervals, specify both the start and end times in this panel in UTC.

     For example, if you select November 15 12:00 AM through December 15 11:59 PM UTC time, the training window includes data from the start day of November 15 through to the end of the day on December 15. If you instead select December 15 12:00 AM, then the training window includes data from November 15 through December 14 11:59 PM.
   - If you choose to use local time, you need to adjust the start and end date and time to match the period for which log data is available in ES.

2. (Optional) Repeat step 1 for each date range of irregular data you want to apply.

   The data set is listed in the **Data sets** table at the bottom of the screen.

3. Click **Next** to move to the next panel.

Schedule the training

Decide whether to run the training setup on demand or to schedule it to run on an ongoing basis.

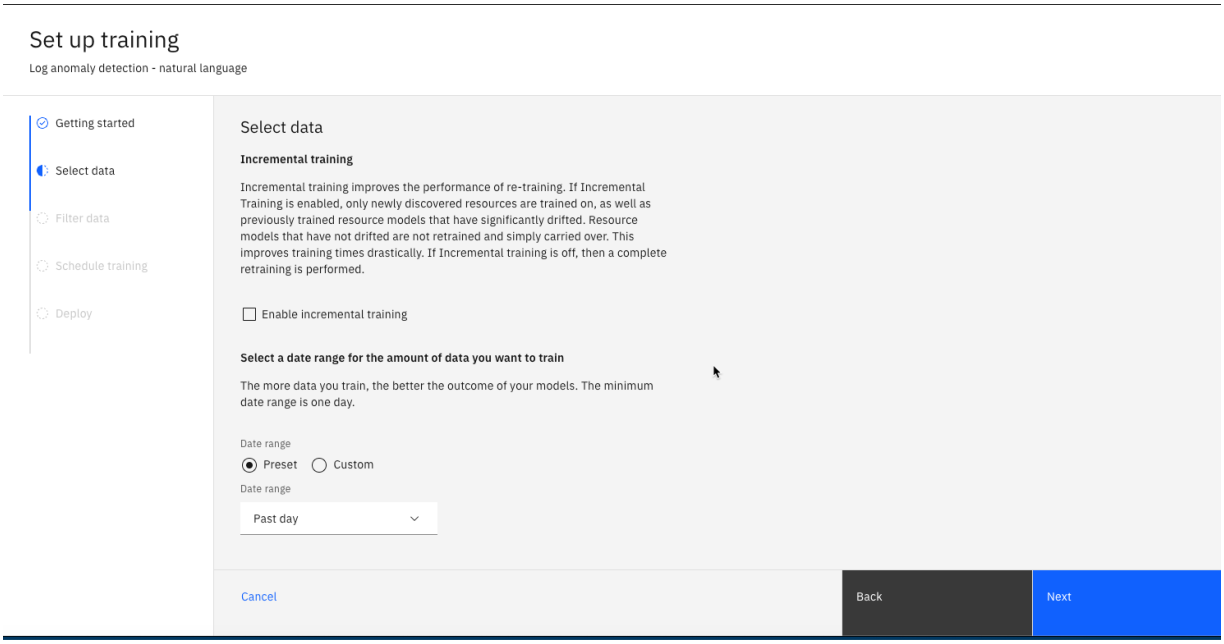

Figure. Schedule training

1. Proceed as follows:
   - To run the training setup on demand, ensure that **Schedule to run** is set to **Off**, and go to step 3.
   - To run the training setup on a schedule, set **Schedule to run** to **Yes**, and go to the next step.
2. Schedule the run. Click this option to specify a schedule. You can specify a start date with an optional end date, a frequency, and a time based on Coordinated Universal Time (UTC).

   Note:

   - 'Start' is when you want the scheduler to begin launching the training run. You can select 'now' for the scheduler to immediately start running, or you can specify a custom time by using the 'on date' option.
   - 'End' lets you specify how long you want the scheduler to manage the training runs. By selecting 'Never', the scheduler will keep running trainings (on the defined frequency) forever. You can also specify a custom end date by selecting 'on date'.
   - 'Frequency' lets you select how often they want the model to be retrained. The possible options are daily, weekly, bi-weekly, or monthly.
3. Click **Next** to move to the next panel.

Deciding how to deploy the training

Decide whether to review the results of training before deploying the model, or to have the system automatically deploy the model.

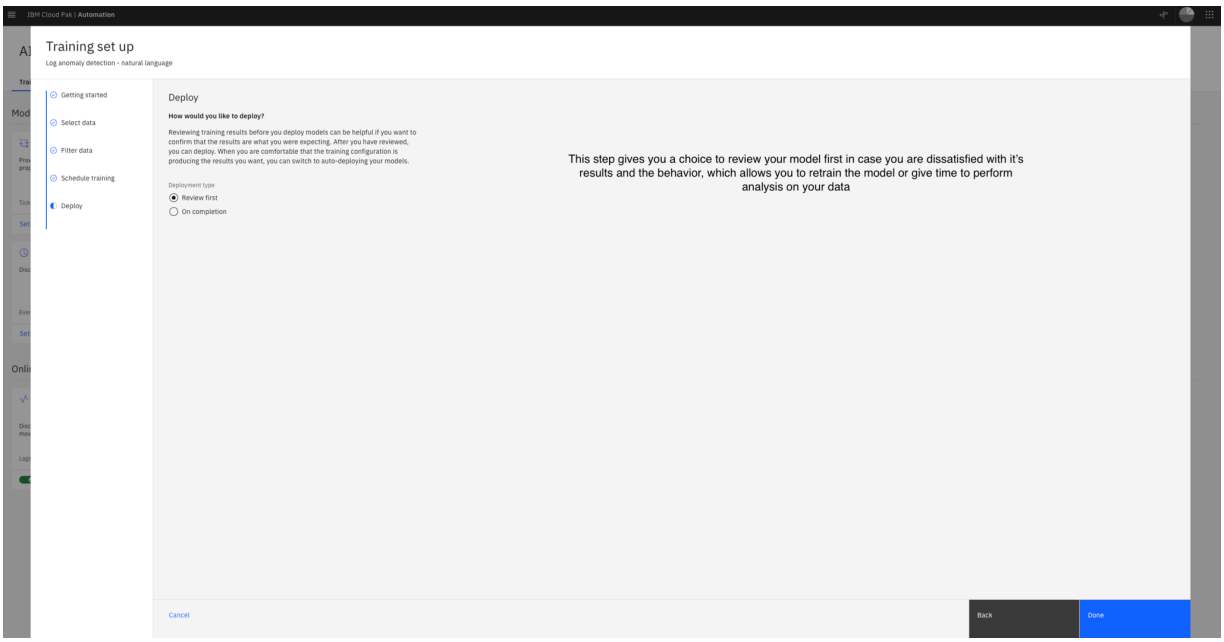

Figure. Deploy training

1. Proceed as follows:
    - To review the results of training before deploying the model, ensure that **Deployment type** is set to **Review first**.
    - To have the system automatically deploy the model, set **Deployment type** to **On completion**.
2. Click **Done** to save the training setup for the algorithm.

Viewing the running jobs

1. From the main navigation of the console, click **AI model management**.
2. Click on the tile of the AI algorithm you want to view.
3. From the **Summary** tab, click **Start training** to begin training your AI algorithm. While the training runs, the jobs and their statuses are displayed in the **Activity** section.

What to do next

Now that the training setup is complete, you can train the algorithm. For more details, see Launching the training.

Setting up training for metric anomaly detection

Set up training for this AI algorithm to detect anomalous behaviour in your metrics and notify you by generating an alert when they occur.

For more information on the metric anomaly detection AI algorithm, see About metric anomaly detection.

About this task

There are multiple parts to this task:

- Starting the training setup
- Getting started
- Deciding how to run the training
- Deciding how to deploy the training
- What to do next

Starting the training setup

Go to the AI Model Management and complete some setup tasks.

1. In the Cloud Pak for AIOps home page, click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **AI model management** to open the AI Model Management.
3. In the AI algorithms tab, click **Set up training** within the **Metric anomaly detection** tile.

Getting started

Review the information on this page. It explains what this AI algorithm is, how it will help in your production environment, and provides information on the data needed for the algorithm.

1. Review the information on this panel to understand more about metric anomaly detection.
2. Click **Next** to move to the next panel.

Schedule the training

Decide whether to run the training setup on demand or to schedule it to run on an ongoing basis.

1. Proceed as follows:
    - To run the training setup on demand, ensure that **Schedule to run** is set to **Off**, and go to step 3.
    - To run the training setup on a schedule, set **Schedule to run** to **Yes**, and go to the next step.
2. Schedule the run. Click this option to specify a schedule. You can specify a start date with an optional end date, a frequency, and a time based on Coordinated Universal Time (UTC).
3. Click **Next** to move to the next panel.

Deciding how to deploy the training

The option to review training results before deployment is disabled for this algorithm. The metric anomalies generated by training the algorithm will automatically be displayed in the Alert Viewer when training is complete.

Click **Done** to save the training setup for the algorithm.

What to do next

Now that the training setup is complete, you can train the algorithm. For more details, see Generating AI models.

Setting up training for similar tickets

Set up training for this AI algorithm to enable the discovery of historical tickets to aid in the remediation of current tickets.

About this task

When an incident occurs, it can be helpful to review details for similar tickets from the past to help determine a resolution. This model aggregates information from past similar tickets. It can also extract the steps that are used to fix previous tickets, if documented.

Training setup of the algorithm is done by completing some setup tasks. When the training setup is complete, you need to go to a different part of the AI Model Management to train the model.

Before you begin

To train similar tickets, you must provide ticket information. There is no set minimum of how much data to provide; the AI trains on whatever amount is available.

However, the more ticket data you can provide, the better. Any data that is collected for historical training is available to use as data. You can also collect data from the live integration and as future tickets are created, they are processed automatically.

Qualifying tickets

Important: Starting with IBM Cloud Pak® for AIOps version 4.1.0, similar incidents, such as from a ServiceNow integration, are called similar tickets.

To pass data precheck, a minimum of five qualifying tickets are needed. Qualified tickets are closed:

- The `state` and `closed_at` fields from the raw ticket schema indicate closure.
- The `close_notes` field from the raw ticket schema includes meaningful resolution notes with actions and entities that the similar tickets algorithm can extract. If your tickets do not include resolutions, or if they include default entries like *Closed by Caller*, these values do not identify paths to remediation, and the similar tickets algorithm is unable to use the tickets to provide recommended actions through similar tickets.

The following required fields are needed for a ServiceNow ticket to be qualified for the similar tickets AI algorithm.

Required attributes for the similar tickets algorithm

Attribute	Description
`short_description`	Short description or title of the ticket.
`number`	Identification number of the ticket.
`opened_at`	Coordinated Universal Time at which the ticket started formatted as `yyyy-mm-ddTHH:MM:SSZ`.
`state`	Current state of the ticket.
`closed_at`	Coordinated Universal Time at which the ticket was closed formatted as `yyyy-mm-ddTHH:MM:SSZ`.
`close_notes`	Comments or closed notes that talk about the list of actions that are taken, or comments that are added by the user who is attending to the ticket.

Running the task

There are multiple parts to this task:

- Starting the training setup
- Checking data integrations
- Deciding how to run the training
- Deciding how to deploy the training
- What to do next

Starting the training setup

Go to the AI Model Management and complete some setup tasks.

1. In the Cloud Pak for AIOps home page, click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **AI model management** to open the AI Model Management.
3. On the **Training** tab, click **Set up Training** within the **Similar tickets** tile under the Trainable AI algorithms section.

Checking data integrations

Review the information on this page. It explains what this AI algorithm is, how it will help in your production environment, and provides a list of integrations needed to generate a model.

1. On the Integrations, check that at least one integration is listed.

   Note: If no integrations are listed, or you expected to see more integrations, click **Go to Integrations** to modify your integrations. For more information, see ServiceNow integration.

2. Click **Next** to move to the next panel.

Schedule the training

Decide whether to run the training setup on demand or to schedule it to run on an ongoing basis.

1. Proceed as follows:
   - To run the training setup on demand, ensure that **Schedule to run** is set to **Off**, and go to step 3.
   - To run the training setup on a schedule, set **Schedule to run** to **Yes**, and go to the next step.
2. Schedule the run. Click this option to specify a schedule. You can specify a start date with an optional end date, a frequency, and a time based on Coordinated Universal Time (UTC).
   - Decide whether to run the training setup on demand or to schedule it to run on an ongoing basis.
   - Training loads existing qualified ServiceNow tickets into the similar tickets AI algorithm.
   - If you set the ServiceNow integration to continuous data collection, scheduling frequent trainings helps ensure that the similar tickets AI algorithm includes the new tickets in its recommendations.
3. Click **Next** to move to the next panel.

Deciding how to deploy the training

The option to review training results before deployment is unavailable for this algorithm. After training is complete, the model is automatically deployed. To see similar tickets appear in your subsequent incidents, go to the **Automations** page and enable **Default story query similar incidents service policy** in the policy list.

Click **Done** to save the training setup for the algorithm.

What to do next

Now that the training setup is complete, you can train the algorithm. For more details, see Launching the training.

Setting up training for temporal grouping

Set up temporal grouping to train policies. Then, choose how to deploy the policies.

For more information about the temporal grouping AI algorithm, see About temporal grouping.

Before you begin

To train a definition for temporal grouping, this AI algorithm needs at least three months of historical event data to learn alert patterns and discover groups. A set of data creates a set of policies. For more information, see Prerequisites.

This AI algorithm can start to discover groups after a pattern is learned, which might take hours or days. For example, if a problem occurs in the first and the fourth week of January and again in March, the algorithm learns to group the alerts that tend to co-occur when the problem happens.

About this task

There are multiple parts to this task:

- Starting the training setup
- Scheduling the training
- Select data
- Deciding how to deploy the training
- Running the training again
- What to do next

Starting the training setup

Go to the AI Model Management and complete some setup tasks.

1. In the Cloud Pak for AIOps home page, click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **AI model management** to open the AI Model Management.

3. In the **Training** tab, click **Set up training** within the **Temporal grouping** tile under the Trainable AI algorithms section.

Scheduling the training

Decide whether to run the training set up on demand or to schedule it to run on an ongoing basis.

1. Proceed as follows:
   - To run the training set up on demand, ensure that **Schedule to run** is set to **Off**, and go to step 3.
   - To run the training set up on a schedule, set **Schedule to run** to **Yes**, and go to the next step.
2. Schedule the run. Click this option to specify a schedule. You can specify a start date with an optional end date, a frequency, and a time based on Coordinated Universal Time (UTC).
3. Click **Next** to move to the next panel.

Select data

Select a date range (either Preset or Custom) for the event data that will be included in the AI training. Including additional data typically improves the effectiveness of the AI models and policies that are generated by the training.

Deciding how to deploy the training

The option to review training results before deployment is disabled for this algorithm. However, you can choose when to deploy the policies that are generated by training the algorithm.

- To review and manually deploy the model, set **Deployment type** to **Review and manually deploy policies**.
- To automatically deploy the model, set **Deployment type** to **Automatically deploy all policies**.

Click **Done** to save the training setup for the algorithm.

Running the training again

- If you run the training again with the same data, expect to receive the same policies.
- If you run the training again with different data, you might receive new policies.

What to do next

Now that the training setup is complete, you can train the algorithm. For more details, see Launching the training.

Managing AI algorithms

Use this information to understand how to generate AI models, and how to perform various administration tasks on the models.

For more information about managing AI algorithms, see the following topics:

- Generating AI models
- Deploying AI models
- Editing algorithm configurations
- Deleting algorithm configurations
- Managing AI model versions
- Draft and archived policies

Generating an AI model

Generate an AI model by training one of the AI algorithms. The AI model that is generated by the training acts on live data and generate insights to your SREs.

About this task

You only need to generate an AI model for trainable AI algorithms. Pre-trained AI algorithms, in contrast, analyze your data in real time and derive insights without the need to generate a model. For more details, see Algorithm types.

Before you begin

You must save at least one algorithm training setup, as described in Setting up training for trainable AI algorithms.

Procedure

1. In the Cloud Pak for AIOps home page, click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **AI model management** to open the Training page.

   A list of algorithms is shown in tile format under sections depending on whether they are trainable or pre-trained AI algorithms.
3. Click 'Set up training' on the trainable algorithm tile for which you want to generate an AI model. When the setup is complete for that algorithm, the details from the 'Training Set up' page appear. To understand a particular model - what it does and what kind of data you need to run it – click *Description* (information icon) next to the tile's title.

   Note: You can run precheck before training your model. Precheck checks the quality of the data first. Regardless, if you try to train models without first running the precheck, AI Models still run the precheck first anyhow. Even if the training data changes, the precheck will be rerun on the new data.
4. If the setup is complete for an algorithm, click the algorithm's tile for more details on that AI model and to begin the training.

   When the model detail page opens, you can click **Precheck data** from the panel on the right side of the screen, before training. This checks the quality of the data. Regardless, if you try to train models without running the precheck, AI models still run the precheck first, anyhow. Even if the training data changes, the precheck will be rerun on the new data. **Note**: There is no data precheck for Metric anomaly detection.
5. In the right side panel, click **Train Models**.

   After a few moments the IBM Cloud Pak for AIOps console responds as follows:

   - A message appears with the text: **Training successfully started**.
   - The **AI Training** tile displays the message: **In Progress**. Training is now in progress.
6. As training progresses it passes through phases, which you can view under *Activity*, in the side panel.

There are six possible phases that are shown, though they vary depending on which algorithm you chose to train:

```
1. **Queued**
2. **Data retrieving**
3. **Quality check**
4. **Preparing data**
5. **Training**
6. **Saving models**
```

Only change risk contains all six phases. Once training is complete, the **AI Training** tile displays the messages:

- **Complete**
- **Deployed** (if indeed it has also been deployed).

At this point AI models have been created, with a specified data quality, which can take one of the following values:

- **Good**
- **Needs improvements**

  Note: No quality check is carried out on the Metric anomaly detection or Temporal Grouping models, as the check is not supported by the API that provides data to these algorithms.

For more details, click the information symbol in the **Data quality** tile. For a full set of data quality measures and messages, see Data quality messages.

For log anomaly detection training, an extra **Models** tile is displayed containing information on the models that were generated during training. For more details, see Displaying log anomaly detection resources and models.

Change risk tiles

For **change risk**, there is a new section entitled **Ticket data quality**, consisting of three tiles:

- *Closed tickets*: A number. For example, 10000. Historical ticket data must be in a terminal state (closed tickets) in order for the algorithm to train.
- *Missing tickets*: Data in high-importance fields within a ticket is needed to create good models. The more complete the data that you have in all fields (such as type, business service, sys domain and short description), the better your models perform. **Note:** if less than 0.5% of the total closed tickets are missing the relevant field (type, business service, and so on), it is displayed as 0% in the UI.
- *Ticket Word Count*: Tickets with a short (<5 words) overall word count generally don't provide enough information for the algorithm to create good models. This field combines long and short count words for the number of tickets, say 10000.

There is also a **Model prediction** tile, which shows the number of incidents causing tickets as a percentage.

What to do next

If you selected manual deployment when setting up training for the model, then you can now proceed to deploy the AI models that you created. For more details, see Deploying models.

If you encountered errors in the training, see the following sections for more information:

- Troubleshooting documentation at Troubleshooting AI model management.
- Release notes at Known issues and limitations.

Reference information

The following information is referenced in this task.

List of algorithm training setups

Column	Description
AI algorithm	The AI algorithm that is related to this record. Possible values are: **Change risk**, **Log anomaly detection**,**Metric anomaly detection**, **Similar incidents**, and **Temporal grouping**.
Latest model version	Latest version of the model. A new version of the model is generated every that time the algorithm training setup is run.
Version deployed	This is the currently deployed version of the model. If training is scheduled and deployment is automatic, then the value in this field always matches the value in the **Version** field.
Date trained	Date and time this training setup was last run. If it has never been run then this field is blank.
Activity	Displays one of the following status values: (a) **Not started**: this training setup has not yet been run; (b) **Training**: the training setup is currently running; (c) **Training queued**: training is currently waiting on another training job to complete; (d) **Training complete**: the most recent training setup run was successful; (e) **Failed**: Training failed.
Danger zone Contains the **Delete** option, which will delete all models for the algorithm.	

Displaying log anomaly detection resources and models

During natural language log anomaly detection, models are produced for each of the resources identified in the log data provided as input to the algorithm. On completion of log anomaly detection training, the system provides information on the models that were generated during training.

About this task

In order to produce a model for a resource, a minimum of 2,000 log lines is required for that resource and the log data must meet formatting requirements. On completion of training, a **Models** tile is displayed containing the details described below.

Models

The main part of the tile displays a donut graph showing resources with models in green and resources without models in red.

- Total number of models identified is shown in the middle of the donut graph.
- Hover over the donut graph to display the number of resources with models and the number of resources without models.

View resources

Click this link at the top right of the **Models** tile to display resource and model details.

Column	Description
Resource name	Name of the resource for which models were produced.
Log lines found	Number of log lines found for this resource in the data supplied when configuring the algorithm. A minimum of 2,000 log lines is required per resource to meet data sufficiency requirements. **Note** The number of log lines displayed here might be smaller than the number of log lines provided by the log data integration and presented in a log aggegator dashboard. This is because log lines are deduplicated during the training process. A log line is said to be duplicated when the combination of **timestamp**, **instance_id** and **message** is exactly the same. The duplicate log lines are not saved on Elasticsearch and are also not used for inference in log anomaly detection. Deduplication has no impact on the quality of the models generated but does have the advantage of lower data storage requirements and also helps to manage Flink restart issues due to collection of the same data multiple times.

Column	Description
Sufficient data	Displays one of the following values: **Passed**: 2,000 log lines or more were found for this resource. **Failed**: Less than 2,000 log lines were found for this resource.
Data format	An indication of whether the data found for this resource meets data formatting needs. This column takes one of the following values: **Passed**: Formatting needs are met. **Failed**: Formatting needs not met. You might need to modify the field mapping of the data. For more information see Mapping data.
Model status	Indicates whether a model was created for this resource. A model is only created if both sufficiency and formatting needs are met.

Data quality messages and alerts

The data quality precheck stage always runs on your input data before it can be approved for training. Once the precheck stage is complete, you are presented with an assessment of the data quality.

The data quality precheck examines whether enough data is available to return meaningful results (*data sufficiency*), and whether the data meets mapping requirements (*data formatting*). A result is displayed on the console, and this result affects the execution of the model training, as if the precheck fails, the training is disabled, and you cannot run training.

If you change the selected training data, the precheck stage is always run again.

Mapping data

Poor *data formatting* is often associated with incorrect field mapping.

Data is collected when you select a source on the Integrations and add a integration. Within the window for configuring the integration, use the **Field mapping** section to map source fields to standard fields. For example, the `_timestamp` in Mezmo data should be mapped to `timestamp` in the standard format. One reason that schema validation might fail, is when incorrect data mappings are entered in the **Mapping** field. For more information on the overall data loading and AI training process, see Planning data loading and training.

Good data quality

Good data quality means that requirements for *data sufficiency* and *data formatting* are met. Good data quality is represented on the Cloud Pak for AIOps console using the following label: **Good data**.

Data quality	Recommendation	Description
Good data	`Precheck came back with good data. You are now ready to start training models.`	Requirements for *data sufficiency* and *data formatting* are met.

Poor data quality

Poor data quality messages vary with the AI algorithm that you are training. Poor data quality is represented on the Cloud Pak for AIOps console using the following label: **Data needs improvement**.

For each of the following AI algorithms, this topic describes the possible data quality messages, provides a brief description of the message, and points to any relevant documentation task, which can support remediation action.

- Change risk
- Log anomaly detection
- Similar tickets

Change risk

This algorithm takes as input change and incident data from ServiceNow. To meet overall data quality requirements, both change and incident data must meet *data sufficiency* and *data formatting* requirements.

Data quality alert	Recommendation	Description	Link
Data needs improvement	`Part of your data did not pass precheck. View recommendations to see how you might improve data quality.`	**Data precheck issue**: Insufficient number of problematic change tickets for a good model. For a closed change ticket count less or equal to 150, you need at least three problematic tickets. For a closed change ticket greater than 150, you need at least two percent of change tickets to be problematic. A problematic change ticket is defined as a change ticket that can either be associated with incident tickets, or have an 'unsuccessful' value set in the change ticket close code field.	See ServiceNow integration

Data quality alert	Recommendation	Description	Link
Data needs improvement	`Change data: The data is not valid according to schema. Check input data mapping or data source.`	**Data formatting issue**: Change data does not meet *data formatting* needs. You might need to modify the data's field mapping.	See ServiceNow integration
Data needs improvement	`More data is needed. You need at least _X_ change tickets for a good model.`	**Data sufficiency issue**: Change data does not meet *data sufficiency* needs. More change ticket data is needed	See ServiceNow integration
Data needs improvement	`Incident data: The data is not valid according to schema. Check input data mapping or data source.`	**Data formatting issue**: Incident data does not meet *data formatting* needs. You might need to modify the data's field mapping.	See ServiceNow integration
Data needs improvement	`More data is needed. You need at least 1 incident data point for a good model.`	**Data sufficiency issue**: Incident data does not meet *data sufficiency* needs. More change ticket data is needed	See ServiceNow integration
Data needs improvement	`Data is insufficient for a good model. You need at least 2 percent of change tickets to either be associated with incident tickets or have an 'unsuccessful' value set in the change ticket close code field.`	**Data sufficiency issue**: Incident data does not meet *data sufficiency* needs. You must provide data with a change ticket failure rate of 2% or higher.	See ServiceNow integration

Log anomaly detection

This algorithm takes as input log data from one or more log systems. The log anomaly detection algorithm itself has multiple underlying microservices. *Data sufficiency* and *data formatting* requirements for this algorithm work as follows:

- Each of these microservices requires a minimum of 2000 data points. To meet the minimum *data sufficiency* requirement for the algorithm as a whole, at least 75% of the algorithms must meet this 2000 data point requirement. For example, if only two microservices out of 10 have less than 2000 data points, and the rest have more than 2000 data points, then *data sufficiency* requirement for the algorithm as a whole is good.
- To meet the *data formatting* requirement for the algorithm as a whole, at least 75% of all data (from all of the microservices) must be valid with respect to the schema.

Data quality alert	Recommendation	Description	Link
Data needs improvement	`Part of your data did not pass precheck. There were not enough logs for X out of Y resources. Models were only created for those where sufficient data existed. You can expand the date range to gather more data and train again to expand coverage.`	**Data precheck issue**: Data does not meet data precheck needs. You might need to modify the data's quality before running the training.	See Train model precheck
Data needs improvement	`There were not enough logs for _X_ out of log_anomaly_detection components. Models were only created for those where sufficient data existed. You can expand the date range to gather more data and train again to expand coverage.`	**Data sufficiency issue**: Data does not meet *data sufficiency* needs. More than 25% of the component microservices have less than the required 2000 data points. More log data is needed. Try expanding the data range of the data provided.	See Natural language log anomaly detection: data to train on
Data needs improvement	`We have detected that a portion of this data set is in an unsupported language, and could affect the quality of this model. We recommend that you remove this data from the data set and retrain the model.`	**Language support issue**: Log anomaly detection only supports the following languages and language combinations: English, Spanish, German, English and Spanish, English and German. Your data contains either an unsupported language or an unsupported language combination.	For more information, see Language support. To remediate this issue, see Managing unsupported languages.

Similar tickets

This algorithm takes as input incident data from ServiceNow. To meet overall data quality requirements, both change and incident data must meet *data sufficiency* and *data formatting* requirements.

- To meet *data sufficiency* requirements, a minimum of five closed incidents with associated resolution is required.

Data quality alert	Recommendation	Description	Link

Data quality alert	Recommendation	Description	Link
Data needs improvement	`Part of your data did not pass precheck. View recommendations to see how you might improve data quality.`	**Data precheck issue**: More data is needed. You need at least five closed incidents with resolution for a good model.	See ServiceNow integration
Data needs improvement	`More data is needed. You need at least 5 closed incidents with resolution for a good model.`	**Data sufficiency issue**: Data does not meet *data sufficiency* needs. More closed incident ticket data is needed.	See ServiceNow integration

Note There is a new data quality alert that appears in the console if the precheck is launched (for all of the three algorithm failures) without any data loaded. The alert tells you that the 'Precheck failed', and the recommendation is 'Cannot find any data'.

Managing unsupported languages

If natural language log anomaly training reports that the model needs improvement because of unsupported language issues, you can remove the offending data from the data set by deleting component-specific logs, and then retrain.

About this task

Log anomaly detection only supports the following languages and language combinations:

- English
- English and French
- English and German
- English and Italian
- English and Spanish
- French
- German
- Italian
- Spanish

If your data contains either an unsupported language or an unsupported language combination, then you will get the following data quality alert on completion of training:

Needs improvement We have detected that a portion of this data set is in an unsupported language, and could affect the quality of this model. We recommend that you remove this data from the data set and retrain the model.

To remediate the situation you must delete all the logs from components whose logs are all or partially in an unsupported language.

Procedure

Perform the following steps to remediate the situation.

1. Log in to your cluster.

   ```
   oc login -u kubeadmin -p <password>
   ```

   For more information, see Logging in to the OpenShift CLI.

2. Run the `oc project` command to set the context to the project where Cloud Pak for AIOps is deployed.

3. Find the name of the apiserver pod.

   ```
   oc get pod | grep api-server
   ```

4. Open a terminal on that pod.

   ```
   oc exec -it <api-server_podname> bash
   ```

5. Run the following `curl` command exactly as specified below to retrieve data quality alert details.

   ```
   curl -k -u $ES_USERNAME:$ES_PASSWORD -X GET "https://$ES_ENDPOINT/prechecktrainingdetails/_search?
   pretty" -H 'Content-Type: application/json' -
   d'{"_source":"dataQualityDetails.languageInfo.components"}'
   ```

   In this command:

   - `ES_USERNAME` is the Elasticsearch username.
   - `ES_PASSWORD` is the Elasticsearch password.
   - `$ES_ENDPOINT` is the Elasticsearch environment variable in the pod.

- `https://$ES_ENDPOINT/precheckstrainingdetails` is the Elasticsearch endpoint for the `precheckstrainingdetails` index, which stores language information associated with the data set sampled for a specific component.

6. In the output that is generated, navigate to the `dataQualityDetails` field, and find the nested `languageInfo` field. Then retrieve the names of the component where the language list has `unknown` as one of the values. For example, in the example below you would select `abc`.

```
"components" : [
            {
              "name" : "abc",
              "language" : [
                  "English",
                  "unknown"
                          ],
```

7. For each component that you identified in the previous step, delete the logs from all log data indices by running the following command.

```
curl -k -u $ES_USERNAME:$ES_PASSWORD -X POST "https://$ES_ENDPOINT/*-logtrain/_delete_by_query" -H
'Content-Type: application/json' -d'{"query": {"bool": {"must": [{"term": {"instance_id.keyword":
"abc"}}]}}}'
```

   Where `abc` must be replaced with the name of the component.

   Note If all components are detected as having logs in an unsupported language, then this step will delete all data from the Elasticsearch indices for log anomaly training. You will need to train again when fresh data arrives.

8. Once you have deleted the relevant logs, you must relaunch the training of your natural language log anomaly detection algorithm, as described in Generating AI models.

Determining which algorithm generated a log anomaly

There are two log anomaly detection AI algorithms, each of which can run independently of the other: natural language and statistical baseline. If both algorithms are enabled, then any log anomalies discovered by both will be reconciled, so that only one alert is generated. Use the information in this topic to work out which log anomaly detection algorithms contributed to the detection of the anomaly.

About this task

There are two ways to check which log anomaly detection AI algorithms generated a given log anomaly:

- By viewing the details of the alert in the Alert Viewer.
- By monitoring the Kafka topic **cp4waiops-cartridge.lifecycle.input.events kafkatopics**, and parsing out the values in the **log_anomaly_model** field.

Viewing details in the Alert Viewer

1. In the Alert Viewer, double click the log anomaly alert of interest. The **Alert Details** panel opens on the right, displaying the properties of the alert.
2. In the **Properties** table, locate the **Description** field.
3. Within the **Description** field, locate the **log_anomaly_model** key. The nested values within this key identify which log anomaly detection algorithm contributed to the detection of this anomaly. Possible nested values are listed in Possible values within the log_anomaly_model JSON key below.

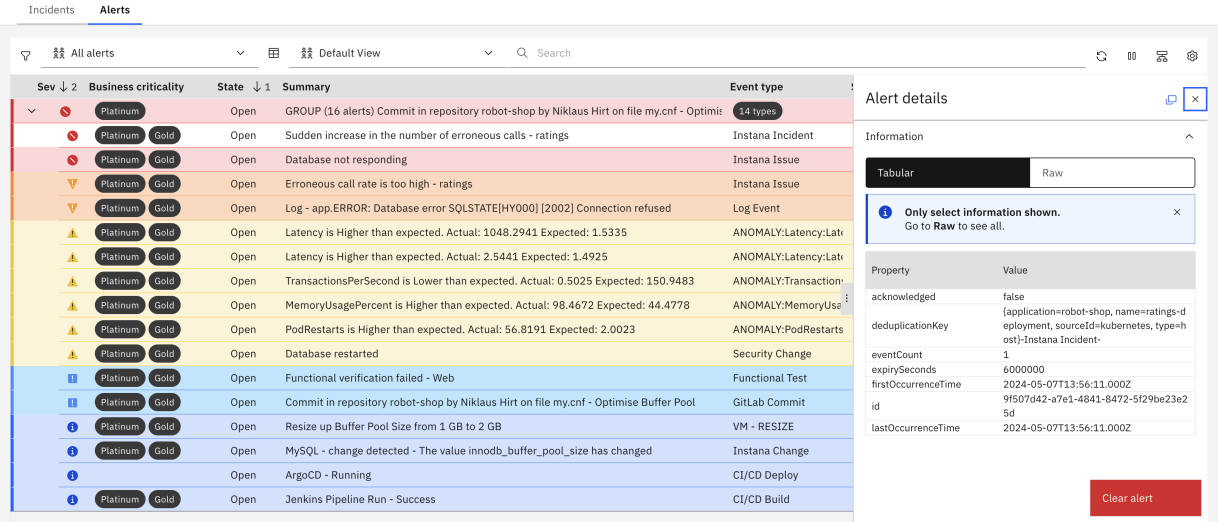

Figure. The Alert details panel

Monitoring the relevant Kafka topic

1. Monitor the Kafka topic **cp4waiops-cartridge.lifecycle.input.events kafkatopics**. This topic provides a Kafka stream of alert instances.
2. Look for a **sender** key where name attribute is "Log Anomaly" to identify those alert instances that were generated by the log anomaly detection AI algorithms.
3. Within that section of the JSON, locate the **log_anomaly_model** key. The nested values within this key identify which log anomaly detection algorithm contributed to the detection of this anomaly. Possible nested values are listed in Possible values within the log_anomaly_model JSON key below.

Reference information

The following information is referenced in this task.

Possible values within the log_anomaly_model JSON key

Value	Algorithm	Meaning
PCA_Stats	Natural language	The time window in which this alert occurred is statstically different to the training data.
PCA_error_or_unknown_template	Natural language	There are error templates or unknown templates in this time window which the algorithm has identified as anomalous.
PCA_low_frequency_error_template	Natural language	There are error templates which occur with low frequency in this time window and the algorithm has identified this as anomalous.
RSM_entities	Statistical baseline	The algorithm has determined that there are significantly different error entities in this time window.
RSM_embeddings	Statistical baseline	The algorithm has found word embeddings for this time window that are distant from the embedding vectors for normal data.
RSM_websphere	Statistical baseline	This value is specific to WebSphere logs. The algorithm has found significantly different error message identifiers or log levels for this time window.

Deploying models

If the model is not autodeployed, then if you are happy with the results, you can now deploy the model.

Before you begin

You only need to perform this task if you generated a model that requires manual deployment.

Procedure

1. From the AI Model Management, click the options menu for the algorithm configuration that includes the model that you want to deploy.
2. Click **Deploy**.

Reference information

The following information is referenced in this task.

List of algorithm configurations

Column	Description
Version	Latest version of the model. A new version of the model is generated every time the algorithm configuration is run.
Deployed version	Currently deployed version of the model. If training is scheduled and deployment is automatic, then the value in this field always matches the value in the **Version** field.
AI algorithm	The AI algorithm related to this record. Possible values are: **Change risk**, **Log anomaly detection**, **Similar tickets**, and **Temporal grouping**.
Schedule	Displays the schedule frequency (**Daily**, **Weekly**, **Biweekly**, or **Monthly**). If no schedule was set, then this field displays the text **Run manually**.
Last trained	Date and time this configuration was last run. If it has never been run then this field is blank.
Status	Displays one of the following status values: (a) **Not started**: this configuration has not yet been run; (b) **Training**: the configuration is currently running; (c) **Training queued**: training is currently waiting on another training job to complete; (d) **Training complete**: the most recent configuration ran was successful; (e) **Failed**: Training failed.

Editing the training setup for an algorithm

You can edit the training setup for any of the existing algorithms.

Before you begin

You must save at least one algorithm training setup, as described in Setting up training for trainable AI algorithms.

About this task

Only algorithms that generate models can be edited. For more details, see Algorithm types.

Procedure

1. From the AI Model Management, under the Training tab, click the tile of the algorithm you want to edit.

   - **Change risk**: Deployment, Training schedule
   - **Log anomaly detection - natural language**: Training data, Deployment, Training schedule
   - **Similar tickets**: Training schedule
   - **Temporal grouping**: Training schedule
   - **Metric Anomaly Detection**: Training schedule

2. Modify the algorithm settings by clicking the **Edit data** icon next to the settings that you want to modify. After you make your changes click **Save** to return to the Overview page.

   Your changes are now saved.

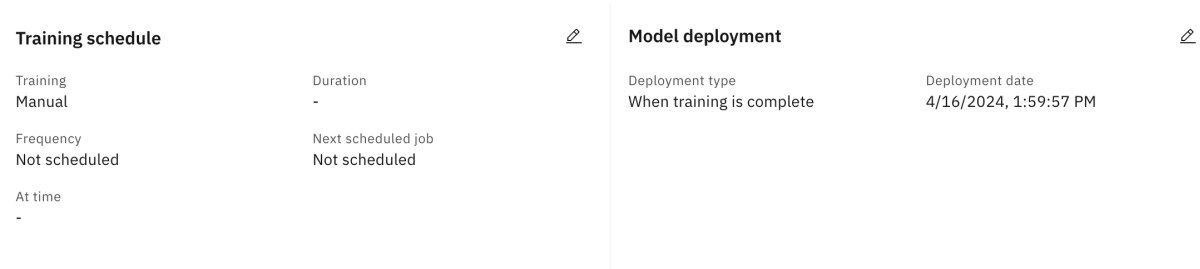

Figure. Editing configurations for the change risk algorithm

Reference information

The following information is referenced in this task.

List of algorithm details

Column	Description
Latest model version	Latest version of the model. A new version of the model is generated everytime that the training succeeds.
Version deployed	Currently the deployed version of the model. If training is scheduled and deployment is automatic, then the value in this field always matches the value in the **Version** field.
AI algorithm	The AI algorithm that is related to this record. Possible values are: **Change risk**, **Log anomaly detection - natural language vs statistical baseline**, **Similar tickets**, **Metric anomaly** and **Temporal grouping**.
Date prechecked	Date and time this training setup was prechecked.
Date trained	Date and time that this training setup was last run. If it has never run then this field is blank.

Deleting the training setup for an algorithm

You can delete the training setup for any of the existing algorithms.

About this tasks

If an algorithm training setup has associated AI models, then the action of deleting the training setup for the algorithm automatically removes any currently deployed model generated based on that training setup. It then deletes all of the models associated with this training setup.

Before you begin

You must have saved at least one algorithm training setup, as described in Setting up training for trainable AI algorithms.

Procedure

1. From the AI Model Management, click the options menu for the algorithm training setup that you want to delete.
2. Click **Delete**.

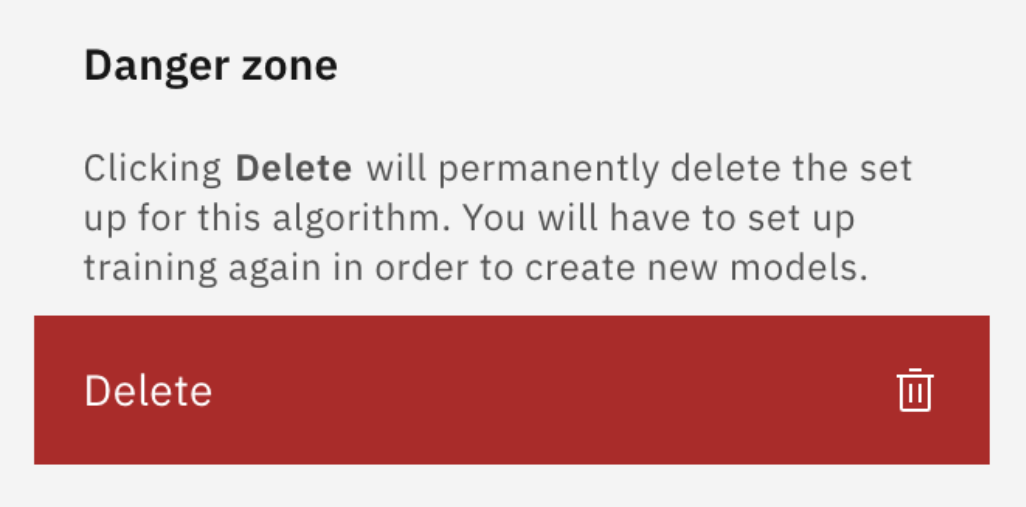

Figure. Deleting an algorithm

Reference information

The following information is referenced in this task.

List of training setups for an algorithm

Column	Description
Version	Latest version of the model. A new version of the model is generated every time the training setup for the algorithm is run.
Deployed version	Currently deployed version of the model. If training is scheduled and deployment is automatic, then the value in this field always matches the value in the **Version** field.
AI algorithm	The AI algorithm related to this record. Possible values are: **Change risk**, **Log anomaly detection**, **Similar tickets**, and **Temporal grouping**.

Column	Description
Schedule	Displays the schedule frequency (**Daily**, **Weekly**, **Biweekly**, or **Monthly**). If no schedule was set, then this field displays the text **Run manually**.
Last trained	Date and time this training setup was last run. If it has never been run then this field is blank.
Status	Displays one of the following status values: (a) **Not started**: this training setup has not yet been run; (b) **Training**: the training setup is currently running; (c) **Training queued**: training is currently waiting on another training job to complete; (d) **Training complete**: the most recent training setup ran was successful; (e) **Failed**: Training failed.

Managing AI model versions

You can change the version of a model that is deployed. You can also delete a model version.

For more information about managing AI model versions, see the following topics:

- Changing the deployed version
- Deleting model versions

Changing the deployed version of a model

Only one version of a model can be deployed at any one time. Where you have multiple versions of a model, you can change the deployed version.

Before you begin

You must have generated at least two versions of an AI model, and deployed one of them as described in Deploying models.

Procedure

1. In the AI Model Management, under *Trainable AI algorithms*, click the tile of the configuration you want to change.
2. When the overview page opens, click the *Model versions* tab. A list of model versions is displayed. For more information, see the List of model versions.
3. To change the deployed version, click the options menu at the far end of the table in the row corresponding to the version that you want to deploy. Then, click **Deploy**. The table updates to show that the version that you selected is now the deployed version.

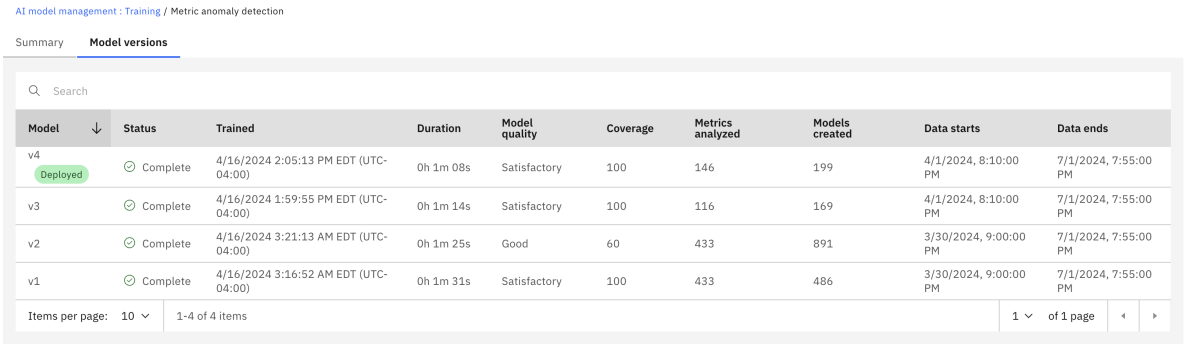

Figure. Model versions in Metric anomaly detection

Reference information

The following information is referenced in this task.

List of algorithms configurations

Column	Description
Name	Name of the algorithm configuration.
Latest model version	Latest version of the model. A new version of the model is generated every that time the algorithm configuration is run.

Column	Description
Version deployed	This is the currently deployed version of the model. If training is scheduled and deployment is automatic, then the value in this field always matches the value in the **Version** field.
AI algorithm	The AI algorithm that is related to this record. Possible values are: **Change risk**, **Log anomaly detection**, **Similar tickets**, and **Temporal grouping**.
Data prechecked	Date and time this configuration was last prechecked.
Date trained	Date and time this configuration was last run. If it has never been run, then this field is blank.

List of model versions

Note: The below columns are common to most algorithms and then they can vary in terms of additional columns. For example, Log anomaly also has 'Totals resources found', and 'Models created', whereas Change risk also includes 'Closed tickets' and 'Incidence avoidance'.

Column	Description
Model	Version of the model. A new version of the model is generated every that time the algorithm configuration is run.
Status	The deployed version is marked as **Deployed** with a comforting green tick to the left of the word **Deployed**. The other versions have the status **Complete**.
Last trained	Date and time when this version of the model was trained.
Duration	Length of time taken to train this version of the model.
Data Quality	Possible values are **Good** and **Needs improvement**. Only deploy model versions that have the status **Good**.

Deleting the log anomaly model versions

You can delete versions of a log anomaly model.

About this task

You cannot delete a deployed version of the model directly. If you want to delete a deployed version, you must first change the deployed version of the model, and then delete the original model.

Procedure

1. From the AI Model Management **Training** tab, click **Log anomaly detection - natural language**.
2. From the **Log anomaly detection - natural language** page, click the **Model versions** tab.
3. To delete a model version, go to the row of the version that you want to delete and click the options menu to expand it. Then, click **Delete**.

Resetting the log anomaly training environment

If you need to reset your log anomaly training environment, complete the following steps. Proceed with caution and do not attempt these steps on a production or critical Cloud Pak for AIOps environment.

Select the instructions for your deployment architecture.

Deployments on Red Hat® OpenShift® Container Platform:

1. Run the `oc project` command to set the context to the project where Cloud Pak for AIOps is deployed.
2. Open another terminal and run port forwarding for Elasticsearch.

   ```
   while true; do oc port-forward statefulset/$(oc get statefulset | grep elasticsearch-es | awk '{print $1}' |head -n 1 ) 9200;done
   ```

3. Get the installation name:

   ```
   oc get installation
   ```

4. Export the credentials by running the following commands:

   ```
   export username=$(oc get secret $(oc get secrets | grep <installation_name>-es-admin-user-connection-secret | awk '!/-min/' | awk '{print $1;}') -o jsonpath="{.data.username}"|base64 -d)
   ```

   ```
   export password=$(oc get secret $(oc get secrets | grep <installation_name>-es-admin-user-connection-secret | awk '!/-min/' | awk '{print $1;}') -o jsonpath="{.data.password}"|base64 -d)
   ```

   Where `<installation_name>` is the name of the installation that was returned after you ran `oc get installation`.

5. **Important:** Do not delete any of the following index files. Deleting these files might delete data that corresponds to other AI activities, such as metric anomaly detection training. However, you can use `_delete_by_query` to delete documents that are referenced by these index files.

   - `trainingdefinition`
   - `trainingsrunning`
   - `trainingrun`
   - `trainingstatus`
6. Specify the variables and delete the following index files. Deleting an index uses a cascading delete and deletes the documents that are referenced by the index.

   - Any `1000-1000-*-logtrain` index files
   - The `1000-1000-vN-*` or `1000-1000-v*-models` index files of the particular version that you want to reset. Specify values for the asterisk (*) and `N` variables. The `N` variable is an integer number that indicates the version, such as in `1000-1000-v1-applications`. If you want to delete all log anomaly model versions, use `1000-1000-vN-*` or `1000-1000-v*-models`.
   - The `1000-1000-log_models_latest` index file
   - See the following command as an example:

     ```
     curl -u $username:$password -XDELETE https://localhost:9200/1000-1000-v1-templates
     ```

Deployments on Linux

1. Run the `oc project` command to set the context to the project where Cloud Pak for AIOps is deployed.
2. **Important:** Do not delete any of the following index files. Deleting these files might delete data that corresponds to other AI activities, such as metric anomaly detection training. However, you can use `_delete_by_query` to delete documents that are referenced by these index files.

   - `trainingdefinition`
   - `trainingsrunning`
   - `trainingrun`
   - `trainingstatus`
3. Specify the variables and delete the following index files. Deleting an index uses a cascading delete and deletes the documents that are referenced by the index.

   - Any `1000-1000-*-logtrain` index files
   - The `1000-1000-vN-*` or `1000-1000-v*-models` index files of the particular version that you want to reset. Specify values for the asterisk (*) and `N` variables. The `N` variable is an integer number that indicates the version, such as in `1000-1000-v1-applications`. If you want to delete all log anomaly model versions, use `1000-1000-vN-*` or `1000-1000-v*-models`.
   - The `1000-1000-log_models_latest` index file
   - See the following command as an example:

     ```
     export ELASTIC_SET="$(oc get statefulset -l app.kubernetes.io/managed-by=ibm-elasticsearch -o jsonpath='{.items[0].metadata.name}')"
     oc exec "statefulset/${ELASTIC_SET}" -- curl -XDELETE -k --fail "http://127.0.0.1:19200/1000-1000-v1-templates"
     ```

Reference information

The following information is referenced in this task.

List of algorithm configurations

Column	Description
Name	Name of the algorithm configuration.
Version	Latest version of the model. A new version of the model is generated every time the algorithm configuration is run.
Deployed version	Currently deployed version of the model. If training is scheduled and deployment is automatic, then the value in this field always matches the value in the **Version** field.
AI algorithm	The AI algorithm related to this record. Possible values are: **Change risk**, **Log anomaly detection**, **Similar tickets**, and **Temporal grouping**.
Schedule	Displays the schedule frequency (**Daily**, **Weekly**, **Biweekly**, or **Monthly**). If no schedule was set, then this field displays the text **Run manually**.
Last trained	Date and time this configuration was last run. If it has never been run then this field is blank.
Status	Displays one of the following status values: (a) **Not started**: this configuration has not yet been run; (b) **Training**: the configuration is currently running; (c) **Training queued**: training is currently waiting on another training job to complete; (d) **Training complete**: the most recent configuration ran was successful; (e) **Failed**: Training failed.

List of model versions

Column	Description
Version	Version of the model. A new version of the model is generated every time the algorithm configuration is run. The deployed version has a green **Deployed** tag to the right of the version number.
Status	The deployed version is marked as **Deployed** with a comforting green tick to the left of the word **Deployed**. The other versions have the status **Training complete**.
Last trained	Date and time when this version of the model was trained.
Duration	Length of time taken to train this version of the model.
Data Quality	Possible values are **Good** and **Needs improvement**. Only deploy model versions that have the status **Good**.

Draft and archived policies

You can manage the alert seasonality and temporal grouping policies that are created by AI analytics.

Procedure

1. In the AI Model Management, under Trainable AI algorithms, click the **Alert seasonality detection** or **Temporal grouping** tile.
2. On the overview page, click the **Draft and archived policies** tab.

   A policies table is displayed with two views: **Draft** and **Archived**. To search the list of policies in either view, click anywhere in the **Search** field and enter a search term. The system shows in the table all policies that contain the search term in the policy names and the policy conditions. Click Refresh to refresh the table at any time.
3. If present, draft policies once reviewed can be deployed if preferred or moved to archived if unwanted.

   When applying actions to draft or archived policies, you can multi-select policies in the table and apply actions to all of your selections at one time. Use the checkboxes at the beginning of the table rows to select multiple policies. You can also select all policies in the table by clicking the checkbox in the table header beside **Policy name**. A banner above the table displays the number of policies that are selected, together with a menu of options. The actions for draft and archived policies are explained below.

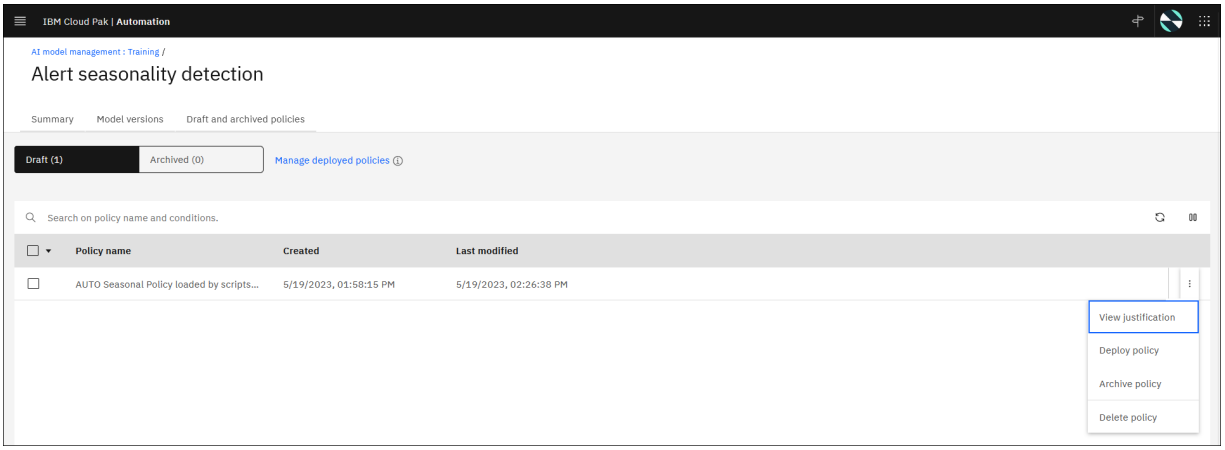

Figure. Draft and archived policies

- **Draft policies**

  The **Draft** tab displays policies that are suggested by AI analytics. Click the options menu (three vertical dots) at the end of a table row to display all of the options available for draft policies:

  - View justification

    Further investigate the seaonality or temporal details and the justification for the policy creation. For more information, see Seasonality policy details and Temporal policy details.

  - Deploy

    Deploy policies that you want to act on incoming alerts. Policies that are deployed from here appear in the Cloud Pak for AIOps Policies table. Click **Manage deployed policies** to display the Policies table that is filtered to include only temporal or seasonal policies. Any existing filters are removed.

- Archive policy

  Archive policies that are not in use.

- Delete policy

  Delete the policy. Note, deleted policies are removed from both the Draft and Archived views. This action cannot be undone.

- **Archived policies**

  Policies that have been archived by administrators or senior operators are shown in the **Archived** view. Archived policies do not act on incoming alerts. Click the options menu on any archived policy to display the available options:

  - View justification

    Further investigate the seaonality or temporal details and the justification for the policy creation. For more information, see Seasonality policy details and Temporal policy details.

  - Deploy

    Deploy policies that you want to act on incoming alerts. Policies that are deployed from here appear in the Cloud Pak for AIOps Policies table. Click **Manage deployed policies** to display the Policies table that is filtered to include only temporal or seasonal policies. Any existing filters are removed. Draft policies can also be either **Archived** or **Deleted**.

  - Unarchive policy

    When a policy is unarchived, it is visible again in the **Draft** view.

  - Delete policy

    Delete the policy. Note, deleted policies are removed from both the Draft and Archived views. This action cannot be undone.

Displaying data assets

List the data assets that are available for analysis by your algorithm configurations.

Before you begin

Before you perform this task, make sure that you load the relevant data for your AI types. For more details, see Prerequisites for AI modelling.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **AI model management** to open the AI Model Management.
3. Click **Data assets**. A list of data assets is displayed. For details of the information is displayed in each row, see the List of data assets below.

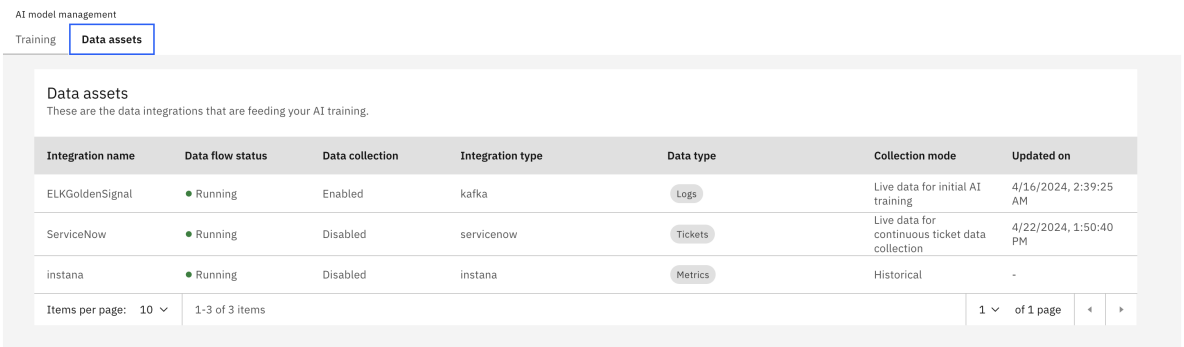

Figure. Data assets in AI model management

Reference information

The following information is referenced in this task.

List of data assets

To modify any of these data integration, you must modify the relevant data integration. For more information, see Configuring Integrations.

Column	Description
Integration name	Name of the data integration.
Data flow	Indicates whether the integration is enabled or disabled.
Integration type	Provides a tag specifying the system from which the data originates.
Data type	Specifies the type of data provided.
Data collected	Indicates whether the data feed is live or historical.
Updated on	Time and date when this integration was last updated.

Managing applications (services) and viewing topologies

Using IBM Cloud Pak for AIOps console you can create applications (services) from bespoke groups of resources, which you can then view in topology or table format. You can analyse incidents and historical data at a granular level using various topology tools, and customize your topology management experience to suit your operational needs.

To access applications (services) and their constituent elements, you launch the *Resource management* page from the main navigation menu. Here data is presented on separate tabs as resources, resource groups, and applications (services).

Note: The following procedure uses 'application' for the data object type that is being managed. Depending on your UI configuration, the term 'service' can be used instead.

Tip for IBM Cloud Pak for AIOps version 4.1.0 and later

You can now configure the UI to label your groups-of-groups collections of resources as either 'applications' or 'services', depending on which term more accurately describes your situation. The system default is 'application', which is also used in the documentation.

- **During installation**, you can set the use of either 'services' or 'applications' by assigning the appropriate value to the TOPOLOGY_TERMINOLOGY environment variable.
- **For an existing installation**, you can run a patch command to switch to the use of 'service'.

  First, confirm the CR name used during installation by running the `oc get installation` command. Use the value returned as **`NAME`** in the following command.

  ```
  oc patch installations.orchestrator.aiops.ibm.com/<NAME> --type merge -p '{"spec":
  {"topologyModel":"service"}}'
  ```

Resources

Resources are the lowest level of element in the system. They are represented in topology visualizations, search experience, and APIs, and form the basis of any topology-based event analytics. Resources are created in the system from observations of different technologies, or from data entered directly, and can represent a multitude of different elements, which are interconnected by their specific relationships and related properties. Relationship types can represent physical connections or logical connections, and all resources together provide an end-to-end view of an environment across data sources and management silos.

Resource groups

Resource groups are an abstraction layer on top of resources and are used to both manage their constituent resources and form the building blocks of applications. You can have resource groups from different sources within an application, or separate from an application.

Resource groups have been collected into a group in order to capture a business or technical context within the environment for both search and correlation purposes. They are either created directly from the topological data discovered via observer jobs, or they are created by defining templates that represent a specific business logic, which dynamically produces resource groups based on defined criteria, such as a model topology structure or a set of tags. Importantly, resource groups are dynamic, which means they change as and when the environment is updated, thereby ensuring the topology data is up-to-date.

Groups allow us to impart meaning to potentially opaque resources, for example, a network interface problem can be prioritized far more effectively if it is known that the resource is part of an important customer application. If required you can create many thousands of groups as

determined by their environment; for example, you could provide tens-of-thousands of applications to your customers, or have a hundred-thousand geographical locations.

Resource groups can only be created and managed through a connected inventory provider, such as Kubernetes, Instana or VMware, or through a resource group template, and cannot be created or deleted from the Resource management page; while the resources within a resource group must be created and managed through the integration with the inventory provider (that is, an observer job). If you need to change resources within a resource group, you do not directly manipulate the resource group. Instead, an administrator user must use the resource group template, or manage the group within the connected inventory provider.

To open a resource group topology view of all of the resources that make up or have relationships to a group, see Viewing topologies.

Applications

Applications can be conceptualised as 'groups-of-groups' and are the highest level of abstraction, considered the starting point for correlating the current environment and managing it in a more coarse-grained and abstract way. An application consists of a collection of resource groups, which can each be created and managed from different sources, designed to best represent a specific business application or service, considering that no one source is likely to provide end-to-end visibility. When combined with resource-level event correlation and grouping mechanisms, applications provide rapid visibility of overall states, allowing operators to prioritize work orders and focus on specific sets of resources that relate to a specific application, thereby excluding resources and resource groups that are not of interest.

For example, an application might be formed by a number of virtual machines and their hypervisors, network equipment, cloud-native applications, and a build pipeline. All of this can form a single holistic representation of the application, which can be used as a shared context between many different teams.

Remember: IBM Cloud Pak for AIOps can model many applications or other 'groups-of-groups' configurations (like services) that you might require for your business application management.

For more information, see the following topics:

- Resource management: Searching and filtering
- The *Resource management* page
- Defining and editing applications
- Managing topologies

Resource management: Searching and filtering

You can search for applications, resource groups, and resources using the Search function. You can further filter the search results by defining filter conditions, which can be saved for future use. For instance, you can define filter conditions to display resources that have a specific tag applied to them.

After you log into IBM Cloud Pak for AIOps console, you open the *Resource management* page from the main navigation menu.

Lists of applications, resource groups and resources are displayed on separate tabs. If many resources are listed, you can use the 'search' or 'filter' functions to identify specific ones, which you can then manage using the tools provided, or display as topologies for further analysis.

Remember: Beginning with IBM Cloud Pak for AIOps version 4.7.1, you can configure the UI to label your groups-of-groups collection of resources as either 'applications' or 'services'. For more information, see the following tip on changing terminology.

Tip: You can now also access the search and filter functionality from the new Resource map (for resources only).

To find aplications, resource groups and resources

1. Activate the Search field.

   As you insert your cursor into the **Search** field, the five most recent searches are listed, and can be selected.

   - You can delete a recent search by clicking the delete button (**X**) next to the suggested search, or by clicking **View all** to display all recent searches.
   - When viewing all recent searches, you can filter the results further using the Filter table Search field, or you can select them and then delete them from the recent searches list.
2. Enter data into Search.

   As you type in a search term, suggested search results are listed, both from the topology database and from recent searches, with your entered text highlighted.

   Tip: You can perform more complex searches, such as searching with multiple search terms. For more information about advanced query syntax, see the topology query reference topic.

3. Select a Search result.

   When you click a search result, the results are listed on the *Results* page under the *Favorites* and *All results* sections, separated into *Applications*, *Resource groups*, and *Resources* tabs, and search is closed with the search term displayed in the Search field.

   Note: (For resources only), you can select the **Include deleted resources** toggle in order to include deleted resources on the *Results* page (unless an administrator has disabled that feature). Deleted resources are marked as such, and the date and time that they were deleted is displayed. If you click the resource name, the deleted resource is displayed as a topology with the history timeline open, and set to 1ms before deletion.

   - For each search result, the name, type and other properties are displayed.
   - If a status other than `clear` exists for a search result, the maximum severity is displayed, and a color-coded information bar above each result displays all non-clear statuses (in proportion).
   - To render a topology view from a search result, click the name.

   Note: You can click the delete button (**X**) next to the search term to return to the previous *Resource management* screen.

4. You can further reduce the number of search results by defining (or using predefined) filters.

To filter applications, resource groups and resources

If filtering from the Resource management page, the Services and Resource group tabs are unavailable (grayed out). Once you have identified a resource you wish to view on a map (defined earlier), click the map icon for that resource in the table (to the right of the 'More details' link).

To see a resticted access filter do the following:

1. Click **Resouce Managment**.
2. Click the **Resources** tab, and then the filter icon in the top left-hand corner.
3. Set the filter as you need, for example you can set the **severity** section to *major*, and **business criticality** to *Auto-medium-criticality*.
4. Then click the three dots icon in the top right-hand corner of the Filter conditions section. 5. Click **Save as new filter**.

   Note: Alternatively, if you are an administrator who has *manage profiles* priviledges enabled, you can set Role Based Access Control (RBAC) functionality that allows you see and click the **Save as a new restriction filter** option, thus applying certain restriction filters to applications, resource groups and resources.

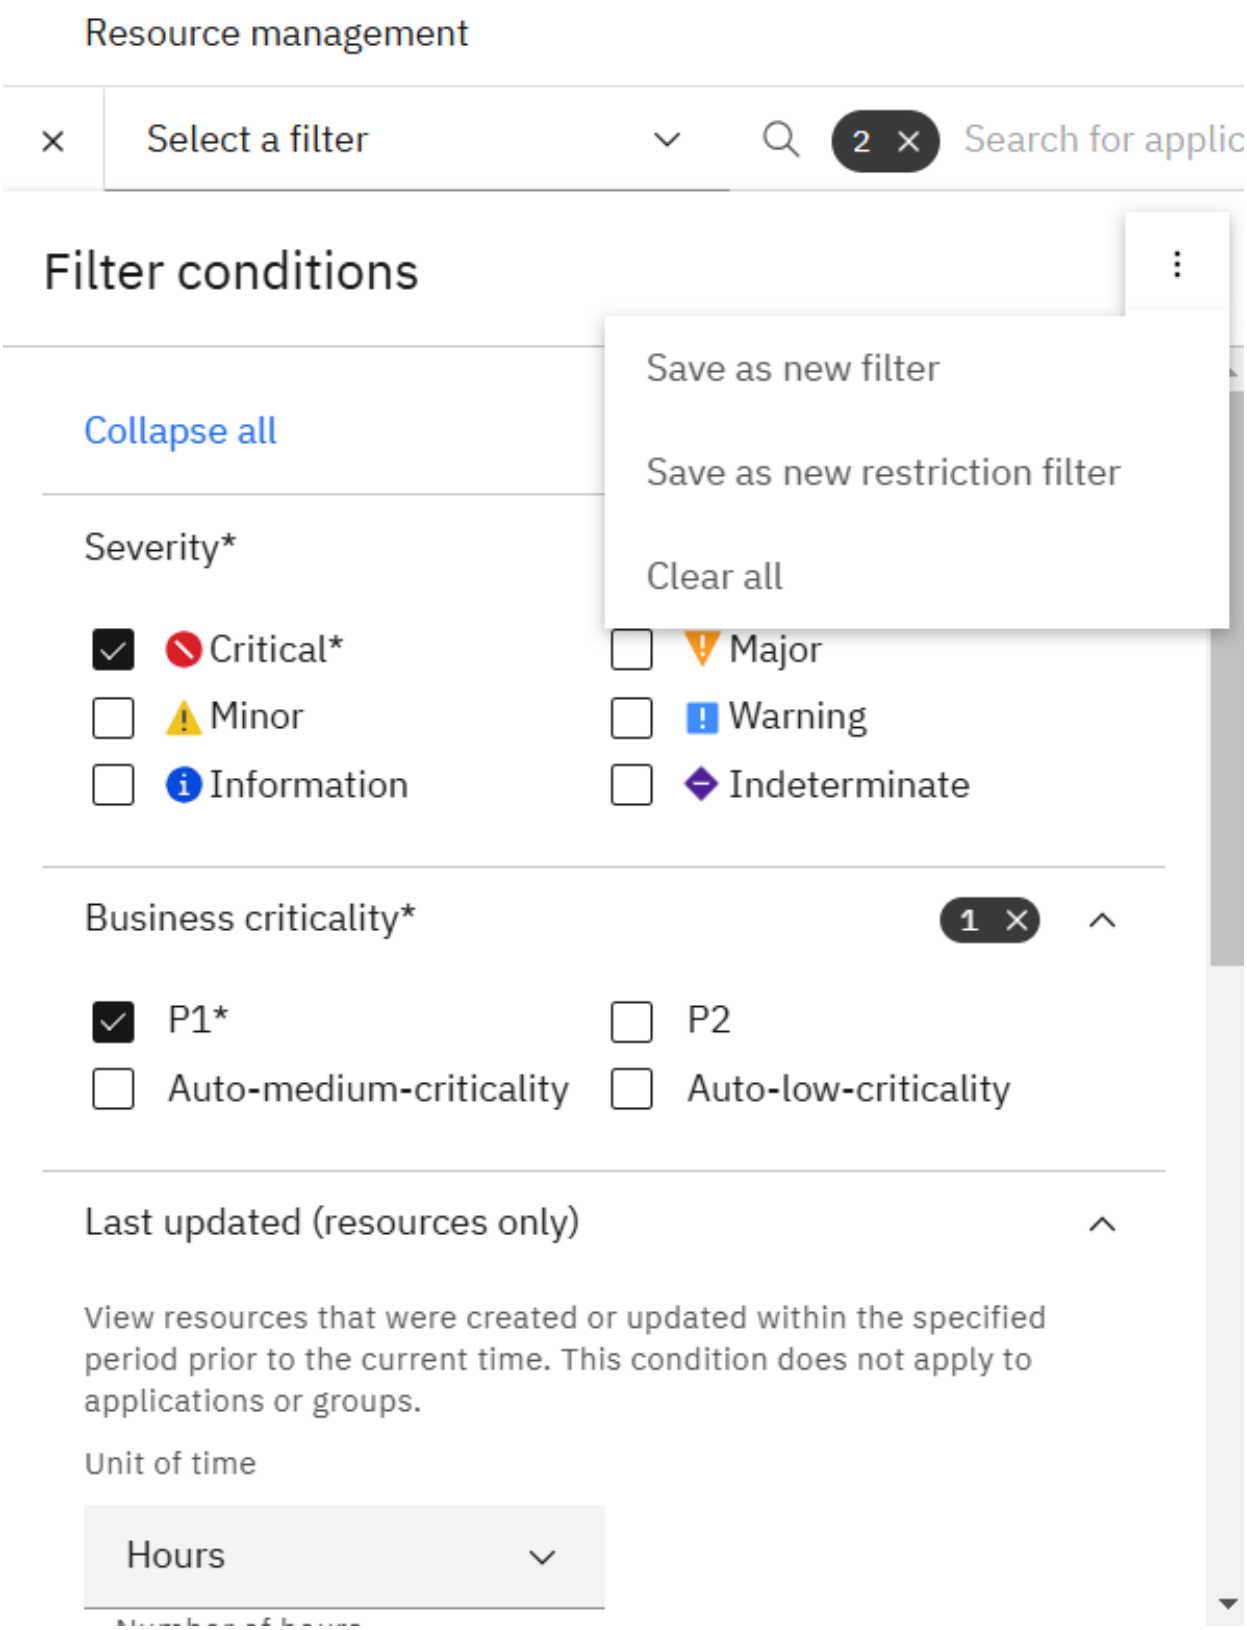

Figure 1. Resource management new restriction filter

If filtering from a Resource map, filters are applied immediately and the map is adjusted.

1. Filter applications, resource groups and resources.

   If many applications, resource groups or resources are displayed, you can filter them using predefined filters, or by defining new filters. You can save filters for your future use, or for use by specified users types.

- To use an existing filter, click **Select a filter** to the left of the Search field to select any previously defined filters to which you have access. If you select a filter, the list of displayed applications, resource groups or resources is updated.
- To define a new filter, click **Open filter** to the left of the **Select a filter** drop-down to open the *Filter conditions* panel. From here, you can define the following filters:
  - **Severity:** Select one or more severity as a filter condition.
  - **Business criticality:** Select a business criticality as a filter condition. Business criticality can be customized by an administrator.
  - **Other properties:** You can set more complex filter condition by clicking **Add condition**. See To use properties to define filters for more details.
  - **For resources only**:
    - Using **Last updated**, you can choose to display only the resources that were created or changed during a specific time period (prior to 'now'). Note that changes in severity or status in this time period are not flagged. Choose either minutes, hours, or days, and select a number between 1 (one) and 500.
    - Using **Geospatial**, you can filter resources that have been enriched with a geographical location. See To define a geospatial filter for more details.

2. To save a filter for future use, complete the following steps:

   a. After you have defined the conditions for a new filter, click **Save as new filter** on the overflow menu.

   b. Define a **Filter name** and **Description** for the filter. The name must be unique.

   c. Define the filter user and their level of access.

   - **`Only me`**: Select for private use.
   - **`Everyone`**: Select either **`Use`** or **`Edit`**. If you select Edit, everyone will be able to change the filter.
   - **`Specified users, user groups or both`**: Select from the available **`Users`** or **`User groups`**, and then specify the level of control, that is, either **`Use`**, **`Use and edit`**, or **`Use, edit and manage`**

   d. Click **Save as new filter**. The specified users will be able to select the filter from the **Select a filter** drop-down list.

   Note: You can delete only the filters that you have created. To do so, select **Delete filter** from the overflow menu.

To use properties to define filters

1. To define a filter condition, complete the following steps:

   a. Select a property from the **Choose a property** drop-down.

   Note: The default Filter builder properties are **`entityTypes`**, **`name`** and **`tags`**. An administrator can add additional properties for filtering.

   b. Select an operator appropriate to that property from the **Choose an operator** drop-down.

   c. Depending on the property selected, either type in a value or select one using the **Value** field (or drop-down).

   d. Click **Apply** to filter the Results table.

   Note: You can delete, edit or disable the filter, or save it for future use. Any filter conditions you set are maintained in the URL, and can therefore be shared via direct-launch URL string.

   Example filters:

   - Example 1: Select the **`tags`** property, then the **`excludes all`** operator, then choose one of the available tags from the Value drop-down. Once applied, all results with that tag are excluded from the *Results* table.
   - Example 2: Select the **`name`** property, then the **`equal to`** operator, then type a resource name into the **Value** field. Once applied, only results of that name are included in the *Results* table.

2. Save your filter.

To define a geospatial filter

1. To set a geospatial filter, define the following scope:

   - **All resources with geospatial data**:

    - All resources that have geospatial properties are displayed.
    - The Area filter parameter is unavailable.
- **All resources without geospatial data**:
    - All resources without geospatial properties are displayed.
    - The Area filter parameter is unavailable.
- **Within area**:
    - Click Select area to open a world map. Use the cursor and zoom function to move to a desired location, then use the selection tool to specify the area. Click Apply selection to return to the previous screen, where all resources that have geospatial properties and are located within the selected area are listed.
    - From here, you can clear or edit the area.
- **Outside area**:
    - Click Select area to open a world map. Use the cursor and zoom function to move to a desired location, then use the selection tool to specify the area. Click Apply selection to return to the previous screen, where all resources that have geospatial properties and are located outside the selected area are listed.
    - From here, you can clear or edit the area.
- **Include resources in overlapping area**:
    - Click Select area to open a world map. Use the cursor and zoom function to move to a desired location, then use the selection tool to specify the area. Click Apply selection to return to the previous screen, where all resources that have geospatial properties and are located within the selected area are listed, as are resources adjacent to or overlapping with the selected area.
- **Exclude resources in overlapping area**:
    - Click Select area to open a world map. Use the cursor and zoom function to move to a desired location, then use the selection tool to specify the area. Click Apply selection to return to the previous screen, where all resources that have geospatial properties and are located within the selected area are listed, though resources adjacent to or overlapping with the selected area are excluded.

2. Save your filter.

The *Resource management* page

You can view your applications (services) and details about them, such as their constituent resource groups and resources, on the *Resource management* page. If you have many applications, resource groups or resources in your topology database, you can use sophisticated searches or define search filters to find them.

Lists of applications, resource groups and resources are displayed on separate tabs.

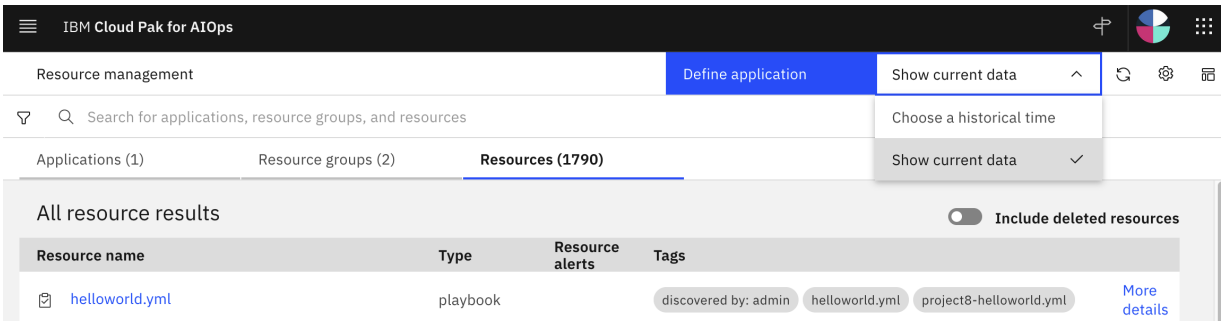

Figure. Resource management page (part)

- About resource management
    - The Applications tab
    - The Resource groups tab
    - The Resources tab

Remember: You can configure the UI to label your groups-of-groups collection of resources as either 'applications' or 'services'. For more information, see the following tip on changing terminology.

Before you begin

In order to view applications and their constituent elements, you must have obtained resource data, created resource groups, and defined applications, as documented in the following sections:

- Configure observers and run jobs.

- Use templates to generate resource groups.
- Define or edit applications.

About resource management

After you log into IBM Cloud Pak for AIOps console, you open the *Resource management* page from the main navigation menu.

Lists of applications, resource groups and resources are displayed on separate tabs. applications and resource groups are divided into 'All results' and 'Favorites' sections. You can display your favorite applications and resource groups either as cards or in a table; however, resources are always displayed in a table, and cannot be designated as favorites.

If many applications, resource groups or resources are listed, you can use the 'search' or 'filter' functions to identify specific ones, which you can then edit or view as topologies. For instance, you can define filter conditions to display the resources that have a specific tag applied to them. For more information on searching, see Resource management: Searching and filtering.

From here, you can define new applications, view your data at a historical point in time, and access the topology configuration, user preferences and template builder functionalities.

If the status for an application, resource group or resource is available, an icon that depicts the status severity level and the number of events that caused the severity are displayed. The severity of a status ranges from **`clear`** (white tick on a green square) to **`critical`** (white cross on a red circle).

Severity status icons

Icon	Severity
	clear
	indeterminate
	information
	warning
	minor
	major
	critical

The Applications tab

The applications tab lists the name, icon, status, tags, business criticality, and number of resource groups for each of the applications in the 'All applications' table. You can define new applications or edit or delete existing ones, assign them a business criticality, add estimated costs for application disruptions, assign favorites, or display them either as a topology or in a tabular format.

For information about defining new applications, see Defining and editing applications.

Application details displayed:

- The overall status of the application.
- The application creation date
- The last updated date
- The included resource groups or resources
- Any associated tags
- Any business criticality set
- Any associated incidents

  An incident is a collection of insights that comes from different data sources such as logs, events, and alerts. Incidents represent the determination of an incident and are categorized by priority from 1 (high) to 5 (low). They build understanding and help drive remediation.

  For more information, see Incidents.

- A link to the *More details* tearsheet (page).

  You can also access more details from the overflow menu to display a sidebar that shows all the current stored properties and values for the specified application in tabular and JSON format. In addition to the Properties tab, the *More details* page also contains Related resources and Related resource groups tabs.

  `**Tip:** If a property has been excluded from view by an administrator, it is removed from the tabular view, but remains visible in JSON format.`

- A heart icon (*Add favorite*) to add the item to the favorites section. When selected as a favorite, the tooltip for the icon changes to *Remove favorite*.

- Click the application name to open a topology view of the application.

  The topology shows you all the resources that make up your business application and how the resources are connected. You can use this interactive tool to drill into individual resource detail and status, enable timeline to view changes over time, and more. You can also use this view to triage issues when an issue occurs.

  For more information, see Managing topologies.

  Note When viewing an application as a topology, you can click **View Legend** to open a Help panel that describes the visual elements, such as symbols, icons and line styles, that are used in the rendering of the topology. You can also click the **Tabular view** button to switch from a topology view to a table view.

- Click **Choose a historical time** on the toolbar to view applications at a historical point in the past (the default selection is **Show current data**.)

  Choose a specific date and time in the past, and click **Apply**.

The Resource groups tab

The Resource groups tab lists the name, icon, type, status, tags, business criticality and number of resources for each of the resource groups in the *All resource groups* table. You can add resource groups to applications, assign them a business criticality, assign them as favorites, or view them either as a topology or in tabular format; however, you cannot create resource groups from here.

For information about using templates to create and manage resource groups, see the template topics.

Resource group details displayed:

- The overall status of the resource group
- The creation date
- The last updated date
- The included resources
- Any associated tags
- Any business criticality set
- Any associated incidents

  An incident is a collection of insights that comes from different data sources such as logs, events, and alerts. Incidents represent the determination of an incident and are categorized by priority from 1 (high) to 5 (low). They build understanding and help drive remediation.

  For more information, see Incidents.

- A heart icon (*Add favorite*) to add the item to the favorites section. When selected as a favorite, the tooltip for the icon changes to *Remove favorite*.
- A link to the *More details* tearsheet (page).

  You can also access *More details* from the overflow menu to display a page that shows all the current stored properties and values for the specified resource group in tabular and JSON format. In addition to the Properties tab, the *More details* page also contains Related resources and Related applications tabs.

  ```
  **Tip:** If a property has been excluded from view by an administrator, it is removed from the tabular view, but remains visible in JSON format.
  ```

- Click the resource group name to open a topology view of the resource group.

  The topology shows you all the resources that make up your resource group and how the resources are connected. You can use this interactive tool to drill into individual resource detail and status, enable timeline to view changes over time, and more.

  For more information, see Managing topologies.

  Note When viewing a resource groups as a topology, you can click **View Legend** to open a Help panel that describes the visual elements, such as symbols, icons and line styles, that are used in the rendering of the topology. You can also click the **Tabular view** button to switch from a topology view to a table view.

- Click **Choose a historical time** on the toolbar to view resource groups at a historical point in the past (the default selection is **Show current data**.)

  Choose a specific date and time in the past, and click **Apply**.

The Resources tab

The Resources tab of the *Resource management* page lists all available resources by name, icon, status, type, tags and business criticality in the 'All resources' table. You can view them as topologies, assign them a predefined business criticality, compare resource details, or open the *Resource details* window to display all resource information.

Optionally, you can list deleted resources.

Resource details displayed:

- The overall status of the resource
- The creation date
- The last updated date
- Any associated tags
- Any business criticality set
- A link to a resource map (if defined)
- A link to **More details**. You can also access more details from the overflow menu to display a sidebar that shows all the current stored properties and values for the specified resource in tabular and JSON format. The details also indicate the data origin, such as observer and observer job name, status, related and neighbor resources and relationships, and location (if defined).

  Tip: If a property has been excluded from view by an administrator, it is removed from the tabular view, but remains visible in JSON format.
- Click **Compare resources** on the overflow menu to open the *Compare resources* dialog. From here, you can search for and select a second resource to compare properties in table format.
- Click a resource name to display it as a topology view.

  From this view, you can drill into individual resource detail and status, enable the historical timeline to view changes over time, and more.

  For more information, see Managing topologies.

  Note When viewing a resource as a topology, you can click **View Legend** to open a Help panel that describes the visual elements, such as symbols, icons and line styles, that are used in the rendering of the topology. You can also click the **Tabular view** button to switch from a topology view to a table view.
- Click **Choose a historical time** on the toolbar to view resources at a historical point in the past (the default selection is **Show current data**.)

  Choose a specific date and time in the past, and click **Apply**.

Defining and editing applications (services)

You can define and edit applications by adding (or removing) resource groups, icons and tags, assigning business criticality levels, and setting application disruption costs.

Remember: Beginning with IBM Cloud Pak for AIOps version 4.7.1, you can configure the UI to label your groups-of-groups collection of resources as either 'applications' or 'services'. For more information, see the following tip on changing terminology.

The following tasks are documented here:

- Defining an application
- Editing an application
- Assigning business criticality
- Adding estimated costs for service disruption
- Deleting an application

Before you begin

- Ensure that you have your system set up with your required inventory integrations, such as for Kubernetes, VMware, or Instana, completed and working. These integrations provide the topological resource data for your applications.
- (Optionally) ensure that business criticality definitions have been created by an administrator user so that you can assign them to an application. This is described in the Defining business criticality topic.
- Ensure that groups of resources are created within your system and are available on the *Resource management* page.

- Resource groups are used to manage specific resources. You can have resource groups within an application and also separate from any application. These groups can be from different sources.
- Resource groups can be created and managed through a connected inventory provider, such as Kubernetes, VMware, or Instana, or through a group template. The resources within a group must be created and managed through the integration with the inventory provider.
- If you need to change the resources within a resource group, do not directly manipulate your group. Use the group template or manage the group within the connected inventory provider.
- When created and available, resource groups display on the *Resource groups* tab of the *Resource management* page and included within applications.

- **Remember** that you can use the searching and filtering functionality to identify and gather the components to include in your applications. For instance, you can define filter conditions to display the resources that have a specific tag applied to them. For more information, see Resource management: Searching and filtering.

About Instana applications

Instana applications are identified by their logo and tag, as well as by their second entity type of **`aiopsManagedApplication`**; however, they cannot be deleted. Instana resource groups cannot be removed from an Instana application, but any user-added resource groups or tags can be removed, and the icon can be changed.

Defining an application

Defining an application involves selecting the groups of resources to compose the application, previewing the application, and then adding any additional details as required.

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**. You can select either the **Applications**, **Resource groups** or **Resource** tabs.
3. Click **Define application**. The page for defining an application is displayed.
4. Select the groups of resources that you want to include in the application.

   When you select a group, the group name is added to the sidebar. This sidebar shows all of the groups that you have selected for the application.

   You can browse through the table of resource groups to select groups or use search to find specific groups. You can search for groups by name, by the group type, or by tags to view similar groups. Use search to narrow the results to help you find specific groups. By default the results display the first results in the system. As you enter a search term, the results are narrowed down based on your entered term. The auto-suggest menu also displays suggested terms based on existing groups.
5. Click **Next** to preview the application.

   When you preview an application, you can use the left checkbox to deselect resource groups on the sidebar in order to visualize your application without those groups. To fully remove any superfluous resource groups from the application, use the **X** to the right of the resource group.
6. Click **Next** to add additional details.
   - Enter a name for the application.
   - Set an icon for the application by using the drop-down list. This icon is used to identify the resource type in the topology view of your applications.
   - (Optional:) Mark the application as a favorite.
   - (Optional:) Select any tags for classifying the application. Tags can be used to identify similar applications and to distinguish applications from other applications. To add a tag, you need to search for the tag by name and then select the tag. To create a new tag, type the tag and then select the **Create tag** option in the dropdown.
   - (Optional:) Select a business criticality from the **Select business criticality** drop-down list.
   - (Optional:) Enter an estimated disruption cost in the form of a numerical value in the **Estimated cost per minute for service disruption** box.
   - (Optional:) Remove any groups that you do not want in the application.
7. Click **Define application**. The application is added to the list of all applications on the page, and if selected, to the list of favorite applications.

After the application is defined, you can view the application in the list of applications on the *Resource management* page. You can also view the application details page to see the status and topology, and any associated incidents for the application. For more information, see Viewing applications.

Editing an application

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**, then select the **Applications** tab.
3. In *Favorites* or *All application results*, find the application that you want to edit. You can use pagination or the search field to find the specific application.
4. Click the options (3-dot icon) for the application entry in the table. From the menu, click **Edit application**. The *Edit application* page is displayed.
5. Edit the groups of resources, then preview the application. Edit any additional details as required.
6. After you complete your changes, click **Update application**.

Assigning business criticality

Note: If you do not want to assign the default business criticalities, bespoke definitions must first be created by an administrator user as described in the Defining business criticality topic.

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**, then select the **Applications** tab.
3. In *Favorites* or *All application results*, find the application that you want to edit. You can use pagination or the search field to find the specific application.
4. Click the options (3-dot icon) for the application entry in the table. From the menu, click **Assign criticality**. The *Assign business criticality* dialog is displayed.
5. Select a pre-defined business criticality from the drop-down list. **Remember:** Custom definitions can only be created by an administrator, as described in Defining business criticality.
6. Click **Save** to set the priority level for your application.

Adding estimated costs for service disruption

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**, then select the **Applications** tab.
3. In *Favorites* or *All application results*, find the application that you want to edit. You can use pagination or the search field to find the specific application.
4. Click the options (3-dot icon) for the application entry in the table. From the menu, click **Edit application**.
5. In the *Edit Application* page, click the *Add Details* tab.
6. Enter a numerical value in the *Estimated cost per minute for service disruption (optional)* box. This value is used to chart disruption costs in the **AIOps Insights** dashboard. For more information, see AIOps Insights dashboard.

Deleting an application

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**, then select the **Applications** tab.
3. In *Favorites* or *All application results*, find the application that you want to delete. You can use pagination or the search field to find the specific application.
4. Click the options (3-dot icon) for the application entry in the table. From the menu, click **Delete service**. (Reminder: Instana applications **cannot** be deleted. The delete function is grayed out.)
5. On the *Confirm delete* dialog, click **Delete application** to confirm the deletion. The application is deleted and no longer displays in the list of all applications. The groups and resources that composed the application are not deleted.

Managing topologies

You can render, view, and manipulate topologies for applications (services), resource groups and resources to help you better understand how they are constructed. You can also configure the topology views to customize the display of topology elements, and add custom elements and tools.

Remember: Beginning with IBM Cloud Pak for AIOps version 4.7.1, you can configure the UI to label your groups-of-groups collection of resources as either 'applications' or 'services'. For more information, see the following tip on changing terminology.

- Rendering a topology
- Viewing a topology
- Templates types
- Defining business criticality
- Running data administration routines
- Configuring topology user preferences
- Configuring topologies

Rendering (visualizing) a topology

You define the scope of the topology that you want to render by specifying a seed resource, the number of relationship hops surrounding that resource, as well as the types of hops. The topology service then supplies the data that is required to visualize the topology.

Before you begin

To visualize a topology, ensure that inventory integrations are configured.

Note: The IBM Cloud Pak for AIOps console has a default timeout set at 30 seconds. If service requests are not received in that time, a timeout message is shown, as in the following example:

```
A time-out has occurred. No response was received from the Proxy Service within 30 seconds.
```

For more information, see Topology render timeout.

For more information about Building custom topology, see Building custom topology.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. Open the *Resource management* page from the main navigation menu.

   Resources are displayed arranged in *Applications*, *Resource groups*, and *Resources* tabs.
3. Find a resource to use as the seed resource of the topology visualization.

   As you type in a search term that is related to the resource that you want to find, such as name or server, a drop-down list is displayed. This contains the suggested search terms that exist in the topology service. If the resource that you want to find is unique and you are confident that it is the first result in the list of search results, you do not need to select a result from the suggested search terms. Instead, choose to click the **View topology for closest matching resource** icon in the **Suggest** drop-down. This renders and displays the topology for the closest matching resource.

   For more information about advanced query syntax, see the topology query reference topic.

   For more information on searching and filtering, see the Resource management: Searching and filtering topic.

   If you select one of the suggested results, the Search Results page is displayed listing possible resource results. The Results are listed under separate **Resources** and **Groups** tabs.

   - Deleted resources

     You can select the **Include deleted resources** toggle in order to include deleted resources in the Results page (unless an administrator has disabled that feature). Deleted resources are marked as such, and the date and time that they were deleted is displayed.

     If you click **View topology**, the resource is displayed in the Topology Viewer with the history timeline open, and set to 1 ms before deletion. When closed, the topology is cleared.

When you search for resources with a previous point in time set in the history timeline, deleted resources are **not** returned and the toggle to include them is not available.

Deleted templates or defined topologies are **not** included in any search results.

- Groups

  Groups **must** be defined before they are listed. If you are defining Group templates in the template builder, search results are listed under separate **Resources** and **Groups** tabs.

  To designate as a favorite a group search result and add it to the collection of topologies accessible from the *Resource management* page, tag it as a favorite by selecting the **Add to favorites** icon next to it.

For each result, the name, type and other properties are displayed.

If a status other than clear exists for a search result, the maximum severity is displayed in the information returned. Also, a color-coded information bar before each result displays all non-clear statuses (in proportion).

You can expand a result in order to query the resource or defined topology further and display more detailed, time-stamped information. Examples of this include its state and any associated severity levels, or when the resource was previously updated or replaced (or deleted).

You can click the **View Topology** button next to a result to render the topology.

Restrictions:

- When you load a predefined topology, it is displayed in a 'group' version of the Topology viewer, which has restricted functionality. You are unable to follow its neighbors, or change its hops, or use its advanced filters.
- You can recenter the defined topology from the context menu, which loads it in the Topology viewer with all its standard functionality.

4. Select a number between one and four to define the number of relationship hops to be visualized from the seed resource. The default value is set at `1`.

   For more information about customizing the maximum hop count, see Configuring advanced settings.

5. Choose one of the following hop types:

   - The **Host to Host** hop type uses an aggregate traversal across elements with the entity type 'host' to generate a view that shows host to host connections.
   - The **Element to Element** hop type (default) performs the traversal by using all element types in the graph.
   - The **Element to Host** hop type provides an aggregated hop view like the 'Host to Host' type, but also includes the elements that are used to connect the hosts.

   For more information about customizing the hop type, see Configuring advanced settings.

6. Filter the topology before rendering it.

   Open the Filter toolbar by using the **Filter** toggle, and apply the resource, relationship, or severity filters required. You can filter resources that are displayed in the topology, or set filters before rendering a topology to prevent a large, resource-intensive topology from being loaded. If a filter is applied to a displayed topology, the text 'Filtering applied' is displayed in the status bar under the topology.

   For more information about using filters, see Viewing a topology.

7. Click **Render** to render the topology.

The *Topology viewer* connects to the topology service and renders the topology. By default, the view is refreshed every thirty seconds, unless specified otherwise.

What to do next

Next, you can refine and manipulate the view for further analysis.

If needed, you can rebuild a topology. For instance, open a topology and use the visualization tools to modify the topology settings and then clicking **Render**. This action runs the topology visualization to render the topology based on your new settings.

Troubleshooting: Topology render timeout

If you receive a timeout message, this can be due to a number of reasons:

- Large amounts of data being retrieved for complex topologies
- Too many hops counts specified
- Issues with the back-end services

Workarounds

- Check that all services are running.

  You can verify that the containers are running by using the following command:

  ```
  oc get pods -n <namespace> | grep <pod_name>
  ```

  The system should return text indicating that all containers have a state of Up.

- Increase the timeout when rendering topology views. The Red Hat OpenShift route used when rendering topologies in the UI has a default timeout of 30 seconds, which might not be long enough to render a large or complex topology view. To increase the timeout value, for example to 300 seconds, add the following code to the spec section of the custom resource of the operator (which is usually the **asm** instance; you can find the instance name using the **oc get asm** command):

  ```
  spec:
     helmValuesASM:
        global.asm.uiApi.topologyServiceTimeout: 300
        global.asm.uiApi.layoutServiceTimeout: 300
  ```

  The up-api pod should restart with the values of the environment variables TOPOLOGY_SERVICE_TIMEOUT and LAYOUT_SERVICE_TIMEOUT now set to 300 seconds.

- You can list the routes by using the **oc get routes** command. To increase the timeout for the UI change, use the following example:

  ```
  oc annotate route noi-ui-api --overwrite haproxy.router.openshift.io/timeout=300s
  oc annotate route noi-ibm-hdm-common-ui-uiserver --overwrite haproxy.router.openshift.io/timeout=300s
  ```

- Lower the hop count to reduce the service load. For more information about customizing the maximum hop count, see the Defining advanced topology settings topic.

Troubleshooting: No results found

When you enter text into the **Resource management** field, surround the text with quotation marks, such as in **"Search value"**. If the quotation marks are omitted, topology viewer doesn't display results even if the search value was included as data.

Building custom topology

Custom topology can be added to the system by using the File and REST SDK observers. These resources can be merged with data from the other observers.

Topology model

The basic topology model consists of the following items:

- Resources can be used to represent anything, such as network elements, software, and people.
- Edges are the relationships between resources.
- Groups collect resources to allow them to be easily viewed and to provide topological correlation.
- Applications or services are a collection of groups.
- Status indicates that alarms are mapped to a resource.

Topology model `partOf` edges

The **partOf** composition edge from child resources to parents is a special case. This edge is not visible in the resource management view and associated configuration. The edge is used for Host to host and Element to host resource management views. The edge is considered when you match the alerts to resources. An alert that is matched against a part of the child is also seen against the parent.

The **partOf** edges have the following limitations:

- A **partOf** relationship is a relationship from many children to a single parent.
  - A child cannot have multiple parents.
- A parent cannot be **partOf** another parent.

Resource lifecycle

Each resource or group within the scope of a provider has a lifecycle that is managed by the job that modeled it. Load jobs are expected to take snapshots of the entire system. If a load job finds the resources X, Y, Z on one run, and the next run finds resources A, B, X, then Y and Z are deleted. The listener jobs need to explicitly delete resources.

Resource lifecycle APIs:

- The `insertReplace` PUT method removes any properties that are not listed.
  - The exception is a placeholder with only **uniqueId** and **_references** properties.
- The `insertUpdate` POST method adds to the existing properties of the Topology model.

Edge lifecycle

To maintain the edge lifecycle, keep the following items in mind:

- Model edges by using **_references** nested within a resource.
- Always use `insertReplace` PUT method semantics.
- Model edges in a consistent direction.
- Edge type and direction per resource provides the replacement scope.
- With the `insertReplace` PUT method, all the edges of the same edgeType and direction are replaced.
- Direction is implied by **_toUniqueId** or **_fromUniqueId**, or use **using _direction** to remove all edges.
- The edge lifecycle can be maintained independently of properties by using a payload with only the **uniqueId** and **_references** properties.

Edge deletion

Edges can be deleted in multiple ways.

For example, if a resource X is defined with an outgoing *uses* edge to another:

```
"_references":[{"_edgeType":"uses","_toUniqueId":"Y"}]}
```

This edge is deleted if:

- Either the `X` or `Y` end is deleted.
- `X` is replaced with:

  ```
  "_references":[{"_edgeType":"uses","_toUniqueId":"not Y"}]
  ```

- `Y` is replaced with:

  ```
  "_references":[{"_edgeType":"uses","_fromUniqueId":"not X"}]
  ```

Note: The following examples show the syntax to remove all the edges of that type and direction.

- `X` is replaced with:

  ```
  "_references":[{"_edgeType":"uses",”_direction":"out"}]
  ```

- `Y` is replaced with

  ```
  "_references":[{"_edgeType":"uses",”_direction":”in"}]
  ```

Viewing topologies

A topology is a graphical representation of an application (service), or a resource group, or an individual resource. When you render a topology, it displays all of the constituent elements and relationships that make up your topology, and then lets you refine and manipulate the view.

You can use the interactive topology tools to drill into the individual resource details and status, enable a timeline to view changes over time, and more. You can also use this view to triage issues when an incident occurs.

When you view a topology, you can zoom in and out of specific areas of the topology or pan across it in various ways. You can auto-fit the topology into the available display window, draw a mini map, or redraw the entire topology. You can also filter your types of resources that are displayed, or your types of relationships that are rendered.

Tip: While viewing a topology, you can click **View legend** to open a Help panel that describes the visual elements used in the display of the topology. Alternatively, you can click **Tabular view** to display the topology of an application or resource group in table format instead.

Severity status

Severity status icons

Icon	Severity
	clear
	indeterminate

Icon	Severity
	information
	warning
	minor
	major
	critical

You can manipulate the topology by using a number of tools:

- To view a topology
  - Modifying the presentation
  - Tabular view
- Visualization tools
- Interacting with a topology

Before you begin

To view a topology, it must be defined first. For more information about creating a topology, see Rendering (visualizing) a topology.

The following procedure details how to view topologies for applications, resource groups and resources. For more information about creating applications, see Defining and editing applications.

About this task

You view a topology from the **Resource management** page.

To view a topology

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**.

   On the *Resource management* dashboard, applications, resource groups and resources are presented on separate tabs. In addition, the dashboard is divided into 'All applications results' and 'Favorites' sections. You can display favorite applications and resource groups either as cards or in a table. Resources are always displayed in a table, and cannot be designated as favorites.
3. To view an application, resource group or resource as a topology, click the name. Alternatively, use Search.

   - **Search:** As you type in a search term, such as a name, tag, entity type or unique Id, a drop-down list is displayed with suggested search terms that exist in the topology service. If you select one of the suggested results, the Search Results page is displayed listing possible resource results that match the selected search term. The Results are listed under separate tabs.

     - If the resource that you are searching for is unique, the resource can be included in the drop-down list of suggestions. If you are confident that the listed suggestion is the resource that you are searching for, you can click the **View topology for the closest matching resource** icon in the drop-down list to render the topology for the closest matching resource to that suggestion.
     - **Optional:** If the resource that you are looking for might be deleted, you can select **Include deleted resources** (unless an administrator disables this feature). When this toggle is enabled, the search results include any deleted resources. Deleted templates or resource groups are **not** included in any search results. Deleted resources are marked as deleted and include the date and time that they were deleted. If you click **View topology**, the resource topology is displayed with the history timeline open. The timeline is set to 1 ms before the resource was deleted. When you close the timeline, the topology is cleared. When you search for resources with a previous point in time set in the history timeline, deleted resources are **not** returned and the toggle to include them is not available.
     - For each serch result, the name, type and other properties are displayed. You can expand a search result entry for more details, such as its status and any associated severity levels, or when the resource was previously updated. If a status other than clear exists for a search result, the maximum severity is displayed.
     - **Tip:** You can perform more complex searches, such as searching with multiple search terms. For more information about advanced query syntax, see the topology query reference topic.

Viewing and modifying the topology presentation

When you view a topology, you can zoom in and out of specific areas of the topology, and pan across it in various ways. You can auto-fit the topology into the available display window, draw a mini map, redraw the entire topology, or filter the types of resources displayed or the types of relationships rendered.

Incidents: The topologies of applications (services) and resource groups are displayed with the Incidents panel open on the right hand side, which you can collapse to increase the topology display area. If you switch to a tabular view and use the Incidents panel functionality to sort or

filter the incidents, the table is dynamically updated to display only the resources affected by the selected incidents.

Tip: Click **View Legend** to open a Help panel that describes the visual elements that are used in the rendering of the topology (such as lines styles, icons, and symbols).

Tip: By default, a topology is displayed in graphical view format. Click the **Tabular view** button to switch to a table view, or the **Map view** button to view the topology resources displayed on a map.

Information bar: A bar at the bottom of the topology visualization displays the status of the rendered topology, including a timestamp on the left to indicate the time of the most recent refresh. If two time periods are being compared, both are indicated. Additional information on the right side of the information bar indicates the number of resources that are rendered, and the number of associated relationships. The bar also indicates whether any of the resources or relationships were added or removed since the last refresh, and whether a filter is applied.

When changes are made to a topology, the following conventions are used to identify the changes:

- Deleted resources

  A minus icon indicates that a resource was deleted since the topology was last rendered. This icon displays when a topology is updated, and within the history views.

- Added

  A purple plus icon indicates that a resource was added since the topology was last rendered. This icon displays when a topology is updated, and within the history views.

- Added (neighbors)

  A blue asterisk icon shows that a resource was added by using the 'get neighbors' function.

You can manipulate the topology by using a number of tools. Depending on whether you are viewing the topology for a resource, resource group or an application, the tools that are available can be different.

Tabular view

If you click **Tabular view** to display the topology in table format, it lists the **`Name`**, **`Type`**, **`Resource alerts`**, **`Tags`** and **`Business criticality`** (if defined) for each resource. The (collapsable) Incidents panel on the right of the topology is open by default.

- **Tip:** If you use the Incidents panel functionality to sort or filter the incidents, the table is dynamically updated to display only the resources affected by the selected incidents.
- You can also dynamically filter the table by creating a filter, using a predefined filter or by typing names, types or tags into the **`Search`** field.

  Note: Elements that are not displayed when viewing resources in table format, such as relationship types, are not available for filtering.

- You can display resources at a historical point in the past by clicking **Choose a historical time** on the toolbar. From the *Choose a historical time* dialog, select a new moment in time up to the data retention limit set for your system (the default is thirty days in the past). If you return to the current time, the data is refreshed.

  Tip: If you switch back from a tabular to a topology view, the time pin has moved according to the historical date you have selected.

- You can click **`Resource details`** on the overflow menu to open the *Resource Details* window.
- You can perform a number of additional context-dependent activities from the overflow menu of each displayed item in the table, such as viewing comments, showing the item in a map, assigning business criticality, opening it in the topology viewer, or building a template.

Tip: You can share a link to the application (or resource group) in tabular format with other users.

Tabular view overflow menu

The overflow menu (the three dots next to each table entry) gives you access to the following functionality:

- Click **Resource details** on the overflow menu.

  The *Resource details* page has a number of tabs.

  Properties: Displays a window that shows all the current stored properties for the specified resource in tabular and JSON format. If a property has been excluded from view by an administrator, it is only visible in JSON format. The resource name is an active link that opens a topology view of the resource in context. Toggle the Show JSON switch On or Off to display the properties in JSON format.

  Alerts: Displays a dialog that shows the time-stamped statuses related to the specified resource in table format.

  Data origin: Displays the point of origin of the resource data, such as a specific observer job. If you have the appropriate user permission, such as the administrator role, the observer job name is an active link, which opens the observer job page from where you can re-run the job, view its history, or edit the job.

Related applications: Displays all related applications as active links, which open the service topologies in new windows. Also lists the group type, number of groups, status, and tags.

Related resource groups: Displays all related resource groups as active links, which open the resource group topologies in new windows. Also lists the resource type, number of resources, status, and tags.

Neighbor resources: Displays all neighboring resources in a table. Click a resource name to open the details page for the resource.

Location: Opens a map in which the resource is geo-located.

Structure view: Displays all resources that are part of a host or parent resource.

- Click **Resource alerts** on the overflow menu to access the *Resource details* page for the selected resource with the Alerts tab selected.
- Click **View related incidents** on the overflow menu to display related incidents for the selected resource on the Incidents panel.
- Click **Comments** on the overflow menu to access the commenting functionality.

  When selected, this displays any comments recorded against the resource. By default, resource comments are displayed by date in ascending order. You can sort them in the following way:

  - Oldest first
  - Newest first
  - User Id (A to Z)
  - User Id (Z to A)

  Users with the appropriate permissions can view or add new comments.
- Click **Assign business criticality** on the overflow menu to define business criticalities for the selected resource.
- Click **Build a template** on the overflow menu to opens the *Create a new template* dialog, from where you can create a new resource group template.
- Click **Compare resources** on the overflow menu to select a second resource for side-by-side comparison in a table.
- Click **Open in Topology viewer** on the overflow menu to open a resource as a topology view.

  From here, you can drill into individual resource details and status, enable a timeline to view changes over time, and more. You can also use this view to triage issues.
- Click **Show on map** on the overflow menu to display the resource on a map.

Map view

The map view displays the topology elements on a map. For more information, see Viewing resources on a map.

Vizualisation tools

A number of tools and functions let you manipulate the topology presentation.

Refresh rate

You can expand the **Refresh rate** drop-down field to select your preferred refresh rate or to pause the option. This rate determines when the topology page auto-updates to search for and include new changes.

You can pause the topology data refresh, or specify the following values: 10 seconds, 30 seconds (default), one minute, or five minutes.

Refresh

You can click **Refresh** to manually refresh the topology data, which also clears all user-specific session data.

About this application

Opening this twisty displays a summary for the selected application topology, such as the date and time it was created, the associated groups and whether any have been added, any tags and business criticalities associated with it, and the date and time it was last updated.

About this resource group

Opening this twisty displays a summary for the selected resource group topology, such as the date and time it was created, the associated applications and whether any have been added, any tags associated with it, and the date and time it was last updated.

Filters

You can either use a predefined filter by selecting it from the **Select a filter** drop-down, or create a new one by clicking the **Open filter** icon and defining new filter conditions.

For more information, see the searching and filtering topic.

Search

While viewing a topology, the Search functionality remains available. As you type in a search term, a drop-down list is displayed that includes suggested search results for the currently rendered topology and other topology entries from the topology database. You can search by name, tag, uniqueId, or entity type.

Tip: If you hover over a search result, the resource is highlighted in the topology window. When you click a search result, the topology highlights the selection and direct relationships, and search is closed.

For more information, see the searching and filtering topic.

Settings

From this menu, you can select to open pages for managing the following types of settings:

- **Topology configuration**

  You can configure the following topology elements to change how users can visualize, manipulate, and use topologies:

  - **Advanced settings**

    Control how the topology user interface works for all users.

  - **Topology tools**

    Create tools that can be accessed from within the topology's context menu.

  - **Resource types**

    Customize the style of your resources.

  - **Relationship types**

    Customize the style and label for relationships.

  - **Custom icons**

    Add custom icons for resources that are displayed in the topology.

  - **Rules**

    Define automated processing rules for your topology data.

  For more information, see Configuring topology elements.

- **Create exact template**

  Opens the *Using resource group templates* page already populated with the current view elements including the preview pane to the right of the Template builder. From here, you can create a new exact resource group template.

  Restriction: While viewing topologies, you can only create exact templates based on element-to-element topologies. The Create exact template option will not appear in the Settings drop-down for other views.

  Tip: As a further refinement, you can adjust your layout by manually positioning the resources in the topology, and this layout is then replicated when you generate a resource group from any exact template that you build from this topology.

- **User preferences**

  You can set your personal preferences for how topologies are rendered. The settings that can personalize are grouped into the following categories:

  - Updates

    These settings determine how and how often topologies are automatically updated.

  - Layout

    These settings determine the default presentation of topologies.

  - Miscellaneous

    Other settings, such as displaying messages, screen reader support, and troubleshooting.

  For more information, see User preferences.

Sharing options

You can share a topology either by obtaining a direct URL linking to the topology view, or by exporting a view of the topology as an image. To select a sharing option, click the **Sharing options** icon and then click your preferred option:

- **Obtain direct URL**

  This option displays the *Direct topology URL* dialog. This dialog includes a displayed URL, which captures the current topology configuration, including the layout type. The layout orientation is not tracked.

  Click the **Copy direct URL to clipboard** icon to the right of the URL to copy the direct-launch URL string for accessing the topology view. You can then share the URL with a colleague or use the URL to directly access the topology later.

  Then, click **Close**.

- **Export as PNG**

  Click this option to export a snapshot of the current topology in PNG format. The snapshot is automatically downloaded based on your browser download settings. By default, the file is saved as **`topology.png`**. You can now share the image as required.

- **Export as SVG**

  Click this option to export a snapshot of the current topology in SVG format. The snapshot is automatically downloaded based on your browser download settings. By default, the file is saved as **`topology.svg`**. You can now share the image as required.

Number of hops (resource topologies only)

The number of relationship hops to visualize from the seed resource. You can define the number of relationship hops to be performed, which can be from zero to four, unless this setting has been customized. The default is set at 'one'.

For more information about configuring the maximum hop count, see the Configuring advanced topology settings.

Type of hop (resource topologies only)

The type of graph traversal used. The options are:

- Element to element (default)

  This type performs the traversal by using all element types in the graph. If no hop type has been defined, a topology is rendered using the element to element hop type as default.

- Host to host

  This type generates a view showing host to host connections.

- Element to host

  This type provides an aggregated hop view like the Host to Host type, but also includes the elements that are used to connect the hosts.

  Tip: The URL allows you to set **`h2h`** for host to host, **`e2e`** for element to element, or **`e2h`** for element to host.

Render (resource topologies only)

This button causes the topology visualization to run to update a topology based on any changes to the topology or the navigation toolbar settings. This process integrates any new resources into the topology. Choosing this option recalculates the topology layout based on your current display settings, which can adjust the displayed topology significantly. Once the rendering is complete, the topology refreshes on a 30-second interval by default. You can pause the auto-update refresh, or select a custom interval.

Tip: The IBM Cloud Pak for AIOps console can time out when a large amount of data is being retrieved for rendering. For more information about how to address this issue, see Rendering (visualizing) a topology.

Delta

You can toggle the **Delta** button to show how your selected topology changes between two points in time.

Timeline

Use the **Timeline** toggle to open and close the History toolbar below the topology. This view shows how the selected resource changed over time. For more information about the details and how you can use this view, see Viewing topology history.

View legend

Click **View Legend** to open a Help panel that describes the visual elements that are used in the rendering of the topology, such as symbols, icons and line styles.

Topology view tools

A list of tool icons is displayed near the top right hand side. You can hover over some icons to display a submenu.

- **Select tool**

  Use this icon to select individual resources by using a mouse click, or to select groups of resources by creating a selection area (using click-and-drag).

- **Pan tool**

  Use this icon to pan across the topology by using click-and-drag on a blank area of the visualization panel.

- **Zoom Select tool**

  Use this icon to zoom in on an area of the topology by using click-and-drag.

- **Zoom In**

  Use this icon to zoom in on the displayed topology.

- **Zoom Out**

  Use this icon to zoom out of the displayed topology.

- **Zoom Fit**

  Use this icon to fit the entire topology in the current view panel.

- **Overview**

  Use this icon to create the overview mini map in the lower right corner. The mini map provides an overview of the entire topology while you zoom in or out of the main topology. The mini map displays a red rectangle to represent the current topology view. **Note:** In some browsers, the use of the mini map might cause performance issues when displaying large topologies.

- **Layout**

  Use this icon to recalculate, and then render the topology layout again. You can choose from a number of layout types and orientations.

  - Layout 1

    A layout that displays all resources in a topology without applying a specific layout structure.

  - Layout 2

    A circular layout that is useful when you want to arrange a number of entities by type in a circular pattern.

  - Layout 3

    A grouped layout is useful when you have many linked entities, as it helps you visualize the entities to which a number of other entities are linked. This layout helps to identify resource groups of interconnected entities and the relationships between them.

  - Layout 4

    A hierarchical layout that is useful for topologies that contain hierarchical structures, as it shows how key vertices relate to others with peers in the topology being aligned.

  - Layout 5

    A peacock layout is useful when you have many interlinked vertices, which resource group the other linked vertices.

  - Layout 6

    A system board rank layout is useful when you want to view how the topology relates to a vertex in terms of its rank, and also how vertices are layered relative to one another.

  - Layout 7

    A rank layout is useful when you want to see how a selected vertex and the vertices that are immediately related to that rank relative to the remainder of the topology (up to the specified number of hops). The root selection is automatic.

    For example, vertices with high degrees of connectivity outrank lower degrees of connectivity. This layout ranks the topology automatically around the specified seed vertex.

  - Layout 8

    A root rank layout similar to layout 7, except that it treats the selected vertex as the root. This layout is useful when you want to treat a selected vertex as the root of the tree, with others being ranked below it.

Interacting with a topology

A displayed topology consists of resource nodes and the relationship links connecting the resources. You can interact with these nodes and links. You can use the topology to also view critical issues and interact with the related resource nodes to troubleshoot the issue.

You can select, move, and view more options for managing nodes and the associated resources.

- Select a node

  Selecting a node highlights that node, and emphasizes its first-order connections by fading all other resources.

- Move a node

  Click and drag a node to move it.

- View the context menu

  Right-click a node to view the context menu. From this menu you can select more options for viewing details and managing the topology. For the included options, see Context menu

Context menu

You open the context menu by using the right-click function. The context menu provides access to the resource-specific actions that you can perform.

For resource entities, you can access the following context menu items:

- Resource details
  - Alerts
  - Structure view
- Comments
- Assign criticality
- Compare resources
- Build a template
- Get neighbors
- Follow relationship
- Show last change in timeline
- Show first change in timeline
- Find path
- Recenter View

Resource details

Note: The details dashboard is accessed either from the topology context menu or the Resource management dashboard. Some items may be unavailable.

If opened from the Resource management tool in the UI, the resource name is an active link that opens a topology view of the resource in context, provided you have the correct user permissions (the **`waiops_manage_integrations`** or **`waiops_view_integrations`** permissions).

If a map has been defined, the Map link next to the resource name opens the Resource map view. When selected while viewing a topology history with delta mode On, the Resource details window displays the properties of the resource at both the reference time and at the delta time. 'Related services' and 'Related resource groups' are only displayed when not in historical mode.

Properties tab: Displays all the current stored properties for the specified resource in tabular and JSON format. If a property has been excluded from view by an administrator, it is removed from the tabular view, but remains visible in JSON format.

Tip: Toggle the **Show JSON** switch On or Off to display the properties in JSON format.

Alerts tab: Displays a dialog that shows the time-stamped statuses related to the specified resource in table format. The Severity and Time columns can be sorted, and the moment (that is, the historical time point) that Resource status was selected is also time-stamped.

You can use the **Show active only** toggle to remove inactive statuses. In addition, if any status tools have been defined, the status tool selector (three dots) is displayed next to the resource's statuses.

Click the status tool selector to display a list of any status tools that have been defined, and then click the specific tool to run it. Status tools are only displayed for the states that were specified when the tools were defined. The severity of a status ranges from 'clear' (white tick on a green square) to 'critical' (white cross on a red circle). For the list of status, see the Severity status table.

Tip: If statuses related to a specific resource are available, the resource is marked with an icon depicting the status severity level, and the Resource status tab will appear on the Resource details window, accessible through the resource context menu.

Data origin tab: Displays the point of origin of the resource data, such as a specific observer job. If you have the appropriate user permission, such as the administrator role, the observer job name is an active link, which opens the observer job page from where you can rerun the job, view its history, or edit the job.

Related applications tab: Displays all related applications as active links, which open the application topologies in new windows. Also lists the group type, number of groups, status, and tags.

Related resource groups tab: Displays all related resource groups as active links, which open the resource group topologies in new windows. Also lists the resource type, number of resources, status, and tags.

Neighbor resources tab: Displays all neigboring resources and their names, relationships and types, alerts (max severity only) and tags.

Location tab: Opens a map in which the resource is geo-located. Zoom functions are enabled, though the map is limited to the More details dialog. To open the full map, use the Map link next to the resource name.

Structure view tab: Displays all resources that are part of a host or parent resource (such as a device), which are linked together in a relationship via the 'partOf' edge regardless of their position; that is, it displays linked resources even if they are several hops removed from one another or from the host (parent) resource.

The Structure view tab displays all the current stored properties for a selected resource on the right in tabular and JSON format (as for the properties tab), with an additional breadcrumb above the details showing its distance from its parent resource.

On the left, a resource tree is shown, expanded to the resource from which the structure view was opened, with the parent resource at the highest level. The highest severity resource status is shown next to the name, although if a status is shown in parenthesis, the status applies to a resource nested at a lower level.

You can click on a resource name to open a topology view of the resource and its parent resource. When you display a parent resource, all resource linked to it via the partOf edge are also depicted. If you activate the Problem view toggle, all resources with no reported issues are filtered out.

Comments

When selected, this displays any comments that are recorded against the resource.

By default, resource comments are displayed by date in ascending order. You can sort them in the following way:

- Oldest first
- Newest first
- User ID (A to Z)
- User ID (Z to A)

To add a comment, enter text into the New Comment field, and then click **Add Comment** to save.

Assign criticality

Business criticality sets the priority level for a resource (or application, or resource group).

To assign a priority, select a definition from the **Business criticality** drop-down, then click **Save**.

Remember: Business criticality definitions must be created by an administrator user before you can assign them to a resource. This is described in the Defining business criticality topic.

Compare resources

You can select two resources and their properties for side-by-side comparison, with different values highlighted.

In Resource management, select the Resources tab, and next to a resource to be compared (Resource A), click **Compare resources** from the overflow menu.

The *Compare resources* page opens with the standard details for Resource A displayed in a table.

Note: Alternatively, you can launch the *Compare resources* page from a specific resource's context (right-click) menu in the topology viewer.

Use the **Search* field to identify and select a second resource (Resource B) for comparison.

The table displays the properties for Resource A and Resource B in adjacent table columns.

- Different property values are highlighted.
- If a historical time point was selected, the properties from that time point are displayed.

Build a template

Select the type of template to use to group resources

- Dynamic template

  This template automatically finds and updates multiple resource groups based on your criteria and how your services and infrastructure change.

- Tag based template

  This template creates and updates a single resource group containing the resources that have a specified set of tags.

- Exact template

For more information, see Resource group templates.

Get neighbors

When selected, a menu opens to display the resource types of all neighboring resources. Each resource type lists the number of resources of that type, and the maximum severity associated with each type.

You can click the menu option **Choose specific** to open a dialog to select specific resources that you want to add to the current topology visualization. You can also choose to include all neighboring resources. When you select a resource, a confirmation option displays for you to either **Add neighbors** or **Cancel**. After you select **Add neighbors**, **Undo** is available for you to undo the last add neighbor request.

Selecting **Get Neighbors** overrides any existing filters.

Follow relationship

When selected, opens a menu that displays all adjacent relationship types. Each relationship type lists the number of relationships of that type, and the maximum severity associated with each type. You can choose to follow all relationships, or only the neighbors of a specific type.

Show last change in timeline

When selected, this displays the history timeline, depicting the most recent change made to the resource.

Show first change in timeline

When selected, this displays the history timeline, depicting the first change made to the resource.

Find path

When you click the **Path tool**, the *Find path* dialog opens. From this dialog, you can define criteria for finding the shortest path between the currently selected resource and a second specified resource within the topology.

Within the **Path definition** section, you need to specify the start and end points (resources) for the path:

- **Path start resource**

  Identifies the selected resource from the topology.

- **Path end resource**

  Search for the resource that you want to use with the starting resource for calculating the shortest path.

Within the **Filters** section, specify the resource types and relationship types to include or exclude from the calculated path topology.

- **Filter mode**

  Choose to **Exclude** or **Include** the resource or relationship types from the path.

- **Resource types**

  Search for or browse the drop-down list of resource types and select any types to be included or excluded. The list includes all defined types.

- **Relationship types**

  Search for or browse the drop-down list of relationship types and select any types to be included or excluded. The list includes all defined types.

- **Maximum number of hops**

  The maximum number of hops you can permit when calculating the path. You can set the value at 1-30 hops. The default is 30 hops.

When you have completed your selections, click **Find path**. A browser tab for the Topology viewer tab opens and is labeled *Path topology*. The shortest path between the start and end resources is calculated and is shown on this *Path topology* tab. This view shows up to a maximum of five

paths. The time taken to calculate the shortest path depends on the complexity of the links between the selected resources. You can continue to work with the current topology while the path is being calculated and the associated topology rendered.

Within the path topology, the start and end resources are highlighted initially. When you hover over a link between any resources, all the paths that include those resources are highlighted.

If needed, you can further filter the displayed topology by using the Filter toolbar.

Recenter View

When selected, the displayed topology is updated from the specified seed resource to include any changes.

Viewing resources on a map

You can view a resource on a map, which gives you access to geospatial analysis functionality.

Before you begin

To geo-locate resources and view them on a map, your administrator must have previously defined a location tile server, and either created a file enrichment rule, or loaded resources with geolocation data another way, for example by using the File or REST observers.

About this task

You access a map from the *Resource* tab on the **Resource management** page, or the **More details** page accessed from the context meny in a topology

Restriction: A resource map is available only for individual resources, not for resource groups or services (applications).

Restriction: For composite resources, geolocation data should only be added to a single resource in the composite.

To view a resource on a map

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**. Open the *Resource* tab.
3. Find the resource you wish to view on a map, and click the **Map** link in the table (on the far right).

   Tip: You can also access a resource map from the *More details* page by clicking the map link next to the resource name. You can access a reduced map with limited functionality from the *More details* 'Location' tab, which is also accessed when you click the location pin in a map.
4. The Resource map gives you access to the following functionality:
   - Hover on the location pin to view a tooltip with the resource name, its icon and type.
   - Click the pin to open the More details page for the resource.
   - Use the mouse wheel (or **Zoom in** or **Zoom out** buttons) to zoom in or out. Alternatively, double-click on the map to zoom in.
   - Zoom out to view the selected resource as part of a cluster of nearby resources. The cluster ring matches the highest severity (status) of the grouped resources.
   - A cluster displays the number of resources it contains. When you hover your cursor over a cluster, the dispersal of resources is indicated as a shape.

   Tip: The granularity of a cluster, that it, the number of resources included in a cluster and at what pixel size, are customizable settings.
   - Click a cluster to zoom into the area of the clustered resources. Continue to drill down to the location pins of individual resources.
   - Use the Zoom fit button to adjust the size of the view to show all the visible locations based on the current viewing criteria.

Viewing topology history

You can view the history of a topology to compare and contrast the current topology with historical versions to see how the topology has changed.

Before you begin

You must have an existing topology. For more information about rendering a topology, see Rendering (visualizing) a topology.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**.

   On the *Resource management* dashboard, applications, resource groups and resources are presented on separate tabs. In addition, the dashboard is divided into 'All applications results' and 'Favorites' sections. You can display favorite applications and resource groups either as cards or in a table. Resources are always displayed in a table, and cannot be designated as favorites.
3. Search for the resource or resource group to find the topology that you want to view.

   As you type in a search term, such as a name, tag, entity type or unique Id, a drop-down list is displayed with suggested search terms that exist in the topology service. If you select one of the suggested results, the Search Results page is displayed listing possible resource results. The Results are listed under separate **Resources** and **Resource groups** tabs.

   - If the resource that you are searching for is unique, the resource can be included in the drop-down list of suggestions. If you are confident that the listed suggestion is the resource that you are searching for, you can click the **View topology for the closest matching resource** icon in the drop-down list to render the topology for the closest matching resource to that suggestion.
   - **Optional:** If the resource that you are looking for might be deleted, you can select **Include deleted resources** (unless an administrator disables this feature). When this toggle is enabled, the search results include any deleted resources. Deleted templates or resource groups are **not** included in any search results. Deleted resources are marked as deleted and include the date and time that they were deleted. If you click **View topology**, the resource topology is displayed with the history timeline open. The timeline is set to 1 ms before the resource was deleted. When you close the timeline, the topology is cleared. When you search for resources with a previous point in time set in the history timeline, deleted resources are **not** returned and the toggle to include them is not available.
   - For each result, the name, type and other properties are displayed. You can expand a search result entry for more details, such as its status and any associated severity levels, or when the resource was previously updated. If a status other than clear exists for a search result, the maximum severity is displayed.
   - **Tip:** You can perform more complex searches, such as searching with multiple search terms. For more information about advanced query syntax, see the topology query reference topic.
4. Click **View topology**.

Note When viewing a topology, you can click **View Legend** to open a Help panel that describes the topology's visual elements.

You can display and refine the topology history in a number of ways:

- Delta mode

  You can enable and disable delta by using the **Delta** toggle in the topology navigation toolbar.

  When Delta mode is **On**, differences in topology are displayed as purple plus or minus symbols next to the affected resource.

  When Delta mode is **On** with History mode **On**, you can compare two time points to view differences in topology. Historical change indicators (blue dots) are displayed next to each affected resource.

  Note: For efficiency reasons, historical change indicators are only displayed for topologies with fifty or fewer resources. You can decrease, but not increase, this default by changing the Historical Change Threshold. For more information, see Defining advanced topology settings.

  - Lock time pin

    On the timeline graph, click the **Lock** icon on a time pin's head to lock a time point in place as a reference point for the comparison. You can then use the second time slider to view topology changes in comparison to the locked point in time.
  - Compare resource properties

    Click **Resource details** on a resource's context menu to compare the resource's data at the two selected time points. You can view and compare the property names and values in table format, or raw JSON format.
- History timeline

  You open the Topology History toolbar using the **Timeline** toggle in the Topology Visualization toolbar (on the left).

Note: Resources with a large amount of history may take longer to display.

You use the time pins to control the topology shown. When you move the pins, the topology updates to show the current topology representation.

While in delta mode you can move both pins to show a comparison between the earliest pin and the latest. The timeline shows the historic changes for a single selected resource, which is indicated in the timeline title. You can lock one of the time pins in place to be a reference point.

When you first display the history timeline, coach marks (or tooltips) are displayed, which contain helpful information about the timeline functionality. You can scroll through these, or switch them off (or on again) as required.

To view the timeline for a different resource, you click it, and the heading above the timeline changes to display the name of the selected resource. If you click the heading, the topology centers (and zooms into) the selected resource.

The history timeline is displayed above a secondary time bar, which displays a larger time segment and indicates how much of it is depicted in the main timeline. You can use the jump buttons to move back and forth along the timeline, or jump to the current time.

You can use the time picker, which opens a calendar and clock, to move to a specific second in time.

To view changes made during a specific time period, use the two time sliders to set the time period. You can zoom in and out to increase or decrease the granularity using the **+** and **–** buttons on the right, or by double-clicking within a timeframe. The most granular level you can display is an interval of 1 second. The granularity is depicted with time indicators and parallel bars, which form **`buckets`** that contain the recorded resource change event details.

The timeline displays changes to a resource's state, properties, and its relationships with other resources. These resource changes are displayed through color-coded bars and dash lines, and are elaborated on in a tooltip displayed when you hover over the change.

You can exclude one or more of these elements from displaying:

- **Relationships**

  This toggle displays or hides the number of relationships with neighboring resources, and whether the relationships were changed. Examples of this include the removal or addition of a relationship, or the modification of an existing relationship.

- **State**

  This toggle displays or hides the number of resource state changes that a resource has undergone.

- **Property**

  This toggle displays or hides the number of times that resource properties were changed. Each time that at least one property was changed is displayed as one property change event regardless of whether one or more properties were changed at the time.

Viewing topologies with direct-launch URLs

You can view specific topologies using a direct-launch URL by setting the topology navigation settings in the URL parameters to directly load a specific topology configuration. This configuration gives you quick access to specific views.

You can obtain a direct-launch URL string from a topology in the IBM Cloud Pak for AIOps console, or create the URL manually.

Before you begin

To obtain a direct-launch URL from the Cloud Pak for AIOps console, complete the process of visualizing a topology. To share a direct-launch URL with other users, those users must have the appropriate role permissions.

About this task

A typical URL starts with the host URL (**`cluster_address`**) and the tenant ID:

`https://<cluster_address>/aiops/<TENANT ID>/topology-viewer`

The **`cluster_address`** is the Cloud Pak for AIOps console route. For more information, see Accessing your cluster by using the console.

Tips

- For filtering a topology, you can specify 'type', and include 'Advanced' resource or relationship filters in your URL (not available for 'Simple' filters).

- For setting conditions for filters, any filter conditions you set on the Resource management page are maintained in the URL, and can therefore be shared.

Example topology URL

```
https://cp-console-cp4aiops.apps.mycluster.mydomain.com/aiops/cfd95b7e-3bc7-4006-a4a8-a73a79c71255/topology-viewer?resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=1&layoutType=5&refreshTime=30000
```

This example URL includes the following parts:

- `resourceId` - Identifies the seed resource.
- `hops` - The number of hops from the seed to be included in the topology. In this example, the `hops` number is set at '1'.
- `layoutType` - Specifies the type of display. In this example, the layout type is `5`.
- `refreshTime` - Specifies how often the view is refreshed. In this example, the refresh time is set at `30000` ms (30 seconds).
- The hop type is 'element-to-element', which does not have to be specified as it is the default.

For more information about the layout type, see layout information in the topic Viewing a group or resource topology.

Tips: By specifying 'type', you can include **Advanced** resource or relationship filters in your URL, which are not available for **Simple** filters. For more information, see the filtering information in the topic Viewing a group or resource topology.

Procedure

Obtain a topology URL from the Cloud Pak for AIOps console

Once you render a topology in the Topology viewer, use the **Sharing options** drop-down to obtain a direct-launch URL string.

Define a URL manually

You can define a URL by editing the parameters, as shown in the following examples:

- Empty topology URL

  For a URL to open the Topology viewer with no configurations, use this type of URL:

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer
  ```

- Specify seed resource by ID in the URL

  To open the page and create a visualization from a specific seed resource by ID, use this format:

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceId=<resource_id>
  ```

- Specify seed resource by name in the URL

  To open the page and create a visualization from a specific seed resource by name, use this format.

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceName=<name>
  ```

- Specify seed resource and hops URL

  To open the page and create a visualization from a specific seed resource with a specific number of hops and hop type, use this format.

  The hopType parameter is only required if you use the host-to-host (that is, `host`) hop type (element-to-element is the default).

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceName=<name>&hops=<hops>&hopType=<host>
  ```

- Specify focus areas for large topologies in the URL

  When you load it, this topology view zooms in on the area specified, preventing very large topologies from being displayed with potentially too much information on view.

  The focusId parameter is required for the topology view to zoom into the area of a particular resource.

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceId=<resource_id>&hops=<hop number>&focusId=<resource_id>
  ```

- Specify more resources to be highlighted in the URL

  Specify an array of resource IDs to highlight more resources in the topology view. These selections override any already selected seed resource.

  The selectedIds parameter is required for the topology view to highlight non-seed resources when the topology is loaded.

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceId=<resource_id>&hops=<number>&selectedIds=["<resource_id>" "" …]
  ```

- Specify seed resource, hops and get neighbor expansions URL

  To open the page and create a visualization from a specific seed resource with a specific number of hops, as well as resource neighbors, use this format.

  This example sets the hop type as element-to-element, and it uses the parameter neighbourRequests, which expects an array of space separated ID strings.

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceName=<name>&hops=
  <hops>&neighbourRequests=["<resource_id>" "<resource id>" …]
  ```

- Specify search parameter (partial resource name) in the URL

  To open the page and create a visualization from a specific resource search value, use this format.

  - If a single resource is found that matches the search parameter, the resource is used as a seed and the topology is drawn.
  - If more than one resource is found that matches the parameter, the Search Results page is displayed listing possible results, including their names, types and other resource properties.
  - If no matches are found, an error message is displayed.

  This example searches for a resource by name, and will return results that match the name either fully or partially.

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?search=<name>
  ```

- Load topology using unique ID to set seed

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceUniqueId=<unique id>
  ```

- Load topology using advanced resource filters

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceFilter=["Type1" "Type2"]
  ```

- Load topology using advanced relationship filters

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?relationFilter=["Type1" "Type2"]
  ```

- Show topology at a specific point in time.

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceName=<name>..<any other
  configuration>..&time=<unixTimeMilliseconds>
  ```

- Show topology in delta history mode, with 'time' as a reference point and deltaTime as the point to delta against

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?resourceName=<name>..<any other
  configuration>..&time=<unixTimeMilliseconds>&deltaTime=<unixTimeMilliseconds>
  ```

- Load topology with side toolbar hidden

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?hideToolbar=<true>
  ```

- Load topology with top search bar hidden

  ```
  https://<cluster_address>/aiops/<TENANT ID>/topology-viewer?hideSearch=<true>
  ```

- Load topology using simple filters in the URL

  You can use simple filters to include specific resource or relationship types, or severities.

  simpleResourceFilter

  ```
  https://<ASM CORE HOST>/aiops/<TENANT ID>/federated/topology-viewer?resourceName=<name>..<any other
  configuration>..&simpleResourceFilter=type1,type2
  ```

  simpleRelationshipFilter

  ```
  https://<ASM CORE HOST>/aiops/<TENANT ID>/federated/topology-viewer?resourceName=<name>..<any other
  configuration>..&simpleRelationshipFilter=type1,type2
  ```

  simpleSeverityFilter

  ```
  https://<ASM CORE HOST>/aiops/<TENANT ID>/federated/topology-viewer?resourceName=<name>..<any other
  configuration>..&simpleSeverityFilter=clear,critical
  ```

  You can extend the use of these simple filters by activating 'Include mode' for a group using the following parameters:

  - includeResourceType
  - includeRelationshipType
  - includeSeverityType

  Examples:

```
https://<ASM CORE HOST>/aiops/<TENANT ID>/federated/topology-viewer?resourceName=<name>..<any other configuration>..&simpleResourceFilter=type1,type2&includeResourceType=true
```

```
https://<ASM CORE HOST>/aiops/<TENANT ID>/federated/topology-viewer?resourceName=<name>..<any other configuration>..&simpleRelationshipFilter=type1,type2&includeRelationshipType=true
```

```
https://<ASM CORE HOST>/aiops/<TENANT ID>/federated/topology-viewer?resourceName=<name>..<any other configuration>..&simpleSeverityFilter=clear,critical&includeSeverityType=true
```

What to do next

With direct-launch URLs for topology visualizations created, you can save the URLs for quick access to specific views, or share them with other users to provide them with specific, instant information.

Viewing static topologies with API

You can use the API to render a static topology view through a cURL command, which you then download as an image. You use the resourceId parameter to seed the topology, and then define a number of other parameters to generate a static server-side topology image.

Deprecation notice: The ability to use the UI-API to render a static topology view through cURL command is no longer being used and can be removed in a future release.

Before you begin

To define a cURL string that renders a topology through the API, you must know the URL for your core host. You must also know the resource ID for your seed resource, as well as the required authentication credentials.

About this task

The API is available on the following endpoints:

- `https://<host>/1.0/ui-api/render/svg`
- `https://<host>/1.0/ui-api/render/png`

After you construct your cURL command in the following steps, you can use the command to download a static topology view as either a PNG or SVG image.

In addition to the `resourceId` parameter, you can use a `Basic` authentication header when calling the API. With this header, you can call the API without needing to log in to the IBM Cloud Pak for AIOps console first.

Tips:

- You can use the width and height URL parameters (exclusively for use with the UI-API) to set the size of the image produced. The default size is `1000 x 700`.
- You can include advanced resource or relationship filters in your URL by specifying 'type'. For more information about topology filtering, see Viewing a topology.
- You can change the label length for your resource types. For more information, see Editing resource type styles.

Example URLs

- PNG example

  ```
  curl -X GET "https://example.host.com/1.0/ui-api/render/png?resourceId=sl1RQ5NCR_ykgciQCTkFGA" -H "accept: image/png" -H "authorization: Basic YXNtOmFzbQ=="
  ```

- SVG example

  ```
  curl -X GET "https://example.host.com/1.0/ui-api/render/svg?resourceId=sl1RQ5NCR_ykgciQCTkFGA" -H "accept: image/svg+xml" -H "authorization: Basic YXNtOmFzbQ=="
  ```

Where:

- The IBM Cloud Pak® for AIOps core host is `asm.example.host.com`
- The resourceId that identifies the seed resource is `sl1RQ5NCR_ykgciQCTkFGA`
- The output format is specified by either `png` or `svg`
- The authorization method is specified as `Basic`
- The encrypted user credentials (username and password) are `YXNtOmFzbQ==`

Procedure

1. Obtain your resource ID, authentication credentials, and host URL.
2. Define a cURL call by editing the parameters, as shown in the following examples.

Example commands

Specify a seed resource by ID

The following cURL call example renders a simple IBM Cloud Pak for AIOps topology view with a host URL of **example.host.com** and a port number of **3080**. The view is based on the **resourceId** parameter with the value of **sl1RQ5NCR_ykgciQCTkFGA**. It returns a **png** image, and performs **Basic** access authentication using the encrypted username and password credentials (**YXNtOmFzbQ==**).

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?resourceId=sl1RQ5NCR_ykgciQCTkFGA" -H
"accept: image/png" -H "authorization: Basic YXNtOmFzbQ=="
```

Specify the hop numbers and types

The image that is returned by this cURL call has the same seed resource as before, but now with the amount of **hops** set at **3**, and a **hopType** of **host**. The **hopType** parameter is only required if you want to use the host-to-host hop type (element-to-element is the default).

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?
resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=3&hopType=host" -H "accept: image/png" -H "authorization: Basic
YXNtOmFzbQ=="
```

Specify focus areas for large topologies

The image that is returned by this cURL call has the same seed resource as before (now with a hop count of three), but now zooms in on the area that is specified by the **focusId** parameter, preventing large topologies from being displayed with potentially too much information on view.

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?
resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=3&focusId=<resource_id>" -H "accept: image/png" -H "authorization:
Basic YXNtOmFzbQ=="
```

Specify more resources to be highlighted

The image returned that is by this cURL call has the same seed resource as before with a hop count of three, but now uses the **selectedIds** parameter to specify other non-seed resources through their IDs to highlight when the image is rendered.

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?
resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=3&selectedIds=<resource_id> <resource_id>" -H "accept: image/png" -H
"authorization: Basic YXNtOmFzbQ=="
```

Specify 'get neighbor' expansion

The image that is returned by this cURL now includes a **neighbourRequests** parameter that gathers a number of other neighboring resources for display, each identified by its resource ID. The **neighbourRequests** parameter expects an array of space-separated ID strings.

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?
resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=3&neighbourRequests=<resource_id> <resource_id>" -H "accept:
image/png" -H "authorization: Basic YXNtOmFzbQ=="
```

Specify advanced resource filters

The image returned now includes a **resourceFilter** parameter that filters out all resources of a specified type. The **resourceFilter** parameter expects an array of space-separated, previously defined resource types.

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?
resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=3&resourceFilter=<Type1> <Type2>" -H "accept: image/png" -H
"authorization: Basic YXNtOmFzbQ=="
```

Specify advanced relationship filters

The image that is returned includes the relation filter parameter (**relationFilter**) to filter out all relationships of a specified type. The **relationFilter** parameter expects an array of space-separated, previously defined resource types.

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?
resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=3&relationFilter=<Type1> <Type2>" -H "accept: image/png" -H
"authorization: Basic YXNtOmFzbQ=="
```

Specify time point

The image that is returned reflects the state of the topology at a specific point in history (in Unix time). The **time** parameter expects the time entered in Unix time.

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?
resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=3&time=<unixTimeMilliseconds>" -H "accept: image/png" -H
"authorization: Basic YXNtOmFzbQ=="
```

Specify delta history mode

The image returned shows the topology in delta history mode, with the specified **time** as a reference point and the **deltaTime** parameter as the point to delta against.

```
curl -X GET "https://example.host.com:3080/1.0/ui-api/render/png?
resourceId=sl1RQ5NCR_ykgciQCTkFGA&hops=3&time=<unixTimeMilliseconds>&**deltaTime**=<unixTimeMilliseconds>" -
H "accept: image/png" -H "authorization: Basic YXNtOmFzbQ=="
```

What to do next

With the topology images created, you can download and save the images for quick access to specific views, or share the images with other users to provide them with specific, instant information.

Topology query syntax

The Inventory service is used by the UI for the querying features that are provided through the search bar and advanced filtering functionality.

While previous searching technology indexed only a subset of the information of a resource or group, the Inventory service can query all of the information.

Query syntax

The main format of a supported query string consists of the following types:

- Fuzzy or full-text search: A text to search its occurrence (or close similarity) over a set of well-known properties.
- Parameterized query: Tries to find items that contain properties with the expected value. For example, matching a certain property=value content. All of the properties of a resource or group can be queried, including custom properties.
- Compound query: A combination of the other two to provide a more complex query where we try to find items matching a full-text search that we further restrict to those also matching properties with some expected value.

Fuzzy or full-text search

A fuzzy query conducts a full-text search to find fragments of information that contain a certain string within the following subset of an item's information:

- uuid
- uniqueId
- name
- keyIndexName
- description
- businessCriticality
- types (that is, entityTypes)
- tokens (all types)

Supported syntax

Provide a string to be found in any part of the queried properties, such as **mystring**, where typically this is a substring of an expected value, although it can also be the full string.

Note: The string can contain spaces.

You can use the wildcard (*) character to specify how a substring should be matched:

- ***string** - expects a suffix matching
- **string*** - expects a prefix matching
- ***string*** - expects a wrapped matching

Note: The wildcard character will only be interpreted when used at the beginning or end of the string.

You can use quotation marks to specify an exact match, as in **"my expected match"**. This syntax functions like the **mystring** matching, but in combination with the wildcard it allows you to define the prefix/suffix matching criteria for a string with spaces, for example:

- **"expected match"*** - looks for the specified string (including the spaces) as the matching prefix

Parameterized query

A parameterized query lets you find items that contain a property matching an expected value. You can query or match any property of a resource or group including any custom property, which means that this query is not limited to a set of well-known properties, unlike the fuzzy query type (or the former Search type).

Supported syntax

The syntax is based on the one defined for the fuzzy or full-text search.

You can specify the exact value, such as `property=value`

You can specify the expected value by using wildcards. For example:

- `property=*value`
- `property=value*`
- `property=*value*`

You can use quotation marks to wrap the expected value (which can have spaces), such as. For example:

- `property="complex value"` (which can also use wildcards)

Operators

This type of query also supports different operators that modulate how the user expects the matching of the expected value, or substring of a matching value.

- **Comparison operators**: **=**, **>**, **>=**, **<**, **<=**

  The comparison operators other than **=** are targeted at numeric properties; so if the property specified has a string as the value, then the comparison is likely to be done on the numeric counterpart of the characters, thereby potentially rendering some unexpected results.

  Note: For the date values either an epoch value or timestamp value is valid.

- **Collection operators**: **:**, **!:**

  Comparison and collection operators accept a comma-separated list of values.

Complex queries

You can specify several property-matching terms in the same query linking them with the **AND / OR** boolean operators to define a complex query criteria. For example:

- `property1=value1 AND property2>value2 OR property3=value3`

Also, each term can in turn be logically negated by using the **NOT** operator, as in the following example:

- `property1=value1 AND NOT property2>value2` where the expected result contains items for which `property2` value is `<=value2` (per the negated term).

Compound query

A compound query combines a fuzzy or full-text query and parameterized query to let you specify a full-text search term and also properties to match as part of the same criteria, such as `string AND property=value`.

The syntax that is described for these two types applies to a compound query, with the following restrictions. If not followed, the query is rejected as being of an invalid format.

- The fuzzy query segment must be specified first.
- The fuzzy query must be connected to the parameterized part by using `AND`.

Examples

Fuzzy query example

Fuzzy matching of items with a couple of words:

- `my server`

Fuzzy query example 2

Fuzzy matching of items with a certain prefix, for example, all FQDN servers for which the user knows the first part of the string:

- `host-*`

Parameterized query example: Discovery date

Finding servers that are discovered after a certain date:

- `entityType=server AND createTime>="2023-02-16T13:30:00.000Z"`

Parameterized query example: Tags

Finding servers tagged with certain values:

- `entityType=server AND tags:production,backend`

Parameterized query example: Busines criticality

Finding servers who have been assigned a business criticality of 'gold':

- `entityTypes=server AND businessCriticality=gold`

  Tip: Defining business criticality is described here.

Parameterized query example: Status

Finding servers with a status of 'critical':

- `entityTypes=server AND alert_severity=critical`

Parameterized query example: Group membership

Finding every member of a specified resource group:

- `memberOfGroup=ID`

You can find the resource group ID listed on the 'Properties' tab of the resource group *More details* page.

Compound query example

Finding images with the string test that also match a custom property for a certain release:

- `test AND entityType=image AND release=1`

Regex for param queries: Pattern Matching (RBAC)

Support has been implemented for the use of regular expressions for matching/finding entries as part of inventory's filtering experience, which is used for creating redaction policies as part of Role Based Access Control (RBAC). The regex syntax specfication will follow *Pattern Matching*. For more information on RBAC Regex for param queries: Pattern matching.

There is an operator (~) for regex matching, which can resemble **<property>~<regex>**.

Template types

Choose from three different template types to group your resources.

- **Dynamic template**

  This template automatically finds and updates multiple resource groups based on your criteria and how your applications and infrastructure change.

  A dynamic template builds multiple resource groups that are similar to the specified seed resource, and relationship or resource type criteria. Resource group creation and membership is dynamically maintained based on the available topology data and how it changes.

  For example, you can use a dynamic template to create dynamic resource groups, one for each of your virtual machines and the Kubernetes services they are running. Resource groups are then added, removed, and updated as you add or remove virtual machines or applications running on them.

- **Tag-based template**

  This template creates and updates a single resource group containing the resources that have a specified set of tags.

  Resource group membership is dynamically maintained to reflect changes in the topology for resources that gain or lose the specified tags.

  For example, you can use a tag-based template to create a dynamic resource group tagged with both 'red' and 'green'. Then, when you add new resources with both of those tags, the resource group will be updated to include them.

- **Token template**

A token template applies rules to resources as they are received via observer jobs.

Token templates are based on rules which use resource parameters as tokens, whose values then become group names for groups which will contain the resources to which each rule is applied. A distinct group is created for each token value.

To form group names from multiple resource property values, you can construct rule tokens using variable substitution (as is possible with all rules).

- **Exact template**

  An exact template builds a single resource group that are centered on a specified seed resource, your criteria and how your applications and infrastructure change. The membership of the resulting resource group includes the seed resource and those matching the specified relationship or resource type criteria. Resource group membership is dynamically maintained for the resulting resource group provided the specified seed resource type remains unchanged.

  For example, you can use an exact template to create a resource group only for a specific Jenkins build pipeline and any new builds or physical server and its connected network switch.

  As a further refinement, you can adjust your layout by manually positioning the resources in the topology, and this layout is then replicated when you generate a resource group from any exact template that you build from this topology.

Viewing resource group templates

You can access **Resource group templates** from the *Resource management* page or while viewing a topology. From the **Resource group templates** page you can edit, delete, or create new templates.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**.
3. Click the **Resource group templates** icon on the upper right corner of the page.
4. Any templates that exist in your system are listed in the Resource group templates table.

   From the **Resource group templates** page, you can delete or edit existing templates, or click **Create a new template**.

   For new templates, select from the following available template types:

   - **Dynamic template**

     This template automatically finds and updates multiple resource groups based on your criteria and how your services and infrastructure change.

   - **Tag-based template**

     This template creates and updates a single resource group containing the resources that have a specified set of tags.

   - **Token template**

     This template applies rules to resources as they are received via observer jobs.

   - **Exact template**

     This template creates and updates a single resource group based on the specified seed resource, your criteria and how your services and infrastructure change.

5. Click **Start** to begin building your selected template type.

   For more information, see Building resource group templates.

Templates table columns

Column name	Description
Name	The template name and the icon associated with the template when it was defined.
Type	The template type; Dynamic, Tag based, or Exact.
Resource groups	The number of resource groups that have been created from the template (Dynamic templates can be more than one).
Description	A description of the template.

Column name	Description
User	The user ID of the user who last modified the template.
Date modified	The date that the template was last modified.

Building resource group templates

You can use the template builder to create topology templates to generate resource groups, which search your topology database for instances that match its conditions. These resource groups are then listed on the Resource management page.

Before you begin

You can access the Template builder from the **Resource group templates** page. You can also right-click a resource in a Topology viewer diagram and select **Build a template** from the context menu.

For more information about the type of template to use to group resources, see Template types.

About this task

You can create a new template, or edit or delete an existing template.

To create a new template, you construct a topology view centered around a seed resource. This lets you search your database for topologies with resources and relationships that match the conditions defined in the template.

These defined topologies are dynamically generated, maintained and updated, and can be searched for and accessed via the Resource management page. Resource groups are dynamically refreshed when accessed.

Dynamic changes to resource group: If edges or resources are removed that render an existing resource group that has already been indexed incomplete, it will remain available, and can therefore still be found and displayed via the search functionality, or via a previously created direct URL. If edges or resources are added or changed that render a resource group that was not indexed previously complete, the resource group will be indexed automatically, thereby becoming accessible via the search service.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**.
3. Click the **Resource group templates** icon on the upper right corner of the page.

   The Resource group templates page is displayed listing existing templates in a table format by name, type, number of resource groups, description, user, and date modified.

   Tip: To reduce the number of templates displayed in the table, use the Filter table text field. The items displayed are filtered as you enter the search text.

   From here, you can perform the following actions:

   - To reload the templates, click **Refresh** (top right). This can be useful if other users are customizing the templates.
   - To delete an existing template, select it in the table, then click **Delete topology template**. If you intend to recreate the template, be aware of the restrictions.
   - To edit an existing template, select it in the table, then click **Edit topology template**.

     Note: When you edit an existing template, the template definition and topology areas are already populated. Also, the Name and Type parameters cannot be edited. You edit the other parameters as for a new template, and when you do, the template definition and topology areas will change. If you require a template with a different name, you must create a new template.
4. To create a new template, click **Create a new template** (top right). You are presented with a choice of template types.
5. Select either a Dynamic, Tag based, Token, or Exact template, then click **Start**.

   For more information about the type of template to use to group resources, see Template types.
6. Search for a resource to get started. Enter a resource name, type, or tags.

As you type, a drop-down menu is displayed with suggested search terms that exist in the topology service. If you select one of these, the search results are displayed underneath the search field, with the results listed under separate columns in the results table for **Resource name**, **Resource type**, and **Tags**.

- For each resource, expand the row to display the properties and property values.
- If you are creating a **Dynamic** or **Exact** template, you can select a resource to view its topology.

7. When you select a resource, a basic topology view centered around the resource as a seed is displayed in the *Topology Visualization* panel on the right.
8. If you are creating a **Tag-based template**, you can either search for the tags directly on the **Tags** tab or drill down into the resources on the **Resources** tab.
9. Enter a name for the template. The name must be unique. You can optionally enter a description.

   Restriction: The following special characters are not supported when specifying template names, custom group types, or tags:

   `. ? + * | { } [ ] ( ) " \ # @ & < > ~`

   If existing resources have names with these characters, you must change them before you can use them to define resource groups.
10. From the drop-down list, select the resource group type that is being defined. This determines what the resource groups generated by your template are going to model (for example, **`cluster`**, **`network`**, or **`storage`**). You can also define your own **`Custom type`**, which will be added to the list of available Resource group types. If you select Custom type, a new text box opens, where you type a name for your new resource group type.

- For **Tag** templates, provide a resource group name.
- For **Token** templates, no resource group name is defined, as groups are automatically named based on the rule tokens.
- For **Dynamic** and **Exact** templates, use name patterns that follow a defined topology. The seed name of the defined topology is substituted when a defined topology is generated, but you can define either a prefix, suffix, or both to create an appropriate name for each defined topology.

  Remember: Although an exact template type focuses on a single resource, it remains dynamic, which means as long as the seed resource itself remains unchanged, the defined topology can change through the removal or addition of connected resources or relationships.

11. Choose an icon to associate with the template using one of the following methods:

- From the **Icon** drop-down list:

  If you open the **Icon** drop-down list, all icons are listed by name in alphabetical order.

- From the **View all icons** button:

  If you click **View all icons**, all icons are displayed in alphabetical order. Click an icon to associate it with the template.

- From the **</> (Advanced mode)** button:

  If you click **</>** , you can define a JavaScript function using the simple script editor to set a different icon based on a resource type's properties, such as tag or status. Ensure that the returned value is a string that matches the name of the icon to be displayed in the topology. Click **Example** for more guidance.

- From the Define new custom icon button:

  From here you can define a custom icon, which is automatically associated with the template when done.

12. Add a tag to be included for each defined topology. With tags, you can group the individually generated resource groups by matching them to resources.
13. Use the following information specific to the type of template you are building:

- For **Token** templates, use the right hand side of the screen to define a new rule.

  Under **Details**, enter a unique **Name** for the rule. Define the **Tokens** for the rule, then click **Add+** You can use variable substitution to combine more than one property value if required.

  Under **Conditions**, select observers to which this rule applies from the **Observer** name drop-down, or leave empty for all observers.

  Select providers to which this rule applies from the **Provider** name drop-down, or leave empty for all providers.

  Select resource types to which this rule applies from the **Resource type** drop-down, or leave empty for all resource types.

  Set the **Token** filter mode to either **Exclude** or **Include**, then define a filter (or filters) in the format of a regular expression. If you choose **Exclude**, tokens which match any one of the expressions will not be applied to resources. If you choose **Include**, only tokens which match

one of the expressions will be applied to the applicable resources.

Optionally, you can validate the filters using the Validate token filters button.

- For **Exact** templates, select the **Maintain displayed resource position** toggle to use the exact resource layout when generating a new resource group.

  Remember: For exact templates, you can also create a view with an exact layout in the Topology viewer and then use the context menu to create the template.

- For **Dynamic**, **Tag** and **Exact** templates, use the Search functionality to find a seed resource (or tag).

  As you insert your cursor into the Search field, the five most recent searches are listed, and can be selected. You can delete a recent search by clicking the delete button (X) to the right of the suggested search.

  If you type in a search term, suggested search results are listed, which contain results both from the topology database and from recent searches, with your entered search text highlighted.

  When you select a search result, the found resources are listed by 'Resource name', 'Type' and 'Tags'. You can expand a resource to display its properties and values, or click its name to render a basic topology view centered around the resource as seed. The topology is displayed on the right of the Template builder.

14. Depending on the type of template you have defined, you can **Preview resource groups** and refine the template further as required.

Note: Token templates only apply rules and create groups as new observations are received from their designated observers, and therefore **cannot** be previewed.

Tip: You can define a default layout for resource groups. When a resource group based on a template is selected, this default layout is used.

Note: It might take some time for large resource groups to display in the **Preview resource groups** section. Also, the previous limit of 5,000 no longer applies, but you might want to consider that to generate and maintain a large number of matches can place additional strain on your system resources.

15. Click **Save template**.

Results

Resource groups created from the templates can be viewed on the Resource management page.

Remember: Resource groups are updated automatically when the database is updated, and generated dynamically as they are displayed.

Application incidents

An incident is a collection of insights that are derived from different data sources such as logs, events, and alerts. Incidents can help you build understanding and help drive remediation.

Incidents represent the determination of an incident and are categorized by priority from 1 (high) to 5 (low).

Before you begin

Incidents are created automatically when the underlying data integrations, AI models, and processes are set up and running. To display an incident against an application, the application must be associated with the incident.

Note: If an issue or an alert occurs and is part of a resource or group of resources but occurs prior to an application being created, then the related incident will not appear in the application details view. It will however appear in the application hub incident count.

1. Configure a ChatOps integration. For more information, see ChatOps insight management
2. Define or edit an application. For more information, see Defining and managing applications.

   The application needs to include the resource groups that are associated with the incident incidents.

3. Configure an integration to the data source that provides the incident data, such as for obtaining event or log data. For more information, see Configuring Integrations.
4. Create and train an AI model to process the data.

   For example:

   Log anomaly detection: You can train a log anomaly detection model to generate log anomalies, which can then be raised through an incident.

Event grouping: You can group multiple events into an incident.

Similar tickets: You can search for similar tickets in the context of an incident.

You might need to enable the integration data flow to collect a sufficient quantity and quality of data from your data source for model training.

For more information, see Managing AI models.

5. After the model training is complete, ensure that the integration data flow is enabled and set to collect live data for event, incident, or anomaly detection.

When you have the ChatOps integration set up, the data flow enabled and AI model training completed and working, incidents are created automatically when incidents occur.

Where incidents are associated with an application, the incidents are shown as summary cards on the details page for that application.

View incidents for an application

When you have integrations set up to begin creating incidents and an incident that is associated with a application, the incident can be viewed against that specific application:

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**.
3. From the *Resource management* page, select the **Applications** tab and find the application which is associated with the incidents that you want to view. Complete either of the following steps:
   - If your application is set as a favorite, click **View details** on the summary card for the application in the *Favorites* section of the page.
   - For any application, find the application in the table of all applications by searching for it or browsing the table.
4. You can view all incidents for that application within the collapsible **Incidents** section on the right side of the page.

   If multiple incidents are associated with the application, you can use the **Search** field to find your incident, or filter the list of incidents by using the **Last updated**, **Priority**, or **Number of alerts** drop-down. You can also click the **Filter** icon to open a filter dialog, which you can use to filter the incidents at a more granular level by priority, status or time range.

For each incident listed in the **Incidents** sidebar, the displayed summary card includes the following information:

- Incident title that is generated based on the events
- Timestamp for when the incident was last **updated**
- Short description of the incident
- Assigned priority
- Status
- Number of alerts generated

Note: You can expand an incident to view more details by clicking anywhere on an incident card. The additional details for the incident include the following information:

- The application name and the link to the application within the *Resource management* page
- The incident Slack or Microsoft teams link, if defined
- Incident ID
- Incident owner
- User group
- Date and timestamp for when the incident was **created**
- Additional **Alert** details
- A **View incident** link

The additional Alert details include **Show history** and **Center to** buttons, which you can click to zoom into the affected resources in the Topology viewer to display the alerts in their historical context.

You can click the **View incident** link to view the same details for the incident.

If you are using a Slack or Teams integration, you can also click the chat link on this dialog to open the connected ChatOps service and work with the incident and related incidents in your ChatOps interface. Threads might be associated with the incident, which can include links to the individual alerts that comprise the incident and any updates to the incident. If the probable cause information is available, the links are highlighted. You can click the probable cause links to open the topology for the associated resource in the Topology viewer.

View relevant events shows the events that are grouped within the incident. You can click the event link to view the log source for that event.

If you click to **Search Recommended actions**, the similar tickets search dialog is opened to show you similar past tickets.

For more information, see ChatOps insight management.

Defining business criticality

You can define the levels of business criticality for your applications (services), resource groups and resources, and then view a list of them on the Business criticality page. These set definitions can then be assigned to an application (or resource/resource group).

Before you begin

As an administrator user, you define the business criticality values that can then be assigned to an application (or resource/resource group).

You do so using the *Business criticality* page, accessed from the *Topology configuration* page.

When you subsequently create or edit an application (or resource/resource group), you can choose from the defined options to set the business criticality. This allows you to dynamically set different alert severity or incident priority levels, depending on the business criticality you have set.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**.
3. From the **Settings** drop-down, click **Topology configuration**, then click **Configure** on the Business criticality card. The *Business criticality* page is displayed listing any existing criticality definitions in a table format by name, description, and criticality value, in sortable columns.

   Tips: To reduce the number of items displayed in the table, use the Filter table text field. The table is filtered as you enter the search text. To reload the items displayed, which can be useful if other users are customizing them, click **Refresh** (top right).

   From here, you can perform the following actions:

   - Sort the table of defined criticality definitions by column header.
   - Delete existing definitions by selecting one or more in the table and clicking **Delete business criticality definition(s)**. **Caution:** Deleting a criticality affects any resource, group or application to which this criticality has been assigned.
   - Edit an existing definition by selecting it in the table, then clicking **Edit business criticality definition**.
   - Create a new business criticality.
   - Start with the default criticalities (Tier 1, Tier 2, Tier 3).
4. Click the **Define criticality +** button to create a new criticality definition, click **Start with presets** (then **Add**), or click the pencil icon next to an existing definition to edit it.
5. Enter or edit a name (required), and description (optional).

   Tip: Use names that reflect your business needs, and that quickly identify the level of importance, for example `Tier 1`, `Level C`, and so on.
6. Enter a criticality value, either by typing a number between 1 and 100, or by using the **+** (plus) and **-** (minus) buttons to select a numerical value.

   Important: The higher the value you specify for the business criticality, the more important it is when assigned to an application (or resource/resource group).
7. Click **Save** (or **Define**). The business criticality definitions are saved and listed on the *Business criticality* page.

Criticality values can now be assigned to applications (or resources/resource groups) from the *Resource management* page or while viewing an application.

Running data administration routines

You can run data management routines from the *Data administration routines* page. You can also view details for any routines that have been run.

Before you begin

You must be an administrator user with `waiops_manage_topology_routines` permissions.

About this task

Long-running routines that perform certain data management activities are run by the system as and when required, and you can view details for these when they have run on the Data administration routines page. You can also run some of these manually when required, for example to re-index vertices for searching, or to delete all resources for a specific provider.

You can run the following routines. After defining the details specific to the routine, you specify the number of updates to be batched up, then run the routine to implement its specific function.

- **Deduplicate** - This routine removes duplicate resources from the system.
- **Delete provider resources** - This routine permanently deletes all the resources and resource groups supplied by a specific provider.
- **Encryption key change** - This routine updates passwords in observer jobs after the encryption key has been changed.
- **Rebroadcast** - This routine rebroadcasts vertices from the topology to force a re-indexing of the search database.
- **Resource status delete** - This routine improves system performance by deleting all status for a single resource that has an excessive amount of status assigned.
- **Status clear** - This routine clears obsolete status if there have been synchronization problems with the event management system.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**.
3. From the **Settings** drop-down, click **Topology configuration**, then click **Configure** on the Data administration routines card.

   The *Data administration routines* page is displayed listing existing routines that have been run. If user-defined display settings are in place, some routines may no longer be displayed. The table footer will indicate if this is the case.

   Tips:

   - To reduce the number of items displayed in the table, use the Filter table text field. The table is filtered as you enter the search text.
   - To reload the items displayed, which can be useful if other users are customizing them, click **Refresh** (top right).

   From here, you can perform the following actions:

   - Sort the table of defined criticality definitions by column header, which are name, type, status (ready or completed), last run, duration, operations (number), or items visited (number).
   - View a routine's parameters and parameter values when run last (by clicking the routine name).
   - Configure which data administration routines are displayed (by setting the display options).
   - Run a routine manually.
4. To define routine display settings, click the **Routine display settings** button (top right). The *Routine display settings* page opens, where you can set the following options:

   Age limit (days) Set the number of days from which a routine will be considered 'old' instead of 'recent'. The default is 30 days.

   Display options Next, select one or more of the following checkboxes to hide the selected routines based on your definitions of 'old' and 'recent':

   - Hide old routines that finished successfully
   - Hide recent routines that finished successfully
   - Hide old routines that were aborted
   - Hide recent routines that were aborted
5. To run a data administration routine manually, click the **Run a routine** button. The *Run a new routine* window opens displaying the available routines that you can run manually.
6. Select the routine to be run, then click **Next**. A window specific to the routine selected is displayed.
7. Define the details for the specific routine to be run.

   Deduplicate This routine removes duplicate resources from the system. Specify the number of updates to be batched up. The default is 1,000 (one-thousand).

   Delete provider resources This routine permanently deletes all the resources and resource groups supplied by a specific provider. Select the provider from a drop-down list of existing providers. Specify the number of updates to be batched up. The default is 1,000 (one-thousand).

   Encryption key change This routine updates the observer job passwords after the encryption key was changed. Enter the old key to be changed. Specify the number of updates to be batched up. The default is 1,000 (one-thousand).

Rebroadcast This routine rebroadcasts topology data to trigger re-indexing of the search database. Specify whether historic resources should be rebroadcast (**true** or **false**). Enter the broadcast IDs to be rebroadcast. You can add more than one. Choose whether the resource status should be rebroadcast (default is 'true'). Choose whether group and composite edges for resources should to rebroadcast (default is 'true'). Specify the number of updates to be batched up. The default is 1,000 (one-thousand).

Resource status delete This routine deletes all status for a single resource. Use the Search field to find the resource to be stripped of its status values. Set the minimum age of any status to be deleted. The default is 12 hours. Set a deletion limits (maximum). The default is 1.000 (one-thousand). Specify the number of updates to be batched up. The default is 1,000 (one-thousand).

Status clear This routine clears all status for the system. Set the minimum age of any status to be deleted. The default is 12 hours. Set a deletion limits (maximum). The default is 1,000 (one-thousand). Specify the number of updates to be batched up. The default is 1,000 (one-thousand).

8. Click **Run**.

When the routine has completed, its details will be displayed on the *Data administration routines* page.

Configuring topology user preferences

Set your personal preferences for how topologies are rendered.

About this task

The settings that can personalize are grouped into the following categories:

- Updates
- Layout
- Miscellaneous

Procedure

You can access the user preferences settings while viewing a topology or from the *Resource manager* page.

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, expand **Operate** and click **Resource management**.
3. Click the **Settings** icon that is next to the search field. Click **User preferences**.
4. Update the setting for any user preference setting that you want to change.
5. Click **Save** when you complete your changes and return to the topology view.

You must reopen the page before any changes to this user preference take effect.

Updates

These settings determine how and how often topologies are automatically updated.

- **Default auto refresh rate (seconds)**

  Set to `30`.

- **Maximum number of resources and relationships to load with auto refresh enabled**

When the set resource limit is reached, auto-refresh is turned off. The maximum value is `2000`. By default, the value is set to `500`.

Tip: If you find that the default value is too high and negatively impacts your topology viewer's performance, reduce this value.

- **Auto render new resources**
  - Enable this option to display new resources at the next scheduled or manual refresh as soon as they are detected. By default, this setting is disabled.
- **Remove deleted topology resources**
  - Enable this option to remove deleted resources at the next scheduled or manual refresh. By default, this setting is disabled.

Layout

These settings determine the default presentation of topologies. You can select the layout type to use for rendering a topology by default. In addition, for some layouts you can select to change the layout orientation for how the layout is displayed.

Tip: A change to a layout type is tracked in the URL (layout orientation is not tracked). You can manually edit your URL to change the layout type display settings.

- **Default layout type**
  - (Default) Use Layout 1
- **Layout 4 orientation**
  - (Default) Top to bottom
- **Layout 6 orientation**
  - (Default) Top to bottom
- **Layout 7 orientation**
  - (Default) Top to bottom
- **Layout 8 orientation**
  - (Default) Top to bottom

Miscellaneous

Other settings, such as displaying messages, screen reader support, and troubleshooting.

- **Information message auto hide timeout (seconds)**

  The number of seconds that information messages are displayed in the IBM Cloud Pak for AIOps console. The default is `3`.

  Tip: If you are using a screen reader, it may be helpful to increase this value to ensure that you do not miss a message.

- **Screen reader support for graphical topology**
  - You can enable the display for more Help text on-screen elements, which can improve the usability of screen readers. By default, this setting is disabled.
- **Client-side debug logging (on supported browsers)**
  - Enhanced client-side ability to log problem diagnosis. If enabled, more debug output is generated, which you can use for defect isolation. By default, this setting is disabled.

  Tip: Use this for specific defect hunting tasks, and then disable it again. If this setting is left enabled, the Topology viewer performance can be reduced.

- **Maintain zoom level on render configuration changes**
  - (Default) Disabled

Configuring topology elements

You can customize a number of IBM Cloud Pak for AIOps console elements for the Topology viewer, such as resource styles and icons. You can also create custom topology tools which users can access through a topology's context menu.

Tip: The Topology viewer loads all configuration settings into memory when it opens. If you change your topology configurations after opening the Topology viewer, you must reopen it before these changes take effect.

For more information on resource properties, status (and states), edges and so on, see the Topology API topics.

Configuring advanced topology settings

You can define advanced topology settings. Examples include the URLs for trusted sites, the required properties for tooltips or relationship type styles, or the maximum hop numbers a user can choose in the topology viewer.

Configuring topology tools

You can create custom topology tools, which users can then access from within a topology's context menu. Use this feature to access properties of a selected item, such as a resource or relationship, and run some customized functions within the context of that item.

Configuring resource types

You assign existing or new custom icons to particular resource types using the Resource types page. Here you can also apply further resource type style edits, such as adding custom labels to a resource type, and changing its shape, size, border and background.

Configuring relationship types

You can customize the styles and labels for specified relationship types using the Relationship types page. You can also delete existing, or create new relationship type styles.

Configuring custom icons

You can add custom icons for resources that are displayed by using the Custom Icons page.

Configuring rules

Rules help streamline topologies and conserve system resources, such as by merging different observer records of the same resource into a single composite resource, or by excluding specific changes from being recorded against a resource history.

Configuring advanced topology settings

You can define advanced topology settings to control how the topology UI works for all users.

You can change settings, such as the URLs for trusted sites or geolocation tile servers, the required properties for tooltips or relationship type styles, or the maximum hop numbers a user can choose in the topology viewer.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, expand **Operate** and click **Resource management**.
3. Click the **Settings** icon that is next to the search field. Click **Topology configuration**.
4. On the *Advanced setting* card, click **Configure**.
5. From the *Advanced topology settings* page, set or change any of the settings or values to meet your needs.

   The settings are included within these categories:

   - Topology rendering
   - Topology search
   - Topology tools
   - Resource map
6. After you have completed your changes, click **Save** to save your changes and return to the *Topology configuration* page.

Topology rendering

Within the *Topology rendering* section, you can set or change the following settings:

- **Default hop type for topology viewer**

  Choose the default hop type to be applied when viewing a resource in the Topology Viewer. The default setting is 'element to element'.

- **Maximum number of hops allowed**

  Select a value in the range 2 - 30 from the drop-down list. The default maximum hop count is `4``.

  Important: Ensure that you set a maximum hop count that does not overload your system data capacity when the maximum hop count is selected.

- **Historical changes threshold**

  This setting defines the maximum size of a topology based on the number of resources for which the historical changes indicators are enabled in delta mode.

  Set the maximum topology size by entering a value up to, but not exceeding `50`.

- **Include adjacent relationships on topological hops**

  Select whether to retrieve all relationships between resources within a topology by enabling or disabling the toggle. By default, this setting is enabled and all relationships are retrieved.

- **Properties required for tooltips or resource and relationship styling**

To improve system performance only specific resource and relationship properties are loaded into the topology viewer. You can specify more properties to be retrieved by adding the properties to the table. These required properties can be uses in topology tooltips, custom status tools or to customize UI elements with JavaScript.

To add a property, enter the property name within the text field and click **Add +**.

After you have added a property, you can choose whether the property can be displayed in a tooltip. If you want to exclude the property from tooltips, clear the **Show in tooltip?** checkbox.

- **Resource types to block from topologies**

  Excluded resource types do not display in the Topology Viewer. Excluding resource types can optimize performance when complex topologies are being rendered. You can see the list of excluded types on the *Filter* toolbar of a topology visualization.

  To exclude a resource type from being displayed in the topology viewer, enter the resource type within the text field and click **Add +**.

  Note: You cannot exclude the seed resource of a topology.

  Tip: If an administrator unblocks a resource or relationship type while it is being viewed, the browser in which the topology viewer is displayed must be restarted for the unblocked types to appear.

- **Relationship types to block from topologies**

  Excluded relationship types do not display in the Topology Viewer. Excluding relationship types can optimize performance when complex topologies are being rendered. You can see the list of excluded types on the *Filter* toolbar of a topology visualization.

  To exclude a relationship type from being displayed in the topology viewer, enter the relationship type within the text field and click **Add +**.

- **Properties to hide in the resource details page**

  Excluded properties do not display on the *Resource details* page. In order to reduce visual clutter, you can hide properties that are of no interest to your operator users.

  If a property has been excluded from view by an administrator, it is removed from the tabular view, but remains visible in JSON format.

  To exclude a property from being displayed on the *Resource details* page, enter the property within the text field and click **Add +**.

Topology search

Within the *Topology search* section, you can define the following settings:

- **Add additional properties for filtering**

  By default, users can filter the resources, resource groups, or applications displayed on the *Resource management* page by using the 'entityTypes', 'name' and 'tags' properties. You can add additional properties to be available for filtering.

  Limitation: You cannot define filters by using properties with values that are sets.

  1. Type in a property name, then click **Add+**.
  2. Select the Operators to be available for the property from the Operators drop-down, then click **Add+** again.

  The added properties will be available when operator users define other filter properties on the Resource management page.

- **Include deleted resources in Search results**

  You can select to include or exclude an option in the topology viewer to include deleted resources within topology viewer search results.

  By default, the display of the option to include deleted resources is enabled. To disable the display of the option to include deleted resources, switch the toggle to **Disabled**..

Topology tools

Within the *Topology tools* section, you can add trusted websites that can be accessed through HTTP.

If you need to link to an HTTP address instead of HTTPS while writing a custom tool definition, and need to request data from a site that uses HTTP instead of HTTPS, then you can use the UI server as a proxy. The URL to the HTTP proxy takes the actual target HTTP site URL as a parameter. The proxy then sends the request itself, and returns the response back to the browser.

For security reasons, the HTTP proxy can access only the URLs defined by an administrator user as 'trusted sites'.

The `trustedSites` property values are a comma-separated list of the trusted sites to which the proxy server can link, and from which it can retrieve information.

Trusted sites operate with a 'starts with' condition.

To add a trusted site, complete the following steps:

1. Within the **Trusted website URL** table, enter the URL of the trusted site.

   For example, if you include the following URLs, the HTTP proxy permits requests for all target URLs that start with included trusted URL.

   - `www.ibm.com`
   - `data-server.intranet.com:8080/network/statistics`

   For instance, you can use the proxy for URLs, such as `www.ibm.com/cloud` or `data-server.intranet.com:8080/network/statistics/1893713/info`.

   You cannot use the proxy for URls such as `www.ibm.co.uk` or `data-server.intranet.com:8080`

2. Click **Add +**.

Resource maps

The geospatial mapping feature lets you plot resources on a Resource map at the required zoom level, and also includes the ability to filter resources according to their geospatial areas.

Important: To enable geospatial mapping, you must configure a tile server to provide map image tiles. Tile server providers are available with a range of licenses from free for limited use to paid for. Alternatively, you can deploy an on-site tile server. Any tile provider or mapping data organization you use requires an attribution credit on all maps displayed.

Tip: For more information and examples of configuring, using or creating a tile server, see the Switch to OpenStreetMap website.

To add a resource map site, complete the following steps:

1. Enter the URL for the map in the Map tile server URL template field.

   Example URL

   `https://tile.<example>.org/{z}/{x}/{y}.png`

   Where {z} is the zoom level, and {x} and {y} the tile coordinates.

   Tip: Variations on this basic format are possible. See the TileLayer section on the Leaflet site for more information.

2. Validate your map using the Test button (which attempts to fetch a single tile image with the three coordinate placeholders set to zero (0)).

   Note: If your server does not pass the test, the Save button remains unavailable.

3. Set server attribution.

   Server attribution is in the form of HTML and should be provided in your tile provider's documentation.

4. Set the parameters for the cluster threshold and the maximum pixel size.

   CAUTION: Accept the default settings unless advised otherwise by an IBM Support representative. Changing your clustering granularity and maximum pixel size affects the performance of your system.

   a. Set Map clustering thresholds (by number of resources).

   When a number of resources are located in close proximity, they are displayed on the Resource map as a cluster. The lower a clustering threshold is set, the coarser your clustering becomes and the more resources will be included when resources are clustered on the Resource map. This may improve system performance.

   - **Threshold 1**
     - Default is 10000.
     - Up to this number of resources, k-means clustering is used, which automatically determines the best cluster split of resources based on the distance between resources.
   - **Threshold 2**
     - Default is 30000.
     - Up to this number of resources, convex grid clustering is used, which splits the area where resources are into an X by X grid based on the map clustering pixel size, and then displays those resources within an appropriately shaped polygon.
   - **Threshold 3**
     - Default is 50000.
     - Up to this number of resources, the grid clustering is displayed as a standard shape determined by the cluster boundaries (rather than a bespoke polygon).
   - **Threshold 4**

- Default is 100000.
- As for the previous threshold, except a larger grid size is used.
- Above this number, grid clustering with a very large grid size is used.

b. Set Map clustering pixel size.

The default is 150. Increasing the maximum pixel size for clustering resources may improve performance at the cost of cluster resolution.

Once a map has been defined, it can be accessed from the Resource management and More details pages, as described here.

Configuring custom tools

You can create custom topology tools, which you and other users can then access and use from the context menu of a topology. Use this feature to access the properties of a selected item, such as a resource or relationship, and run some customized functions within the context of that item.

Before you begin

Ensure that you are proficient in JavaScript. You must use JavaScript to define custom tools.

About this task

Custom tools can be accessed through the right-click context menu in the UI. All users with permission to access topologies can access the tools, but only administrators with permission to manage topology tools can customize them.

Note: Some topology tools might fail due to browser restrictions, such as when the tool needs to load external content. Security measures for Firefox and Chrome, which prevent click-jacking and similar risks, can also prevent the loading of third-party content over HTTPS into an iframe. An iframe mechanism can be used by custom topology tools to display contextual information, and as such can be affected. As a workaround for Firefox browsers, users can select an option to load the content in a separate window.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, click **Resource management**, then access a topology.
3. In the navigation toolbar for a topology, click the **Settings** icon. From the drop-down menu, click **Topology configuration**. The *Topology configuration* page is displayed. The page includes cards for each category of topology elements and settings that can be configured or customized.
4. On the *Topology tools* card, click **Configure**. The *Topology tools* page is displayed, listing all of your defined tools in table format in sortable columns. These are the tool name, menu label, last update, the items the tool applies to, whether special conditions exist, and its description.

   From here you can create a new topology tool, or select existing tools in the table and edit or delete them.

   Tip: To reduce the number of items displayed in the table, use the Filter table text field. The table is filtered as you enter the search text. You can also click **Refresh** (upper right) to reload the items displayed, which can be useful if other users are customizing them.
5. Click **New** to create a new tool. The New topology tool page is displayed consisting of the expandable Details, Implementation, and Conditions sections.
6. In the **Details** section, enter the general details for your new tool:

   - **Name**

     Required. Enter a unique internal name for your tool. This name is used as an internal reference for identify individual tools.

   - **Menu label**

     Required. The menu label is the text that is shown in the context menu. This can be the same name as used by other tools, which is why the unique name is required.

   - **Description**

     Optional. A description to help administrative users record the tool's purpose. This text does not display in the context menu.

   - **Menu priority**

Optional. The menu priority slider defines where in the context menu the tool is displayed. Available values are one to ten.

For example, tools with a priority of two will be displayed higher in the menu than tools that have a priority of four.

7. In the **Implementation** section, define the JavaScript implementation for your tool.

   If needed, you can click **Example** to view example JavaScript to show you how to format your code. The code for your tool runs when the tool is accessed by an operator, such as when a user from the context menu of a topology.

   To help you create tools, you have access to custom helper functions

8. In the **Conditions** section, select any conditions for using the tool.

   Select the resources, relationships, and status for which the tool applies. A user must select one of these items for the tool to display in the context menu.

   Use the **Applicable item type for tool definition** field to select between the types of topology items for which the tool is applicable:

   - **Resource**

     Select one or more resource types from the list displayed.

   - **Relationship**

     Select one or more relationship types from the list displayed.

   - **Resource and Relationship**

     Select one or more resource or relationship types from the combined list.

   - **Status**

     Select from the following possible states for which the tool will be available:

     - **Clear**
     - **Indeterminate**
     - **Information**
     - **Warning**
     - **Minor**
     - **Major**
     - **Critical**

   Depending on your selection, a number of checkboxes are displayed, which you can use to configure which resources, relationships or states are included. If you select **Resource**, **Relationship**, or **Resource and Relationship** (but **not** Status), a JavaScript editor is displayed, letting you define additional conditions for the display of the topology tools.

   The following relationship example creates a tool that shows only relationships that have source resources with the name 'kafkaService', or relationships that have target resources with 'entityType' properties that also include 'container':

   ```
   if (asmSourceProperties.name === "kafkaService" ||
   asmTargetProperties.entityType.includes("container")) { return true; } else { return false;}
   ```

   The following relationships and resources example is for relationships and resources that have a property that is called 'kubernetes_namespace':

   ```
   if (asmProperties.kubernetes_namespace) { return true; } else { return false; }
   ```

   For each category, you can also select **All types** if you want the tool to be displayed for all types under the selected category. The tool also displays for any specific types under the selected category that is not listed.

   Remember: When you are creating status tools, the properties that you use in your JavaScript reference the properties for the status item. The properties that you use in your resource or relationship tools reference the properties for the resources or relationships.

9. Click **Save** to save your configuration and create the tool.

   Once you save your changes, you must close the Topology Viewer, and then reopen the UI to make the new tool available. Tools are also available on the context menu of a topology only when the configured conditions are met.

Custom helper functions

To help you create custom topology tools, you can use the following custom JavaScript helper functions:

asmProperties

Your tool implementation can access the properties of the relevant resource, relationship, or status through the `asmProperties` JavaScript object, which contains all the properties.

You can access the properties by using standard JavaScript, but you must protect against the property value not being present. For example, if you intend to use the property 'latitude', you must verify that it is present before using it. To do so, you can use the following check command:

```
asmProperties.hasOwnProperty('latitude')
```

If the property is present, the Boolean value true will be returned.

Status-related tool properties

For **Status**-related tool properties, you use JavaScript that is similar to the JavaScript that you use when creating resource or relationship tools. However, the properties that you must use in your status tool implementation, such as **`asmProperties`**, must reference the properties for the status item. For **Resource** or **Relationship** related tools, the implementation needs to instead reference the properties for the resources or relationships.

For example, if you use **`asmProperties.location`** in a status tool implementation, a corresponding **`location`** property must be in the status record. When creating status tools, the **`asmProperties`** object has a property that takes the form of an array that is called **`resources`**, which represents the resources in the topology with which this status is associated. Each item in the **`resources`** array is an object with properties that represent the properties of that resource. If a status is associated with two resources, the **`uniqueId`** property of the first of those two resources can be referenced in the JavaScript by using **`asmProperties.resources[0].uniqueId`**.

In addition, you can access the properties of the resource for which you are intending to use a status tool by using the **`asmSourceProperties`** object when scripting the status tool.

asmSourceProperties

You can access information about the source properties of any relationship or status that the custom tool is acting upon through the **`asmSourceProperties`** JavaScript object.

The following example shows the use of the helper function in a custom relationship stroke definition:

```
if (asmSourceProperties.myProp === 'high') {
    return 'blue';
} else {
    return 'black';
}
```

Note: The arrows on the topology indicate a relationship point from the source to the target.

asmTargetProperties

You can access information about the target properties of relationships that the custom tool is acting upon trough the **`asmTargetProperties`** JavaScript object.

asmFunctions

You can use a number of other helper functions, which are accessed from the asmFunctions object, which includes the following functions:

showConfirmationPopup(title, message, onOk)

Creates a confirmation dialog to allow the tool to confirm an action. This function takes a title and message, which is displayed on the dialog, and a function definition, which is run when the user clicks the **OK** button on the dialog.

showToasterMessage(status, message)

Opens a window toaster message with the appropriate status coloring and message.

showPopup(title, text)

Shows a dialog with a title and text body, which can be generated based on the properties of the resource or relationship.

Tip: With the **`asmFunctions.showPopup`** helper function, you can use markdown to create more sophisticated HTML pop-up windows. For more information about markdown syntax, consult a reputable markdown reference site.

showIframe(url)

Displays a dialog that fills most of the page, which wraps an iframe, showing the page of the URL. Use this function to embed more pages.

Restriction: You must add any websites that are referenced by the **`url`** parameter to a list of your trusted sites. For more information about adding sites to this list, see Defining advanced topology settings.

getResourceStatus(<resource_id>, <callback_function>, [<time_stamp>])

Use this function to request status information from a tool definition for a resource by using its **`_id`** parameter.

- **`resource_id`**

  Required. This value can be obtained from a resource through **`asmProperties._id`** and from a relationship by using **`asmSourceProperties._id`** or **`asmTargetProperties._id`**.

- **`callback_function`**

  Required. This function is called when the status data is collected from the topology service, with a single argument that contains an array of status objects.

- **`time_stamp`**

  Optional. A Unix millisecond timestamp to get the status from a set point in time.

The following example shows the status information of a source resource from a relationship context to the browser console log:

```
let printStatusCallback = function(statuses) {
    statuses.forEach(function(status) {
        console.log('status:', status.status,
                    'state:', status.state,
                    'severity:', status.severity,
                    'time:', new Date(status.time));
    })
}
asmFunctions.getResourceStatus(asmSourceProperties._id, printStatusCallback);
```

Tip

- The resource properties available in the UI are 'status', 'state', 'severity', 'time', 'id' and 'resource_id'.
- When the optional parameter **`_include_status_severity`** is set to true, the **`_hasStatus`** field will reflect the maximum and most severe severity of all of the status records related to a resource (such as **`_hasStatus": "critical"`**).

sendHttpRequest(url, options)

Use this function to send an HTTP or HTTPS request to a remote web server by using the IBM Cloud Pak® for AIOps backend server rather than the browser to avoid browser domain-blocking.

- **`url`**

  Required. The full URL of the remote site to be accessed, for example:

  `https://data-svr-01.uk.com/inv?id=1892&offset=0`

  Restriction: You must add any websites that are referenced by the **`url`** parameter to a list of trusted sites. For more information about adding sites to this list, see Defining advanced topology settings.

- **`options`**

  Optional parameters that you can include:

  - **`method`**

    The HTTP method to use. You can use the following methods:

    - GET (default)
    - POST
    - PUT
    - DELETE

  - **`headers`**

    An object that defines any required special request headers.

  - **`body`**

    A string that contains the body data for the request. Use POST and PUT requests only.

  - **`autoTrust`**

    A flag to indicate whether the remote web server can be automatically trusted. This flag is required when the website uses a self-signed SSL certificate with no CA, or uses a CA that is unknown to IBM Cloud Pak for AIOps. The value for the flag can be **`true`** or **`false`**. The default value is **`false`**.

  - **`onSuccess`**

    A callback function to run if the HTTP request succeeds. This function is passed the following three parameters:

    - Response text

- HTTP status code
- Response header

- **onError**

  A callback function to run if the HTTP request fails. This function is passed the following three parameters:

  - Response text
  - HTTP status code
  - Response header

The following sample JavaScript, shows the use of the **options** parameter:

```
{
    method: 'GET',
    headers: {
        Content-Type: 'application/json',
        X-Locale: 'en'
    }
    body: '{ "itemName": "myData1" }',
    autoTrust: true,
    onSuccess: _onSuccessCallback,
    onError: _onErrorCallback
}
```

Example tools

Use the following examples to help you create the JavaScript implementation for your own custom topology tools. This implementation needs to define the action that occurs when a user selects the tool from the context menu.

Example: Send HTTP GET request for external REST data

The following example uses the **asmFunctions.sendHttpRequest(url, options)** helper function to send an HTTP GET request for external REST data, which is then displayed in a dialog on the Topology viewer.

Reminder: You must add any websites that are referenced by the **url** parameter to a list of trusted sites. For more information about adding sites to this list, see Defining advanced topology settings.

```
// Get the unique id from the resource and use it to send a REST request
var extId = asmProperties.uniqueId;
if (!extId || extId === '') {
    asmFunctions.showToasterMessage('warning', 'The resource does not have a unique identifier.');
} else {
    var options = {
        method: 'GET',
        onSuccess: _onSuccess,
        onError: _onError
    };
    asmFunctions.sendHttpRequest('https://api.data.uk/resource/' + extId, options);
}

function _onSuccess(response, status, headers) {
    // Start to build text for the info dialog
    var output = 'Here are details for ' + asmProperties.name + ':\n\n';

    var data;
    try {
        data = JSON.parse(response);
    } catch (e) {
        data = {};
    }
    var props = data.additionalProperties;
    if (!props || props .length === 0) {
        asmFunctions.showToasterMessage('information', 'No information exists for this resource.');
    } else {
        for (var idx in props) {
            var prop = props[idx].key;
            var val = props[idx].value;
            if (!prop.endsWith('Id')) {
                output += props[idx].key + ' = ' + props[idx].value + '\n';
            }
        }

        // Show the output in an ASM popup dialog
        asmFunctions.showPopup('External Details', output);
    }
}

function _onError(response, status, headers) {
    if (!response || response === '') {
```

```
        asmFunctions.showToasterMessage('critical', 'HTTP request failed with status code ' + status);
    } else {
        asmFunctions.showToasterMessage('critical', 'HTTP request failed: ' + response);
    }
}
```

Example: Splunk integration

When you are configuring a custom tool, you can create a custom tool integration with Splunk. As an example, you can create an integration that allows you to search a Splunk repository through the context menu of a selected resource in the Topology viewer. For more information, see Example: Splunk integration.

Splunk integration example

With IBM Cloud Pak® for AIOps, you can add custom tools to the topology viewer, such as a custom tool integration with Splunk. The following example creates a custom tool for searching a Splunk repository. This tool can be accessed from the right-click context menu on the topology viewer when you are viewing a resource topology.

Note: You must install Splunk Enterprise and Splunk Forwarder before you can define a custom tool with the following example. The following example was tested with Splunk 8.1.0. For more information, see Splunk.

About this example

The following example code creates a custom tool that can be accessed from the right-click context menu. With this tool, you can use the properties of the resource that is selected in a topology when you click to open the tool to search a specific Splunk repository. This specific tool searches Splunk for logs that match the name of an IBM Cloud Pak for AIOps resource. This search can help you determine whether Splunk has registered any log information about the selected resource.

If you want to customize the following example code, you can change the values for the following properties:

- **`splunkUrl`**

  The base URL of your Splunk instance

- **`splunkRepository`**

  The Splunk repository you want to search

- **`searchValue`**

  The dynamically created **`searchTerm`** used in Splunk

In addition, you can use any IBM Cloud Pak for AIOps properties that are associated with the resource to create your tool. You can also define the tool response for when a search is unsuccessful.

Example

```
// Set the Splunk instance url
var splunkUrl = 'host:port';
// This will store the value that you want to search in Splunk
var searchValue = '';
// This will search results for defined period
//    0 = all time
// -15m = last 15 mins
// -24h = last 24 hours
//  -7d = last 7 days
var searchEarliest = "0";
// This flag is set if you find a valid search value
var foundValidSearchValue = false;
if (asmProperties && asmProperties.name) {
    searchValue = "\"" + asmProperties.name + "\"";
    foundValidSearchValue = true;
} else {
    var status = 'critical';
    var message = 'Unable to find name property for Splunk search request';
    asmFunctions.showToasterMessage(status, message);
}
// DO NOT MODIFY THE LINES BELOW
if (foundValidSearchValue) {
        var searchLatest = '';
        if(searchEarliest!="0") {
                searchLatest="now"
        }
```

```
    var encodedSearchValue = encodeURI(searchValue);
    var searchQuery = '/en-US/app/search/search?
q=search%20index%3D*%20'+encodedSearchValue+"&earliest="+searchEarliest+"&latest="+searchLatest;
        window.open(splunkUrl+searchQuery);
}
```

Configuring resource types

You can assign existing or new custom icons to particular resource types by using the Topology viewer *Resource types* page in the UI console. You can also apply further resource type style edits, such as adding custom labels to a resource type, and changing the resource type icon shape, size, border, and background.

You can define a custom icon as part of editing a resource type to have the icon immediately assigned to the selected resource type. However, if you want to create a number of icons without assigning them to specific resource types, or you simply want to edit or delete icons, use the *Custom icons* page. For more information, see Defining custom icons.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, expand **Operate** and click **Topology viewer**.
3. From the topology navigation toolbar, expand **Settings**, and click **Topology configuration**.
4. On the *Resource types* card, click **Configure**.

   The Resource Types page is displayed, which lists all existing resource types in table format in sortable columns. The table also displays the icons for the resource types and their names, categories (if defined), whether they are system icons or custom icons, and whether they have custom labels, styles or shapes. From here, you edit existing resource types, and then associate existing icons with them, and apply resource styling.

   Tips: To reduce the number of items displayed in the table, use the Filter table text field. The table is filtered as you enter the search text. You can click **Refresh** (top right) to reload the items displayed, which can be useful if other users are customizing them. You can select more than one resource type and reset them to their default values, or perform a batch edit.
5. To edit resource types, select them in the table and click **Edit resource type** (or **Batch edit resource types**). The *Configure relationship type* page is displayed.

   The *Edit Resource Type* page is displayed. You can toggle between the **Identification** and the **Styling** tabs. Use the options on these tabs to define the resource type.

   - Use the **Identification** tab to define the selected resource type's icon, label, and shape.
   - Use the **Styling** tab to define the selected resource type's border color, border pattern, background color, and resource display size.

   Restriction: You cannot change the name of an existing resource type.

   Tip: To quickly revert resource stype styles to their default, select them in the table, then click **Reset to defaults**.
6. Click **Save** when you are finished with your edits to save your changes and return to the *Resource types* page. The table displays your changes for the resource type and the associated icon.

Identification

On the **Identification** tab, define the selected resource type icon, label, and shape:

- Choose an icon to associate with the resource type by using one of the following methods:
  - **Icon** drop-down list

    If you open the **Icon** drop-down list, all icons are listed by name in alphabetical order.
  - **View all icons**

    If you click **View all icons**, all icons are displayed in alphabetical order. Click an icon to associate it with the resource type.
  - **Quick assign**

    If an icon exists with the same name as the resource type, click the **Quick assign** button to select it without having to sort through all existing icons. This function is useful if you have added a custom icon, and are now assigning it to a resource type with the same name.

- **</>** (Advanced mode)

  Define a JavaScript function using the simple script editor to set a different icon based on a resource type's properties, such as tag or status. Ensure that the returned value is a string that matches the name of the icon to be displayed in the topology.

  Click *Example* for more guidance.

- **Define new custom icon**

  From here you can define a custom icon, which is automatically associated with the resource type when done.

  - Click the **Define new custom icon** button to display the Custom Icons page.
  - Click **New** to create a new icon. Alternatively, click the *edit* symbol to edit an existing icon. After you have selected or created an icon, the *Configure resource type* page is displayed. Use the following information to define the icon:

    Icon properties

    Each custom icon must have a name that uniquely identifies the icon when assigning it to a type.

    Remember: You cannot change the name of an existing icon. If you want an icon to have a different name, create a new icon, then delete the old one.

    Icons are defined inside an SVG editor, which runs an XML validation check. Each icon definition must be valid SVG XML with a viewBox, which is important to ensure scaling of the image.

    The SVG definition must include inline styling of the image, such as stroke color and fill color. Use of style classes is not advised, as it can cause visualization issues on some browsers. If style classes must be used, naming must be unique for each svg image to prevent class definitions from being overwritten.

    Optionally, each icon can be assigned to a category, so you can group icons of the same type or function together when displaying them in a list.

    Remember: You can also create custom icons from the Custom Icons page accessed through DASH, which is described in the Defining custom icons topic.

- Define the label for the resource type by editing the following fields:

  - Label

    By default the name of a property (**`asmProperties.name`**) is used as the label that is displayed in the topology. You can replace this by typing in a custom label for the resource type.

  - Label Maximum Length

    You can override the default label length of 15 characters to avoid truncating the displayed label.

    Warning: Avoid labels that are too long, as long labels can overlap in the topology. The maximum suggested label length is 20 characters.

- Choose a shape for the resource type from the **Resource Shape** drop-down list.

  The default shape for a resource in the Topology Viewer is a circle, or a square for a host server. You can change the shape of the resource type to one of the following shapes:

  - Circle
  - Square
  - Hexagon
  - Vertical hexagon

Styling

On the **Styling** tab, you can define the selected resource type border color, border pattern, background color, and resource display size:

- For the border color, enter a hex definition. The default border color is **`#171717`**.
- For the border pattern, the default pattern is `''`.
- For the resource background color, the default is **`#F3F3F3`** (light gray).
- For the size, the default is medium.

  You can further refine the size function by specifying how certain resource properties affect the size of the resource type displayed. For example, resource types can appear larger depending on the number of connections they have with other resources.

Configuring relationship types

You can customize the styles and labels for specified relationship types using the Relationship Types page. You can also delete existing, or create new relationship type styles.

You customize styles in two steps. First, you identify the relationship type to be customized, or create a relationship type. Then, you can customize the style elements for the relationship type. To customize the style, you can set the relationship line color, thickness, style, and label.

Any resource or relationship properties that are used in custom relationship styles must be added as required properties to the *Advanced topology settings*. If the properties do not exist in the advanced topology settings, you are prompted to add the properties when you save a new relationship style. For more information, see Advanced topology settings.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, expand **Operate** and click **Topology viewer**.
3. From the topology navigation toolbar, expand **Settings**, and click **Topology configuration**.
4. On the *Relationship types* card, click **Configure**.

   The *Relationship types page* is displayed and lists all of your existing customized relationship types in a table with sortable columns. The table also displays the last updated timestamp, and indicates whether a relationship type has a custom label, custom color, or custom width defined. From here, you can choose to delete or edit configurations. You can also create a relationship type configuration.

   Tips: To reduce the number of items displayed in the table, use the Filter table text field. The table is filtered as you enter the search text. You can click **Refresh** (top right) to reload the items displayed, which can be useful if other users are customizing them. You can select more than one relationship type and reset them to their default values, or perform a batch edit.
5. Select the action that you want to complete:
   - To delete a relationship type, select them in the table and click **Delete relationship settings**.
   - To revert to default settings, select an item in the table and click **Reset to defaults**.
   - To edit existing relationship types, select them in the table and click **Edit relationship type** (or **Batch edit relationship types**). The *Configure relationship type* page is displayed.
   - To create a new relationship type, click **New**. The *Configure relationship type* page is displayed.
6. Select the **Identification** tab on the *Configure relationship type* page.
   - Relationship Type

     Choose the relationship type that you want to configure from the dropdown list.

     Note: Only relationship types that exist in your topology database are listed.
   - Label Function

     Example of a JavaScript function to define a label for the relationship using the resource properties:

     ```
     return asmProperties.labelText;
     ```
7. Select the **Style** tab on the *Configure relationship type* page.

   Warning: If you use the advanced JavaScript format to define colors, do not define a numeric value instead of an actual color, as this will prevent the topology rendering from being completed.
   - Line Color Function

     Example JavaScript function to define link color:

     ```
     return 'blue';
     ```

     Default function:

     ```
     return '#171717';
     ```
   - Line Width Function

     Example JavaScript function to define line width for the relationship using the source resource properties:

     ```
     return asmSourceProperties.myProp > 10 ? '9px' : '1.5px';
     ```

     Default function:

```
return '0.5px';
```

- Line Pattern Function

  Example of a JavaScript function to define the line pattern:

  ```
  return '3 4 5';
  ```

  Default function:

  ```
  return null;
  ```

8. Click **Save**.

   If any resource or link properties are not defined in the *Advanced topology settings*, you are prompted to save the properties now.

The relationship style and label for the specified relationship type is customized.

Style restrictions

- The line color (strokeWidth) property can have a maximum value of 9px. Any higher value can cause styling problems.
- The label (linkLabel) property must return a valid string to be displayed alongside the relationship.

For detailed SVG style definition information, see:

- Line color (stroke)
- Line width (stroke-width)
- Line pattern (stroke-dasharray)

Accessing properties for styling functions

When you are defining styles, you can access dynamic properties of the relationship or connected resources.

- To access the properties of resources, use the **asmProperties** JavaScript object.
- To access the properties of relationships, use the **asmSourceProperties** or **asmTargetProperties** JavaScript objects.

  Remember: The arrows indicating a relationship point from the source to the target.

- To access the highest open severity status from the source or target resource, use the **asmSourceProperties._hasStatus** or **asmTargetProperties._hasStatus** JavaScript objects. The following example uses the **_hasStatus** parameter to modify the relationship label:

```
if (asmSourceProperties._hasStatus || asmTargetProperties._hasStatus) {
    // object of all ASM's status severities
    let severityRank = {
        clear: 0,
        indeterminate: 1,
        information: 2,
        warning: 3,
        minor: 4,
        major: 5,
        critical: 6
    };
    let sourceSeverityRank = severityRank[asmSourceProperties._hasStatus] || 0;
    let targetSeverityRank = severityRank[asmTargetProperties._hasStatus] || 0;
    let labelString = asmProperties._edgeType;
    // Show highest Status on relationship label
    if(sourceSeverityRank > targetSeverityRank) {
        labelString += ': Status = ' + asmSourceProperties._hasStatus;
    } else {
        labelString += ': Status = ' + asmTargetProperties._hasStatus;
    }
    return labelString;
} else {
    // No status for source or target resources use plain label
    return asmProperties._edgeType;
}
```

Configuring custom icons

You can add custom icons for resources that are displayed in the IBM Cloud Pak for AIOps console using the *Custom Icons* page.

Before you begin

To access the *Custom Icons* page, you must have the required permissions.

About this task

Tip: Instead of using the following procedure, you can first select a specific resource type from the Resource Types page, and then define a custom icon for that specific resource type only. This is described in Editing resource type styles. However, if you intend to create a number of icons without assigning them, or simply want to edit or delete icons, use the following procedure.

Icon properties

- Each custom icon must have a name that uniquely identifies the icon when assigning it to a type. You cannot change the name of an existing icon. If you want an icon to have a different name, create another icon, then delete the old icon.
- Icons are defined inside an SVG editor, which runs an XML validation check. Each icon definition must be valid SVG XML with a **`viewBox`**, which is important to ensure scaling of the image.

  The SVG definition must include inline styling of the image, such as stroke color and fill color. Use of style classes is not advised, as it can cause visualization issues on some browsers. If style classes must be used, naming must be unique for each svg image to prevent class definitions from being overwritten.
- Optionally, each icon can be assigned to a category, which allows you to group icons of the same type or function together when displaying them in a list.

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, expand **Operate** and click **Topology viewer**.
3. From the topology navigation toolbar, expand **Settings**, and click **Topology configuration**.
4. On the *Custom icons* card, click **Configure**. The Custom icons page lists the custom icons in table format by name, icon, category, last update, and size, in sortable columns.

   Tip: To reduce the number of items displayed in the table, use the Filter table text field. The table is filtered as you enter the search text. You can also click **Refresh** (top right) to reload the items displayed, which can be useful if other users are customizing them.
5. Click **New** to create an icon. Alternatively, select icons in the table to edit or delete them.
6. On the *New custom icon* page, enter the details for your custom icon:
   - Enter a unique name. Each icon must have a name, which uniquely identifies the icon when assigning it to a type.

     Remember: You cannot change the name of an existing icon. If you want an icon to have a different name, create an icon, then delete the old icon.
   - Optionally, enter a category name. Each icon can be assigned to a category. You can use categories to group icons of the same type or function together.
   - Enter the SVG XML to define the icon. Use the editor to enter valid XML.

     Each icon definition must be valid SVG XML with a viewBox, which is important to ensure scaling of the image. The SVG editor rejects any invalid XML entered.

     The XML editor includes a Preview area where the results of your edits display. The following conditions apply:
     - Height or width should not be specified.
     - Inline styles, such as stroke color and fill color, should be used and not style classes. Naming must be unique for each SVG image to prevent class definitions from being overwritten.
     - SVG namespace is required: **`xmlns="http://www.w3.org/2000/svg"`**

   Example: Use the following definition for the **`disk`** icon as guidance:

```
<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 0 64 64">
   <ellipse style="fill-opacity:0;stroke:currentColor;stroke-width:12.12270069;" id="path4139"
cx="33.627117" cy="32.949142" rx="16.803904" ry="17.210684"/>
   <circle cx="33.827423" cy="33.055576" r="3.3037829"/>
</svg>
```

7. Click **Save**.

What to do next

You can assign your custom icons to particular resource types using the *Resource types* page. On that page, you can also apply further style edits to the resource types.

Configuring rules

Rules help streamline topologies and conserve system resources, such as by merging different observer records of the same resource into a single composite resource, or by excluding specific changes from being recorded against a resource history.

Before you begin

Ensure that you have the details to hand about the resources for which you intend to develop rules. For example, to create merge rules, you must know which resources exist as duplicate records before you can merge these into composites.

About this task

Resource filters: Resource filters let you use resource properties to either include or exclude all resources with these properties from having a rule applied to them. You can add more than one property as a filter. Resource filters cannot be set for history or event rules.

Tokens: Rules copy the values of properties to a token. Tokens are sets of strings that behave in ways specific to each rule type. You can combine several properties into a single token by using **`${propertyName}`**.

Token filters: An 'Include' token filter applies only to resources or groups having the listed tokens. You can use an 'Include' token filter simply to include (or exclude) specific properties, or extend its use with regular expressions to manipulate the input property.

Example use of tokens and token filters

Token	Include token filter	Input properties	Single output token value
host		host=example.ibm.com	example.ibm.com
${host}		host=example.ibm.com	example.ibm.com
${host}location-${location}		host=example.ibm.com,location=1	example.ibm.com location-1
host	host=~/^(.?)/..$/	host=example.ibm.com	example
${uniqueId}Location-x	uniqueId=~/^.(.)$/	uniqueId=anything	Location-X

Tip: See the Rules reference topic for additional information.

Rule types

You can use a number of different types of rules for different purposes. The rule type (**`ruleType`**) can be one the following rules.

Merge rules (mergeRule)

- Define a merge rule to populate the mergeTokens of resources matched by the rule to prevent duplicate records of the same resource from being displayed in the topology.
- A merge rule copies particular properties of a resource into the resource's mergeTokens property.

Match token rules (matchTokensRule)

- Define a match tokens rule to copy the value of another field to the matchTokens field so that it can be used to match events to resources.
- A match token rule populates the matchTokens of resources matched by the rule.

Tags rules (tagsRule)

- Define a tags rule to copy the value of another field to the tags field so that it becomes searchable in the UI.
- A tags rule populates the tags of resources matched by the rule.

  Tip: Any field that isn't indexed and can therefore not normally be searched for becomes searchable if copied to the tags property. For a list of indexed properties, see the 'Generic properties' table.

History rules (historyRule)

- Define a history rule to identify properties that change every observation, but that don't indicate an important change, for example a host's sysUpTime property.

- A history rule excludes properties from being retained in history, thereby saving resources by not maintaining detailed historical records of changes to these properties.

File enrichment rules

- Define a file enrichment rule in order to enrich resources as they are loaded into the topology service database with their geographical location.

Events filter rules (eventsFilterRule)

- Define an events filter rule to prevent status derived from observer jobs from generating events in the system.

Business criticality rules

- Define a business criticality rule to copy a particular property of a resource into the resource's businessCriticality property, which is then used to create a business criticality rule.

Accessing the Rules administration page

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, expand **Operate** and click **Topology viewer**.
3. From the topology navigation toolbar, expand **Settings**, click **Topology configuration**, and then open the *Rules administration* page.
4. Select the appropriate rules tab.

Defining merge rules

A merge rule copies particular properties of a resource into the resource's mergeTokens property. Resources which contain the same merge token will be merged so that they are treated as a single 'composite' resource. In this way, the topologies from different data sources can be connected.

About this task

Different observers deployed as part of the Agile Service Manager solution may record and then display the same resource as two (or more) resources. To prevent this, you create a merge rule that ensures that the separate records of the same resource share values in their tokens set, which then triggers the merge service to create a single composite resource vertex. Composite, merged resources are displayed in the Topology Viewer as a single resource, which includes the properties of all merged resources. Merge rules are applied to a resource in an observer job before it is sent to the topology service.

Rules can be managed using the Rules REST API in the Merge Service. For each Agile Service Manager observer, merge rules control which tokens are considered merge tokens.

Procedure

1. On the *Rules administration* page, select the **Merge rules** tab.
2. Complete the **Details** section by defining the name, status, and tokens for the rule.

   a. Enter a name, which must be unique within the context of the tenant.

   You cannot change the name of an existing rule. If you want a rule to have a different name, create a new rule, then delete the old one.

   b. Toggle the rule status to be either **Enabled** or **Disabled**.

   When observer jobs are run, they apply only the rules that are in an enabled state.

   c. Define merge tokens for the rule, then click **Add+**.

   The tokens defined as part of a rule contain the list of shared resource parameter names that will become merge tokens for those resources to which the rule is applied. Merge tokens can be constructed using variable substitutions, which allow you to combine more than one property value in a token and also combine them with literal strings, as shown in this example.

   Important: The tokens are the shared elements that the duplicate records to be merged have in common.
3. Complete the **Conditions** section by selecting the observers, provider, and resource type for the rule, and by setting the token include / exclude switch.

a. Select observers to which this rule applies from the Observer name drop-down. Leave empty to apply the rule to all observers.

b. Select providers to which this rule applies from the Provider name drop-down. Leave empty to apply the rule to all providers.

c. Select resource types to which this rule applies from the Resource type drop-down. Leave empty to apply the rule to all resource types.

d. Set the Resource filter mode to either Exclude or Include, then define a filter by specifying a property. You can add more than one property as a filter.

- **Exclude:** Resources with properties that match any of these filters will not have the rule applied to them.
- **Include:** Only resources with properties that match any of these filters will have the rule applied to them.

e. Set the Token filter mode to either Exclude or Include, then define a filter in the format of a regular expression. You can set more than one filter.

- **Exclude:** Tokens which match any one of the expressions will not be applied to resources.
- **Include:** Only tokens which match one of the expressions will be applied to the applicable resources.

4. Validate your filters using the **Validate token filters** button.

5. Click **Save**.

Examples

Default merge rule for the Docker Observer**

The following example is the default merge rule defined for the Docker Observer:

```
rules:
    - name: dockerId
      ruleType: mergeRule
      ruleStatus: enabled
      tokens: [ dockerId ]
      entityTypes: null
      observers: [ docker-observer ]
      providers: null
    - name: almExternalId
      ruleType: mergeRule
      ruleStatus: enabled
      tokens: [ externalId ]
      entityTypes: null
      observers: [ alm-observer ]
      providers: null
```

Note that the rules name in this example is **`dockerId`**, and that it applies only to instances of observers named **`docker-observer`**. The ruleType property here specifies the mergeRule rule type. This merge rule applies to all entity types and all providers and will copy the dockerId property into the merge tokens for all resources that have this property set.

Sample rules for merging resources

A composite resource has its own unique identifier, and the merged resources continue to exist separately. The following example shows the individual and composite resources when retrieved from the topology Resources API.

Resource one

```
https://<your_NASM_host>/1.0/topology/resources/ABC
{
  "_id": "ABC",
  "name": "host1",
  "propertyAbc": "This property only exists on ABC",
  "entityTypes": [ "host" ],
  "tokens": [ "host1MergeToken" ],
  "_compositeId": "XYZ"
}
```

The resource has an id of **`ABC`**, and the value of **`compositeId`** denotes the single, merged resource, which is **`XYZ`**.

Resource two

```
https://<your host>/1.0/topology/resources/DEF
{
  "_id": "DEF",
  "name": "host1",
  "propertyDef": "This property only exists on DEF",
  "entityTypes": [ "host" ],
  "tokens": [ "host1MergeToken" ],
  "_compositeId": "XYZ"
}
```

The resource has an id of **DEF**, and the value of compositeId denotes the single, merged resource, which is **XYZ**.

Composite resource

```
https://<your_NASM_host>/1.0/topology/resources/XYZ
{
  "_id": "XYZ",
  "name": "host1",
  "propertyAbc": "This property only exists on ABC",
  "propertyDef": "This property only exists on DEF",
  "entityTypes": [ "host" ],
  "tokens": [ "host1MergeToken" ],
  "_compositeOfIds": [ "ABC", "DEF " ]
}
```

The resource has an id of **XYZ**, and the value of **compositeOfIds** lists the ids of the merged resources, in this case **ABC** and **DEF**. The XYZ composite resource includes the properties from both of the merged resources.

Resource with variable substitutions and exclude list

```
{
  "name": "sysNameMatching",
  "tokens": [ "sysName", "${name}/${customField}"],
  "ruleStatus": "enabled",
  "entityTypes": [ "host", "server" ],
  "observers": [ "ITNM", "TADDM" ],
  "providers": [ "*" ],
  "customField": "string",
  "excludeTokens": [ "^asm-default.*"]
}
```

The **^asm-default.*** value set for excludeTokens ensures that any values that match the regular expressions are excluded. The merge token with the value of **${name}/${customField}** combine the **${name}** and **${customField}** properties using the **${}** syntax, and demonstrate how variable substitutions work.

Literal values are entered as they are in the merge token, which in this case is the / character.

To be backwards compatible, tokens consisting of a single value, as in the sysName example, are treated as variable substitutions, that is, as if they are ${sysName}.

Tip: You can find more information on merge rules at the following blog post: **https://medium.com/@ibmjdiaz/using-merge-rules-in-agile-service-manager-b66b36707b1c**

Defining match tokens rules

A match tokens rule copies the value of another field to the matchTokens field so that it can be used to match events (alerts) to resources.

About this task

A match tokens rule populates the matchTokens of resources matched by the rule (a simple example is included below the procedure).

Procedure

1. On the *Rules administration* page, select the **Match tokens rules** tab.
2. Complete the **Details** section by defining the name, status, and tokens for the rule.

   a. Enter a name, which must be unique within the context of the tenant.

   You cannot change the name of an existing rule. If you want a rule to have a different name, create a new rule, then delete the old one.

   b. Toggle the rule status to be either **Enabled** or **Disabled**.

   When observer jobs are run, they apply only the rules that are in an enabled state.

   c. Define merge tokens for the rule, then click **Add+**.

   The tokens defined as part of a rule contain the list of shared resource parameter names that will become match tokens for those resources to which the rule is applied. Match tokens can be constructed using variable substitutions, which allow you to combine more than one property value in a token and also combine them with literal strings.

3. Complete the **Conditions** section by selecting the observers, provider, and resource type for the rule, and by setting the token include / exclude switch.

   a. Select observers to which this rule applies from the Observer name drop-down. Leave empty to apply the rule to all observers.

   b. Select providers to which this rule applies from the Provider name drop-down. Leave empty to apply the rule to all providers.

   c. Select resource types to which this rule applies from the Resource type drop-down. Leave empty to apply the rule to all resource types.

   d. Set the Resource filter mode to either Exclude or Include, then define a filter by specifying a property. You can add more than one property as a filter.

   - **Exclude:** Resources with properties that match any of these filters will not have the rule applied to them.
   - **Include:** Only resources with properties that match any of these filters will have the rule applied to them.

   e. Set the Token filter mode to either Exclude or Include, then define a filter in the format of a regular expression. You can set more than one filter.

   - **Exclude:** Tokens which match any one of the expressions will not be applied to resources.
   - **Include:** Only tokens which match one of the expressions will be applied to the applicable resources.
4. Validate your filters using the **Validate token filters** button.

5. Click **Save**.

Examples

Default merge rule for the Docker Observer**

The following example is the default merge rule defined for the Docker Observer:

```
rules:
    - name: dockerId
      ruleType: mergeRule
      ruleStatus: enabled
      tokens: [ dockerId ]
      entityTypes: null
      observers: [ docker-observer ]
      providers: null
    - name: almExternalId
      ruleType: mergeRule
      ruleStatus: enabled
      tokens: [ externalId ]
      entityTypes: null
      observers: [ alm-observer ]
      providers: null
```

Note that the rules name in this example is **dockerId``, and that it applies only to instances of observers named** docker-observer``. The ruleType property here specifies the mergeRule rule type. This merge rule applies to all entity types and all providers and will copy the dockerId property into the merge tokens for all resources that have this property set.

Example

Match token rules

A match token rule allows the value of another field to be copied to the matchTokens field so that it can be used to match events to resources. It populates the matchTokens of resources matched by the rule.

Simple example of a matchTokensRule:

```
- name: matchRule
  ruleType: matchTokensRule
  ruleStatus: enabled
  tokens: [ name ]
  entityTypes: null
  observers: null
  providers: null
```

Resource with variable substitutions and exclude list

```
{
  "name": "sysNameMatching",
  "tokens": [ "sysName", "${name}/${customField}"],
  "ruleStatus": "enabled",
  "entityTypes": [ "host", "server" ],
  "observers": [ "ITNM", "TADDM" ],
  "providers": [ "*" ],
  "customField": "string",
```

```
  "excludeTokens": [ "^asm-default.*"]
}
```

The **^asm-default.*** value set for excludeTokens ensures that any values that match the regular expressions are excluded. The merge token with the value of **${name}/${customField}** combine the **${name}** and **${customField}** properties using the **${}** syntax, and demonstrate how variable substitutions work.

Literal values are entered as they are in the merge token, which in this case is the / character.

To be backwards compatible, tokens consisting of a single value, as in the sysName example, are treated as variable substitutions, that is, as if they are ${sysName}.

Defining tags rules

A tags rule copies the value of another field to the tags field so that it becomes searchable in the UI.

About this task

A resource's tags can be searched via the UI, and matching resources can be displayed. Resources with common tags can optionally be grouped using a tag-based template definition.

A tags rule populates the tags of resources matched by the rule. Examples are included below the procedure.

Tip: Any field that isn't indexed and can therefore not normally be searched for becomes searchable if copied to the tags property.

ITNM Observer tip: You can create custom tags on IBM Tivoli Network Manager, which the ITNM Observer can integrate into Agile Service Manager tags. For information on creating custom tags in Network Manager, see the 'A'dding name-value pairs to entities using the File finder' topic in the IBM Tivoli Network Manager IP Edition documentation.

Having added a custom tag in Network Manager, you can extract the value into an Agile Service Manager tag. The following example uses a regular expression to extract the value of the **Country** custom tag:

```
customTags=~/[\\{]Country=(.+?)[,\\}]/
```

Procedure

1. On the *Rules administration page, select the **Tags rules** tab.
2. Complete the **Details** section by defining the name, status, and tokens for the rule.
    1. Enter a name, which must be unique within the context of the tenant.

       You cannot change the name of an existing rule. If you want a rule to have a different name, create a new rule, then delete the old one.
    2. Toggle the rule status to be either **Enabled** or **Disabled**.

       When observer jobs are run, they apply only the rules that are in an enabled state.
    3. Define merge tokens for the rule, then click **Add+**.

       The tokens defined as part of a rule contain the list of shared resource parameter names that will become tags for those resources to which the rule is applied. Tag tokens can be constructed using variable substitutions, which allow you to combine more than one property value in a token and also combine them with literal strings.
3. Complete the **Conditions** section by selecting the observers, provider, and resource type for the rule, and by setting the token include / exclude switch.
    1. Select observers to which this rule applies from the Observer name drop-down. Leave empty to apply the rule to all observers.
    2. Select providers to which this rule applies from the Provider name drop-down. Leave empty to apply the rule to all providers.
    3. Select resource types to which this rule applies from the Resource type drop-down. Leave empty to apply the rule to all resource types.
    4. Set the Resource filter mode to either Exclude or Include, then define a filter by specifying a property. You can add more than one property as a filter.
        - **Exclude:** Resources with properties that match any of these filters will not have the rule applied to them.
        - **Include:** Only resources with properties that match any of these filters will have the rule applied to them.

5. Set the Token filter mode to either Exclude or Include, then define a filter in the format of a regular expression. You can set more than one filter.

    - **Exclude:** Tokens which match any one of the expressions will not be applied to resources.
    - **Include:** Only tokens which match one of the expressions will be applied to the applicable resources.

4. Validate your filters using the **Validate token filters** button.

5. Click **Save**.

Example 1

This tags rule allows the value of another field to be copied to the tags field so that it becomes searchable in the UI. It populates the tags of resources matched by the rule.

Simple example of a tagsRule:

```
- name: tagRuleCustomProp
  ruleType: tagsRule
  ruleStatus: enabled
  tokens: [ name ]
  entityTypes: null
  observers: null
  providers: null
```

Example 2

The following example creates tags rules for the Docker Observer and will add **`com.docker.compose.service`** and **`com.docker.compose.project`** properties to the tags list, for entities of the type **`container`**:

```
curl -k -s -X POST --user $PROXY_USER:$PROXY_PASSWORD --header 'Content-Type: application/json' --header
'Accept: application/json' --header 'X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255' -w "Response code: %
{http_code}\n" -d '{
  "tokens": [
    "com.docker.compose.service",
    "com.docker.compose.project"
  ],
  "name": "tag-docker-container-service-project",
  "ruleStatus": "enabled",
  "ruleType": "tagsRule",
  "observers": [
    "docker_observer"
  ],
  "entityTypes": [
    "container"
  ]
}
' "https://${PROXY_HOST}/1.0/merge/rules"
```

To verify:

```

  "vcs-type": "git",
  "vendor": "IBM",
  "version": "1.0.10-SNAPSHOT"
}
```

Example 3

Resource with variable substitutions and exclude list:

```
{
  "name": "sysNameMatching",
  "tokens": [ "sysName", "${name}/${customField}"],
  "ruleStatus": "enabled",
  "entityTypes": [ "host", "server" ],
  "observers": [ "ITNM", "TADDM" ],
  "providers": [ "*" ],
  "customField": "string",
  "excludeTokens": [ "^asm-default.*"]
}
```

The **^asm-default.*** value set for excludeTokens ensures that any values that match the regular expressions are excluded. The merge token with the value of **${name}/${customField}** combine the **${name}** and **${customField}** properties using the **${}** syntax, and demonstrate how variable substitutions work.

Literal values are entered as they are in the merge token, which in this case is the / character.

To be backwards compatible, tokens consisting of a single value, as in the sysName example, are treated as variable substitutions, that is, as if they are ${sysName}.

Defining history rules

A history rule identifies properties that change every observation, but that don't indicate an important change, for example a host's **sysUpTime** property. A history rule allows you to exclude properties from being retained in history, thereby saving resources by not maintaining detailed historical records of changes to these properties.

About this task

A history rule populates the **historyExcludeTokens** field with field names.

When a resource is updated, the topology service checks if all the updates are on fields that are listed in **historyExcludeTokens**, and if they are, it updates the resource without creating history.

Procedure

1. On the *Rules administration* page, select the **History rules** tab.
2. Complete the **Details** section by defining the name, status, and tokens to be used for the rule.

   a. Enter a name, which must be unique within the context of the tenant.

   You cannot change the name of an existing rule. If you want a rule to have a different name, create a new rule, then delete the old one.

   b. Toggle the rule status to be either **Enabled** or **Disabled**.

   When observer jobs are run, they apply only the rules that are in an enabled state.

   c. Define a token for the rule, then click **Add+**.

   The tokens defined as part of a rule contain the list of shared resource parameter names that will become **history exclude** tokens for those resources to which the rule is applied. Merge tokens can be constructed using variable substitutions, which allow you to combine more than one property value in a token and also combine them with literal strings.
3. Complete the **Conditions** section by selecting the observers, provider, and resource type for the rule.

   a. Select observers to which this rule applies from the Observer name drop-down. Leave empty to apply the rule to all observers.

   b. Select providers to which this rule applies from the Provider name drop-down. Leave empty to apply the rule to all providers.

c. Select resource types to which this rule applies from the Resource type drop-down. Leave empty to apply the rule to all resource types.

4. Click **Save**.

Defining file enrichment rules

A file enrichment rule provides additional resource information (via file) that is matched to specific resources via a specified resource identifier (the token).

About this task

The supplemental resource information provided via a file enrichment rule can be geolocation data provided as a GeoPoint file, or any other data provided as a more complex JSON file.

Using GeoPoint

Using JSON

Using a GeoPoint file

The GeoPoint format is specific to geolocation data. A file enrichment rule matches a specified resource identifier (the token) to the longitude and latitude (the geographical location) of the resource. Resources that have been enriched with a geographical location can be displayed on the topology resource map.

Before you begin

Remember: To enrich your resource records with geolocation data, you can use a file enrichment rule as described here, or you can load resource data with geolocation properties included, for example by using the File or REST observers.

Create a file that contains the location information for your resources.

The file enrichment rule uses the following parameters for GeoPoint:

```
{
"tokens" : ["clli"],
"fileName" : "example-geopoint.txt",
"format" : "geoPoint,
...
}
```

File format - The file you use must be in the TSV (tab-separated values) format. - The values on each line are 'token', 'longitude' and 'latitude':

```
token longitude latitude
```

Tip: CLLI (Common Language Location Identifiers) are supported and can be used as tokens.

Example

A file enrichment rule allows the value of a token to be used to map that resource to its location on a map.

Example TSV file

```
LONDON-CTR-01    -0.120226    51.509287
LONDON-CTR-02    -0.108514    51.485100
MCHSTR-CTR-01    -2.248665    53.482641
LVERPL-CTR-01    -2.996455    53.403925
```

Example rule

```
* name = serverBuildingLocations
* enabled = true
* token = buildingCode
* file = server-buildings.tsv
```

Example resource

```
{
  "uniqueId": "server-001",
  "name": "server-001",
  "entityTypes": [
    "server"
  ],
```

```
  "buildingCode": "LONDON-CTR-01"
}
```

Procedure

1. On the *Rules administration* page, select the **File enrichment rules** tab.
2. Complete the **Details** section by defining the name, status, token and file to be used for the rule.

   a. Enter a name, which must be unique within the context of the tenant.

   You cannot change the name of an existing rule. If you want a rule to have a different name, create a new rule, then delete the old one.

   b. Toggle the rule status to be either **Enabled** or **Disabled**.

   When observer jobs are run, they apply only the rules that are in an enabled state.

   c. Define a token for the rule, then click **Add+**.

   The token is used to uniquely identify the resource to which the rule is applied, against which a location is mapped using the data contained in the rule file. Only a single token is used to map a location, but you can construct it using variable substitutions, which lets you combine more than one property value if required.

   d. Specify the format of the enrichment file, in this case **GeoPoint**.

   Remember: You must create this file before you can create a new file enrichment rule.

   e. Specify the enrichment file to be uploaded.

   Under **File mode**, select one of the following options:

   - Upload local file: Either drag-and-drop or click and browse to choose a file.
   - Use server file: Specify the name of the file to be loaded. The file must have been uploaded previously. Do not specify a path.
3. Complete the **Conditions** section by selecting the observers, provider, and resource type for the rule, and by setting the token include / exclude switch.

   a. Select observers to which this rule applies from the Observer name drop-down. Leave empty to apply the rule to all observers.

   b. Select providers to which this rule applies from the Provider name drop-down. Leave empty to apply the rule to all providers.

   c. Select resource types to which this rule applies from the Resource type drop-down. Leave empty to apply the rule to all resource types.

   d. Set the Resource filter mode to either Exclude or Include, then define a filter by specifying a property. You can add more than one property as a filter.

   - **Exclude:** Resources with properties that match any of these filters will not have the rule applied to them.
   - **Include:** Only resources with properties that match any of these filters will have the rule applied to them.

   e. Set the Token filter mode to either Exclude or Include, then define a filter in the format of a regular expression. You can set more than one filter.

   - **Exclude:** Tokens which match any one of the expressions will not be applied to resources.
   - **Include:** Only tokens which match one of the expressions will be applied to the applicable resources.
4. Validate your filters using the **Validate token filters** button.
5. Click **Save**.

Results

Additional resource information added via the file enrichment functionality is displayed on the Resource details screen.

Using a JSON file

The JSON file format lets you enrich resource data with any custom properties required. A file enrichment rule using a JSON file matches a specified resource identifier (the token) as well as a file enrichment key (a second token) in order to provide additional data for specified resources.

Before you begin

Create a file that contains the additional information for your resources.

The file enrichment rule uses the following parameters for JSON:

```
{
"tokens" : ["uniqueId"],
"fileName" : "example-json.txt",
```

```
"format" : "json",
"fileEnrichmentKey":"cityName",
...
}
```

File format - The JSON file format requires separate tokens for the resource and for the file data.

Example

```
- name = fileEnrichmentKey
- token = uniqueId
```

```
{"name":"Ireland","capital":"Dublin","tags":["green","wet"]}
{"name":"UK","capital":"London","geolocation":{"geometry":{"type":"Point","coordinates":[0.00000,0.00000]}}}
{"name":"France","capital":"Paris","population":70000000}
{"name":"Germany","capital":"Berlin","entityTypes":["rave scene"]}
{"key":"Switzerland","capital":"Bern"}
```

Resources

```
V:{"uniqueId":"Ireland","entityTypes":["country"],"tags":["republic"]}
V:{"uniqueId":"UK","entityTypes":["country"]}
V:{"uniqueId":"France","entityTypes":["country"]}
V:{"uniqueId":"Germany","entityTypes":["country"]}
V:{"uniqueId":"Switzerland","entityTypes":["country"]}
```

Enriched resources

```
V:{"uniqueId":"Ireland","entityTypes":["country"],"tags":["republic","green","wet"],"capital":"Dublin"}
V:{"uniqueId":"UK","entityTypes":["country"],"capital":"London","geolocation":{"geometry":
{"type":"Point","coordinates":[0.00000,0.00000]}}}
V:{"uniqueId":"France","entityTypes":["country"],"population":70000000,"capital":"Paris"}
V:{"uniqueId":"Germany","entityTypes":["country","rave scene"],"capital":"Berlin"}
V:{"uniqueId":"Switzerland","entityTypes":["country"],"capital":"Bern"}
```

Procedure

1. On the *Rules administration* page, select the **File enrichment rules** tab.
2. Complete the **Details** section by defining the name, status, token and file to be used for the rule.

   a. Enter a name, which must be unique within the context of the tenant.

   You cannot change the name of an existing rule. If you want a rule to have a different name, create a new rule, then delete the old one.

   b. Toggle the rule status to be either **Enabled** or **Disabled**.

   When observer jobs are run, they apply only the rules that are in an enabled state.

   c. Define a token for the rule, then click **Add+**.

   The token is used to uniquely identify the resource to which the rule is applied.

   Remember: The **`fileEnrichmentRule`** you are creating uses this token to match the file to the resource.

   d. Specify the format of the enrichment file, in this case **JSON**.

   Remember: You must create this file before you can create a new file enrichment rule.

   e. Specify the enrichment file to be uploaded, and the enrichment file key.

   - Under **File mode**, either upload a local file (drag-and-drop or click and browse), or specify the name of the file to be loaded from a server (uploaded previously; do not specify a path).
   - Specify the enrichment file key. This identifies the property in each line of the enrichment file to be matched against the rule token.

     Remember: The **`enrichmentFileKey`** is the token used in the JSON file to perform the matching against the token chosen in step 2c.
3. Complete the **Conditions** section by selecting the observers, provider, and resource type for the rule, and by setting the token include / exclude switch.

   a. Select observers to which this rule applies from the Observer name drop-down. Leave empty to apply the rule to all observers.

   b. Select providers to which this rule applies from the Provider name drop-down. Leave empty to apply the rule to all providers.

   c. Select resource types to which this rule applies from the Resource type drop-down. Leave empty to apply the rule to all resource types.

d. Set the Resource filter mode to either Exclude or Include, then define a filter by specifying a property. You can add more than one property as a filter.

- **Exclude:** Resources with properties that match any of these filters will not have the rule applied to them.
- **Include:** Only resources with properties that match any of these filters will have the rule applied to them.

e. Set the Token filter mode to either Exclude or Include, then define a filter in the format of a regular expression. You can set more than one filter.

- **Exclude:** Tokens which match any one of the expressions will not be applied to resources.
- **Include:** Only tokens which match one of the expressions will be applied to the applicable resources.

4. Validate your filters using the **Validate token filters** button.
5. Click **Save**.

Results

Additional resource information added via the file enrichment functionality is displayed on the Resource details screen.

Defining events filter rules

An events filter rule prevents the status derived from observer jobs from generating events in the system. You specify observers, providers and resource types to which the rule is applied.

About this task

You define events filter rules to prevent the unnecessary proliferation of system events, for example under testing conditions or any other scenarios where you do not require new events to be created for specific observers, providers or resource types.

Procedure

1. On the *Rules administration* page, select the **Events filter rules** tab.
2. Complete the **Details** section by defining the name and status for the rule.

   a. Enter a name, which must be unique within the context of the tenant.

   You cannot change the name of an existing rule. If you want a rule to have a different name, create a new rule, then delete the old one.

   b. Toggle the rule status to be either **Enabled** or **Disabled**.

   When observer jobs are run, they apply only the rules that are in an enabled state.
3. Complete the **Conditions** section by selecting the observers, provider, and resource type for the rule, and by setting the token include / exclude switch.

   a. Select observers to which this rule applies from the Observer name drop-down. Leave empty to apply the rule to all observers.

   b. Select providers to which this rule applies from the Provider name drop-down. Leave empty to apply the rule to all providers.

   c. Select resource types to which this rule applies from the Resource type drop-down. Leave empty to apply the rule to all resource types.
4. Click **Save**.

Defining business criticality rules

A business criticality rule uses a rule token, which becomes the business criticality value for those resources to which the rule is applied.

About this task

A token can be constructed from resource parameters using variable substitution, which allows you to combine more than one property value if required. Only one token should be specified.

A business criticality rule populates the `businessCriticality` property of resources matched by the rule.

Procedure

1. On the *Rules administration* page, select the **Business criticality rules** tab.
2. Complete the **Details** section by defining the name, status, and single token for the rule.

   a. Enter a name, which must be unique within the context of the tenant.

   You cannot change the name of an existing rule. If you want a rule to have a different name, create a new rule, then delete the old one.

   b. Toggle the rule status to be either **Enabled** or **Disabled**.

   When observer jobs are run, they apply only the rules that are in an enabled state.

   c. Define a token for the rule, then click **Add+**.

   The single token specified as part of a rule becomes the business criticality value for those resources to which the rule is applied.
3. Complete the **Conditions** section by selecting the observers, provider, and resource type for the rule, and by setting the token include / exclude switch.

   a. Select observers to which this rule applies from the Observer name drop-down. Leave empty to apply the rule to all observers.

   b. Select providers to which this rule applies from the Provider name drop-down. Leave empty to apply the rule to all providers.

   c. Select resource types to which this rule applies from the Resource type drop-down. Leave empty to apply the rule to all resource types.

   d. Set the Resource filter mode to either Exclude or Include, then define a filter by specifying a property. You can add more than one property as a filter.

   - **Exclude:** Resources with properties that match any of these filters will not have the rule applied to them.
   - **Include:** Only resources with properties that match any of these filters will have the rule applied to them.

   e. Set the Token filter mode to either Exclude or Include, then define a filter in the format of a regular expression. You can set more than one filter.

   - **Exclude:** Tokens which match any one of the expressions will not be applied to resources.
   - **Include:** Only tokens which match one of the expressions will be applied to the applicable resources.
4. Validate your filters using the **Validate token filters** button.
5. Click **Save**.

Rules reference

Use the following reference information when constructing rules.

Token referencing rules

The rule mechanism supports a number of key use-cases, for example:

```
- Event correlation
- Merging data from multiple data sources
- Tagging resources
```

Rules extract data in a common or standardized way to support such use cases. Data structures can be complex, for example they may include nested key-value pairs in maps and lists, and the rule processing mechanism supports the extraction of data from such structures into a variable known as a 'token'. These tokens are used when applying the rules in order to modify the resource records being processed.

For example, you may wish to extract the value of a nested property and combine it with a literal string that you provide and treat that combination as a single resource tag.

Given the following input:

```
{{{key1=value1, customTags={field1_2=level1, field1_1={field2_2=level2, field2={field3=
{nestedKey=level3}}}}}}
```

The following token definitions result in the shown result:

Table 1. Tokens and results

Token	Result
`key1`	`[value1]`

Token	Result
`${key1}`	`[value1]`
`customTags`	`[{field1_2=level1, field1_1={field2_2=level2, field2={field3={nestedKey=level3}}}}]`
`${customTags}`	`[{field1_2=level1, field1_1={field2_2=level2, field2={field3={nestedKey=level3}}}}]`
`${customTags->field1_2}`	`[level1]`
`${customTags->field1_1}`	`[{field2_2=level2, field2={field3={nestedKey=level3}}}]`
`${customTags->field1_1->field2_2}`	`[level2]`
`${customTags->field1_1->field2}`	`[{field3={nestedKey=level3}}]`
`${customTags->field1_1->field2->field3}`	`[{nestedKey=level3}]`
`${customTags->field1_1->field2->field3->nestedKey}`	`[level3]`
`${customTags->field1_1->field2>field3->nestedKey}`	`[]`
`${customTags->unknown_key}`	`[]`
`${unknownKey->unknown_key}`	`[]`
`${customTags->->unknown_key}`	`[]`
`${customTags->->field1_1}`	`[]`
`${customTags->}`	`[]`
`${->customTags}`	`[]`
`${>customTags>}`	`[]`
`${key1}and${customTags->field1_2}`	`[value1-and-level1]`

Table 2. Changes

Token	Revious result	New result
`{{${whatever}:${name}`	`[[foo, boo]:dinoop]`	`[foo:dinoop, boo:dinoop]}}`
`{{${whatever}:${name}:${place}`	`[[foo, boo]:dinoop:india]`	`[foo:dinoop:india, boo:dinoop:india]}}`
`{{${name}:${whatever}`	`[dinoop:[foo, boo]]`	`[dinoop:foo, dinoop:boo]}}`
`{{${place}:${whatever}:${name}`	`[India:[foo, boo]:dinoop]`	`india:foo:dinoop, india:bar:dinoop, india:zoo:dinoop}}`
`{{${whatever}:newlist`	`[[foo, boo]:newlist]`	`[foo:newlist, boo:newlist]}}`

Table 3. No changes

Token	Revious result	New result
`{{name`	`[dinoop]`	`[dinoop]}}`
`{{${name}`	`[dinoop]`	`[dinoop]}}`
`{{${place}:${name} }}`	`{{[india:dinoop]`	`[india:dinoop]}}`
`{{${age}:${name}`	`[30:dinoop]`	`[30:dinoop]}}`
`{{${whatever}`	`[[foo, boo]]`	`[[foo, boo]]}}`
`{{whatever`	`[boo, foo]`	`[boo, foo]}}`
`{{mymap`	`[{key1=val1}]`	`[{key1=val1}]}}`
`{{${mymap}`	`[{key1=val1}]`	`[{key1=val1}]}}`
`{{${mymap}:${name}`	`[{key1=val1}:dinoop]`	`[{key1=val1}:dinoop]}}`
`{{${whatever}:${newlist}`	`[[foo, boo]:[abc, xyz]]`	`[[foo, boo]:[abc, xyz]]}}`
`{{${whatever}:${mymap}`	`[[foo, boo]:{key1=val1}]`	`[[foo, boo]:{key1=val1}]}}`

Managing incidents and alerts

IBM Cloud Pak® for AIOps enables you to identify health issues across your application, services, and network infrastructure on a single management console. A **Incident list** displays each incident's priority, status, and description. Drill down into an incident to see the probable cause alerts, alert topology, and associated automations.

The Alert Viewer brings together alert details, alert severity, and alert filtering. Some alerts in the console are presented in alert groups, based on analytics. Using the alert list you can explore why these alerts were grouped together, and this can further help with alert resolution.

For more information about incidents and alerts, see the following topics:

- About events, alerts and incidents
- Incidents
- Alerts

About events, alerts and incidents

IBM Cloud Pak® for AIOps represents the state of managed entities using the following three concepts:

- **Events**

  An event is a record containing structured data summarizing key attributes of an occurrence on a managed entity, which might be a network resource, some part of that resource, or other key element associated with your network, services, or applications.

  An event might or might not indicate something anomalous and is a point-in-time, immutable statement about the entity in question.

- **Alerts**

  Alerts represent an ongoing anomalous condition against a single managed entity. Unlike events, alerts might evolve over time as the condition changes. Alerts have a start and an end time. The creation and evolution of alerts are informed by events.

- **Incidents**

  Incidents represent the context around an issue which is currently severely impacting operations. This includes all alerts that are related to the issue and information about how the affected resources are related. The creation and evolution of incidents are informed by alerts.

Alert creation

Alerts are created when one or more events indicate an anomalous condition. This is determined based on the **`type.eventType`** field of an event being set to **`problem`**. When such an event is received by the system, if no alert already exists for the condition, a new alert is created.

Where multiple events occur, indicative of the same condition on the same resource, the events update an existing open alert where one exists rather than creating a new one. This is determined based on events having the same values for the **`resource`** and **`type`** fields as the event that originally created the alert.

If a matching event occurs with a **`type.eventType`** set to **`resolution`**, the alert changes to the **`clear`** state. It stays in this state for 2 minutes after the last update. During this time, if another matching **`problem`** event occurs, the alert re-opens. If however, no more matching events occur, the alert enters the **`closed`** state. Once an alert is in the **`closed`** state, it can no longer be re-opened and any subsequent events create a new alert.

Note: Alerts that are closed are purged from the active store after 2 minutes.

Alert correlation

IBM Cloud Pak® for AIOps automatically correlates your alerts to determine what alerts are likely to share a common cause. This is determined based on a combination of the following mechanisms:

- **Scope-based correlation** - Any alerts which have the same value for the **`resource`** field are correlated.
- **Temporal correlation** - The system continually analyzes past alerts to determine which alerts tend to frequently co-occur. When these alerts occur together again, they are correlated.
- **Topological correlation** - Any alerts which refer to resources within the same Resource group are correlated.

For all of these mechanisms, the correlation only occurs where the last related alert was created within the past **15 minutes**. If an alert is created more than 15 minutes after the last alert, they are not correlated.

Incident creation

Incidents are created when you enable one of the two preset default incident creation policies in the Policies UI, or create your own custom incident creation policy. The preset incident creation policies are disabled by default.

Note: If you are upgrading a deployment of Cloud Pak for AIOps from version 3.2.1 or version 3.2.0, the "Default incident creation policy for high severity alerts" remains enabled by default. This is to retain the same behavior as before the upgrade.

IBM Cloud Pak® for AIOps determines which of your alerts were caused by the same problem. If a relevant incident already exists for a given problem, a new incident is not created. An existing incident is deemed relevant if it was created due to any other alert which shares a common cause with the alert in question. If a relevant incident does already exist and is currently open, the alert is added to the incident as an additional *trigger alert*. An incident's trigger alerts are defined as any alert that either caused the incident to be created, or would have caused creation had an incident not already existed. An incident takes the name of its first trigger alert.

When an incident is created, any alerts sharing the same cause as the incident's trigger alerts are automatically added as *contextual alerts*. This list is kept up to date as subsequent related alerts are detected.

In a incident overview (or a in a ChatOps notification), you can also find alerts that are ranked as *probable cause alerts* by Cloud Pak for AIOps. That is, the alerts that are most likely to be the probable cause of the incident. The distinction between *probable cause alerts* and *trigger alerts* is that the trigger alert(s) indicated that the problem is severe enough to warrant an incident (and therefore triggered its creation), but they did not necessarily cause the issue the incident represents. The probable cause alert (which could be a contextual alert) might have caused the incident,

as it caused the underlying issue. Without the trigger alert(s), the incident is not created, but other parts of the issue (including the cause) might still be there.

The state of the incident is linked to the state of the incident's trigger alerts. If all trigger alerts within an incident enter the **`clear`** state, the incident enters the **`resolved`** state, and is closed 2 minutes after the last update. Likewise, an incident can become unresolved (that is, go back to in progress) if any of the triggered alerts become open again. This can happen when a new problem alert is received before the incident was closed.

Incidents

The **Incidents** tab displays information such as incident's priority, status, description, and when it was opened. From here, you can change the status or priority of an incident, and also manage the assignees. Drill down into any incident in the list to see the probable cause alerts, alert topology, and any associated automations. When you click an incident in the table, you can see more details in the side panel.

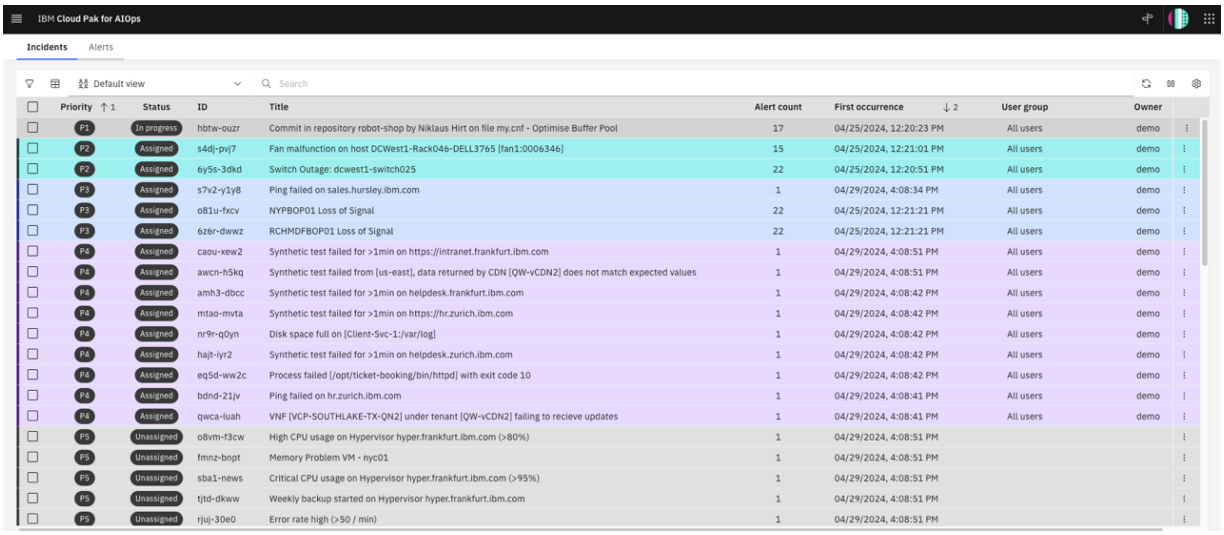

Figure. Incidents UI

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Incidents**.
    - Click the menu overflow icon of any incident (the three dots at the end of the row) to **Change priority** (from P1 - highest priority to P5 - lowest), **Change status** (Unassigned, In progress, On hold, or Resolved), **Change title**, or **Manage assignees**.
    - Click on an incident's **Title** text to open the incident's **Overview** page.

Side panel

Click in the row of an incident you are interested in to open a **side panel** on the right-hand side of the table. It shows the incident's **Priority** (Priority 1 - highest priority through to Priority 5 - lowest) and current **Status** (Unassigned, In progress, On hold, or Resolved). You can click the options menu at the top of the side panel (three vertical dots) to change the incident's status, priority, or manage the assignees.

The **Incident ID**, the linked **ServiceNow** incident number, the linked **Slack** message and Slack reactive channel name, and when the incident was **Opened** are all displayed in the side panel. Click **Investigate** to go to the incident **Overview** page.

If the incident is assigned, the side panel shows the **Group** and **Owner** on the incident. If the incident is not yet assigned, click **Assign** to assign a group or owner. To change a current assignment, click **Edit** .

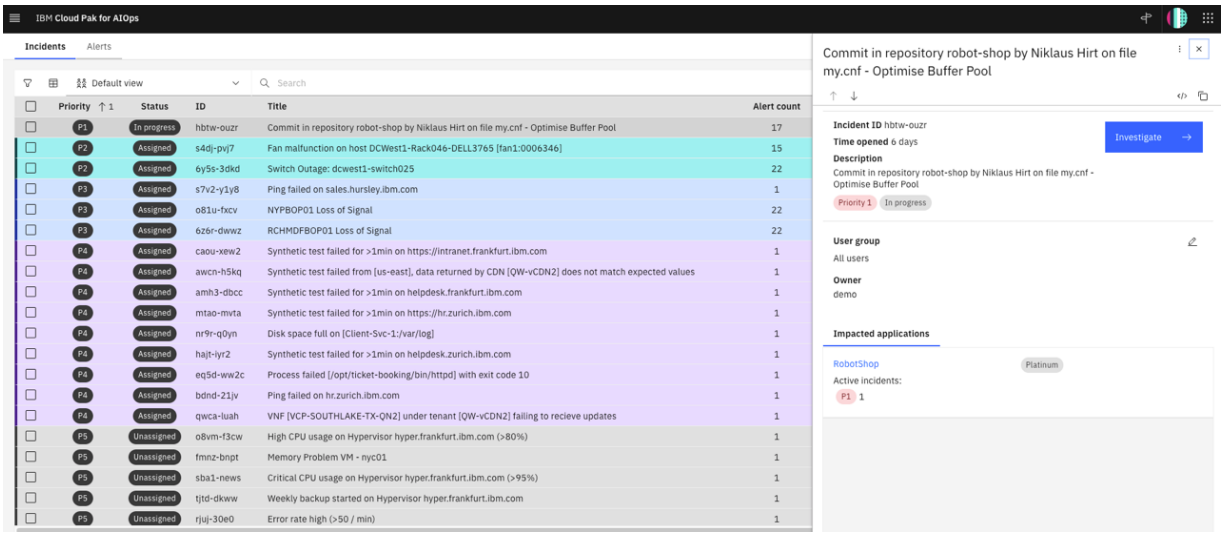

Figure. Incident Side panel

Applications that are impacted by the alerts that are part of the incident are listed under **Impacted applications**. The number of **Active incidents** that the application is impacted by is displayed. These incidents are categorized by **Priority level**. The importance of each impacted application to the business is also shown by a **Business criticality** indicator on the right of the side panel. Applications are sorted based on priority. You can click an application name to launch out to the application in **Resource management**.

The following table lists the columns present in the **Incidents** tab.

Table. Incident attributes

Column	Description
Priority	Indicates the impact level of an incident on customer. Priority levels range from **P1** (highest priority) to **P5** (lowest).
Status	An incident can have a status of **Unassigned**, **Assigned**, **On hold**, **In progress**, or **Resolved**.
Description	A description of the incident. Hover the cursor over the text in the **Description** column to display a link to the Incident overview.
Time open	Time period since the incident was created.
User group	Group assigned to the incident.
Owner	User assigned to the incident.

The following icons are used on the incident list:

Table. Incident icons

Icon	Name	Description
	Search	Click this icon to search for text in any of the columns displayed in the table.
	Filter	Click the filter icon to filter the incidents in the table based on any of the following criteria: • Priority • Status • Impacted applications • User groups • Owner • First occurrence
	Refresh	Refresh the incident list to view all the latest incidents at the current point in time.

For more information about incidents in Cloud Pak for AIOps, see the following topics:

- Incident overview
- Searching and filtering incidents
- Managing multiple incidents

Incident overview

The incident **Overview** functions as a report on the best course of action by presenting the top probable causes, as well as similar past resolution tickets, associated automations to remediate the alerts, and a host of other information.

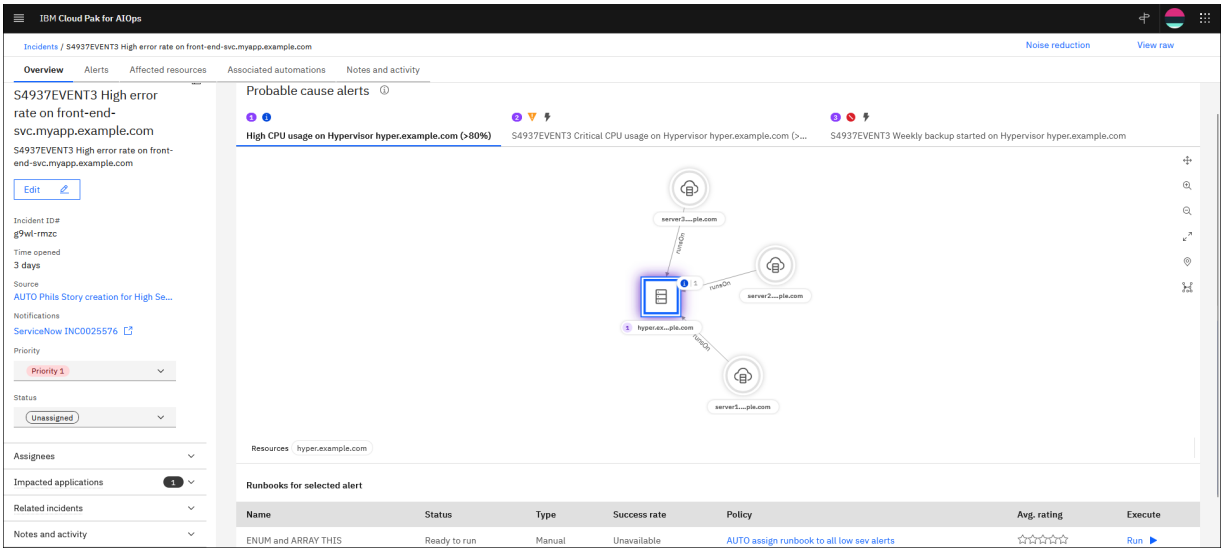

Figure. Incident overview

From a ChatOps integration (Slack, Microsoft Teams, or ServiceNow), you can launch into an incident's overview from the **incident title link** in the notification. From within Cloud Pak for AIOps, complete the following steps to navigate to an incident's overview page.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Incidents**.
3. From the **Incidents** tab, select an incident from the list and click the text in the **Title** column.

The **Noise reduction** indicator (upper right) shows how Cloud Pak for AIOps reduces the number of IT events that your operations staff must evaluate. The Noise reduction percentage shows the reduction in the number of events that are correlated and grouped into alerts that are included in each incident.

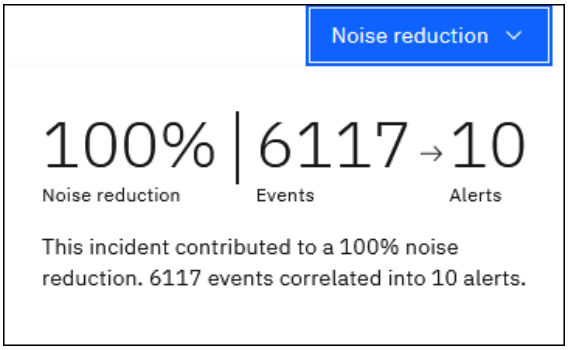

Figure. Noise reduction

Next to Noise reduction, you can click **View raw** if you want to view the incident data in raw JSON format.

The following sections are presented on the incident **Overview** page:

- Probable cause alerts
- Alert topology
- Collapsible side panel
- Probable alert automations
- Similar past resolution tickets

For more information about the **Alerts** tab and **Topology** tab, see Alert Viewer and Viewing a topology.

Probable cause alerts

Based on the topology that is associated to an incident, and the classification of the alerts, the alerts that are most likely to be the probable cause of the incident are presented here. Probable cause alerts show the top three most likely cause alerts, ranked in order of probability of being the cause of the incident.

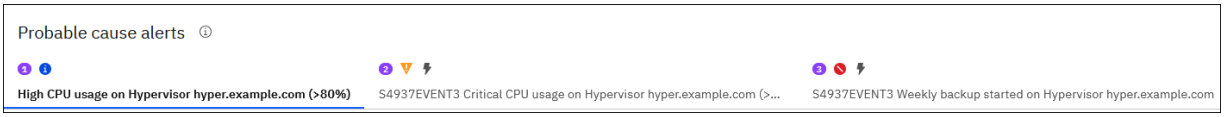

Figure. Probable cause alerts

The following information is displayed for each probable cause alert:

- **Probable cause ranking** 1 2 3

  Probable cause assigns a ranking to all of the alerts in the incident. Alerts are ranked in order of likelihood of being the cause of the incident.

- **Severity indicator**

  Indicates the severity of the alert. The following severity icons are used:

  - Critical
  - Major
  - Minor
  - Warning
  - Informational
  - Indeterminate

- **Trigger alert**

  Denotes alerts that are defined as trigger alerts. That is, an alert that either caused the incident to be created, or would have caused creation had an incident not existed.

- **Summary**

  A description of the alert.

Note: Where probable cause cannot be identified, the section **Top Alerts** appears instead, listing the top 3 alerts for the incident ranked in order by severity, first occurrence, trigger alerts, and finally by the availability of associated automations.

Select any of the probable cause or top alerts to see topology information for that alert.

To get more details about a probable cause alert, click **View alert** below the topology diagram. This brings you to the Alert Viewer, with the relevant alert selected and the **Alert details** displayed.

Alert topology

Select a probable cause alert (or top alert) from the list. If the resource on which the alert occurred can be located in the network topology system, a one hop topology map is displayed for this alert, centered on the resource on which the alert occurred.

Restriction: For an incident topology to be generated from the alert, at least one topology group that is enabled for correlation **must** have been added to the alert.

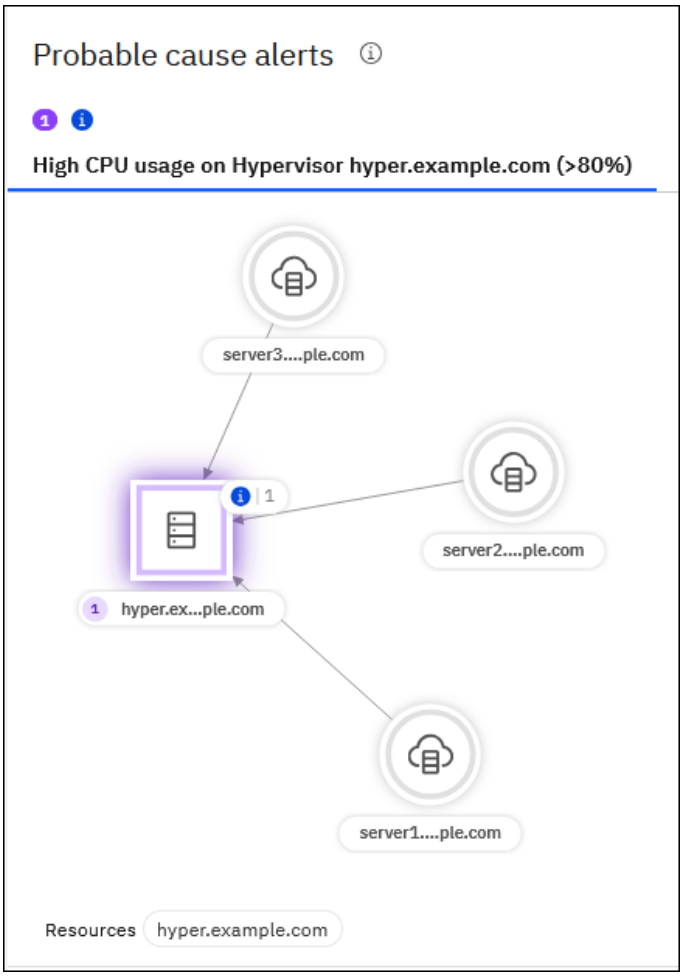

Figure. Alert topology

To investigate the incident topology, click **View topology** below the topology diagram. If the topology group condition is met, then this action opens the **Topology** tab, which provides a holistic view of the relationships between different infrastructure and application components.

For each resource associated with the incident, you can see the number of alerts, severity indicator, and probable cause ranking. This information can be used to rapidly identify the root cause and the impact of the issue on your environment before acting.

Side panel

The side panel is displayed by default on the Incident overview page. You can click **Edit** in the side panel to change the incident name or description.

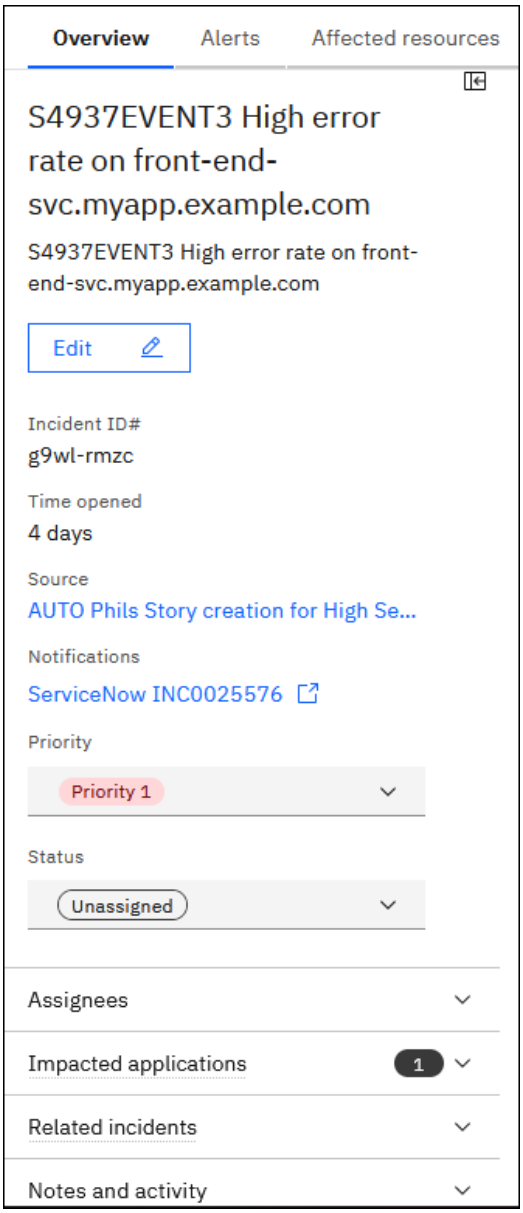

Figure. Incident Side panel

The following incident information is displayed in the Overview side panel:

- *Incident ID* - A unique number that is assigned to the incident
- *Time opened* - How long the incident has been opened for.
- *Source* - The IBM Cloud Pak for AIOps policy that created the incident. Click the link to locate that policy on the Policies UI.
- *Notifications* - When available, the linked **ServiceNow** incident number.
- *Priority* - Priority level that indicates the impact level of an incident on the customer. Priority 1 is the highest priority, through to Priority 5 the lowest. You can change an incident's priority level from the drop-down menu in the side panel.
- *Status* - Unassigned, In progress, On hold, or Resolved. You can change an incident's status from the drop-down menu in the side panel.

The overview **side panel** also contains the following sections:

- **Assignees**

  If the incident is assigned, the **Group** and **Owner** of the incident are listed under Assignees. If the incident is not yet assigned, expand **Assignees** to assign a group or owner.

- **Impacted applications**

  Applications that are impacted by the alerts that are part of the incident are listed under Impacted applications. A number indicates how many applications have been impacted. Click the arrow ⌄ to expand the list of applications. The importance of each impacted application

to the business is shown by a **Business criticality** indicator on the right of the side panel. The number of **Active incidents** that the application is impacted by is also displayed. These incidents are categorized by **Priority level**. Applications are sorted based on priority. You can click an application name to launch out to the application in **Resource management**. If there are more than five applications, you can click **View all** to open a modal containing the complete list. You can sort the applications in the table by clicking on each column header within the modal table. To filter the list of impacted applications, enter a search string in the **Search** box within the modal and start typing the name of the application you are looking for. As you type, the list displays only applications that contain the typed text. As with the applications displayed in the side panel, clicking an application's name opens that application.

- **Related incidents**

  Any incidents that share contextual alerts are listed in the **Related incidents** section of the side panel. Related incidents can provide more context when you are resolving an incident. A number indicates how many related incidents have been found. Click the arrow to expand the list of incidents. The priority and status of each incident is displayed, and the number of associated alerts. Related incidents are sorted based on priority. You can click an incident's title text to go to the incident's **Overview** page. If there are more than five related incidents, you can click **View all** to open a modal containing a complete list. You can sort the incidents in the table by priority, status, and alert count. To filter the list of incidents, enter a search string in the **Search** box within the modal and start typing the name of the incident you are looking for. As you type, the list displays only incidents that contain the typed text. As with the incidents displayed in the side panel, clicking the title text opens that incident's **Overview** page.

- **Notes and activity**

  A timeline of major events that have occurred in the lifecycle of an incident. Click View all notes and activity to go to the **Notes and activity** tab.

  To collapse the side panel, click the arrow at the top of the panel beside the incident name.

Probable alert automations

The overview page for an incident displays the top three probable alerts for an incident. Runbooks that are associated with those alerts are visible in a table below the selected alert's topology. Select an alert to display the associated runbooks.

Similar past resolution tickets

It can be helpful to review the details of similar past resolution tickets to help determine the best course of action. Click **Add tickets to incident** button to open the window.

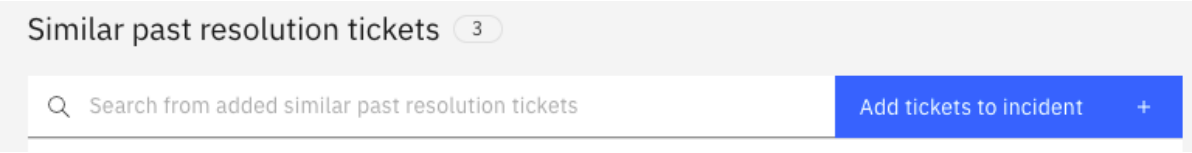

Figure. Similar past resolution tickets window

When the *Add tickets to incident* window opens you can search, select tickets from the past, and click **Add to incident** button to add the selected tickets to this incident. The following diagram shows the capability to add tickets to an incident.

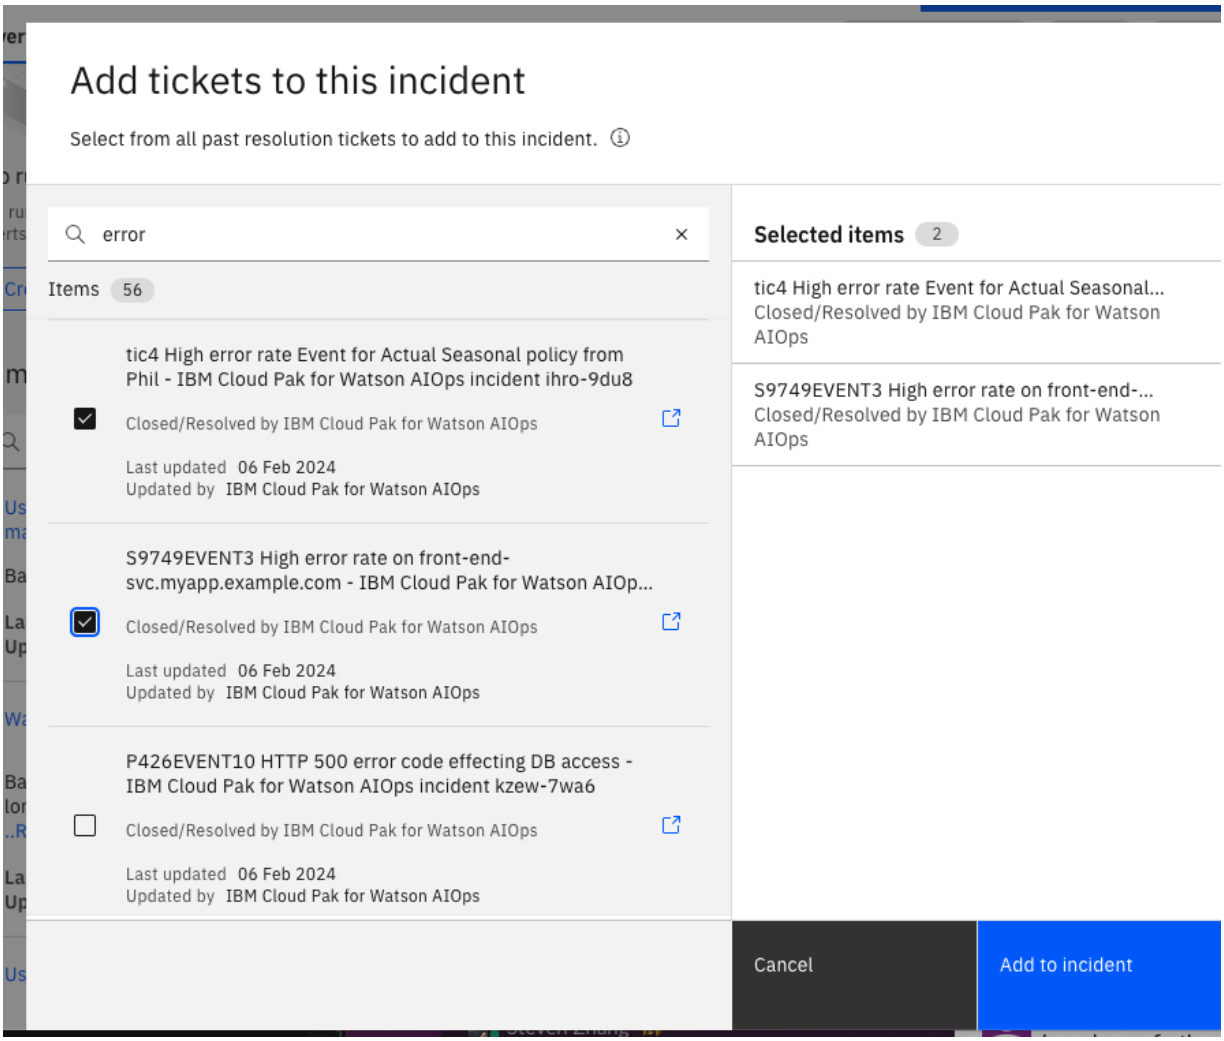

Figure. Add tickets to the incident by using the Add to incident button

The following prerequisites must be met for the data to show in the ticketing insights window.

1. Setup ticketing integrations. For more information about Integrations, see Integrations.
2. Run Similar tickets training. For more information about setting up Similar tickets training, see Setting up training for similar tickets.
3. Enable the *default story query similar incidents service* policy. To enable this policy, go to **Automations** > **Policies**. Set the state of this policy to *enabled*.
4. A minimum of five qualifying tickets are needed. **Qualified tickets are closed**. For more information about the required attributes for similar tickets, see Qualifying tickets.

Insights are used to display any similar past resolution tickets that are associated with the incident, together with a description of each ticket. You can remove the past resolution tickets from an incident. You can click the **dismiss (-)** button to remove the past resolution ticket. The following diagram shows the ability to remove tickets from an incident.

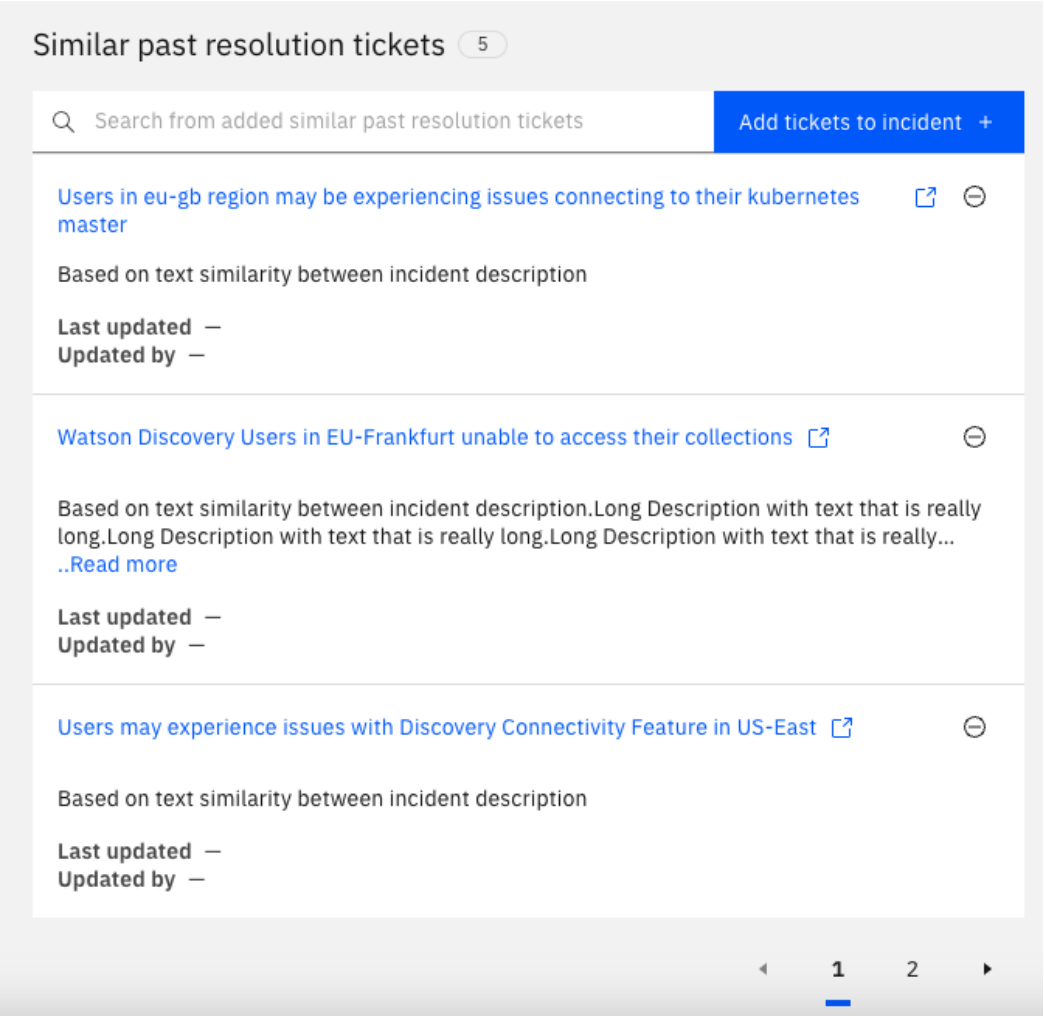

Figure. Remove tickets to the incident by using the dismiss button

Click the title of a past-resolution ticket to open the linked ticket. For example, the ticket can be a ServiceNow ticket.

You can navigate to the following **tabs** from the incident overview:

Alerts

Click the **Alerts** tab for a list of all the alerts that are associated to the incident.

Affected resources

Shows the relationships of impacted resources. Note, this view is only populated when an incident has an associated topology.

Associated automations

See an aggregate of automations associated with alerts within the incident. For a given automation, the table displays various details and you can navigate to the associated policy, alert, or run the automation.

The following information is displayed for each recommended runbook:

- **Status**

  Successfully executed, Failed, Cancelled, In progress, or Completed.

- **Type**

  Indicates the Runbook type: Manual or Automated.

- **Success rate**

  The success rate is calculated by using the number of successful and unsuccessful executions of the runbook.

- **Policy**

Shows the Cloud Pak for AIOps policy that assigned the runbook to the selected alert. Click the policy name to locate that policy on the Policies UI.

- **Average rating**

  Operations analysts can provide feedback about the quality of a runbook including a rating, which is displayed here (five stars is the top rating).

- **Associated alert**

  Click to view the alert that is associated to the runbook in the Alert Viewer.

- **Execute**

  Click **Run** to run the runbook.

Notes and activity

A timeline of major events that have occurred in the lifecycle of an incident. The following events are logged to the Activity timeline:

- When an incident is created.
- Incident is assigned to new owner or team.
- An alert has been associated with the incident.
- Incident state changes. For example, the incident has been set to **On hold** from **In progress**, or marked as **Resolved**.
- Changes to the incident title or description.
- User added comment.

To add a comment to the incident timeline, type a comment in the field that is provided and click **+** Add comment. A maximum of 250 characters are supported. The comment is stored in the timeline in chronological order with the other entries.

For more information, see the following pages:

- About events, alerts and incidents
- Viewing a topology
- Runbooks
- Policies

Searching and filtering incidents

Search for incidents by name, or filter the list based on selected critria.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Incidents**.

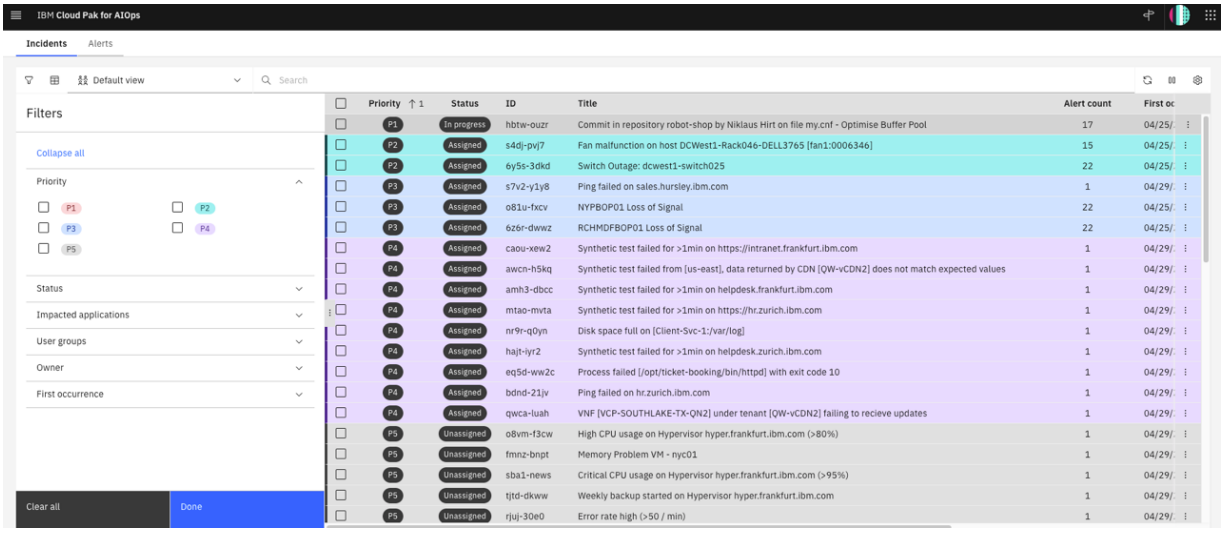

Figure. Search and filter incidents

- To search for an incident in the table:
  - Click anywhere in the **Search** field.
  - Start typing a description of the incident in the search field. For example, type "failed" and the system will show in the table all incidents that contain the text "failed" in the description.

- To filter the list of incidents in the table:
    - Click **Filter** to open the filter side panel.
    - Select from the following filters for incidents:
        - Priority: P1 - highest priority, through to P5 - lowest.
        - Status: Unassigned, Assigned, In progress, On hold, or Resolved.
        - User groups: Find user groups to filter by.
        - Owner: Find owners to filter by.
        - Time open: under 1 hour, 1 hour to 1 day, 1 day to 7 days, 7 days to 15 days, 15 days to 30 days, 30 days and above.
    - Click **Done** to close the Filter window.

3. To clear all filters, click **Filter** and then **Clear all**.

To save a new filter

1. Apply the filters preferences you want and then Click **Save as a new filter**.

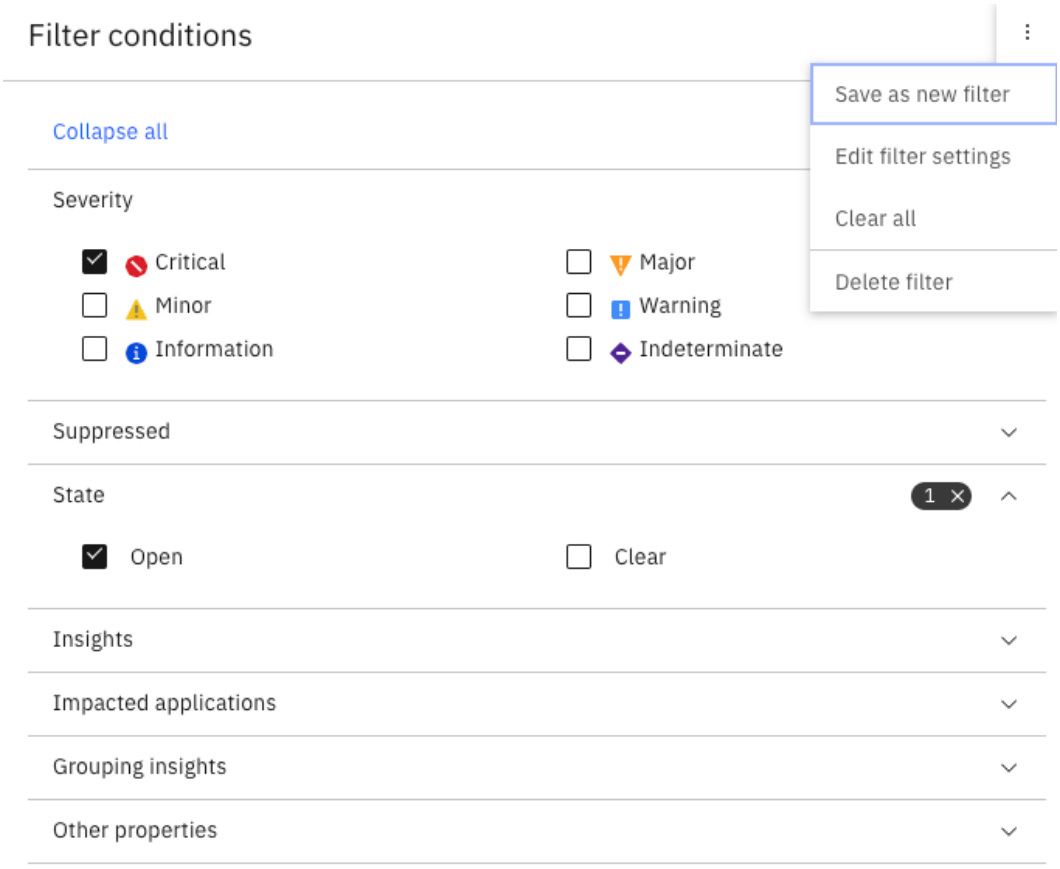

Figure. Save new restriction filter dialog

Note:: Alternatively, if you are an administrator who has *manage profiles* priviledges had enabled, you can set Role Based Access Control (RBAC) functionality that allows you see and click the **Save as a new restriction filter** option, thus applying certain restriction filters, incidents in this case.

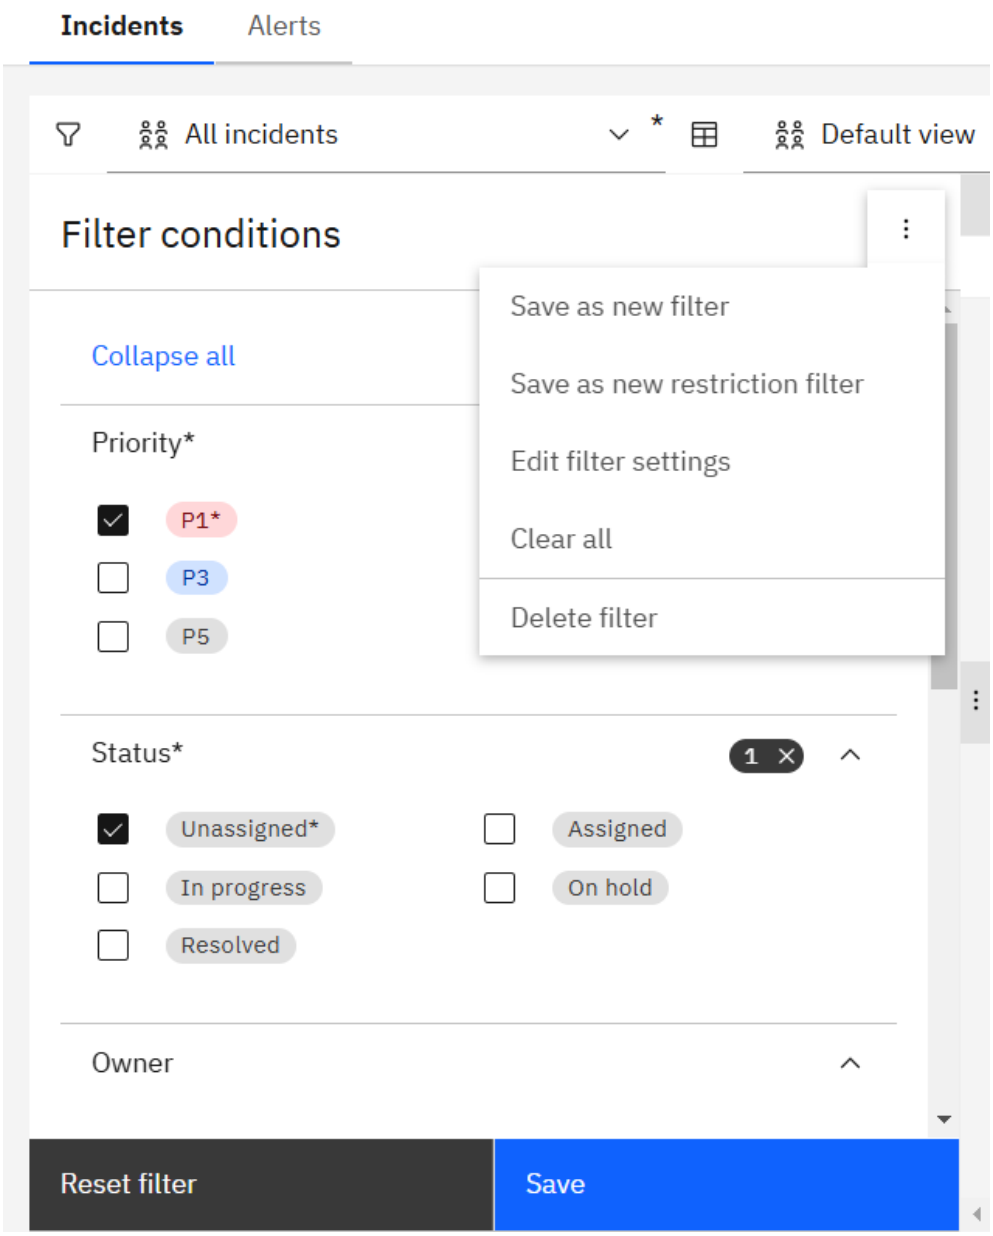

Figure. Save as new restriction filter

The *Save a new restriction filter* dialog that opens is slightly different to the regular *Save a new filter dialog* window also in terms of fields to fill in, as shown below.

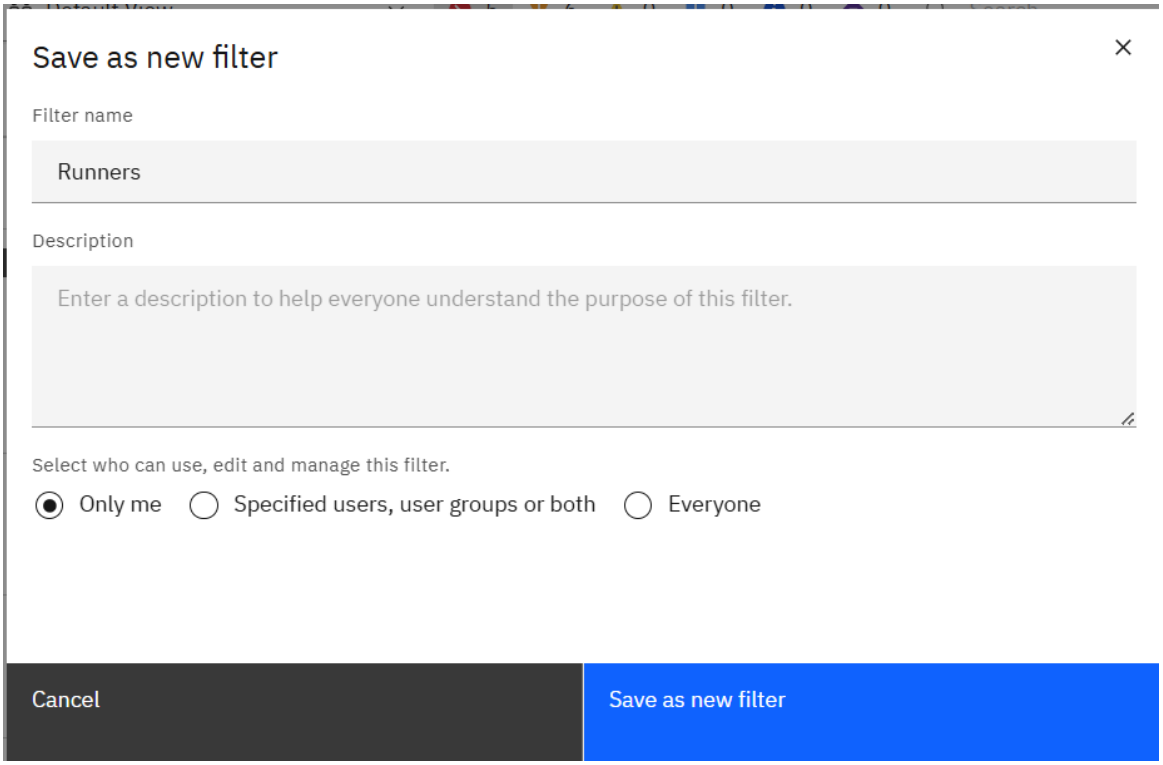

Figure. Incidents save a new filter

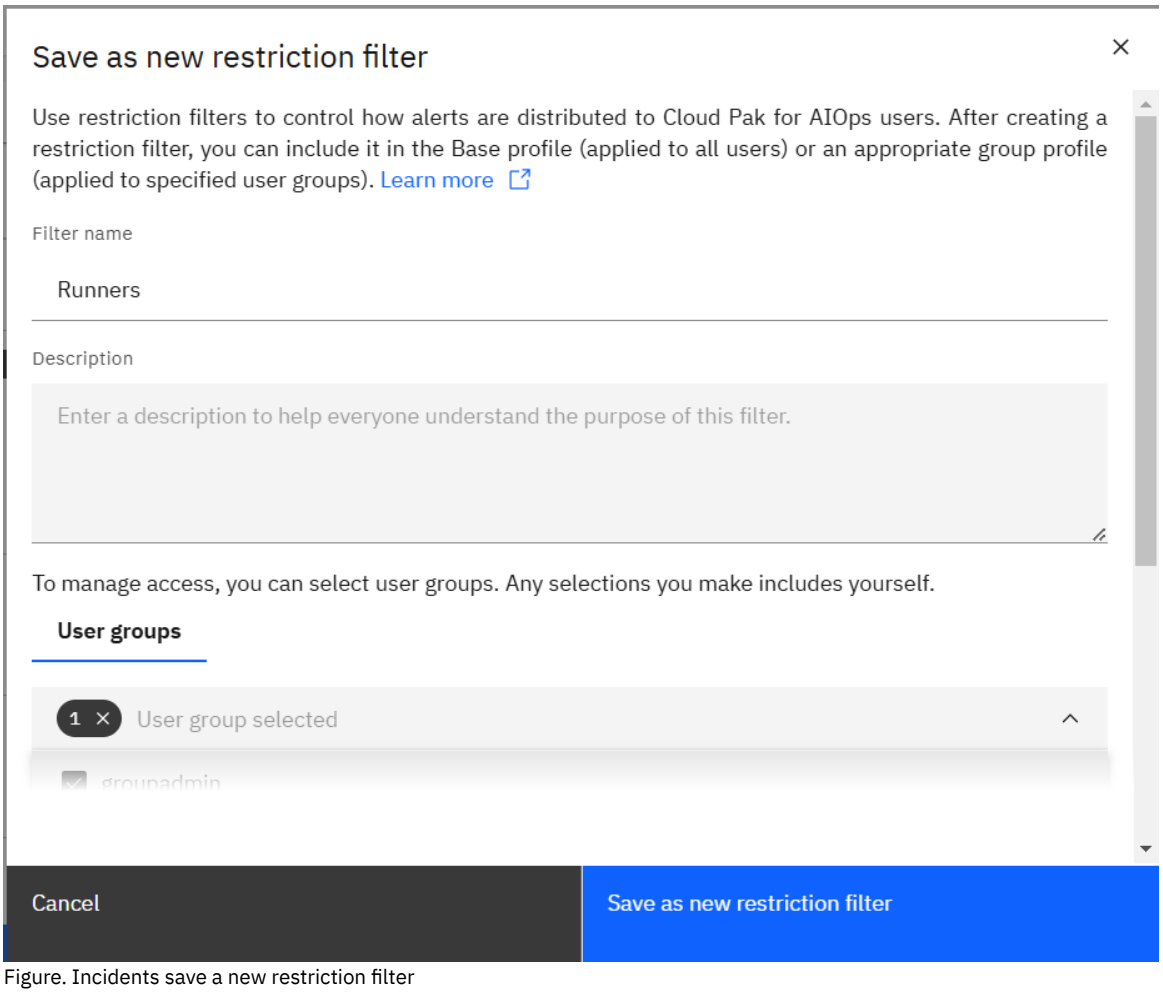

Figure. Incidents save a new restriction filter

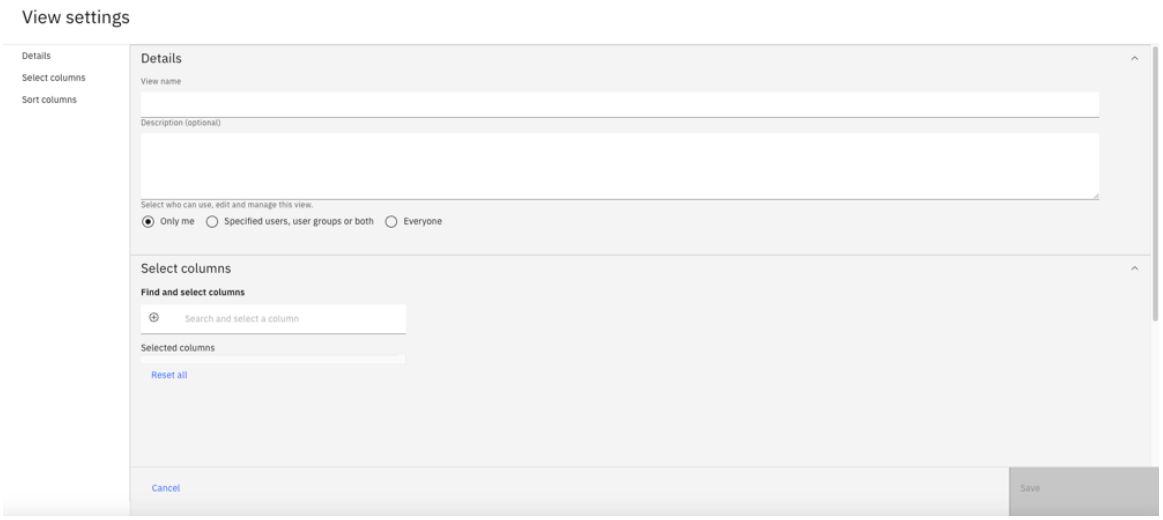


Note: A Role Based Access Control (RBAC) restriction filter can be applied to a user that filters the data they see, but they can additionally apply their own filter conditions on top of that RBAC filter.

Creating views

Create custom views that are dynamically applied to the Incident list. The views determine what information is displayed from the available incident data.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Incidents**.
3. On the toolbar, click **View configuration** > **Create a new view**.
4. Configure the following properties for a custom view:

- **Details**
  - View name
  - Description
  - Select who can use, edit, and manage this view:
    - *Only me*
    - *Specified users, user groups, or both*
    - *Everyone*

View settings - Details

- **Select columns**

  Select from incident attributes that are predefined for Cloud Pak for AIOps and common to most incidents. Click anywhere in the field provided to display the variable catalog. Move the cursor over the attributes to display the descriptions. You can also type the name of the property that you are looking for and the system will show in the drop-down list all incident properties that contain the typed text. You can drag and drop the columns to determine the order of the columns appearing in the Incident list.

  Important: Select at least one column for each view.

  - **Configure selected columns**

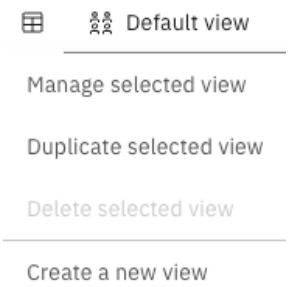
    Configure the following properties to customize the columns that display incident data:

    - *Column header title*: type a new title for the column or keep the default.
    - *Header alignment*: set the position of the title text in the column heading.
    - *Data alignment*: set the position of the incident data in the columns.
    - *Lock column*: locked columns are always displayed when you scroll an incident list horizontally. Locked columns appear at the left side of the view.
    - *HTML*: enable clickable links in the Incident list cells.
    - *Width*: type a numeric value in the Width field to change the width of a column.

View settings - Select columns

- **Sort columns**

  Add new columns in the Select columns section. Then, in the Sort columns list, single click on a column item to set ascending order. Click the column twice to sort in descending order. Drag and drop columns to prioritise sorting across columns.



View settings - Sort columns

What to do next

- **Manage selected view**

  1. From the view list on the incident page, select the view that you want to edit. The incident list updates with the view properties.
  2. Click **View configuration** > **Manage selected view**.

     View configuration
  3. Edit the **View settings** as required.
  4. Click **Save** to save the view.

- **Duplicate selected view**

  1. From the view list on the incident page, select the view that you want to copy. The incident list updates with the view properties.
  2. Click **View configuration** > **Duplicate selected view**.

A copy of the view is displayed. By default, the view name is set to "Copy of *view name*."

3. Edit the **View settings** as required.
4. Click **Save** to save the view.

- **Delete selected view**

1. From the view list on the incident page, select the view that you want to delete. The incident list updates with the view properties.
2. Click **View configuration** > **Delete selected view**. This action cannot be undone. Once the view has been deleted, your view is updated based on the first view in the list.
3. Click **Delete view** to confirm deletion.

Setting user preferences for the Incidents list

You can configure the appearance and behavior of the Incidents list via the **Settings**.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Incidents**.
3. On the upper right corner of the page, click **Settings**.

   The following preferences can be applied to the **Incidents** list:

   - **Row size**

     Select from the following table row sizes:

     - Very small
     - Small
     - Medium
     - Large
   - **Incident details launch type**

     Selecting an incident in the table opens the incident details for that incident. These can be displayed in a **Side panel** or in a separate **Pop-up window**.
   - **Incident details should open on:**

     - Double-click
     - Single-click
   - **Incident activity entries sorting**

     - Newest at the top
     - Newest at the bottom
   - **Row coloring**

     Change how incident priority is depicted in the table by applying a different color background for each priority level.
   - **Table auto-refresh**

     Enable auto-refresh to have the incident list automatically updated at predescribed intervals.
   - **Table auto-refresh interval (s)**

     Auto-refresh interval in seconds.
4. Click **Save** to apply your changes to the incident list.

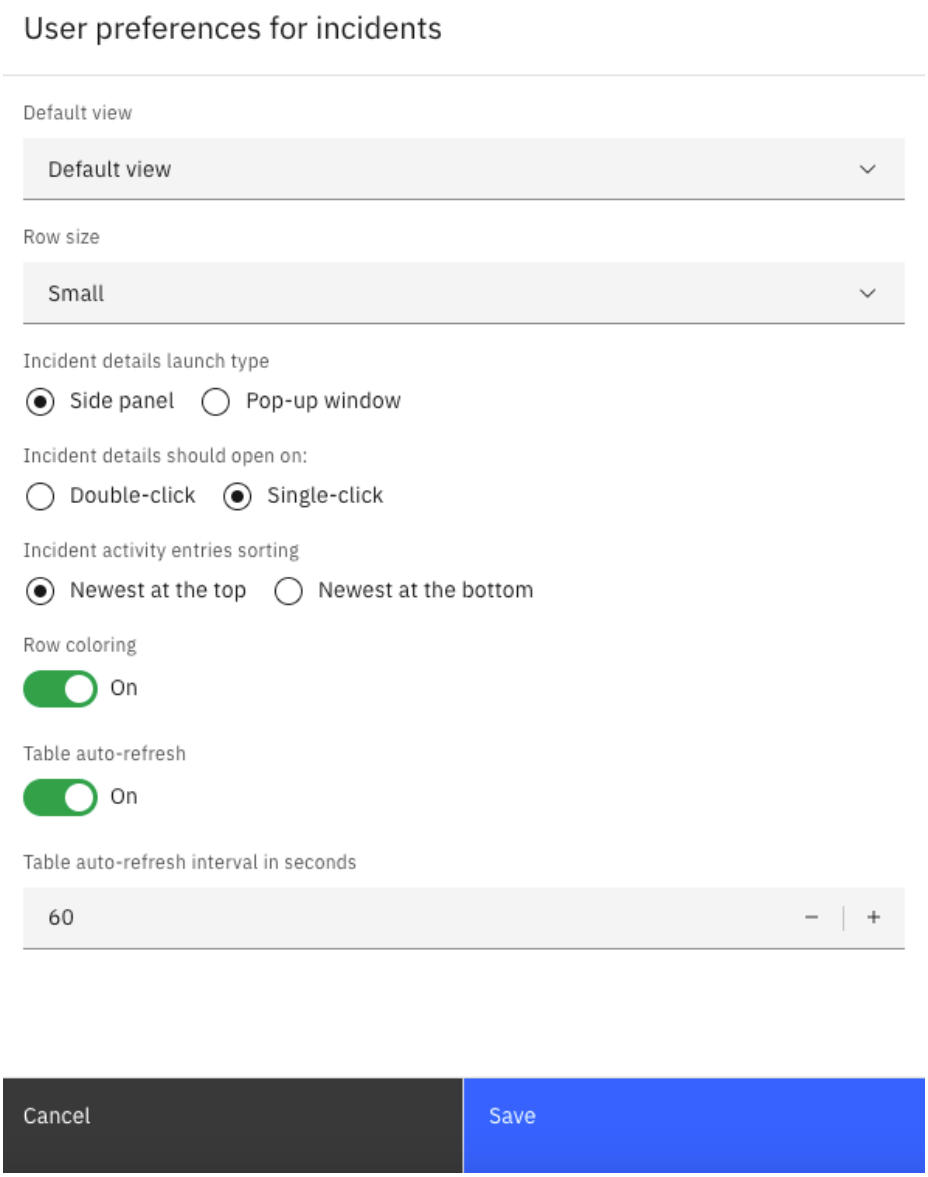


Figure. Incident preferences

Managing multiple incidents

You can multi-select incidents and apply actions to all of your selections at one time.

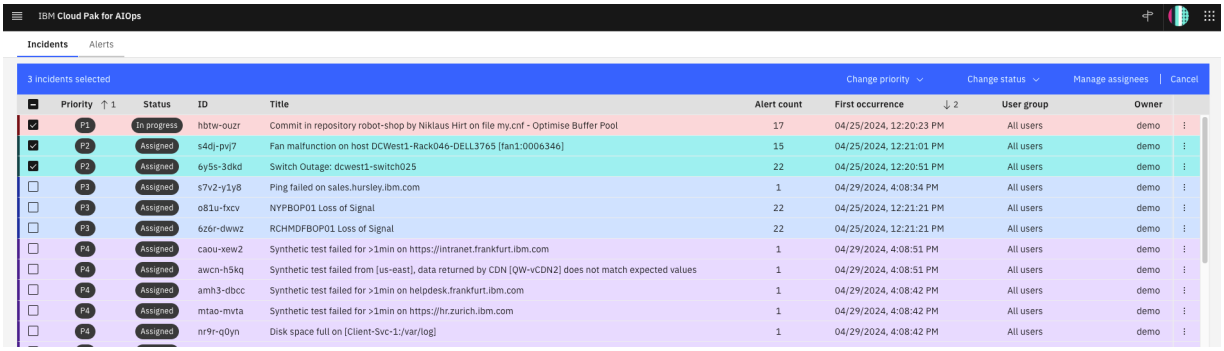
Procedure

1. Select multiple incidents from the table by using the checkboxes at the beginning of the table rows.

   Tip: You can select all of the incidents in the table by clicking the checkbox in the table header beside **Priority**.

2. A banner above the table displays the number of incidents that are selected, together with a menu of options. The following actions can be applied to multiple incidents at the same time:

   - Change priority: select from a range of **P1** (highest priority) to **P5** (lowest).
   - Change status: to **In progress**, **On hold**, or **Resolved**.
   - Manage assignees: assign a **Group**, **Owner**, and **Collaborators** to the incidents.



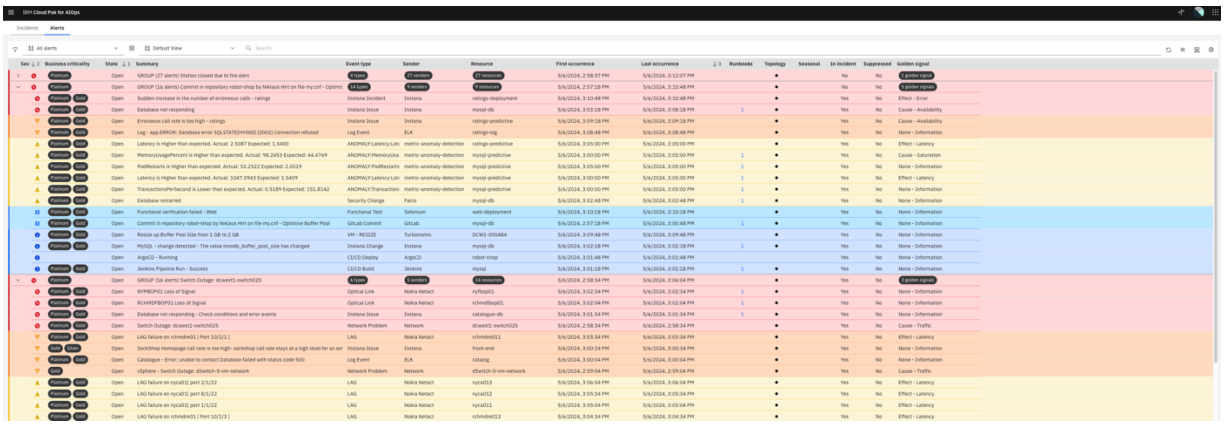


Figure. Managing multiple incidents

Alert Viewer

Alerts are displayed in the Alert Viewer. From a ChatOps integration (Slack or Microsoft Teams), you can launch into an Alert Viewer that shows the alerts that are associated to a specific incident. The numbers on the columns represent sort order. By default, alerts are sorted in the table by **Severity**. Where severity is the same, alerts are sorted by **First occurrence**. Each increasing sort order only sorts equivalent values. So once all values in a column sort order are unique (not equivalent), subsequent sort orders are ignored.

Figure. Alert viewer

There is also an alert list that displays all of the alerts found by IBM Cloud Pak® for AIOps. Follow the steps below to navigate to the main Alert Viewer.

Viewing alerts

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Alerts**.

The following table lists alert attributes.

Table. Alert attributes

Attribute	Description
Severity	Displays the severity of the alert. The possible values that can display in the Severity column are 6: Critical, 5: Major, 4: Minor, 3: Warning, 2: Informational, 1: Indeterminate.
Business criticality	Set in **Resource management** to define the importance of an application, resource group, or resource to the business.
State	An alert has one of the following three states: **Open** - Always has a severity other than `clear` to indicate an active issue that can require your attention. **Clear** - Working as expected, also has a severity of `clear`. **Closed** - No longer active or relevant, a deleted event. Also has a severity of `clear`.
Ranking	Probable cause assigns a ranking to all of the alerts in the incident. Alerts are ranked in order of likelihood of being the cause of the incident.
Summary	Provides more detail about the alert. For possible log anomaly summaries, see Log anomaly summaries.
Event Type	Describes the type of alert, for example, Utilization, Anomaly, System status, or Threshold breach. For possible log anomaly alert types, see Log anomaly alert types.
Sender	Identifies what, such as a log anomaly, that sent the alert. Different senders can result in different alert attributes.
Resource	The source from which the alert originated. This attribute can be a device name or hostname, service name, or application.

Attribute	Description
First occurrence	Displays the date and time in which the alert first occurred. The date format shown is based on your browser locale settings. Refer to the browser help for instructions on display format for dates, times, and numbers.
Last occurrence	Displays the date and time in which the alert last occurred. The date format shown is based on your browser locale settings. Refer to the browser help for instructions on display format for dates, times, and numbers.
Runbooks	A number in this column indicates the number of runbooks that are associated to an alert. Click the number to display the runbook details in the side panel. From here, you can see more information, preview, and run the runbook.
Topology	If the resource on which an alert occurred can be located in the network topology system, a large dot ● is presented in the alert's Topology column. Click the ● to display a topology map for this alert, centered on the resource on which the alert occurred.
Seasonal	Alerts that occur within a seasonal time window. Alerts that are not part of an alert group, that have associated seasonality, have a circle ○ visible in this column. Alerts that are part of an alert group, that have associated seasonality, have a dot ● in this column. Click the circle or dot to display more information in the **Seasonality** section of the **Alert details** panel.
In incident	Indicates if the alert is associated to an incident.
Trigger *	Denotes alerts that are defined as trigger alerts. That is, an alert that either caused the incident to be created, or would have caused creation had an incident not already existed. An incident takes the name of its trigger alert.
Suppressed	A 'Yes' in this column indicates that the `alert.suppressed` flag is set to `true` for the alert. The alert is still present in the system and can be viewed in the Alert Viewer, but the alert is filtered out of the view by default.
Golden signal	A label based on the value of `alert.type.classification` that describes the type of the event. For example, utilization, system status, threshold breach, and so on. Golden signal labels are divided into the categories of **Effect**: latency, error, availability. **Cause**: saturation, traffic. **None**: information.

*Only displayed on alert lists within the context of an incident.

Click the **Correlation information** icon to enable the Correlation column and display three more icons under this column. If the alert is part of an alert group, the type of analysis that is used to generate the group is indicated in these columns.

Table. Alert groups

Correlation column	Description
Temporal group	Details of a temporal group in which this alert is involved.
Scope-based group	Details of a scope-based group in which this alert is involved.
Topological group	Details of a topology group in which this alert is involved.

For more information, see Displaying analytics details for an alert group.

Figure. Correlation information

To view more detailed information about the alert list count, click the information icon at the bottom of the table.

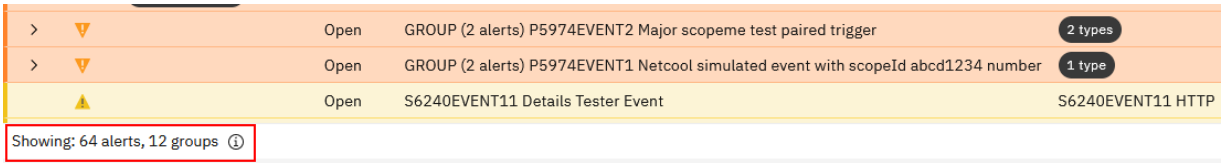

Figure. Alert count

The following alert list information is displayed:

- **Showing** (alerts): The number of alerts that are shown in the alert list.
- **Showing** (groups): The number of alert groups that are shown in the alert list.
- **Grouped**: The number and percentage of alerts that are part of a group shown in the alert list.

- **Limit**: The limit for the number of alerts you can view in the alert list at one time. This value is set by an administrator.
- **Total matched**: The number of alerts identified in the system that match the current saved filter. This can be higher than the number shown when there is a limit set to improve performance.
- **Total active**: The total number of alerts in the system that haven't been archived. Historical alerts are archived for AI training.

Alert anomaly detection

Default alert expectations are calculated by the Metric Manager based on the input data. If an anomalous alert rate is detected, an alert is raised and displayed as a metric anomaly in the Alert Viewer. When you click this alert, the Alert details panel depicts the expected values against the actual values.

Icons used in the Alert Viewer

Use this information to understand the purpose of the different icons used in the Alert Viewer.

Table. Icons used in the Alert Viewer

Icon	Name	Description
	Critical alert	A service-affecting condition has occurred, and corrective action is immediately required. For example, a system or device has gone out of service and needs to be restored.
	Major alert	A service-affecting problem occurred. Corrective action is urgently required. For example, a severe degradation occurred in the capability of a system or device and full capability must be restored.
	Minor alert	A non-service affecting problem occurred; take corrective action to prevent alerts of higher severity. For example, a problem occurred on a system or device but it does not impair the capacity or performance of the device.
	Warning alert	Potential or impending problems were detected. Further investigation is needed to prevent alerts of higher severity.
	Information alert	Alerts that are for information purposes only. Further investigation might be needed.
	Indeterminate alert	The severity level cannot be determined.
	Search	Click this icon to search for text in any of the columns displayed in the table.
	Correlation information *	Click this icon to display alert grouping information.
	Filter	Click this icon to filter the alerts in the table based on one of the following criteria: severity, enrichment, grouping, state, or alert type.
	Refresh	Refresh the Alert Viewer to view all the latest alerts at the current point in time.
	Temporal *	Based on alert history, these alerts tend to occur within a short time of each other.
	Scope-based *	Scope-based alerts occur within a configurable time window on an administrator-defined scope, such as a location, service, or resource.
	Topological *	Topological alerts occur on resources within a predefined section of your network topology.
	Trigger alert *	Denotes alerts that are defined as trigger alerts. That is, an alert that either caused the incident to be created, or would have caused creation had an incident not existed.
	Seasonal alert	Denotes a seasonal occurrence of an alert.
	Seasonal alert	Denotes a non-seasonal occurrence of a seasonal alert.

*Displayed only on alert lists associated to an incident.

Alert details

The **Alert details** side panel is accessed in the Alert Viewer. From here, you can quickly clear alerts or access additional information about the alert properties.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. For the complete list of Cloud Pak for AIOps alerts, click **Operate** > **Alerts**.

   For the alerts associated to a specific incident, click **Operate** > **Incidents** > ***Incident Title*** > **Alerts**.

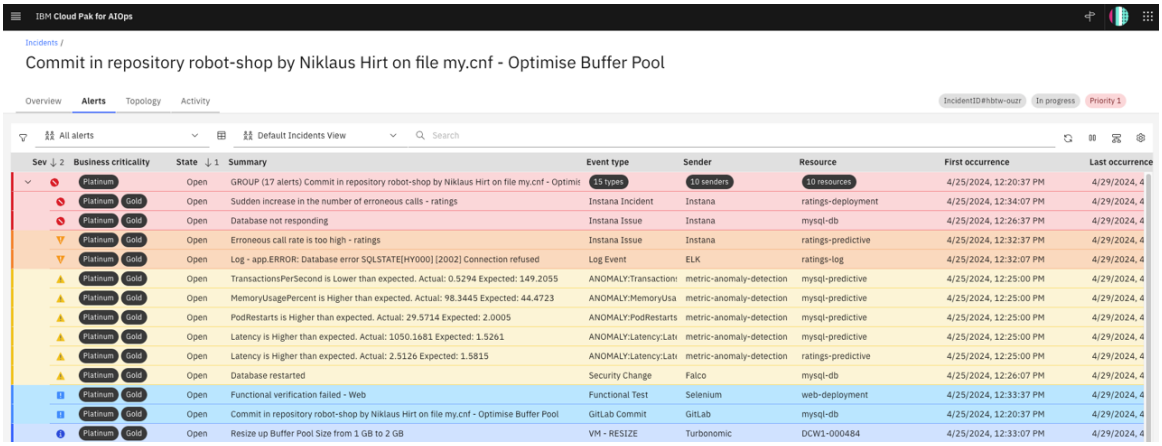

Figure. Incident alerts

3. Double click an alert in the table to display the **Alert details** side panel for that alert. The **Information** section is open by default in the side panel.

   Tip: To clear the selected alert, scroll to the end of the side panel and click **Clear alert** and then click **Clear** to confirm.

   To display **Alert details** in a new window, click the pop-up icon in the side panel.

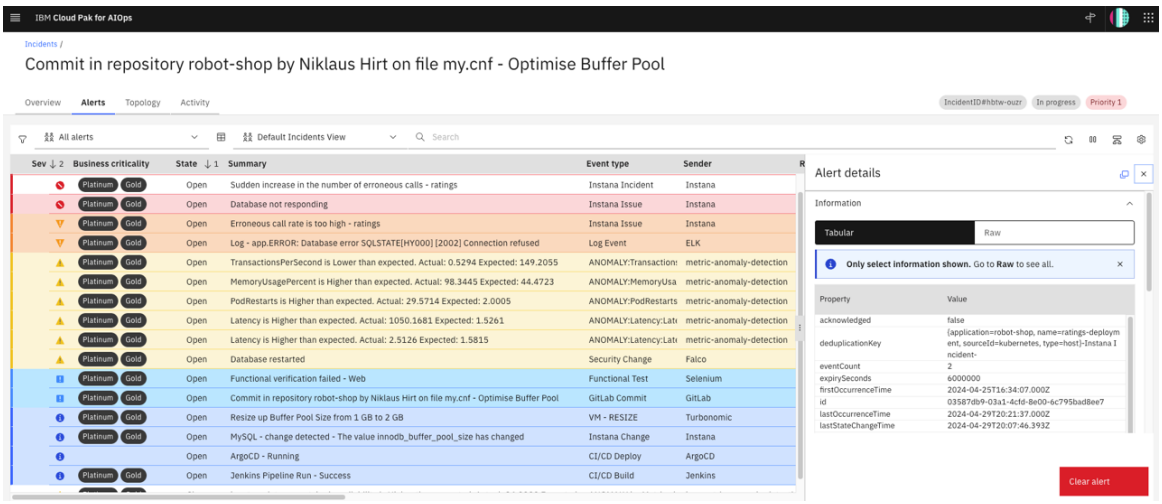

Figure. Alert side panel

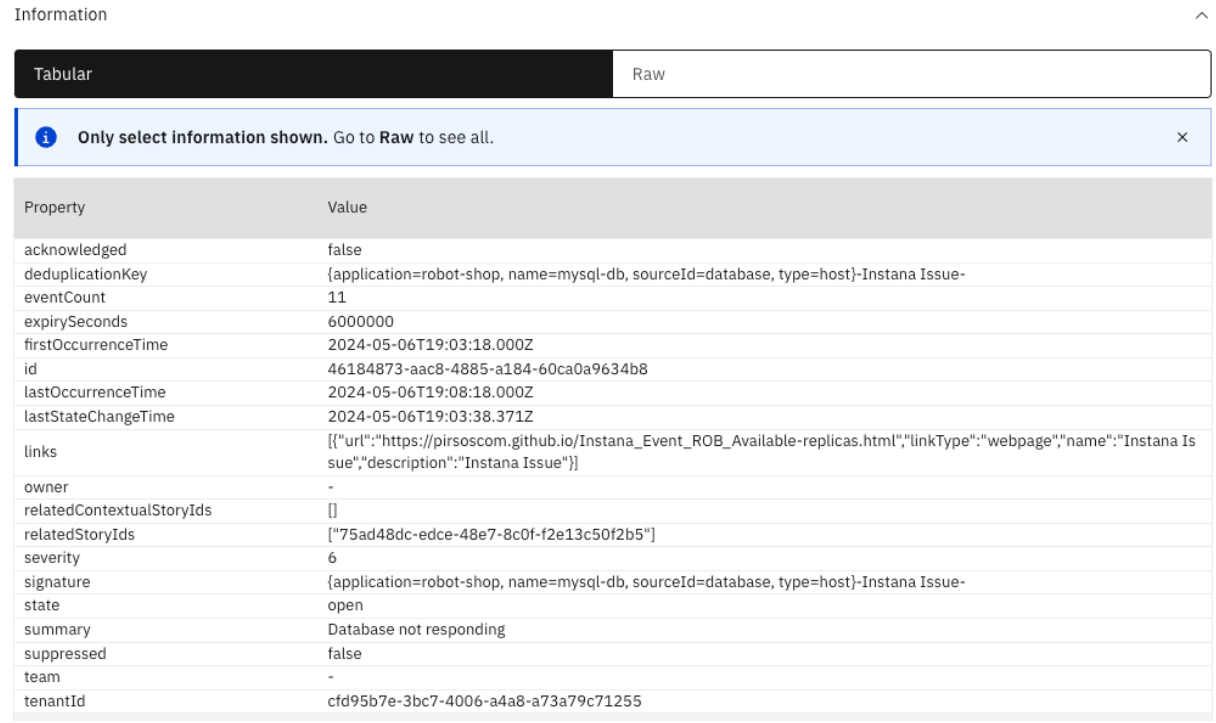
Depending on the alert selected, **Alert details** can contain the following sections:

- Information
- Activity
- Anomaly insights
- Runbooks
- Topology
- Log anomaly
- Metric anomaly
- Recommended actions
- Correlation information

Information



Under Information, alert properties can be viewed in two different formats:

- **Tabular**

  Alert properties are displayed in a table format of **Property** - **Value** pairs.

- **Raw**

  Raw data in a JSON format. Click **Copy** to copy the alert data to the clipboard.

Property	Value
acknowledged	false
deduplicationKey	{application=robot-shop, name=mysql-db, sourceId=database, type=host}-Instana Issue-
eventCount	11

Figure. Alert information

Activity

A timeline of major events that have occurred in the lifecycle of an alert. The following events are logged to the Activity timeline:

- When an alert is created
- Alert is assigned to new owner or team
- Alert is acknowledged/de-acknowledged
- Alert is suppressed/de-suppressed
- Alert state changes (open or clear)
- Alert severity changes
- User added comment

To add a comment to an alert at any time, type a comment in the field that is provided and click **+** Add comment. A maximum of 250 characters are supported. The comment is stored in the timeline in chronological order with the other entries.

Figure. Alert activity

Anomaly insights

In the Alerts table, if you select an alert that contains anomaly insights, the Alert details panel contains an Anomaly insights section. This section shows Property, which is the Key Performance Indicator (KPI) type, and Value, which is the name, for each anomaly insight. Use this information to understand the anomaly and why an alert was generated. You can also use this information to create a policy. For example, you can suppress the alert or associate it with a runbook. For more information, see Supported Anomaly insights properties.

Runbooks

The following information is displayed for each runbook in **Alert details**:

- **Status**

  Successfully executed, Failed, Cancelled, In progress, or Completed.

- **Success rate**

  The success rate is calculated by using the number of successful and unsuccessful executions of the runbook.

- **Average rating**

  Operations analysts can provide feedback about the quality of a runbook including a rating, which is displayed here (five stars is the top rating).

- **Type**

  Indicates the Runbook type: Manual or Automated.

- **Policy**

  Shows the Cloud Pak for AIOps policy that assigned the runbook to the selected alert. Click the policy name to locate that policy on the Policies UI.

Click the menu overflow icon (the three dots) and click **Preview** to view the runbook or click **Run** to re-run the runbook.

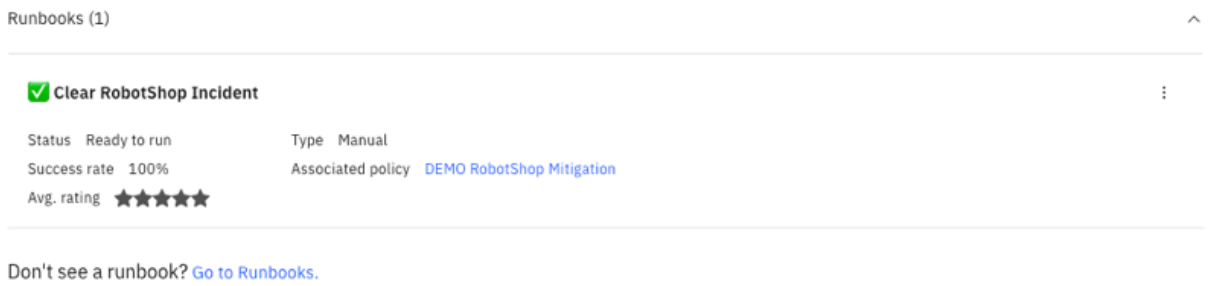

Figure. Runbooks

Topology

If the resource on which an alert occurred can be located in the network topology system, you can collapse the **Information** section in the side panel to view the **Topology** section. For more information, see Displaying alert topology.

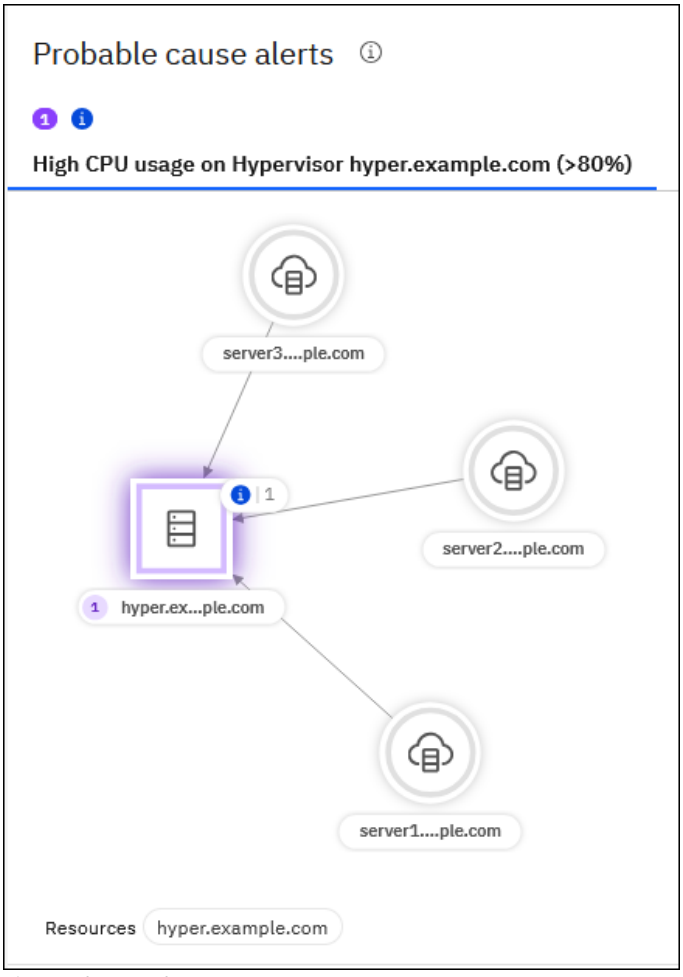

Figure. Alert topology

Log anomaly

When you select a log anomaly alert in the table, the **Alert details** panel contains a **Log anomaly details** section. For more information, see Log anomaly alerts.

Domain-specific log anomaly alert details

Select a domain-specific log anomaly alert, such as one pertaining to IBM MQ or WebSphere, in the **Alerts** table. The **Alert details** panel contains a **Log anomaly** details section with the following information:

Table. Alert detail explanation

Detail	Explanation
Message code	Every domain-specific log includes a message code, and message codes are summarized in an alert. This message code is the most significant domain-specific message code for the current alert.
Short explanation	The title of the log anomaly is based on the message code.
Detailed explanation	The description of the log anomaly is based on the message code.
Category and Subcategory	The log anomaly is assigned to a category and subcategory based on the message code.
Message codes and frequencies	A log anomaly alert consists of multiple logs, and each log has a message code. The frequency shows how often a certain message code appears in the logs that make up the log anomaly alert.

Metric anomaly

Default alert expectations are calculated by the Metric Manager based on the input data. If an anomalous alert rate is detected that is either higher or lower than expected, an alert is raised and displayed as a **`Metric anomaly`** in the Alerts table. When a metric anomaly alert is selected in the table, the **Alert details** panel contains a **Metric anomaly details** section and depicts the expected values against the actual values. For more information, see Metric anomaly details.

Recommended actions

For domain-specific log anomaly alerts, up to three links for resolving the alert are included. Each link consists of a title and a short description of the resolution. These links are based on the message code and past resolution tickets that are associated with the selected alert.

Correlation information

If you are viewing an incident's alert list, and the selected alert is part of an alert group, the Alert details side panel displays information about the underlying temporal, topological, or scope-based groups.

Working with alerts and menu customization

Actions for alerts can be accessed via the right-click context menu.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Alerts**.
3. Right-click any alert (or multiple alerts) in the Alert Viewer and select from the following actions:

- **Acknowledge**

  Acknowledge an alert when you want to work on that alert. The acknowledged status is recorded as **`true`** in the Alert details.

- **De-acknowledge**

  De-acknowledge an alert if you are no longer working on it. The acknowledged status is recorded as **`false`** in the Alert details.

- **Update severity**

  Select from the following alert severities:

  - Indeterminate
  - Informational
  - Warning
  - Minor
  - Major
  - Critical

- **Suppress**

  When an alert is suppressed in Cloud Pak for AIOps, the **`alert.suppressed`** flag is set to **`true`**. The alert can still be viewed in the Alert Viewer, but the alert is filtered out of the view by default.

- **De-suppress**

  Changes the **`alert.suppressed`** flag from **`true`** to **`false`**. The alert is not filtered out of the view by default.

- **Take ownership**

  Take ownership of an alert if you want to work on resolving that alert.

- **Assign owner**

  Use this command to assign an alert to another user. That user then becomes the alert owner. You must select a user group the owner belongs to.

- **Assign user group**

  Use this command to assign an alert to a group.

- **Clear**

  Change the alert state to Clear.

- **Quick Filter**

  Use quick filters to display alerts that match a selected criteria. For more information, see Creating quick filters.

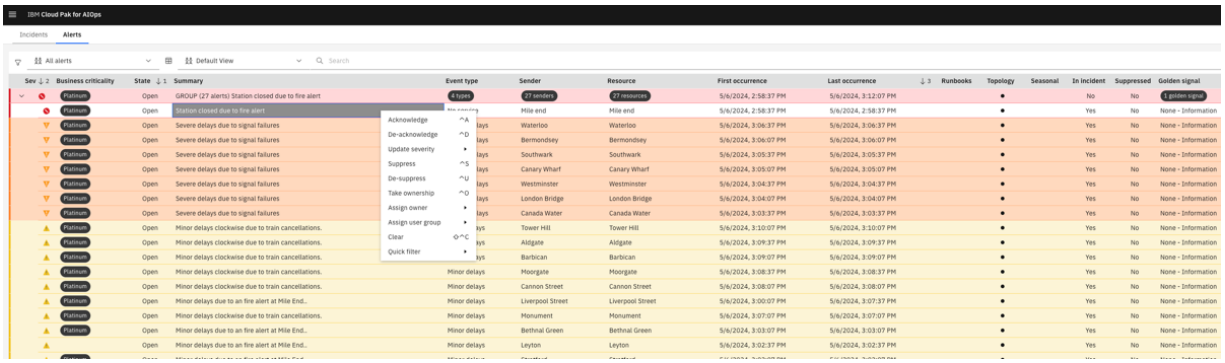

Figure. Alert actions

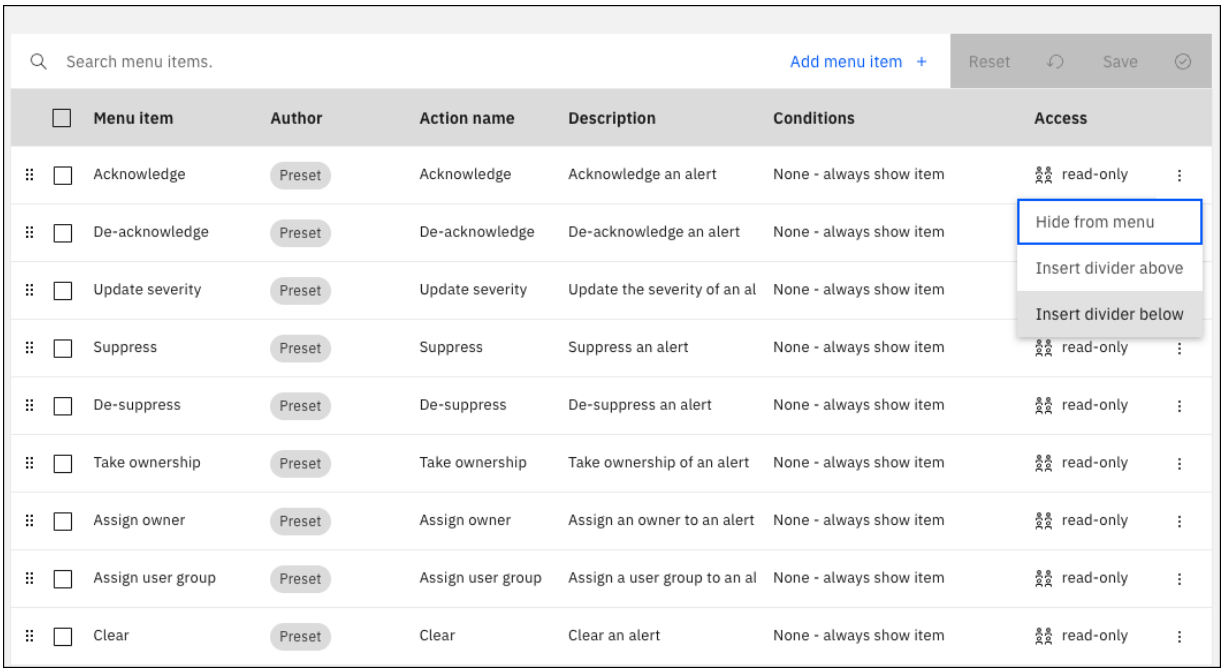


Menu customization

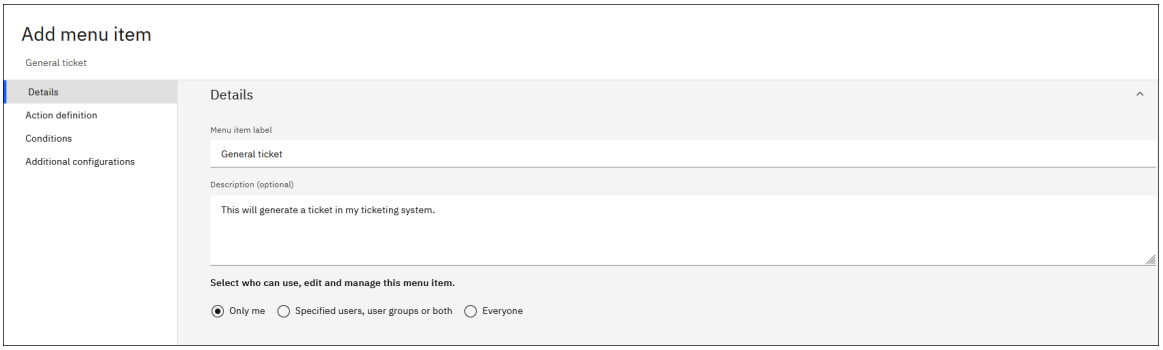
You can personalize the arrangement of right-click menu items. The arrangement is only visible to the user customizing the menu. That is, each user can define how their own menu looks. Users can control the following settings:

- Menu items are hidden or visible
- The order of menu items within the menu
- Grouping menu items with dividers

To access menu configuration in the Alert Viewer, click ⚙ > **Configure alerts contextual menu**.

The menu configuration page represents the layout of the menu. From here, you can click and drag menu items to re-arrange the order. You can also click the options menu (three vertical dots) to hide or show menu items, and group menu items with dividers.

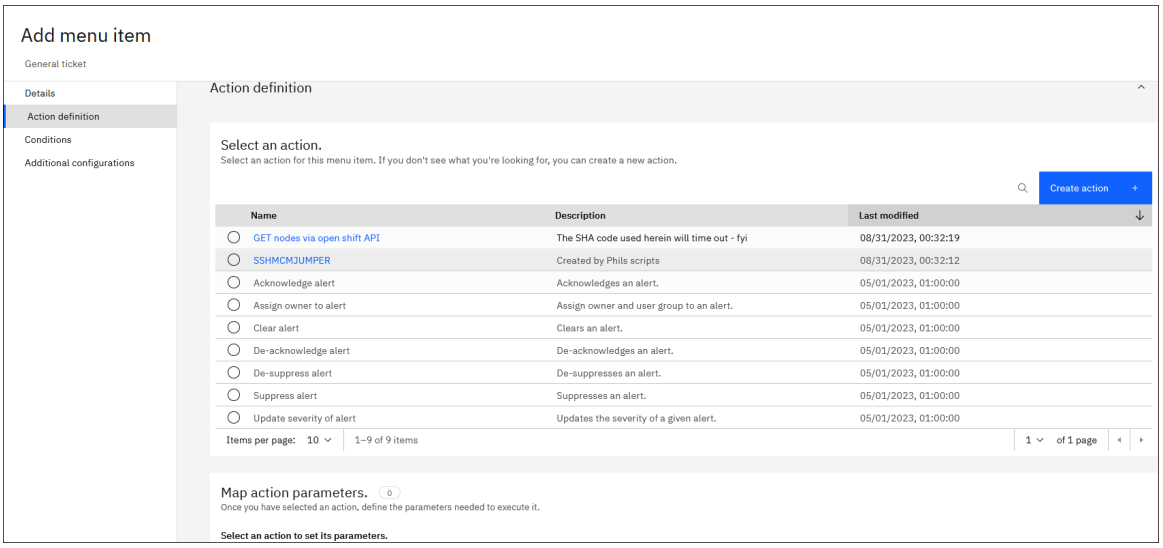
Menu configuration page



If a user has access to shared menu items, initially these items are shown as disabled in the menu configuration page. To enable shared menu items, select **Show in menu** from the options menu.

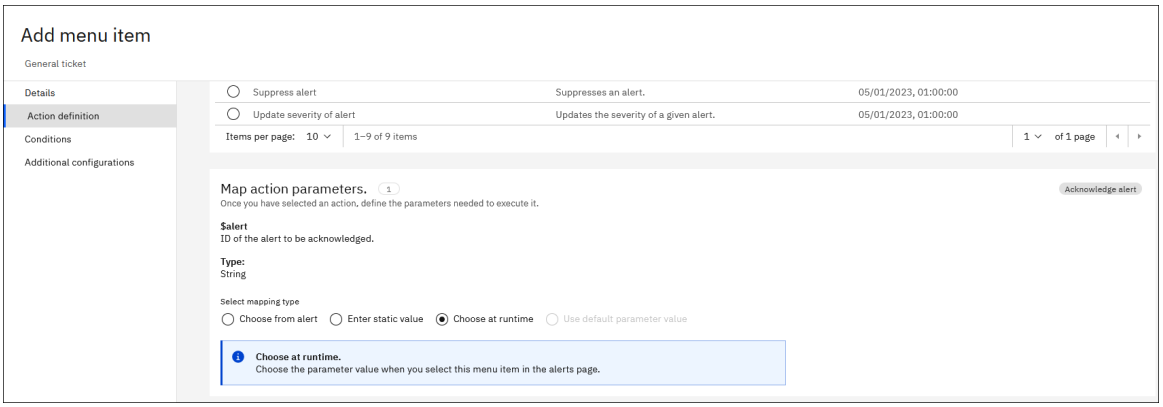
Add menu items

To add custom menu items for use in your personal menu, or to share with everyone, click **Add menu item +** from the menu configuration page.



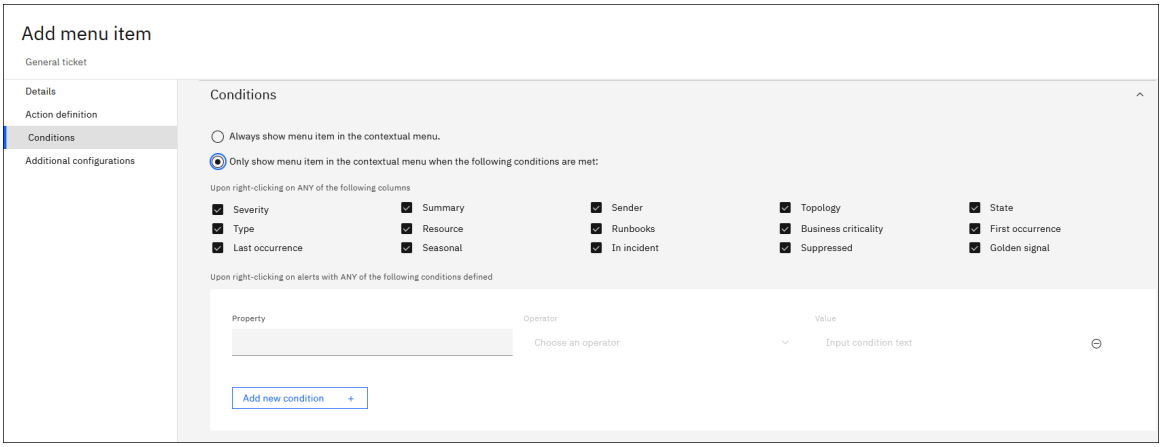
Configure the following properties for a custom menu item:

- **Details**
  - Display name
  - Description
  - Select who can use this menu item (**Only me** or **Everyone**).

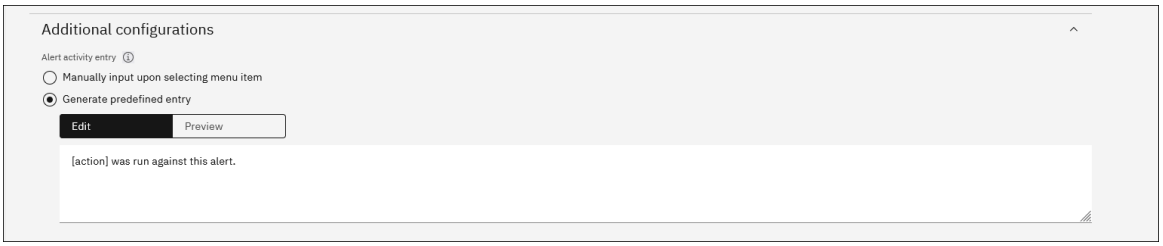


Add menu item - Details

- **Action definition** and parameter-mapping that includes the following options:
  - Choose from alert: based on the selected alert(s), set the desired properties as the action parameter value. If you want to minimize the scope to a singular key within the alert's details, enter a string value that matches a key from an alert's details. For example, if you enter "`field1`" in the Property field, it is understood as "`alert.details.field1`". **Note**: The permitted characters for the "`details`" field are A to Z, a to z, 0-9, and the underscore symbol (_).
  - Static value: set a fixed value for a parameter.
  - Default value: use the default value specified in the Automation action definition.
  - Choose at run time: input the value at the time the menu item is run.



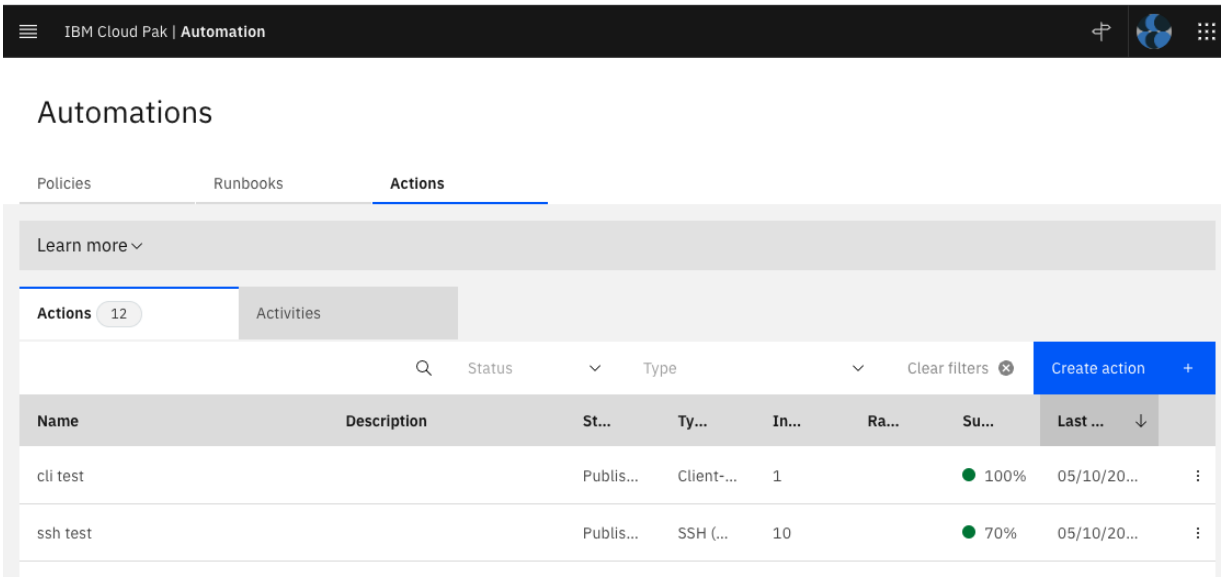
Add menu item - Action definition



Add menu item - Map action parameters

- **Conditions** to define when a menu item should show on an alert right-click action:
  - Columns: select specific columns for which the menu item will surface.
  - Property: select from alert attributes that are predefined for Cloud Pak for AIOps and common to most alerts. If you want to minimize the scope to a singular key within the alert's details, enter a string value that matches a key from an alert's details. For example, if you enter "**`field1`**" in the Property field, it is understood as "**`alert.details.field1`**". Then, enter the string value in the **Value** field. **Note**: The permitted characters for the "**`details`**" field are A to Z, a to z, 0-9, and the underscore symbol (_).
  - Operator: select a comparison operator from this list. The range of comparisons available is determined by your selection in the Property field.
  - Value: the fields (or free-form string value) that appear here are dependent on the options selected in the Property and Operator lists.

Add menu item - Conditions



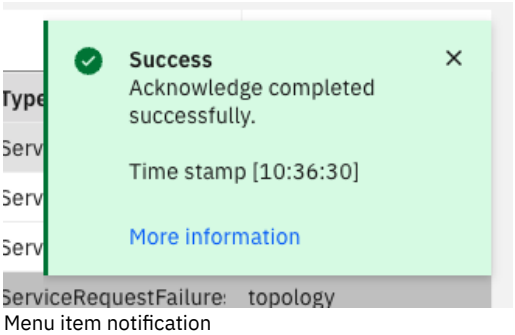
- **Additional configurations** to define the alert activity entry. This is the message that will appear in an alert's activity once this menu item has been selected to act on the alert. To change the default entry, edit the message and preview the output.

Add menu item - Additional configurations

Implementation

The actions that are associated with custom menu items are implemented as Automation Actions.

Automation Actions



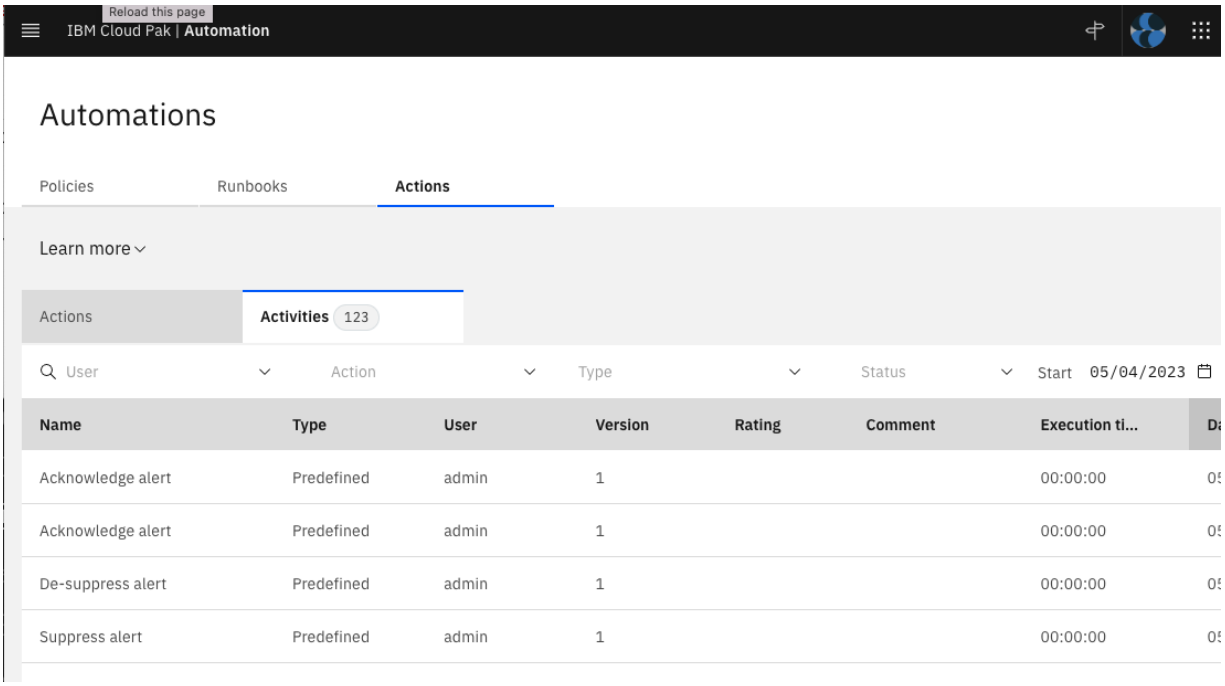
Actions are one of the following types:

- HTTP
- SSH
- Client-side

One benefit of using the Automation action framework for implementation is that these actions can be used independenly of the right-click menu, either stand-alone or within a runbook. For more information, see Managing actions.

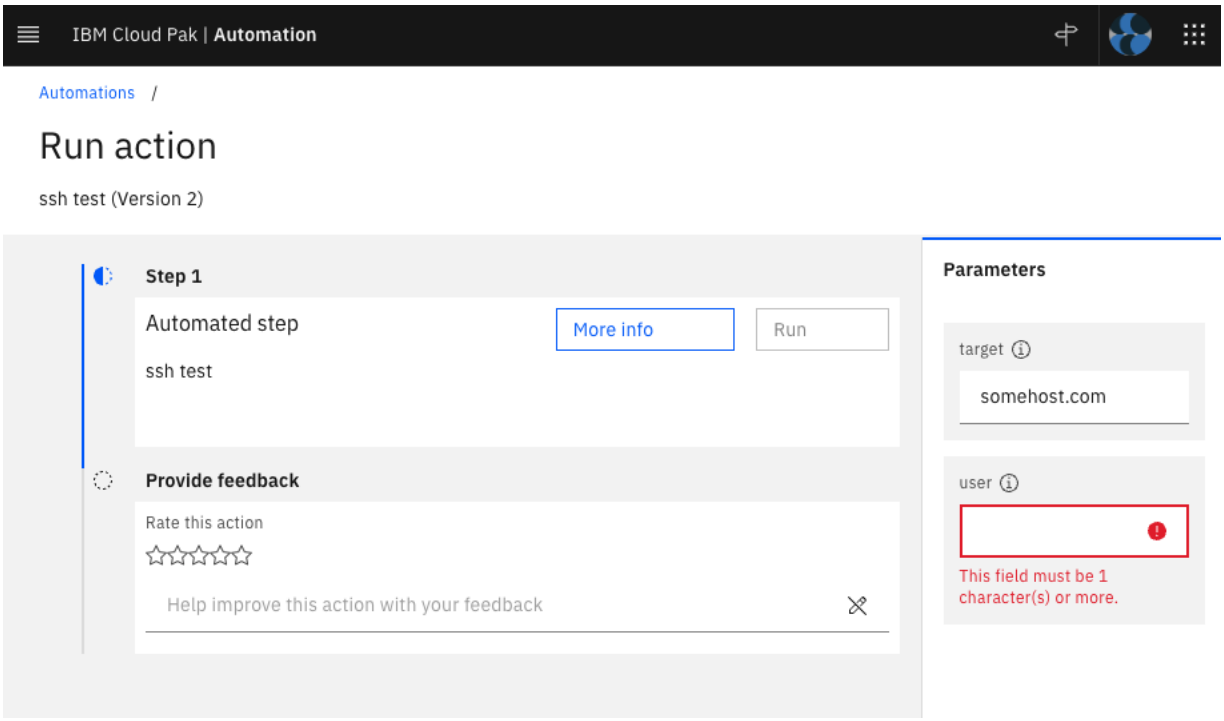
Menu item execution

Upon clicking a menu item, the actions will run in the background for each selected alert if there are no parameter mappings specified as **Choose at run time**. When all actions are completed, a notification is displayed with results for each selected alert.



Menu item notification

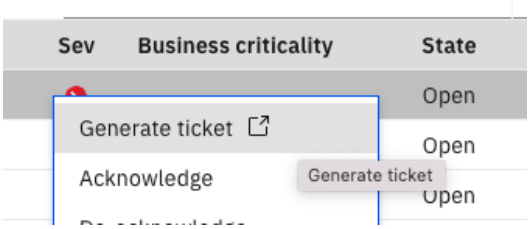
Click the **More information** link in the notification to show the raw output from the action execution, which can be copied with the copy icon .



More information

An audit of all action executions is available on the Automations > Actions > **Activities** page.

Activities page



If a menu item has a parameter mapping specified as **Choose at run time**, the user is directed to the **Run action** page to complete the parameter input and run the action when clicking a menu item.

Run action

In this scenario, when multiple alerts are selected the alert properties are combined into a comma-delimited list. The automation action can then process this list as required.

For menu items using an action of type Client-side, if there are no parameter mappings of **Choose at run time**, the parameter values are mapped to URL query parameters and a new browser tab opens with the resolved URL when running the menu item. These menu items are differentiated by the "launch" icon. Note, menu items of this type only work for single alerts. If multiple alerts are selected, properties of the context menu alert are used to resolve parameter mappings.

Launch icon

Access control

Access control is applied at the menu item level. The menu items available for a user's personal menu consist of items the user has authored themselves, or items set with "Everyone" access. Preset menu items are read-only for everyone. Custom menu items can be updated by anyone with access to the menu item.

Searching and filtering alerts

Search for alerts by name, or filter the list based on selected criteria. You can also save a filter configuration for future use.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Alerts**.

Search alerts

To search for an alert in the table:

- Click anywhere in the **Search** field.
- Start typing a description of the alert in the search field. For example, type "error" and the system will show in the table all alerts that contain the text "error" in the summary.

Figure. Search bar

Note: A search term entered in the **Search** text field is not part of a saved filter. Only the configuration applied in the **Filter conditions** side panel is part of the saved filter.

Predefined alert filters

All Alerts are displayed in the alert list by default. Click the Down chevron icon to select from the following predefined filters:

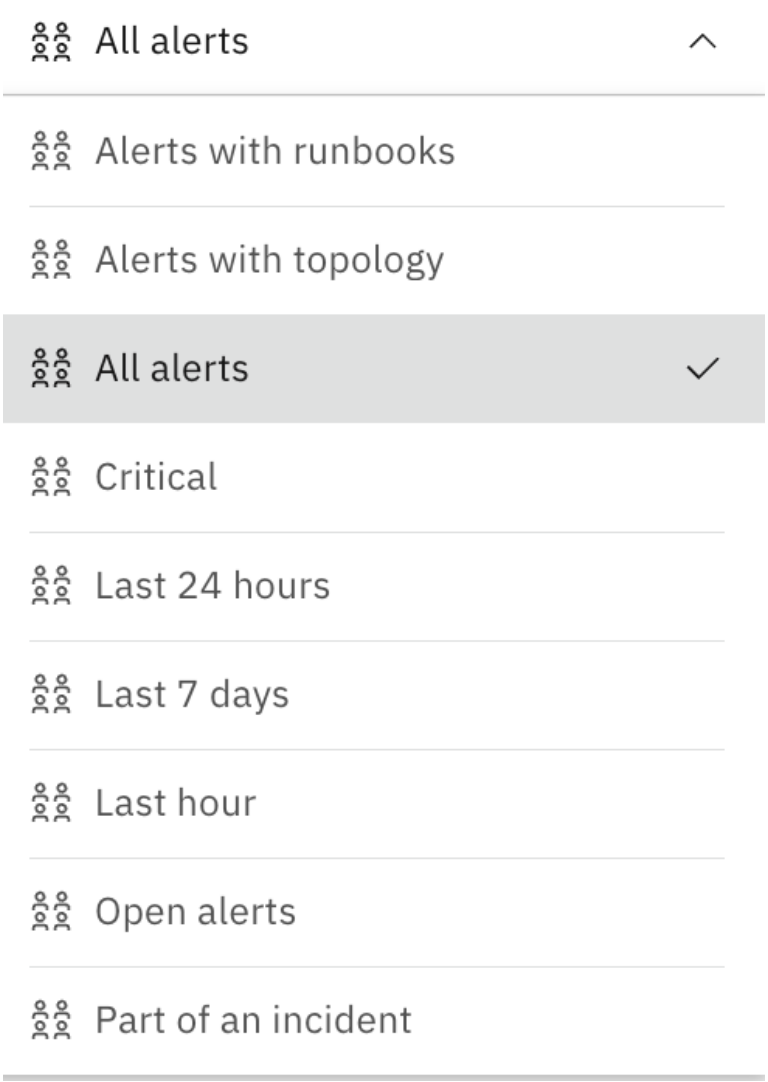


Figure. Predefined filters

Customized alert filters

1. Select an existing filter from the drop-down menu or use the default All Alerts.
2. Click the Filter icon to open the filter side panel.

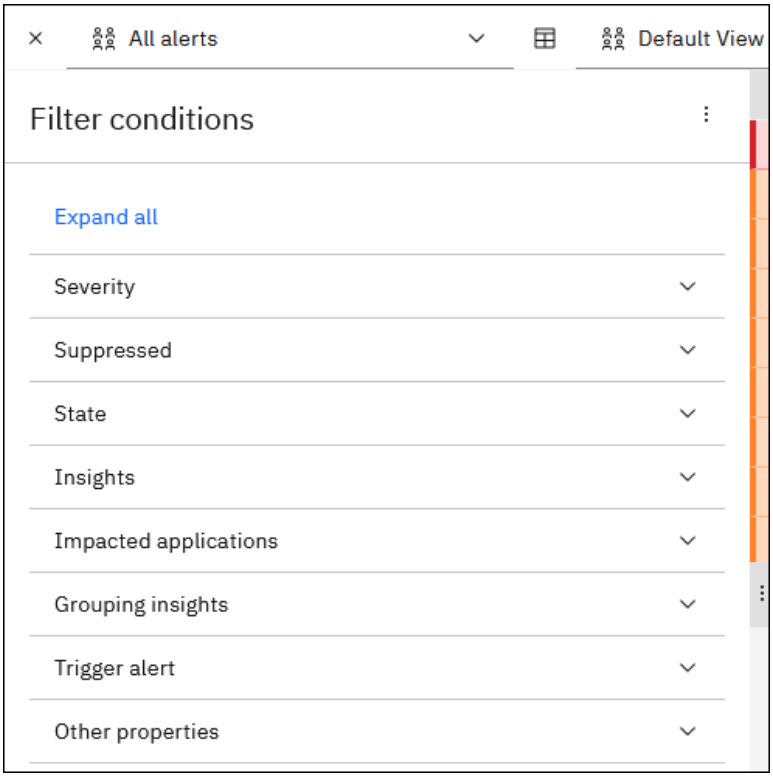

Figure. Alert filters

3. Apply filters to the alert list (or apply additional criteria to an existing filter). Select from the following filters for alerts:

- **Severity**:
  - Critical
  - Major
  - Minor
  - Warning
  - Informational
  - Indeterminate
- **Suppressed**:
  - Yes
  - No
- **State**:
  - Open
  - Clear
  - Closed
- **Insights**:
  - Part of an incident
  - Runbooks available
  - Enrichment
- **Impacted applications**:

  Find impacted applications to filter by.
- **Grouping insights**:

- Temporal
- Scope-based
- Topological

- **Other properties**

  You can create more personalized filters by using alert properties. Expand the **Other properties** section and complete the fields as follows:

  - **AND and OR**: when adding conditions, you can join multiple condition types by using the AND and OR operators. The AND operator means that alerts are matched only if all of the individual conditions are true. The OR operator means that alerts are matched if any of the individual conditions are true. The default behavior for alert filter conditions is AND.
  - **Property**: select from alert attributes that are predefined for Cloud Pak for AIOps and common to most alerts.
    - If you want to minimize the scope to a singular key within the alert's details, enter a string value that matches a key from an alert's details. For example, if you enter "`field1`" in the Property field, it is understood as "`details.field1`". Then, enter the string value in the **Value** field. **Note**: The permitted characters for the "`details`" field are A to Z, a to z, 0-9, and "_" (underscore).
    - You can also access additional properties of `alert.sender`, `alert.resouce`, and `alert.type` by typing your custom property in the Property field. For example, to filter alerts where the `alert.sender.customProperty` = "custom", type `sender.customProperty` and select "`Property: sender.customProperty`". The only permitted special character for custom properties is "_" (underscore).

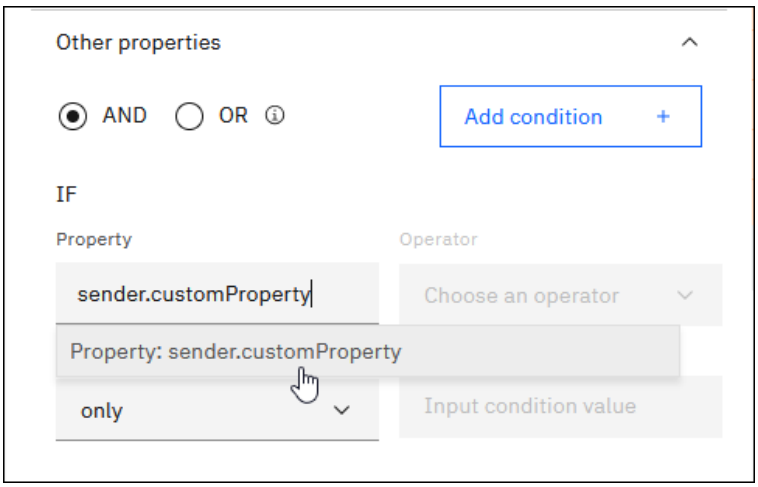

Figure. Custom property filter

  - **Operator**: select a comparison operator from this list. The range of comparisons available is determined by your selection in the Property field.
  - **Value**: the fields (or free-form string value) that appear here are dependent on the options selected in the Property and Operator lists.

To update an existing filter

1. After you have modified the existing filter criteria, click **Save**.
2. A **Filter updated** message is displayed to confirm that your changes have been saved.

   Note: An asterisk (*) is displayed next to the filter name if there are unsaved changes to the selected filter. An asterisk is also displayed when another user has modified the current filter. Unsaved filters are only applied to the already fetched alerts. Click **Reset filter** in the filter side panel to get the latest changes to the filter and have them applied to the alert list.

To save as a new filter

1. After you have applied the filters, click the three vertical dots in the **Filter conditions** side panel to open the list of options.
2. Click **Save as a new filter**.

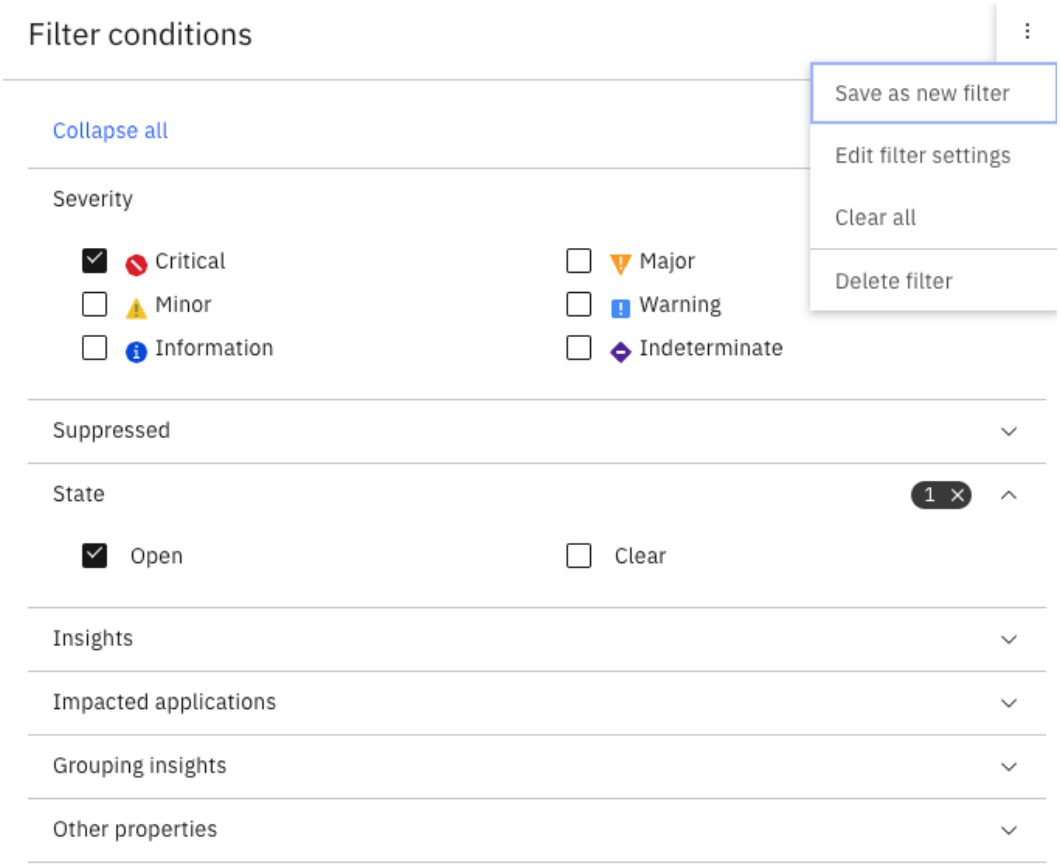

Figure. Save as new filter dialog

Note:: Alternatively, if you are an administrator who has *manage profiles* priviledges had enabled, you can set Role Based Access Control (RBAC) functionality that allows you see and click the **Save as a new restriction filter** option, thus applying certain restriction filters to data types and resources, alerts in this case. The *save a new restriction filter dialog* window is slightly different to the *Save a new filter dialog* also.

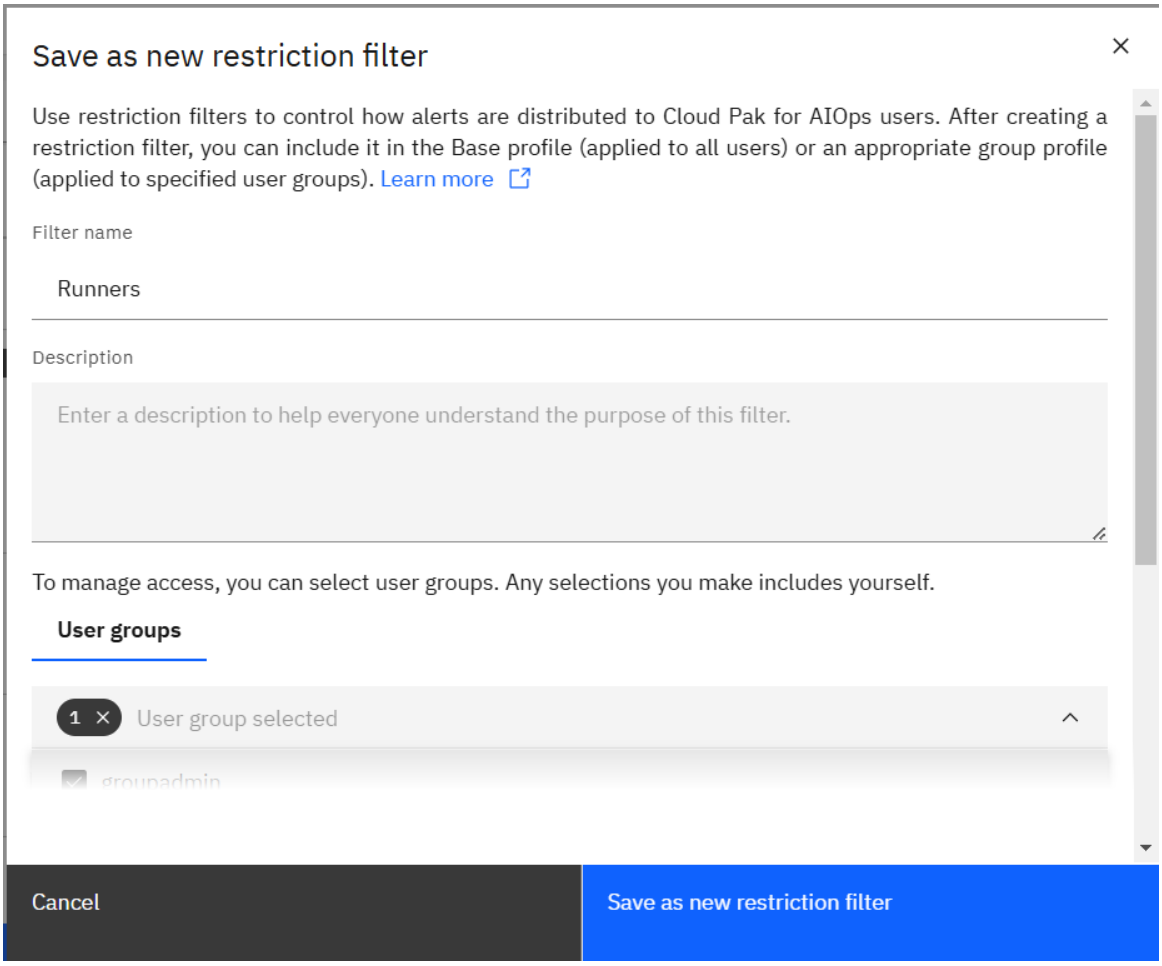

Figure. alerts save a new filter

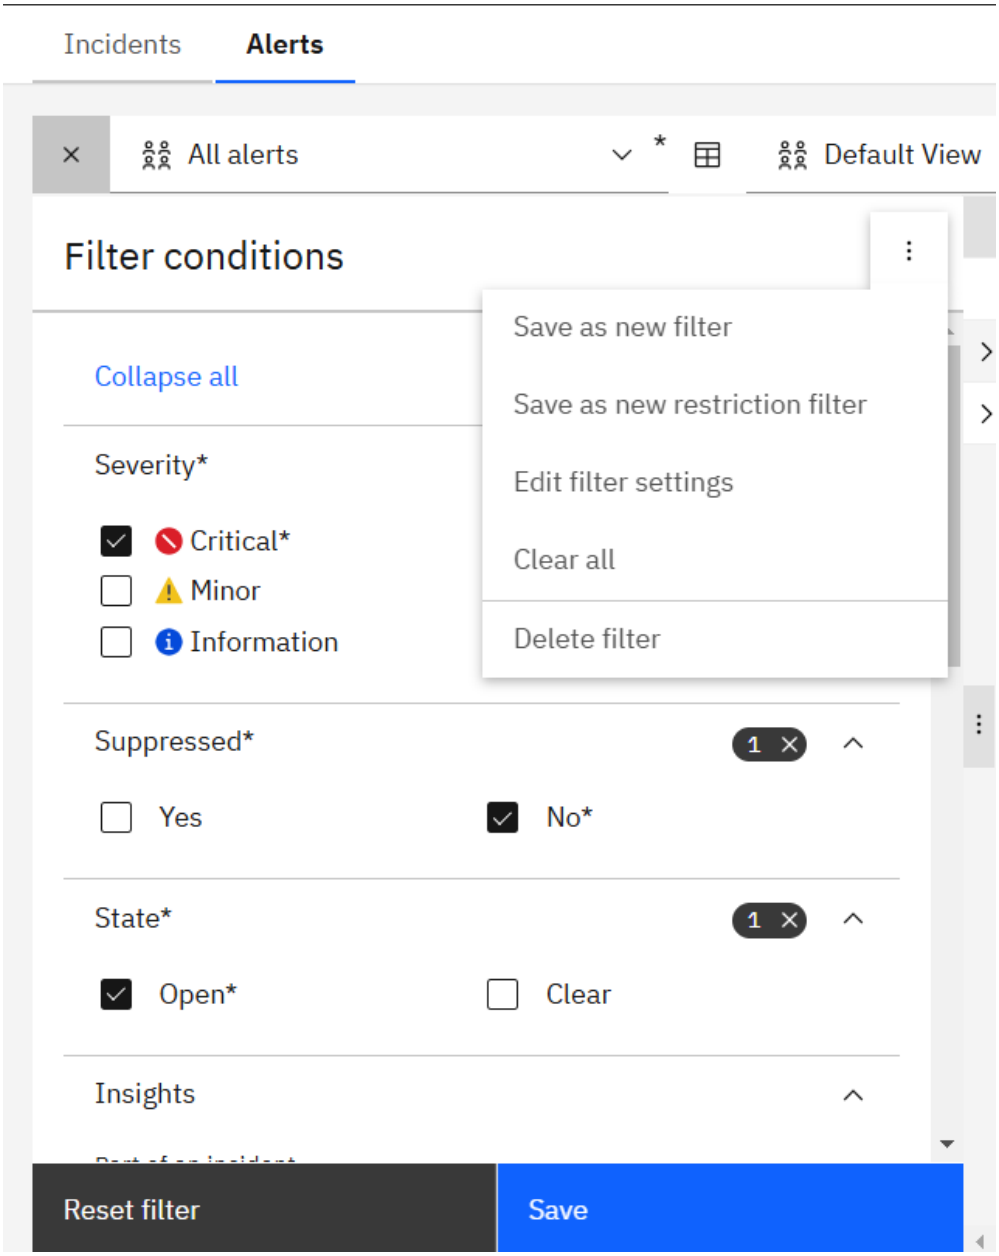

Figure. Filters side panel

3. Enter a **Filter name** and **Description**.

   Note: Filter names must be unique across different categories of filters, whether a normal filter or a restriction filter set by an administrator. If a chosen filter name is already in use for any type of filter, an error message is displayed to say the filter name already exists.

   Select who can use this filter from the following options:

   - **Only me**
   - **Specified users, user groups, or both**: to manage access, you can select users, user groups, or both. Any selections you make includes yourself. After you select the users or user groups who can use the filter, you must specify their level of access:
     - **Can use**: users can see the filter in the drop-down list and apply it to the list of alerts.
     - **And edit**: users can use, edit, and save the filter.
     - **And manage**: users can use, edit, and manage the filter name, description, and access control.

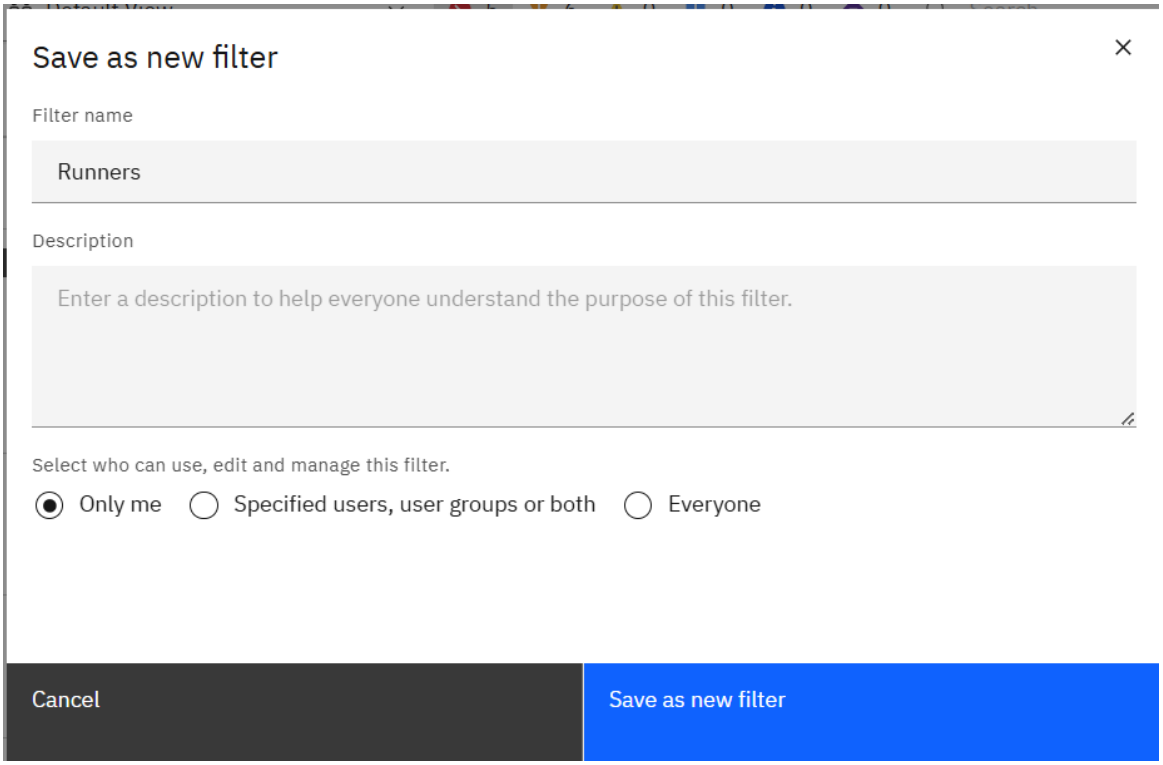

Figure. alerts save a new filter

- **Everyone**: additionally specify if everyone can **Use this filter** or **Edit this filter**.

To clear changes that have been applied to a filter, click **Reset filter** in the filter side panel or **Clear all** from the list of options (three vertical dots). From the options list you can also **Delete filter** and **Edit filter settings**.

Managing multiple alerts

You can multi-select alerts and apply actions to all of your selections at one time.

Procedure

1. To multi-select alerts that are not next to each other in the Alert Viewer, press and hold down the Ctrl key (Command key on Mac) and click the alerts that you want to select.
2. If you want to multi-select alerts that are next to each other in the table, you don't have to click each alert. First, press and hold down the Shift key. Then, click on the top alert and bottom alert in your selection. All the alerts between the first and last are also selected.
3. Actions for alerts can be accessed via the right-click context menu. For more information, see Working with alerts and menu customization.

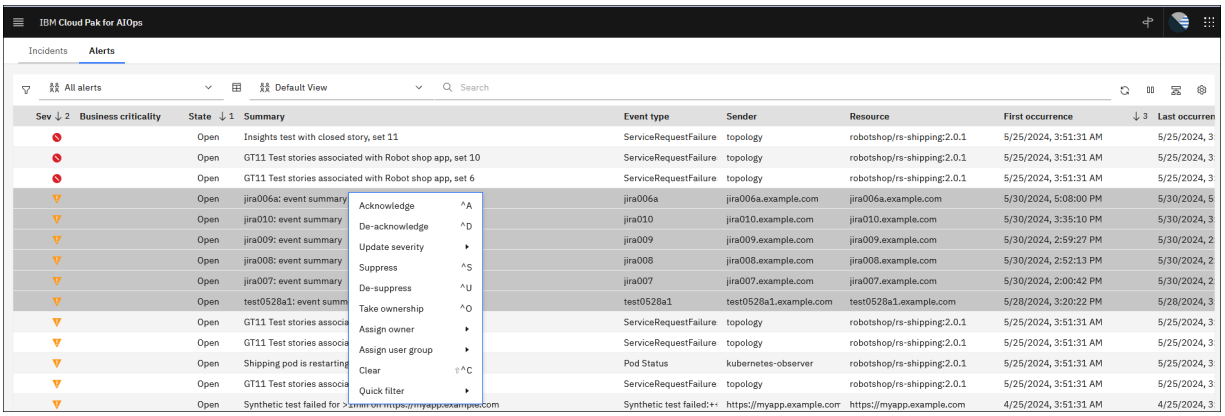

Figure. Managing multiple alerts

Creating views

Create custom views that are dynamically applied to the Alert Viewer. The views determine what information is displayed from the available alert data.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Alerts**.
3. On the toolbar, click **View configuration** > **Create a new view**.

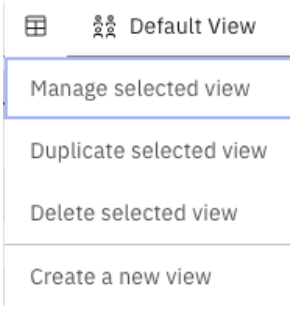

Figure. Create a view

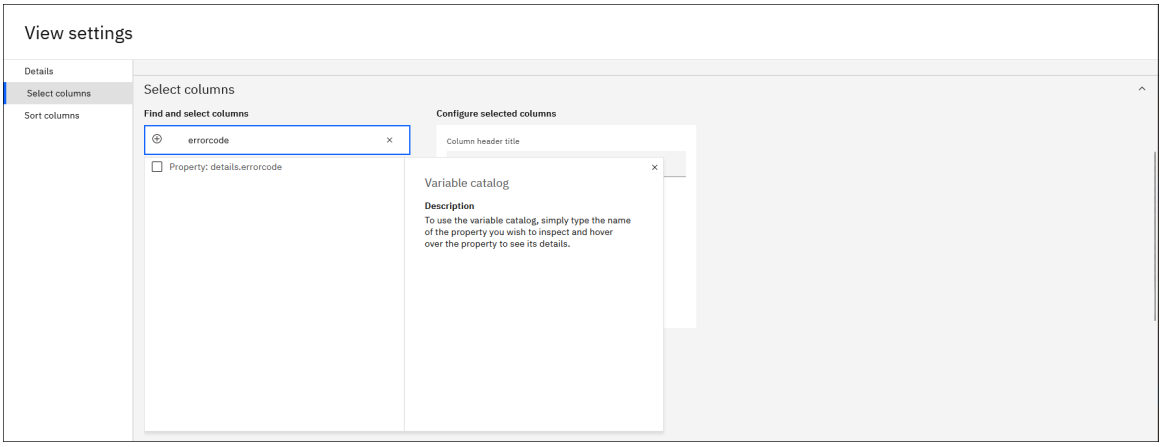
4. Configure the following properties for a custom view:

- **Details**
  - View name
  - Description
  - Select who can use, edit, and manage this view:
    - *Only me*
    - *Specified users, user groups, or both*
    - *Everyone*



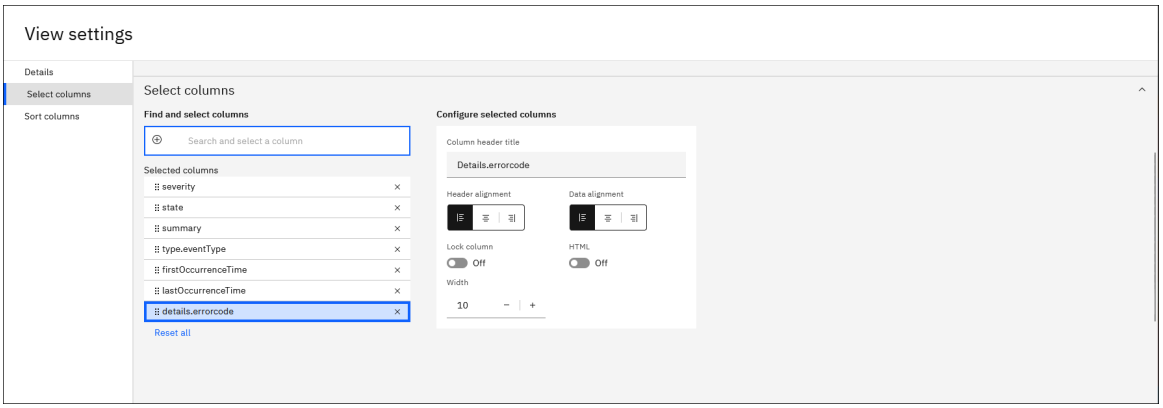
View settings - Details

- **Select columns**

  Select from alert attributes that are predefined for Cloud Pak for AIOps and common to most alerts. Click anywhere in the field provided to display the variable catalog. Move the cursor over the attributes to display the descriptions. You can also type the name of the property that you are looking for and the system will show in the drop-down list all alert properties that contain the typed text. You can drag and drop the columns to determine the order of the columns appearing in the Alert Viewer.

  - **Columns from custom properties**

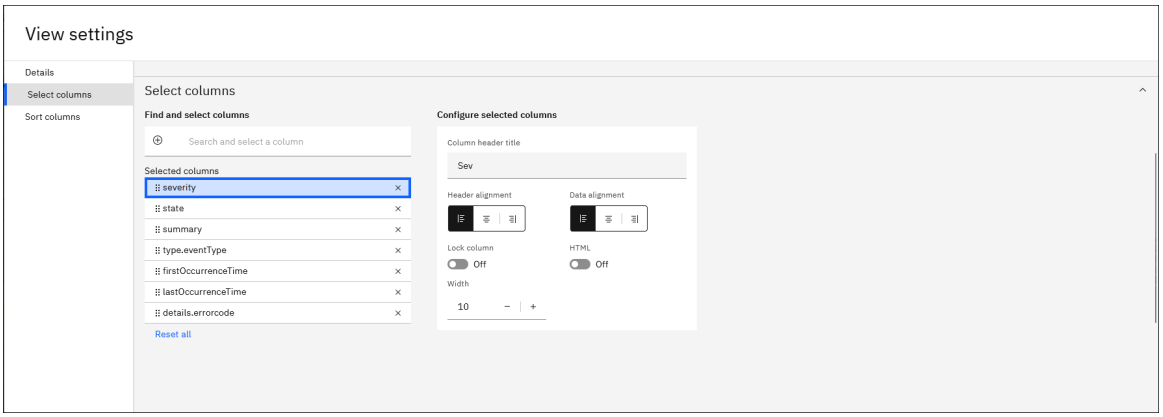
    Columns can also be added based on custom properties that have been mapped to the alert inside the **`details`** property. For example, if you have mapped some data to **`details.errorcode`** you can then utilise that property as a column in the Alert Viewer. Simply type the property name, **`errorcode`** in this example, and select the resulting property with the "**`details.`**" prefix:



View settings - Custom properties

View settings - Custom properties

Close the catalog and you will find the property added at the bottom the list:



View settings - Custom properties

Important: A view must contain the **ID** and **Summary** columns.

- **Configure selected columns**

  Configure the following properties to customize the columns that display alert data:

  - *Column header title*: type a new title for the column or keep the default.
  - *Header alignment*: set the position of the title text in the column heading.
  - *Data alignment*: set the position of the alert data in the columns.
  - *Lock column*: locked columns are always displayed when you scroll an alert list horizontally. Locked columns appear at the left side of the view.
  - *HTML*: enable clickable links in the Alert Viewer cells.
  - *Width*: type a numeric value in the Width field to change the width of a column.

View settings - Configure selected columns

- **Sort columns**

  Add new columns in the Select columns section. Then, in the Sort columns list, single click on a column item to set ascending order. Click the column twice to sort in descending order. Drag and drop columns to prioritise sorting across columns.

View settings - Sort columns

What to do next

- **Manage selected view**
  1. From the view list in the Alert Viewer, select the view that you want to edit. The alert list updates with the view properties.
  2. Click **View configuration** > **Manage selected view**.
  3. Edit the **View settings** as required.
  4. Click **Save** to save the view.
- **Duplicate selected view**
  1. From the view list in the Alert Viewer, select the view that you want to copy. The alert list updates with the view properties.
  2. Click **View configuration** > **Duplicate selected view**.

     A copy of the view is displayed. By default, the view name is set to "Copy of *view name*."
  3. Edit the **View settings** as required.
  4. Click **Save** to save the view.
- **Delete selected view**
  1. From the view list in the Alert Viewer, select the view that you want to delete. The alert list updates with the view properties.

2. Click **View configuration** > **Delete selected view**. This action cannot be undone. Once the view has been deleted, your view is updated based on the first view in the list.
3. Click **Delete view** to confirm deletion.

Creating quick filters

You can use quick filters as a fast way of displaying alerts that match a selected criteria. For example, you can quickly display only those alerts that occurred at the same time as, or before, a selected alert. A quick filter is applied via the right-click context menu. Quick filters when applied are merged into the filter side panel together with the base filter selection.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Alerts**.
3. Right-click on any column or cell in the Alert Viewer, then select **Quick Filter** and choose from the following operators:
   - Equals
   - Does not equal
   - Contains
   - Does not contain

   The **Insights** columns for **Part of an incident**, **Runbooks**, and **Topology** can be filtered using the **Contains** operator.

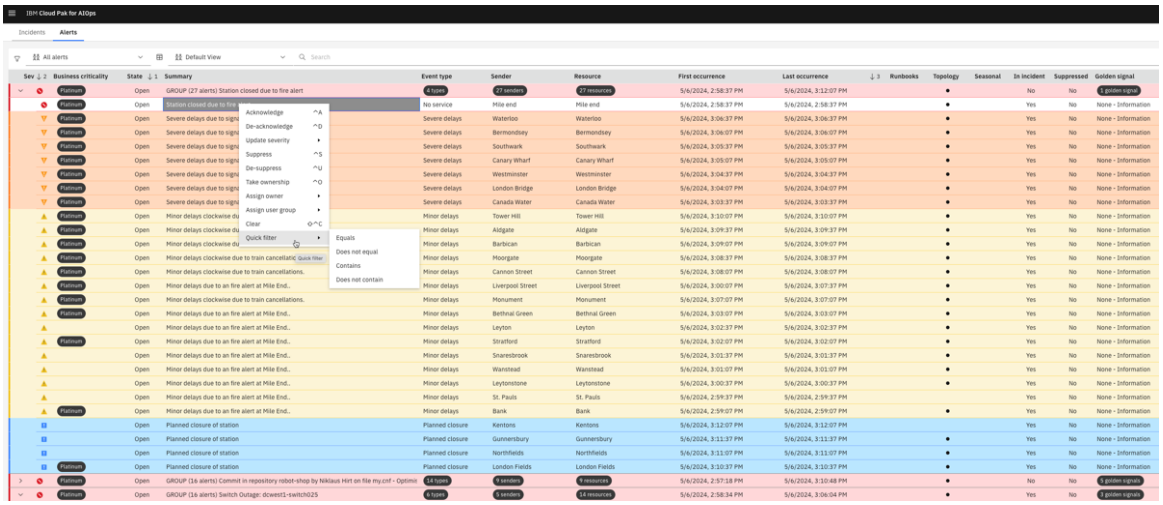


Figure. Quick filter option

Results

The alerts are filtered to only those that meet the filter condition. The applied filter condition is displayed in the filter side panel.

Related links

Menu customization

You can personalize the arrangement of right-click menu items. The arrangement is only visible to the user customizing the menu. That is, each user can define how their own menu looks.

Using custom fields

Use the custom fields associated with alerts in IBM Cloud Pak for AIOps.

Alerts in Cloud Pak for AIOps contain a set of predefined attributes that cover the general use cases. For more information about predefined attributes, see Alert and Event schemas.

In some cases you might want to add custom fields to alert properties, which are specific to your processes. For example, a retail store might want to keep track of a store id, or a communication service provider might want to track the location of a cell tower. These custom fields can be used for mapping incoming data, determining which policies to execute, or as part of automation actions. You can view custom fields alongside the predefined fields in Alert Viewer.

You can use custom fields in integrations that allow JSON mapping. These integrations include IBM Netcool Operations Insight ObjectServer and Webhook.

For more information about IBM Netcool Operations Insight ObjectServer integration, see Creating IBM Netcool Operations Insight ObjectServer integrations.

For more information about Webhook integration, see Creating Generic Webhook integrations.

If you want to use custom fields when you map incoming data (within an integration), then you need to define **details** field in the JSON. Add key and value pairs for your custom fields within the **details** object.

Use the following format for the custom fields:

```
{
 "details": {
    "myCustomField": "value"
 },
}
```

Following sample example shows the usage of custom fields within IBM Netcool Operations Insight ObjectServer integration:

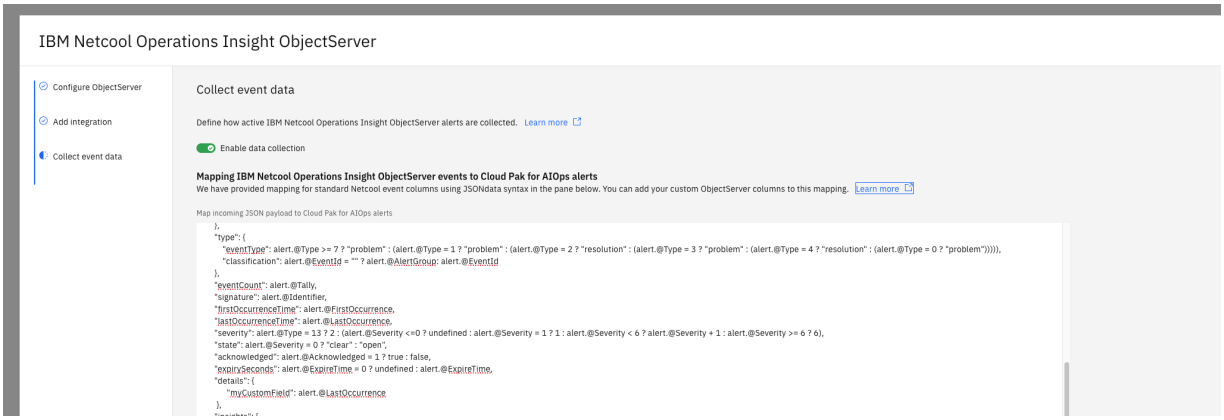

Figure. Custom fields

For more information about displaying custom fields in Alert Viewer, see **Columns from custom properties** section in Creating views.

For more information about usage of custom fields when you create or customize a policy, see Policy editor.

Setting user preferences for the Alert Viewer

You can configure the appearance and behavior of the Alert Viewer via the **User preferences** .

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Alerts**.
3. On the upper right corner of the page, click > **User preferences**.

   The following preferences can be applied to the Alert Viewer:

   - **Default filter**

     Set a default filter for the alert list from the predefined or customized alert filters available in the drop-down list. For more information, see Searching and filtering alerts.

   - **Default view**

     Set a default view for the alert list from the predefined or customized views available in the drop-down list. For more information, see Creating views.

   - **Default view for alerts in incidents**

     Set a different default view for alerts in incidents.

   - **Default filter for alerts in incidents**

Set a different default filter for alerts in incidents.

- **Row size**

  Select from the following table row sizes:

  - Very small
  - Small
  - Medium
  - Large
- **Alert details launch type**

  Selecting an alert in the table opens the alert details for that alert. These can be displayed in a **Side panel** or in a separate **Pop-up window**.

- **Alert details should open on:**

  - Double-click
  - Single-click
- **Alert activity entries sorting**

  - Newest at the top
  - Newest at the bottom
- **Row coloring**

  Change how alert severity is depicted in the table by applying a different color background for each priority level.

- **Table auto-refresh**

  Enable auto-refresh to have the alert list automatically updated at predescribed intervals.

- **Table auto-refresh interval (s)**

  Auto-refresh interval in seconds.

- **Warning prompts**

  Turn on or off.

- **Select child alerts on parent alert right-click**

  Turn on or off.

4. Click **Save** to apply your changes to the Alert Viewer.

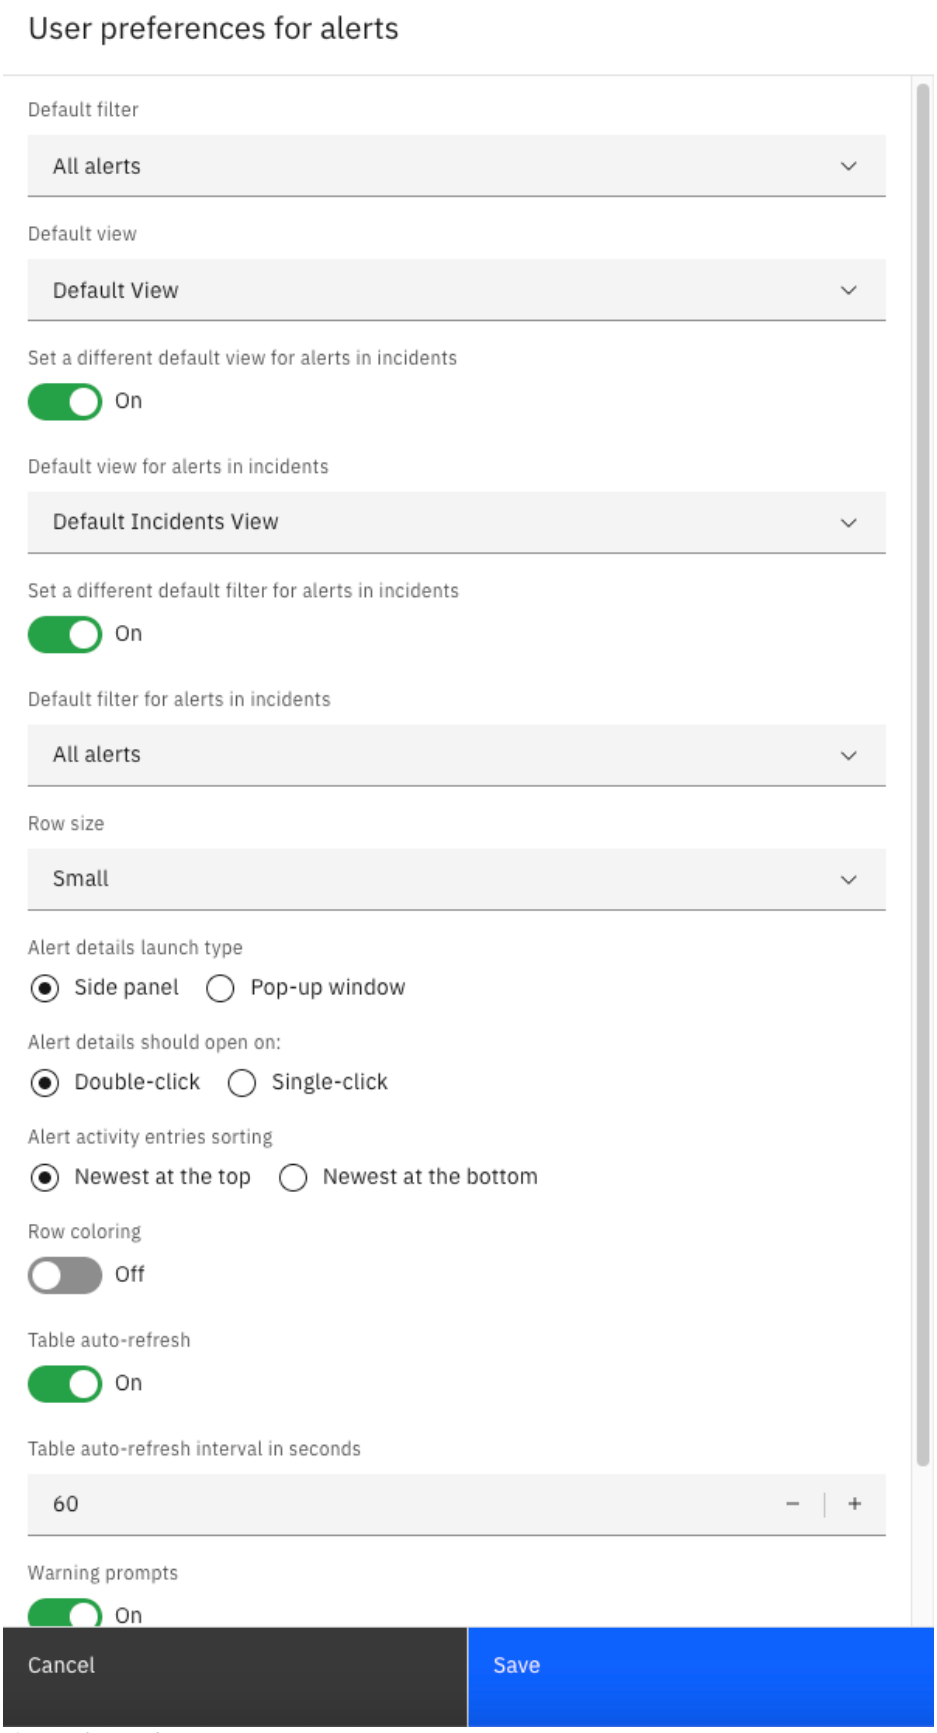

Figure. Alert preferences

About alert groups

An alert group is a group of two or more alerts that Cloud Pak for AIOps has correlated together because the underlying analytics have determined that these alerts belong together.

Alerts can be added to an alert group because of one or more of these factors:

Table. Factors for alert groups

Correlation type	Example
Temporal groups: based on alert history, these alerts tend to occur within a short time of each other.	A "Latency" alert on a server is regularly followed by a "Ping response time high" alert on that same server. These alerts are grouped into a temporal subgroup.
Topological groups: the alerts occur on resources within a predefined section of your network topology.	If there is a predefined section of the network that groups together a specific switch and all the nodes that depend on that switch, then any alerts occurring on that specific switch or the nodes connected to it are grouped together. These alerts are grouped into a topological subgroup.
Scope-based groups: the alerts occur on a user defined scope.	An administrator defines a `ScopeID` based on properties that define the scope for how alerts are grouped. Any alerts that match the scope and occur within a default time window are then automatically grouped together. An example would be where an alert storm occurs on the `london145.acme.com` server. All of the alerts in that storm will be grouped together as they match the `alert.resource.location= london145.acme.com`, and they occur within the default time window. These alerts are grouped into a scope-based subgroup.

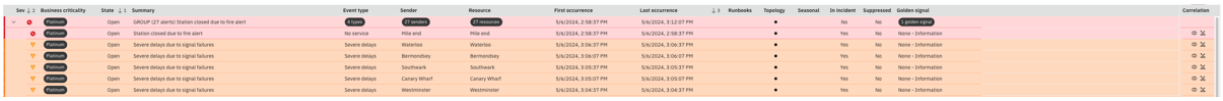

Figure. Alert groups

Displaying an alert group

Expand an alert group to display the alerts that were correlated together within the group.

An alert group contains two or more alerts, which are correlated together by the underlying analytics. The group can include **Temporal** groups , **Topological** groups , and **Scope-based** groups .

1. Identify an alert group within the table.

   You can identify a group using the following signs:

   - It has a Down chevron icon in its row in the table.
   - By default, it has a summary that includes the words: GROUP (n alerts), where n is the number of the alerts in the group.

Figure. Alert groups

2. Open the alert group by clicking the Down chevron icon in its row in the table.

   The group's alerts are now displayed under the parent alert.

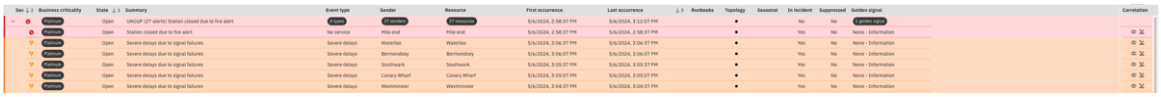

Figure. Alert groups

Displaying alert topology

If the resource on which an alert occurred can be located in the network topology system, then a large dot ● is presented in the alert's Topology column. Double-click the large dot ● to display a topology map for this alert, centered on the resource on which the alert occurred.

Procedure

1. Double-click the large dot ● in the Topology column for the alert of interest.

   A side panel containing multiple information sections opens on the right side of the table. The Topology section is open and provides the following information:

   - **Resource**

     Name of the resource on which the alert of interest occurred.

   - **Begin time**

     Date and time when the topology for this resource was last updated.

   - **Observed time**

     Date and time when the alert of interest was observed on this resource.

   - **Topology pane**

     Shows a one hop topology map for this alert, centered on the resource on which the alert occurred.

2. To investigate the topology further, click the **More information** link, which is located at the end of the side panel's Topology section.

   This action opens the Topology viewer, which displays the same topology map, with the full topology display experience. For more information on how to use the Topology viewer to explore topology, see the related link at the bottom of this topic.

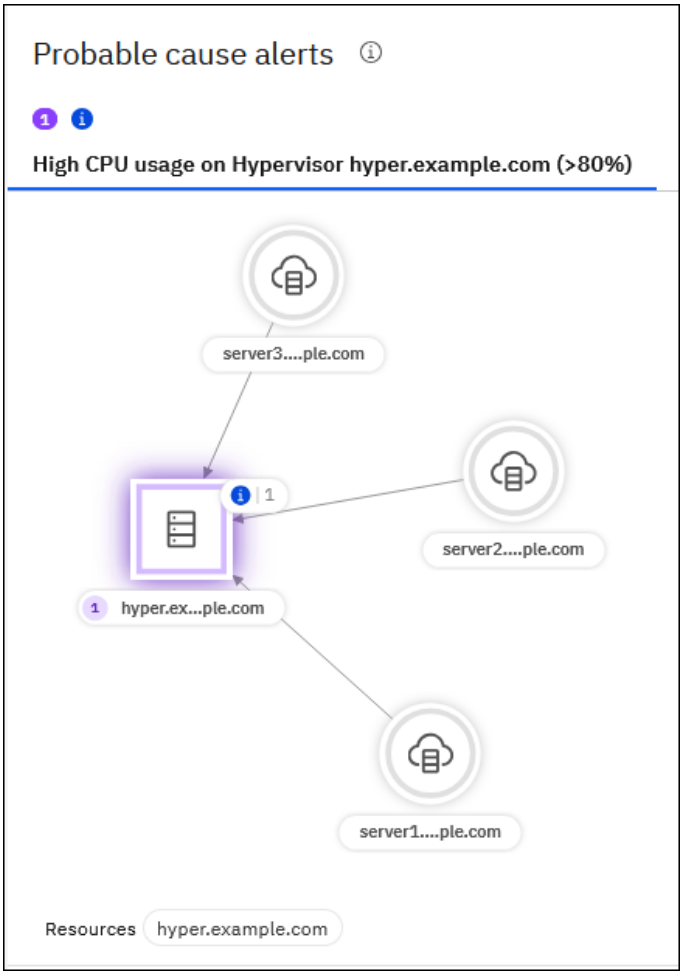

Figure. Alert topology

Note: From an incident's Alert Viewer, the Topology viewer opens in the **Topology** tab on the same page. From the general Alert Viewer, the Topology viewer opens in a separate browser tab.

Related links

Viewing a topology

You can use the interactive Topology viewer tool to drill into the individual resource details and status, enable a timeline to view changes over time, and more.

Displaying alert seasonality

Alerts can occur within a seasonal time window. For example, an alert might tend to occur on a certain day of the week or a certain time of the day. Alerts that tend to occur within a seasonal time window are highlighted in the Alert Viewer using a circle or a circle with a check mark in the alert's **Seasonal** column. Click these icons to find out when the alert tends to occur.

Examples of seasonal time windows include the following times:

Hour of the day

`Between 12:00 and 1:00 pm`

Day of the week

`On Mondays`

Day of the month

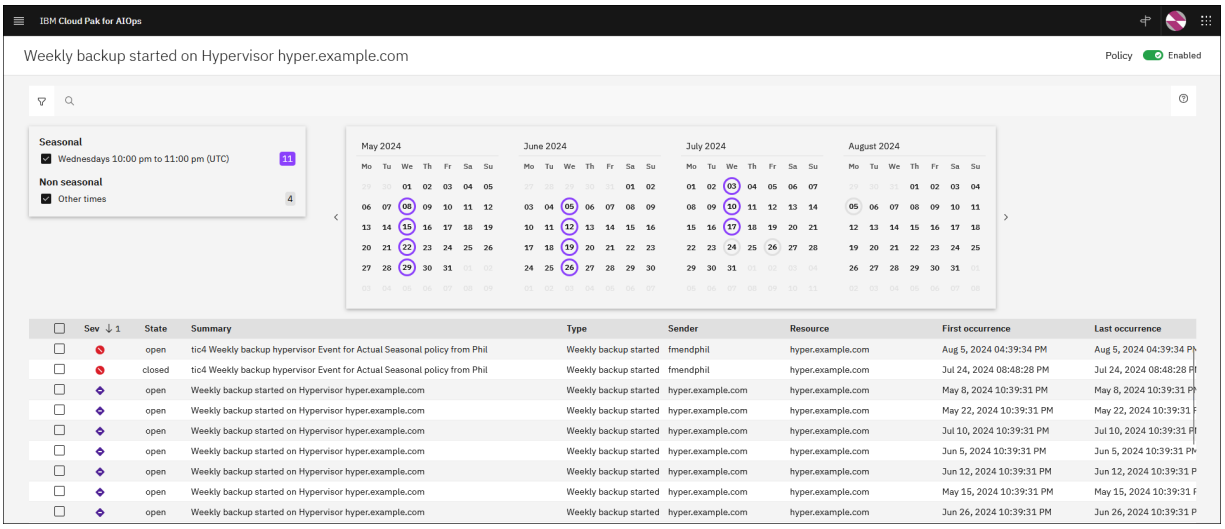
`On the 3rd of the month`

Day of the week at a specific hour

`On Mondays, between 12:00 and 1:00 pm`

Day of the month at a specific hour

`On the 3rd of the month, between 12:00 and 1:00 pm`



Procedure

1. Identify alerts that are seasonal.
   - Alerts that are not part of an alert group, that have associated seasonality, have a circle visible in the **Seasonal** column.
   - Alerts that are part of an alert group, that have associated seasonality, have a circle with a check mark in the **Seasonal** column, but you must first open the alert group in order to see the alert. Open the alert group by clicking the Down chevron icon in the parent alert group row.
2. Click the circle or dot to display more information on the alert of interest.

   A side panel that contains multiple information sections opens in the table. The **Seasonality** section is open and displays one or more seasonal time windows for the selected alert.
3. Click the Down chevron icon next to each seasonal time window to see a visual representation of the time window.

   For example, if the underlying algorithm has identified that the selected alert tends to occur between 12 noon and 1:00 pm, then this alert will have a seasonal time window as follows, and this will be displayed using a clock-based representation:

   `Between 12:00 and 1:00 pm`
4. Click the **More information** link at the end of the side panel's **Seasonality** section to launch out to the **Seasonality details** page.

Seasonality details

This page provides a calendar view of all of the historical alerts that contributed to the selected seasonal alert. One or more seasonal time windows are listed in the top left pane. Select a seasonal time window to filter the view to show just historical alerts that contributed to that time window. The **Seasonality details** page contains the following sections:

- **Toolbar**
  - Search: searches alert data in all event group instances that are shown on this page.
  - Filter: filters the alerts that are shown by severity level:
    - Critical
    - Major
    - Minor
    - Warning
    - Informational
    - Indeterminate
- **Seasonal time windows**

  One or more seasonal time windows are listed together with a number indicating how many historical alerts occurred within this time window during the historical period analyzed. The color of the square is the color code for the respective seasonal time window. Select a seasonal time window to filter the Calendar and the Historical alert table to show just historical alerts that contributed to that time window.
- **Calendar**

  A calendar of the historical period analyzed (the last three months or more) showing days on which the historical alerts of interest occurred, and colored with the color code for the respective time window. Click one or more days in the calendar view to filter the table of alerts details to the selected date.
- **Historical event table**

  Table listing the historical alerts during the historical period analyzed.

Displaying temporal correlation

The system continually analyzes past alerts to determine which alerts tend to frequently co-occur. When these alerts occur together again, they are correlated.

The temporal details page shows the alerts that make up a temporal group, together with all of the historical instances of the group. You can navigate into these instances to view detailed timelines of each instance. You can also view alert details.

Procedure

1. Identify alerts that are temporal in the Alert Viewer. You can click the Filter icon to filter by Grouping insights.
2. Click the **View correlation** icon to display the **Correlation** column in the table.
3. Clicking the temporal icon in this column opens the sidebar, with the **Temporal correlation** section open. This section contains the following information:

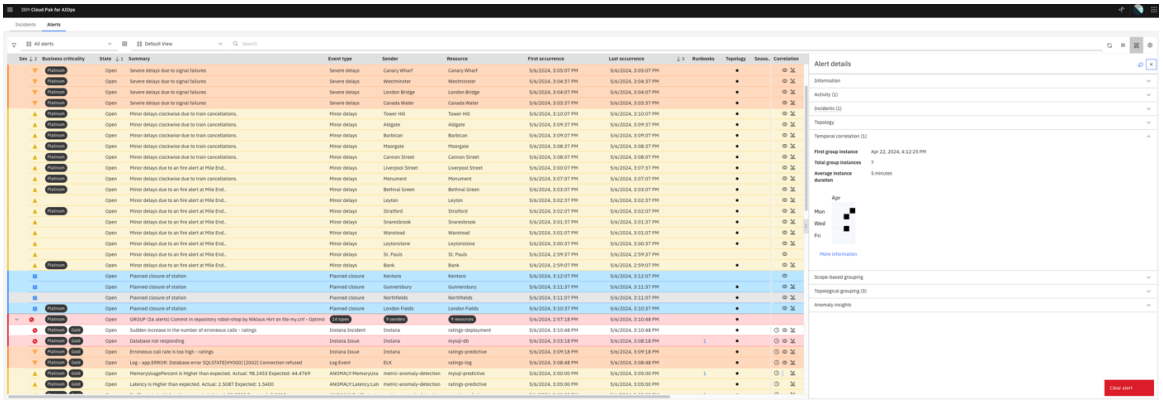
- **First group instance**

  Date and time of first instance of this group.
- **Total group instances**

  Total number of historical instances of this group. For details of when these instances occurred and how many alerts occurred in each instance, see the Group instance heatmap.
- **Average instance duration**

  Average time in seconds that this group instance lasted.
- **Group instance heatmap**

Time-based heatmap showing recent historical period in days with a gray square for each day. Each darker square indicates a day on which there was at least one group instance. Hover over the square to see details of this group instance.



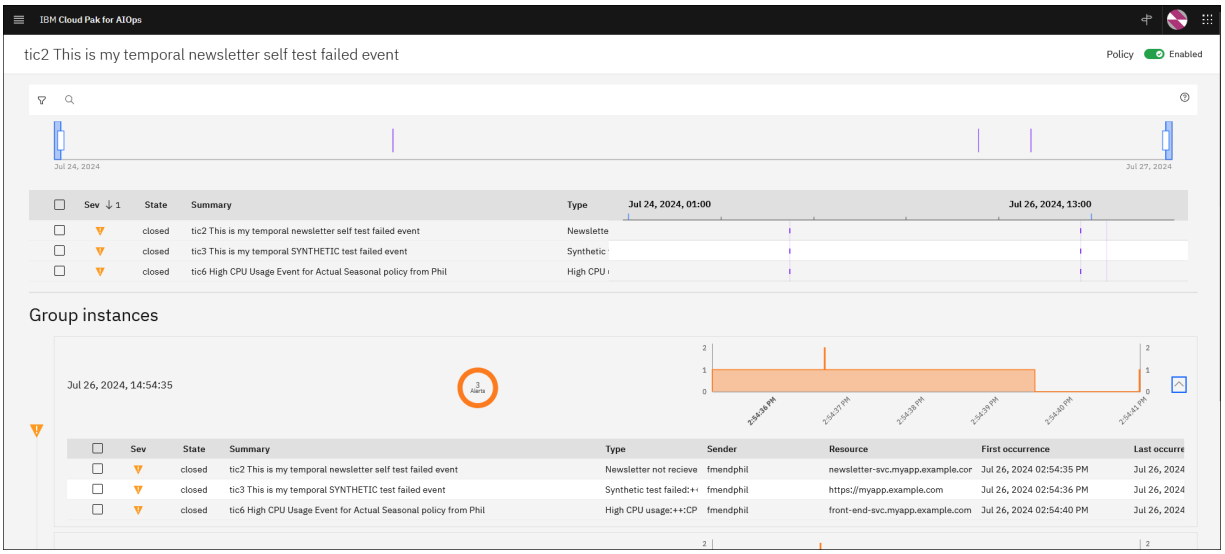


Figure. Temporal correlation section

4. Click the **More information** link at the end of the side panel's **Temporal correlation** section to launch out to the temporal details page.

temporal correlation details

The temporal details page shows the alerts that make up a temporal group, together with all of the historical instances of the group. You can navigate into these instances to view detailed timelines of each instance. You can also view alert details. The temporal details page contains the following sections:

- **Toolbar**
  - Search: searches alert data in all event group instances that are shown on this page.
  - Filter: filters the alerts that are shown by severity level:
    - Critical
    - Major
    - Minor
    - Warning
    - Informational
    - Indeterminate
- **Overview timeline**

  Displays alert group instances over time and controls the display of alert group instance data on the rest of the page. By default the time range sliders are open sufficiently to show data on all alert group instances. Modify the time range by either clicking and dragging over the desired range inside the timeline, or by dragging the sliders to the desired range. The rest of the screen updates accordingly.
- **Alert group instance timeline**

Displays all of the alerts that have historically participated in instances of this temporal alert group. The instance map provides a graphical view over time of when the various instances have occurred.

- **Alert group instance details**

  Displays the following information for each alert group instance:

  - Start date and time of event group instance: indicates the first occurrence value of the first alert in the alert group instance.
  - Distribution of event severity values: pie chart providing a visual indication of the alert severity values. Hover over the pie chart for more details.
  - Sparkline: chart of alert occurrence over time.
  - Duration of event group instance: duration of the alert group instance, in text.
  - Down chevron icon: click the down chevron icon ⌄ to see an alert table showing column details for each alert in this group instance.

Log anomaly alerts

Log anomaly alerts have a **Sender** attribute of **Log Anomaly** if you use natural language processing and statistical baseline methods. If you use log anomaly detection - golden signals, the **Sender** attribute is **log-metric-anomaly-detection**.

Types

For log anomaly alerts, the **Type** attribute shows which of the log anomaly models detected the anomaly:

- Natural language anomaly
- Statistical baseline anomaly

Summaries

The **Summary** attribute of an alert provides more detail about why an anomaly was detected.

A summary might look similar to the following example:

```
Logs containing errors for component: QMA with a primary message code of AMQ9665E. Evidence includes: domain-specific entities.
```

- The **Evidence includes** statement can show the following values:
  - `domain-specific entities`, for example, message codes
  - `embeddings (statistical baseline)`
  - `error entities`, for example, HTTP error codes and exceptions
  - `patterns + embeddings (natural language)`
- A **primary message code**, such as `AMQ9665E`, is included only for alerts where an anomaly is detected in logs that originate from a domain-specific source, such as IBM MQ or WebSphere.

Categorization of log anomaly alerts

During the training phase, templates are extracted based on the input logs. Models are trained to represent the normal behavior of a component or service in an incident-free window. In the inference, any incoming new live log data is matched against the templates that were extracted during training, and the distribution for a fixed window is computed. Any new logs, error logs, or deviation from the normal distribution from training might be flagged as an anomalous window and generate a log anomaly event.

A template is classified as an error by using keyword matching with a predefined error dictionary and error symptom words.

Alerts that are generated for log anomalies come in two types:

- Alerts with the `Logs containing errors for` prefix are log anomaly alerts that are generated when an error template is included in the alert. Templates include internal lists of error keywords. For example, a template can be classified as `Logs containing errors for` when it includes the keywords `expires`, `failure`, or `incomplete`.
- Alerts with the `Abnormal behavior in the logs for` prefix are log anomaly alerts that are generated when no error templates are included in the alert.

Explainability

An alert is generated when a log anomaly is detected. The metadata for an alert contains fields and information that can help you understand the identified log anomaly.

See the following alert field descriptions to better understand reported log anomalies:

- **`description`**: If error templates were found in the ten-second window and if the count of these templates is greater than **`0`**, these templates are captured in the **`description`** field. If error templates are not present after an internal ranking algorithm is applied, the top five templates that have a count value greater than **`0`** are included in this field.
- **`details`**: This field includes the **`text_dict`** field, which contains critical fields, such as **`template_ids`** and **`template_list`**. This field includes the sorted templates and entities based on an internal ranking algorithm that corresponds to the log anomaly. This ranking algorithm prioritizes error templates and low occurrence error templates. It also prioritizes error entities over other types of entities. Based on the ranking, only the top 5 templates are shown.

Microsoft Teams and Slack integrations

If a Microsoft Teams or Slack integration is set up, the alerts are also sent to those integrations. The same alert data is parsed and shown in Microsoft Teams or Slack.

- The Microsoft Teams or Slack UI parses and displays the templates that are associated with the alert.
- Use the **preview logs** feature to see a sample of the logs that are associated with a template.
- When you click **Attach log message patterns** on the Microsoft Teams or Slack UI, you receive all anomalous and normal logs in the ten-second window time range for the resource, also known as the application component, that is associated with the alert.
- For more information, see Configuring Slack applications for integration and Creating a Microsoft Teams integration.

High risk alerts from change risk

When a new, incoming change request is evaluated as high risk, an alert is posted to the IBM Cloud Pak® for AIOps Platform UI. It can be included in the Events report and can be grouped into an incident. By reporting these alerts, high risk insights can be used for incident avoidance and mitigation.

A change risk high risk alert can be identified in the Alert Viewer when the **Sender** column for an alert contains **`change-risk`**. So a high risk alert resembles this example:

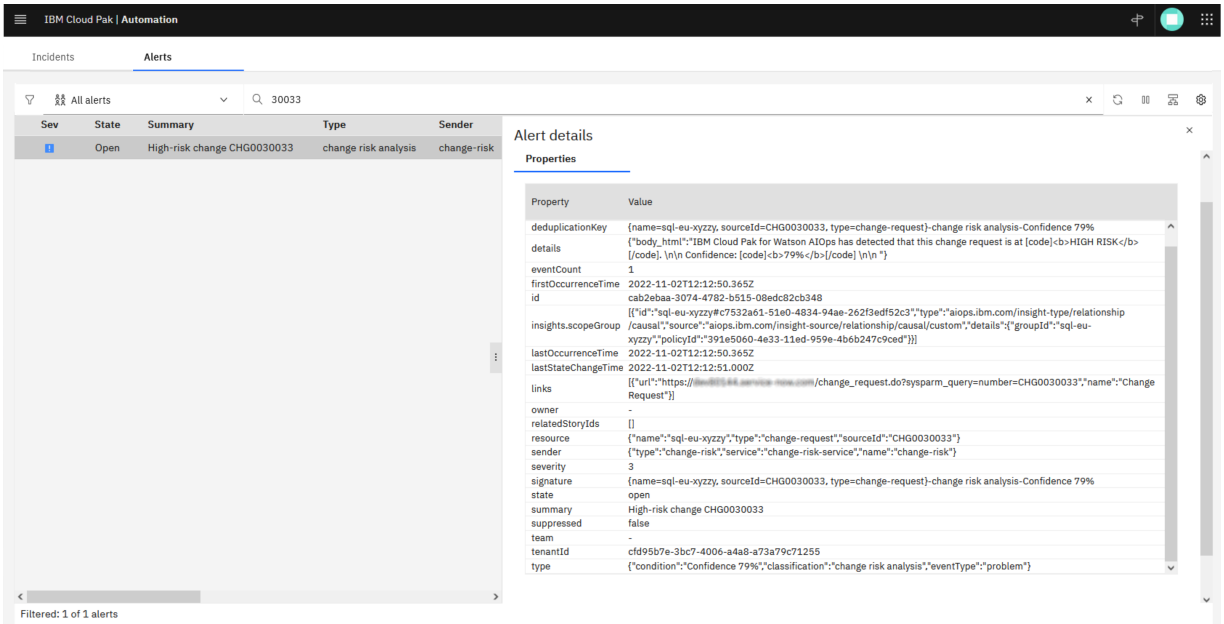

Figure. Alert viewer high risk

High risk in Events example:

```
id: UUID (str)
 sender: {
     service: "change-risk-service"
     name: "change-risk",
     type: "change-risk"
 }
 resource: {
     name: str, optional - Service Now CMDB ID (if present)
     sourceId: str - Change number (e.g. "CHG12345")
```

```
    type: "change-request"
}
type: {
    classification: "change risk analysis"
    condition: str - Confidence level (e.g. "Confidence 94%")
    eventType: "problem"
}
severity: 3 (int)
summary: str - Change reference (e.g. "High-risk change CHG1")
details: {
    body_html: str - HTML-marked English description of the change, related changes, and related incidents.
}
occurrenceTime: datetime (str, UTC, ISO 8601 with timezone) - Time the risk evaluation was processed
expirySeconds: 0 (int)
links: [
    {
        name: "Change Request",  (e.g. 'Change Request')
        url: str (e.g. 'https://example.service-now.com/change_request.do?sysparm_query=number=CHG1')
    }
]
insights: [] (empty list)
```

Viewing metric anomaly details

In **Incidents and alerts**, alerts can appear in the Alert Viewer table to indicate metric anomaly detection. More detailed information on these alerts, and a Key Performance Indicator (KPI) timeseries chart, can be viewed by opening the *Alert details* panel.

KPI: A KPI is made up of a resource, which is a physical entity such as a network interface card, and a metric. For example, if a server has 2 network interface cards and you want to analyze data for 10 metrics on each network card in the server, the total number of KPIs is 20. KPIs are often interchangeably referred to as metrics, so a metric can sometimes refer to a measurement that is taken for a type of device - for example **`CPU_Context_Switches`**, and sometimes it can refer to an instance of that metric - for example **`CPU_Context_Switches`** on server **`ABC.acme.com`**.

Alert count metric anomalies: Default alert expectations are calculated by the metric manager capability based on the input data. If an anomalous alert rate is detected that is either higher or lower than expected, an alert is raised and displayed as a **`Metric anomaly`** in the Alerts table. When selected, the *Alert details* window depicts the expected values against the actual values. If required, an administrator can disable this specific functionality by editing the **`feature-flags-configmap.yaml`** file, and setting the **IBM_IR_AI_ALERT_COUNT_METRICS_ENABLED** flag to **`false`**.

Procedure

1. In the Alert Viewer (**Incidents and alerts** > **Alerts** tab) click anywhere on the row of a metric anomaly alert (identified by ANOMALY displayed in the *Type* column in the table).
2. An *Alert details* side panel opens. By default, the *Metric anomaly details* chart displays, showing the properties of the alert and associated values.
3. The chart plots the activity of the anomaly over a 2-day period (the two days up to the date in the date field).
4. You can increase the viewing size of the chart within the panel:
    - Click the 3 vertical dots in the gray tab on the left side of the panel. Then, drag the tab to the left.
    - Select a **Graph start date** and **Graph end date** to view data for the selected date range.

Understanding the chart

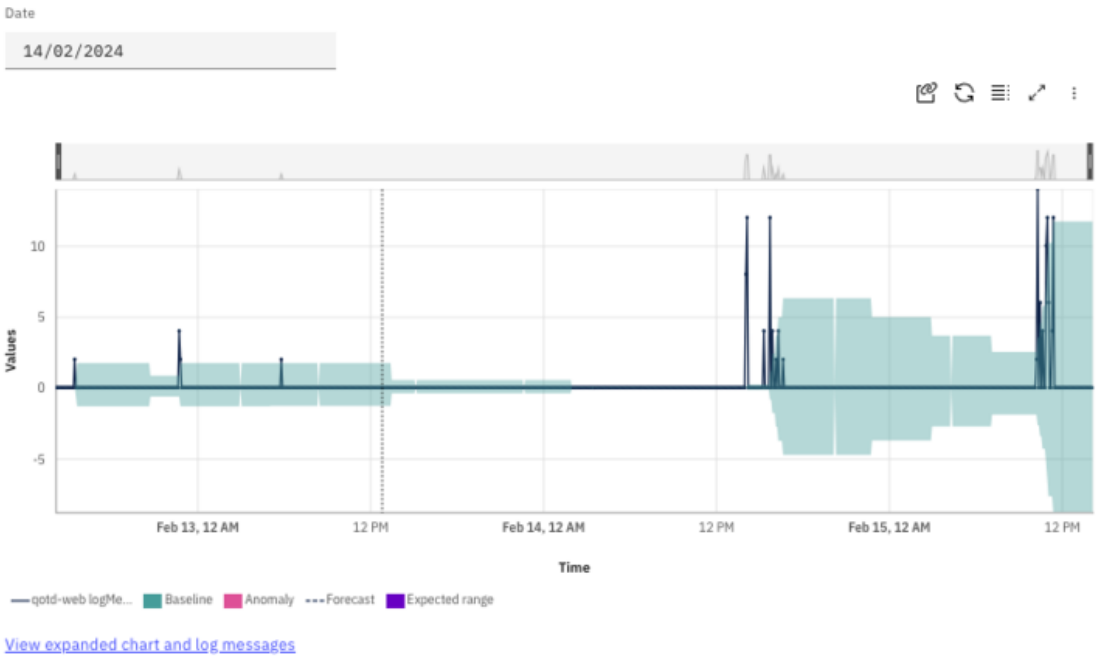

Figure. 2-day chart

- The unbroken black line that is labeled with the name of the metric resource that is plotted on the chart represents the values of the selected metric over time.
- A green-shaded area (labeled *Baseline*) represents the acceptable operating range of that anomaly.

  Note: The default KPI Baseline is always that of the primary metric. To change to another Baseline, from related alerts or additional metrics, click the radio button (blank circle) attached to another KPI. Making this Baseline adjustment also changes the KPI that is forecast. If you select multiple metrics, you can choose to view only one Baseline from all of the KPIs that are in the related alerts and additional metrics tabs.
- A red-shaded area or red vertical line (labeled *Anomaly*) indicates where the metric is anomalous: one or more of the anomaly detection algorithms determined the metric was not behaving in accordance with the learned normal behavior.
- A purple area in the chart (labeled *Expected range*), with a dashed line (labeled *Forecast*) indicates forecasted metric anomalies. For more information, see Metric anomaly forecasts.

  Note: Sometimes the purple range is not shown, or is only partially shown. This is because the range becomes too wide to show it. The dashed line denoting the forecast will still be shown unless there is some reason that the forecast is not produced, for example if there are too many gaps in the timeseries, or if data availability is too low.

Tooltip: Hover the cursor over any part of a time-series graph to view tooltip information that is related to multiple anomalies at a particular point in time.

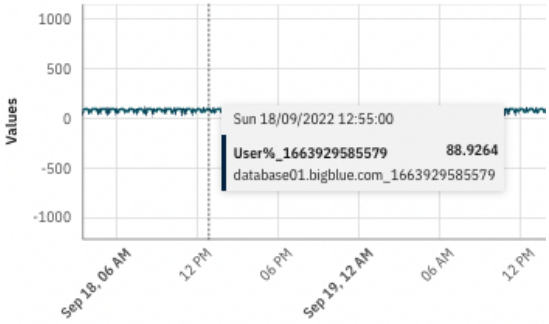

Figure. Tooltip

Chart Icons

Icon	Name	Description
	Copy link	Copies URL link of chart to clipboard.

Icon	Name	Description
	Show as table	Tabular representation of anomaly, including occurrence times and values, which can be downloaded as a CSV or JSON file.
	Make fullscreen	Maximizes size of chart to fit onto full page.
	More options	Allows chart to be exported as a CSV, JSON, PNG, or JPG file. PNG and JPEG options are only available when you use the Chrome browser.

Zooming in on the timeline

On the main chart, place and click the "+" "cursor at the beginning of the time period you want to focus on, then drag it along the timeline, to your chosen endpoint. The main chart adjusts to the selected timeline.

For a more controlled zoom, use the zoom scale (miniaturized chart on top of the main chart) to focus on a particular date range. Select and move the vertical slider black bars, left or right:

Figure. Metric anomaly chart zoom

Expanding the timeline of the chart

- For metric anomaly detection alerts, click **View expanded chart** to change the 2-day timeline in the side panel to a larger, 7-day timeline chart.
- For **Log Anomaly - Golden Signals** metric anomalies, click **View expanded chart and log messages**.

The **Metric anomaly details** page opens.

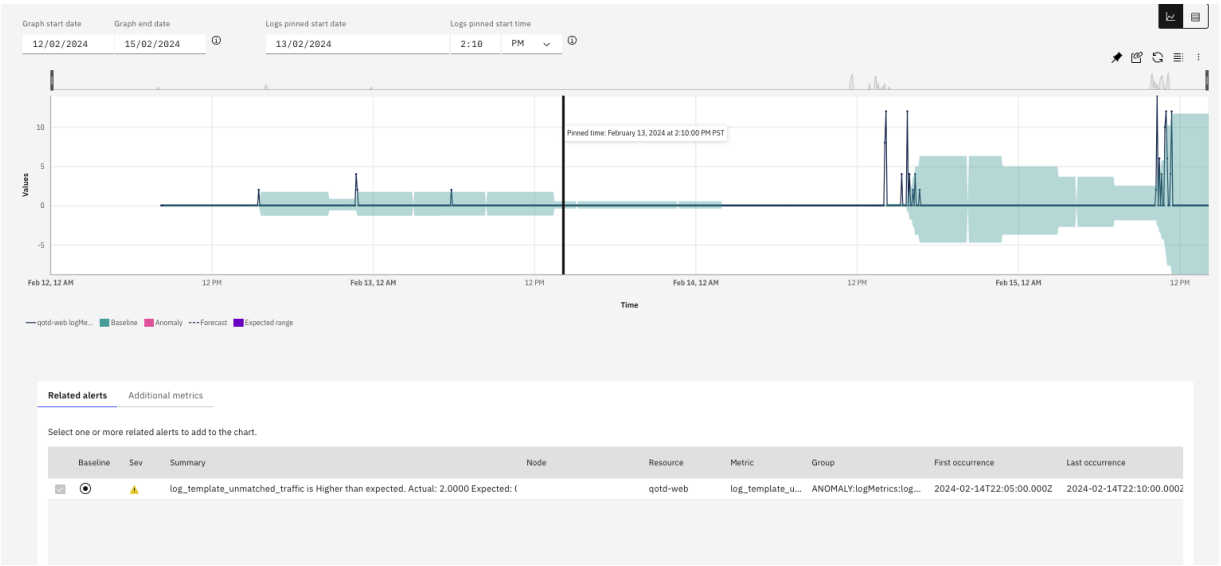

Figure. The metric anomaly expanded chart with the Related alerts and Additional metrics tabs

Metric anomaly graph

From the **Metric anomaly details** page for **Log Anomaly - Golden Signals** metric anomalies, the **Metric anomaly graph** section includes a **Graph view** and a **Logs view**.

- Both the **Graph view** and **Logs view** include filters to specify the date and time you want to display.
  - Select a **Graph start date** and **Graph end date** to view data for the selected date range.
  - Select a **Logs pinned start date** and a **Logs pinned start time** to specify a pinned time in the graph. Click **Pin logs start time** or **Unpin logs start time** to pin or unpin the specified time. Pinning can help you see how the logs in the **Logs view** correspond to the graph in the **Graph view**.
- The **Graph view** is displayed by default and shows the timeline. Baseline data is omitted where the value on the graph is zero.
- Click the **Logs view** to view a table of log messages that correspond to the alert and template ID.
  - To filter the logs that are shown, specify the date and time or search for keywords.
  - Download the logs by clicking **Export to CSV file**.
  - If the alert was derived from live logs that can be found in the log aggregator, you can click **Launch log aggregator** to open a log aggregator at the pinned start time.

Related alerts table: If alerts related to the primary metric are detected, then a tab for *Related alerts* appears in the expanded view of the chart. When this tab is selected, a table of related alerts appears. Up to 4 related alert metrics can be added to the chart as KPIs, in addition to the main metric KPI. For more information, see Related alerts table.

Additional metrics

Use the *Additional metrics* tab to add up to another 3 KPIs to the Metric anomaly details chart.

1. Click **Add metric**.
2. Select an item from each field: *Metric group*, *Metric*, and *Resource*.
3. When selection is complete, the timeline of the KPI is added to the chart.
4. Repeat steps 1-3 up to 2 more times.

To modify a selection, remove the current item by clicking ✕ in the *Metric group*, *Metric*, or *Resource* fields. Then, click inside the empty field, and a menu displays all available items for that field.

To delete a KPI, click ✕ in the *Metric group* field or the ⊖ icon.

Note: Entering part of a string in a field filters the menu so that it displays only the items that contain that element. In the following example, in the *Resource* field, entering 02 brings up all resources that contain the string 02.

Related topics

- Viewing multiple metrics on the metric anomaly chart

Metric anomaly forecasts

Forecasting can indicate when an alert can become critical and help avoid an outage. Use the metric anomaly details chart to view forecasts for a metric anomaly.

Procedure

Open the metric anomaly details chart, as normal (see Viewing metric anomaly details, for more information).

The forecasted trend is the area of the chart that has a dashed (--) line rather than an unbroken (–) line, which indicates historical data. The dashed line might have a purple "confidence interval" around it that shows the likely range of values for the forecast. In some cases, this confidence interval is not shown due to a high level of error that would result in large confidence intervals.

To get more a detailed view of where historical data ends and forecasted data begins, expand the chart by

- clicking and dragging the gray tab with the three vertically aligned dots on the side panel
- or clicking the maximize icon
- or clicking **View expanded chart**

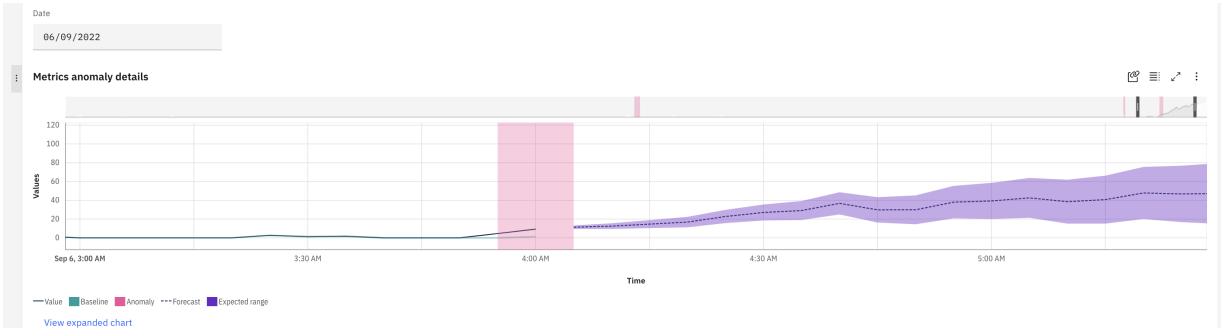

Figure. Expanded and zoomed

When in an enlarged view, you can continue to zoom in on the chart, as normal.

Viewing multiple metrics on the metric anomaly chart

Add multiple metrics (KPIs expressed in a timeseries) to a metric anomaly chart by using the *Related alerts* table or the *Additional metrics* tab.
Note: The Related alerts table is available when the alert is associated with an Incident.

Figure. Related alerts tab

Procedure

Two methods are available to view the *Related alerts* table. Use the Alert viewer or the Incident viewer.

- To access from Alert viewer
    1. In the **Alerts** tab, open the side panel that contains the metric anomaly details. If multiple alerts are grouped or in an Incident, they are shown in the **Related Alerts** table. For more information, see Viewing metric anomaly details.
    2. Click the **View expanded chart** link beneath the chart.
    3. In the expanded view, any alerts (metric and nonmetric) related to the selected alert are listed in the *Related Alerts* table.
- To access from Incident viewer
    1. In **Incidents and alerts**, click the **Incidents** tab.
    2. For the Incident metric you want to investigate, hover over the text in the *Title* column and click the link.
    3. The Incidents *Overview* page opens. Click a metric anomaly in the *Probable cause alerts* or *Top alerts* (when probable cause ranking is not available) column and the metric anomaly chart opens.

Figure. Metric anomaly chart

    4. Click ⧉ to open the chart in its own window.
    5. If related alerts are present, they are listed in the *Related alerts* table. Depending on your screen size, you might have to scroll down to view this table.

Related alerts table

Use the checkboxes in this table to enable or disable Key Performance Indicators (KPIs) on the chart.

Note: A KPI is made up of a resource, which is a physical entity such as a network interface card, and a metric. For example, if a server has 2 network interface cards and you want to analyse data for 10 metrics on each network card in the server, the total number of KPIs is 20. KPIs are often interchangeably referred to as metrics, so a metric can sometimes refer to a measurement that is taken for a type of device - for example **`CPU_Context_Switches`**, and sometimes it can refer to an instance of that metric - for example **`CPU_Context_Switches`** on server **`ABC.acme.com`**.

The checkbox of the main KPI is enabled by default and cannot be deselected. The Baseline radio button is also selected by default, but it can be deselected by clicking the radio button (circle icon) of another KPI.

Up to 4 KPIs from the *Related alerts* table can appear on the timeseries chart at the same time.

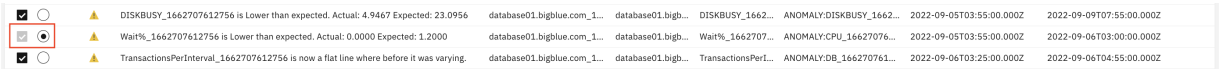

Figure. Multi-Metric chart 2

Note: You cannot apply multiple baselines to a chart. Only one baseline can appear at any one time.

Tooltip: Hover the cursor over any part of a time-series graph to view tooltip information that is related to multiple anomalies at a particular point in time.

First occurrence

When a nonmetric alert is selected on the *Related Alerts* table, a blue vertical line or bar can display, if it is in the same timeline as the metric data displayed. The line indicates the first occurrence of this alert in the selected time period.

Additional metrics

To find and add up to 3 more KPIs to the chart, do the following.

1. Click the *Additional metrics* tab.
2. Find a particular metric by selecting an available value from each field, *Metric group*, *Metric*, and *Resource*.
3. When selection is complete, the KPI is added to the chart.

To modify a selection, remove the current item by clicking ✕ in the *Metric group*, *Metric*, or *Resource* fields. Then, click inside the empty field and a drop-down displays all available items for that field.

To delete a KPI, click ✕ in the *Metric group* field or the ⊖ icon.

Note: Entering part of a string in a field filters the drop-down menu so that it displays only the items that contain that element. In the following example, in the *Resource* field, entering 02 brings up all resources that contain the string 02.

Normalization

The different scales of different metrics can make it difficult to compare them when viewing absolute values together. For example, some metrics can have values of less than 100, while others can have values of more than 10 million. Normalization is used to accommodate comparison, so the scale-bar for the y-axis is not shown. To view absolute values of a metric, uncheck selected metrics until all remaining metric time-series are on the same scale, with the y-axis visible.

Note: If a tooltip is applied to the chart, the absolute value displays, not the normalized value.

Using Metric search to create a timeseries chart

Visualize one or more KPIs, with or without an anomaly, in a Key Performance Indicator (KPI) timeseries chart.

Note: A KPI is made up of a resource, which is a physical entity such as a network interface card, and a metric. For example, if a server has 2 network interface cards and you want to analyse data for 10 metrics on each network card in the server, the total number of KPIs is 20. KPIs are often interchangeably referred to as metrics, so a metric can sometimes refer to a measurement that is taken for a type of device - for example **`CPU_Context_Switches`**, and sometimes it can refer to an instance of that metric - for example **`CPU_Context_Switches`** on server **`ABC.acme.com`**.

Procedure

1. Go to the Cloud Pak for AIOps console.
2. In the **Overview** menu, click **Metric search**.
3. On the **Metric search** page, refine your search to a specific KPI by selecting options from the *Metric group*, *Metric*, and *Resource* menus. The date that is selected represents the endpoint of the chart. KPI.

Figure. Metric search panel

Adding more KPIs to the chart

View up to 5 KPIs on the same timeseries chart.

Assuming that your first-searched metric is plotted on the chart as the primary KPI.

1. Click **Add metric**.
2. Select an item from each field: *Metric group*, *Metric*, and *Resource*.
3. When selection is complete, the KPI timeseries is added to the chart.
4. Repeat steps 1-3 up to 3 more times.

To modify a selection, remove the current item by clicking × in the *Metric group*, *Metric*, or *Resource* fields. Then, click inside the empty field and a drop-down displays all available items for that field.

To delete a KPI, click × in the *Metric group* field or the ⊖ icon.

Note: Entering part of a string in a field filters the drop-down menu so that it displays only the items that contain that element. In the following example, in the *Resource* field, entering 02 brings up all resources that contain the string 02.

Understanding the chart

- The chart displays 7 days of data by default. You can zoom out to see all historical data, including historical data for KPIs that you added to the chart.
- An unbroken black line that is labeled with the name of the KPI that is plotted on the chart represents the values of the selected KPI over time.
- A green-shaded area (labeled *Baseline*) represents the acceptable operating range of that KPI.

Note: The default KPI Baseline is always that of the metric first searched. To change to another Baseline, click the radio button (blank circle) attached to another KPI. Making this Baseline adjustment also changes the KPI that is forecast.

- A red-shaded area or red vertical line (labeled *Anomaly*) indicates where the metric is anomalous: one or more of the anomaly detection algorithms determined the metric was not behaving in accordance with the learned normal behavior.
- A purple area in the chart (labeled *Expected range*), with a dashed line (labeled *Forecast*) indicates forecasted metric anomalies. For more information, see Metric anomaly forecasts.

Blocking, unblocking, and purging metrics

Learn how to add a resource to a blocklist so that it is not processed by metric anomaly detection. You can remove a resource from a blocklist to resume processing metric data. You can also purge all metric data from listed resources.

Blocking metrics

1. Find the metric group that you want to block and click the overflow menu.
2. Select **Block resource**. The **Resource added to blocklist** notification appears.

Unblocking metrics

1. To unblock a resource, click **View resource blocklist**. The **Resource blocklist** window appears.
2. For the resources that you want to unblock, select **Remove from blocklist**.
3. Click **Save**. The resources are unblocked.

Purging metrics

1. Find the metric group that you want to delete and click the overflow menu. Select **Purge metric data**. The **Purge metric data from selected resource** window appears.
2. Confirm purge and click **Purge**. The metric data is purged.

Purge metrics from the **Resource blocklist** window:

1. Click **View resource blocklist**. The **Resource blocklist** window appears.
2. Click **Purge all metric data from listed resources**.
3. Click **Save**. The **Purge metric data from selected resource** window appears.
4. Confirm purge and click **Purge**. The metric data is purged.

Displaying analytics details for an alert group

On alert lists associated to an incident, click the option to show the correlation information to understand why these alerts were grouped together. This option displays the underlying temporal, topological, and scope-based groups.

Procedure

1. In the Alert Viewer, click the Click the **View correlation** icon to display the **Correlation** column in the table.

   - **Temporal group column**

     Based on alert history, the alerts in this column that are marked with a large dot ● tend to occur within a short time of each other.

   - **Scope-based group column**

     The alerts in this column that are marked with a large dot ● occur within a configurable time window on an administrator defined scope, such as a location, service, or resource.

   - **Topological group column**

     The alerts in this column that are marked with a large dot ● occur on resources within a predefined section of your network topology.

2. Click a dot ● to see more details on any of these sub-groups.

Temporal group column

Clicking a dot ● in this column opens the sidebar, with the **Temporal correlation** section open. This section contains the following information:

- **First group instance**

  Date and time of first instance of this group.

- **Total group instances**

  Total number of historical instances of this group. For details of when these instances occurred and how many alerts occurred in each instance, see the Group instance heatmap.

- **Average instance duration**

  Average time in seconds that this group instance lasted.

- **Group instance heatmap**

  Time-based heatmap showing recent historical period in days with a gray square for each day. Each darker square indicates a day on which there was at least one group instance. Hover over the square to see details of this group instance.

Scope-based group column

Clicking a dot ● in this column opens the sidebar, with the **Scope-based** section open. This section contains the following information:

- Group duration

  Duration of the scope-based group. For example: "These alerts were found to share a cause as they all occurred on the same resource within **N** minutes of each other." **N** being the configured time.

Topological group column

Clicking a dot ● in this column opens the sidebar, with the **Topological** section open. This section contains the following information:

- **Topology group name**

  Name of the topology defined in the topology management service, on which this topology group is based.

- **Topology**

  Pane showing the resources in the topology on which this topology group is based. You can perform the following actions on the topology:

  - Click the resource to displays the relationship between that resource and neighboring resources. The relationships are displayed in text on the lines connecting the resources. Examples of relationships include: runsOn, members, exposes.
  - Right-click the resource to display the context menu. For more information about the actions available from the context menu, see see Viewing a topology.

Viewing incidents that are displayed in outgoing integrations

View incidents in outgoing integrations.

When a new anomaly is detected, IBM Cloud Pak for AIOps generates an incident. If an outgoing integration is configured, the incident is sent to ServiceNow, Slack, or Teams.

- In ServiceNow, an incident is created, and a link to the incident is added to the IBM Cloud Pak for AIOps incident and to the Slack or Teams message if those integrations are also configured.
- In Slack or Teams, the IBM Cloud Pak for AIOps incident appears as a message, and a link to the message is added to the IBM Cloud Pak for AIOps incident.

Viewing a ServiceNow incident

1. See the incident section.

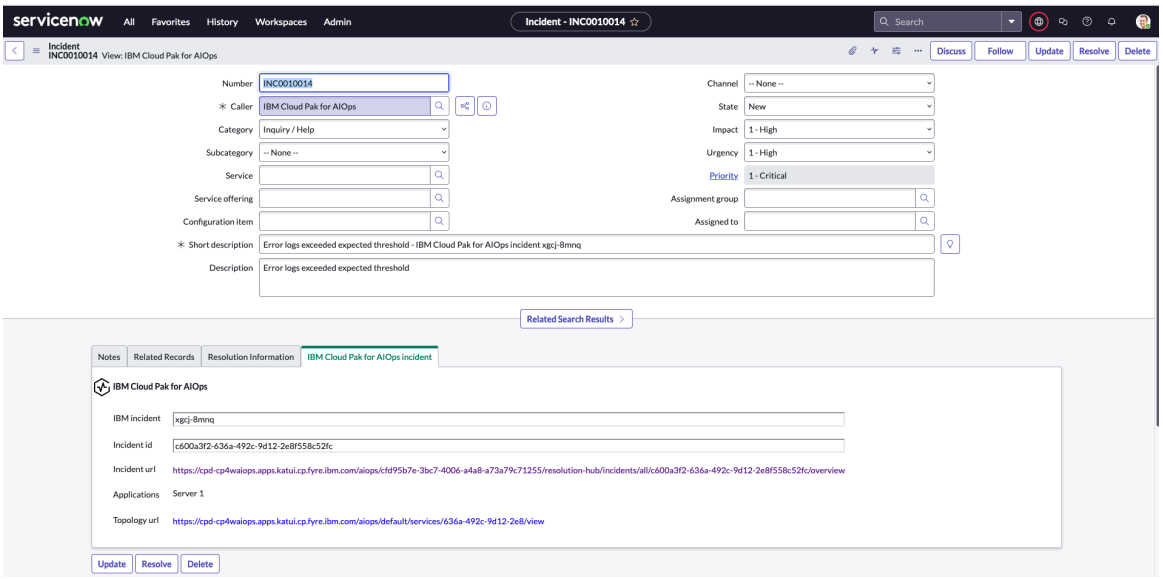

Figure. ServiceNow incident overview

Number: The incident number identifies the incident across IBM Cloud Pak for AIOps, Slack, and ServiceNow.

Caller: The caller is the user who was used to set up the ServiceNow Integration in IBM Cloud Pak for AIOps.

Impact and Urgency: Impact and urgency are set to map the severity of the incident to the priority field of the incident in ServiceNow.

Short description and **Description**: These values are set to the title and long description of the incident. You can change the values in the ServiceNow ticket as well, but the changes are not sent back to IBM Cloud Pak for AIOps.

2. See the IBM Cloud Pak for AIOps section.

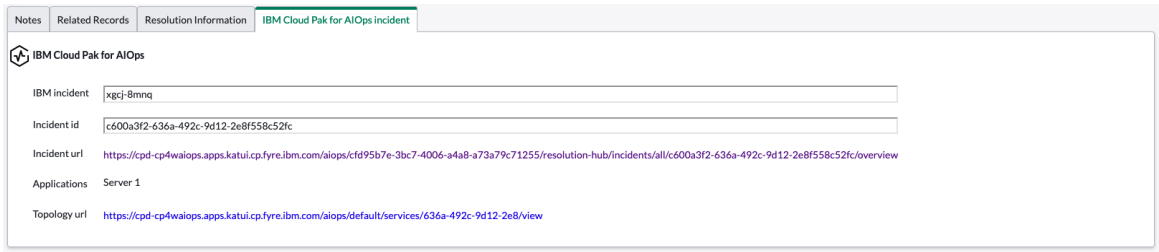

Figure. IBM Cloud Pak for AIOps incident details in ServiceNow

Incident number and ID: The incident number and ID are used to identify the incident in IBM Cloud Pak for AIOps.

Incident URL: The incident URL is a link to the incident in the IBM Cloud Pak for AIOps UI. Click the URL to open the IBM Cloud Pak for AIOps UI to the corresponding incident.

Applications: This value lists the names and URLs of the applications that the incident is associated with. If no applications are detected, `N/A` is shown.

Topology URL: This URL links back to the IBM Cloud Pak for AIOps UI to show topology details.

3. See the IBM Cloud Pak for AIOps incidents tab.

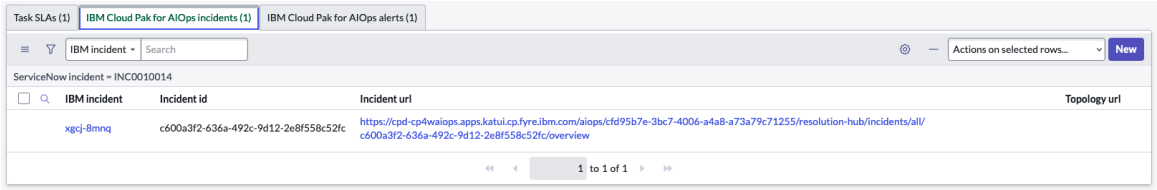

Figure. The IBM Cloud Pak for AIOps incidents tab in ServiceNow

This information is the same as in the IBM Cloud Pak for AIOps section. Click the incident number link to go to the IBM Cloud Pak for AIOps table and view all the IBM Cloud Pak for AIOps incidents in ServiceNow.

4. See the IBM Cloud Pak for AIOps alerts tab.

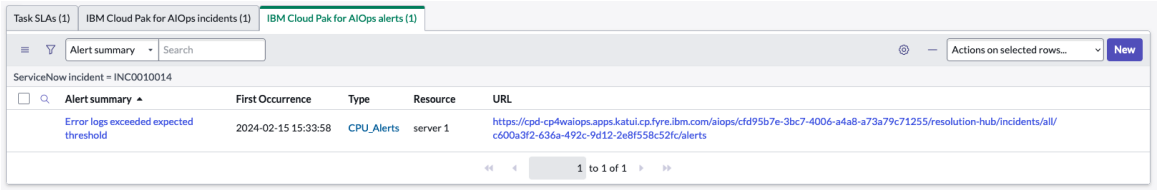

Figure. IBM Cloud Pak for AIOps alerts tab in ServiceNow

IBM Cloud Pak for AIOps incidents are made from a collection of alerts. View alerts that contributed to this incident in the IBM Cloud Pak for AIOps alerts tab.

Event enrichment

Event enrichment is the process of enhancing alerts or incidents by updating their standard attributes or populating custom attributes such as, adding, updating, or removing them. This process is driven by user-defined logic, allowing for tailored enrichment to meet specific needs.

Event enrichment in IBM Cloud Pak for AIOps is done by using Netcool/Impact. For more information about event enrichment, see Event enrichment.

For more information about how to develop an event enrichment solution by using Netcool/Impact, see Event enrichment tutorial.

Event mapping and alert severity

The following table identifies the mappings from IBM Netcool Operations Insight **`alerts.status`** table columns to the IBM Cloud Pak for AIOps event that is sent to lifecycle for processing.

Creating a Netcool integration is a prerequisite to synchronize your event data into IBM Cloud Pak for AIOps. For more information, see Creating Netcool integrations.

The second table represents the differences in alert severities between IBM Cloud Pak for AIOps and IBM Netcool Operations Insight.

Event mappings from IBM Netcool Operations Insight to IBM Cloud Pak for AIOps

IBM Cloud Pak for AIOps property	IBM Netcool Operations Insight column	Comment
id	N/A	IBM Cloud Pak for AIOps generated identifier for event.
occurrenceTime	LastOccurrence	
summary	Summary	
severity	Severity	Severity is remapped to IBM Cloud Pak for AIOps scale.
type.classification	[EventId + ':++:' +] AlertGroup	If no EventId is provided, only the value from AlertGroup is used. The separator (:++:) is only present if EventId contributed to the classification value and indicates the extent of EventId and AlertGroup in the string.
type.eventType	Type	
sender.service	Agent	

IBM Cloud Pak for AIOps property	IBM Netcool Operations Insight column	Comment
sender.name	Manager	If the Manager column is not defined, it is set to unknown.
resource.name	Node	If the Node column is not defined, it is the value of NodeAlias column if one has been defined.
resource.hostname	Node	If value is hostname, or NodeAlias if hostname and Node are not defined.
resource.ipaddress	NodeAlias	If the value is an IP address, otherwise not set.
resource.location	Location	
resource.sourceId	BSM_Identity	
resource.service	Service	
resource.port	PhysicalPort	
resource.physicalslot	PhysicalSlot	
resource.physicalcard	PhysicalCard	
resource.interface	LocalPriObj or LocalRootObj	If the value starts with "ifEntry." or "ospfIfEntry.", the trailing interface details will be mapped. Example: "ifEntry.eth0". **Note**: Where values exist for both LocalPriObj and LocalRootObj, the LocalPriObj value will be used, as it is the primary object element of topology. If it has no value, but LocalRootObj is populated, then this will contribute to resource mapping information.
resource.component	LocalPriObj or LocalRootObj	If the value starts with "entPhysicalEntry.", the trailing component details will be mapped. Example: "entPhysicalEntry.name" **Note**: Where values exist for both LocalPriObj and LocalRootObj, the LocalPriObj value will be used, as it is the primary object element of topology. If it has no value, but LocalRootObj is populated, then this will contribute to resource mapping information.
resource.scopeId	ScopeID	
expirySeconds	ExpireTime	
details	alerts.details	The set of details that are stored in details table for event as name-value pairs.

Differences between alert severities in IBM Cloud Pak for AIOps and IBM Netcool Operations Insight

Alert	IBM Netcool Operations Insight severity	IBM Cloud Pak for AIOps severity	Comment
Critical	5	6	
Major	4	5	
Minor	3	4	
Warning	2	3	
Informational	N/A	2	No informational level in IBM Netcool Operations Insight.
Indeterminate	1	1	
Clear	0	N/A	IBM Cloud Pak for AIOps alerts have a state property that indicates an alert is open, clear, or closed. Allows alerts original severity to be maintained.

Managing ChatOps insights

The insights produced by IBM Cloud Pak® for AIOps surface in ChatOps. Whether you use Slack or Microsoft Teams as your ChatOps interface, the experience is consistent with the IBM Cloud Pak for AIOps Platform UI.

For more information about setting up ChatOps integrations, see:

- Creating Microsoft Teams integrations
- Creating a ServiceNow integration
- Creating Slack integrations

Prerequisites

When you configure your ChatOps integration, you must set up two types of channels for your insight flow

- A *reactive* channel for your incidents and alerts
- A *proactive* channel for notifications (from change risk)

Verifying your ChatOps integration

After you create your ChatOps integration, you can use the *reactive* channel to verify that the integration is up and running, by tagging the bot. For example, @**<bot_name>** hello.

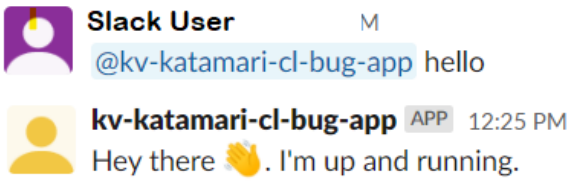

Figure. Slack hello

To get the botName, see Configuring Slack or Configuring Microsoft Teams for more details.

In Microsoft Teams, when you enter **`hello`** the response is **`I'm sorry, I don't understand the message`**. This response indicates that although it does not understand the message, the message was received, so the integration is verified.

Welcome tour

In Slack, after you are added to the *reactive* channel, you will receive a welcome message.

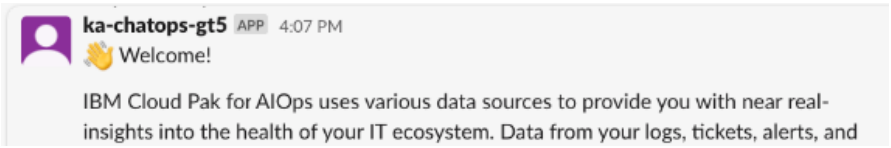

Figure. Slack message

Choose one of the following options:

- *Take tour* Provides an example of incident notification details.
- *Close welcome* Closes the welcome message.
- *Learn more* Links to additional information in the IBM Cloud Pak for AIOps documentation.

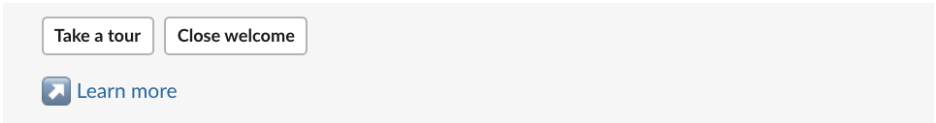

Figure. Slack welcome

In Microsoft Teams, when you receive the welcome notification, select one of the following options to continue:

- *Take tour* Provides an example of incident notification details.
- *Learn more* Links to additional information in the IBM Cloud Pak for AIOps documentation.

Click Teams in the sidebar to access the ChatOps *reactive* channel, anytime.

For more information about working with your insights from your ChatOps integration, see the following topics:

- Managing Incidents In ChatOps
- Probable cause
- Incident Resources
- Recommended runbooks
- Recommended actions
- Viewing alerts in ChatOps
- Change risk in ChatOps

Managing Incidents In ChatOps

Incidents appear in the *reactive* channel of your ChatOps interface. They provide the context for an issue that is severely impacting operations. Included are all alerts that are relevant to the issue, and information about how the affected resources relate to one another. The creation and evolution of incidents is informed by alerts.

Learn more about events, alerts and incidents.

Note: For reasons of convenience and consistency, on this page and on related pages, icons and screen grabs are taken from a Slack implementation of ChatOps.

ChatOps Icons

Icon	Description
	Priority
	Critical Alert (Sev 6)
	Major/Minor Alert (Sev 5 or 4)
	Warning (Sev 3)
	Information/Indeterminate (Sev 2 or 1)
	Link to Platform UI or other online resource
	Probable cause
	Alerts
	Trigger alert
	Recommended runbooks
	Recommended actions
	Incident resources

	Log anomaly

Incident statement

Every incident on a ChatOps interface has an Incident statement area that provides a quick overview of a potential problem. The statement includes a description of the incident, its priority, and when the incident was triggered. The status reflects the current state of the incident and can be set by the SRE.

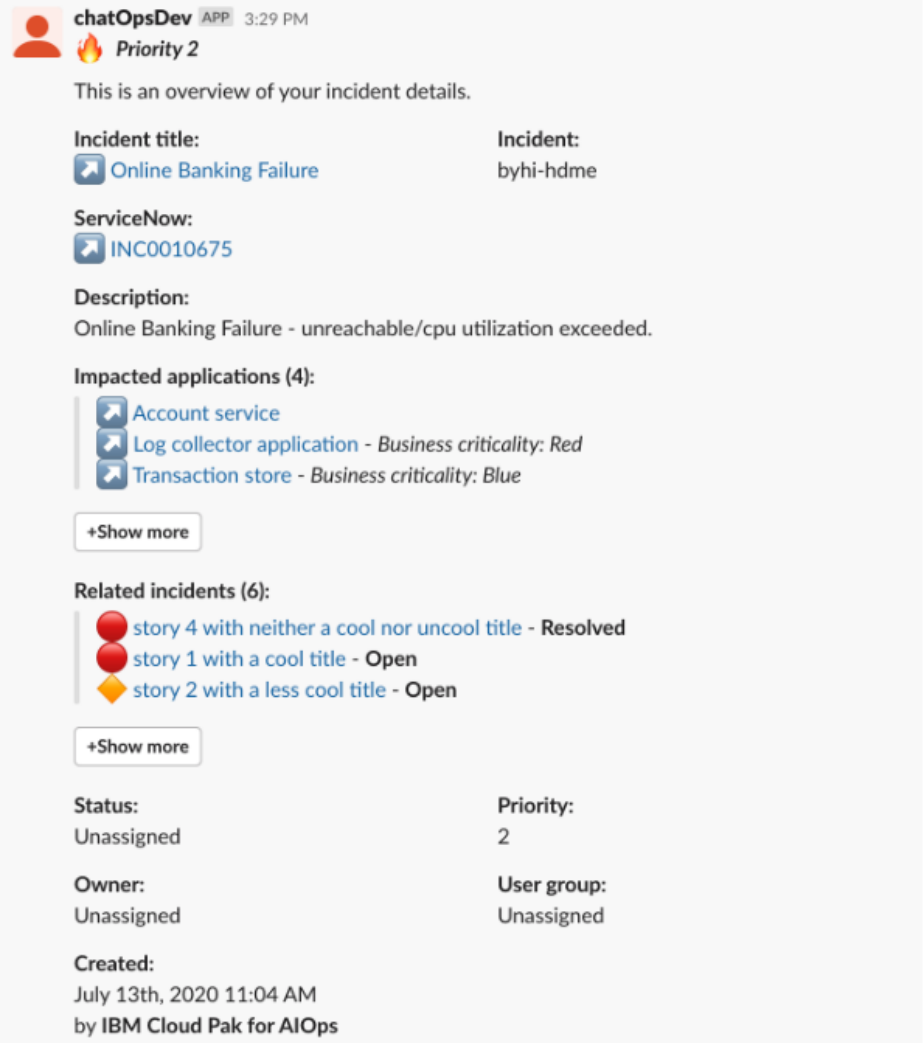

Figure. Incident statement

The Incident statement contains overall information relevant to an incident, including:

Table 1. Incident detection information

Field name	Description
Priority	Priority level that indicated the impact level of an incident on customer.
Incident title	A title that describes the incident. Set as a summary of the first trigger alert, unless it is modified by the user.
Incident	A unique number that is assigned to the incident, also shown within the Platform UI.
ServiceNow	The linked ServiceNow incident number. For more information about configuring a ServiceNow integration, see Configuring the ServiceNow App for IBM Cloud Pak for AIOps.
Description	A summary of the incident, including number of alerts and log anomalies.
Impacted applications	List of applications impacted by incident. Access the applications directly that use the hyperlinks.
Status	*Open*: Incident is open and unassigned *In progress*: Incident is assigned and is being worked on. *Resolved*: Incident is resolved. *Closed*: Incident is closed.
Owner	The email registered to the Slack/Microsoft Teams accounts assigning themselves to the incident. It is recommended that this email matches the email that is registered in the Platform UI.
Created	Date and time that the incident is created.
Updated	Last date and time that the incident is updated.

Updating an incident

At the end of each incident entity, there are options to assign and update the incident.

Figure. Update incident

Click *Edit* to revise incident title, description, group, or priority level. Users can also self-assign the incident and mark it in progress or resolved.

Self-assign and Set to in-progress

The incident owner is set by clicking *Self-Assign* or *Set-in-progress*. When either option is selected, incident ownership is immediately set to the current user. **Note:** It is not currently possible to assign other users as owners.

Tagging users in Slack

When you *Set to in-progress* an incident, you can also tag other users by adding their names to the *Users to notify* field. However, to be tagged, users must be part of the workgroup (**Note:** If even one of those tagged is not in the workgroup, then tagging fails for all users). When tagged, the user is automatically added to the channel and receives notifications to the incident.

Incident resolution and closure

Where an incident status is *Resolved*, it is eventually moved to *Closed* status, in accordance with retention policy period.

Note: When an incident has the status *Resolved* or *Closed*, the functions in ChatOps are limited and no action or link is provided for that incident.

For more information about working with insights from ChatOps, see the following topics:

- Probable Cause
- Incident resources
- Recommended runbooks
- Recommended actions
- Viewing alerts in ChatOps
- Change risk in ChatOps

Probable cause in ChatOps

When an incident is created or updated in response to an issue, IBM Cloud Pak® for AIOps automatically determines which of the related alerts were the likely cause of that issue. For more information, see About probable cause ranking.

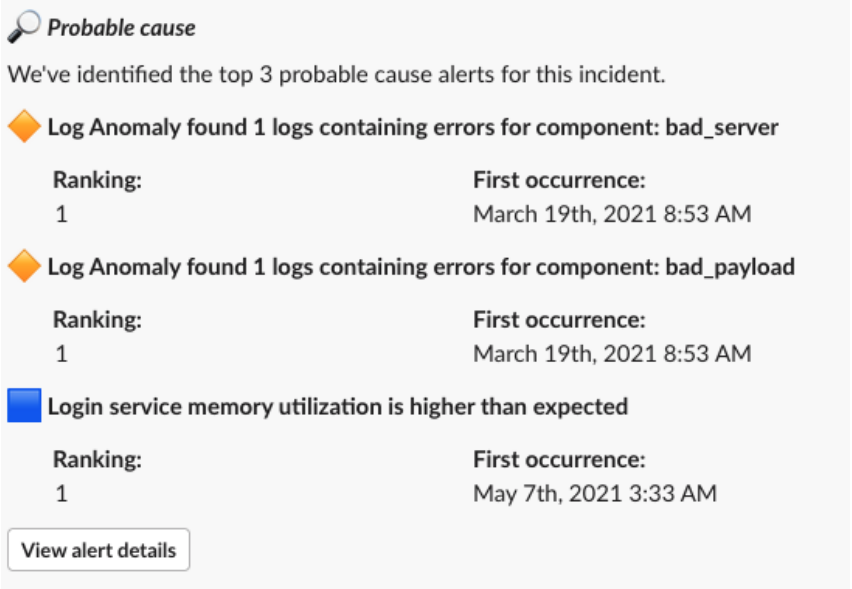

Figure. Probable cause

The *probable cause* section in ChatOps displays the top three alerts, ranked from 1 (highest) to 3 (lowest) in order of probability of being the cause of the incident. To find more information, including severity levels of these alerts, click **View alert details**.

Where *probable cause* alerts cannot be ranked because of similar ranking values, a link is available to the Alert Viewer in the IBM Cloud Pak for AIOps console, where all probable causes are listed.

Note: Where *probable cause* cannot be identified, the section **Top Alerts** appears instead, listing the top three alerts for the incident ranked by severity and first occurrence. A modal can be opened which shows the expanded alert details of this section.

Next steps

For more information on creating access tokens for the Probable Cause Customization APIs, see Probable Cause Customization API.

Incident resources

The topology view in ChatOps' *Incident resources* provides a holistic view of the relationships between different infrastructure and application components.

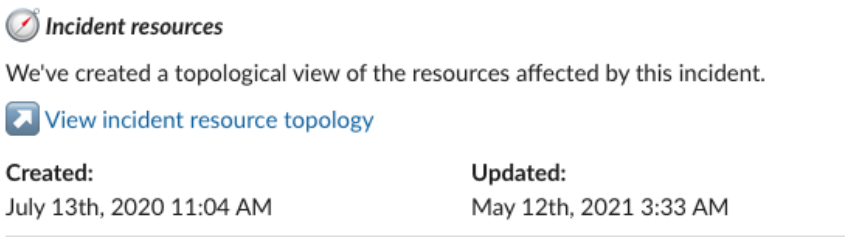

Figure. Incident resources

It can be used to rapidly identify the root cause and the impact of the issue on the wider environment, before any action is taken, avoiding interruption to business-critical activities.

Under *Incident resources*, click **View incident resource topology** to go directly to the Platform UI where you can access topological details about individual entities within an incident.

Note: *Incident resources* is not visible where no application can be associated with the incident.

Associated automations

Runbooks are automated solutions that can be triggered to resolve certain issues. They can be created, edited and updated in IBM Cloud Pak for AIOps.

When an incident surfaces in ChatOps, you can access runbooks associated with this incident. Click the *View Runbook* automations link. This will take you directly to the Platform UI where more information is available about the associated automations:

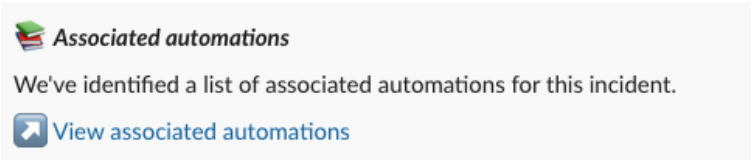

Figure. Associated automations

For more information on runbooks in IBM Cloud Pak for AIOps, see Runbooks.

Recommended actions

ChatOps displays the top three *Recommended actions* based on past resolution tickets that are associated with the incident presented. If you have similar ticket training that is completed for ServiceNow (see Setting up training for similar tickets), you can also search for other past tickets.

Insights and context from your training materials are used to suggest paths to remediation. Use the hyperlinks to go directly to IBM Cloud Pak for AIOps Platform UI.

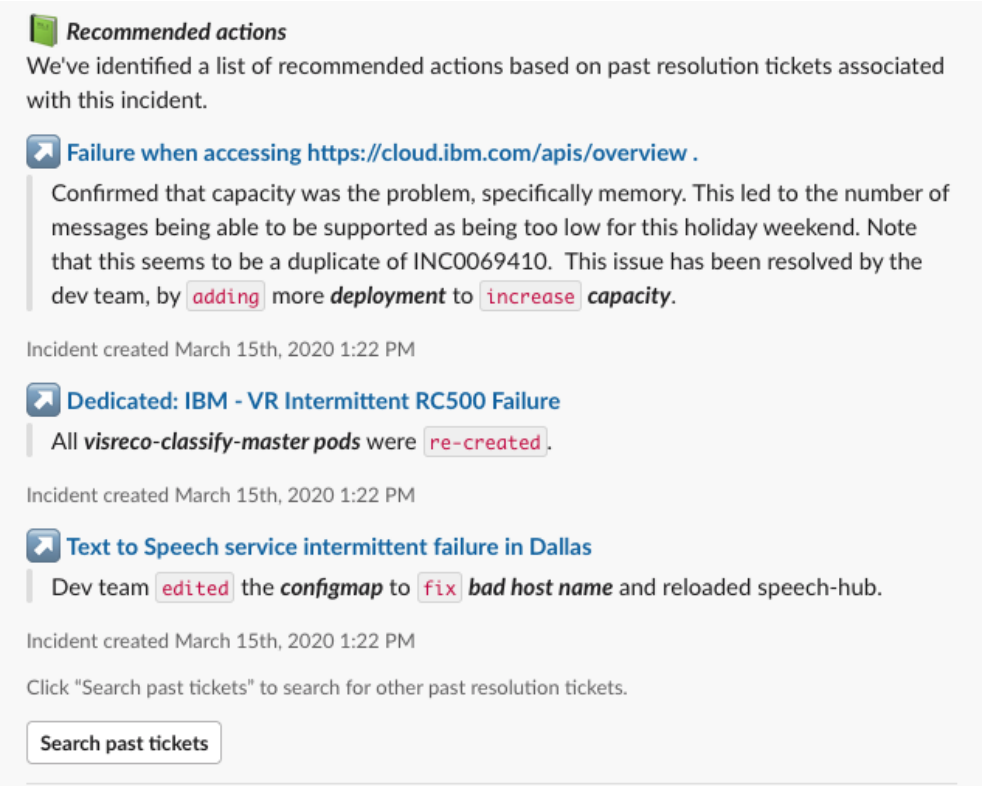

Figure. Recommended actions

Searching recommended actions

Site Reliability Engineers (SRE) can search past tickets in *Recommended actions* to zero-in on likely solutions from similar past tickets.

Search steps

1. Open the *Recommended actions* modal.
2. Click **`Search past tickets`** for any event.
3. Enter search parameters in the *Search past resolution tickets* dialog box.

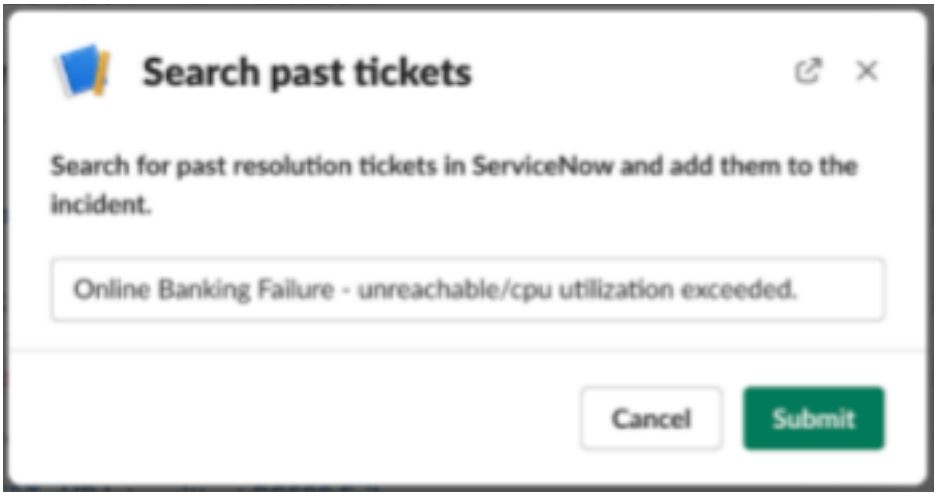

Figure. Search action dialog

Click **Done**. A list of similar tickets appears, with a description for each search result, and details of the action that was taken. You can click the title to go to the issue, or add the issue to the incident by clicking **Add to Incident** .

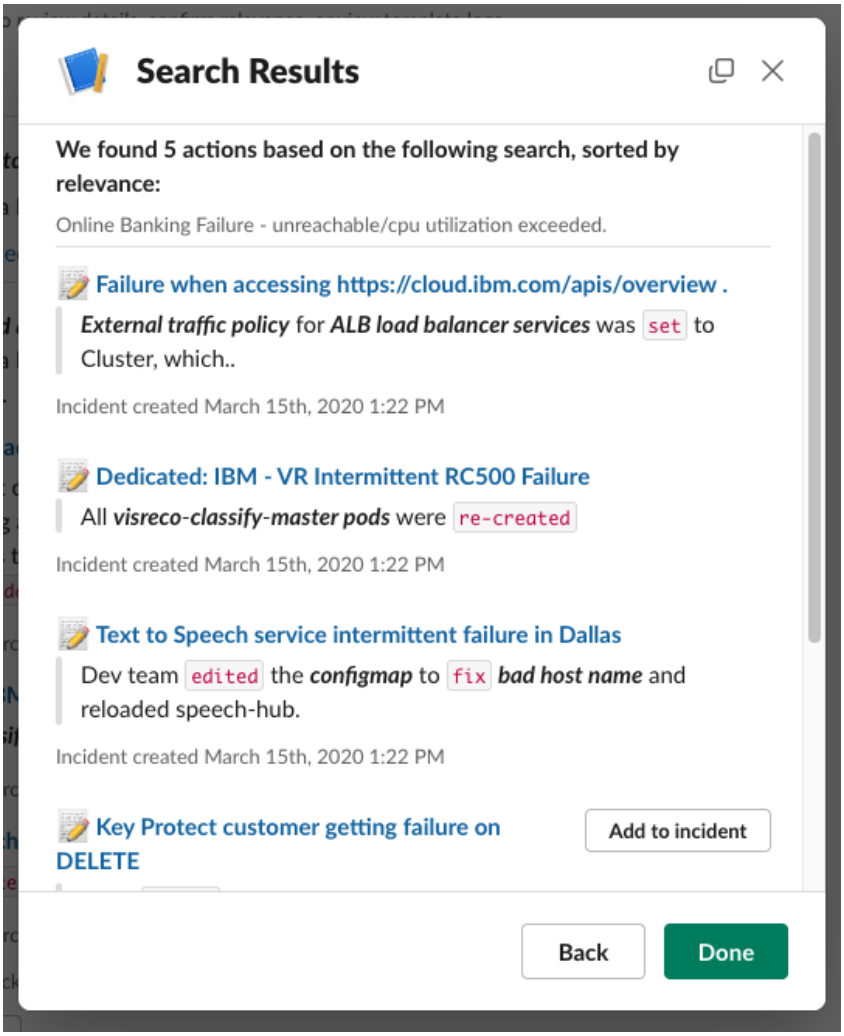

Figure. Search results

Viewing alerts in ChatOps

The *Alerts* area in ChatOps provides details and traceable evidence about alerts. View details of potentially relevant alerts and log anomalies to help you better understand the incident, determine the cause for the alerts, and confirm a diagnosis. Alerts are grouped based on three algorithms: Scope-based, Temporal, and Topological.

- View basic Alerts information
- View detailed information on Alerts
- Investigating log anomalies
- Domain-specific log anomalies

View basic Alerts information

1. Open ChatOps in Slack or Microsoft Teams.
2. Select an incident from your incident (*proactive*) channel, then scroll down to the *Alerts* section of the Incident. This entity presents alerts that are associated with the incident, including their severity level. Click **View in Alert Viewer** in ChatOps to access the *alerts* in IBM Cloud Pak® for AIOps Platform UI.

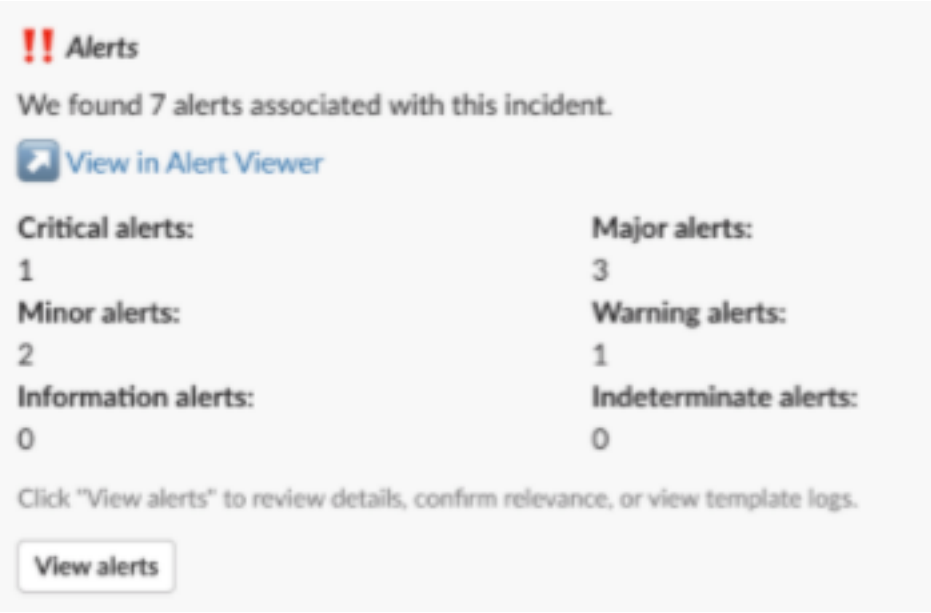

Figure. Alerts

View detailed information on Alerts

In the *Alerts* section of your incident, click **View alerts**. The *View alerts* modal opens.

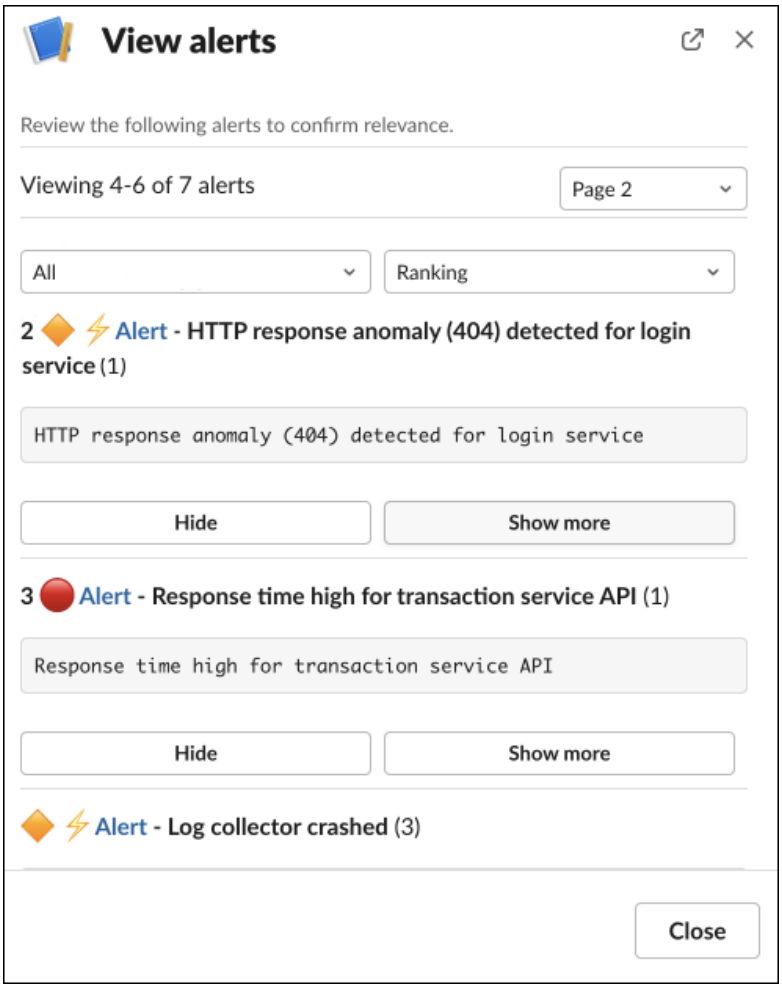

Figure. View alerts

- Use the two dropdown menus to filter alerts by type of alert, severity, status and rank.
- If necessary, scroll down to find all alerts associated with the incident.
- An alert listing can have a number and icon label that is attached to it.

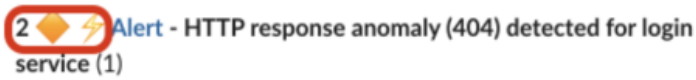

Figure. Icons label

These labels indicate probable cause ranking, severity of alert and if the alert is a trigger alert - indicated by a lightning icon. **Note:** These labels are present only if the alert is a trigger alert and/or if it is a probable cause of the incident - or both.

- You can hide any listed alerts for a specific incident entity by clicking **Hide** for that alert. Click **Done** when you are done hiding alerts. **Note**: To see alerts that you hid, select the entity, and click **Unhide**.
- For more information on an alert, click **Show more** on the **View alerts** modal to view the alert's *Status*, *Source*, *First occurrence*, *Last occurrence* and *Resource*, *Ranking* and *Severity*.

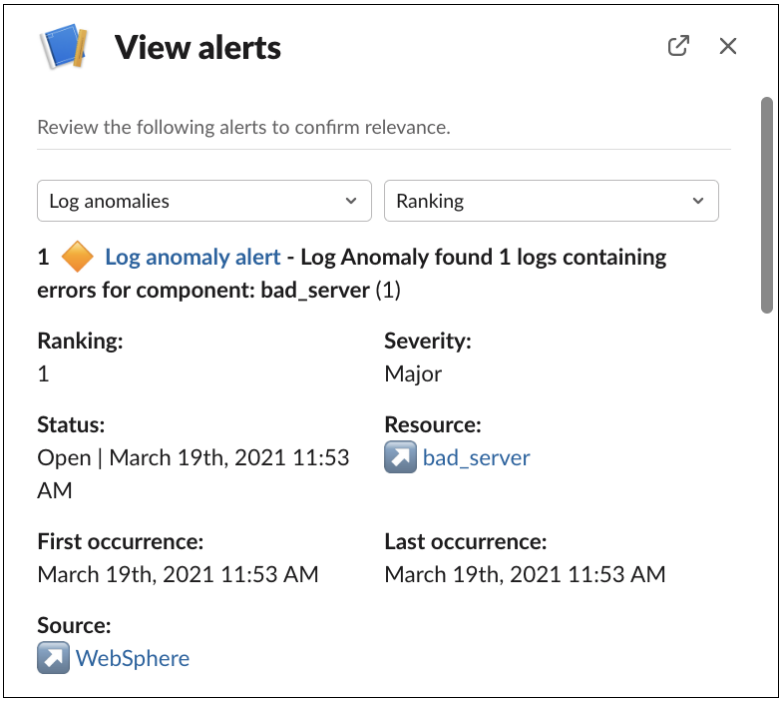

Figure. Show more

Investigating log anomalies

Based on an analysis of your log data performed during AI model training, templates are built that model each type of log message identified. Live log data is analyzed with respect to these templates and any surprises are reported as log anomaly alerts. Here are some examples of log anomaly alerts:

- A log message was expected but is not present in the log data within a time range.
- A log message was not expected but is present in the log data within a time range.
- A log message occurred with a higher or lower frequency than expected within a time range.

Select *Log anomalies* from the dropdown menu in the *View alerts* modal to view the templates that are used to identify anomalous behavior in your log files.

To view the entire log of a log anomaly (the log for all of the templates), click **Attach template logs**. This action attaches the entire log to your Slack channel where you and your collaborators can view the log in its entirety.

This window also reports surprises associated with individual log anomaly templates. For each surprise, the following information is provided.

- Log anomaly **Template or label**. If this log message has never been seen before, one of the following labels will appear:
  - `Unknown_error`: the log message has not been seen before and it contains error information.
  - `Unknown_normal`: the log message has not been seen before but it does not contain error information.
- **Actual**: The number of times this log message actually occurs in the log data within a time range.
- **Expected**: The number of times this log message is expected to occur in the log data within a time range.
- **Preview log**: Click this button to view the actual occurrences in your log. The *Log preview* window shows a maximum of 3000 characters.

  Note: In Microsoft Teams, logs are saved to Microsoft Sharepoint and can be shared from there.

Example 1

Template or label	Actual	Expected
`stdout F {"name":"@pod75wd5abd11","__in":<NUM>, "hostname":"backend-456b7373c9efgh","pid":<NUM>,"module": "announceCycle/agentHostLookup","level":<NUM>,"msg":"Extremely unusual message for system`	0	3.12

In this example, three log messages matching the template were expected in a given timeframe, but there were no log messages present in the log data. You need to investigate why the expected log messages did not appear. **Note** Expected_count is shown as a float with two digits after the decimal point. This value is calculated based on the statistical analysis described in Workflow of natural language log anomaly detection and Workflow of statistical baseline log anomaly detection.

Example 2

Template or label	Actual	Expected
`Unknown_error`	2	0

In this example, a log message that has never been seen before was present in the live log data, twice within the time range. This unexpected log message also contains error information so should be investigated with urgency.

Domain-specific log anomalies

If an alert is identified as a log anomaly from a specific domain, such as IBM MQ or WebSphere, you can scroll to the (**View Alerts** > **Show more**) modal to find more details about the anomaly. View *Message Code*, *Explanation*, *Categories*, *Frequency of related message codes* and *Recommended actions*, which can contain documentation links that might help resolve the alert.

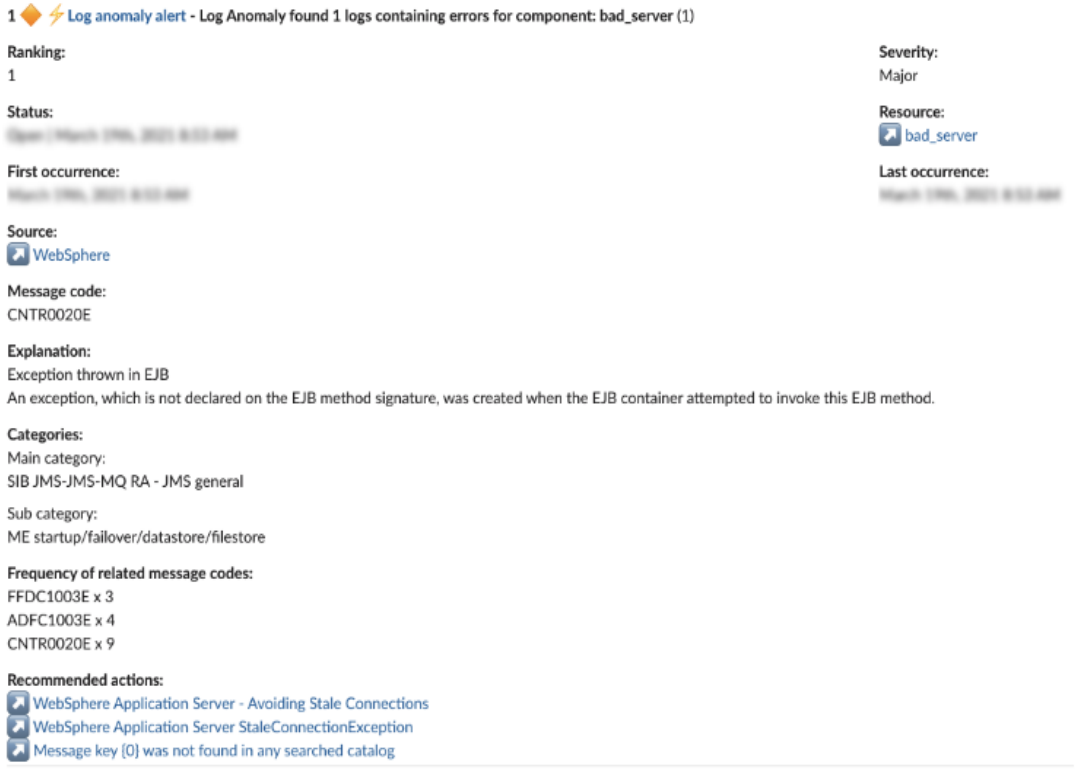

Figure. WebSphere

For more information, see Domain-specific log anomaly alert details.

Change risk in ChatOps

Change risk assessments, which can be notified in ChatOps, provide you with a *Confidence* percentage that represents the confidence level in the AI's prediction of the impact of a change. This percentage is relative to the risk associated with a new or updated ServiceNow change request ticket.

Figure. Chatops change risk

The *Confidence* percentage is calculated based on the change risk AI model and the data that you feed into it. Change can be evaluated based on any type of change, whether it is to code, or to configurations, or to data. If you have historical change request tickets for that type of change, IBM

Cloud Pak® for AIOps can provide a confidence percentage for it.

NOTE: Feedback options (thumbs up and thumbs down) appear under the change risk assessment, to allow users to provide input on the assessment and the relevancy of related change requests. Providing feedback helps improve the quality of the change risk model.

Prerequisites

To implement change risk notifications:

- In ServiceNow, any change needs to be recorded in the Change Request Ticket Fields
- In ServiceNow, any deviation from an expected standard of operation must be documented in an incident ticket field

Change Request Ticket Fields

Change request tickets in ServiceNow record detailed information about a change, such as the reason for the change, the priority, the risk, the type of change, and the change category. This information is used to calculate a confidence percentage.

Required fields for change request tickets expect a **`str`** data type value and include the following fields:

- *sys_id*
- *number*
- *assigned_to*
- *sys_created_by*
- *sys_domain*
- *business_service*
- *type*
- *state*
- *short_description*
- *impact*
- *reason*
- *justification*
- *description*
- *backout_plan*
- *close_code*
- *close_notes*

For more information about change request fields, see Change Request in the ServiceNow documentation.

Six incident fields in ServiceNow are scanned for the presence of change ticket numbers: " *description*", "*short_description*", "*work_notes*", "*caused_by*", "*close_notes*", "*comments_and_work_notes*".

Incident Ticket Fields

You create an incident record to document a deviation from an expected standard of operation. The following list describes required fields for incident tickets:

- *number*
- *opened_at*
- *short_description*
- *description*
- *work_notes*
- *caused_by*
- *rfc*
- *close_code*
- *close_notes*
- *closed_at*
- *cmdb_ci*
- *active*
- *assignment_group*
- *comments_and_work_notes*
- *impact*
- *problem_id*
- *priority*
- *severity*
- *state*
- *urgency*

Note: All fields expect an **`str`** data type value, except "*work_notes*", which expects a **`List[str]`** data type.

For more information on incident ticket fields, see Incident Request in the ServiceNow documentation.

Linking Change Tickets and Incidents

Without the correct linkage information generated from these fields, the change risk assessment logic can fail or provide incomplete results. Also, if no linkage is found, the training is marked as unsuccessful or aborted.

When you determine the linkage between the change tickets and the incidents, you also need to look at data interdependence, such as that of the start and end dates. Set the Change Start Date to earlier than the Incident Start Date because the incident occurs after the changes are made.

For more information about change management in ServiceNow, see Change management in the ServiceNow documentation.

In order for you to receive change risk notifications, you must satisfy the following requirements:

1. Set up ServiceNow and your ServiceNow integration
2. Set up your ChatOps integration
3. Train your change risk AI model

Managing automations

By creating automations in IBM Cloud Pak® for AIOps, you can proactively set up policies, runbooks, and actions to detect and remediate events, both current and future.

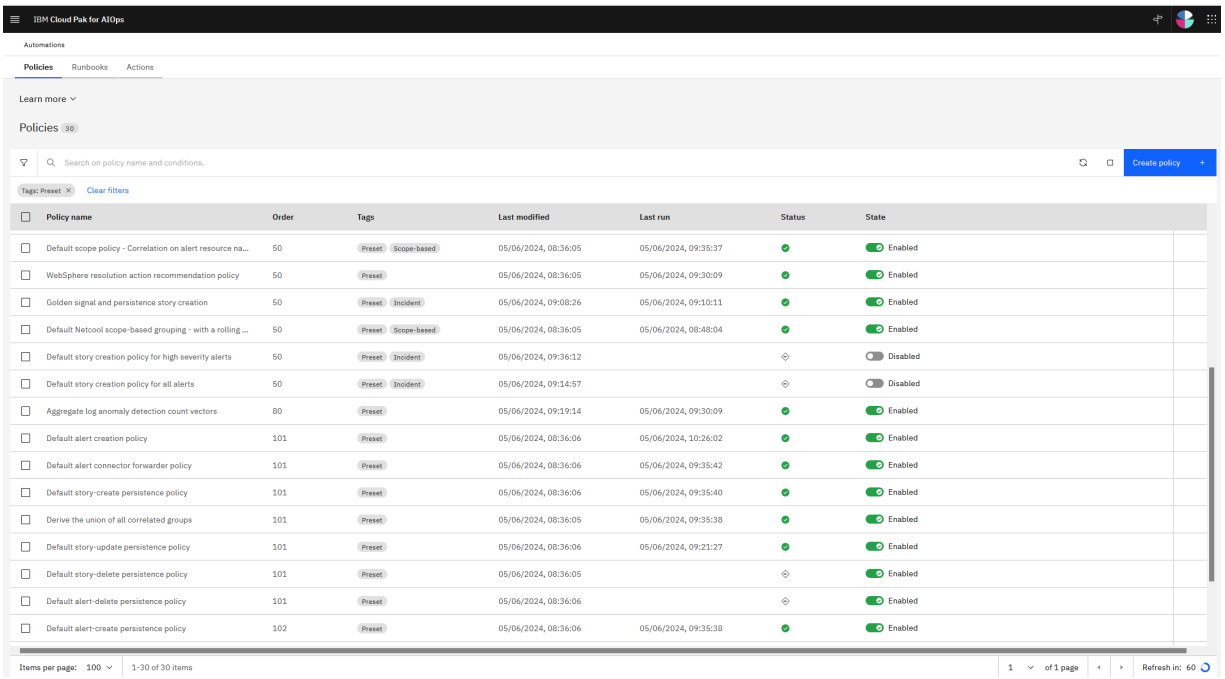
Policies are rules that contain conditions and a set of actions that can be manual or automated. With policies, you can automatically suppress alerts, group alerts based on scope, assign runbooks to alerts, and promote alerts to an incident.

When you create a runbook, you can define the required steps to resolve a situation. If you don't have any runbooks, you can create a new one or load some sample runbooks.

Actions in runbooks are the collection of several manual steps into a single automated entity. An action improves runbook efficiency by automatically performing procedures and operations.

For more information about automations, see the following topics:

- Policies
- Runbooks
- Actions



About policies

Policies are rules that contain multiple condition and action sets. They can be triggered to reduce noise by suppressing alerts or grouping alerts together, automatically promote alerts to incidents, assign runbooks to remediate alerts, and invoke IBM Tivoli Netcool/Impact policies to take actions on your alerts.

Cloud Pak for AIOps policies are created in the Policy editor, where you can build condition sets based on Alert properties and Alert insights.

The policies table displays all of the Cloud Pak for AIOps policies that are preset, created by you and your team, or generated by AI analytics. You can enable or disable these policies, create new ones, and edit existing policies. When you click a policy in the table, you can see more details in the side panel. The list of policies is split by pagination, use the navigation arrows beneath the table to move between the next or previous page of policies. To customize the number of rows that are displayed in the table, click the **Down chevron** icon ⌄ next to the **Items per page**.

By default, policies are sorted in the table by **Order** ascending (policies with a lower number are processed first). Where execution order is the same, policies are sorted by **Last run** descending (the most recent policies are displayed first in the table).

Policy UI

Note: Preset policy names and internal action references to "story" or "stories" are synonymous with incidents. Incident triggers and condition references supported in the "Invoke IBM Tivoli Netcool/Impact" policy template are stored as story. For policy search based on conditions, use "story" instead of "incident". For example, to find incident.title in a policy search, use story.title. These internal references and policy names have no bearing on actual behavior and are for internal processing purposes only. Any references to "story" in preset policy names, or other policy details or specifications is not an error, and is equivalent to incident in all respects.

Policies table columns

Policies table columns

Column	Description
Policy name	A name to identify the policy. The default name of a policy is automatically created based on the alert summary field, and specifically on the alert with the highest severity that has ocurred most frequently. To customize a policy name, point the cursor over the name and click Edit. Preset policy names cannot be customized.
Order	Determines the order in which the policy is executed. Execution order is set at policy creation time, on a sliding scale of 1-100. Policies with a lower number are processed first. This is especially important for incident policies. Set the execution order lower for your most important incident policies. Values outside of 1-100 are reserved for suppression, some analytics, and preset policies that handle system needs. **Note:** Actual execution order is a combination of trigger type and execution order. So when the table is sorted by execution order, you might see later **Last run** times on higher priority policies. This is because the processing for different triggers occurs at different times.
Tags	Tags are used to identify the different types of policies. Cloud Pak for AIOps policies are tagged with the following policy types: • Analytics: policies generated by AI analytics. Analytics policies can be viewed, enabled, disabled, and deleted from the Policies table. • Impact: a Cloud Pak for AIOps policy that invokes a IBM Tivoli Netcool/Impact policy, through a IBM Tivoli Netcool/Impact integration. By default, IBM Tivoli Netcool/Impact policies are invoked without input or transformation. Editing options are available in the IBM Tivoli Netcool/Impact policy template. • Incident: policies to create actionable incidents from alerts to improve insights into your issue. • Preset: preset policies define the core behavior of event and alert processing. Preset policies can be viewed, enabled, or disabled from the Policies table. • Runbooks: policies that assign a runbook to alerts for easier automated resolution. • Scope-based: policies that group alerts based on common properties and time of occurrence to identify when issues might be related. • Seasonal: policies that group alerts together that occur within a seasonal time window. • Suppression: suppress alerts that do not need attention to reduce noise and improve team focus. • Temporal: policies that group alerts together that occur within a short time of each other. • User: policies that can be edited by the user. All Runbook and Incident policies, even if tagged as Preset, are also tagged with User. User policies can be viewed, enabled, disabled, modified, and deleted from the Policies table.

Column	Description
Last modified	Displays a timestamp of the last modification to the policy. The date is expressed as month, day, year. The time is expressed as hours:, minutes:, seconds. The time also indicates whether AM or PM. For example, 3/9/2022, 4:45:17 PM. Enabling or disabling a policy, renaming or editing a policy, and adding a comment from the **Journal** tab in the side panel will all update the last modified time stamp.
Last run	Specifies the date and time on which a policy was last run. The date is expressed as month, day, year. The time is expressed as hours:, minutes:, seconds. The time also indicates whether AM or PM. For example, 3/9/2022, 4:45:17 PM. **Note:** If an alert meets the incident-creation conditions of multiple policies, only one incident is created. However, all policies that proposed an incident, and the system incident creation policy will have the same **Last run** time.
Status	The icons in this column indicate one of the following execution states for a policy: • Policy successful, no recent failures • Policy has not been attempted • Policy successful, but has had recent failures • Policy failed on last attempt
State	Denotes if a policy is Enabled or Disabled. You can click the toggle button to change a policy state. Disabled policies do not take any action against incoming alerts. You can also enable or disable a policy in the policy details side panel, or directly within a seasonality or temporal policy details page. **Note:** Disabling preset policies will prevent some event and alert processing features from working.

Note: A yellow execution status will remain for 8 hours in the event where a policy fails, but then works. Irrespective of how many times the policy works in that 8-hour period. If a policy is "flapping", that is alternating between failing and working, the execution status flips between a yellow and red status.

For more information about policies, see the following topics:

- Searching and filtering policies
- Policy details
- Default incident creation policies
- Default Netcool scope-based grouping
- Creating policies
- Policy editor
- Refreshing the policies table
- Managing multiple policies
- Renaming policies

The following policy templates are available:

- Suppress alerts
- Group alerts based on scope
- Assign a runbook to alerts
- Promote alerts to an incident
- Invoke IBM Tivoli Netcool/Impact

Searching and filtering policies

Text entered in the search field searches for the characters in the policy names and the policy conditions. Note, some conditions are internal, so the search might return policies that you are not expecting. You can also filter the list based on the policy type or current state.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.

To search for a policy in the table:

Click anywhere in the **Search** field and enter a search term, for example, type *hostname*. The system shows table with all the policies that contain *hostname* in the policy names and the policy conditions.

Note: Searches are not case-sensitive.

To filter the list of policies in the table:

Click the Filter icon to open the filter side panel.

- Select from the following **Tags** to filter by policy type:
  - Analytics
  - Impact
  - Dashboard
  - Incident
  - Preset
  - Runbooks
  - Scope-based
  - Seasonal
  - Suppression
  - Temporal
  - User
- Filter policies by **Status**:
  - Policy successful, no recent failures
  - Policy successful, but has had recent failures
  - Policy failed on last attempt
  - Policy has not been attempted

  Note: Failed policies turn red. In the event where a policy fails but then works, a yellow execution status will remain for approximately 8 hours. Policies with a red or yellow status will move back to green after approximately 8 hours.
- Filter policies by **State**:
  - Disabled
  - Enabled
- Filter policies by **Triggers**:
  - Before an alert is created
  - After an alert is created
  - After an alert has been updated
  - After an incident is created
  - After an incident has been updated
  - System triggers

  Within a filter type, multiple selections are summed together. For example, if you select both **Runbooks** and **Incident** under the **Tag** filter, you will see the list of policies that contain **either** of these tags.

  Between filter types, the AND operator is used. For example, if you select **Incident** under the **Tag** filter and **Enabled** under the **State** filter, you will see the list of policies that contain **both** of these conditions.

3. Click **Apply** to apply your selected filters to the policies table.
4. Click **Clear filters** above the table header row to clear all searches and filters.

Note: Preset policy names and internal action references to "story" or "stories" are synonymous with incidents. Incident triggers and condition references supported in the "Invoke IBM Tivoli Netcool/Impact" policy template are stored as story. For policy search based on conditions, use "story" instead of "incident". For example, to find incident.title in a policy search, use story.title. These internal references and policy names have no bearing on actual behavior and are for internal processing purposes only. Any references to "story" in preset policy names, or other policy details or specifications is not an error, and is equivalent to incident in all respects.

Policy details

When you click a policy of interest in the table on the Policy UI, a side panel containing multiple information sections opens on the right-hand side of the table. Use the up and down arrows to navigate through the list of policies. Where permissions allow, you can Edit and Delete or enable and disable some policies here. You can also archive alert seasonality and temporal grouping policies that are not in use, or further investigate the justification for their creation directly from the side panel.

The four tabs that are displayed in the side panel are **Details**, **Journal**, **Specification**, and **Source**.

- **Details**:

This tab displays the complete set of column data for the selected policy, including familiar fields, such as **State**, **Status**, **Tags**, **Created by**, **Last modified by**, **Last run**, and **Execution status**. The **Last failure** is the timestamp that the selected policy last failed. **Number of failures** indicates how many times the policy has failed, and **Last failure details** is the error message. Click **Copy** to copy Last failure details to the clipboard.

The **Matched** number is incremented by 1 if one or more actions is proposed or performed by a policy. However, when errors occur during policy execution, matched might not be incremented. Therefore, you might see failures but the **Matched** count indicates 0. Matched may only be incremented upon successful policy execution.

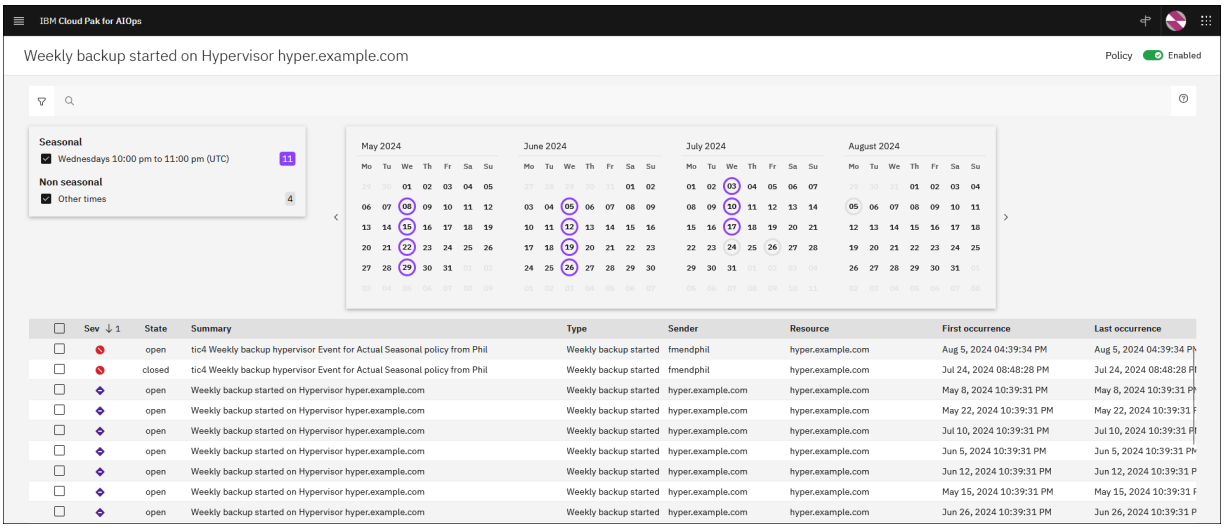
Note: In a case where an alert meets the incident-creation conditions of multiple policies, only one incident is created. However, all policies that proposed an incident, and the system incident creation policy will have the same **Last run** times. Each of these policies will also have their **Matched** counts incremented by one.

- **Journal**:

  The Journal tab displays any comments added by operators to record manual changes or updates to the policy. Comments are shown in chronological order. The policy creation date is also displayed.

- **Specification**:

  Shows you the key information about your conditions and policy. Each condition set of a policy is detailed in the Specification tab, as well as what is created by the policy.



- **Source**:

  View a policy in its raw form in either JSON or YAML format, depending on your requirements. Click **Copy** to copy the policy data to the clipboard.

Note: Preset policy names and internal action references to "story" or "stories" are synonymous with incidents. Incident triggers and condition references supported in the "Invoke IBM Tivoli Netcool/Impact" policy template are stored as story. For policy search based on conditions, use "story" instead of "incident". For example, to find incident.title in a policy search, use story.title. These internal references and policy names have no bearing on actual behavior and are for internal processing purposes only. Any references to "story" in preset policy names, or other policy details or specifications is not an error, and is equivalent to incident in all respects.

Seasonality policy details

The seasonality details page provides a calendar view of all of the historical alerts that contributed to the selected seasonal policy. One or more seasonal time windows are listed under the filter icon. Select a seasonal time window to filter the view to show just historical alerts that contributed to that time window.

Seasonality details

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Filter the table to display **Temporal** and/or **Seasonal** policies, or search for a policy by entering a search term in the field provided.

4. Locate the policy of interest and do one of the following to launch out to the policy details page:
    - Click the options menu (three vertical dots) at the end of the policy's table row and then click **View justification**.
    - Click anywhere in the policy's table row and then click **Justification** in the side panel displayed.

The seasonality policy details page contains the following sections:

- **Header**:
    - Policy name
    - Toggle button to change the policy state to enabled  or disabled  . Disabled policies do not take any action against incoming alerts.

      Note: Users must have the *Edit operational policies* permission to enable or disable policies from the seasonality policy details page. The toggle button for policy state will be disabled without this permission. For more information, see Roles and permissions.
- **Toolbar**:
    - Search: searches alert data in all event group instances that are shown on this page.
    - Filter: filters the alerts that are shown by severity level:
        -  Critical
        -  Major
        -  Minor
        -  Warning
        -  Informational
        -  Indeterminate
- **Seasonal time windows**:

  One or more seasonal time windows are listed together with a number indicating how many historical alerts occurred within this time window during the historical period analyzed. The color of the square is the color code for the respective seasonal time window. Select a seasonal time window to filter the Calendar and the Historical alert table to show just historical alerts that contributed to that time window.
- **Calendar**:

  A calendar of the historical period analyzed (the last three months or more) showing days on which the historical alerts of interest occurred, and colored with the color code for the respective time window. If you hover over any indicated day in the calendar, a tooltip displays a breakdown of the seasonal alerts for that day.
- **Historical event table**:

  Table listing the historical alerts during the historical period analyzed.

Temporal policy details

The temporal policy details page shows the alerts that make up a temporal group, together with all of the historical instances of the group. You can navigate into these instances to view detailed timelines of each instance. You can also view alert details.

Temporal policy details

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Filter the table to display **Temporal** and/or **Seasonal** policies, or search for a policy by entering a search term in the field provided.
4. Locate the policy of interest and do one of the following to launch out to the policy details page:
   - Click the options menu (three vertical dots) at the end of the policy's table row and then click **View justification**.
   - Click anywhere in the policy's table row and then click **Justification** in the side panel displayed.

The temporal policy details page contains the following sections:

- **Header**:
  - Policy name
  - Toggle button to change the policy state to enabled or disabled. Disabled policies do not take any action against incoming alerts.

    Note: Users must have the *Edit operational policies* permission to enable or disable policies from the temporal policy details page. The toggle button for policy state will be disabled without this permission. For more information, see Roles and permissions.
- **Toolbar**:
  - Search: searches alert data in all event group instances that are shown on this page.
  - Filter: filters the alerts that are shown by severity level:
    - Critical
    - Major
    - Minor
    - Warning
    - Informational
    - Indeterminate
- **Overview timeline**:

  Displays alert group instances over time and controls the display of alert group instance data on the rest of the page. By default the time range sliders are open sufficiently to show data on all alert group instances. Modify the time range by either clicking and dragging over the desired range inside the timeline, or by dragging the sliders to the desired range. The rest of the screen updates accordingly.
- **Alert group instance timeline**:

Displays all of the alerts that have historically participated in instances of this temporal alert group. The instance map provides a graphical view over time of when the various instances have occurred.

- **Alert group instance details**:

  Displays the following information for each alert group instance:

  - Start date and time of event group instance: indicates the first occurrence value of the first alert in the alert group instance.
  - Distribution of event severity values: pie chart providing a visual indication of the alert severity values. Hover over the pie chart for more details.
  - Sparkline: chart of alert occurrence over time.
  - Duration of event group instance: duration of the alert group instance, in text.
  - Down chevron icon: click the down chevron icon ⌄ to see an alert table showing column details for each alert in this group instance.

Default incident creation policies

IBM Cloud Pak® for AIOps provides two preset (or default) incident creation policies. For incident creation to occur, you must enable one of these default policies, or create your own custom incident creation policy. These policies are disabled by default.

Default incident creation policy for high severity alerts

This policy proposes an incident based on a Major or Critical severity alert. The policy contains one condition set and action.

Condition set 1

If this condition is met:

Property	Operator	Matches	Value
Value of: alert.severity	greater or equal	only	5-Major

The following action is taken: Create a **Priority 1** incident.

Default incident creation policy for all alerts

This policy proposes an incident based on any alert. The policy contains the following condition sets and actions.

Note: In incident policies, only the actions from the first matching condition set are executed.

Condition set 1

If this condition is met:

Property	Operator	Matches	Value
Value of: alert.severity	equal to	only	1-Indeterminate

The following action is taken: Create a **Priority 5** incident.

Condition set 2

If this condition is met:

Property	Operator	Matches	Value
Value of: alert.severity	equal to	only	2-Information

The following action is taken: Create a **Priority 4** incident.

Condition set 3

If this condition is met:

Property	Operator	Matches	Value
Value of: alert.severity	equal to	only	3-Warning

The following action is taken: Create a **Priority 3** incident.

Condition set 4

If this condition is met:

Property	Operator	Matches	Value
Value of: alert.severity	equal to	only	4-Minor

The following action is taken: Create a **Priority 2** incident.

Condition set 5

If this condition is met:

Property	Operator	Matches	Value
Value of: alert.severity	greater or equal	only	5-Major

The following action is taken: Create a **Priority 1** incident.

Default Netcool scope-based grouping - with a rolling window of 15 minutes

IBM Cloud Pak® for AIOps provides a preset (or default) Netcool scope-based grouping policy. Provided that the `ScopeID` field in your IBM Netcool Operations Insight system is mapped to the `alert.resource.scopeId` field in Cloud Pak for AIOps, this policy uses that value to create scope-based groupings. The policy is enabled by default.

If scope-based grouping is used in an existing Netcool environment, you need to disable `correlation_triggers` groups in the ObjectServer infrastructure, and the correlation needs to done at the Cloud Pak for AIOps layer.

Condition set

If this condition is met:

Table #1. Condition set

Property	Operator	Matches	Value
Value of: alert.resource.scopeId	not empty		

The following action is taken: **Create a scope-based grouping**.

ScopeID

The ScopeID are the properties that define the scope for how alerts are grouped.

The ScopeID in this policy is **alert.resource.scopeId**.

Time window

This default policy has a 900-second **Rolling** time window. That is, 900 seconds is the threshold that needs to pass with no further alerts, after which the system stops including alerts in the group.

Incident Creation based on Persistence and Golden Signal

BETA *Incident creation based on persistence and golden signal* is available only for technology preview, not for production usage.
Incident prioritization uses the golden signal policy and the alert suppression policy to filter out incidents when the observed alerts contain a golden signal and are not suppressed. The policy suppresses alerts that do not need attention.

An incident is only created when the following criteria are met:

1. Events persist for a significant duration, leading to an unsuppressed alert.
2. The golden signal that is associated with the alert is of the type `EFFECT`.

Prerequisites

Configuration prerequisites

To enable the X in Y algorithm, use the following steps.

1. Log in to your Red Hat OpenShift Container Platform cluster as an administrator where Cloud Pak for AIOps is installed.

2. Create or update the ConfigMap with the **IBM_IR_AI_X_IN_Y_PREVIEW_ENABLED** field. Set the value of this field to **true**. A sample YAML file can resemble the following example:

```
apiVersion: v1
data:
  IBM_IR_AI_X_IN_Y_PREVIEW_ENABLED: "true"
kind: ConfigMap
metadata:
  name: feature-flag-configmap
  namespace: <namespace>
```

   Where **<namespace>** is the namespace where IBM Cloud Pak for AIOps is installed.

3. If you are not running these steps before installation or upgrading, delete the **ibm-ir-ai-operator-controller-manager** pod. When the pod is deleted, OpenShift automatically creates and starts a new pod.

Data prerequisites

Historical alert data is used in the training process to learn values of X and Y, which are later employed for creating XinY alert suppression policies.

1. In the Cloud Pak for AIOps console, click **Operate** > **AI model management** and find the *Alert suppression XinY policies* tile. If this tile does not appear, delete the **aimanager-aio-ai-platform-api-server** pod using the OpenShift console. When the pod is deleted OpenShift automatically creates and starts a new pod.

   For more information, see The Alert suppression XinY policies tile does not appear in AI model management.

2. Click the tile and follow the steps to train the model and then deploy it. For more information, see training a model.

This instantiates the policy and adds it to the policy list in **Automations**.

Note: To create effective Alert Suppression policies, a minimum of 7 days' worth of historical alert data is needed. This data can be supplied either during the training phase or continuously gathered from the alerts that are received after integrating your application with IBM Cloud Pak for AIOps.

About this task

After you train your model with historical data, you are ready to proceed to using the incident creation based on persistence and golden signal policy.

Procedure

1. Go to the **Automations** page and click the **Policy** tab to see all available policies.
2. Click the **Toggle filters** icon and select **Suppression** from the list.
3. Any policies that have suppressions are listed. Find the policy that contains the prefix *X-in-Y-alert-suppression*. If it is not there, try clicking the refresh icon, to update the policy list.
4. Click the *X-in-Y-alert-suppression* policy to open a sidebar information panel. In the panel, slide the **Status** switch to **Enabled**.
5. Next, close the panel, click the *Tag* header column, clear *Suppression*, and check the *Incident* box.
6. Among the incident policy listings are the *Golden Signal and Persistence incident creation* policy. Click this policy to open the sidebar panel.
7. In the sidebar panel, set the **Status** switch to **Enabled**.
8. The *Golden Signal and Persistence incident creation* must be the only *Incident* tagged policy that is enabled. If other *Incident* policies are enabled, then click them, in turn, and disable them in the sidebar panel.

You now have a policy that combines the two policy values when creating incidents. Now when alerts come in, they must fulfill the conditions of the two policies to be promoted as incidents:

- They need to contain a Golden Signal **Error**
- The X and Y values must be outside the allowed range set when the model was trained – for example, where the model has the value of 12 events within 60 minutes, an anomaly only surfaces when the events are 12 or above.

Creating policies

Click the **Create policy** button and choose from a set of templates to help you get started.

See the following topics for more information about creating policies:

- Suppress alerts
- Group alerts based on scope

- Assign a runbook to alerts
- Promote alerts to an incident
- Invoke an IBM Tivoli Netcool/Impact policy

For a detailed breakdown of the policy editor, see Editing policies.

Suppress alerts

Some alerts might not be important for monitoring your organization's environment. For alerts that do not need to be viewed or acted on, use suppression policies to reduce noise for your operations teams by suppressing unwanted alerts. When an alert is suppressed in Cloud Pak for AIOps, the **`alert.suppressed`** flag is set to true. The alert is still present in the system and can be viewed in the Alert Viewer, but the alert is filtered out of the view by default. Incident creation and runbook policies do not run for suppressed alerts. However, scope-based grouping policies continue to run so there is a scenario where suppressed alerts can be included in incidents.

You can also give feedback to Cloud Pak for AIOps to indicate whether an alert was correctly identified and add a suppression policy to suppress low voted items. For more information about giving feedback, see Alert details.

Enabling X in Y alert rate suppression

Many alerts can represent problems where performance thresholds were breached, for example, a switch that reaches its maximum bandwidth capacity during a peak period. These temporary threshold breaches are often expected, and the business policy might be to ignore them unless the breach is sustained for a prolonged but specific period. However, if such alerts are sustained beyond these specified time periods, operators must take action. In this classic X in Y alert rate scenario, the operator is only interested in alerts that occur more than X times in Y minutes. When the alert rate breaches the threshold, the described alerts should not be suppressed. Until the threshold is breached, the alerts do not need to be acted upon.

In suppression policies, you enable X in Y alert rate suppression under actions in the policy editor. Select **Suppress the described alerts until:**. Then, specify your values for X (number of alerts) and Y (minutes).

Attention: Please be aware about alert states that contribute to the X count. The X value is incremented for deduplicated problem and resolution alerts. Therefore, if a deduplicated alert flaps 10 times (alternating between open and clear) "X" would contain a value of 20 (not 10 for just the problem alerts).

Limitations

While the suppression policy can be applied to all alerts, and all alerts can use the Alert property condition to identify when to suppress an alert, use of the Alert insight conditions have certain limitations.

- Anomaly insights are available on all metric anomaly alerts and on certain log anomaly alerts.
- Only a subset of log anomaly alerts identify an exception or error code.
- The statistical baseline log anomaly algorithm typically identifies these exceptions or error codes.

About this task

In this example, preproduction, development, and test environments are monitored by the same monitoring tools as the production environments. The development and test environments naturally have ongoing changes that might trigger various warnings and notifications all the time. These warnings and notifications are relayed to Cloud Pak for AIOps as alerts. However, these alerts do not require action as they are from resources that change constantly as part of the preproduction work. The monitoring tools are usually set up to avoid sending such alerts to the operations teams. However, if such alert information is sent to Cloud Pak for AIOps, for example, due to a misconfiguration, then the operations team might face unnecessary noise.

To save your operations team from being distracted by alerts from such environments, you can create a suppression policy to suppress alerts that come from the monitored resources that make up these environments.

Important:

- Unlike other Cloud Pak for AIOps policy templates, suppression policies contain a single condition set.
- The supported **Anomaly insights** properties for suppression policies are displayed in the tree view of the **Property** field. To display the available options, click **Add condition** > **Alert insight** and place the cursor in the Property field. For more information, see Supported Anomaly insights properties.

Example

1. Click the navigation icon to go to the main navigation menu.

2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Create policy**.
4. Click the **Suppress alerts** tile.
5. Enter a name in **Policy name**, for example, the name can be "Suppress events from preproduction environment". You can also add an explanation of the policy in **Description** to help you and others understand the purpose of the policy, for example, "Suppress alerts from hosts in the preproduction environment to prevent incidents from being created for development and test hosts".

   User-created suppression policies are always the first user policies to be run. The order is set to 0 and cannot be changed.
6. To define the conditions for alerts to activate alert suppression, click **Add condition** and select **Alert property** or **Alert insight** attributes. For this example, Alert property is used.
7. For each attribute, select values for **Property**, **Operator**, **Matches**, and **Value**. For **Alert insights** attributes, also select an **Insight type** value, such as **Anomaly** or **Business criticality**.

   For this example, select **`alert.resource.hostname`** from the **Property** list .You can type **`hostname`**, and the system shows in the property list all alert properties that contain the text **`hostname`**. Then, select **`alert.resource.hostname`**.
8. From the **Operator** list, select **starts with**.
9. From the **Matches** list, select **any of**.
10. In the **Value** field, enter **`dev`** and select **`String: dev`**. In the same field, enter **`test`** and select **`String: test`**.

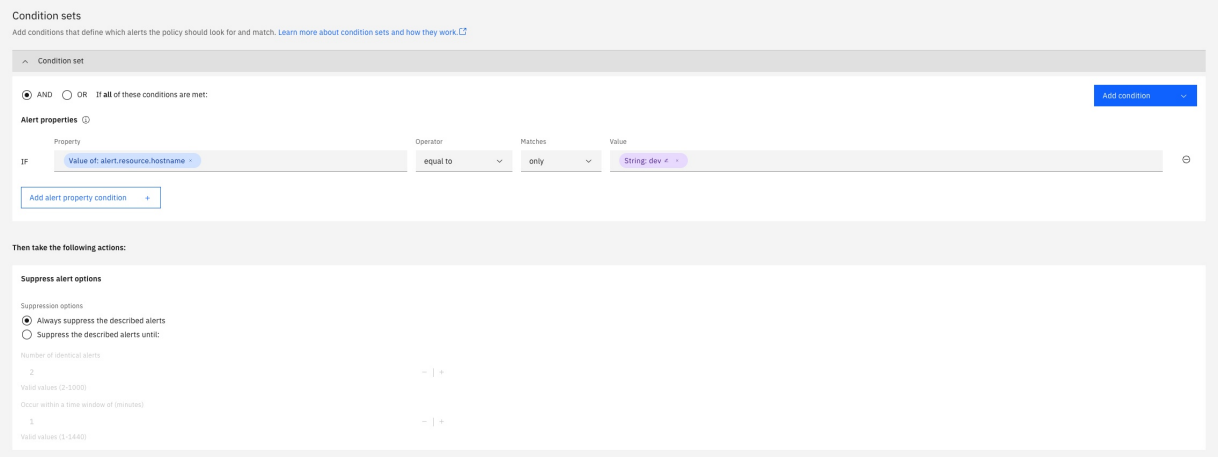


Figure. Supression policy

11. Select **Always suppress the described alerts** or **Suppress the described alerts until** and specify the number of identical alerts or how many alerts occur within a time window of minutes.
12. Click **Create policy**.

New and updated policies can take up to 2 minutes to take effect.

Note: Suppression occurs on the alert level, not the event level. If a suppression policy for a specific condition is enabled, any matching alerts are suppressed. If the policy is removed later, any future matching alerts are not suppressed, and any existing alerts are not unsuppressed. If the suppressed alert is not closed, for example, if the problem is still active, any future events are deduplicated into the suppressed alert until the problem is resolved.

Scenario where alerts can be both suppressed and part of an incident

Suppressed alerts are not typically included in incidents. However, take a scenario where a group of alerts are subject to a scope-based policy. One alert in the group is not suppressed, and also matches the conditions of an incident policy. Then it is possible for the other alerts to show suppressed and in an incident. They are added to the incident because the scope grouping makes them contextual alerts for that incident.

In this image the one alert which is not suppressed is subject to the same scope-based policy as all the suppressed alerts. If that alert also matches an incident policy, then the other "suppressed" alerts are all included in the incident. This is expected as scope policies still run for suppressed alerts. On the Alert Viewer then it is possible if these circumstances occur for alerts to be both suppressed and part of an incident.

In incident	Suppressed
Yes	Yes
Yes	Yes
Yes	No

Suppressed alerts and part of an incident

Suppress seasonal alerts

Generate a new suppression policy to suppress the in-season alerts identified by an analytics-created seaonal policy. After the suppression policy is created, you can edit it to add conditions if needed.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**. The Policies table is displayed.
3. Click the Filter icon to open the filter side panel.
4. Select the **Seasonal** tag and click **Apply**.
5. In the Policies table, click anywhere in the row of the analytics-created seaonal policy that you want to generate a suppression policy for.
6. In the side panel displayed, click the plus icon "**+**" beside **Generate suppression policy**.
7. Enter a name for your policy that is 1-120 characters. Leading and trailing blank spaces will be removed from the policy name if provided.
8. Click **Generate policy**.

The new suppression policy is created and available in the Policies table. You can edit the policy to add conditions if required.

To see how many suppression policies or other policies reference a seasonal policy ID, complete the following steps:

1. In the Policies table, select the seasonal policy of interest.
2. If one or more related policies are found, click the search icon for **All related policies**.

The list displayed is generated by searching all policy names and conditions for the policy ID of the selected seasonal policy. You can click **Clear filters and show policies in table** to launch out to the related policies in the Policies table.

Suppress seasonal alerts using the policy templates

You can also create your own suppression policy for seasonal alerts by using the policy template and condition builder.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Create policy**.
4. Click the **Suppress alerts** tile.
5. Enter a **Policy name** and optionally a **Description**.
6. Suppress seasonal alerts by making the following selections in a condition set:
    1. Click **Add condition** and select **Alert insight**.
    2. Set the Insight type to **Seasonal**.
    3. From the Property drop-down list, select `insight.details.policyId`.
    4. Set the Operator to **equal to**.
    5. Set Matches to **only**.
    6. Set the Value to the seasonal policy ID.

For more information about alert seasonality, see Displaying alert seasonality.

Group alerts based on scope

Group alerts based on common properties and time of occurrence to identify when issues might be related. When related alerts are grouped based on their scope, you can view the details in the Alert Viewer.

For example, a scope-based grouping policy might be to group events together that occur at the same physical geographical location within a 5 minute window. The scope can be any attribute that makes sense in the context of the correlation: the same application group, business unit, or physical building.

Note: There can be multiple scope-based policies each with different time windows.

IBM Cloud Pak for AIOps includes two scope-based grouping policies:

- Group alerts that have the same resource name (host name), and use a 15 min rolling window (default).
- Group alerts that come from a Netcool environment where the *ScopeID* field is set, based on its value, and use a 900 second rolling window.

The default scope-based policy in Cloud Pak for AIOps is a correlation on alert.resource.name constrained by a rolling window of 15 minutes. By using this template, you can override the default scope-based groupings.

Note: Alerts in Cloud Pak for AIOps can have multiple scopes and be members of more than one scope-based group at once. If groups have common events, these groups are automatically merged in Cloud Pak for AIOps into super groups.

About this task

In this example, you want to scope alerts by their cluster name and by their location.

Example

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Create policy**.
4. Click the **Group alerts based on scope** tile.
5. Enter a name in **Policy name**, for example, the name can be "Sales region 2 scope policy". You can also add an explanation of the policy in **Description** to help you and others understand the purpose of the policy, for example, "Scope alerts from the sales region 2 cluster by location".
6. Set the **Execution order** to higher.
7. Define the following conditions for alerts that will activate scope-based alert grouping, based on the ScopeID that is specified:
    1. Click **Add condition** and select **Alert property**.
    2. From the Property drop-down list, select **alert.resource.cluster**. You can type "cluster" and the system will show in the property drop-down list all alert properties that contain the text "cluster", which in this case is two properties.
    3. From the Operator drop-down list, select **equal to**. From the Matches drop-down list, select **only**.
    4. In the Values field, enter **SALES.REGION2.CLUSTER** and select **String:SALES.REGION2.CLUSTER**.
8. Add alert properties, strings, or both to create the ScopeID for this group. These properties define the scope for how the alerts are grouped. If **`alert.details`** is selected in the property field, a secondary input box is displayed underneath. The **Details name** field is an optional input where you can minimize the scope to a singular key within the alert's details. For example, if you enter **`specificKey`** in the Details name field, it is understood as **`alert.details.specificKey`**. You must enter a string value that matches a key from an alert's details.

    Note: For ScopeID you can send only specific alert details by name and not the entire **`alert.details`** object. You must enter a string value in the **Details name** field.

    In this example, the two alert fields in **ScopeID** are separated with string ":". This will group all alerts from the cluster (SALES.REGION2.CLUSTER), but sub-divide them based on their locations (for example, Dallas, New York).

    Tip: To reorder the ScopeID fields, click on the Draggable icon within a 'Value of' or 'String' field and move it to the desired location in the **ScopeID** field.

    For this example specify the following ScopeID:

    1. Click anywhere in the properties field and select **alert.resource.cluster** (or type "cluster" and select it from the options displayed).
    2. In the same field, enter a colon **":"** and select **String::**.
    3. Finally, click in the field again and select **alert.resource.location** (or type "location" and select it from the options displayed).

Example scope-based policy

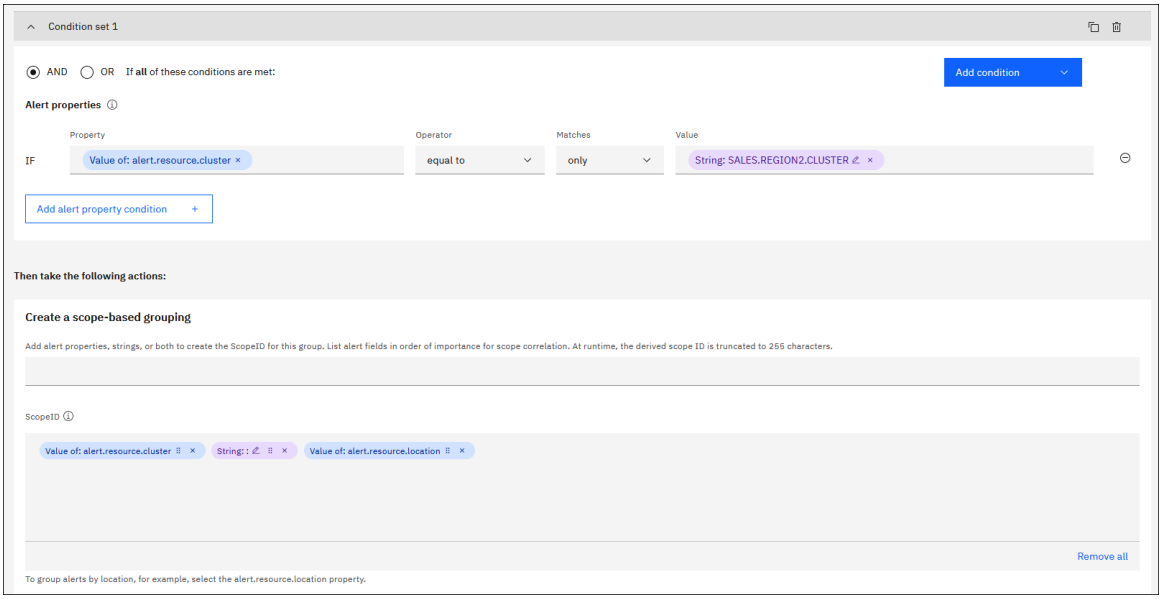

Figure. Scope-based policy

9. Specify a **Time window** (in seconds) to group alerts that match the scope. The minimum value is 10 seconds. The maximum recommended value should not exceed 3600 seconds (1 hour).

   Select the time window **Type**:

   - **Rolling**: The time window value is the threshold number of seconds that need to pass with no further alerts, after which the system stops including alerts in the group.
   - **Fixed**: The time window value is a set amount of time during which incoming alerts are included in the group.

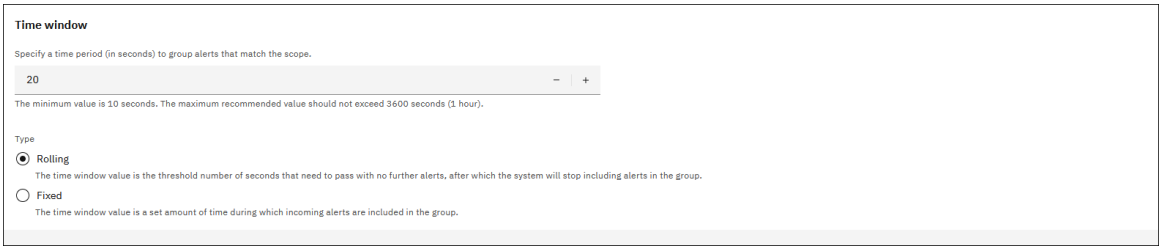

Figure. Time window for scope-based policy

10. Click **Create policy**.

Scope-based alert grouping is activated for alerts that match the condition, based on the ScopeID specified.

New and updated policies can take up to 2 minutes to take effect.

Assign a runbook to alerts

Assign a runbook to alerts for easier automated resolution.

Important: in runbook policies, the actions from every matching condition set are executed. Policies are triggered upon alert creation only.

About this task

In this example, you want to have a runbook take action when you receive alerts warning that your disk space is filling up. The runbook could delete the contents of the `/tmp` directory to free up space. You can create a policy to use this runbook every time alerts warn of your disk space becoming full.

Note: This example assumes you have a runbook that is called **Clear tmp directories**. For information about setting up runbooks, see Runbooks.

Example

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.

2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Create policy**.
4. Click the **Assign a runbook to alerts** tile.
5. Enter a name in **Policy name**, for example, "Clear tmp directories". You can also add an explanation of the policy in **Description** to help you and others understand the purpose of the policy, for example, "Policy to assign a runbook to alerts that indicate that disk is full due to /tmp filling up".
6. Set the **Execution order** to 50.
7. Define how the policy is triggered to assign a runbook to alerts. Once triggered, it will look for alerts that match the conditions you specify in order to take action. The policy triggers are when an alert is created, updated, or both. Updated means the alert state changes. For example, if an alert changes from Severity 1 to Severity 5. In this example, select **An alert is created**.
8. Define the following conditions for alerts that will assign a runbook to alerts:
    1. Click **Add condition** and select **Alert property**.
    2. From the Property drop-down list, select **alert.type.classification**. You can type "class" and the system will show in the property drop-down list all alert properties that contain the text "class", which in this case is only alert.type.classification. From the Operator drop-down list, select **equal to**. From the Matches drop-down list, select **only**. In the Values field, enter **Disk Full** and select **String:Disk Full**.
    3. Click **Add alert property condition**.
    4. From the Property drop-down list, select **alert.severity**. From the Operator drop-down list, select **greater or equal**. From the Matches drop-down list, select **only**. In the Values field, select **5-Major**.
    5. Click **Add alert property condition**.
    6. For the third condition, select **summary** from the Property drop-down list. From the Operator drop-down list, select **contains**. From the Matches drop-down list, select **only**. In the Values field, enter **/tmp** and select **String:/tmp**.
9. In **Assign Runbook(s)**, select one or more runbooks from the list to assign. In this example, select the **Clear tmp directories** runbook.
10. Review the list of parameters that are required for each runbook selected. You must decide how the values of the runbook parameters are filled by creating a parameter mapping. Select from the following mapping options:

    - **Choose from alert**: Select the name of an alert field from the tree view, its value will be passed to the runbook parameter. For string variable type parameters only, you can select **`alert.details`** as the alert property. The **Details name** field is an optional input where you can minimize the scope to a singular key within the alert's details. For example, if you enter **`specificKey`** in the Details name field, it is understood as **`alert.details.specificKey`**. You must enter a string value that matches a key from an alert's details.

      Note: For runbook parameters you can send only specific alert details by name and not the entire **`alert.details`** object. You must enter a string value in the **Details name** field.

      Important: The parameter **Type** is displayed on the UI. If this option is selected, you should select alert fields that contain matching types of data. For example, strings vs integers.

    - **Enter static value**: A fixed value for the parameter at runtime.
    - **Choose at runtime**: After launching the runbook from the incident page, if this option is selected, you must provide a value at runbook execution time. Sometimes the default value as set in the runbook is prefilled for the parameter, in this case just edit the value at execution time.
    - **Use default parameter value**: If the runbook defines a default value for this parameter, you can use that value. This option is grayed out if no default was set in the runbook.

For this example, select **Use default parameter value**.

Example runbook policy

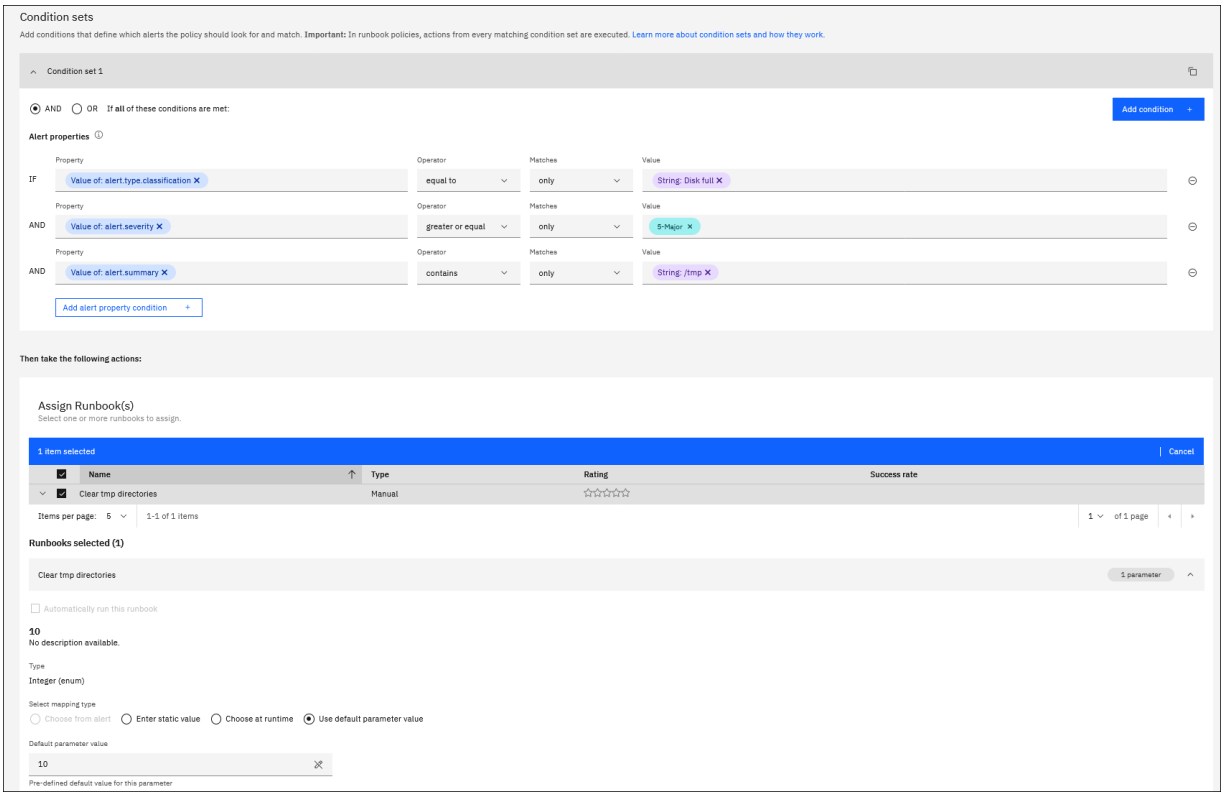

Figure. Supression policy

11. Click **Create policy**.

New and updated policies can take up to 2 minutes to take effect.

Note: If more than one runbook policy is triggered for the same alert and the same runbook is assigned, the policy parameter selections from the last matching condition set or policy are passed to the runbook.

Promote alerts to an incident

Create actionable incidents from alerts to improve insights into your issue. You can then automatically assign incidents to a user group and owner. You can also send notifications about the incident through ChatOps.

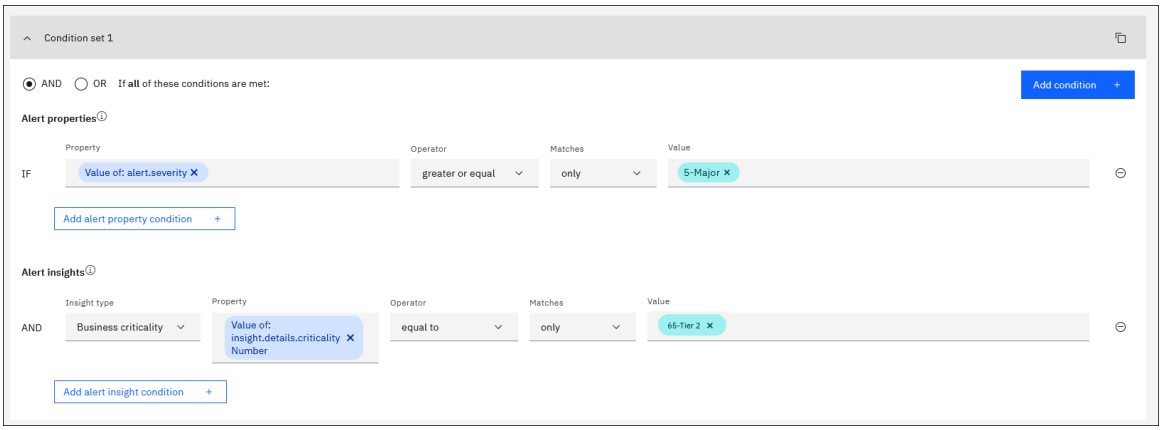
Important: In incident policies, only the actions from the first matching condition set are executed. Policies are triggered upon alert creation only.

About this task

In this example, all high priority incidents that include alerts at or higher then a defined business criticality level are automatically assigned to the Db2 admin group with a notification sent to the group's team leader of such incidents.

There are three preset business criticalities available in Cloud Pak for AIOps:

Table. Preset business criticalities



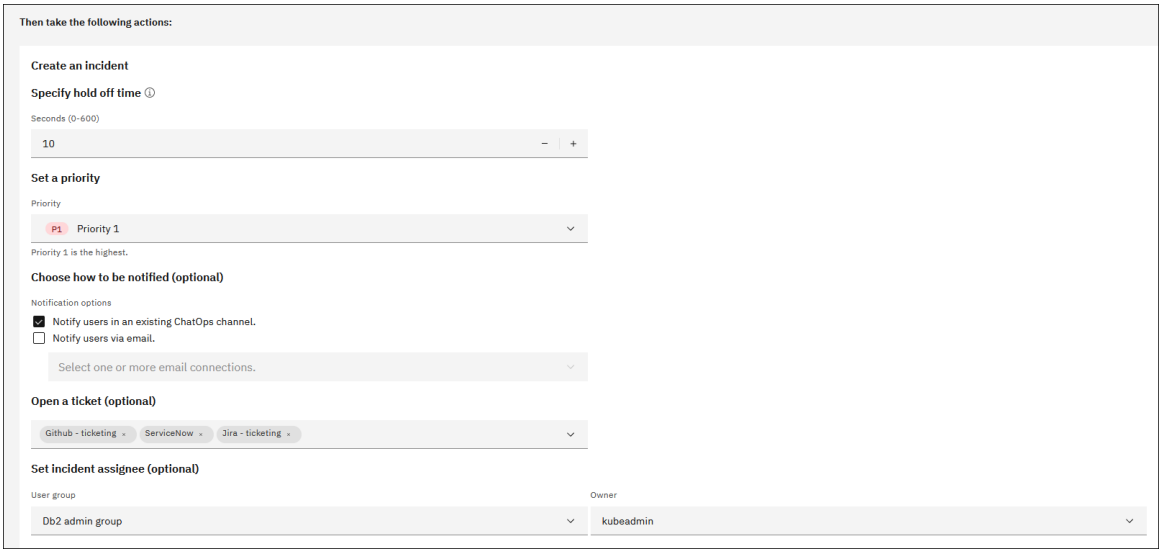
Name	Description	Criticality score
Tier 1	Highest priority	100
Tier 2	Medium priority	65
Tier 3	Lowest priority	25

Note: Preset business criticalities can be edited after they are added to your environment. For more information, see Defining business criticality.

Example

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.

3. Click **Create policy**.
4. Click the **Promote alerts to an incident** tile.
5. Enter a name in **Policy name**, for example, "Assign high priority Db2 incidents to Db2 admins". You can also add an explanation of the policy in **Description** to help you and others understand the purpose of the policy, for example, "Automatically assign any priority 1 incidents from Db2 hosts to the Db2 admin group, and notify team leader".
6. Set the **Execution order** to 1.
7. Define how the policy is triggered to create an incident. Once triggered, it will look for alerts that match the conditions you specify in order to take action. The policy triggers are when an alert is created, updated, or both. Updated means the alert state changes. For example, if an alert changes from Severity 1 to Severity 5. In this example, select **An alert is created**.
8. Define the following conditions for alerts that will trigger the creation of an incident:
    1. Click **Add condition** and select **Alert property**.
    2. From the Property drop-down list, select **alert.severity**. You can type "sev" and the system will show in the property drop-down list all alert properties that contain the text "sev", which in this case is only alert.severity. From the Operator drop-down list, select **greater or equal**. From the Matches drop-down list, select **only**. In the Values field, select **5-Major**.
    3. Click **Add condition** and select **Business criticality**.
    4. The Property field contains the business criticality value by default. From the Operator drop-down list, select **greater or equal**. From the Matches drop-down list, select **only**. In the Values field, select **65-Tier 2**.



Incident policy condition set

9. **Set hold off time**. Delaying the creation of an incident provides time for data about the issue to be ingested. This can allow the system to make a better decision about what incidents should be created. For example, for flapping alerts or alerts which might be resolved by an automated runbook. In these cases, the incident would only be opened if the alert remains open beyond the hold off time. Eliminating incidents from the UI which ultimately are not actionable.

    Enter the number of seconds that you want to wait before the incident is created (maximum 600 seconds). In this example, the hold off time is 10 seconds.
10. **Set priority**. Give a priority level to the incident that is created when the policy conditions are met. For this example, select **Priority 1**.
11. Select how you want to receive **Notifications** about the incident (optional):
    - Notify users in an existing ChatOps channel.
    - Notify users via email. To use this option, you must have an email notification integration set up.
12. Open a ticket (optional). You can multi-select ticketing options from the drop-down menu. The required connections for GitHub, ServiceNow, or Jira must be set up in Integrations.
13. Assign a user group and owner to route the incident to (optional). In this example, the user group is the Db2 admin group, and the owner the group's team leader.

    Example incident policy actions:

Incident policy actions

14. Click **Create policy**.

New and updated policies can take up to 2 minutes to take effect.

Invoke an IBM Tivoli Netcool/Impact policy

Enable Cloud Pak for AIOps to invoke an IBM Tivoli Netcool/Impact policy that will take actions on your alerts.

Note: If you have existing **Impact Policy Language (IPL) policies** (versus JavaScript policies) that you want to use in Cloud Pak for AIOps to return the event, you must modify the return statement from:

```
ReturnEvent(EventContainer);
```

To:

```
AIOPS_IPL_Utils.AIOPSReturnEvent(EventContainer);
```

For example:

```
@Summary=EventContainer.mynewsummary + " Enriched with this message";

AIOPS_IPL_Utils.AIOPSReturnEvent(EventContainer);
```

About this task

For example, you want Cloud Pak for AIOps to invoke an existing IBM Tivoli Netcool/Impact policy called Notify_Customer_Email. The policy accepts incoming event information from an event reader service and uses this information to look up affected internal customers in an external database. The policy then sends an email to each customer and reports the event data to a third-party help desk system that uses the web services API provided by that application.

For more information about setting up IBM Tivoli Netcool/Impact policies, see the IBM Tivoli Netcool/Impact documentation.

Important:

- To successfully enable your IBM Tivoli Netcool/Impact policy with Cloud Pak for AIOps, you must first configure an IBM Tivoli Netcool/Impact integration in **Define** > **Integrations**.
- By default, IBM Tivoli Netcool/Impact policies are invoked without input or transformation. Editing options are available in the policy template.

Example

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Create policy**.

4. Click the **Invoke Netcool/Impact** tile.
5. Enter a name in the **Policy name**, for example, "Notify customer help desk". You can also add an explanation of the policy in the **Description** to help you and others understand the purpose of the policy, for example, "Look up customers affected by the event in the external database."
6. Set the **Execution order** to 50.
7. Define how the policy is triggered to invoke an IBM Tivoli Netcool/Impact policy. Once triggered, it looks for alerts or incidents that match the conditions you specify in order to take action. First, select the entity that this policy acts on. Choose either **Alert** or **Incident** properties. The default trigger entity is Alert.

   The policy triggers are when an alert or incident is created, updated, or both. Updated means the alert or incident state changes. For example, if an alert changes from Severity 1 to Severity 6, or if an incident escalates from Priority 5 to Priority 1 (this is an escalation as Priority 1 is the highest priority level).

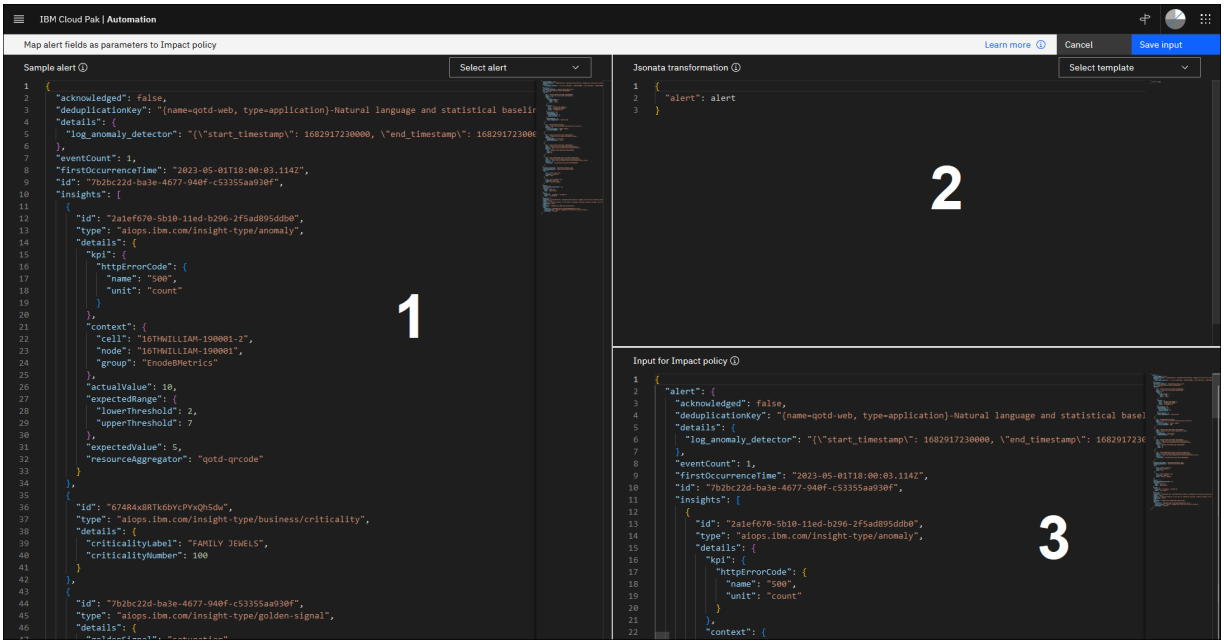
   Note: Switching between alert and incident entities resets the input fields for triggers, condition sets, and actions.

   For this example, we select **After an alert is created**.
8. Define the following conditions for alerts that trigger your IBM Tivoli Netcool/Impact policy:
   1. Click **Add condition** and select **Alert property**.
   2. From the Property drop-down list, select **alert.severity**. You can type "sev" and the system will show in the property drop-down list all alert properties that contain the text "sev", which in this case is only alert.severity. From the Operator drop-down list, select **greater or equal**. From the Matches drop-down list, select **only**. In the Values field, select **5-Major**.
9. In **Invoke Netcool/Impact**, specify the IBM Tivoli Netcool/Impact integration instance to invoke the policy. If you don't see anything in the **Impact connection** dropdown list, see IBM Tivoli Netcool/Impact integrations.
10. Select your **Impact policy** Notify_Customer_Email from the drop-down list. You can start typing the policy name in the field that is provided and the matching IBM Tivoli Netcool/Impact policy names are suggested.
11. By default, your IBM Tivoli Netcool/Impact policy parameters are mapped to all alerts or all incidents. Select from the following IBM Tivoli Netcool/Impact policy parameter-mapping options:

    - Send the full alert or incident
    - No input
    - Customize

Send the full alert or incident

Send the entire alert or incident without alteration. Click **Create policy** to save the policy.



No input

Your IBM Tivoli Netcool/Impact policy requires no input. Click **Create policy** to save the policy.

Customize

Select this option if you want to customize alert or incident field parameters that are used as input for your IBM Tivoli Netcool/Impact policy. Click **Edit parameter mapping** to continue.

In this example, alert fields are being mapped as parameters to an IBM Tivoli Netcool/Impact policy. If incidents are selected as the policy trigger entity (see step 7 in the preceding example), then incident fields are mapped as parameters here. The editor is divided into three sections. You can click and drag the vertical and horizontal middle lines to resize the sections.

Edit parameter mapping

- Section 1: **Sample alert**

  Use the **Select alert** drop-down menu to load a sample alert, or go to the Alert Viewer to copy and paste a raw alert by opening **Alert details** > **Information** > **Raw** > **Copy to clipboard**. For more information, see Alert details.

  The sample alert provides variables available for use in your mapping, including the alert that the policy is acting on. You can modify the variables to test out different possible inputs to your IBM Tivoli Netcool/Impact policy, for example, by overriding the alert with one from your alert list.

  Note: The sample alert is only used to test your transformation and has no bearing on the execution of your policy.

- Section 2: **JSONata transformation**

  A JSONata expression translates between the variables available to the Cloud Pak for AIOps policy and the EventContainer object that is made available to the IBM Tivoli Netcool/Impact policy during execution. Use the JSONata transformation section to include your own arguments for an IBM Tivoli Netcool/Impact action by making a selection from the **Select template** drop-down menu. If you are invoking an IBM Tivoli Netcool/Impact policy that was originally written for an IBM Tivoli Netcool/Impact EventReader, you will likely want to translate the alert variable to a set of ObjectServer columns here.

  When you start typing in **JSONata transformation** (or press Ctrl + Space), a suggestion panel with alert properties is shown. Move the cursor into the panel to scroll and select from the list of properties. As you make changes in this section, the **Input for Impact policy** (section 3) shows a preview of your transformation.

  Note: Policies support individual details by name. However, there is no **`alert.details.detailsname`** displayed in the JSONata transformation list of properties. To pass such a value, select **`alert.details`** and then add **`."details_name"`**. The **`alert.details`** name must be specified in quotation marks (**`" "`**). That is **`alert.details."details_name"`**. The value of **`alert.details."details_name"`** will then be passed at run time.

Parameter suggestion panel

Warning: Any changes that you make to the source alert are reset if you reedit the parameter mapping.

- Section 3: **Input for Impact policy**

  This section shows the results of your transformation and what the content of the EventContainer variable in IBM Tivoli Netcool/Impact will contain, based on the current sample alert and transformation rules that are used in section 2.

12. Click **Save input** to save your changes and close the editor. Then, click **Create policy** to save the policy.

    New and updated policies can take up to 2 minutes to take effect.

Populate a dashboard or report

BETA The dashboard or report policy is available only for technology preview, and is not for production usage.

Send alerts or incidents from Cloud Pak for AIOps to populate a dashboard or report.

About this task

Adding an IBM Db2 integration enables your organization to store alert and incident data in a Db2 database. Using this template, you can create policies that send that alert or incident data from Cloud Pak for AIOps to populate a dashboard or report in IBM Cognos® Analytics.

In this example, you want to send alerts to populate a dashboard when a new alert is created or when an alert severity level changes. The policy should look for and match only alerts that have an alert summary.

Example

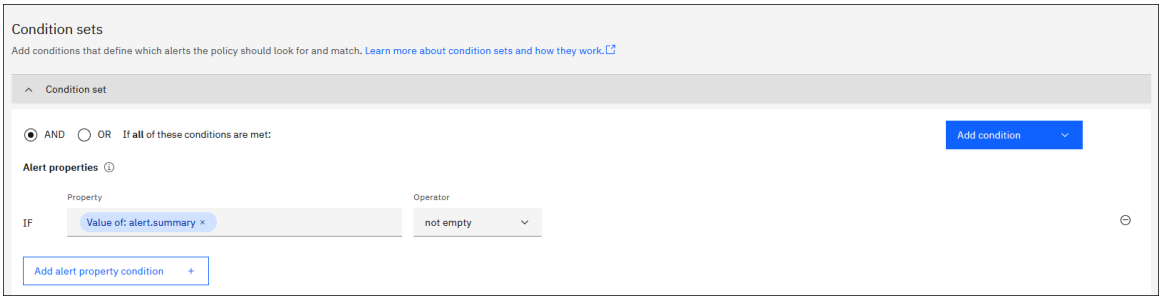
1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Create policy**.
4. Click the **Populate a dashboard or report** tile.
5. Enter a name in the **Policy name**, for example, "Alerts Dashboard". You can also add an explanation of the policy in the **Description** to help you and others understand the purpose of the policy.
6. Set the **Execution order** to 50.
7. Define how the policy is triggered to invoke a dashboard policy. Once triggered, it looks for alerts or incidents that match the conditions you specify in order to take action. First, select the entity that this policy acts on. Choose either **Alert** or **Incident** properties. The default trigger entity is Alert.

   The policy triggers are when an alert or incident is created, updated, or both. Updated means the alert or incident state changes. For example, if an alert changes from Severity 1 to Severity 6, or if an incident escalates from Priority 5 to Priority 1 (this is an escalation as

Priority 1 is the highest priority level).

Note: Switching between alert and incident entities resets the input fields for triggers, condition sets, and actions.

For this example, we select **After an alert is created** and **After an alert has been updated**.

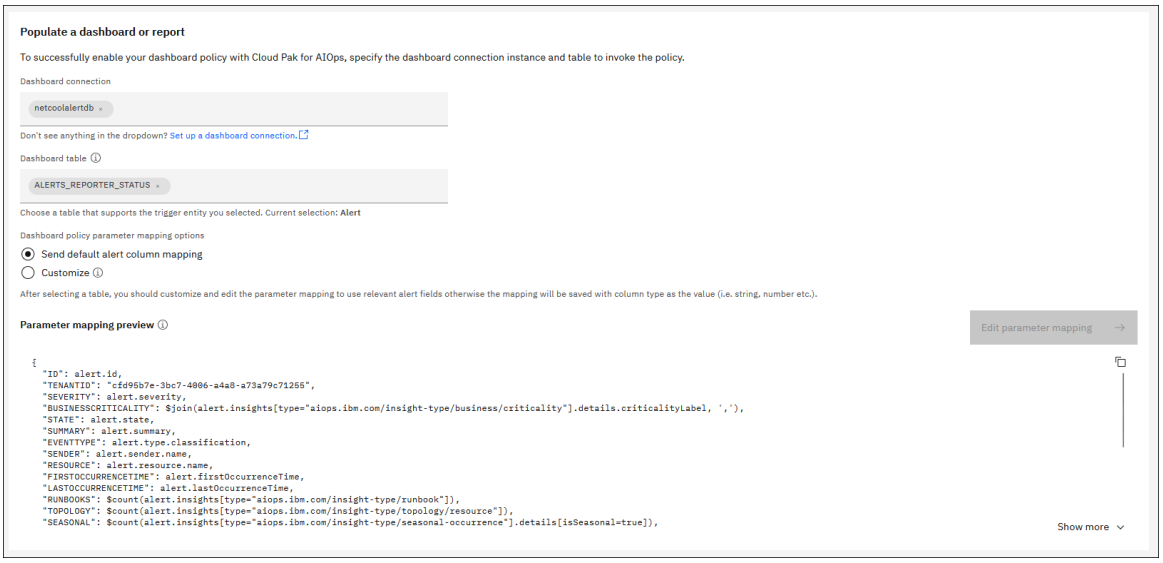


8. In the alert property drop-down list, select **alert.severity**. You can type "sev" and the system will show in the property drop-down list all alert properties that contain the text "sev", which in this case is only alert.severity.

Policy triggers

9. Define the following conditions for alerts that trigger your dashboard policy:

    1. Click **Add condition** and select **Alert property**.
    2. From the Property drop-down list, select **alert.summary**. From the Operator drop-down list, select **not empty**.



Policy conditions

10. In **Populate a dashboard or report**, specify the Dashboard connection instance and table to invoke the policy. If you don't see anything in the **Dashboard connection** dropdown list, see IBM Db2 integration.

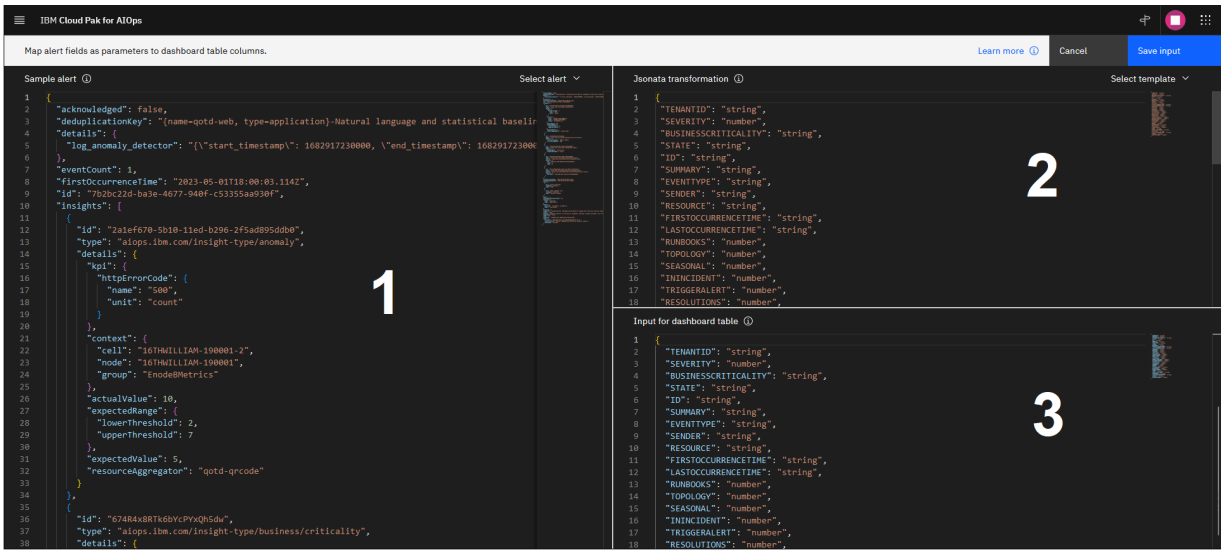
11. Select your Dashboard table from the drop-down list. You can start typing the table name in the field that is provided and the matching table names are suggested. When selecting the default tables **`ALERTS_REPORTER_STATUS`** or **`INCIDENTS_REPORTER_STATUS`**, a default mapping is provided that matches table columns with relevant alert and incident fields. Ensure that you include the columns "ID" and "TENANTID".

    Note: The database schemas must be installed so that the relevant reporting tables are in place. For more information, see Data flow configuration.

Policy actions

12. Select from the following dashboard policy parameter-mapping options:

    - Send default alert column mapping
    - Customize



Send default alert column mapping

Send the default alert column mapping without alteration. Click **Create policy** to save the policy.

Customize

Select this option if you want to customize alert or incident field parameters that are used as input for your Dashboard table. Click **Edit parameter mapping** to continue.

In this example, alert fields are being mapped as parameters to a Dashboard table. If incidents are selected as the policy trigger entity (see step 7 in the preceding example), then incident fields are mapped as parameters here. The editor is divided into three sections. You can click and drag the vertical and horizontal middle lines to resize the sections.

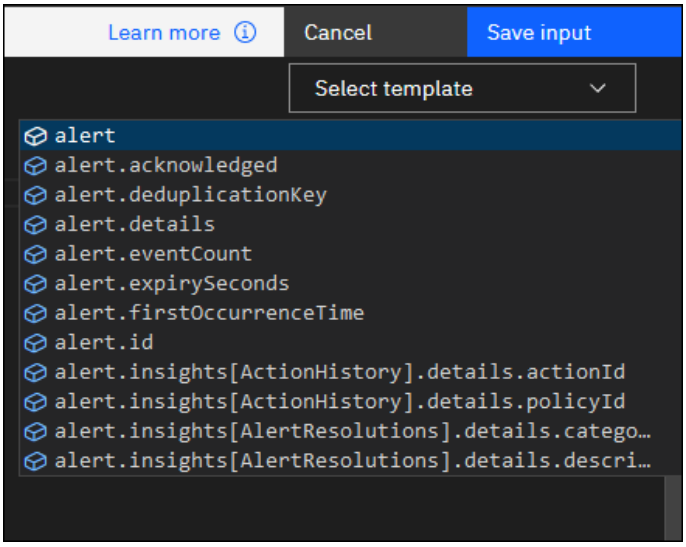
Edit parameter mapping

- Section 1: **Sample alert**

  Use the **Select alert** drop-down menu to load a sample alert, or go to the Alert Viewer to copy and paste a raw alert by opening **Alert details** > **Information** > **Raw** > **Copy to clipboard**. For more information, see Alert details.

  The sample alert provides variables available for use in your mapping, including the alert that the policy is acting on. You can modify the variables to test out different possible inputs to your dashboard policy, for example, by overriding the alert with one from your alert list.

  Note: The sample alert is only used to test your transformation and has no bearing on the execution of your policy.



- Section 2: **JSONata transformation**

  A JSONata expression translates between the variables available to the Cloud Pak for AIOps policy and the dashboard table columns from a given connection. To avoid max transfer sizes the number of transformation key/value pairs is limited to 100.

  Instances of "string" and "number" indicate the type of data that a given column supports. Columns with type "number" only support integer values, any string sent to these columns will cause errors. Ensure that you replace instances of "string" and "number" in the transformation or remove the column if not needed, otherwise, those values are sent to the column.

  The keys "ID" and "TENANTID" are required when using the default tables.

  Use the JSONata transformation section to include your own arguments for dashboard table columns by making a selection from the **Select template** drop-down menu. Choose between **Show sample column mapping** or **Use columns from table**. When you start typing in the **JSONata transformation** (or press Ctrl + Space), a suggestion panel with alert properties is shown. Move the cursor into the panel to scroll and select from the list of properties. As you make changes in this section, the **Input for dashboard table** (section 3) shows a preview of your transformation.

Parameter suggestion panel

  Warning: Any changes that you make to the source alert are reset if you reedit the parameter mapping.

- Section 3: **Input for dashboard table**

  This section shows the results of your transformation and what the content of the table columns contain based on the current sample alert and transformation rules that are used above. For columns that rely on date/time, such as "FIRSTOCCURRENCETIME", use the value from the selected entity (that is, `"FIRSTOCCURRENCETIME": alert.firstOccurrenceTime`).

13. Click **Save input** to save your changes and close the editor. Then, click **Create policy** to save the policy.

    New and updated policies can take up to 2 minutes to take effect.

Policy editor

You can create or customize policies by adding or editing conditions in the policy and the actions that are triggered. Policies are triggered upon alert creation only. This topic contains an example of editing a policy from the policy table. You can also edit a policy from the **Details** tab in the side panel.

Important: In incident policies, only the actions from the first matching condition set are executed. In runbook policies and scope-based policies, the actions from every matching condition set are executed. Suppression policies contain only one condition set.

Policy details and Execution order

The first two sections of the policy editor are **Policy details** and **Execution order**. Here you name (or rename) the policy and add a description. To set the execution order for the policy, use the slider or enter a value between 1-100. Policies with a lower number are processed first. Preset policies that handle system needs are executed before or after those with a value of 1-100. User-created suppression policies are always executed first. The order is set to 0 and cannot be changed.

To see how your current policies are set, click on the following number of policies listed for each range.

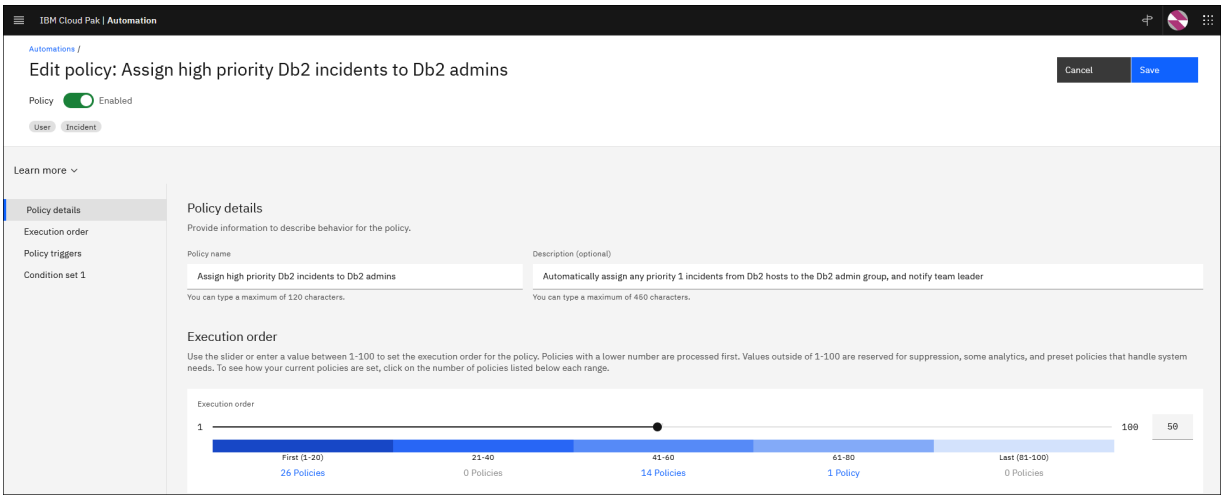


Figure. Policy details

Policy triggers

With the exception of suppression policies, all other policy types have a **triggers** section. These policies are triggered when an alert is created, updated, or both. Updated means the alert state changes. For example, if an alert changes from Severity 1 to Severity 5. If the policy is triggered by the alert create or update, then the conditions are consulted.

If you select **After an alert has been updated**, alert properties can be specified in the policy trigger. As with condition sets, when **`alert.details`** is selected you can specify a singular key within the alert's details to minimize the scope of the policy trigger. You must enter a string value that matches a key from an alert's details. If the Details name input is left empty, all of the details and the details' names are searched. You can also access additional properties of **`alert.sender`**, **`alert.resouce`**, and **`alert.type`** by typing your custom property (for example, **`alert.type.customProperty`**) and selecting the "**`Value of: alert.type.customProperty`**" option. The supported special characters "-" (dash) and "_" (underscore) must be used with square brackets (that is, [custom-name]). There is a character limit of 255.

Figure. Policy triggers

Note: With the Invoke an IBM Tivoli Netcool/Impact policy, you can select either alert or incident properties in the trigger section.

Condition sets

In a **Condition set** you configure the conditions that alerts must meet. For new policies, start by adding a condition set. At least one is required. Condition sets are created based on alert properties and Cloud Pak for AIOps alert insights. Click **Add condition** to select a new condition type from the drop-down menu.

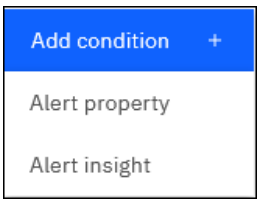

Figure. Custom alert insights

Choose from the following condition types:

- **Alert properties**: Alert attributes that are predefined for IBM Cloud Pak for AIOps and common to most alerts. For more information, see Alert details.

- When **`alert.details`** is selected in the property field or the value field, a secondary input box is displayed underneath. The **Details name** field is an optional input where you can minimize the scope to a singular key within the alert's details. For example, if you enter **`specificKey`** in the Details name field, it is understood as **`alert.details.specificKey`**. If the Details name input is left empty, all of the details and the details' names are searched and operators of **`contains`**, **`does not contain`**, **`is empty`** and **`not empty`** are the most useful. The Details name field does not provide suggestions for possible keys. You must enter a string value that matches a key from an alert's details. Details name if provided cannot contain spaces, double quotes, backslash, or square brackets.
- You can also access additional properties of **`alert.sender`**, **`alert.resouce`**, and **`alert.type`** that are not in the default alert schema. Type your custom property (for example, **`alert.type.customProperty`**) and select the "**`Value of: alert.type.customProperty`**" option. The supported special characters "-" (dash) and "_" (underscore) must be used with square brackets. (that is, [custom-name]). There is a character limit of 255.

- **Alert insights**:
  - *Anomaly*: Log anomaly and metric anomaly attributes that are predefined for IBM Cloud Pak for AIOps. For more information, see Supported Anomaly insights.
  - *Business criticality*: Set in Resource management to define the importance of an application, resource group, or resource to the business. For more information, see Defining business criticality.
  - *Golden signal*: Select from predefined golden signal **`labels`** and **`types`**.
    - *Labels*: **`traffic`**, **`latency`**, **`error`**, **`saturation`**, **`availability`**, **`information`**.
    - *Types*: **`effect`**, **`cause`**, **`none`**.
  - *Seasonal*: Alerts that occur within a seasonal time window.

Note: Schema descriptions for both Alert properties and Alert insights are displayed on the UI. Click anywhere in **Property** field and move the cursor over the properties to display the descriptions.

Schema descriptions

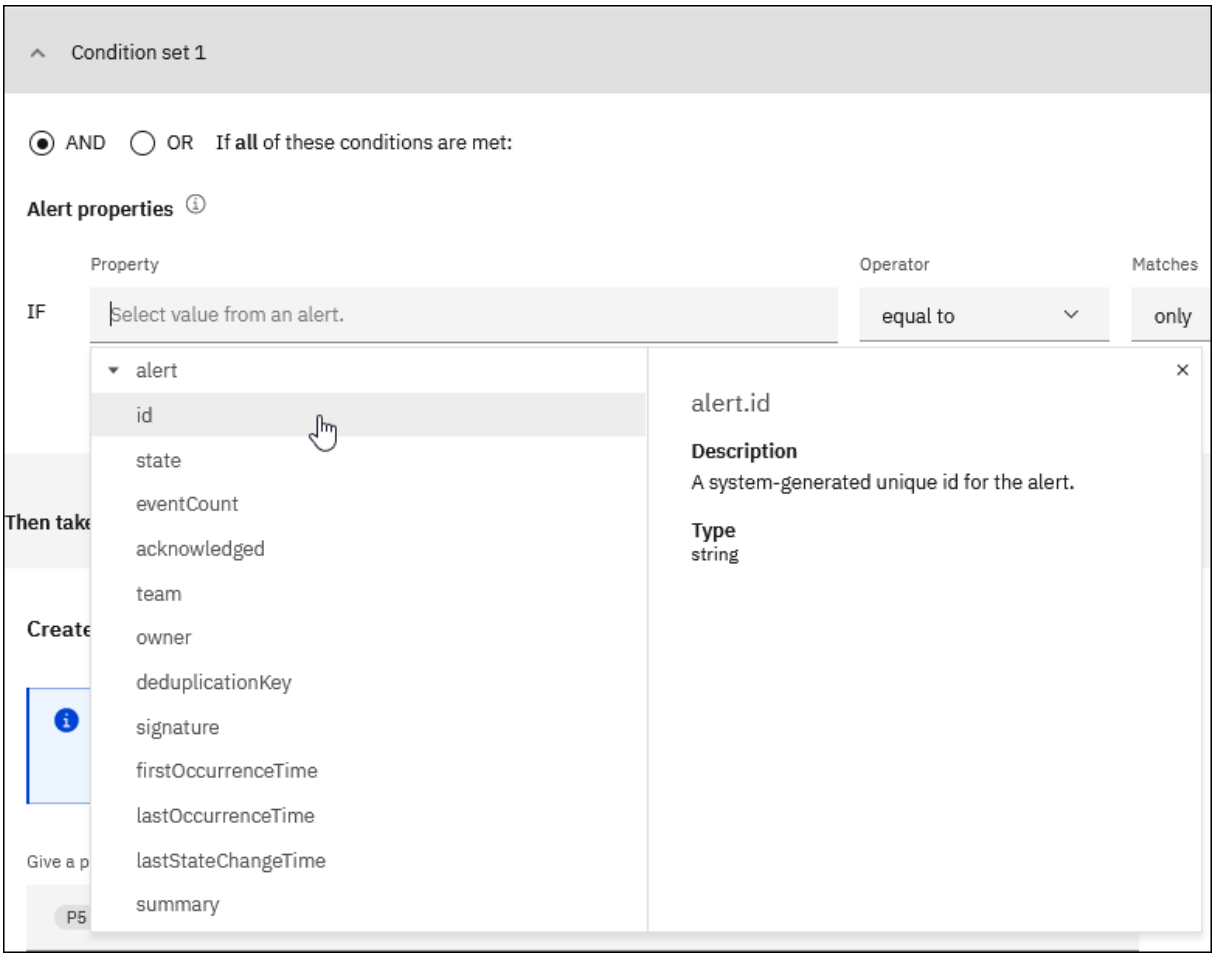

Figure. Schema descriptions

When adding conditions, you can join multiple condition types by using the AND and OR operators. The AND operator means that alerts are matched only if all of the individual conditions are true. The OR operator means that alerts are matched if any of the individual conditions are true.

In the fields provided, select the **Property**, **Operator**, **Matches**, and **Value** for the new condition. Setting a **Value** field to the value of another property allows you to compare the value of one property to one or more other properties. Click anywhere in the **Value** field and scroll the tree-view to select from the available options. You can also enter the last part of the fully qualified tree-view name to see and select the tree-view "value of" alert or insight field. To enter a string value, type the string (e.g. "Error") in the **Value** field and then select **String: Error** from the drop-down. If you enter a fully qualified tree-view value, you can save it as a string versus the "value of". To enter a numerical value, type the number (e.g. "10") in the **Value** field and then select **Number: 10** from the drop-down. Note, negative values are also supported for type Number fields.

If you need more than one condition set, click **Add condition set**. Alternatively, to copy and paste an existing condition set click **Copy condition set**. To rename a condition set, point the cursor over the condition set name and click Edit. You can use the sidebar to navigate a policy's condition sets and actions. To remove a condition set, click **Delete**. At least one condition set is required.

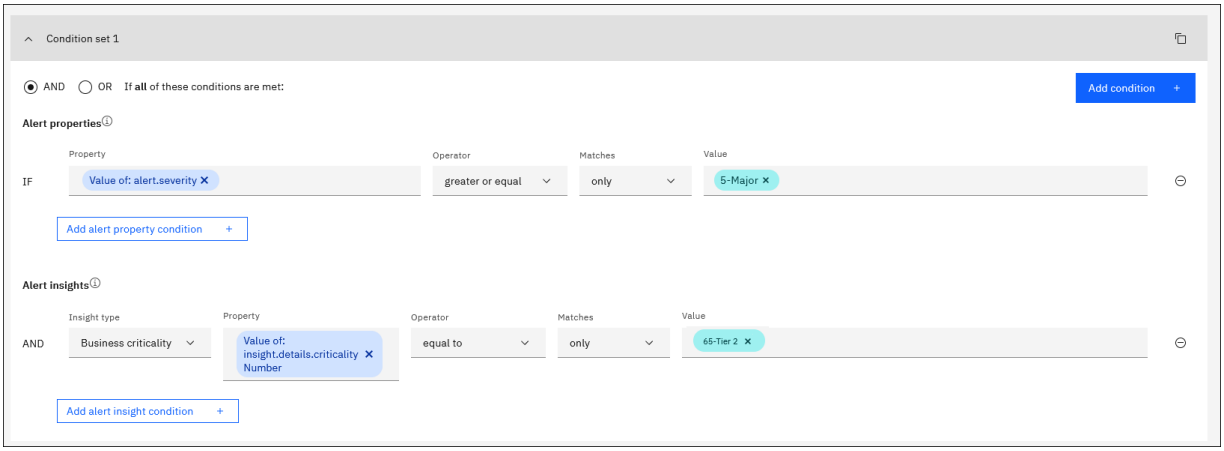

Figure. Condition set

Notes:

- Suppression policies contain only one condition set. You cannot add or copy condition sets in these policies.
- Some information icons in the Policy editor are activated by hover-over, others are activated by clicking. This depends on nearby controls and groups on the UI. Some pages can contain a mixture of hover-over and clickable information icons.
- Unlike **Alert details** properties, **Alert insights** conditions like **Business criticality** and **Anomaly** conditions cannot evaluate `true` where Business criticality or Anomaly insights contain no value. For these two property types, Cloud Pak for AIOps checks first for a value, and if it is not present, `false` is returned. If the value is present, the condition that is assigned by the user is evaluated, and `true` or `false` is returned as determined. Therefore, it is a best practice to avoid use of the negative **Operator** property "**not equal to**" when you use Business criticality and Anomaly insights properties.

Actions

Actions are where you specify what is triggered when the policy conditions are met:

- Suppression policies: the action is always to suppress the alerts described in the condition sets.
- Scope-based policies: the action that is taken is defined by alert properties and strings to create the ScopeID for a group. These properties define the scope for how the alerts are grouped.
- Runbook policies: choose one or more runbooks to assign when the policy conditions are met, and select how parameters are passed.
- Incident policies: the action is the creation of an incident with a specified priority level (example below). You can optionally delay the creation of an incident by setting a hold off time, select how you want to be notified about the incident, open a ticket (GitHub or ServiveNow), and assign a user group and owner.
- Invoke an IBM Tivoli Netcool/Impact policy: enable Cloud Pak for AIOps to invoke an IBM Tivoli Netcool/Impact policy that will take actions on your alerts.

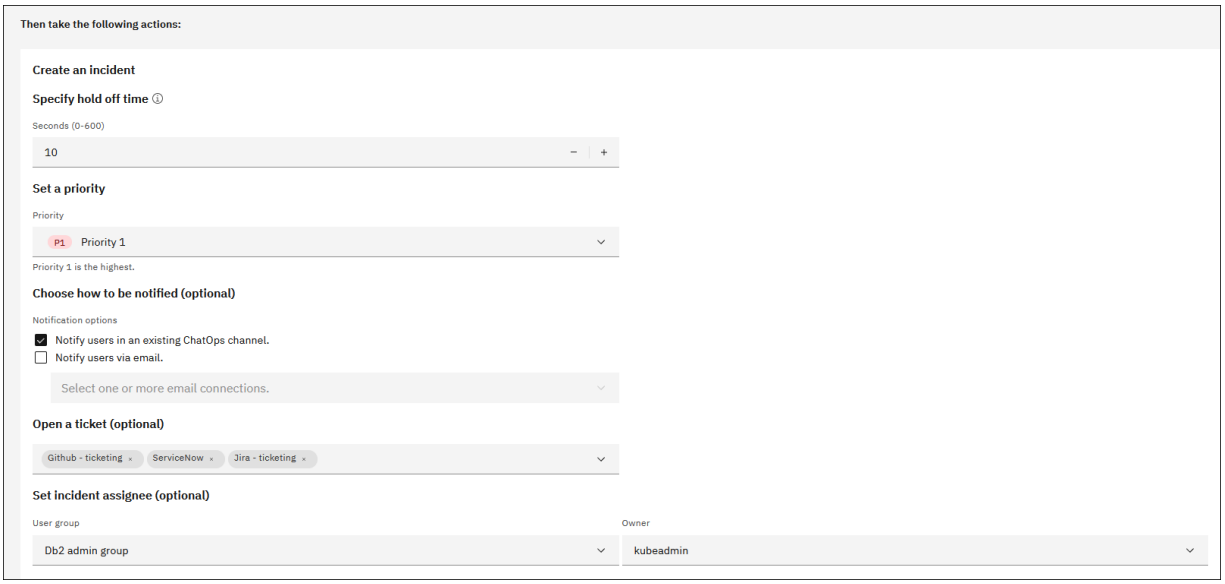

Figure. Actions

Example

In the following example, a condition is added to an existing policy so that the policy applies only to alerts that have a prefix of either "Error" or "Warning" in their Summary field.

1. Click the navigation icon in the toolbar to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. In the table row of the policy that you want to edit, click the menu overflow icon (the three dots at the end of the row) to and select **Edit policy**.
4. Click **Add condition** and select **Alert property**.
    1. From the Property drop-down list, select **alert.summary**. You can type "sum" and the system will show in the property drop-down list all alert properties that contain the text "sum", which in this case is only alert.summary.
    2. From the Operator drop-down list, select **Contains**.
    3. From the Matches drop-down list, select **any of**.
    4. In the Values field, type **Error** and then click **String:Error** in the pop-up. In the same field, type **Warning** and click **String:Warning**.

    

    Figure. Policy example
5. Click **Save** to save your changes.

    If the save button is not active, one or more items might be missing in the conditions or runbook parameter sections. If clicking save fails to exit the edit session, again, check that no required details are missing.

Note: New and updated policies can take up to 2 minutes to take effect.

IBM Cloud Pak® for AIOps determines which of your alerts were caused by the same problem. If an active incident exists for a given problem, a new incident is not created.

For more information about creating policies, see the following topics:

- Suppress alerts
- Group alerts based on scope
- Assign a runbook to alerts
- Promote alerts to an incident

Supported Anomaly insights properties

In a policy condition set, you can suppress alerts and create reports from alerts by using the following types of **Anomaly insights** properties:

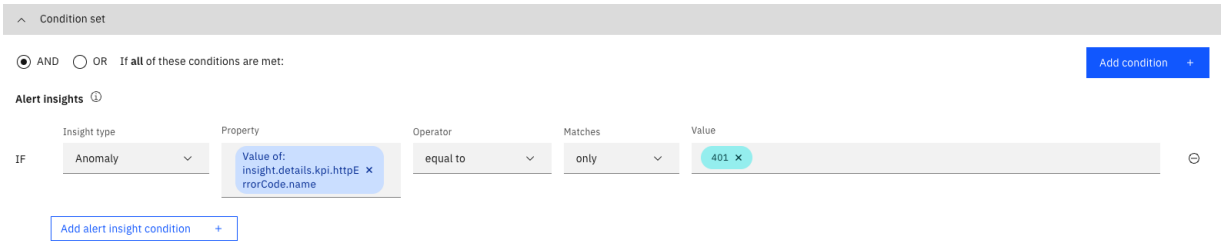

Table. Anomaly insights properties

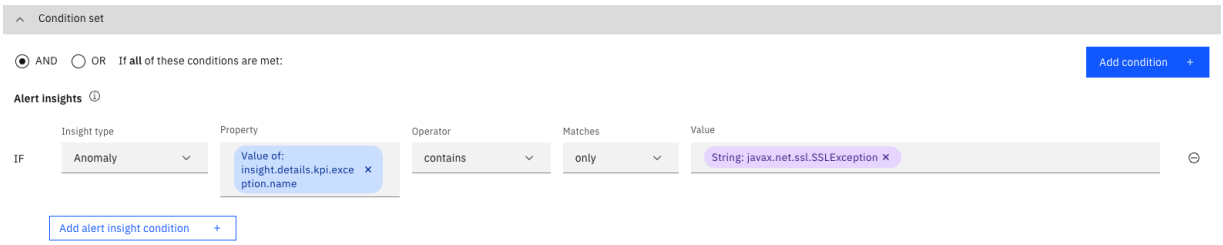
Property	Description	Type	Possible values
`httpErrorCode.name`	HTTP error code	`string`	400, 401, 403, 408, 429, 500, 502, 503, 504, 5xx
`httpErrorCode.unit`	Unit for the HTTP error code KPI	`string`	Count
`exception.name`	Name of the exception (for example, a token that contains the string `exception` found within a Log)	`string`	
`exception.unit`	Unit for the exception KPI	`string`	Count
`messageId.name`	An IBM WebSphere MQ message ID	`string`	
`messageId.unit`	Unit for the message ID KPI	`string`	Count
`metric.name`	Metric name	`string`	
`metric.unit`	Unit for the metric KPI (for example, bytes, mb, ms, s)	`string`	
`actualValue`	The observed value for a KPI.	`number`	
`expectedlValue`	The expected value for a KPI.	`number`	
`expectedRange.upperThreshold`	The expected upper bound of the count/frequency of the KPI in a given time aggregated window.	`number`	
`expectedRange.lowerThreshold`	The expected lower bound of the count/frequency of the KPI in a given time aggregated window.	`number`	
`resourceAggregator`	This field is optional. An entity in the underlying client application that can be used to logically aggregate all anomalies that are related to the same application resource. For example, in the context of Metric anomalies this would be a server that might be used to aggregate anomalies across all ports exposed by that server. For Log anomalies, this might be a Kubernetes ReplicaSet that aggregates all the pods it manages.	`string`	

Using properties for alert suppression

Scenario 1: Alert suppression based on HTTP error codes

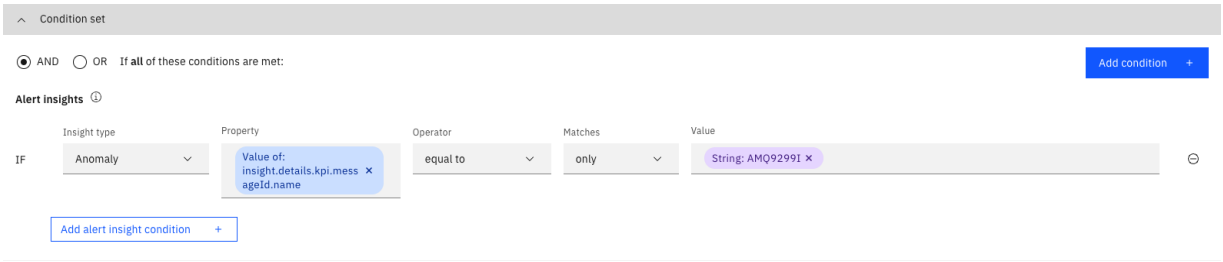
You might expect the system to generate certain HTTP error types at regular intervals. However, these alerts do not require action and you do not want alerts and incidents generated based on these errors. You can enable alert suppression to avoid new alerts from being generated.



Example 1: Suppress alerts for any 401 error code.

Scenario 2: Alert suppression based on exceptions present in log messages

Some exceptions present in log messages might not be a priority or cause any outages for your environment. As a result, you might want to suppress any alerts that are generated by these exceptions captured in logs.

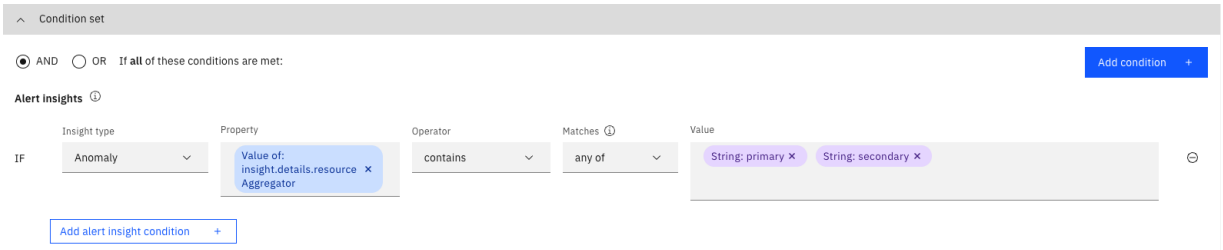


Log anomaly suppression policies can reference only computed or derived entity values from the RSA algorithm, such as the exception name. To suppress certain log anomaly alerts based on the exception name, go to the IBM Cloud Pak® for AIOps Suppress Alerts automation page. Then, from the Alert insight category suppression options, choose the **`insight.details.kpi.exception.name`** property. However, you cannot define a log anomaly suppression policy that references the string message that is found in the log record.

Example 2: Suppress all alerts generated by exceptions of the type javax.net.ssl.SSLException.

Scenario 3: Alert suppression based on domain-specific error code entities that are present in the logs

Domain-specific logs, such as IBM MQ or WebSphere, include error code entities that you can use to set policies to suppress alerts. For example, use the **`insights.details.kpi.messageId.name`** field in an Anomaly insights condition set to suppress alerts that match that entity.

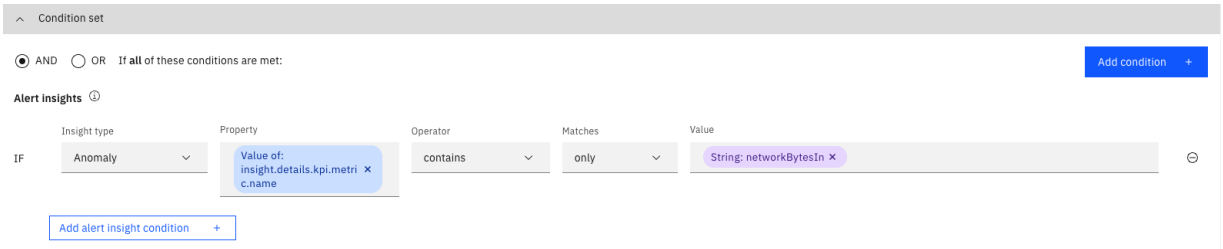


Example 3: Alert suppression based on an incident where the message name equals AMQ9299I.

Using properties for creating runbooks

Scenario 4: Create a runbook based on resource name

Use the **`resourceAggregator`** field in an Anomaly insights condition set to create a runbook based on resource name.



Example 4: Create a runbook for any resource that contains either primary or secondary.

Using properties to invoke IBM® Tivoli® Netcool®/Impact

Scenario 5: Invoke Netcool/Impact based on metric name

Use the **`metric.name`** field in an Anomaly insights condition set to invoke Netcool/Impact based on metric name.

Example 5: Invoke Netcool/Impact where the metric name contains networkBytesIn.

Best practices for condition sets

For certain scenarios, some best practices are recommended for the **Operator** and **Matches** fields in a policy condition set.

Scenario: comparing against multiple string values

- For the operator **not equal to** use **all of**. If the property under test is null a false positive will occur, therefore, also add a check for **not empty** property.
- For the operator **does not contain** use **any of**. If the property under test is null a false positive will occur, therefore, also add a check for **not empty** property.
- For the operator **contains** use **any of**.

Scenario: looking for unassigned owners

- If you need a policy condition to search for unassigned owners or teams, the **is empty** operator does not work with the `alert.owner` or `alert.team` properties. Use the **equal to** operator instead, with **only** and enter a minus sign (-) value.

Example: search for unassigned owners

Refreshing the policies table

Refresh the policies table to view all the latest policies at the current point in time.

If any filters are applied to the table, click **Clear filters** first to view a complete list of policies.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click Refresh to refresh the table at anytime. A refreshed policy count is displayed above the table beside **Policies**.
4. You can also click start to refresh the table with with auto-refresh every 90 seconds. Click stop to turn off auto-refresh.

Note: Applying filters automatically refreshes the table.

Managing multiple policies

You can multi-select policies and apply actions to all of your selections at one time.

Note: When a multi-select of policies includes different policy types, not all actions can be applied. For example, preset policies cannot be deleted.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Select multiple policies from the table by using the checkboxes at the beginning of the table rows.

   Tip: You can select all of the policies in the table by clicking the checkbox in the table header beside **Policy name**.
4. A banner above the table displays the number of policies that are selected, together with a menu of options. The following actions can be applied to multiple policies at the same time:

   - **Enable**
   - **Disable**
   - **Archive** (Seasonal and Temporal policies only)
   - **Delete**

Renaming policies

A global unique identifier string is used to identify analytics policies. You can rename policies to give them more meaningful names. Preset policy names cannot be customized.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Point the cursor over the **Policy name** that you want to change and click Edit.
4. Enter a new policy name in the field provided.
5. Click the check mark to save the policy name or click cancel to discard your changes.

Note: When editing is enabled for the policy, the name can also be updated in the policy editor.

Archiving policies

You can archive alert seasonality and temporal grouping policies that are not in use. Archived policies don't act on incoming alerts.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Filter the table to display **Temporal** and/or **Seasonal** policies, or search for a policy by entering a search term in the field provided.
4. In the table row of the policy that you want to archive, click the options menu (three vertical dots) at the end of a table row and select **Archive policy**.
5. To confirm the archive, click **Archive policy**.

Archived policies can be viewed and managed in Draft and archived policies.

Migrating Netcool correlations to Cloud Pak for AIOps

Many deployments of Cloud Pak for AIOps are done where an existing Netcool environment already exists. Part of the migration over to Cloud Pak for AIOps is the deactivation of event correlation in the Netcool layer, and its reimplementation in Cloud Pak for AIOps. This is necessary because how groupings are created is different between Netcool and Cloud Pak for AIOps and the representation and linkages are not compatible:

- Netcool uses either real or synthetic parent events whose children are linked via a key linkage field - often `@ParentIdentifier`.
- Cloud Pak for AIOps stores grouping information as metadata within each correlated event - parent events are only virtual and are rendered in the Alert Viewer.

The major advantage of Cloud Pak for AIOps over Netcool is that events can be a member of any number of groups, either of the same or different kinds of groups. Whereas Netcool requires a linkage between a parent event and a child event via a static field, Cloud Pak for AIOps stores this metadata within the alert payload. There is no programmatic limit on how much metadata can be stored in an Cloud Pak for AIOps alert, which results in a much more flexible grouping model.

There are three main grouping capabilities that are provided in both Netcool Operations Insight and Cloud Pak for AIOps. The following paragraphs outline how these groupings can be migrated from the Netcool layer to the Cloud Pak for AIOps layer:

- **Temporal**

  Temporal groupings that are found in either the Netcool/Impact based Event Analytics or the newer Cloud Native Event Analytics (CNEA) engine are not transferable to Cloud Pak for AIOps. Cloud Pak for AIOps must ingest event data from Netcool (and other sources) and retrain on the data internally. Any temporal grouping in Netcool Operations Insight should be deactivated before enabling temporal grouping in Cloud Pak for AIOps.

- **Topology-based**

  Netcool Operations Insight includes the same topology capability as Cloud Pak for AIOps and also supports topology-based event correlation. It works the same in both environments and must be set up in Cloud Pak for AIOps to match the configuration in Netcool Operations Insight. Any topology-based grouping in Netcool Operations Insight should be deactivated before enabling topology-based grouping in Cloud Pak for AIOps.

- **Scope-based**

  Netcool Operations Insight includes a similar scope-based grouping capability as Cloud Pak for AIOps. By default, the Netcool Connector maps `@ScopeID` in Netcool Operations Insight to `resource.scopeId` in Cloud Pak for AIOps. The default Cloud Pak for AIOps policy called Default Netcool scope-based grouping - with a rolling window of 15 minutes will automatically detect any inbound events with the `resource.scopeId` attribute set and perform scope-based grouping on it. As the name suggests, this is done with a rolling 15-minute window. This policy provides a convenient like-for-like function and makes migration from Netcool to Cloud Pak for AIOps relatively easy in this respect. You can also disable this default policy and create your own, if you have more specific or complex requirements - for example, you require various time windows for different correlation scenarios.

  Note: Netcool/OMNIbus in the absence of Netcool Operations Insight only has scope-based event correlation, if enabled. For more information, see https://www.ibm.com/docs/en/netcoolomnibus/8.1?topic=netcoolomnibus-enabling-scope-based-event-grouping.

Custom correlations in Netcool

Many implementations of Netcool include custom correlations where one or more child events are linked to a parent event. While the grouping engine itself is eventually deactivated at the Netcool layer, in a combined Netcool and Cloud Pak for AIOps deployment, the correlation logic can remain in-place. With the grouping instead done at the Cloud Pak for AIOps layer. A method for achieving this is outlined here.

Procedure

1. Create a custom correlation field.

   Create a custom field to hold the key data value that will tie each event set together. Use the `nco_sql` utility to create the field:

   ```
   1> ALTER TABLE alerts.status ADD COLUMN CustomCorrelation1 VARCHAR(64);
   2> go
   ```

2. Modify the correlation logic.

   The next step is to modify the automation that is correlating the events together, whether it's a Netcool/OMNIbus ObjectServer trigger or a Netcool/Impact policy. The logic of the automation remains the same as before, the only change being how the events are tied together. In the new correlation design, the automation must compute a key data value that is set in the newly created custom correlation field - in this case `@CustomCorrelation1`. The value must be set to the same value across all members of the correlation set, and be sufficiently unique so that incorrect items are not inadvertently correlated together.

3. Map the custom correlation field.

   Map the custom correlation field to Cloud Pak for AIOps. This is done in Cloud Pak for AIOps by editing the mapping of your Netcool integration instance and adding in a details attribute. The following extract from a Netcool integration mapping shows the insertion of the details section into the mapping, immediately under the **expirySeconds** attribute:

   ```
   "eventCount": alert.@Tally,
   "signature": alert.@Identifier,
   "firstOccurrenceTime": alert.@FirstOccurrence,
   "lastOccurrenceTime": alert.@LastOccurrence,
   "severity": alert.@Severity < 0 ? 1 : alert.@Severity = 0 ? 2 : alert.@Severity < 6 ? alert.@Severity +
   1 : alert.@Severity >= 6 ? 6,
   "state": alert.@Severity = 0 ? "clear" : "open",
   "acknowledged": alert.@Acknowledged = 1 ? true : false,
   "expirySeconds": alert.@ExpireTime = 0 ? undefined : alert.@ExpireTime,
   "details": {
       "customCorrelation1": alert.@CustomCorrelation1 = "" ? undefined : alert.@CustomCorrelation1
   },
   ```

   Click **Save** to save your new integration mapping. Note, this results in the Netcool Connector pod restarting. The new mapping will only take effect on events that are newly inserted into the Netcool/OMNIbus ObjectServer. You can add as many custom correlation fields (comma separated) as required to this details section.

4. Create a Cloud Pak for AIOps correlation policy.

   The final step is to create a scope-based grouping automation policy in Cloud Pak for AIOps to group the incoming event stream by your newly created attribute.

   1. Give your policy a meaningful name.
   2. Set the priority.
   3. For the policy trigger, select **Before an alert is created**.
   4. Add a condition that the policy fires when your custom attribute is "**not empty**".
   5. Under **Create a scope-based grouping**, enter your custom attribute.

6. Specify the required time window.
7. Specify whether the time window is rolling or fixed.

   Example scope-based policy

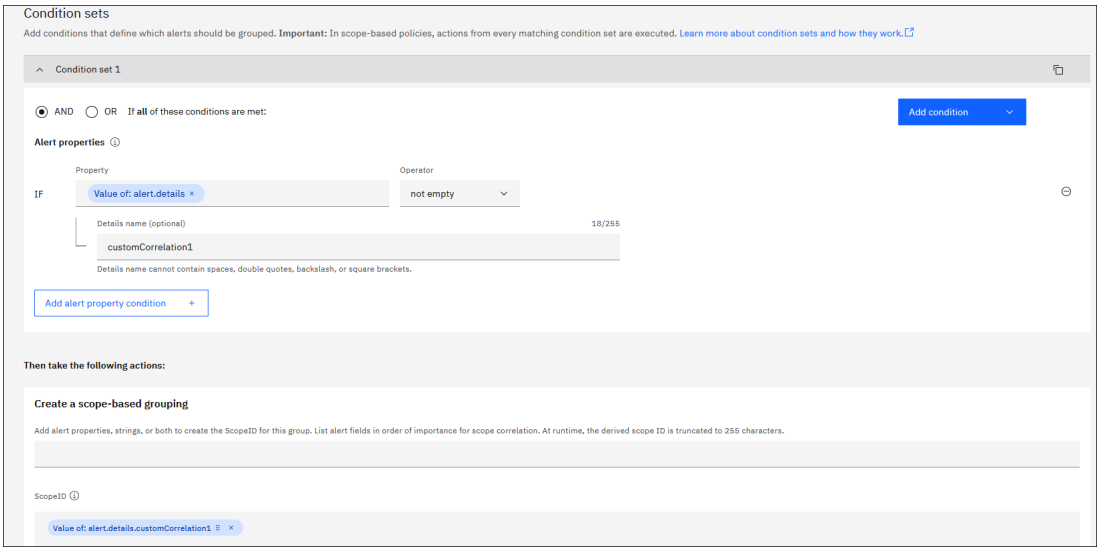


Figure. Scope-based policy

8. Click **Create Policy**.

You should now start to see your custom correlation working in Cloud Pak for AIOps. Remember, this policy will only work for new events, not existing events.

One of the major advantages in Cloud Pak for AIOps over Netcool is that you can set up as many scope-based grouping automations as required. Therefore, you can use this process to migrate all of your custom correlations in Netcool over to Cloud Pak for AIOps.

About runbooks

Use Runbook Automation to build and execute runbooks that can help IT staff to solve common operational problems. Runbook Automation can automate procedures that do not require human interaction, thereby increasing the efficiency of IT operations processes. Operators can spend more time innovating and are freed from performing time-consuming manual tasks.

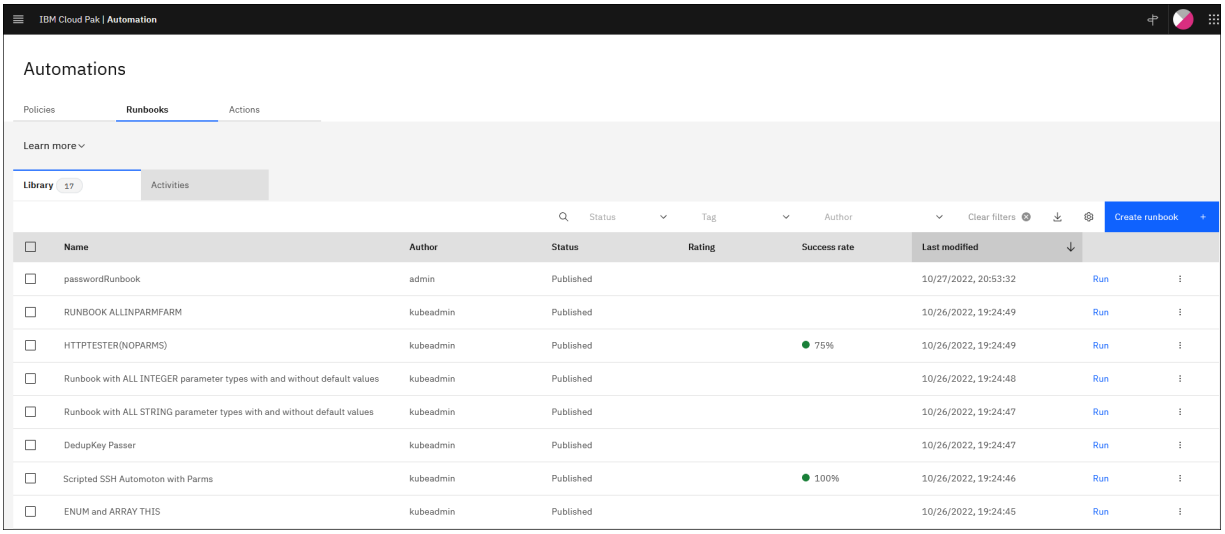

Figure. Runbooks Library UI

- What problems does Runbook Automation address?

  IT systems are growing. The number of events are increasing, and the pressure to move from finding problems to fixing them is increasing. Runbook Automation supports operational and expert teams in developing consistent and reliable procedures for daily operational tasks.

- How can I simplify daily operational tasks?

Using Runbook Automation, you can record standard manual activities, so that they are run consistently across the organization. The next step is to replace manual steps with script-based tasks.

- What is a runbook?

  A runbook is a controlled set of automated and manual steps that support system and network operational processes. A runbook orchestrates all types of infrastructure elements, such as applications, network components, or servers.

Runbook Automation helps users to define, build, orchestrate, and manage runbooks. Metrics about runbooks are also provided. A knowledge base is built up over time through collaboration between Subject Matter Experts (SMEs) and operational staff.

Runbook types

Transfer your procedure based documentation to manual runbooks. Then add actions and continue with semi-automated runbooks or fully automated runbooks.

Runbook Automation supports three different types of runbooks:

- Manual runbooks

  Steps describe the exact procedure that an operator must follow. The operator uses standard tools, which can be accessed from their working environment.

- Semi-automated runbooks

  Each step describes exactly what an operator must do. Additionally, the operator can run an automated task on a target system.

- Fully automated runbooks

  The runbook runs automatically without operator interaction.

Actions

Actions are a task that run autonomously on a target system. For example, a shell script that identifies many files in a file system.

Runbook Automation supports the following technologies to connect to a backend system:

- Script

  Actions of this type contain a complete script. When a SSH Action runs, the content is sent to the target system and executed. Scripts can be of type Bash or PowerShell, depending on the target system.

- HTTP

  Actions of this type define the specific properties to make a secure HTTP call.

- Ansible

  Actions of this type reference existing Job Templates or Workflow Job Templates on an Ansible Automation Platform Controller server and run them with the defined variables.

For more information, see Actions.

Runbooks Library

View the available runbooks, find matching runbooks for the alerts that you need to resolve, and run the runbooks. You can also review the runbooks that you have used to date. The library also provides ready-to-go sample runbooks. Load the examples to explore what you can do with runbooks. Document your existing operational procedures using the runbook editor. Share the knowledge and experience that you documented in a runbook with your team members. The runbook editor provides editing capabilities as well as runbook elements that help to document operational procedures. Runbook elements are designed to avoid mistakes.

For more information about the Runbooks Library, see the following topics:

- Run your first runbook
- Load example runbooks
- Create a runbook
- Edit a runbook

- Configuring runbook creation
- Runbook versions
- Save and publish a runbook
- Filtering runbooks
- Assigning runbooks to groups
- Export and import runbooks
- Delete a runbook

Run your first runbook

If you are using Runbook Automation for the first time, it is recommended to load example runbooks and then edit and publish a runbook. For more information, see Load and reset example runbooks and Edit a runbook.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Runbooks**.

   The **Library** tab is displayed by default.
4. Select a runbook and click the menu overflow icon (the three dots at the end of the row) and select **Preview** to find out what a runbook consists of:

   - **Procedure**:

     The Procedure section displays the runbook steps. For more information about the runbook elements, see Edit a runbook.

   - **Information**:

     The information tab provides descriptive details of the runbook and contains the following fields:

     - Description: shows a description of the runbook.
     - Runbook ID: ID of the runbook which can be used to identify the runbook using the Runbook Automation HTTP REST Interface.
     - Created by: the user who created the runbook.
     - Last modified at: the date and time the runbook was last modified.
     - Last modified by: the user who last modified the runbook.
     - Type: indicates the runbook type, that is manual, semi-automated, or fully automated.
     - Tags: categorization tags associated with the runbook.
   - **Versions**:

     Shows all draft, published, and archived versions of the runbook. You can also see the user that created each version and the creation date.
5. Back on the main **Runbooks** page, select one of the runbooks and click **Run**.
6. The **Run runbook** page opens, which consists of a procedure description on the left side of the window and a **Details** and **Information** section on the right. **Details** contains the following collapsible sections:

   - **Parameters** – displays a list of the parameters used.
   - **Actions** – displays a list of the actions used.
7. In the **parameters** section you are requested to enter parameter values. Click the information icon to see a description and a reference to where this parameter is used within the runbook. Enter the parameter values, for example host1 for the parameter **`HOSTNAME`** and click **Start runbook**.

   Note:

   - In some cases, you might not know the parameter value when starting the Runbook. For example, the parameter could be determined by a runbook step during the runbook execution. In this scenario, as soon as the parameter value is known, go back to the parameter section and enter the parameter value. To apply the value click **Update parameters**. The **Update parameters** button is only displayed if the parameter value has been entered.
   - In any step of a runbook, you can select the parameter section of the runbook in the **Details** on the right of the window. You might need to first expand the section if it is collapsed. The parameter can then be changed to a new value. To apply the new value click **Update parameters** (the **Update parameters** button is only displayed if the parameter value has been changed). As soon as a parameter has been used by a Runbook step, it cannot be changed.
8. Click **Start runbook**.
9. Follow the instructions in the runbook and proceed to the next step by clicking **Next step**.

10. If the step contains a command, use the **Copy** button within a command to copy the command to your clipboard. Open a command-line window and paste the command.
11. If the step contains an action, click on the action and select **Run** to run the action. **Note**: If running the action is not appropriate in the particular situation, then you can also choose to proceed without selecting **Run**. If you select **Run**, the action output is displayed in a text box. If an action produces JSON output, the JSON document is automatically formatted for better readability. Select **More info** to see description, parameter values, and type information.

    If the type of action is "Client-side", then the label of the **Run** button is replaced with **Launch**. Clicking this button launches the URL from the Client-side action in a new browser tab. You can review the resulting URL in the action output area and launch it again by clicking the displayed URL hyperlink.
12. You can pause or cancel the runbook by clicking **Pause** or **Cancel**. Pause temporarily suspends the execution of the runbook. You can pick up later from where you left off. You can use **Pause** to handle long running actions, for example actions that take longer than 10 minutes. The actions that are in progress continue while you pause the runbook. If you cancel the runbook you are prompted to select a reason. This feedback is helpful to the author of the runbook.
13. After you completed all steps, click **Complete** at the end of the runbook. Provide a rating, a comment (both optional), and a final assessment of the runbook. You are taken back to the **Library** page.
14. The **Activities** tab provides the **Runbook activities** table. Here you can find all the runbooks that were executed with information such as Status, Start time, Version, Comments, and if the runbook is automated. Filters such as user, runbook status, runbook type and runbook name can be applied. For more information, see Activities.

Load and reset example runbooks

Load ready-to-go sample runbooks to explore what you can do with runbooks.

Warning: If you want to edit a sample runbook and adjust it to your requirements, or if you are considering publishing a modified sample runbook to use in production, it is recommended to first create a copy of the sample runbooks and then edit and publish the copy. Similarly, if the sample runbook uses an automated step, then create a copy of the automation action and use that copy within your new runbook. This is to avoid losing your work (or even disrupting production) if somebody deletes or reloads the sample runbooks.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Integrations**.
3. Ensure that a connection of type "SSH" has been configured. If not, you can configure it now (with default values).
4. From the main navigation menu, click **Operate** > **Automations**.
5. Click **Runbooks**.

    The **Library** tab is displayed by default.

Load sample runbooks

Load all pre-defined examples. You can also edit the example runbooks and create new versions.

1. Click **Load sample runbooks** on the upper right of the window (beside the **Create runbook** button) and select **Load sample runbooks**.
2. The sample runbooks are shown in the **Library** page. The runbooks will show up for Operators if they are published. The samples are marked by the text "Example:".
3. Click **Preview** to view the runbook and see what it does.
4. Click **Run** to run your first runbook. For more information about how to run a runbook, see Run your first runbook.

Sample runbooks with special administrative use cases

Some of the following sample runbooks go beyond just illustrating the features of runbooks:

- **Example: Convert existing operational procedures into runbooks**: This runbook explains how to convert your existing operational procedures into runbooks. It covers file based procedures and web/wiki based procedures.
- **Example: Import runbooks from an existing runbook deployment**: Provides instructions on how to export runbooks from one deployment and import them to another deployment. It uses the RBA API for both operations.

- **Example: Reduce amount of data in runbook data stores** and its automated variant **Example: Automatically reduce amount of data in runbook data stores**: Offload runbook execution data into a secondary data store for auditing or long-term storage purposes. This will delete that data from the production data store to ensure less disc space usage and faster response times on the active system.
- **Example: Add new SSH key to target systems** and **Example: Remove old SSH key from target systems**: These sample runbooks assist you during deployment migration. As part of the migration, you must install the SSH key of the new deployment to all target systems that were previously reached from the old deployment, using that old deployment's SSH key. This is a prerequisite step when you plan to migrate your runbooks and script actions from the old deployment to the new deployment. For more details, see Installing new SSH key during migration.
- **Example: Using the alerts API (basic)** and **Example: Using the alerts API (advanced)**: These sample runbooks demonstrate how you can create actions that use the Issue Resolution API to get and modify alerts. You can reference these actions within new custom menu items in the Alert Viewer as described in Working with alerts and menu customization to extend the built-in capabilities for managing alerts.

  As the Issue Resolution API is one of the supported IBM Cloud Pak® for AIOps APIs for HTTP actions, authentication is handled automatically provided that they are being run manually. For more information about automatic authentication, see the API endpoint section in Creating HTTP actions.

Reset sample runbooks

Follow these steps if you edited the examples and would like to reload the original version, or if you have upgraded to a new version and want to get the latest versions of the examples:

- Open the runbook **Library** page.
- Open the **Reload sample runbooks** menu.
- Select **Delete sample runbooks** and wait for the sample runbooks to be deleted.
- Open the Load sample runbooks menu.
- Select the **Load sample runbooks** menu item and wait for the sample runbooks to be loaded.

Convert a sample runbook to a regular runbook

To save a sample runbook as a regular runbook:

1. On the runbook that you want to convert, click the menu overflow icon (the three dots at the end of the row) and select **Copy runbook**.
2. Change the runbook name. You can optionally update the description.
3. Click **Save**.

   After saving, the runbook will no longer be tagged as an example.
4. If the sample runbook references an action, then you need to create a "deep copy" manually:
   - Navigate to the **Actions** table and select the referenced sample action.
   - Copy the sample action and modify its name so you can identify the copy.
   - Edit the copy of the sample runbook, and replace the reference to the original sample action with a reference to your new copy of the sample action.

Delete sample runbooks

1. Click **Load sample runbooks** and select **Delete sample runbooks**.
2. Confirm that you want to delete the sample runbooks from the **Library** page.

Creating a runbook

Document your existing operational procedures using the runbook editor. Share the knowledge and experience that you documented in a runbook with your team members.

Runbooks are created for one of the following reasons:

- Operators document their daily tasks in documents. Runbooks allow you to document and store these procedures in an ordered manner. When a runbook is published the knowledge can be shared between all operators.
- As a special case, create reusable runbook assets to combine those sequences of steps that otherwise would have to be repeated over and over again, and add them to your runbook as nested runbooks.

- A new set of events has occurred and a couple of skilled operators work out a new procedure to solve the issue that caused these events.

Procedure

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Runbooks**.

   The **Library** tab is displayed by default.
4. Click **Create runbook**. The runbook editor opens. For more information about how to use the editor, see Edit a runbook.
5. Provide data to describe the runbook. Make sure that you use a **Name** for the runbook that describes what problem this runbook solves.

   Restriction: Avoid using commas in runbook names. Runbook names containing commas cannot be filtered in the **Library** or on the **Activities** page.
6. (Optional): Provide a **Description**. The description contains information about specific situations that this runbook solves. Operators use the description to decide if a runbook meets their requirements.
7. (Optional): Add **Tags**. These help to filter a large amount of runbooks, as well as group runbooks with the same content.
8. Start adding steps to the runbook. Click **Add manual step**, **Add nested runbook step**, or **Add automatic step**.
9. Click inside the editor and describe the first step of your procedure. Use **commands**, **parameters**, **actions**, or **GOTO** elements to distinguish between different types of elements within a runbook. Remember to always create a new step if you start to describe a new task that the operator can run.
10. When all steps have been documented, click **Save draft** > **Save draft & close**.
11. Test the runbook. Search for your runbook on the **Library** page. Click **Run** to test the execution of the new runbook. Modify the runbook if necessary.
12. Publish your runbook.
    1. Click **Edit** to open the runbook editor.
    2. Click **Publish**. The runbook is now available to all operators.

Note: Runbooks are limited to a size of 1 MB. This relates to runbook metadata and its content (including embedded images). Attempts to create or edit runbooks in a way that exceeds this limit will result in an error.

Editing a runbook

The runbook editor provides editing capabilities as well as runbook elements that help to document operational procedures. Runbook elements are designed to avoid mistakes.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Runbooks**.

   The **Library** tab is displayed by default.
4. Click **Create runbook** to create a new runbook, or scroll through the list of runbooks and click the menu overflow icon and select **Edit** to open an existing runbook in the editor.

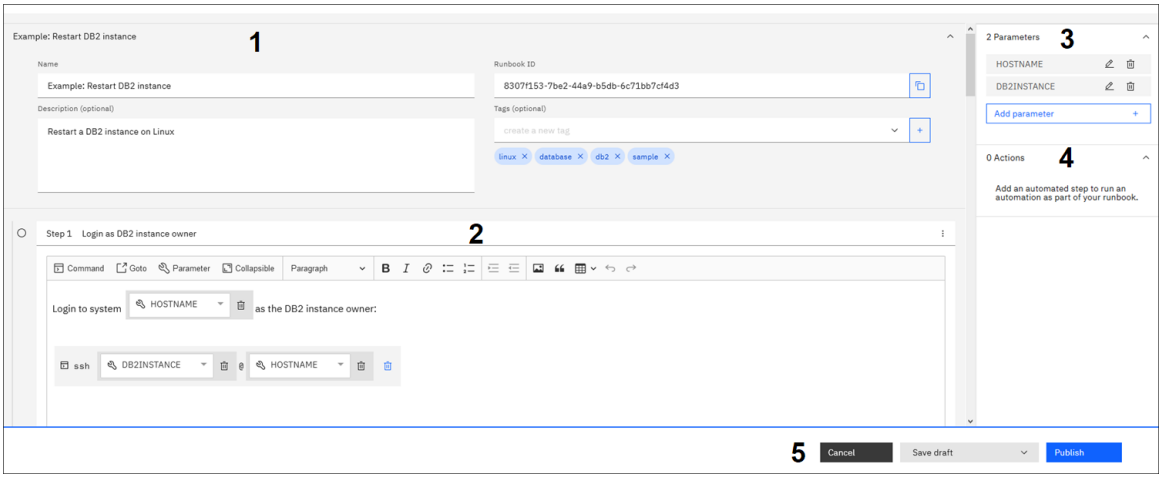

Figure. Runbook editor

Region 1 **Runbook details:** Enter descriptive data about the runbook.

- Name: the name identifies the runbook. Try to be as precise as possible and describe the problem that this runbook solves.
- Description: describe the problems that this runbook solves in more detail and sketch out the solution.
- Tags: provide tags to filter runbooks. You can select any existing tags from the drop-down list and click the plus icon "**+**" to add them. To create a new tag, type the text into the field, select the text string displayed, and click the plus icon "**+**".
- Runbook ID: this field is generated by Runbook Automation. The Runbook ID can be used to identify the runbook using the Runbook Automation HTTP REST Interface. Use the copy button to copy the ID to the clipboard.

Region 2 **Editor:** Provides text edit actions and runbook elements to describe operational tasks. Each step has its own section with an optional title. Manual steps cannot contain automation elements. Automated steps must be added for actions.

Region 3 **Parameters:** Create parameters that are used in this runbook.

Region 4 **Actions:** Add pre-defined actions to the runbook. Action steps only contain an action, no text.

Region 5 **Save and Publish** the runbook.

For more information about editing a runbook, see the following topics:

- Runbook elements and editing actions
- Adding actions
- Adding parameters
- Parameter types
- Adding a GOTO element

Runbook elements and editing actions

Use the editor to describe your daily tasks step by step. The editor provides editing actions and runbook specific elements to help you write the instructions.

Click **Add manual step** and use the following runbook elements and text editing actions to edit and format your operator instructions.

Icon	Name	Editing action
Command	Add command	Click the editor canvas. Select **Add command** and enter your command. Click **Enter** to quit the command and continue in the next row. Another way to enter a command is to mark the command and click **Add command**. As the command is still selected, you have to click on the canvas to deselect the command. Click **Enter** to quit the command and continue in the next row. **Keyboard shortcut:** Use the **tab key** to move the focus on the canvas. Press Ctrl + 4 and begin typing your command. **Remove command:** You can remove the command by placing the cursor in the command and clicking **Remove**.

Icon	Name	Editing action
	Add GOTO	Click the editor canvas. Select **Add GOTO**. A goto element is added with the label **END**. Click the GOTO element and select the step that you want to jump to. You can select any subsequent step. **Keyboard shortcut:** Use the **tab key** to move the focus on the canvas. Press Ctrl + 5. The GOTO element is added. **Remove GOTO:** Select the GOTO element and click **Remove**. For more information about how to use the GOTO element, see Adding a GOTO element.
	Add Parameter	To add a parameter, go to the **Parameter** palette and drag the parameter that you require to the canvas. Or mark the text which should be a parameter name and click **Add parameter**. **Keyboard shortcut:** Use the **tab key** to move the focus on the canvas. Press Ctrl + 8. A parameter menu is added. Click the arrow and select the required parameter. **Remove parameter:** Select the parameter and click **Remove**. For more information about creating parameters, see Adding parameters.
	Add collapsible details	To add collapsible details, click the icon and enter a title for the collapsible section. Then enter the information that you want to collapse and expand in a section. **Keyboard shortcut:** None. **Remove collapsible details:** Use the delete or backspace key to delete collapsible details.
	Paragraph or Heading	Switch between paragraph style or select from the available heading styles.
	Bold	Select a text and make it bold by selecting **b**.
	Italic	Select a text and make it italic by selecting **i**.
	Insert Link	If you want to insert a link, click **Insert Link** and enter in the URL field the link. Do not forget to provide the link text and decide whether you want this link to be opened in another tab.
	Bulleted list	Select text that is spread over a couple of rows and click bulleted list. All lines are indented and bulleted.
	Numbered list	Select text that is spread over a couple of rows and click numbered list. All lines are indented and numbered.
	Increase indent	Select text that is spread over a couple of rows and click increase indent. The whole text section is moved to the right.
	Decrease indent	Select text that is spread over a couple of rows and click decrease indent. The whole text section is moved to the left.
	Insert image	If you want to add a screen capture for example, select **Insert Image**.
	Block quote	If you want to add a quotation that is set off from the main text, select **Block quote**.
	Insert table	If you want to insert a table, click **Insert Table**. Enter the number of rows and columns that you need and specify the column with and width unit.
	Undo	You can undo your last 20 editing actions.
	Redo	You can redo your last 20 editing actions.

Adding actions

Actions are used to run several steps automatically. Use the **Actions** page to create actions.

The job of an operator can involve repetitive tasks, such as, *"Logon to DB2"*, or running the command `start server dagobert45` to start a server. Actions are scripts or Ansible templates that document these steps. If you use actions within your runbook then the operator does not have to manually run these steps. They can run all steps with one click.

For more information about how to create actions, see Creating an action.

The runbook editor displays any created actions in the **Actions** pane.

Manual steps cannot contain action elements. Automated steps must be added for actions.

It is common practice for actions to contain parameters. When adding actions to a runbook you must decide how the values of the action parameters are filled by creating a parameter mapping. Select from the following options:

- **Use a runbook parameter:** a runbook parameter, which can be filled manually by an operator executing the runbook, is used to fill the specific action parameter. When adding an action to a runbook, you can select existing runbook parameters or directly create a new runbook parameter.
- **Define a fixed value:** the action added to the step of a runbook will always be launched with a fixed value for the parameter. (If the same action is used in a different runbook – another fixed value could be defined there.)
- **Use the default from the action:** if the action defines a default value for this parameter, it is possible to use that value.
- **Use the output of a previous action:** the output of an action that was added to a previous step can be used as input for the action of the current step.

- **Use the logged in user:** the parameter value will be filled with the username of the user, who is logged in to Runbook action at the time when the runbook is run.

  Note: If the username contains the @ symbol, for example because the username is an email address, the @ symbol and all characters that follow it are removed from the username.

Conditional branching is supported for fully automated runbooks. You can configure which step to run next if running the current action ends with status ***successful***, and another step to run next if the current action ends with another status. Depending on the remediation procedures that are available for the current step, this allows you to automatically perform error handling such as the following:

- Analysis and remediation of the error
- Cleanup of leftovers from the error
- Falling back to the previous state
- Collecting diagnostic data

With conditional branching enabled for all applicable steps, the runbook activity of the fully automated runbook will report as ***successful*** even if one or multiple steps have failed. Only if the last step fails, or if another step fails that has no conditional branching configured, will the overall runbook activity also be marked as not successful. For more information about the available exit states of actions, see How is the success rate of an action calculated?

Procedure

1. In the New (or edit) runbook editor, click **Add automated step**.
2. Search for the action. Click the search icon and type in the search term that describes the action that you need.
3. Choose the action that you want and then click **Select this action**.
4. Select the parameter mapping type. A window opens with action details and the parameter definitions. In the **Mapping** column, select how action parameters are to be filled with values. You can choose from the following options:

   - **New runbook parameter:** add a parameter. If default values are provided, update the default values as required. Enter a new parameter name and description.
   - **Fixed value:** an entry field is provided to enter the parameter value.
   - **(Existing) runbook parameter:** select the parameter from the list of existing parameters.
   - **Use default:** use the default value set by the action.
   - **Action output:** use the action output from a previous runbook step. The output value of the action will be used as the parameter value for the current action. Note, if the action in the previous runbook step is a script action or a HTTP action then you can filter the output of that action as described in Creating SSH actions or Creating HTTP actions, respectively. This option is only available if the runbook contains a previous step with an action.
   - **Use logged in user:** select this option to fill the parameter value with the username of the user who is logged in to Runbook action at the time when the runbook is run.

     Note: If the username contains the @ symbol, for example because the username is an email address, the @ symbol and all characters that follow it will be removed from the username.
5. If your runbook only contains automated steps (except for client-side actions), then each automated step, except for the last step, provides the option to configure conditional branching. With conditional branching enabled, you can select which step to run as the next step depending on the result of the current action (***successful*** or ***not successful***), or if the runbook should stop (that is, go to the end).

   Notes:

   - When you add a manual step, a nested runbook step, or an automated step with a client-side action, the runbook can no longer be run in fully automated mode. All previously added configurations for conditional branching are removed.
   - Conditional branches are primarily intended to take effect when running the runbook in fully automated mode. When running the same runbook manually, the conditional branching is also observed. The flow of execution proceeds to the appropriate target step based on the result of the automated action. If the automated action has not been run yet, its result is considered as not successful.

Next steps

- **Edit parameter configuration:** if you want to edit the parameter configuration of your action, select the action and click **Change parameter mappings**  . Change your settings and click **Save**.
- **Action with errors:** if the action is decorated with an error symbol, then the parameter settings are not correct. Click **Change parameter mappings**  to correct the parameter settings.
- **Delete an action:** if you want to remove the action, click **Remove selection**  .

Adding nested runbooks

Nested runbooks are used to collect sets of steps that are commonly used, so they can be reused by other runbooks.

About this task

Create reusable runbook assets to combine those steps that otherwise would have to be repeated over and over again in various runbooks. For example, if you have a 3-step login procedure, you can describe this procedure once in a runbook, and then reuse this runbook by adding it as a nested runbook step within all other runbooks that require the 3-step login procedure. When the 3-step login procedure needs to be changed to become a 5-step login procedure, you only need to change the nested runbook. Once the nested runbook has been published, all runbooks that refer to this nested runbook inherit the updated 5-step procedure.

Once the reusable runbook has been created and published, it is ready to be referenced by other runbooks as a nested runbook.

Runbooks that include nested runbooks are always considered as "manual" runbooks, even if all nested runbooks contain automated steps only, and the runbook itself does not contain manual steps.

Nested runbooks allow a maximum nesting depth of 10 runbooks, and the complete nesting structure cannot contain more than 100 nested runbooks. Attempts to create or change runbooks in ways that exceed these limits will fail.

The statistics for nested runbooks are unchanged when running the parent runbook. Statistics (such as success and failure, but also rating and feedback comment) are always recorded at the level of the runbook that was started, and not propagated to any nested runbooks.

It is common practice for nested runbooks to contain parameters. When adding a nested runbook to a runbook you must decide how the nested runbook's parameter values are filled by creating a parameter mapping. Select from the following options:

- **Use a runbook parameter**: a runbook parameter, which can be pre-filled automatically from an event or edited manually by an operator executing the runbook, is used to fill the parameter of the nested runbook. When adding a nested runbook to a runbook, you can select from existing runbook parameters or directly create a new runbook parameter within the parent runbook.
- **Define a fixed value**: the nested runbook added to the step of a runbook will always be launched with a fixed value for the parameter. (If the same nested runbook is used in a different runbook, another fixed value could be defined there.)
- **Use the default value from the nested runbook**: if the nested runbook defines a default value for this parameter, it is possible to use that value.
- **Use the output of a previous automation**: the output of an automation that was added to a previous step can be used as input for the nested runbook of the current step.
- **Use the logged in user**: the parameter value will be filled with the username of the user who is logged in at the time when the runbook is run.

Note: If the username contains the @ symbol, for example because the username is an email address, the @ symbol and all characters that follow it are removed from the username.

Procedure

1. In the New (or edit) runbook editor, click **Add nested runbook step**.
2. Search for the published runbook that you want to add. Click the search icon and type in the search term that describes the runbook that you require as a nested runbook.
3. Choose the runbook and click **Select this runbook**.
4. If the selected runbook contains parameters, you are now asked to define the parameter mappings. A window is displayed with the list of parameters that are defined in the nested runbook. In the **Mapping** column, select how each of the parameters of the nested runbook is to be filled with its corresponding value. You can choose from the mapping options that are described above.

Next steps

- **Edit parameter configuration**: if you want to edit the parameter mapping, click **Change parameter mappings** . Change your settings and click **Apply**.
- **Nested runbook with errors**: an error message is displayed when you open the runbook editor again after the parameter list of the nested runbook has been changed, so the parameter mappings are no longer valid. This can happen when the parameter list of the nested runbook has been changed, and the changed nested runbook has been published again. Click **Change parameter mappings** to adjust the parameter mappings.

- **Delete nested runbook**: if you want to remove the nested runbook, click **Remove selection** .

Adding parameters

Parameters are used as general placeholders for values that are used on a frequent basis. Examples of parameters are **DATABASE_NAME**, **DIRECTORY**, **HOSTNAME**, **URL** and so on.

You can use runbook parameters in the following scenarios:

- Parameters can be used as variables that get substituted by a value in the text of a runbook step, for example:

  ```
  STEP 2
  In this step you determine the longest running process of system $SYSTEM
  ```

- As input to a command defined in a runbook, for example:

  ```
  STEP 5
  Now issue the command: cd $DIRECTORY
  ```

- Parameters of an automation can be filled with the value of a parameter defined for the runbook.
- Actions of type Script have a system parameter **`target`** which defines the target system where the script is run.
- Actions of type Script have a system parameter **`user`** that specifies the UNIX username which is used to run the script on the target system. This parameter can be mapped automatically to the user who is currently logged in to Runbook Automation. For more information, see Adding actions.

Operators enter values such as **`username`**, **`password`**, **`hostname`**, **`database name`** or **`URL`** on a frequent basis. If you have to deal with many different computer systems, you must remember numerous user names, passwords, host names or database names. In order to avoid typos or having to remember values, you can define parameters. For example, you can define a parameter **`DATABASE_NAME`** and either provide a default value or enter the value when you run the runbook. Default values are the best fit if you do not want operators to remember and enter the value.

Parameters are local to the runbook. They are not available for other runbooks.

Parameters are used within runbooks and for actions. Within runbooks, you can use parameters either standalone, for example **`URL`**, or within a command, for example **`connect to HOSTNAME`**.

Parameters must be filled with values when executing a runbook. This can be done in the following ways:

- When a runbook is launched by clicking the execute button from the Runbook Automation UI, an operator must first enter the parameter values. The operator is prompted with the name and description of all parameters defined for the runbook, as well as an optional default value.
- When a runbook is launched from an event, a Trigger defines which values of the event data are mapped to which parameter of the runbook. Values that are entered in this way cannot be changed.

Runbook parameter values can be changed during the execution of a runbook. In any step of a runbook, you can select the parameter section of the runbook in the sidebar. You might need to expand the section first, if it is collapsed. The parameter can then be changed to a new value. To apply the new value click **Update** (the Update button is only displayed if the parameter value has been changed). Steps of the runbook that are not yet executed will reflect the new value.

Runbook parameters can be used to define parameter values for actions within the same runbook. Parameter values for actions can be filled using the result of a previously executed automation.

In this way, the parameter Action output of a previous automation **`Find large file systems`** is an automatic parameter available for actions in the current step. It is possible to use the output of any automation that ran before in this runbook.

Procedure

1. Create a parameter. Click **Add Parameter** Parameter. A dialog box opens where you can enter the parameter name, the description, and the default value. If you select **Optional** you can start the runbook execution without defining a value, and set the parameter value during runbook execution. This setting is useful if the parameter value is not available at the beginning of the execution, but during execution.

   When you enter the runbook parameter name you can use alphanumeric characters, characters from national languages, and some special characters. But do not use the special characters ampersand (&), backslash (\), space ( ), greater than (>) or less than (<) when you define runbook parameter names.

   As a result, a parameter of the runbook is created and can be used as a variable in the text of a step, as a variable value of a command, or as input of an automation added to a runbook step. For more information about how to use parameters, see Runbook elements and editing

actions.

2. Edit a parameter. Click **Edit** next to the parameter that you want to edit.
3. To edit a parameter used by an automation, click **Edit** for the automation you have added to a runbook step.

Parameter types

Runbook Automation supports multiple parameter types. You can select parameter type when you create or modify a runbook parameter in the runbook editor, or when you create or modify an action parameter in the edit action dialog.

Depending on the action type, certain parameter limitations might apply. Supported parameter types are string, integer, Boolean, and array.

String

When defining a parameter of type string, an operator running your runbook has a free text input element to enter a parameter value. You can specify the minimum or maximum number of characters that the operator can use. You can also mark a string parameter as a password so that any input that is entered by the operator is not displayed.

Any runbook or action parameter that is created before June 2021 is of type string.

Integer

When defining a parameter of type integer, an operator running your runbook has an integer input element to enter a parameter value.

You can specify the minimum or maximum value for the integer value.

Boolean

When defining a parameter of type Boolean, an operator running your runbook has a toggle element to enter a parameter value.

Array

When defining a parameter of type array, an operator running your runbook has an input element to define a various number of inputs. The array parameter must define what type of inputs are allowed. You can use an array of either strings, integers, or Booleans.

Enumerations

To restrict the input for a specific parameter to a discrete set of values, you can extend the parameters with an optional enumeration list. Enumeration support is available for parameters of the following types:

- string
- integer
- arrays with string or integer as their item type

You can define any number of allowed discrete values for your enumeration. The user will then be given the choice of selecting any one of them in the Runbook Automation UI, or multiples of those in the case of an array parameter. If a user tries to send a value which is not part of the enumeration, for example through an API call, the action is rejected with an error message.

Additionally, you can assign labels for any or all of the values of an enumeration for integer or string parameters. Labels are optional. If a label is present, the label is displayed in the Runbook Automation UI together with the value.

Example: If you are writing an application which accepts the days of the week as numeric values from 0-6, you can define the following enumeration list with labels:

Value	Label
0	Monday
1	Tuesday
2	Wednesday
3	Thursday
4	Friday
5	Saturday
6	Sunday

This way, the user can only choose a valid value (0-6), but is also shown the appropriate meaning of the value, as presented by the label.

Action parameter support

The following table contains details about the parameter type to use for each type of automation.

Action type	String	Integer	Boolean	Array
Script/Bash	String value is exported as a variable.	Integer value is exported as a variable.	Boolean is exported as variable with either value "true" or value "false".	Not supported
Script/Powershell	String value is available as a variable of type `System.String`.	Integer value is available as a variable of type `System.Int32`.	Boolean value is available as a variable of type `System.Boolean`.	Array variable is available as a variable of type `System.Array`.
HTTP	String value is substituted where ever the parameter name occurs in HTTP action API endpoint, credentials, or body.	Integer value is substituted where ever the parameter name occurs in HTTP action API endpoint, credentials, or body.	Not supported	Not supported
Ansible	Ansible parameters extra variables, limit, tags, skip tags, job type and all survey parameters of type text, password, or multiple choice are harvested as string parameters.	Ansible parameters verbosity, inventory, credentials, and all survey parameters of type integer are harvested as integer parameter types.	Ansible parameter diff mode is harvested as Boolean parameter type.	Survey parameters of type "multiselect" are harvested as an array parameter type.

Adding a GOTO element

The GOTO element is used to skip steps or jump to the end of the runbook.

See the following example scenarios where the GOTO element is used.

- **Example: Run optional steps as result of a check**:

  1. Log in to the server where you want to start the application server.
  2. Check the current CPU consumption. If it is less than 80% **GOTO Step 5**.
  3. Find the process consuming the most CPU.
  4. Determine the process.
  5. Start the application server.
  6. Check the log file for confirmation that the application server is started.
- **Example: The execution was successful and you can complete the runbook**:

  1. Restart the Application Server.
  2. If this was successful, then GOTO END.
  3. Check your log files.

Configuring runbook creation

Use these procedures to define the runbook creation process and control the publication of runbooks.

- Configuring runbook approval

  Define whether to use the approval workflow or the direct publish workflow to make runbooks available for execution by operators.

- Runbook approval process

  The Runbook approval process offers control over the publication of runbooks. This is beneficial if a mandatory review process is necessary, if prematurely released runbooks could be harmful, or when auditable information on the publication is required.

Configuring runbook approval

Define whether to use the approval workflow or the direct publish workflow to make runbooks available for execution by operators.

1. Navigate to the **Runbooks Library**.
2. Click **Settings** next to the **Create runbook** button.
3. Select **Approve runbooks before publish** if you want runbooks to be approved before they are published.
4. If you want to enforce that an approval must be refreshed at a regular interval, select **Set expiration date after xxx days** and choose a time interval. If this option is enabled, the runbook approval will expire after the specified number of days and can no longer be executed until the runbook is reviewed, submitted for approval, and approved again.

   The deactivated approval process is described in Create a runbook.

   The activated approval process is described in Runbook approval process.

   Note: If the approval process is deactivated, all pending approvals are deleted.

Runbook approval process

The runbook approval process offers control over the publication of runbooks. This is beneficial if a mandatory review process is necessary, if prematurely released runbooks could be harmful, or when auditable information on the publication is required.

Figure 1. Runbook approval process

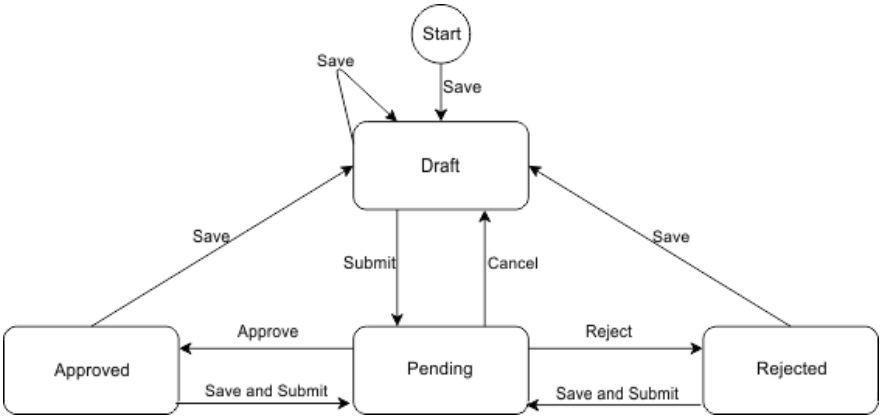

Figure. Runbook approval process

Figure 1 illustrates the states and transitions of the runbook approval process. If the approval process is enabled, it is not possible to directly publish a runbook. Instead an option to submit the runbook is displayed. The following options are then available:

List all runbooks that must be approved

1. Open the **Library** page.
2. From the **Status** filter drop-down menu, select **Approval pending**.
3. All runbooks for which approval is pending are shown.

List all runbooks that are approved

1. Open the **Library** page.
2. From the **Status** filter drop-down menu, select **Approved**.
3. All approved runbooks are shown.

Note: You can also filter for a status of **Approval expired** and **Approval rejected**.

Submit a runbook draft for approval

1. Create or edit a runbook and click **Submit for approval**.
2. Enter the name of the approver in the field provided and click **Send**.

The runbook is now in a pending state. It can no longer be edited, except for changes to its state.

Cancel a pending runbook approval

1. Locate the runbook on the **Library** page.
2. Click the menu overflow icon (the three dots at the end of the row) and select **Remove approval**.

The runbook is now in normal draft mode and can be edited. The assignee can no longer approve or reject the runbook.

Approve a runbook

Only the assigned person from the submission can approve a runbook.

1. Locate the runbook on the **Library** page.
2. Click the menu overflow icon and select **Approve**.

The runbook now has a status of approved, which is the default for execution. New drafts can be created. Information pertaining to the approval assignee and timestamp is stored within the runbook.

Reject a runbook

Only the assigned person from the submission can reject a runbook.

1. Locate the runbook on the **Library** page.
2. Click the menu overflow icon and select **Reject**.

The runbook now has a status of rejected and can be edited again. Information pertaining to the approval assignee and timestamp is stored within the runbook until a new draft version is created and the old information is deleted.

Runbook versions

You can use versioning to create incremental improvements to runbooks and monitor the success of changes. Subject Matter Experts can continuously improve the quality of runbooks by using the comments provided and the available run metrics. As a result, different versions of a runbook are created.

All available runbooks are listed on the **Library** page. Click the menu overflow icon (the three dots at the end of the row) and then click **Preview** > **Versions** to display all the versions of a runbook.

- **Draft**:

  The Draft version is a work-in-progress runbook. It is marked with a draft flag. A draft runbook is not yet published and does not run in production. It is not visible to any operator. You can run and test the current draft.

- **Latest published**:

  The latest published version is the version that is running and used by all operators. This is the version that the operations analyst can preview and work with.

- **Archived**:

  Archived versions are previously used versions. They are not in production and cannot be used by any operations analyst. The metrics of the previous versions help the Subject Matter Expert to monitor continuous improvements of the runbook. You can run archived version to learn why this runbook did not run successfully.

Save and publish a runbook

Creating a runbook involves documenting complex steps. These steps must be reviewed and tested before you can publish the runbook for use in production.

After a runbook is published and used in production, you might improve it based on the feedback that you receive from comments, success rate, and ratings. The runbook editor provides the following actions.

- **Cancel:** closes the runbook editor without saving any changes.
- **Save as:** use this action to save a copy of the runbook using a different runbook name.
- **Save draft:** saves the updates that are added. The editor remains open. **Save draft** is useful if you are editing a runbook and you want to take a break and continue later. Or you just want to save your changes as you go.
- **Save draft & close:** saves your changes and closes the editor. You use this option if you need to stop and work on something else.
- **Publish:** this button is only available when the approval process has been deactivated. After a runbook has been published it can be used by all operators in a production environment.
- **Submit for Approval:** this button is only available when the approval process is enabled.

If the approval process has been activated, see Runbook approval process for more information about approval before publication.

Filtering runbooks

Filter by status, groups or tags to easily locate runbooks.

1. Open the **Runbooks Library** page.
2. To filter for runbook status, select one or more items in the **Status** filter. The filter matches any selected status (or condition).

   Note: Filtering for status **Draft** displays runbooks that have never been published. Draft versions of already published runbooks are not displayed.

   - To filter for tags, select one or more items in the **Tag** filter. All tags must match to apply the filter (and condition).
   - To filter for authors, select one or more authors in the **Authors** filter. The filter matches any selected Authors.
   - If a combination of several filters are used, all filters must match to apply the filter (and condition).
   - Additionally, you can filter by runbook name using the **Search** field.

     The search field allows to search using regular expressions. If you want to search for special characters that are used by regular expressions, for example plus (+), asterisk (*), question mark (?), brackets (() [] {}), or backslash (\), you must escape those characters. For example, if you want to search for (T), you must enter \(T\) as the search string.

     Note: The filter drop-down list displays up to 50 available filtering options. You can start typing the name of the filter option that you are looking for. As you type, the list displays only items that contain the typed text.

Assigning runbooks to groups

Each runbook can be assigned to one or more groups, or can remain unassigned.

Runbooks can only be assigned to user groups if the respective feature is by an administrator. If the feature is enabled and if you only want to check what groups a runbook is assigned to, complete steps 1 - 3 from the following instructions for *Using the feature* section but do not make any changes.

Assigning runbooks to groups allows you to organize runbooks in a more efficient manner. There are two main reasons for assigning runbooks to groups:

- Groups determine the visibility of runbooks for operations analysts.
- It is easier to find relevant runbooks in the **Library** page when Filtering runbooks by groups.

Part 1: Enabling the feature

1. Navigate to the Runbook **Library** page.
2. Click the Configure settings icon next to the New runbook button.
3. Select the **Allow users to assign runbooks to groups** checkbox.
4. Save the changed setting.

Part 2: Using the feature

1. Go to **Library**.
2. Use the check boxes to select one or more runbooks.
3. An action bar is displayed. The bar shows available actions and how many runbooks are selected.
4. On the action bar, click **Grant permission**.
5. Use check boxes to choose which groups the selected runbooks should belong to. You can also select all or clear all groups by using the checkbox in the header row.

   Note: Some checkboxes might appear selected, but dimmed. This is an intermediate state that occurs when some (but not all) of the selected runbooks belong to the group.
6. Click **Assign** to confirm the selection or **Close** to discard any changes.

Export and import runbooks

Export and import runbooks by sending requests to the HTTP API. You can use existing tools to send requests, for example cURL, Postman for Chrome, or RESTClient for Firefox.

Before you can send requests, you need to create an API key for authentication. See API Keys and navigate to section *Get authentication by using Zen API Key* for instructions on how to create and encode an API key (**`ZenApiKey`**).

In addition, determine the host name part of your IBM Cloud Pak for AIOps user interface URL. The base URL for sending API requests has the format **`https://<waiops-hostname>`**, for example, **`https://cpd-cp4waiops.apps.mycluster.mycompany.com`**.

Runbooks are identified by an ID that gets generated when you create the runbook. For example, this ID is used when you create a runbook policy to link the runbook to alerts that match a specific filter pattern. When you plan to export the runbook and import it again at a later time (for example, to restore a backup version of the runbook after the runbook has been removed), you must use the "**`keepId`**" parameter to include the runbook ID during the export. This is so the integrity of the runbook policy is preserved when the runbook is imported later on.

Depending on your certificate configuration, you might need to add the "**`-k`**" or the "**`--insecure`**" option for the sample curl commands listed below.

Export Runbooks

The following two calls create output, which can be imported again.

Use the following API to export all runbooks (including runbook IDs):

```
GET api/v1/rba/runbooks?exportFormat=keepId
```

When enabling the option exportFormat via the query parameter, the usual output of the command is replaced by an array of JSON objects. These JSON objects can be used to create the runbooks by using the import API endpoint. The following call is an example:

```
curl --header "Authorization: ZenApiKey <ZenApiKey>" https://cpd-
cp4waiops.apps.mycluster.mycompany.com/aiops/api/story-manager/rba/v1/runbooks?exportFormat=keepId
```

Replace **`<ZenApiKey>`** with the encoded Platform UI (Zen) API key token that you created before.

Use the following API to export a single runbook:

```
GET api/v1/rba/runbooks/<RunbookId>?exportFormat=keepId
```

Replace **`<RunbookId>`** with the ID of the runbook. You can retrieve this ID, for example, from the **Edit Runbook** window. The following call is an example:

```
curl --header "Authorization: ZenApiKey <ZenApiKey>" https://cpd-
cp4waiops.apps.mycluster.mycompany.com/aiops/api/story-manager/rba/v1/runbooks/*<RunbookId\>*?
exportFormat=keepId > exportedRunbook.json
```

Replace **`<ZenApiKey>`** with the encoded Zen API key token that you created before. Replace **`<RunbookId>`** with the ID of the runbook.

Import Runbooks

Use the following API to import runbooks:

```
POST api/v1/rba/runbooks/import
```

The following call is an example:

```
curl -H "Expect:" -H "Content-Type: application/json" --header "Authorization: ZenApiKey <ZenApiKey>" -
d@./exportedRunbooks.json https://cpd-cp4waiops.apps.mycluster.mycompany.com/aiops/api/story-
manager/rba/v1/runbooks/import
```

Replace **<ZenApiKey>** with the encoded Zen API key token that you created before. Note: **./exportedRunbooks.json** is the output file that is created from the previous example.

Note: If you previously exported a lot of runbooks (or some very large runbooks), you might face the 10 MB upload limit of the Runbook API when trying to import them again. The runbook file must be split into multiple JSON files, and each of these chunks must be imported separately. The following examples assume that you have the **jq** tool installed.

- **Example**: Split by maximum file size

  If your runbooks do not reference any automation actions, or if your automation actions are not shared between multiple runbooks, you can use the following command to split the file into chunks of a maximum of 10 MB each, named **exportedRunbooks.json.aa**, **exportedRunbooks.json.ab**, etc.:

  ```
  cat exportedRunbooks.json | jq .[] -c | split -C 10485760 --filter='jq . -cs > $FILE' -
  exportedRunbooks.json.
  ```

- **Example**: Split by automation actions

  If **exportedRunbooks.json** is larger than 10 MB and if it contains multiple runbooks that reference the same automation action, then try to group all these runbooks into a single chunk file. This avoids creating multiple copies of the same automation action during the import. You can use the following command to split the original file into multiple JSON chunk files, named **exportedRunbooks.json.aa**, **exportedRunbooks.json.ab**, etc. Each of these files contains all the runbooks that reference the same set of automation actions:

  ```
  cat exportedRunbooks.json | jq 'group_by(.automations)'[] -c | split -l 1 - exportedRunbooks.json.
  ```

General Notes on export and import

- Exporting runbooks returns the data of referenced automations inline. These automations are created new when the runbook is imported.
- Import actions do not overwrite existing runbooks, automations, or both.
- Exporting multiple runbooks at once will consolidate automations that are referenced by more than one runbook and only create the minimum necessary number of new automations.
- Imported runbooks are in draft state and do not retain any kind of version, execution, or approval history. The user performing the import action is visible as the runbook creator.
- Exporting runbooks returns the data of referenced runbooks depending on the chosen export format mode.
- In normal mode, nested runbooks are exported in the "flat" structure, where all runbook references are resolved and runbooks are exported as if they did not contain references to other runbooks.
- In keepId export mode, nested runbooks are exported while retaining their referencing structure. Referenced runbooks are included in the data as additional runbooks. Runbooks that are referenced by their latest version keep their ID. Runbooks that are referenced by a fixed version create an additional entry with a placeholder ID, which is replaced by a new random ID upon importing the data set.
- Importing a data set which includes nested runbooks fails to create any runbooks referencing other runbooks if the "publish" flag is not set. This occurs because referencing other runbooks is only allowed on published runbooks, not on drafts.
- When exporting multiple runbooks, ones with invalid nested runbook references and invalid automation action references will not be exported. The export will include all other runbooks, and all errors are logged in the runbook service.

For more information about creating an API key, see API Keys.

For more information about the API, see Automation (runbook) API.

Related links

Installing new SSH key during migration

The SSH key that is associated with an SSH connection cannot be moved or copied to another deployment.

Delete a runbook

Users assigned the Service Administrator, Automation Administrator, or Administrator role can delete a runbook.

1. Open the **Runbooks Library** page.
2. Use the check boxes to select one or more runbooks.
3. An action bar is displayed showing the available actions and the number of runbooks selected.
4. On the action bar, click **Delete** 🗑. If you delete a runbook, all versions and the activity history of the runbook are deleted as well.

Activities

See recently executed runbooks, including runbooks in progress. Up to 1000 records matching the current criteria are displayed on the **Activities** UI. More records can be retrieved through the runbook API. If you need to see the records on the UI, use the filters on the page to refine the search criteria so that less records match.

On the **Activities** page, you can find all runbooks that have been started. You can filter your list by the following criteria:

- User

  Click the **User** filter and select one or more user names. All runbook activities for the selected user names are shown.

- Runbook name

  Click the **Runbook** filter and select one or more runbook names. All runbook activities for the selected runbook names are shown.

- Runbook type

  Click the filter **Type** and select **Automatic Manual**. Fully automated runbooks are runbooks in which each step contains an automation. An operator does not need to interact with the runbook. Automated runbooks can be mapped with events by creating a trigger. To see the automated runbooks that are started by a trigger, click **Automatic**.

- Runbook execution status

  Click the **Status** filter and choose a status such as Success, Failed, Cancelled, In progress, or Completed. For example, you can find all runbook activities that are paused by selecting **In progress**. When you are ready to return to the task you can resume the runbook. Select the **Canceled** status if you want to see all canceled runbooks and the reason why they have been canceled.

You can take the following actions on the **Activities** page:

- **Resume** activities that are paused or in progress.

  This lets you continue with the activity's current step, and it displays the activity's history up to that point including which steps have been skipped as well as all relevant action results.

- **View** past runbook activities' details.

  This displays the entire history of the activity. In the case of a fully automated activity, the details also include action activity errors when available. Only activities that are in progress or paused can be changed, so this view of the activity is read only.

Monitor runbook history

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Runbooks**.
4. Select a runbook.
5. Click the menu overflow icon (the three dots at the end of the row) and select **View history**.

   The activity history table and runbook details such as description, type, rating, success rate, and activity statistics are displayed.

6. Use the filter boxes on the page to display only specific runbooks, for example:

   1. To see runbook activities for a specified time frame, select the dates in the **Start** and **End** fields.
   2. To see runbook activities that are still in progress, select **In progress** from the Status filter. If you want to resume a runbook execution, click **Resume**.

Actions

In runbooks, actions are the collection of several manual steps into a single automated entity. An action improves runbook efficiency by automatically performing procedures and operations.

The Service Delivery Engineer can provide an action to replace frequently used steps with a single click. Depending on the action type, defining an integration might be a prerequisite. For more information about how to set up a integration, see Configuring Integrations.

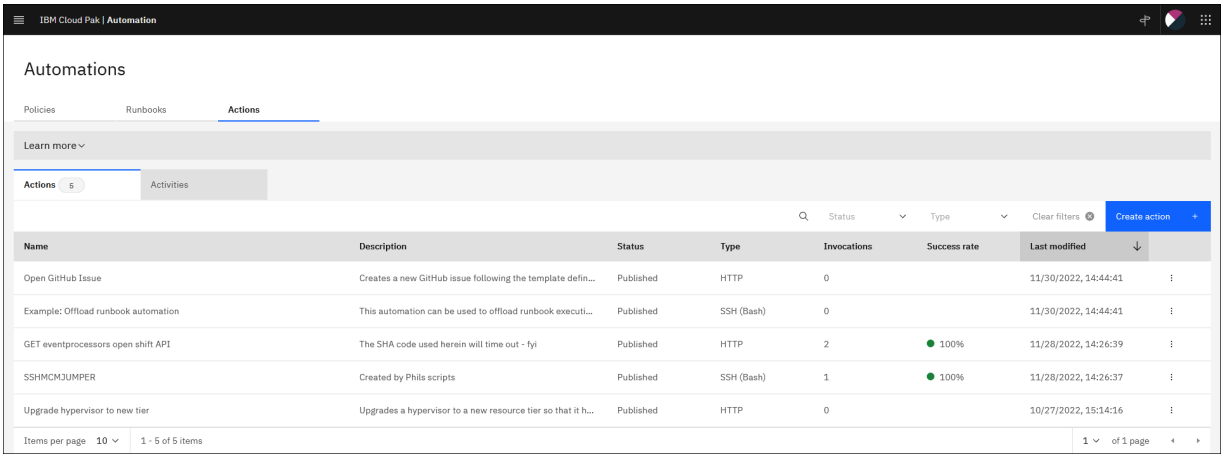

Figure. Actions UI

For more information about runbook actions, see the following topics:

- Managing actions
- Creating an action
- Ansible actions
- Predefined actions
- Action versions
- Save and publish an action
- Testing an action
- Running an action
- Activities

Managing actions

As a Service Delivery Engineer, you are interested in how the actions run and how to keep them running smoothly. Use the **Actions** page to test actions, view statistics, and administer the available actions.

The following types of runbook contain actions:

- Semi-automated runbooks: runbooks that contain one or more actions. These runbooks consist of manual and automated steps.
- Fully automated runbooks: runbooks that contain an action in each step. If fully automated runbooks are started by a trigger, you can find their status on the **Activities** page. Select the filter **Type** and select **Triggered automatically**.

On the **Actions** page, you can find all available actions with the following information displayed in the table:

- **Name**:

  Name of the action.

- **Description**:

  Description of the action.

- **Type**:

  Actions are of the type SSH, HTTP, Client-side, Predefined, or Ansible, depending on the connection type used.

- **Invocations**:

  The number of times the action has been used in runbooks.

- **Rating**:

  Average rating, based on the ratings provided by operators and administrators who ran the action and provided a rating.

- **Success rate**:

  How reliably did this action run so far? The success rate indicates how well an action ran.

- **Last modified**:

  A timestamp of when the action was last modified.

- **Actions**:

  As a Subject Matter Expert you can **Test**, **Edit**, **Copy**, and **Delete** an action unless the action is of type **Predefined** or **Ansible**.

  Select an action in the table to display the **Preview** side panel for that action. You can Edit, Copy, Test, and Delete actions directly from the side panel. The **Details** section is open by default and displays the **Description**, **Action ID**, **Prerequisites**, **Success rate**, and **Last modified by**.

  The **Parameters** tab contains the name, description, and default values of the parameters contained in the action.

  The **Content** tab of the side panel shows the script content in the case of script actions, or the Method and API endpoint in the case of HTTP actions.

  Click the **X** in the top right corner to close the side panel.

How is the success rate of an action calculated?

An action can have the following exit states:

- **failed**:

  The action failed to complete, either because it could not even be started, for example because of an invalid hostname, unsuccessful authentication, or incorrect parameters (in the case of an Ansible action), or it failed during execution because of an internal issue such as a zone failure.

- **unsuccessful**:

  The action could be started but has a return code indicating an error, for example for ssh actions the exit code is not 0, for http actions the http return code is >= 400.

- **successful**:

  The action could be started and has a return code indicating success, for example for ssh actions the exit code is 0, for http actions the http return code is <400.

The success rate indicates the quality of an action. For example, for ssh actions it indicates the quality of the corresponding scripts. For Ansible actions, the success rate indicates the quality of the corresponding Ansible playbooks.

It does not indicate if the configuration is correct. For example, if an ssh action cannot be executed because of an invalid hostname or authentication failure, you will see this in the success rate of the runbook, but not in the success rate of the action.

Therefore, the success rate is calculated using the number of unsuccessful and successful action activities. It does not include the number of failed action activities.

The total number of action invocations that is listed in the **Actions** table includes all action activities, including the failed ones.

Creating an action

Create an action by defining the action type and configuring the parameters and fields.

Actions are routines that run a task automatically. There are different types of actions depending on how tasks are run. Runbook Automation supports actions of type SSH (script), HTTP, Client-side, Predefined, and Ansible. For actions of type script and Ansible, an integration must be configured. Ansible automations are harvested directly from Ansible, so they appear in the automations table as soon as the Ansible connection is configured. For more information about how to set up a connection, see Configuring Integrations.

- **Creating SSH actions** - You can create an action of type script by using the **SSH provider**. The Operating System of the endpoint system can be either UNIX® (including AIX® and Linux®) or Windows™. For UNIX®, the SSH provider executes a script using the default shell. Alternatively, a shebang (#!) can be used to execute the script in any scripting language the target system can interpret. The SSH provider does not require an additional agent as it uses a direct remote execution connection through SSH.
- **Creating HTTP actions** - The HTTP action provider allows you to send HTTP requests to a specified web service.
- **Creating Client-side actions** - Client-side actions provide a mechanism to launch out from the Cloud Pak for AIOps user interface in the user's browser to any third-party web site.

Creating SSH actions

You can create an action of type script by using the SSH provider. The Operating System of the endpoint system can be either UNIX (including AIX® and Linux®) or Windows. For UNIX, the SSH provider executes a script using the default shell. Alternatively, a shebang (#!) can be used to execute the script in any scripting language the target system can interpret. The SSH provider does not require an additional agent as it uses a direct remote execution connection through SSH.

For Windows, the SSH provider can execute a Powershell script.

Note:

- To access the system through SSH you must set up an SSH server on the Windows system, for example OpenSSH for Windows Server 2019 or Windows 10. The Windows System must have Powershell installed as the default shell of the SSH server.
- If you are using a jumpserver, the jumpserver must be a Linux system. You cannot use a Windows system as a jumpserver.

Complete the following steps to enable script actions:

1. Create an SSH integration. For more information about how to set up an integration, see Configuring Integrations.
2. Create an action of type SSH. Click **Actions** > **Create action**. Complete the following fields:
    - **Type**:

      Select SSH. If you want to run a script as an action, you must configure an SSH Action Provider on the **Integrations** page.
    - **Name**:

      Provide a name that describes what this action does. For example, the name can be *Find large file systems*.
    - **Prerequisites**:

      If this action requires prerequisites, add this information. For example, **`Db2 10.5 or higher`**.
    - **Description**:

      Provide any helpful additional information so that the user can immediately understand which problem this action solves.
    - **Tags**:

      Provide tags to filter actions. You can select any existing tags from the drop-down list and click the plus icon "+" to add them. To create a new tag, type the text into the field, select the text string displayed, and click the plus icon "+".
    - **Shell**:

      Select **Bash** for scripts that run on UNIX systems using **`bash`** as the ssh shell. Within the script you can specify other script interpreters that are installed on the target system, for example **`python`**. See the item "Script" below for an example.

        - Notes about how Runbook Automation invokes Bash scripts:
            - It generates a temporary file with the script content.
            - It exports parameters as environment variables.
            - It runs the temporary script file.
            - It deletes the temporary script file.
            - It returns the script return code of the temporary script execution.

      Select **Powershell** for scripts that run on Windows systems using **`powershell`** as the ssh shell (using **`cmd`** as the ssh shell is not supported).

        - Notes about how Runbook Automation invokes Powershell scripts:
            - It assigns parameter values to variables with the selected type.
            - It executes the commands from the script.
    - **Script**:

      You can either select **Import** to select the script from your file system, or you can directly enter the script into the editor. If you selected **Bash** the script can only be run on UNIX systems using the default shell or the interpreter, which is specified after the shebang **`#!`**. If you selected **Powershell** the script can only be run on Windows systems using Powershell.

      Notes:

        - Imported scripts must be in UTF-8 format if they contain non-ascii characters (for example, Chinese).
        - If the "Bash" shell type is selected, then any Windows line endings from the imported script are automatically converted to UNIX line endings.

      Examples:

- Create an SSH action with the following Bash script that uses the **python** interpreter:

  ```
  #!/usr/bin/env python3
  import os
  import platform
  print("Your message \'" + os.environ.get("message") + "\' is presented by python version " +
  platform.python_version())
  ```

  Create a parameter **message** and assign the default value *Hello python* to the parameter. Run the script on a target system where **python3** is installed. The output looks similar to the following output:

  ```
  Your message 'Hello python' is presented by python version 3.9.13
  ```

- Create an SSH action with the following Bash script that uses the IBM WebSphere Application Server CLI to start, stop, or get the server status of the server:

  ```
  $profilePath/bin/$serverAction.sh $serverName
  ```

  Create the parameters:

  - **profilePath** (the path name of the WAS profile, set the type to a single string, example default value: **/opt/IBM/JazzSM/profile**)
  - **serverAction** (the action to take on the WAS server, set the type to an enumeration of strings (**serverStatus**, **startServer**, **stopServer**), example default value: **serverStatus**)
  - **serverName** (the name of the WAS server, set the type to a single string, example default value: **server1**).

  Run the script on a target system where IBM WebSphere Application Server is installed and has administrative credentials configured in **$profilePath/properties/soap.client.props**. Alternatively, add parameters for the administrative user name and password and modify the CLI command accordingly.

- **Action output**:

  - **Filter action output** By default, all action output gets collected and printed to the action output field. If you are only interested in a subset of the action output (for example, because you want to create a chain of two actions within a runbook, where some particular information from the first action is used as input to the second action, then you can enable the **Filter action output** toggle and specify a pattern that controls which part of the action output gets returned.
  - **Choose query syntax** Depending on the type of output that gets created you can choose between three types of pattern-matching engines and their respective syntax:
    - **XPath**: best suited for parsing XML data
    - **JSONPath**: best suited for parsing JSON data
    - **Regular expression**: best suited for parsing unstructured data
  - **Choose query syntax at runtime** Select this checkbox if you want to allow the query syntax to be chosen when testing the automation, and also within the parent runbook. This checkbox is typically disabled. If this checkbox is enabled, the system property **filter-syntax** is added to the action.
  - **Enter query pattern** Enter a pattern that is supported by the selected query syntax. For example, if the JSON output object is expected to contain an attribute called "version" and you selected the "JSONPath" query syntax, then you can use the query pattern "$.version" to pick the value of the version attribute out of the overall JSON output.
  - **Enter query pattern at runtime** Select this checkbox if you want to allow the query pattern to be chosen when testing the automation, and also within the parent runbook. If this checkbox is enabled, the system property **filter-query** is added to the action.
  - **Test output filter** Click this link (or the **Test** button in the actions menu) when you are ready to test the action. This saves the action and directly opens the **Test action** page for the current action. For many developers, working with query patterns is an iterative process. Therefore it is recommended to enable **Enter query pattern at runtime** at least while you are developing the action, and switch to **Test action** to fine-tune the query pattern. The development of the query pattern is also supported within the **Test action** page itself, where you can toggle between **Show filtered output** and **Show unfiltered output** after you have run the action. You can also toggle between **Edit action** and **Test action** until you are satisfied with the result.
- **Parameters:**

  Add input parameters to run the action script. Those input parameters are available to the script as environment variables. For example, a parameter **filesystem** is used in a Linux script as **$filesystem**. The **$** sign is automatically added to distinguish user-defined parameters from system parameters such as **target** and **user**. The parameter is exported without the dollar sign. **Note:** input parameter names must consist of alphanumeric characters and the underscore character only. System parameters are not available for use within your own script code. If you want to use some of that data within your script code, you must create related user-defined parameters. The following system parameters exist:

  - **target**: Mandatory parameter. Applies to actions of type Script. The **target** parameter is created to define the target machine where the script is running. By default, it is assumed that the SSH server on the target machine is listening on port 22. If a different SSH port is used, then set the value for the **target** parameter to **hostname:port**, for example, **mytarget.mycompany.com:2022**.

  - **user**: Mandatory parameter. Applies to actions of type SSH. The **user** parameter defines the UNIX or Windows username that is used to run the script on the target machine.

- **filter-syntax, filter-query**: These system parameters are added if you enable the related checkboxes for action output parsing.

  Note: If the value of the user parameter contains the @ symbol, for example an email address, the @ symbol and all characters that follow it are ignored.

3. Add the action to the runbook, see Adding actions.
4. Run the runbook, see Run your first runbook.

For more information about SSH actions, see the following topics:

- **Single and Multi Target Actions**
- **Output format of Multi Target Actions**
- **Comparison of Single and Multi Target Actions**

Single and multi target actions

You can use single target or multi target actions to execute script actions.

Single Target

The parameter with the name **target** has special meaning to script actions as it defines the system on which the action will run. The system can be defined by a short hostname, a FQDN, or an IP address. When executed a script action will connect to the system identified by the **target** and execute the script there.

The execution result of the script will be reflected in the status of the action. Possible action states are **executing**, **successful**, **unsuccessful**, **failed**, and **unknown**. In the case of a fully automated runbook execution, this status will also be used to decide whether the runbook will be canceled or continued.

Examples:

- An action which receives **prod-server1**, as the content of the target variable will execute this action on the system **prod-server1**. The script exited with return code of zero and the state of the action instance is set to **successful**.
- An action which receives **192.168.55.56**, as the content of the target variable will execute this action on the system with the matching IPv4 adress. The script exited with a non-zero return code and the state of the action instance is set to **unsuccessful**.
- An action which ran in step 1 of a fully automated runbook failed to reach the endpoint (for example because the server was not available) and the action could not be executed at all. The status of the action instance is **failed**. This status is reflected in the status of the execution. The execution will stop after the first step and report a failure.

Multi Target Actions

The other mode of operation of an action is the **Multi Target Action** (MTA). In order to execute an action as an MTA, specify the target string in the following format: **[$target1, $target2, ..., $targetN]** or as a comma-separated list without square brackets: **$target1, $target2, ..., $targetN**.

The following rules apply to MTAs:

- If you use the format with brackets, then the target string must begin with a left square bracket (**[**) and must end with a right square bracket (**]**).
- Define a list of systems separated by comma (**,**).
- Duplicated entries are detected and ignored. This means specifying the same target multiple times will have no effect.
- An empty list in the format **[ ]** is also allowed.

Multi Target Actions allow you to execute the same action on any number of targets in parallel, removing the necessity to execute the same action with different targets sequentially. If the target is specified in such a way, how the action is executed and how the results are treated will be different. The following criteria apply to MTAs:

1. For every entry in the comma-separated list, the script will be executed on the specified target. **Note:** you cannot specify the same target more than once.
2. All actions and information are summarized in one log. This log follows a specific format, see Output format of Multi Target Actions.

3. The status of the execution will be **executing** as long as at least one execution is still ongoing and **successful** once all script processes are finished. The result will be **successful** even if some or even all actions reported **unsuccessful**, **failed**, or **unknown**.
4. Specifying an empty array is allowed. No actual execution occurs, but an execution record is still created.
5. The record will always report **successful** as its state. So if the runbook is executed fully automated, the runbook instance will proceed to the next step. This allows the use of multi-target automations as **Conditional Automations**: use the returned lists of previous multi-target automations in subsequent multi-target automations to only run the subsequent automation where the script in the previous automation was successful. Or where it was unsuccessful.

Examples:

- An action receives **[prod-server1]** as the target. It will execute the script on the system **prod-server1**. The script exited with a non-zero return code. The status of the execution is **successful**. The output of the action instance contains information that this script execution was **unsuccesful** on **prod-server1**.
- An action receives **[prod-server1**, **prod-server2**, **prod-server3]** as the target. It will execute the script on three systems in parallel. All scripts exit with zero as the return code. The output and status of each of the three script activities is written to the output. The status of the overall execution is **successful**.
- An action receives **[]** as the target. This triggers the conditional action workflow No execution will take place. The execution record will have an almost empty output and the status will be **successful**.

Output format of multi target actions

Despite being executed on any number of endpoints, the results of multi target actions (MTA) are consolidated into one activity record. This record combines the information from all activities.

The output is formatted as follows:

- If the script produces output the output is displayed after two prefixes. The first item is the name of the target. The second item is either **out** or **err** depending on whether the output was written to `stdout` or `stderr`.
- The log will group the output by target. So the complete output of the first target will be displayed before the output of the second target is displayed and so on. This means the output is not ordered chronologically, although the output by target is.
- At the end of the output a summary is always present. The summary consists of three additional lines. They follow the pattern **$status : [$listOfTargetsWithThisState]**. Where **$status** is one of the following: **unsuccessful**, **successful**, or **failed**.
- If the target array is an empty array, the output will only contain the summary.

Example

An automation has been executed with the target **[prod-server1, prod-server2]**. The execution on **prod-server1** was successful, while the execution on **prod-server2** was unsuccessful. The output will look as follows:

```
prod-server1 out: Some output from the script to stdout happening at 08:34
prod-server1 out: More output from the script to stdout happening at 08:36
prod-server1 out: Script prints more to stdout
prod-server1 status: successful

prod-server2 out: Some output from the script happening at 08:35
prod-server2 out: More output from the script happening at 08:37
prod-server2 err: Script prints output concerning a failure to err
prod-server2 status: unsuccessful

unsuccessful: [prod-server2]
successful: [prod-server1]
failed: []
```

Comparison of single and multi target actions

The following table outlines the difference between the operation modes:

Table. Operation mode differences for target actions

Aspect	Single Target	Multi Target Action
Number of parallel activities	One	Number of entries in target array

Aspect	Single Target	Multi Target Action
Final execution status	Equal to status of automation	Always successful
Failure during fully automated runbook (FARB) execution	Aborts the FARB	Proceeds the FARB
Specifying an empty target	Failure to execute automation	Enters special case for empty array

Creating HTTP actions

The HTTP action provider allows to send HTTP requests to a specified web service. These requests must be sent using the HTTPS protocol.

To create an action of type HTTP, click **Actions** > **Create action** and complete the following fields:

- **Type**:

  Select **`HTTP`**.

- **Name**:

  Provide a name that describes what this action does. For example, **`IBM Watson Translate`**.

- **Description**:

  Provide any helpful additional information so that the user can immediately understand which problem this action solves.

- **Prerequisites**:

  If this action requires prerequisites, add this information. For example, **`Watson service credentials are required`**.

- **Tags**:

  Provide tags to filter actions. You can select any existing tags from the drop-down list and click the plus icon "+" to add them. To create a new tag, type the text into the field, select the text string displayed, and click the plus icon "+".

- **API endpoint**:

  Specify the API endpoint of the web service to which the HTTP request will be sent to. It is mandatory to use the HTTPS protocol, so the API endpoint URL must start with "https://".

  You can choose between a custom API endpoint or one of the supported Cloud Pak for AIOps APIs.

  Note that these supported Cloud Pak APIs automatically handle authentication. Provided that the action is run manually (for example, inside of a manual runbook or via a contextual menu item in the Alert Viewer) by passing through the executing user's information.

  This automatic authentication is not supported in fully automated runbooks. To create an action that calls a supported Cloud Pak API and that can be used in a fully automated runbook, you must explicitly specify an Authorization header as documented for the respective API.

  If you want to access any other Cloud Pak for AIOps API you should do this via the internal hostname **`https://ibm-nginx-svc:443/aiops/api`** instead of using the external hostname. In this case, you must specify an Authorization header as documented for the respective API.

  For example, to retrieve some data from the Metric API, you can use **`https://ibm-nginx-svc:443/aiops/api/app/metric-api/v1/metrics`** with an Authorization header that contains your API (Zen) key. Alternatively, you can use a parameter for the entire URL that contains a full valid web service URL at the time when the HTTP action is started.

- **Method**:

  Choose the HTTP method. For example **`POST`**.

- **Username**:

  If basic authentication is required to use the web service, specify the API user name for basic authentication.

- **Password**:

  If basic authentication is required to use the web service, specify the API password for basic authentication.

- **Accept**:

  Specify the accept request header. The accept header is used to specify the media types which are acceptable for the response of the request. For example **`text/html`**.

- **Accept-Language**:

Specify the accept-language request header which is used to restrict the set of languages that are preferred for the response of the request. For example `en-US`.

- **Additional header**:

  Optionally, specify any additional request headers that are needed for the request. For example `accept-charset: utf-8`.

- **Ignore certificate errors**:

  Select this check box to ignore certificate errors. Use this option only for test purposes. In production environments, ensure that the correct certificates are installed on the target web service.

- **Action output**:

  - **Filter action output** By default, all action output gets collected and printed to the action output field. If you are only interested in a subset of the action output (for example, because you want to create a chain of two actions within a runbook, where some particular information from the first action is used as input to the second action, then you can enable the **Filter action output** toggle and specify a pattern that controls which part of the action output gets returned.
  - **Choose query syntax** Depending on the type of output that gets created you can choose between three types of pattern-matching engines and their respective syntax:
    - **XPath**: best suited for parsing XML data
    - **JSONPath**: best suited for parsing JSON data
    - **Regular expression**: best suited for parsing unstructured data
  - **Choose query syntax at runtime** Select this checkbox if you want to allow the query syntax to be chosen when testing the automation, and also within the parent runbook. This checkbox is typically disabled. If this checkbox is enabled, the system property `filter-syntax` is added to the action.
  - **Enter query pattern** Enter a pattern that is supported by the selected query syntax. For example, if the JSON output object is expected to contain an attribute called "version" and you selected the "JSONPath" query syntax, then you can use the query pattern "$.version" to pick the value of the version attribute out of the overall JSON output.
  - **Enter query pattern at runtime** Select this checkbox if you want to allow the query pattern to be chosen when testing the automation, and also within the parent runbook. If this checkbox is enabled, the system property `filter-query` is added to the action.
  - **Test output filter** Click this link (or the **Test** button in the actions menu) when you are ready to test the action. This saves the action and directly opens the **Test action** page for the current action. For many developers, working with query patterns is an iterative process. Therefore it is recommended to enable **Enter query pattern at runtime** at least while you are developing the action, and switch to **Test action** to fine-tune the query pattern. The development of the query pattern is also supported within the **Test action** page itself, where you can toggle between **Show filtered output** and **Show unfiltered output** after you have run the action. You can also toggle between **Edit action** and **Test action** until you are satisfied with the result.

- **Parameters**:

  Add input parameters to run the action. Those input parameters can be referred in the entry fields. For example, a parameter `text` can be referred as `$text`.

Creating Client-side actions

Client-side actions provide a mechanism to launch out from the Cloud Pak for AIOps user interface in the user's browser to any third-party website.

The **Client-side** action provider allows you to build a URL from a core URL string and some optional parameters. The URL must use the HTTPS protocol. To run a client-side action, (for example, as an automated step within a runbook) click the **Launch** button. When running a client-side action, the parameters are replaced with the actual values, and the resulting URL is launched in a new browser tab. You can review the URL in the action output area and launch it again by clicking the displayed URL hyperlink.

Client-side actions are composed in the runbook back-end service but they are run in the browser context. Therefore, all runbooks that contain automated steps with client-side actions are considered as manual runbooks. Runbooks that are intended to be run fully automated must not contain client-side actions.

If the third-party website requires authentication, then it will typically ask to provide login credentials before opening the requested page. It is not recommended to use parameters within the client-side action to contain sensitive information (such as user passwords), as they can be seen in clear text in the resulting URL. As a result, password-style string parameters are not supported for client-side actions.

1. To create a client-side action, click **Actions** > **Create action** and complete the following fields:.

- **Type**:

  Select `Client-side`.

- **Name**:

Provide a name that describes what this action does. For example, **`IBM homepage search`**.

- **Description**:

  Provide any helpful additional information so that the user can immediately understand which problem this action solves. For example, **`Search the IBM home page for the given subject`**.

- **Tags**:

  Provide tags to filter actions. You can select any existing tags from the drop-down list and click the plus icon "+" to add them. To create a new tag, type the text into the field, select the text string displayed, and click the plus icon "+".

- **Action client URL**:

  Configure the URL for your action. It is mandatory to use the HTTPS protocol, so the API endpoint URL must start with "https://". You can use parameters. Parameter names must be prefixed with the **`$`** character. For example, **`https://www.ibm.com/search?q=$query`**. Alternatively, specify a parameter that contains a full valid URL of the third-party website at the time when the client-side action is started. For example: **`$openTicketWebPageURL`**.

- **Action parameters**:

  Add input parameters to run the action. Those input parameters can be referred in the URL. For example, a parameter **`query`** can be referred as **`$query`**. The parameter query can be defined as follows:

  - Name: **`query`**
  - Description: **`The subject to be searched on the IBM home page`**
  - Type: **`A single string value`**
  - Minimum length: **`1`**
  - Maximum length: **`not selected`**
  - Password: **`not selected`**
  - Set a default value: **`selected`**
  - Default value: **`runbook`**

2. Add the action to the runbook, see Adding actions.
3. Run the runbook, see Run a runbook.

Deleting an action

Users assigned the Service Administrator, Automation Administrator, or Administrator role can delete an action.

1. Open the **Actions** page.
2. Use the check boxes to select one or more actions.
3. An action bar is displayed showing the available batch actions and the number of actions selected.
4. On the action bar, click **Delete**.
5. A dialog will open, showing you any potential warnings or reasons why some actions cannot be deleted. Select the ones that you want to delete and confirm. If you delete an action, all versions and the activity history of the action are deleted as well.

Ansible actions

The Ansible action provider harvests Ansible type actions from the connected Ansible Automation Platform Controller server. These actions are created automatically and reference an existing asset from an integrated Ansible installation.

Ansible Actions can reference the following:

- Job Templates
- Workflow Job Templates

Unlike SSH Actions, Ansible Actions do not define new automation content inside IBM® Runbook Automation. Instead they point to an existing automation, present in the Ansible Automation Platform Controller server, which is a job or job workflow template.

When an Ansible Action runs, it calls the specific "launch" operation of that template on the connected Ansible Automation Platform Controller server. If the template requires prompting for specific variables, these variables are sent by Runbook Automation. Runbook Automation allows these variables to be defined as Action parameters.

The integration with Ansible has been verified with Ansible Automation Platform 2.4 and Automation Controller 4.5.2. Note that the set of parameters that can be actively used in the related automation actions is limited to what is documented at Job Template parameters and surveys.

Warning: Runbook integration with Ansible Automation Platform 2.5 is not supported by IBM Cloud Pak for AIOps 4.7.1.

See the topics that follow this section for more information about Ansible Actions.

- Harvesting Ansible actions
- Ansible Action interactions
- Job Template parameters and surveys

Harvesting Ansible actions

Complete the following steps to allow Runbook Automation harvest all Job Templates and Workflow Job Templates and create Ansible actions from those templates.

1. Set up an integration to Ansible.
2. Click **Actions**.
3. Check the Actions for the harvested Ansible Actions.

Ansible action interactions

The Ansible Action Provider automatically converts job templates into actions. These actions are read only in Runbook Automation, but they pick up any change to the original template made in Ansible. To change any aspect of the automation, you can edit the original template.

If you change the Ansible connection, for example to point to another Ansible Automation Platform Controller server with different templates, the previously harvested templates are no longer visible from the Actions page. Runbooks containing those templates can no longer run the actions. Instead, the templates from the new Ansible Automation Platform Controller server are visible.

If you change the Ansible connection back to a previous configuration, the actions that are harvested from this connection reappear, together with their statistics. All runbooks that contain those templates are again able to run those actions.

Note that harvested templates are cached in Runbook Automation, so changes made to the original templates might take up to five minutes to be reflected in the corresponding actions.

All runbook instances continue to be fully visible, independent of the state of the Ansible connection.

Job Template parameters and surveys

In Ansible a Job Template or Workflow Job Template can define a number of parameters and properties. They can be defined directly in Ansible's template itself, or can be set to *prompt on launch*. Every parameter that's set to be prompted must be supplied during template launch by Runbook Automation. In the case of an Ansible action executed through Runbook Automation, this translates to action parameters.

Job Templates in Ansible can accept input for the following parameters:

- diff_mode (type: boolean)
- extra_vars (type: string in JSON format)
- inventory (type: integer)
- credentials (type: integer; enumeration with labels)
- limit (type: string)
- verbosity (type: integer; range 0-5)
- tags (type: string)
- skip_tags (type: string)
- scm_branch (type: string)
- execution_environment (type: integer; enumeration with labels)
- labels (type: integer array; enumeration with labels)
- forks (type: integer)
- job_slice_count (type: integer)
- timeout (type: integer)
- instance_groups (type: integer array; enumeration with labels)

Note: Runbook Automation supports only single values for the "credential" parameter. Launching job templates that require more than one credential value to be specified is not supported.

Workflow Job Templates in Ansible can accept input for the following parameters:

- extra_vars (type: string in JSON format)
- inventory (type: integer)
- labels (type: integer array; enumeration with labels)
- tags (type: string)
- skip_tags (type: string)

Additionally, you can define any number of additional parameters to be prompted from the user through the **`survey`**. For every parameter defined in the survey an additional Action parameter is created. These parameter names are prefixed with **`extraVariables`**. and have a schema similar to the one defined for the survey parameter. For example, if you define a survey parameter with the name "age" and define it as an integer with minimum value **`0`** and maximum value of **`99`**, then the Action will have a parameter called "extraVariables.age" of type "integer", with minimum value of **`0`** and maximum value of **`99`**.

Note: Float and textarea parameters are not yet supported and will not show up as independent parameters. If you have surveys using these types of survey parameters, enable the *Prompt on launch* flag for the *Extra Variables* selection in your template. That way users can specify the values using the **`extraVariables`**. parameter.

The Ansible Action Provider will harvest the existing Job Templates and Workflow Job Templates and create matching Actions out of them. Those Actions are automatically created and kept synchronized with Ansible. They cannot be changed inside Runbook Automation. To change these Actions, directly edit the Job Template or Workflow Job Template inside Ansible. Runbook Automation will pick up the change and update the Action referencing the asset. Note that harvested templates are cached in Runbook Automation, so changes made to the original templates might take up to five minutes to be reflected in the corresponding Actions.

If an Ansible Action changes, make sure to update any parameter mappings made towards that Action in your runbooks.

If a parameter is set to *Prompt on launch* in Ansible, but also defines a value, Runbook Automation will import the default value defined in Ansible into the automation parameter.

During execution of Ansible Actions the Runbook Automation UI ensures that you can only pass values that conform to the parameter schemas. If you are using the API, make sure to pass the correct values by comparing your input to the parameter schemas.

Define default values in Ansible for parameters you want to prompt for. For more details on parameters, see the Ansible Documentation for Job Templates or Workflow Job Templates.

Predefined actions

Predefined actions perform some standard changes on alerts, like acknowledging the alert, assigning the alert, or modifying the severity of the alert.

Predefined actions are typically invoked from the right-click menu on entries in the Alert Viewer. You can also use predefined actions in the context of your own runbooks, for example to clear the related alert once all steps of the runbook have been performed successfully. Predefined actions may be used in fully-automated runbooks.

If you run an action (either from the actions table or as an automated step within a runbook) and no error occurs, then the resulting success message is not localized. Instead, an English message is displayed, so you can parse the output in a subsequent automated step of your runbook and proceed as appropriate. See the following table for the expected success message for each predefined action.

If you run an action and an error occurs, then whenever possible the output area displays a localized error message, for example: **`ARBA1102E Alert with ID '1234' does not exist`**. In some cases we receive just a generic message and wrap it, for example: **`ARBA1103E Predefined action failed: 400: Bad Request`**. In those cases check if the values of the other parameters (like **`team`** or **`owner`** for action **`Assign owner to alert`**) are typed correctly.

Predefined actions are immutable actions that exist after product installation. Each predefined action indicates that the action was last modified by user **System**. The modification date of a predefined action indicates when its source code was created or modified and is independent of the time when the product was installed.

You cannot create additional predefined actions. Similarly, you cannot copy, edit, test, or delete predefined actions.

The following table lists the existing predefined actions.

Predefined actions

Predefined action	Parameters	Expected output
Acknowledge alert	**`alert`**: ID of the alert to be acknowledged	**`Alert acknowledged`**

Predefined action	Parameters	Expected output
De-Acknowledge alert	`alert`: ID of the alert to be de-acknowledged	`Alert deacknowledged`
Assign owner to alert	`alert`: ID of the alert to be assigned; `team`: Name of the user group to be assigned to the alert (the user who performs this action must be a member of that particular user group; use the value `-` (hyphen) to set the `team` to "unassigned"); `owner`: User ID of the owner to be assigned to the alert (use the value `-` (hyphen) to set the `owner` to "unassigned")	`Alert assigned`
Update severity of alert	`alert`: ID of the alert to be changed; `severity`: New severity (choose from enumeration)	`Alert severity updated`
Suppress alert	`alert`: ID of the alert to be suppressed	`Alert suppressed`
De-Suppress alert	`alert`: ID of the alert to be de-suppressed	`Alert desuppressed`
Clear alert	`alert`: ID of the alert to be cleared	`Alert cleared`

Action versions

You can use versioning to create incremental improvements to actions and monitor the success of changes.

- **Draft**:

  The Draft version is a work-in-progress action. It is marked with a draft flag. A draft action is not yet published and does not run in production. The draft is not visible to any operator. You can run and test the current draft.

- **Latest published**:

  The latest published version is the version that is running and used by all operators. This is the version that will be used in runbooks where the action is referenced.

- **Archived**:

  Archived versions are previously used versions. They are not in production and cannot be used by any operations analyst. You can still run archived actions in "Test action".

Save and publish an action

Creating an action involves defining routines that run a task automatically.

After an action is published and used in production, you might improve it based on its success rate. The following actions are available:

- **Cancel:** closes the editor without saving any changes.
- **Save draft:** saves the updates that are added. The editor remains open. **Save draft** is useful if you are editing an action and you want to take a break and continue later. Or you want to save your changes as you go.
- **Save draft & close:** saves your changes and closes the editor. You use this option if you need to work on a different item.
- **Publish:** publishes a new version of the action and makes it available for use in runbooks and for operators.

Testing an action

As a Service Delivery Engineer, you can test an action before you use it within a runbook. This allows you to quickly develop and test actions.

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Actions**.
4. Select an action in the table to display the **Preview** side panel for that action.

5. Click **Test** to start the test procedure for the action. Alternatively, click the options menu of the action and click the **Test** option.

   Note: You can select a different version of the automation if you don't want to test the latest version.

6. Follow the instructions on the **Test action** page.
7. Verify the result of the action.
8. You can test the action multiple times.
9. Parameter values can be modified between test runs of the action. To copy test parameter values to the action editor, click **Edit action**. In the dialog that's displayed, select the test parameter values that you want to bring to the action editor and click **Edit action**. Any changes made in the editor must still be saved.
10. When you are finished testing the action, click **Close**.

Running an action

As an Operator or as a Service Delivery Engineer, you can run the latest published action directly, without wrapping the action into a runbook first. If the action has never been published before, Service Delivery Engineers can also run the draft (although they would typically use **Test action** instead, as the test page is more tightly integrated with **Edit action** and generally allows you to test the latest draft).

1. Click the navigation icon at the upper-left corner of the screen to go to the main navigation menu.
2. In the main navigation menu, click **Operate** > **Automations**.
3. Click **Actions**.
4. Select an action in the table to display the **Preview** side panel for that action.
5. Click **Run action** at the bottom of the side panel to start the run procedure for the action. Alternatively, click the options menu of the action and click the **Run** option.
6. Follow the instructions on the **Run action** page.
7. Verify the result of the action.
8. You can run the action multiple times. Parameter values can be modified between runs of the action.
9. When you are finished running the action, click **Complete**.
10. In the **Provide feedback** section, you can provide a rating and a comment. This information is intended to be evaluated by administrators, so they can easily identify those actions that need to be improved, and understand what exactly needs to be improved.
11. When you are finished with providing feedback, click **Close**.

Activities

In the **Activities** tab on the main page, you can find all actions that have been run, including actions in progress.

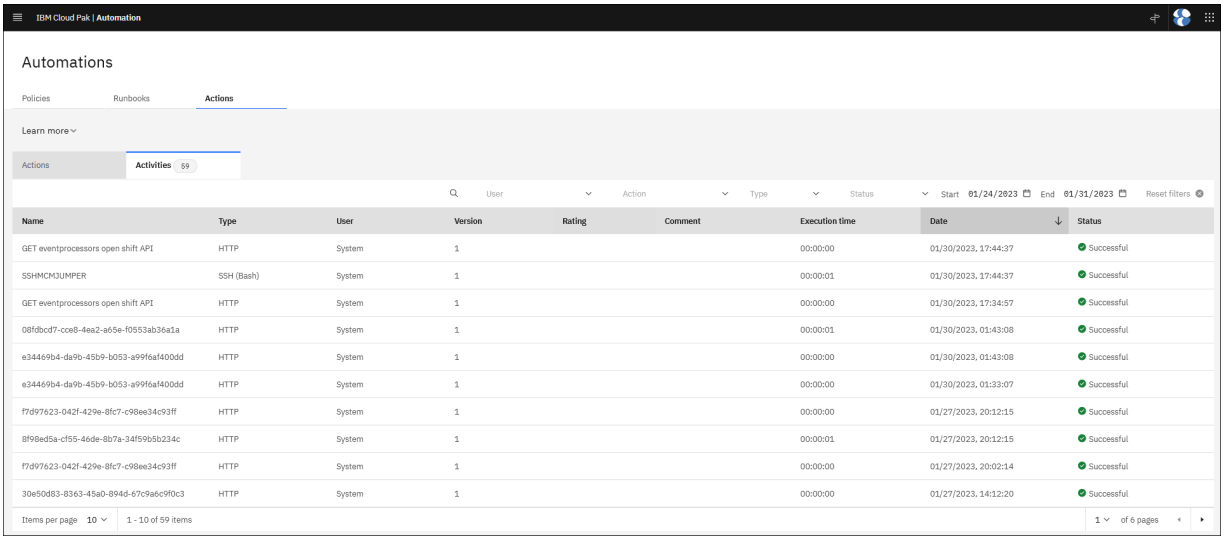

Figure. Activities UI

You can filter your list by the following criteria:

- **User**:

  User that ran the action.

- **Action name**:

  The action that was run.

- **Type**:

  Ansible, HTTP, SSH (Bash), SSH (PowerShell), Client-side, Predefined

- **Status**:

  Current status of the action activity. Valid statuses are "Executing", "Failed", "Successful", and "Unsuccessful".

The columns **Rating** and **Comment** display the detailed feedback information that has been provided by the operators who have run the action. Service Delivery Engineers can evaluate this feedback to identify those actions that should be improved (for example, as a combination of a high number of invocations and a low average rating, as displayed in the **Actions** table, and the detailed feedback comments on the **Activities** page). Ideally, the feedback comments provided by the operators describe the pain points in sufficient detail, so the Service Delivery Engineer can improve the action efficiently.

Visualizing dashboards and reports

IBM Cloud Pak for AIOps includes support for analyzing and visualizing data through an integration with IBM Cognos Analytics. IBM Cognos Analytics integrates reporting, modeling, analysis, exploration, dashboards, and stories, so you can understand your organization's data, and make effective business decisions.

IBM Cognos Analytics is a proven, self-service, dependable analytics solution that provides scalability and analytics governance.

This integration provides you with tools to create custom IBM Cognos Analytics dashboards and reports.

With IBM Cognos Analytics dashboards, you can build visualizations of your IBM Cloud Pak for AIOps data, such as alert and topology data, to monitor your data at a glance. IBM Cognos Analytics includes a wide range of customizable visualization options to help you create these interactive dashboards. You can then use the exploration, analysis, and reporting capabilities within IBM Cognos Analytics to discover patterns and relationships and gain further insights into your IBM Cloud Pak for AIOps data.

With IBM Cognos Analytics reports, you can use the provided web-based report authoring tool to build sophisticated, multiple-page, multiple-query reports whenever you require, such as for creating alert resolution rates or impacted resource reports.

When you set up this integration, you can open IBM Cognos Analytics from the Cloud Pak for AIOps console.

Note: This functionality is not enabled for deployments of IBM Cloud Pak for AIOps on Linux®.

Before you begin

- IBM Cognos Analytics requires a database to act as a 'Content store' that contains IBM Cognos Analytics configuration and settings. You can use the same IBM Db2 instance that you use to sync your IBM Cloud Pak for AIOps data to, but in a separate database. For more information about using IBM Db2 as a content store in IBM Cognos Analytics, see the IBM Cognos Analytics documentation.

  The complete list of components that must be installed and configured for the integration between IBM Cloud Pak for AIOps and IBM Cognos Analytics is the following:

  1. Install IBM Db2.
  2. Install IBM Cognos Analytics (using IBM Db2 as a content store).
  3. Link IBM Cognos Analytics and IBM Cloud Pak for AIOps.
  4. Create the data flow.
  5. Create the data module.
  6. Create a dashboard.
- Entitlement to IBM Cloud Pak for AIOps provides limited entitlement to using IBM Cognos Analytics and IBM Db2 for IBM Cloud Pak for AIOps data sources only. Review the IBM Cloud Pak for AIOps license terms.

Installing and configuring the integration

You can configure an existing IBM Cognos Analytics environment with IBM Cloud Pak for AIOps. For more information, see Integrating IBM Cognos Analytics with IBM Cloud Pak for AIOps.

For information about new IBM Cognos Analytics installations, see the IBM Cognos Analytics documentation.

You must configure IBM Cloud Pak for AIOps to synchronize data with IBM Cognos Analytics through an IBM Db2 integration. For more information and instructions, see IBM Db2 integration.

Getting started with IBM Cognos Analytics

When you have the integration configured you can access and use IBM Cognos Analytics.

As a starting point, review the IBM Cognos Analytics documentation Getting started - User interface. This page and section of documentation provide basic information about navigating the IBM Cognos Analytics user interface, and creating and managing the application content.

The full set of documentation for using IBM Cognos Analytics is available in the IBM Cognos Analytics documentation. This documentation describes all features of IBM Cognos Analytics, including features that are not supported in IBM Cognos Analytics for IBM Cloud Pak for AIOps.

Opening IBM Cognos Analytics

You can open the IBM Cognos Analytics UI from the Cloud Pak for AIOps console main navigation menu by clicking **Visualize** > **Cognos**. The IBM Cognos Analytics UI opens in a new browser tab.

The IBM Cognos Analytics UI includes an AI **Assistant** (left pane of the UI), and a **Details** pane (right side of the UI), to help interpret the chart that you are viewing. The **Assistant** supports natural language exploration, while the **Details** pane provides system-generated plain-language information to augment the chart. The **Explore** feature reduces the guesswork that is associated with data exploration by finding the strongest relationships in your data. The relationships are displayed in the relationship diagram, and suggested starting points are offered for more data exploration.

Important: To access and use IBM Cognos Analytics to create and use dashboards and other visualization tools, you must have a user role with the following permissions:

- **Manage dashboards/reports**
- **View dashboards**

Supported features

The following features are supported in IBM Cognos Analytics for use with IBM Cloud Pak for AIOps data:

- Dashboards

  Note: Embedding visualization code is not supported.

- Stories
- Explorations
- Data modules
- Reporting

Working with dashboards

You can create a dashboard within IBM Cognos Analytics to build visualizations of your IBM Cloud Pak for AIOps data, such as alert and topology data. IBM Cognos Analytics dashboards help you to monitor events or activities at a glance by providing key insights and analysis about your data on one or more pages or screens. For more information, see Creating a dashboard. For more information about editing an existing dashboard, see Editing a dashboard.

For detailed instructions and information about working with dashboards, review the IBM Cognos Analytics documentation Dashboards. This page lists various topics to explore to learn more about using and understanding dashboards within IBM Cognos Analytics. For tutorial about the basics for creating a dashboard, see Cognos Analytics dashboards: a tutorial

For more information about building the visualizations on your dashboard, see the IBM Cognos Analytics documentation Visualizations. As part of building the visualizations, you can use IBM Cloud Pak for AIOps widgets within IBM Cognos Analytics.

You can also create custom visualizations to meet your specific business needs. For more information, see Custom Visualizations Developer. For a step-by-step guide for how to set up your development environment, create custom visualizations, and deploy and authorize the visualization, see Step-by-step guide for custom visualizations.

IBM Cloud Pak for AIOps widgets

IBM Cloud Pak for AIOps provides a default setup for creating 4 custom widgets. When you have configured the data flow to include IBM Cloud Pak for AIOps data in IBM Cognos Analytics, you can create these widgets. For more information, see:

- Alert list custom widget
- Topology viewer custom widget
- Incident list custom widget
- Button custom widget

These widgets can be combined with other IBM Cognos Analytics widgets in your IBM Cognos Analytics dashboards to create custom views for analyzing your data to meet your operational requirements and use cases.

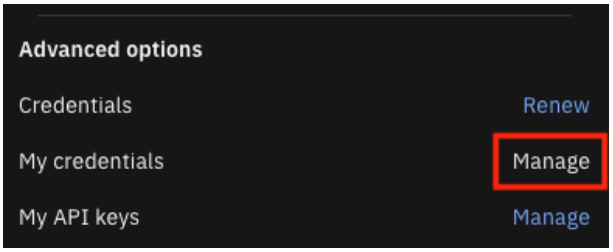
Working with reports

You can create reports to meet your various needs, such as alert resolution rates or impacted resource reports. When you create a report, you are actually creating a report specification. The report specification defines the queries and prompts that are used to retrieve data and the layouts and styles used to present the data. For simplicity, the report specification is named by the same name as the report. For more information about creating and using reports, the IBM Cognos Analytics documentation Reporting. This page lists various topics to get started with creating reports based on your data within IBM Cognos Analytics.

Integrating IBM Cognos Analytics with IBM Cloud Pak for AIOps

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

Run the **`setupCognos.sh`** command to configure OpenID Connect (OIDC) authentication and single sign-on (SSO) between IBM Cloud Pak for AIOps and IBM Cognos Analytics.



Before you begin

Important: You must have a deployment of IBM Cognos Analytics set up in order to integrate with IBM Cloud Pak for AIOps. For information about IBM Cognos Analytics installations, see the IBM Cognos Analytics documentation.

- Clone the repository containing the required scripts from github.com: aiops-cognos-analytics. For example:

  ```
  git clone git@github.com:IBM/cp4waiops-samples.git
  ```

- If required, install jq where you plan to run this script. To install jq, see Download jq.
- Obtain a IBM Cognos Analytics API key from an administrator.
  - The IBM Cognos Analytics administrator can get the key from any existing namespace under **Profile and Settings** > **My API keys**.
  - The IBM Cognos Analytics administrator must first **Renew** credentials if **My credentials - Manage** is disabled.

  - The IBM Cognos Analytics user should have the administration capabilities to **Manage Namespaces** and **Users, Groups, and Roles**.

- From the command-line, authenticate with the IBM Cloud Pak for AIOps cluster as an admin user.
- Add the IBM Cloud Pak for AIOps cluster CA to IBM Cognos Analytics as documented here. If you're using the default Red Hat OpenShift ingress CA, find it by running the following command:

  ```
  kubectl get -n openshift-ingress-operator secrets router-ca -o jsonpath={.data."tls\.crt"} | base64 --decode
  ```

- Restart the IBM Cognos Analytics server.

Procedure

Run the following command:

```
./setupCognos.sh -u cognos_url [-k cognos_api_key] [-n cognos_namespace] [-g cognos_gateway] [-c aiops_client] [-r]
```

Where:

`-u cognos_url` (required) IBM Cognos Analytics server in the form of **`hostname:port`**.

`-k cognos_api_key` (optional) API key of the IBM Cognos Analytics user under which the setup will run. If no API key is specified, anonymous user is used.

`-n cognos_namespace` (optional) name of the IBM Cognos Analytics namespace that will be created for IBM Cloud Pak for AIOps users. If not specified, the IBM Cloud Pak for AIOps cluster name is used.

`-g cognos_gateway` (options) path of the IBM Cognos Analytics gateway. If not specified, **`/bi`** is used.

`-c aiops_client` (optional) name of the OIDC client that will be created in IBM Cloud Pak for AIOps. If not specified, the IBM Cloud Pak for AIOps cluster name is used.

`-r` (optional) remove the IBM Cognos Analytics namespace and OIDC client.

Configuring permissions to see IBM Cognos Analytics navigation entry in IBM Cloud Pak for AIOps

For any roles that require visibility of the IBM Cognos Analytics navigation entries, you can add the required permission through the **Access control** page. For more information about managing permissions, see Managing user access control and Roles and permissions.

The following permissions are required for such users:

- **Manage dashboards/reports**
- **View dashboards**

Notes

- SSO with Red Hat OpenShift is not supported.
- If the IBM Cloud Pak for AIOps cluster uses self-signed certificates, you must add a browser security exception before using these widgets in IBM Cognos Analytics. Refer to your browser documentation for instructions.
- IBM Cognos Analytics users cannot modify a namespace that they're using.
- For SSO to be effective, anonymous access must be disabled after successfully running this script.

Data flow configuration

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

After you install IBM Cognos® Analytics, you can configure Cloud Pak for AIOps to synchronize data with IBM Cognos® Analytics through an IBM Db2 integration. You can then create a policy to send alerts or incidents from Cloud Pak for AIOps to populate a dashboard or report.

The following components are required for alert data to flow from IBM Cloud Pak for AIOps to IBM Cognos Analytics.

Figure. Alert data flow from Cloud Pak for AIOps to IBM Cognos Analytics

Before you begin

You must have IBM Cloud Pak for AIOps 4.7.1, IBM Db2, and IBM Cognos Analytics installed before proceeding.

Complete the following steps to push Cloud Pak for AIOps alerts to IBM Db2 for use with IBM Cognos Analytics dashboards.

Procedure

1. Implement the database schemas so that the relevant reporting tables are in place. The schemas can be installed from: github.com: aiops-cognos-analytics/schemas.
2. Create a new IBM Db2 integration so that you can store IBM Cloud Pak for AIOps data in your IBM Db2 database. For more information, see IBM Db2 integration.
3. Connect IBM Cognos Analytics to your IBM Db2 database.
    1. In IBM Cognos Analytics, navigate to **Menu** > **+ New** > **Data server connections**.
    2. In **Select sources**, click **Data servers and schemas**, and select your database, followed by the schema.
    3. Click **New +** and select **Data server**.
    4. Provide a name, optional description, and select the relevant IBM Db2 connection type.
    5. Provide the connection details. In the **Authentication** section, you can create a **Signon** in which you provide the username and password for IBM Db2. Select **Use signon** in the drop-down list, click **Add signon** and then provide the details.
    6. Test the connection before saving.
    7. Select the newly created data server.
    8. Click the Action menu for the respective schema row in the table (the three dots at the end of the row).
    9. Select **Assets**.
    10. Click the Action menu for the asset row and select **Load metadata**. This loads the tables for the database.
    11. Click **Done** when complete.

    For more information, see Using data servers as data module sources.
4. Switch to the Cloud Pak for AIOps Policy UI and create policies to send alerts or incidents from IBM Cloud Pak for AIOps to populate a dashboard or report in IBM Cognos Analytics. For more information, see Populate a dashboard or report.
5. Ensure that you configure the policy to trigger when new alerts are added, or existing alerts are updated, so that the live alerts and the alerts in IBM® Db2® are in sync.

Creating a Data Module in IBM Cognos Analytics

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

When you have connected to IBM Db2, you can start using the database. The next step is to create a Data Module.

Procedure

1. In IBM Cognos Analytics, navigate to **Menu** > **+ New** > **Data Module**.
2. From **Select sources**, click **Data servers and schemas**, and select your database, followed by the schema.
3. Click **OK**.
4. Now, you can choose either to **Select tables** or **Discover related tables**. Discover related tables is a tool that is provided by IBM Cognos Analytics that uses NLP and AI to help suggest relationships between tables. For more information, see the IBM Cognos Analytics documentation. For this example, choose **Select tables** then **Next**.

5. Select all the tables and click **OK**.
6. You now have a Data Module containing the entire schema. If you view the **Relationships** tab, you can see that IBM Cognos Analytics has detected some relationships due to the structure of the schema.
7. If more data sources are needed for your dashboard requirements, you can include them into the data module and relationships that are formed between the Alerts/Incidents schema and others.
8. Save your Data Module after completing any changes.

Creating a dashboard

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

You can create a dashboard within IBM Cognos Analytics to build visualizations of your IBM Cloud Pak for AIOps data, such as alert and topology data. IBM Cognos Analytics dashboards help you to monitor events or activities at a glance by providing key insights and analysis about your data on one or more pages or screens.

Building a dashboard involves dragging data sources, visualizations, and widgets to the main canvas. You can also customize the appearance of the visualizations to make the data more visually appealing.

With a dashboard created, you can then use the analysis and reporting capabilities within IBM Cognos Analytics to discover patterns and relationships and gain further insights into your IBM Cloud Pak for AIOps data.

Before you begin

To create a dashboard within IBM Cognos Analytics, you must have a role with the following permission:

- **Manage dashboards/reports**

You can download example dashboards for Cloud Pak for AIOps using IBM Cognos Analytics from github.com: aiops-cognos-analytics/examples.

Procedure

1. From the main navigation menu, click **New** .
2. Click **Dashboard**.
3. Select a template to use and click **Create**.

   Predefined templates contain grid lines for easy arrangement and alignment of visualizations and other elements. For example, you can create an infographic to convey information with pictures on one page that you scroll through.

   The dashboard displays a blank canvas that is ready for you to visualize your data. If this is your first time using this dashboard, the dashboard also processes your data sources. The **Selected sources** pane displays the progress of the data sources as a percentage until the processing is complete. Some functions in the dashboard are only available after the processing is complete.
4. Ensure that the data sources that you want to use are displayed in the **Selected sources** pane.

   If no data source is displayed, click **Select a source** to find and chose your data source. If you want to add another data source, click the **Add a source** Add icon icon and select your data source.
5. Work with charts on the dashboard. You can add visualizations to the dashboards in one of the following ways:
   - Have Cognos Dashboards choose the visualization for you. Cognos Dashboards provides a number of recommended visualizations based on the data that you are working with.

     To have Cognos Dashboards choose the visualizations for you, drag a measure or column on to the canvas. You can change to another visualization from either Recommended or from More.
   - Choose the visualizations yourself. You can customize your dashboard by choosing your own visualizations:
     - Click the **Visualizations** icon to display the available charts for your dashboard.
     - Click the chart to insert it automatically to the canvas. You can also drag the chart and drop it to the canvas. After you insert the chart into the canvas, the dashboard automatically selects the **Sources** icon for you to select the data for your chart.
     - To move the chart on the canvas, click and drag the corresponding **Move widget** icon

- From the Sources section, select your data source, then browse to a data column.
- Drag the data columns and drop them to an available section of the chart or graph. The chart uses the entire set of data from the data column.
- To filter the data column values, click the **Filters**  Filters icon icon in the toolbar, then drag the data column and drop it to the **All tabs** icon or the **This tab** icon, then specify the filter settings. If you have multiple tabs, the filter settings that you specify in All tabs apply to all your tabs.

6. Customize the appearance of the dashboard.
    1. Click the Widgets icon to display the list of available widgets and icons.
    2. Click a widget insert it automatically to the canvas. You can also drag the widget and drop it to the canvas.

       For more information about IBM Cloud Pak for AIOps widgets, see IBM Cloud Pak for AIOps widgets within IBM Cognos Analytics.
    3. To move the widget on the canvas, click and drag the corresponding **Move widget** icon.
7. Click **Save** to save your changes and create the dashboard.

   Note: Even if you do not manually save your dashboard, IBM Cognos Analytics automatically saves any changes that you made every 5 seconds.

Sharing the dashboard

You can share your dashboard with other users by copying the dashboard's URL. From the toolbar, click the **Share** icon. Chose your preferred method for sharing the dashboard, and then share the link, embedded code, or PDF. The user that you share the dashboard with can only edit the dashboard if they have the required permissions.

Editing the dashboard

If you return to the dashboard, the dashboard is in read-only mode if the **Edit** icon is gray . If you want to edit the dashboard again, enable the edit mode by clicking the **Edit** icon until it is green with a checkmark .

IBM Cloud Pak for AIOps widgets within IBM Cognos Analytics

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

As part of the integration with IBM Cognos Analytics, IBM Cloud Pak for AIOps provides a default setup for creating 4 custom widgets.

When you have configured the data flow to include IBM Cloud Pak for AIOps data in IBM Cognos Analytics, you can create these widgets. For more information, see:

- Alert list custom widget
- Topology viewer custom widget
- Incident list custom widget
- Button custom widget

These widgets can be combined with other IBM Cognos Analytics widgets in your IBM Cognos Analytics dashboards to create custom views for analyzing your data to meet your operational requirements and use cases.

Alert list custom widget

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

The Cloud Pak for AIOps Alert list custom widget can use data selection events from IBM Cognos Analytics visualizations. For example, a bar chart visualization represents severity data. If a high severity bar is selected in the visualization, the Alert list custom widget corresponds and shows high severity alerts only. The assumption is that the related data source column and Alerts property names are matched. Configure the column mapping if that is not the case.

Procedure

1. Download the IBM Cloud Pak for AIOps widgets and other artifacts that are needed from: github.com: aiops-cognos-analytics/widgets.
2. Create a zipped file out of the entire **widgets** folder.

   On macOS: right-click the widgets folder and select **Compress "widgets"**.

   On Windows: right-click the widgets folder and select **Send to** > **Compressed (zipped) folder**.
3. Log in to IBM Cognos Analytics. The base URL is `https://<CLUSTER_NAME>/cognosanalytics/aiops/bi/?perspective=home`.
4. From the main navigation menu, click **Manage** > **Customization** > **Extension**.

   Click the Upload extension icon and navigate to your compressed file.

   The Cloud Pak for AIOps Alert list custom widget is now available to use in new dashboards.
5. From the main navigation menu, click **New** > **Dashboard** > **Create**.
6. Click Custom widgets.
7. Select the **AIOps Alert list** and drag it onto the canvas.
8. Click **Properties** to configure the Cloud Pak for AIOps Alert list in the properties side panel:
   - **Filter**: Sets the default Filter.
   - **View**: Sets the default View.
   - **Show toolbar**: Enables or disables the Alert list toolbar.
   - **Show details**: Enables or disables the Alert list details side panel.
   - **Column mapping**: Allows mapping of IBM Cognos Analytics data source columns to Alert properties. The mapping is defined through JSON format, for example:

     ```
     {"SEVERITY": "severity"}
     ```

     The value on the left represents the IBM Cognos Analytics data source column. The value on the right represents the Alert properties.

     Note: Identifier strings for data source columns in IBM Cognos Analytics cannot consist entirely of a reserved keyword. Therefore, some identifiers are appended with an underscore ("_") which must be added to the column name for mapping to work. For example, the mapping of the STATE column would be as shown:

     ```
     {"STATE_":"state"}
     ```

Related links

- Creating a dashboard
- Editing a dashboard

Topology viewer custom widget

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

Procedure

Skip steps 1 - 4 if you have already completed them for the Alert list custom widget.

1. Download the IBM Cloud Pak for AIOps widgets and other artifacts that are needed from: github.com: aiops-cognos-analytics/widgets.
2. Create a zipped file out of the entire **widgets** folder.

   On macOS: right-click the widgets folder and select **Compress "widgets"**.

   On Windows: right-click the widgets folder and select **Send to** > **Compressed (zipped) folder**.
3. Log in to IBM Cognos Analytics. The base URL is `https://<CLUSTER_NAME>/cognosanalytics/aiops/bi/?perspective=home`.
4. From the main navigation menu, click **Manage** > **Customization** > **Extension**.

Click the Upload extension icon and navigate to your compressed file.

The Cloud Pak for AIOps Topology viewer custom widget is now available to use in new dashboards.

5. From the main navigation menu, click **New** > **Dashboard** > **Create**.
6. Click Custom widgets.
7. Select **AIOps Topology viewer** and drag it onto the canvas.
8. If you have the alert list viewer open, double-clicking an alert with topology generates the topology map for that alert.
9. Click **Properties** to configure the Cloud Pak for AIOps Topology viewer in the properties side panel:
    - **Hops**: Sets the number of hops in the topology map.
    - **Show toolbar**: Enables or disables the topology viewer toolbar.
    - **Show search**: Enables or disables the topology viewer search bar.
    - **ResourceId/StatusId**:
        - If you have a custom column name that stores the resource/status ID for the topology viewer, enter the name in one of these boxes.
        - The topology viewer looks for this column name in the IBM Cognos Analytics data to retrieve the resource ID.
        - Otherwise, topology viewer will only work with the Alert list viewer.

Incident list custom widget

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

The Cloud Pak for AIOps Incident list custom widget can use data selection events from IBM Cognos Analytics visualizations. For example, a bar chart visualization represents priority data. If a high priority bar is selected in the visualization, the Incident list custom widget corresponds and shows high priority incidents only (if the related data source column and Incident property names are matched in the column mapping).

You can use the Incident list widget in conjunction with an Alert list widget. To see the alerts related to a specific incident, select the incident in the widget and the alerts in the Alert list widget are filtered down to the alerts for that incident.

Procedure

Skip steps 1 - 4 if you have already completed them for another widget.

1. Download the IBM Cloud Pak for AIOps widgets and other artifacts that are needed from: github.com: aiops-cognos-analytics/widgets.
2. Create a zipped file out of the entire **widgets** folder.

    On macOS: right-click the widgets folder and select **Compress "widgets"**.

    On Windows: right-click the widgets folder and select **Send to** > **Compressed (zipped) folder**.
3. Log in to IBM Cognos Analytics. The base URL is `https://<CLUSTER_NAME>/cognosanalytics/aiops/bi/?perspective=home`.
4. From the main navigation menu, click **Manage** > **Customization** > **Extension**.

    Click the Upload extension icon and navigate to your compressed file.

    The Cloud Pak for AIOps Incident list custom widget is now available to use in new dashboards.
5. From the main navigation menu, click **New** > **Dashboard** > **Create**.
6. Click Custom widgets.
7. Select the **AIOps Incident list** and drag it onto the canvas.
8. Click **Properties** to configure the Cloud Pak for AIOps Incident list in the properties side panel:

- **Filter**: Sets the default Filter.
- **View**: Sets the default View.
- **Show toolbar**: Enables or disables the Incident list toolbar.
- **Show details**: Enables or disables the Incident list details side panel.
- **Column mapping**: Allows mapping of IBM Cognos Analytics data source columns to Incident properties. The mapping is defined through JSON format, for example:

  ```
  {"Priority": "priority"}
  ```

  The value on the left represents the IBM Cognos Analytics data source column. The value on the right represents the Incident properties.

Button custom widget

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

The Cloud Pak for AIOps Button custom widget allows you to create a button with an associated alert filter. Customize the button properties to your requirements and set the desired target. The button can update an alert list in your existing dashboard, or launch an alert list in a new browser tab.

Procedure

Skip steps 1 - 4 if you have already completed them for another widget.

1. Download the IBM Cloud Pak for AIOps widgets and other artifacts that are needed from: github.com: aiops-cognos-analytics/widgets.
2. Create a zipped file out of the entire **widgets** folder.

   On macOS: right-click the widgets folder and select **Compress "widgets"**.

   On Windows: right-click the widgets folder and select **Send to** > **Compressed (zipped) folder**.
3. Log in to IBM Cognos Analytics. The base URL is `https://<CLUSTER_NAME>/cognosanalytics/aiops/bi/?perspective=home`.
4. From the main navigation menu, click **Manage** > **Customization** > **Extension**.

   Click the Upload extension icon and navigate to your compressed file.

   The Cloud Pak for AIOps Button custom widget is now available to use in new dashboards.
5. From the main navigation menu, click **New** > **Dashboard** > **Create**.
6. Click Custom widgets.
7. Select the **AIOps Button** and drag it onto the canvas.
8. Click **Properties** to configure the Cloud Pak for AIOps Button in the properties side panel:
   - **Filter**: Select from the list of filters to associate a filter to the button.
   - **Shape**: Choose between Rectangular or Round for the button shape.
   - **Button label**: Select from Filter name, Alert count, or Both for the button label.
   - **Target**: The action to be taken when the button is clicked. It can update the alert list in your existing dashboard, or launch an alert list in a new browser tab.
   - **Refresh interval**: Auto-refresh interval in seconds.

Example configurations

BETA The installation and integration of IBM Cognos® Analytics is available only for technology preview, and is not for production usage.

You can quickly appreciate the value of your IBM Cognos Analytics integration with some example configurations that are ready for immediate use.

Before you begin

This requires IBM Cognos Analytics version 11.2 or higher.

Download the Example dashboards zip file.

Procedure

Download installation video demo

1. **Find the location of IBM Cognos Analytics extensions**.

   For Cognos running within an Red Hat OpenShift cluster, locate the pod that contains **/data/deployment/**. Search for **ca-** to find Cognos pods.

   ```
   kubectl get pods | grep ca-
   ```

   ```
   ca1721852474940188-artifacts-bc9d68dc4-gzk6p 1/1 Running 0 21d
   ca1721852474940188-ca-cpd-cm-78676c5d8f-gctsj 1/1 Running 0 21d
   ca1721852474940188-ca-cpd-reporting-94bd774b8-d2thf 2/2 Running 0 21d
   ca1721852474940188-ca-cpd-rest-bd5667547-m7dxq 2/2 Running 0 21d
   ca1721852474940188-ca-cpd-smarts-7bbdd6ff97-vnwvl 2/2 Running 0 21d
   ibm-ca-operator-controller-manager-7b7d67667b-tks6b 1/1 Running 6 (4h36m ago) 21d
   ```

   Check whether the pod contains **/data/deployment/**.

   ```
   kubectl exec <pod_name> -- find / -type d -name 'deployment' 2>/dev/null
   ```

   ```
   /data/deployment
   /deployment
   ```

   For stand-alone IBM Cognos Analytics, this file is on the Cognos server, typically under **/opt/ibm/cognos/analytics/deployment**.

2. **Install the example .zip file.**

   For IBM Cognos Analytics running within a Red Hat OpenShift cluster:

   ```
   kubectl cp "./<example>.zip" "<pod_name>:/data/deployment/<example>.zip"
   ```

   For a stand-alone IBM Cognos Analytics server:

   ```
   cp ./<example>.zip /opt/ibm/cognos/analytics/deployment/<example>.zip
   ```

3. Open the Administration console in the IBM Cognos Analytics UI.
4. Go to **Configuration** > **Content Administration** and then select the new import button.
5. Select the **Cloud_Pak_for_AIOps_examples** package and click **Next**.
6. You are be prompted for a passcode. Enter **examples**, and click **OK**.
7. Optionally, update the name and description and click **Next**.
8. Select the checkbox next to the **Cloud_Pak_for_AIOps_examples** folder, and click **Next**.
9. Click **Next** through the remaining steps, updating defaults as required.
10. Click **Finish** > **Run** > **OK**. The examples package is displayed in the content list.
11. The incident dashboard example requires a custom funnel extension. Download and install this extension from the **Manage** > **Customization** > **Custom Visuals** menu option on the IBM Cognos Analytics home page.
12. The examples folder is displayed under **Content** > **Team content** from the IBM Cognos Analytics home page.

- If you don't immediately see the examples, you might need to wait a minute and then reload the **Team content** page.

13. Example dashboards use mock data by default. Complete the following steps to use your own live data with the examples:

    1. Create an IBM Db2 integration.
    2. Relink the example Db2 data module to use your database server connection from the previous step.
    3. Relink the dashboard to use the Db2 data module.

Troubleshooting

1. Color of severity is off: Install the Custom color extension, which provides a richer color palette.
2. The funnel graph is blank: Install the Custom funnel extension.
3. Missing Data in the Db2 module: Relink the provided Db2 data source in the **Data** subfolder to your own IBM Db2 server connection. Or try loading the page in a private browser window.
4. Warning "One or more data caches could not be loaded." This message can be dismissed. It can occur after relinking data sources to inform you that the data from the new source is not found in the local cache.

Cloud Pak administration

After you install IBM Cloud Pak® for AIOps, you can access several options for administering and customizing the IBM Cloud Pak and IBM Cloud Pak® foundational services.

- UI console
- Managing user access control
- Secret rotation
- Administering data storage
- Restricting the number of alerts returned by the datalayer
- Updating usage data collection preferences
- Clearing out topology data without reinstalling
- Setting the idle session timeout
- Configuring probable cause

For platform specific administration topics, see also:

- Administering IBM Cloud Pak for AIOps on OpenShift
- Administering IBM Cloud Pak for AIOps on Linux

Administering the UI console

Learn how to access the IBM Cloud Pak for AIOps console, and how to use some of the console components.

- Supported browsers
- Accessing the console
- Customizing the platform

Supported browsers

You can access the UI console from Mozilla Firefox, Google Chrome, Microsoft™ Edge, and Safari.

Table. Supported browsers

Platform	Supported browsers

Platform	Supported browsers
Microsoft Windows	• Microsoft Edge - latest version • Mozilla Firefox - latest version for Windows • Google Chrome - latest version for Windows
Linux®	• Mozilla Firefox - latest version for Linux • Google Chrome - latest version for Linux
macOS	• Mozilla Firefox - latest version for Mac • Google Chrome - latest version for Mac • macOS Safari - latest version

Accessing your cluster by using the console

You can access your console from a supported web browser.

Procedure

1. In a browser, go to the URL **<https://<cluster_address>**. See the following definitions:

   <cluster_address> is the IBM Cloud Pak console route. You can get the IBM Cloud Pak console route by running the following command:

   ```
   oc get route -n <your-foundational-services-namespace> cp-console -o jsonpath='{.spec.host}' && echo
   ```

   Following is a sample output:

   ```
   cp-console-cp4aiops.apps.mycluster.mydomain.com
   ```

   Based on the example output, your console URL would be **https://cp-console-cp4aiops.apps.mycluster.mydomain.com** .

   The username and password are defined in the **config.yaml** file.

2. Access your cluster from a web browser. For a list of supported browsers, see Supported browsers.

3. Log in to the console. You might have different authentication types available for you to select from to authenticate your user credentials.

   The default username to access the console is **cpadmin**.

   You can get the password for the **cpadmin** username by running the following command:

   ```
   oc -n <your-foundational-services-namespace> get secret platform-auth-idp-credentials -o
   jsonpath='{.data.admin_password}' | base64 -d && echo
   ```

   Following is a sample output:

   ```
   EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA
   ```

   Based on the example output, you would use **EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA** as the password.

   You can change the default password at any time. For more information, see Changing the administrator password.

   Note: Any user with access to your IBM Cloud Pak foundational services project (namespace) can retrieve this password since it is stored in a secret in that namespace. To minimize password exposure, allow limited users to access your IBM Cloud Pak foundational services namespace.

Customizing the platform

As an administrator, you can customize the IBM Cloud Pak for AIOps console to meet the needs of your enterprise.

Complete the appropriate types of customization for your environment:

- Enabling and disabling tours

  As an administrator, you can customize the Cloud Pak for AIOps console to enable or disable the Tours feature for all users on the platform. For instance, if you do not need the tours to be available to users, you can disable the feature. If you, or another administrator, previously disabled the feature and you want the tours available for your users, you can enable the feature.

- Customizing the Platform UI (Zen) route

  You can set or change parameters to control the Platform UI (Zen) route. This change can be done before or after installation to change the route.

- Customizing the branding of the Cloud Pak for AIOps console

  As an administrator, you can customize the Cloud Pak for AIOps console with your company's branding. You can customize the name that is displayed in the Cloud Pak for AIOps console and use a custom logo on your home page.

- Customizing the home page

  As an administrator, you can customize the content that users can see on the home page. You can specify which cards are enabled and which links are displayed in the **Support** section of the home page.

Enabling and disabling guided tours

As an administrator, you can customize the IBM Cloud Pak for AIOps console to enable or disable the *Tours* feature for all users on the platform.

If you do not need the tours to be available to users, you can disable the feature. If you, or another administrator, previously disabled the feature and you want the tours available for your users, you can enable the feature.

Tours are included in the Cloud Pak for AIOps console to help users learn about the IBM Cloud Pak for AIOps platform and features. Some tours introduce high-level concepts, while others offer step-by-step guidance. More tours can be accessed by a user at any time from the Cloud Pak for AIOps console page that is assoicated with the feature to get a better understanding of how to get started with different tasks and components. Users can access available tours by clicking the **Tours** icon in the Cloud Pak for AIOps console toolbar, and clicking their preferred tour.

First-time users are also presented with a guided tour upon login to the Cloud Pak for AIOps console. This tour introduces them to the various home page components, shows how to access tools and capabilities, and where to complete key tasks across the platform.

Before you begin

Required permissions: To customize the home page, you must have one of the following permissions:

- *Administer platform*

Procedure

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the navigation menu, select **Administration** > **Customizations**.
3. Click **Tours**.
4. Change the setting of the **Enabled**/**Disabled** toggle to either enable or disable the tours feature and to hide the **Tours** icon in the Cloud Pak for AIOps console toolbar.

   Your selection is saved and applied automatically.

Disabling auto complete on the login page

In Common Web UI version 4.x.x, there is a new option to disable auto complete on the login page.

Note: The disable option is not supported on Firefox since it does not honor the autocomplete off setting in HTML.

Procedure

To disable auto complete on the login page, complete the following steps:

1. Edit the configmap named `common-web-ui-config` in the common services namespace by running:

   ```
   oc -n <common services ns> edit cm common-web-ui-config
   ```

2. In the `data` section, add the following option:

   ```
   disable-autocomplete: "true"
   ```

3. Save the changes and auto complete will be disabled when you access the login page.

Customizing the Platform UI (Zen) Route

Overview

The ZenService CR spec contains a few parameters that control the Zen route. This document describes what those parameters are and how to set them. At any time before or after installation, you can modify the ZenService CR to trigger a Zen operator reconcile, so that the route can be changed even after installation.

Reencrypt

When the Zen route is set to reencrypt, a TLS connection that is established from a client terminates at the Red Hat® OpenShift® Container Platform router. A second TLS connection is established from the router to the ibm-nginx pods. It is this second hop that requires packets to be "reencrypted", which is where this routing type gets its name.

The following parameters show what must be set in the ZenService custom resource (CR) to configure a reencrypt route. After changing the values in the ZenService CR, in order for them to take effect, a full Zen operator reconcile will take place. To know whether the reconcile is complete, check the **`Status → Progress`** field in the ZenService CR object. The **`Status → Progress`** value will show as 100% after reconcile is complete.

```
zenDefaultIngressReencrypt: true
zenCustomRoute:
  route_host: <hostname> # OPTIONAL
  route_reencrypt: true
  route_secret: anything-but-external-tls-secret
```

The ZenService CR parameters relevant to a reencrypt connection are defined as follows:

- **zenDefaultIngressReencrypt**: If present, this value must be set to `true`.
- **route_host**: This value must reflect the external domain that a user uses to interact with the cluster. The domain specified here must match the domain that is presented by the Certificate in the `tls.crt` value of `route_secret`.
- **route_reencrypt**: Set to `true` for reencrypt.
- **route_secret** : This new value of `route_secret`, should indicate the name of a Kubernetes Secret that will hold the `tls.crt`, `tls.key`, and `ca.crt` values necessary for customizing the certificate that is provided by a reencrypt route. `route_secret` is ONLY valid for a reencrypt route type.

Important: Key names for `route_secret` must use `tls.crt`, `tls.key`, and `ca.crt`. If any other names are used (for example, `cert.crt`, `cert.key`), the route does not apply the values. If any of the three values of `tls.crt`, `tls.key` or `ca.crt` are missing, the ibm-zen-operator ignores the secret, use the default ingress-controller certificate, and issue a WARNING.

Example `create secret` command:

```
oc create secret generic cpd-tls-secret --n <aiops_project>
--from-file=ca.crt=./<ca-certificate-file-name>
--from-file=tls.crt=./<tls-certificate-file-name>
--from-file=tls.key=./<tls-key-file-name>
```

Rotating the Reencrypt Certificate

To rotate the certificate that is used in a reencrypt route, the easiest way to force a reconcile of the Zen operator to accept the new Certificate is to create a new `route_secret` and update that in the ZenService CR. The updated ZenService CR triggers a Zen operator reconcile, which updates the route.

If the same secret is reused after the data values have been updated, there would be no noticeable change to the ZenService CR spec, which means that the Zen operator will not know to reconcile. If the same secret is being used, the Zen operator can still be triggered to reconcile by making changes to the ZenService CR for reconciliation.

Example YAML:

1. Create a reecrypt route with a custom hostname

```
spec:
zenCustomRoute:
  route_host: cloudpak.mycompany.com
  route_reencrypt: true
  route_secret: cpd-tls-secret
```

2. Create a reencrypt route with a custom hostname but accept the default Ingress Controller certificate

Create a reencrypt route with a custom hostname, but accepting the default Ingress Controller certificate (that is, no custom route Certificate provided). This will only work if the Ingress Controller certificate has already been setup to protect the “cloudpak.mycompany.com” domain.

```
spec:
zenCustomRoute:
  route_host: cloudpak.mycompany.com
  route_reencrypt: true
```

Updating default routes to custom hostname

If needed, you can change the default hostname for IBM Cloud Pak® for AIOps and Managed services.

Use the following steps to use a custom hostname for both Cloud Pak for AIOps and Managed services.

1. Follow the DNS update steps in Customizing the Platform UI (Zen) route.
2. Log in to Red Hat OpenShift Container Platform online console.
3. Click **ConfigMap** and click on **router-config** ConfigMap. If the value of the **ZEN_Host** shows as default value, then update this field to use a custom hostname.
4. Follow the DNS update steps for `cp-console` hostname in Updating cp-console hostname and TLS secret by using a configmap.
5. Click **ConfigMap** and click on **oauth-client-map** ConfigMap. Verify the values for **CLUSTER_CA_DOMAIN** and **MASTER_IP** fields and update the fields with the correct domain.
6. Run the following three commands to restart the platform pods:

   ```
   oc delete pod -l app=platform-auth-service
   ```

   ```
   oc delete pod -l app=platform-identity-management
   ```

   ```
   oc delete pod -l app=platform-identity-provider
   ```

   Verify that the pods starting with the name **platform** are up and running.
7. Run the following command to restart Zen base pods:

   ```
   oc delete pod -l app=0020-zen-base
   ```

   Verify that the pod names starting with **zen** are up and running.
8. Run the following command and verify that the progress under Status shows as 100%.

   ```
   oc get zenservice iaf-zen-cpdservice -o yaml
   ```
9. Run the command to restart Managed services pods.

   ```
   oc delete pod -l release=cam
   ```

   Verify that the pod names starting with **cam** are up and running.
10. When all the pods are up and running, navigate to **Library** and **Instances** pages in Infrastructure Automation UI console.
11. If any issue persists, try the following steps:
    1. Check the `cam-tenant-api` pod logs.
    2. Search the logs for the term **apikey** in configboot. A valid key is displayed. If the key is empty restart the **cam-tenant-api** pod.
12. Go to **Service catalog** page. If the page shows an error, restart the following two pods:

    ```
    oc delete pod -l app=cam-service-library-ui-api
    ```

    ```
    oc delete pod -l app=cam-service-library-ui
    ```
13. If the issue still persists, contact IBM Support.

(Optional) Refresh ChatOps pods

If the default cpd route is updated, then ChatOps does not work until the new URL is passed into the deployments. Run the following 3 commands to trigger a rolling restart of the pods:

```
oc set env deployment/$(oc get deploy -l app.kubernetes.io/component=chatops-orchestrator -o
jsonpath='{.items[*].metadata.name }') ZEN_URL=<new_url>
oc set env deployment/$(oc get deploy -l app.kubernetes.io/component=chatops-slack-integrator -o
jsonpath='{.items[*].metadata.name }') ZEN_URL=<new_url>
oc set env deployment/$(oc get deploy -l app.kubernetes.io/component=chatops-teams-integrator -o
jsonpath='{.items[*].metadata.name }') ZEN_URL=<new_url>
```

Where **<new_url>** is the updated URL for the default cpd route.

Customizing the console branding

As an administrator, you can customize the console with your company's branding. You can customize the name that is displayed in the console, and use a custom logo, browser icon, home page and login image.

Before you begin

Required permissions

To customize the branding of the console, you must have one of the following permissions:

- **Administer platform**

About this task

Product name

If you change the product name in the console, the custom name is used throughout the console. For example, the custom name is used on the home page and on the banner of every page in the console.

Logo

If you upload a logo, the logo is displayed in the welcome section of the home page.

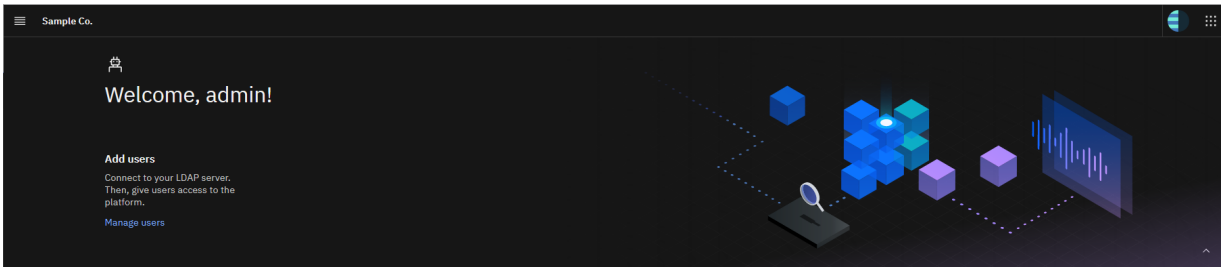

Figure 1. Console with a custom name and logo

Browser icon

If you upload a browser icon, the icon is displayed on the console tab in the browser.

Home page image

If you upload a home page image, the image is displayed on the console home page.

Login image

If you upload a login image, the image is displayed upon login.

Procedure

1. Log in to the console.
2. From the navigation menu, select **Administration** > **Customizations**.
3. Click **Branding**.
4. To use a custom name, select the **Custom name** option under **Product name** and enter the name that you want to use in the console.
   - The name must be 40 characters or less.
   - The product name cannot include the following characters: `<`, `>`, `/`, `\`, `'`, `(`, `)`, or `-`.

5. To use a custom logo, select **Use your own logo** and drop a JPG or PNG file or browse for a file to upload as the home page logo.
    - You can supply a JPG or PNG file.
    - The image is re-sized to fit in a 512 px × 512 px space.
    - The image must be 500 KB or less.
6. To use a custom browser icon, select **Use your own icon** and drop a JPG or PNG file or browse for a file to upload as the browser icon.
    - You can supply a JPG or PNG file.
    - The image is re-sized to fit in a 512 px × 512 px space.
    - The image must be 500 KB or less.
7. To use a custom home page image, select **Use your own image** and drop a JPG or PNG file or browse for a file to upload as the home page image.
    - You can supply a JPG or PNG file.
    - The image must be less than 500 KB for best results, though the limit for an image is 20 MB.
8. To use a custom login image, select **Use your own image** and drop a JPG or PNG file or browse for a file to upload as the login image.
    - You can supply a JPG or PNG file.
    - The image must be less than 500 KB for best results, though the limit for an image is 20 MB.
9. Click **Apply**.

If you want to remove your customizations, click **Restore defaults**.

Customizing the home page

As an administrator, you can customize the content that users can see on the home page. You can specify which cards are enabled and which links are displayed in the **Support** section of the home page.

Before you begin

Required permissions

To customize the home page, you must have one of the following permissions:

- **Administer platform**

About this task

Cards

Cards give users easy access to recently used items and an overview of important changes and alerts.

The list of available cards is determined by the services that are installed on the platform. You can also add custom cards to the home page with the custom cards API. You can prevent certain cards from being displayed on the home page by disabling them.

Each user might see only a subset of the cards based on their permissions and the services that they have access to, so consider how disabling a card will affect users with different roles.

Support links

Support links give users easy access to content that they can use to learn about the platform or to get help.

The default support links are accessible to all users on the platform. However, you can add custom links that are available to specific users based on their permissions.

When you save a change to the home page configuration, the change is immediately applied to the home page. However, if a user is currently logged in to the console, the user must refresh the home page to see the changes.

Procedure

1. Log in to the console.
2. From the navigation menu, select **Administration** > **Customizations**.
3. Click **Home page**.
4. To customize the cards that are displayed on the home page:

1. Open the **Cards** tab.
2. Select a card from the list of cards and decide whether you want to display the card on the home page. If you want to suppress the card, toggle the card to **Disabled** and click **Save**.

Restriction: You cannot add custom cards from the console. You must use the custom cards API.

5. To customize the list of links that are displayed in the **Support** section of the home page:
    1. Open the **Support** tab.
    2. Select a link from the list of links and decide whether you want to display the link on the home page. If you want to suppress the link, toggle the link to **Disabled** and click **Save**.
6. To reorder the list of links that are displayed on in the **Support** section of the home page:
    1. Click the **Reorder** icon .
    2. Drag the links to reorder them.
    3. Click **Save**.
7. To add a link to the list of links that are displayed on in the **Support** section of the home page:
    1. Open the **Support** tab.
    2. Click the **Add custom link** icon .
    3. Specify the label for the link.
    4. Specify the icon to display next to the link.

       You must specify an icon from the Carbon Icon Library.

       By default, when you copy an icon code from the Carbon Design Library, the icon code specifies the 32 px version of the icon. For example, if you copy the code for the Home icon, the following snippet is copied to your clipboard: `<Home32 />`. However, the console uses the 16 px version of the icon. When you paste the snippet into the console:

       1. Remove the angle brackets (`< >`) and the forward slash (`/`).
       2. Change 32 to 16
    5. Specify the URL that you want users to access.
    6. Specify who can see this link:
        - If you select **All users**, all platform users can see the link.
        - If you select **Users with any of the selected permissions**, only users with one or more of the selected permissions can see the link.
    7. Click **Save**.

Supported languages

IBM Cloud Pak Administration panel and IBM Cloud Pak for AIOps console both support multiple languages.

The following table lists the languages that are supported with IBM Cloud Pak Administration panel and IBM Cloud Pak for AIOps console.

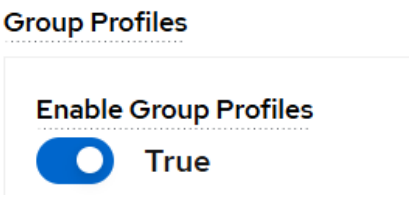
Table. Supported languages

Language	Language code
English	"en"
French	"fr"
German	"de"
Spanish	"es"
Italian	"it"
Japanese	"ja"
Brazilian Portuguese	"pt"
Simplified Chinese	"zh-Hans"
Traditional Chinese	"zh-Hant"

Managing user access control

As an administrator for Role Based Access Control (RBAC) in IBM Cloud Pak for AIOps, you are responsible for determining and implementing the best approach for authenticating and managing users.

You use the access control features within IBM Cloud Pak for AIOps to add users and user groups, create and assign roles, and create user group profiles to fine-tune access control. For instance, you can use profiles to control the visibility of management artifact properties and content that is visible to users. Profiles and associated filters and policies can be used to control the visibility of alerts, incidents, applications, resource groups and resources.



To add to the platform, enable their access to features, and fine-tune their access, you need to complete the following tasks:

1. Configure identity provider connections so that your users can be added to IBM Cloud Pak for AIOps.
2. Add your users to the platform.
3. (Optional) create, and include your users within, user groups.
4. Create and assign roles and permissions to your users and user groups.
5. (Optional) Define any redaction policies or restriction filters for accessing features or data for specific user groups.
6. (Optional) Create profiles to apply redaction policies, restriction filters, and other conditions to your user groups.

Prequisites

As an administrator for Role Based Access Control (RBAC) in IBM Cloud Pak for AIOps, you are responsible for determining and implementing the best approach for authenticating and managing users. To work with profiles, and their associated restriction filters and redaction policies, you must possess an administrative user account with the **Manage profiles** role. For more information, see Roles and permissions.

Note: In the installation resource you are using you need to set the *Enable Group Profiles* radio button to *True*.

Identity provider connections

User records are stored in an internal repository database. You are recommended to use an enterprise-grade password management solution through identity provider connection, such as an LDAP server for password management. To connect to an identity provider, use the Identity Management (IM) service. You can open the IM service from the **Access control** page, by clicking **Configure identity provider**. For more information about connecting to an LDAP provider with the IM service, see Identity providers.

If you configure an identity provider connection to an LDAP server, ensure that you grant administrator privileges to a user in your LDAP server.

Important:

- You cannot create a user from the **Access control** page of your cluster Cloud Pak for AIOps console. You can use the **Access control** page to add only an existing LDAP user to your cluster.
- You must use the configured identity provider (LDAP) to manage users that are added from that provider system. For instance, to change or reset the password for a user, you must complete that change in your configured provider system. You cannot change or reset a user password with the Cloud Pak for AIOps console.

  To see your configured identity providers, navigate to **Administration** > **Identity providers** in the Cloud Pak for AIOps console.
- Identity Management (IM)

Adding users and user groups

An administrator can manage the permissions that users and groups have on the platform. However, users might need additional permissions.

A user can have multiple roles. The roles can be assigned directly to a user or can be assigned to the user through a user group. If a user has multiple roles, the user has all of the permissions from all of the roles that are assigned to them.

Tip: You can see all of the roles (and permissions) that a user has from the user's profile page, which you can access from the **Access control** page, on the **Users** tab.

If you update a user's role or their group membership and the user is logged in, the user must log out and log back in for the changes to take effect. If the user does not log out, their session will be refreshed after the session times out.

Before you add users to the platform, consider the following questions:

- Do you want to use an LDAP server to manage users' passwords?
- Do you want to use an LDAP server to manage access to the platform?
- Do you want to use user groups to manage users with similar access requirements?
- Do you want to be able to add all of the users in an LDAP group to a user group?
- Do the default roles meet my business requirements?
- Adding users
- Managing user groups

Role-based access control

An administrator can manage the permissions that users and groups have on the platform. However, users might need additional permissions. Cloud Pak for AIOps provides enhancements to meet customers' RBAC/ABAC needs around data-access control for many data types such as incidents, alerts, resources, resource groups and applications.

A user can have multiple roles. The roles can be assigned directly to a user or can be assigned to the user through a user group. If a user has multiple roles, the user has all of the permissions from all of the roles that are assigned to them.

- Roles and permissions

Tip: You can view all of the roles (and permissions) that a user has from the user's profile page, which you can access from the **Access control** page, on the **Users** tab.

Note: If a user role or user group is updated while an associated user is logged in, the user must log out and log back in for any changes to take effect. If they do not log out, their session is refreshed when a session timeout occurs.

Fine-tuning role-based access control with profiles

As an administrator, you can define redaction policies and restriction filters for hiding specific data for alerts, incidents, applications, resource groups, and resources in a unified way based on available properties, including custom ones. The policies and filters can be assigned to a profile that can then be applied to one or more user groups. This level of access control is an addition to the use of roles and permissions for accessing features.

By using these profiles, policies, and filters, you can determine the specific data that your users can and cannot view. With this finer level of access control you can better manage data privacy to meet your business needs.

For instance, if IBM Cloud Pak for AIOps is monitoring a network infrastructure that includes multiple devices, each device, and any related alerts, can contain properties for identifying the managing team (user group). This property can be a simple enrichment such as a field that denotes the managing group. The property can also be based on the naming characteristics of the device or alert payload. You can use profiles with redaction policies and restriction filters to ensure that users from one location (A) are not able to view resources in another location (B), such as VM resources. You can also configure the policies and filters so the same users (A) cannot view any alerts from those VM resources. This can ensure that users in one location do not have full visibility of alert and topology data coming from another location (B).

This fine-tuning configuration of access control is managed from the **Profiles** UI page. This page includes three key features across individual tabs:

- Profiles
- Restriction filters
- Redaction policies

User preferences and authentication

When your users are added to the platform and able to access the UI and features they can complete the following user account management tasks to manage their user settings and obtain authentication keys for accessing the IBM Cloud Pak for AIOps API:

- Setting your preferences
- Generating API keys for authentication

Identity Management (IM)

This topic covers the Identity Management (IM) features and concepts that are available with IBM Cloud Pak for AIOps. These identity management features are provided by IBM Cloud Pak foundational services and are available for you to leverage when you install IBM Cloud Pak for AIOps.

At a high level, your IBM Cloud Pak for AIOps provides authentication support through the OpenID Connect (OIDC) specification. IBM Cloud Pak for AIOps also supports Security Assertion Markup Language (SAML)-based federated authentication is also supported.

The authentication and authorization details are explored in the following topics:

- IM for your product platform users

For troubleshooting, see Troubleshooting Identity Management (IM)

For APIs, see Identity Management (IM) APIs

Multiple LDAP domains

There is a growing need for IBM Cloud Pak® for AIOps users to be able to authenticate across multiple LDAPs. Sometimes large organizations might have an LDAP domain controller for different global regions or subsidiaries.

Users can have a mix of directory types such as AD, Tivoli, OpenLDAP etc.

Users can configure multiple directories in the LDAP configuration in IBM Cloud Pak for AIOps. IBM Cloud Pak for AIOps uses WebSphere Liberty Server OpenID Connect as an authentication service which does administration and authentication against the appropriate directory.

Note: Currently, IM doesn't support LDAP failover.

Multiple LDAP registration

As a cluster administrator, you can configure multiple LDAP domains by adding multiple directory entries to the LDAP configuration in **`server.xml`**.

Open LDAP server.xml AD Tivoli Cluster Persist LDAP config Configure each LDAP WebSphere Liberty

In a multiple domain configured environment, a new user administration on IBM Cloud Pak for AIOps platform enforces a selection of appropriate domains and the user is added to the Team.

The user profile and the domain name is maintained by IBM Cloud Pak for AIOps and is further used for user management. The ability to chose domain before selecting users, such as for a team, allows administrator to isolate teams with a specific domain.

Note: User credentials are passed by IBM Cloud Pak for AIOps to WebSphere Liberty OIDC server which resolves the user domain and authenticates the user with a matching domain.

Authentication types

You can configure multiple authentication types for single sign-on (SSO).

You can then access your IBM Cloud Pak® console by using the configured authentication type.

The following authentication types are supported:

- IBM provided credentials (admin only). The default authentication type that you configure during IBM Cloud Pak® installation. This configuration is usually the Administrator username and password. The foundational services installer generates a password for the default username `admin`, which is a cluster administrator role.
- Enterprise LDAP
- Enterprise SAML
- OpenShift authentication
- OpenID Connect username

Note: Multiple factor authentication (MFA) uses multiple authentication technologies to verify a user's identity. foundational services IAM supports MFA using the third-party identity provider MFA capability. If IAM is integrated with the third-party identity provider through SAML or OIDC, Cloud Pak can support MFA to authenticate users when the identity provider enables MFA.

After you install your IBM Cloud Pak®, when you access the console, you can see the login options that are available. You can see the login options only for the authentication types that are configured in your cluster. If you configure only the default authentication type (IBM provided credentials), you do not see any login option. You must then access your IBM Cloud Pak® console by using the default authentication type.

The console login cookie saves the authentication type that you select for 24 hours. When you access the login page within 24 hours, you see the login page for the same authentication type. You can choose another authentication type by clicking **Change your authentication type**.

Note: If you remove the Enterprise LDAP or disable Enterprise SAML configuration from your cluster, first clear the browser cache before you access the console login page.

Setting the preferred login options

When you configure multiple authentication types in your cluster, all the configured types are displayed on the console login page as authentication options.

If you want the console login page to display any one or a selected set of the configured login options, you can set the preferred login options.

To set the preferred login options before IM service installation, see setting the preferred login options in Configuring foundational services by editing the CommonService custom resource.

To set the preferred login options after IM service installation, complete these steps:

1. Log in to your infrastructure node by using the oc login command.
2. Edit the **platform-auth-idp** configmap.

   ```
   oc edit cm platform-auth-idp -n <your-foundational-services-namespace>
   ```

   In the data section, you see the **PREFERRED_LOGIN** data definition, which has no values set by default.
3. Add the login options that you want to display on the console page.

   For example, **PREFERRED_LOGIN: "SAML","LDAP","OIDC"**. Use the following parameter values:

   - For default authentication, use **DEFAULT**
   - For enterprise LDAP, use **LDAP**
   - For enterprise SAML, use **SAML**
   - For OpenShift authentication, use **ROKS**
   - For OpenID Connect, use **OIDC**

   Note: If you set the **PREFERRED_LOGIN** to SAML or OIDC with one provider only, the console redirects you to the login page of the configured provider.
4. Restart the **platform-identity-management** pod by deleting it.

   1. Get the platform-identity-management pod name.

   ```
   oc get pods -n <your-foundational-services-namespace> | grep platform-identity-management
   ```

   Following is a sample output:

   ```
   platform-identity-management-785df784f5-qcx4z                     1/1     Running   0          39d
   ```

   2. Delete the platform-identity-management pod.

   ```
   oc delete pod <platform-identity-management-pod-name> -n <your-foundational-services-namespace>
   ```

   5. Restart the **common-web-ui** pod by deleting it.
   6. Get the common-web-ui pod name.

   ```
   oc get pods -n <your-foundational-services-namespace> | grep common-web-ui
   ```

   2. Delete the **common-web-ui** pod.

   ```
   oc delete pod <common-web-ui-pod-name> -n <your-foundational-services-namespace>
   ```

   After the pods restart, your preferred login options are visible on the console login page.

Using foundational services IM for authentication

You can log in to the Red Hat® OpenShift® Container Platform console by using your foundational services or the IBM Cloud Pak access credentials.

Delegating authentication to OpenShift

Authenticate with Red Hat® OpenShift® Container Platform.

If you are installing IBM Cloud Pak for AIOps on an environment that uses the built-in OpenShift OAuth server, you can use the OpenShift OAuth server for authentication.

Note: In foundational services version 4.x.x, OpenShift authentication is enabled by default. You can disable it by using Identity Provider V3 API. To disable the OpenShift authentication, see Disabling OpenShift authentication by using IdP V3 API.

Note: If you are upgrading your cluster, the authentication configuration is not changed after the upgrade. For example, if you did not configure OpenShift authentication in the previous release, the OpenShift authentication is not enabled after you upgrade.

Updating OpenShift authentication before you install the IM Operator

Complete the following steps to update the OpenShift authentication parameters. You must complete these steps after you install the IBM Cloud Pak foundational services operator, but before you install the foundational services in your cluster:

1. From your Red Hat® OpenShift® Container Platform console, click **Operators** > **Installed Operators**.
2. Search for **IBM Cloud Pak foundational services** and click the **IBM Cloud Pak foundational services** operator name to open the Details tab for the operator.
3. Select the **Common Service** tab. You see an instance of the CommonService that is installed in your cluster.
4. Edit the `common-service` instance.
5. In the YAML file, scroll down to `spec.services.ibm-im-operator.spec.authentication.config` section.

   Note: Create the `spec.services.ibm-im-operator.spec.authentication.config` section if it does not exist.

   The following example shows the `spec.services.ibm-im-operator.spec.authentication.config` section in the YAML file:

   ```
   apiVersion: operator.ibm.com/v3
   kind: CommonService
   metadata:
     name: common-service
     namespace: <your-foundational-services-namespace>
   spec:
   size: ...
     ...
     services:
      - name: ibm-im-operator
        spec:
          authentication:
           config:
            roksEnabled: false
            roksURL: <endpoint url>
            roksUserPrefix: 'IAM#'
   ```

6. Update the values of the following parameters:

   - `roksEnabled:` Set to `false:` to disable authentication with Red Hat® OpenShift® Container Platform. The default value is `true`.
   - `roksURL:` The public service endpoint URL of your public cloud cluster. Use the following command to get the endpoint URL.
   - `roksUserPrefix:` Prefix to be used with the username. When you access your cluster console or CLI, you use the prefix along with the username to authenticate with OpenShift. The default value is `""`. If you are using IM with Red Hat® OpenShift® on IBM Cloud® service in the IBM Cloud, you must set the prefix to `IAM#`.

   Note: You need `jq` to run the following command. To install `jq`, see Download jq.

   ```
   curl -sk https://<server-URL>/.well-known/oauth-authorization-server | jq -r '.issuer'
   ```

   For example:

   ```
   curl -sk https://api.par-test.os.fyre.ibm.com:6443/.well-known/oauth-authorization-server | jq -r
   '.issuer'
   ```

   Following is a sample output:

   ```
    https://oauth-openshift.apps.par-test.os.fyre.ibm.com
   ```

   The following shows a configuration of the `ibm-im-operator` with the OpenShift authentication configuration in the **CommonService** YAML file:

```
- name: ibm-im-operator
    spec:
      authentication:
        config:
          roksEnabled: true
          roksURL: 'https://oauth-openshift.apps.par-test.os.fyre.ibm.com'
          roksUserPrefix: 'IAM#'
```

7. Save the YAML file.

When you access IBM Cloud Pak for AIOps console, you can see the **OpenShift authentication** as a login option.

Changing the default cloud pak administrator

The IBM Cloud Pak foundational services installation creates a default **admin** user, who is a administrator. If you are delegating authentication to OpenShift, you can customize the default openshift username by using the **bootstrapUserId** parameter. This user will have the cloud pak administrator access.

To add the **bootstrapUserId** parameter before IM service installation, see Assigning the cloud pak administrator privileges to an OpenShift user.

To add the **bootstrapUserId** parameter after IM service installation, complete these steps:

1. Log in to your infrastructure node by using the **oc login** command.
2. Edit the **platform-auth-idp** configmap.

   ```
   oc edit cm platform-auth-idp -n <your-foundational-services-namespace>
   ```

   In the **data** section, the **"BOOTSTRAP_USERID"** is set to **kubeadmin** by default. Change **kubeadmin** to the OpenShift user who you want to make the cloud pak administrator.

3. Run the following CURL command to update default admin username:

   ```
   curl -X PUT 'https://cp-
   console.apps.mycluster.mydomain.fyre.ibm.com/idmgmt/identity/api/v1/users/defaultAdmin' \
       --header 'Content-Type: application/json' \
       --header 'Accept: application/json' \
       --header "Authorization: Bearer $ACCESS_TOKEN" \
       -d "{\"username\": \"${new_admin_username}\"}" \
       --insecure
   ```

4. Restart the **platform-identity-provider** and **platform-auth-service** pods by deleting them.

   1. Get the **platform-identity-provider** pod name and **platform-auth-service** pod name .

      ```
      oc get pods -n <your-foundational-services-namespace> | grep platform-identity-provider
      ```

      ```
      oc get pods -n <your-foundational-services-namespace> | grep platform-auth-service
      ```

   2. Delete the **platform-identity-provider** pod and **platform-auth-service** pod.

      ```
      oc delete pod <platform-identity-management-pod-name> -n <your-foundational-services-namespace>
      ```

      ```
      oc delete pod <platform-auth-service-pod-name> -n <your-foundational-services-namespace>
      ```

After the pods restart, the OpenShift user can access with administrator privileges.

OIDC registration with the client custom resource

Create a custom resource for OpenID Connect (OIDC) registration.

The controller for OIDC registration generates secret objects by using a client ID and secret key. The secret objects can be used for OIDC challenges. The identity management (IM) service applies role-based access control (RBAC) to the OIDC registration custom resource and binds the ability to allow operator or higher roles to create, view, and list these objects.

- The custom resource is added to the appropriate roles so that users with that role can create OIDC Client resources.
- The OIDC Client resource contains the OIDC registration payload and the name of the secret that is required to inject the resulting OIDC Client ID and secret.
- The OIDC registration controller watches for the OIDC Client resource to be created and then processes it.
- The processing status of the OIDC Client resource is stored in the status portion of the resource, and the secret is created with the client ID and secret information.

Complete these steps to create the **Client** custom resource. After you create the custom resource, you can integrate it with your application to enable OIDC-based authentication.

1. Define a custom resource named **Client** and save it as a YAML file. For example, **sample-oidc-client.yaml**. To ensure that the namespace is authorized by the namespace scope operator, see Authorizing foundational services to perform operations on workloads in a namespace.

Following is a sample custom resource:

```
apiVersion: oidc.security.ibm.com/v1
kind: Client
metadata:
  name: eventstreams-client
  namespace: default
spec:
  secret: eventstreams-oidcclient-secret
  oidcLibertyClient:
    post_logout_redirect_uris:
    - <console URL>:443
    redirect_uris:
    - <console URL>:443/api/auth/callback
    trusted_uri_prefixes:
    - <console URL>:443
```

The **spec** section includes information about initiating the OIDC Client registration process.

- **secret** is the name for the secret that is generated during registration.
- **oidcLibertyClient** contains the post logout redirect urls (**post_logout_redirect_uris**), trusted url prefixes (**trusted_uri_prefixes**), and redirect urls (**redirect_uris**).

Following is a sample custom resource:

```
apiVersion: oidc.security.ibm.com/v1
kind: Client
metadata:
  name: eventstreams-client
  namespace: default
spec:
  secret: eventstreams-oidcclient-secret
  oidcLibertyClient:
    post_logout_redirect_uris:
    - https://myapp.example.com:443
    redirect_uris:
    - https://myapp.example.com:443/api/auth/callback
    trusted_uri_prefixes:
    - https://myapp.example.com:443
```

2. Create the custom resource.

   ```
   oc create -f <crd-yaml-file-name>.yaml
   ```

   Following is an example command:

   ```
   oc create -f sample-oidc-client.yaml
   ```

   The command creates the resource, registers the client, and generates the secret (which is **eventstreams-oidcclient-secret** in the example), which includes the client ID and client secret.

3. Check whether the registration is successful.

   ```
   oc get Client <client-resource-name> -n <client-resource-namespace>
   ```

   Following is an example command:

   ```
   oc get Client eventstreams-client -n default
   ```

   If the resource is successfully registered, you see a message similar to the following message:

   ```
   status:
     conditions:
       lastTransactionTime: "2019-12-12T23:17:42Z"
       message: OIDC client registration successful
       reason: CreateClientSuccessful
       status: "True"
       type: "Ready"
   ```

APIs

You can use the following APIs to create and manage OIDC registration custom resource.

Before you use these APIs, see Preparing to run component or management API commands.

The **<cluster_address>** is the IBM Cloud Pak console route. You can get the IBM Cloud Pak console route by running the following command:

```
oc -n <your-foundational-services-namespace> get route cp-console -o yaml
```

The IBM Cloud Pak console route is in the **spec.host** section.

Create OIDC registration

```
curl -X "POST" --header 'Content-Type: application/json' --header 'Accept: application/json' --header
"Authorization: bearer $ACCESS_TOKEN" --data @registration.json
"https://<cluster_address>:443/idprovider/v1/auth/registration" --insecure
```

Update existing OIDC registration

```
curl -X "PUT" --header 'Content-Type: application/json' --header 'Accept: application/json' --header
"Authorization: bearer $ACCESS_TOKEN" -d --data @registration.json
"https://<cluster_address>:443/idprovider/v1/auth/registration/$CLIENT_ID" --insecure
```

GET existing OIDC registration information

```
curl -X "GET" --header 'Content-Type: application/json' --header 'Accept: application/json' --header
"Authorization: bearer $ACCESS_TOKEN"
"https://<cluster_address>:443/idprovider/v1/auth/registration/$CLIENT_ID" --insecure
```

DELETE existing oidc registration

```
curl -X "DELETE" --header 'Content-Type: application/json' --header 'Accept: application/json' --header
"Authorization: bearer $ACCESS_TOKEN"
"https://<cluster_address>:443/idprovider/v1/auth/registration/$CLIENT_ID" --insecure
```

Auditing IM service

Identity Management (IM) uses HTTP ingest endpoint to send the IM related audit records to the Audit logging service of the foundational services. IM sends the audit logs to **zen-audit-svc** when you enable auditing service for IM.

By default, the audit logs are disabled in IM. You can enable the auditing service in IM with the following methods:

- Enabling auditing service with **oc** command
- Enabling auditing service with console

Prerequisites

- Ensure that the audit logging service (**zen-audit**) is running in your cluster.

```
$ oc get pods |grep zen-audit
```

```
zen-audit-789bfdc9d4-2hkmn                                        1/1     Running     0          3h25m
```

- If **zen-audit** is not installed in your cluster, IM sends the audit logs to the docker logs in the container.

  The following is the sample **platform-auth-idp** configmap:

  ```
  apiVersion: v1
  data:
   AUDIT_ENABLED_IDMGMT: "true"
   AUDIT_ENABLED_IDPROVIDER: "true"
   BASE_AUTH_URL: /v1
   BASE_OIDC_URL: https://127.0.0.1:8443/idauth/oidc/endpoint/OP
   CLUSTER_NAME: mycluster
   HTTP_ONLY: "true"
   MASTER_HOST: mycluster.icp
   NODE_ENV: production
   OAUTH2DB_DB_PORT: "3306"
   OIDC_ISSUER_URL: https://mycluster.icp:8443/oidc/endpoint/OP
   SESSION_TIMEOUT: "43200"
    .
    .
    .
  ```

Enabling auditing service with oc command

To enable the auditing in the IM with the **oc** command, complete the following steps:

1. Edit the **platform-auth-idp** configmap in the **foundational-services** namespace:

   ```
   oc -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

2. Set the following attribute values to **true**:

   - AUDIT_ENABLED_IDPROVIDER: 'true'
   - AUDIT_ENABLED_IDMGMT: 'true'

3. Save the configmap.

4. Delete the the **platform-auth-service**, **platform-identity-provider**, and **platform-identity-management** pods.

   ```
   oc -n <your-foundational-services-namespace> delete pods <pod_name>
   ```

5. To check whether the audit logs are generated, go to the **zen-audit** pod logs. Run the following command to see the **zen-audit** pod name. Replace the **<common-services-namespace>** variable with the namespace in which foundational services is installed.

   ```
   oc get pods -n <common-services-namespace> | grep zen-audit
   ```

6. To see the pod logs, enter the following command. Replace the **<zen-audit-pod-name>** variable with the **zen-audit** pod name.

   ```
   oc logs -f <zen-audit-pod-name>
   ```

After you complete these steps, the audit logs are forwarded to the appropriate security information and event management [SIEM] tool that is configured within the **foundational-services** namespace.

Enabling auditing service with console

1. Log in to the Red Hat® OpenShift® Container Platform console.
2. From the navigation menu, click **Workloads** > **Config Maps.**
3. Search for **platform-auth-idp**.
4. Click **...** > **Edit Config Map**.
5. Set the following attribute values to **true**:

   - AUDIT_ENABLED_IDPROVIDER: 'true'
   - AUDIT_ENABLED_IDMGMT: 'true'

   Note: A **resource is managed by example-authentication and any modifications may be overwritten** warning message is displayed. You can ignore this message.
6. Click **Save**.
7. From the navigation menu, click **Workloads > Deployments**.
8. Locate **platform-auth-service** pods.
9. Click **...** > **Edit Deployment**. A window for editing displays.
10. Click **Save** without making any change. This step is to reload the **platform-auth-service** pods with the latest ConfigMap values.
11. Click **platform-auth-service**.
12. Wait for some time. Then, check the status of the **platform-auth-service** pods in the **Pods** pane. The status of the pods must show as **1/1** under the **Ready** field name.
13. To check whether the audit logs are generated, go to the **zen-audit** pod logs.
14. Repeat steps 8 through 13 for the **platform-identity-provider** and **platform-identity-management** deployments.

To forward audit records to a SIEM solution such as Splunk, Mezmo, or QRadar, see Exporting Cloud Pak for Data audit records to a security information and event management solution.

IM for IBM Cloud Pak for AIOps platform users

Identity Management (IM) for platform users includes authentication that includes OIDC and SAML.

Authentication

IBM Cloud Pak® for AIOps uses WebSphere Liberty OpenID Connect (OIDC) 1.0 for authentication. It calls the standard OIDC endpoints **`/authorize`** and **`/token`** to initiate an OAuth dance. OpenID in Liberty can be configured with Lightweight Directory Access Protocol (LDAP), after which an LDAP user can authenticate to IBM Cloud Pak for AIOps by using the same OpenID endpoints. For single sign-on (SSO) based authentication, OIDC is configured with Security Assertion Markup Language (SAML) to interact with your enterprise identity source.

Authentication protocols supported

IBM Cloud Pak for AIOps supports the following two authentication protocols:

1. OIDC-based authentication
2. SAML-based federated authentication

OIDC and SAML are both used for SSO with IBM Cloud Pak for AIOps but for different purposes.

IBM Cloud Pak for AIOps is an OIDC identity provider that provides authentication and authorization services to IBM Cloud Pak for AIOps console and APIs. It works along with one or more LDAP providers to authenticate the user ID and password with the LDAP service and to provide an access token for subsequent requests to IBM Cloud Pak for AIOps services. IBM Cloud Pak for AIOps is an identity provider through LDAP.

IBM Cloud Pak for AIOps can be configured as a SAML service provider, which allows federated authentication with an external SAML 2.0 identity provider. When you configure SSO, IBM Cloud Pak for AIOps redirects your console browser to the third-party login page, and OIDC issues you a bearer token.

The OIDC-based authentication service is the default authentication service in IBM Cloud Pak for AIOps. If required, you can configure a SAML server to provide federated authentication.

OIDC-based authentication

You must configure and connect an LDAP directory with your product cluster, and provide cluster administrator, Cloud Pak administrator, or administrator access level. For more information, see Configuring LDAP connection. You must set up the LDAP connection before you create a team and add users to the team. Only LDAP users who are assigned to a team can log in to the console.

Configuring single sign-on with the SAML using IdP APIs

Metadata files are used for communication between IBM Cloud Pak for AIOps and your enterprise SAML server.

Note: If you see the error **`404`** during SAML configuration, check with the administrator whether SAML is enabled for the Cloud Pak at the Identity Provider.

Before you configure SSO, you must configure a fully qualified domain name (FQDN) for accessing your cluster.

Note: If you are configuring SSO by using SAML, you must manually register the IdP by using Identity provider APIs in the following scenarios:

- If you do not have the IdP registration.
- If you are installing foundational services for the first time.
- Irrespective of SAML dependency on LDAP.

To verify whether you have an IdP registration, see Get IdP registration by query.

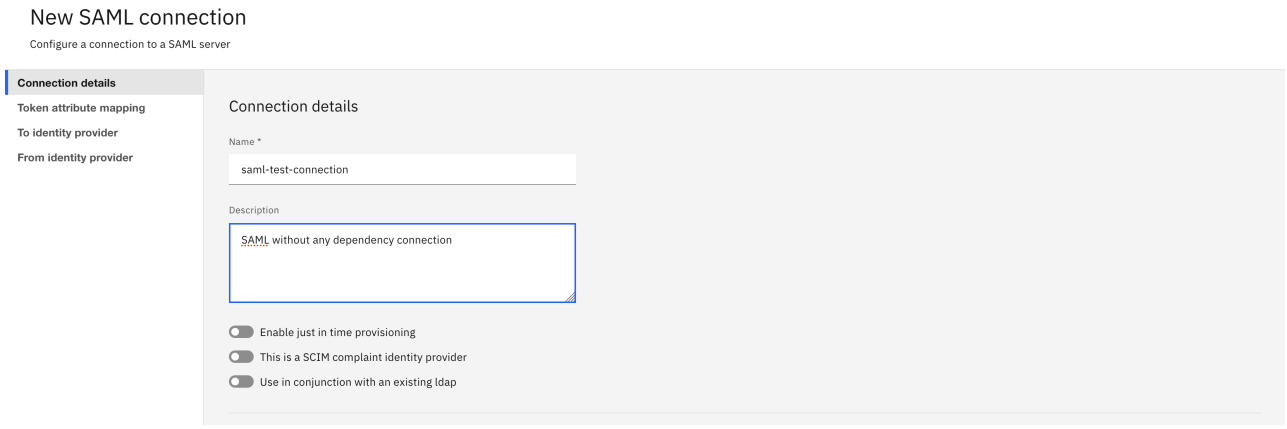
To configure SSO, complete the following sequence of steps:

1. Configure SAML and import metadata that is sent by your enterprise SAML server by using IdP V3 APIs.
2. Export the metadata of IBM Cloud Pak for AIOps to your enterprise SAML server. After you complete this task, a metadata file is downloaded. For more information, see SAML metadata export by using samlmetadata API.
3. Verify whether SAML was successfully configured.
4. Configure the SAML connection with one of the following methods:
    - **SAML with SCIM dependency:** You can directly connect with the SAML IdP if it is SCIM-enabled. SCIM is supported to connect with the registered IdP and import the users by using the IdP APIs. If you are manually registering SAML with SCIM-enabled IdP, see SAML with SCIM dependency registration. Based on your requirement, you can update the values of the schema elements, **`name`**, **`description`**, **`idp_type`**, **`scim_base_path`**,**`token_attribute_mappings`**, **`scim_attribute_mappings`**, and **`config`**. To understand the use of schema elements, see Different schema elements.
    - **SAML without any dependency:** If you are using SAML without LDAP dependency or SCIM-enabled IdP, you can register the IdP by using SAML registration without any dependency. Based on your requirement, you can update the values of schema elements, **`name`**, **`description`**, and **`token_attribute_mappings`**. To understand the use of schema elements, see Different schema elements.

- **SAML with LDAP dependency:** Optional: Connect with an LDAP server and import users who might use the SSO request. For more information, see Configuring LDAP connection. See the following notes:
  - You can also connect IBM Cloud Pak for AIOps with the same LDAP server that your enterprise SAML server uses for authentication.
  - If you are connecting LDAP by using SAML, see SAML with LDAP dependency registration. Based on your requirement, you can update the values of the schema elements, `name`, `description`, `scim_base_path`, `token_attribute_mappings`, and `saml_ldap`. To understand the use of schema elements, see Different schema elements.

Configuring single sign-on with the SAML using IBM Cloud Pak for AIOps console

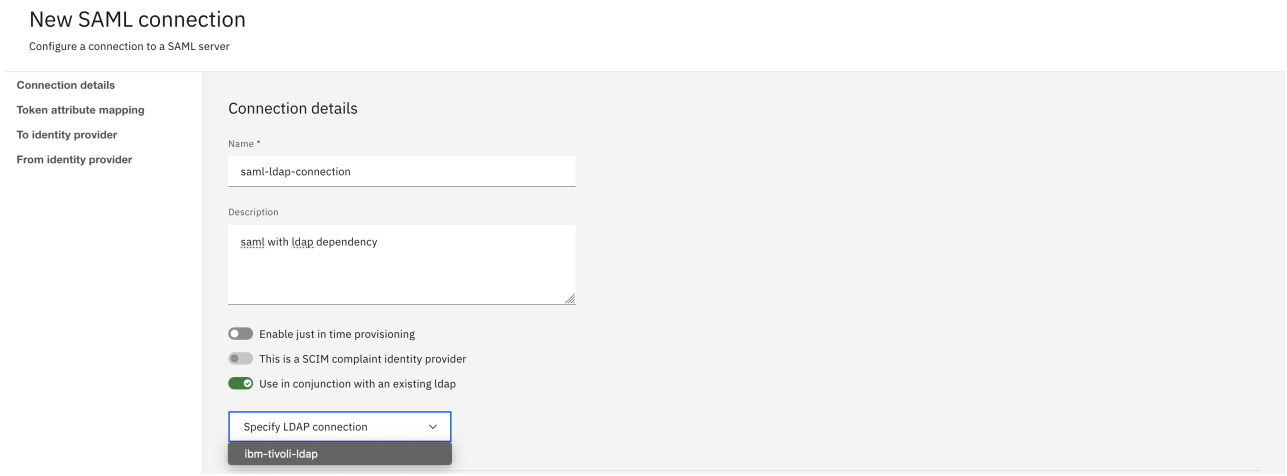
Configure single sign-on (SSO) by using Security Assertion Markup Language (SAML) from IBM Cloud Pak for AIOps console.



Note: You can configure only one SAML connection.

You can configure the SAML connection by using any of the following methods:

- SAML with SCIM dependency
- SAML without any dependency
- SAML with LDAP dependency



Setting up the SAML connection

1. Log on to the console as an administrator.
2. From the navigation menu, click **Administer** > **Identity providers**.
3. Click **Create Connection**. Select **SAML 2.0** as the protocol type and click **Next**. The **New SAML Connection** page is displayed.
4. In the **New SAML Connection** page, select the **Connection details** tab. It contains the following options that you are required to fill:
   - `Name`: A name for the SAML connection.
   - `Description`: Description of the SAML connection.
5. Choose the type of SAML that you want to configure.
   - For SAML without dependency, do not change the toggle options. By default, these toggle options are disabled.

   - For SAML with LDAP dependency, enable **Use in conjunction with an existing ldap** toggle option. From the **Specify LDAP Connection** drop-down list, choose the existing LDAP to integrate.

Note: You must configure the LDAP connection before you configure SAML with LDAP dependency. **Important:** When you enable **Use in conjunction with an existing ldap**, you won't see the login option for LDAP authentication on the console login page.

- For SAML with SCIM dependency, enable **This is a SCIM compliant identity provider** toggle option.

6. Select the **Token attribute mapping** tab. It contains the following options that you are required to fill:

   - `Subject`
   - `Given name`
   - `Family name`
   - `Groups`
   - `Email`

   See the following notes:

   - By default, the **Token attribute mapping** values are pre-defined if you do not specify the mapping. It is recommended to modify the default values according to the SAML claim. The following default values are displayed if you do not specify the mapping values:
   - `Subject` : uid
   - `Given name` : firstName
   - `Family name` : lastName
   - `Groups` : blueGroups
   - `Email` : emailAddress
   - The `uniqueSecurityName` option is not supported from the product console. If the `uniqueSecurityName` is required in **Token attribute mapping**, see Different schema elements for IdP V3.

7. Select **To identity provider** tab. Click **Download metadata** link to download the SAML 2.0 metadata. Once you download the metadata, you can upload that metadata to your identity provider to generate identity provider metadata.

8. Select **From identity provider** tab. Upload the identity provider metadata in `*.xml` file that is supplied by your identity provider.

   Note: The maximum accepted size of the metadata file is `2 MB`. If the size of the metadata file is more than 2 MB, the `Payload Too Large` error is displayed in the console.

9. The **SCIM configuration** tab is enabled when you choose to configure SAML with SCIM dependency. It contains the following fields:

- **`Scim base path`**: It is required to uniquely identify the service instance.
- **`Grant type`**: It identifies the token generation flow.
- **`Token URL`**: It is the token endpoint of the IdP. It is used to request the token.
- **`Client ID`**: It is used for the client credentials flow.
- **`Client Secret`**: It is used for the client credentials flow.

Also, you need to configure the SCIM attribute mapping for the **`user`** and **`group`** resources. By default, these fields are pre-defined as the **`principalName`** in both **`user`** and **`group`** attributes. It is recommended to modify the values based on the SCIM IdP configuration.

10. Click **Create**.

Configuring single sign-on using OpenID Connect (OIDC)

Using OIDC, you can configure single sign-on (SSO) between IBM Cloud Pak® for AIOps and supported providers. You can configure OIDC with just-in-time (JIT) provision only.

OIDC is an authentication protocol layer that is built on the OAuth 2.0 protocol. It allows the third-party applications to:

- Verify the identity of the users.
- Get the basic profile information about the users.

The following steps represent the flow that happens during SSO configuration by using OIDC:

1. A user attempts to access a service in IBM Cloud Pak for AIOps through a web browser.
2. IBM Cloud Pak for AIOps verifies whether an authentication token is present.
3. If no authentication token is present, IBM Cloud Pak for AIOps redirects the request for authentication to the third-party authorization server of the user.

4. The authorization server presents a login page to the user.
5. If the user logs in successfully, the authorization server redirects the user, along with the OIDC response, to IBM Cloud Pak for AIOps.
6. IBM Cloud Pak for AIOps generates an authentication token and grants access to the service that the user requested.

Note: You can use PKCE with OIDC for protection from authorization code interception attacks for OAuth 2.0 public clients. For more information, see PKCE support for OpenID Connect clients. The IM service enables PKCE by default. If your OIDC provider configures PKCE, you can use it for authentication in the IM login flow. If the OIDC provider does not configure PKCE, it does not impact the IM login flow.

Configuring SSO in IBM Cloud Pak for AIOps by using OIDC

See the following notes:

- You can configure SSO with OIDC support by using the IdP V3 APIs. For more information, see IdP V3 APIs.
- Currently, OIDC is the only supported protocol with the IdP V3 version.
- To verify whether you have OIDC support or not, see Getting the list of registered OIDC clients by query.

Before you begin

Log in to any of the following platforms by using the provided IdP links and register yourself in the application. During registration, use application URL as cp-console URL and redirect URL as **`https://<cp-console-url>/ibm/api/social-login/redirect/<name of the oidc>`**. Once you are registered, you can get the unique client ID, client secret and **`discovery_url`** endpoint. Currently, only these platforms are verified to register the OIDC by using the IdP V3 API.

Verified platforms to register OIDC provider using IdP V3

Platform	IdP link
IBM Security Verify (ISV)	https://www.ibm.com/docs/en/erqa?topic=using-security-verify-as-oidc-provider **Note:** Whenever you perform the attributes mapping through the OIDC provider in the ISV application, enable the **Send all known user attributes in the ID token** option. And, ISV groups must not contain spaces.
Google Cloud Platform	https://cloud.google.com/identity-platform/docs/web/google
Microsoft	https://cloud.google.com/identity-platform/docs/web/microsoft
Okta	https://help.okta.com/en-us/Content/Topics/Apps/Apps_App_Integration_Wizard_OIDC.htm

Procedure

To configure SSO, complete the following sequence of steps:

1. Register the OIDC clients. For more information, see Registering the OIDC clients.
2. Get the list of registered OIDC clients. For more information, see Getting the list of registered OIDC clients.

   If you need to delete the registration of the client, see Deleting the registration of the client.
3. Open the Cloud Pak home page to verify whether the OIDC is successfully configured.

   Note: After the OIDC is successfully configured, you can log in to the cp-console. However, to log in to the Cloud Pak Platform and to get the OIDC successfully configured, first you need to onboard the OIDC users into the Cloud Pak Platform. Then, the OIDC users are able to log in to the Cloud Pak Platform.
4. To authenticate, click the corresponding OIDC link in the Cloud Pak home page.

Granting an admin role to Cloud Pak Platform

Before you begin, onboard OIDC users into the Cloud Pak Platform.

Important: If you configure multiple authentication types (SAML, LDAP, and OIDC) in your cluster, and onboard same users to all the authentication types, the users might not be able to log in the first time by using OIDC. They might be able to log in the second time. To overcome the limitation, onboard users by following the instructions in Integrating IBM Cloud Pak SAML with Azure Active Directory.

Now, complete the following steps to grant an Admin role for Cloud Pak Platform. The procedure is based on the APIs.

1. Configure environmental variables:
   1. Obtain an IM access token for the default admin user. For more information, see Preparing to run API commands.
   2. Set the HOST environment variable. To get the host value, run the following command:

```
oc get route -n <your-foundational-services-namespace>
```

Set the HOST to the cp-console route. For example, `export HOST=<cp-console>`.

3. Set CPHOST to the cpd route with corresponding `ibm-nginx-svc` service name. For example, `CPHOST=cpd-cp4i.apps.bunny.cp.abc.ibm.com`.

2. Get the IBM Cloud Pak access token for the admin user.

```
curl -ki -X GET 'https://'$CPHOST'/v1/preauth/validateAuth' --header 'username: cpadmin' --header "iam-token: $TOKEN"
```

Note: The default `username` for the new cluster installation is `cpadmin`. If you upgrade the existing cluster, the default username is `admin`.

3. Create a user group with the role that you want to assign to the user.

```
curl -k -s  -X POST 'https://'$CPHOST'/usermgmt/v2/groups' \
--header 'Content-Type: application/json'   \
--header 'Accept: application/json'   \
--header "Authorization: Bearer $CPTOKEN" \
-d
'{"name": "isv group",
"description": "Group default ISV group",
"role_identifiers": ["zen_user_role"]
}'
```

Note: To create an admin group, in "role_identifiers", specify the “zen_administrator_role”.

Verify whether the group is listed, and get the group ID:

```
curl -k -s  -X GET 'https://'$CPHOST'/usermgmt/v2/groups' \
--header 'Content-Type: application/json'   \
--header 'Accept: application/json'   \
--header "Authorization: Bearer $CPTOKEN"
```

4. Add the `isv` group into the user groups:

```
curl -k -s  -X POST 'https://'$CPHOST'/usermgmt/v2/groups/<group_ID>/members' \
--header 'Content-Type: application/json'   \
--header 'Accept: application/json'   \
--header "Authorization: Bearer $CPTOKEN" \
-d
'{
"ldap_groups": ["admin"]
}'
```

In the command, the **group_ID** is the `isv` group ID that you got in the previous step.

The configuration is complete.

5. Verify whether the user who is a member of the `isv` group can log in to Cloud Pak Platform with proper permissions. To verify, open the Cloud Pak Platform in your browser by using the URL of $CPHOST.

Configuring LDAP connection

Configure an LDAP (Lightweight Directory Access Protocol) connection for your product cluster.

You must connect an LDAP directory with your product cluster. You can then add users from your LDAP directory into your cluster.

IM supports the `LDAPEntityType` configuration for LDAP User and Group entities as default to define the `ObjectClass` or `ObjectCategory` attributes automatically in the Liberty XML file. The `ObjectClass` or `ObjectCategory` attributes of the User and Group are retrieved from the `User` and `Filter` fields that are defined in the LDAP IDP V3 idsource API. For existing LDAP connection, you need to restart the `platform-auth-service` pods to enable the `LDAPEntityType` configuration. For more information, see Enabling `LDAPEntityType` configuration for existing LDAP User and Group entities.

The following LDAP types are supported:

- IBM Tivoli Directory Server
- IBM Lotus Domino
- IBM SecureWay Directory Server
- Novell eDirectory
- Sun Java™ System Directory Server
- Netscape Directory Server
- Microsoft Active Directory
- Custom

Note: You can configure an account lockout policy when you set up your LDAP server. An account lockout policy provides more security by restricting access to the account if multiple login attempts fail.

Important: If Platform UI (`ibm-platformui-operator`) service is installed, user management capabilities are available for managing LDAP user and user groups roles, and permissions. You can add an LDAP or OpenShift user to your cluster. When you add a user, you must specify the OpenShift or LDAP login ID of the user in the `Username` field.

Required user type or access level: Cluster administrator or Cloud Pak administrator

Enabling `LDAPEntityType` configuration for existing LDAP User and Group entities

Restart the `platform-auth-service` pods to enable the `LDAPEntityType` configuration for the existing LDAP connection.

1. Get the `platform-auth-service` pod name.

   ```
   oc get pods -n <your-foundational-services-namespace> | grep platform-auth-service
   ```

2. Delete the `platform-auth-service` pod.

   ```
   oc delete pod <platform-auth-service-pod-name> -n <your-foundational-services-namespace>
   ```

The procedure is not applicable for new LDAP connection.

Connecting to your LDAP directory

Follow these steps to set up your LDAP connection.

Pre-requisite: Install the cluster. Once the cluster is installed, the admin username, password, and the URL are displayed.

1. Log on to the console by using the URL and enter the username and password.

   Note: The console can be Platform UI or Common UI. For more information, see Accessing your cluster by using the console.

2. From the navigation menu, click **Identity and access** > **Identity providers**.

3. Click **Create Connection**. The "LDAP connection" page is displayed.

4. Enter the following details to set up your LDAP connection.

   Note: You can configure multiple LDAP connection instances to the same LDAP server. However, ensure that you meet the following requirements:

   - Both the `Base DN` and connection `Name` must be unique.
   - The username from the LDAP attribute that you specified in the `User ID map` must be unique across your LDAP instances. This requirement is because WebSphere Liberty uses federated registries for the multiple LDAPs by default. For more information, see Configuring LDAP user registries in Liberty.
   - IBM Cloud Pak foundational services provides a default `admin` user ID. If your LDAP registries have `admin` user IDs, you must rename the default `admin` user ID that foundational services provides. For more information about how to change the default name, see Changing the default admin username or Changing the cluster administrator username.

LDAP connection

Enter connection information.

- **Connection name:** A unique name for the LDAP connection. Format: 3 - 30 alphanumeric characters; Special characters that are allowed: - _
- **Server type:** A list of directory server types to which you can connect. Select one from the list.
- **Case insensitive user search:** Set the value to `true` or `false` to enable or disable case sensistivity for the LDAP usernames.

LDAP authentication

Enter authentication information.

- **Base DN**: The distinguished name of the search base. Example: dc=abc,dc=com. Format: 1 - 255 alphanumeric characters; Special characters that are allowed:
  - `=`
  - `.`
  - `,`
  - `-`

- **Bind DN**: The user who is allowed to search the base DN. Example: cn=admin,dc=abc,dc=com. This parameter is optional. If specified, the **`Bind DN password`** parameter must also be specified. If no user is specified in the **`Bind DN`** parameter, the LDAP connection is established without authentication. Format: 0 - 255 alphanumeric characters; white space is allowed; Special characters that are allowed:
  - `=`
  - `.`
  - `,`
  - `-`
  - `:`
  - `@`
  - `(`
  - `)`
  - `_`
  - `\`
- **Bind DN password**: The password of the user specified in the **`Bind DN`** parameter. This parameter is required if a user is specified in **`Bind DN`**. A maximum of 255 characters are allowed. Only ASCII characters are allowed; non-ASCII characters are not supported.

  Note: The configuration of **Base DN** and **Bind DN** values must be set as case-sensitive and must be a full distinguished name (DN) path. The DN path, including spaces, commas, and other characters, must be the same as configured in the LDAP server. See the following example:

  ```
  Base DN : DC=mycompany,DC=com
  Bind DN : CN=Administrator,CN=Users,DC=mycompany,DC=com
  ```

  For **`Base DN`**, the following values are invalid:

  - dc=mycompany,dc=com because **`DC`** is lowercase alphabet.
  - DC=mycompany, DC=com because there is a space between the parameters.

  For **`Bind DN`**, the following values are invalid:

  - cn=Administrator,cn=Users,dc=mycompany,dc=com because **`CN`** and **`DC`** are lowercase alphabets.
  - CN=Administrator,DC=mycompany,DC=com because **`CN=Users`** parameter is missing.
  - CN=Administrator,CN=Users, DC=mycompany,DC=com because there is a space between the parameters.
  - CN=administrator,CN=Users,DC=mycompany,DC=com because the **`administrator`** parameter value starts with a lowercase alphabet.

  Note: Microsoft Active Directory server does a strict check of **`Base DN`** and **`Bind DN`** values while it establishes a connection.

You can click **Test connection** to verify whether the LDAP connection details are valid.

LDAP server

Enter the server URL for your connection.

- **URL**: The LDAP directory domain name or IP address, and the LDAP port number. The domain name must begin with **`ldap(s)://`**. Example URL: **`ldap(s)://corpldap.abc.com:389`** or **`ldap://10.10.10.1:389`**.

For LDAP over SSL (LDAPS), you must use the domain name, and the URL must begin with **`ldaps://`**. Example URL: **`ldaps://corpldap.abc.com:636`**.

Note: If you are unable to connect to your LDAPS server by using the host name, add the IP address and host name of the LDAPS server in your local DNS. The LDAPS server host name must be resolvable from your master node.

LDAP filters

Note:

- If your LDAP server is compliant with LDAP version 3, then the filters are not sensitive to alphabet case or to white spaces.
- From foundational services version 3.19 and later, **`Group filter`** and **`Group member ID map`** filters support one or more than one value.

Enter information about the search filters. For default LDAP filters by LDAP type, see Default LDAP filters by LDAP type.

- **Group filter**: The filter clause for searching groups. From foundational services version 3.23 and later, IM supports all the special characters but following are the validated and tested special characters: white space, **`= ; . , & % () {} <> | !`**
- **Group ID map**: The filter to map a group name to an LDAP entry. Format: 1 - 255 alphanumeric characters; Special characters that are allowed: white space, **`* : = ; . , & % () {}`**
- **Group member ID map**: The filter to map a user to a group. Format: 1 - 255 alphanumeric characters; Special characters that are allowed: white space, **`* : = ; . , & % () {}`**
- **User filter**: The filter clause for searching users. From foundational services version 3.23 and later, IM supports all the special characters but following are the validated and tested special characters: white space, **`= ; . , & % () {} <> | !`**

- **User ID map**: The filter to map a username to an LDAP entry. Format: 1 - 255 alphanumeric characters; Special characters that are allowed: white space, `* : = ; . , & % () {}`

5. Click **Create**.

Your cluster is now connected with your LDAP directory.

Note: To block other hosts, see Adding egress firewall to prevent DNS loop to unknown hosts

Note: If you are using an LDAPS connection, the SSL (Secure Sockets Layer) certificates that are required for your LDAPS connection are automatically configured when you connect with your directory.

If your LDAPS connection is not successful, you can try setting up the connection manually. For more information, see Configuring LDAP over SSL.

Next, you can add your LDAP users and user groups to your cluster.

Note: The Cluster Administrator or Cloud Pak administrator must provide the Administrator with view access to the LDAP directory. Only then, the Administrator can use the console to add users or groups to teams.

Default LDAP filters by LDAP type

Note: There is a limitation on liberty, that is, the LDAP **`userFilter`** and **`groupFilter`** fields must contain an attribute with **`=%v`** value. For example, **`(cn=%v)`** for Cloud Pak and Cloud Pak for data login flow to work.

The following table represents the name of the filters, their data types and their default values. The **`groupFilter`** and **`groupMemberIdMap`** can have one or more than one default value from foundational services version 3.19 and later.

For example:

- **`groupFilter`** = (&(cn=%v)((objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
- **`groupMemberIdMap`** = groupOfNames:member;groupOfUniqueNames:uniqueMember

Table 1. List of default IBM Tivoli Directory Server LDAP filters

Attribute name	Data type	Default value
groupFilter	String	(&(cn=%v)(objectclass=groupOfUniqueNames))
groupIdMap	String	*:cn
groupMemberIdMap	String	groupOfUniqueNames:uniquemember
userFilter	String	(&(emailAddress=%v)(objectclass=person))
userIdMap	String	*:emailAddress

Table 2. List of default Custom Server LDAP filters

Attribute name	Data type	Default value
groupFilter	String	(&(cn=%v)(objectclass=groupOfUniqueNames))
groupIdMap	String	*:cn
groupMemberIdMap	String	groupOfUniqueNames:uniquemember
userFilter	String	(&(uid=%v)(objectclass=ePerson))
userIdMap	String	*:uid

Table 3. List of default Microsoft Active Directory LDAP filters

Attribute name	Data type	Default value
groupFilter	String	(&(cn=%v)(objectcategory=group))
groupIdMap	String	*:cn
groupMemberIdMap	String	memberOf:member
userFilter	String	(&(sAMAccountName=%v)(objectclass=person))
userIdMap	String	user:sAMAccountName

Table 4. List of default IBM Lotus Domino LDAP filters

Attribute name	Data type	Default value
groupFilter	String	(&(cn=%v)(objectclass=dominoGroup))
groupIdMap	String	*:cn
groupMemberIdMap	String	dominoGroup:member
userFilter	String	(&(uid=%v)(objectclass=Person))
userIdMap	String	person:uid

Table 5. List of default IBM SecureWay Directory Server LDAP filters

Attribute name	Data type	Default value
groupFilter	String	(&(cn=%v)((objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
groupIdMap	String	*:cn

Attribute name	Data type	Default value
groupMemberIdMap	String	groupOfNames:member;groupOfUniqueNames:uniqueMember
userFilter	String	(&(uid=%v)(objectclass=ePerson))
userIdMap	String	*:uid

Table 6. List of default Sun Java System Directory Server LDAP filters

Attribute name	Data type	Default value
groupFilter	String	(&(cn=%v)(objectclass=ldapsubentry))
groupIdMap	String	*:cn
groupMemberIdMap	String	nsRole:nsRole
userFilter	String	(&(uid=%v)(objectclass=inetOrgPerson))
userIdMap	String	inetOrgPerson:uid

Table 7. List of default Netscape Directory Server LDAP filters

Attribute name	Data type	Default value
groupFilter	String	(&(cn=%v)((objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
groupIdMap	String	*:cn
groupMemberIdMap	String	groupOfNames:member;groupOfUniqueNames:uniqueMember
userFilter	String	(&(uid=%v)(objectclass=inetOrgPerson))
userIdMap	String	inetOrgPerson:uid

Table 8. List of default Novell eDirectory LDAP filters

Attribute name	Data type	Default value
groupFilter	String	(&(cn=%v)(objectclass=groupOfNames))
groupIdMap	String	*:cn
groupMemberIdMap	String	groupOfNames:member
userFilter	String	(&(cn=%v)(objectclass=Person))
userIdMap	String	person:cn

Adding egress firewall to prevent DNS loop to unknown hosts

Run the following command to retrieve the egress network policy:

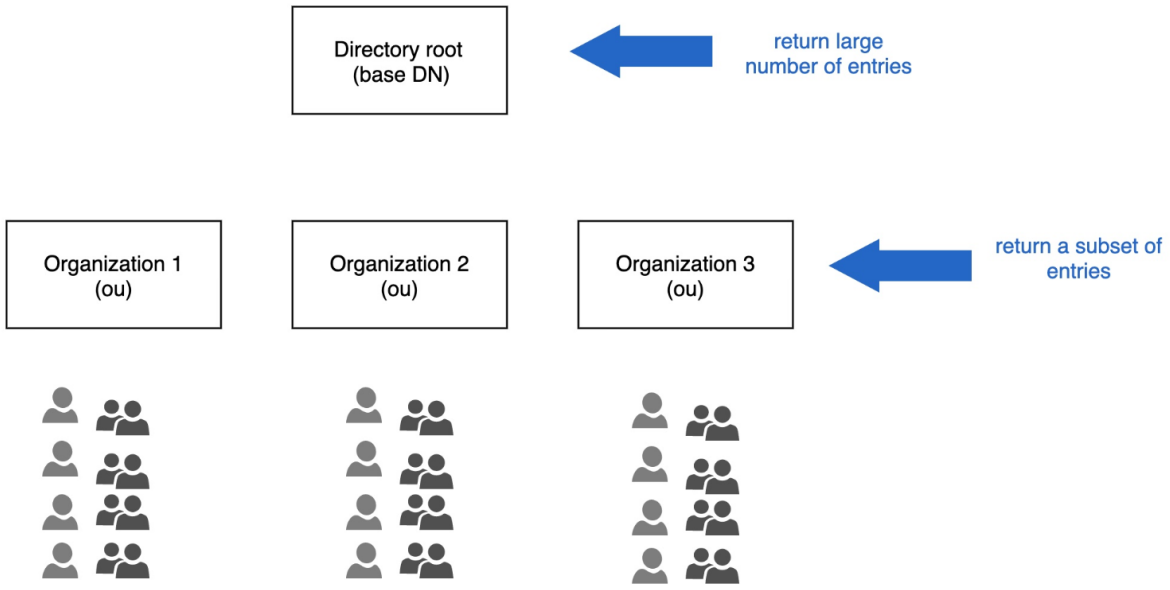
```
oc get egressnetworkpolicy ldap-firewall
```

Sample output:

```
NAME             AGE
ldap-firewall    16m
```

The following sample YAML spec defines the LDAP firewall egress network policy. To block other hosts, update the spec to specify the hosts that you want to deny access. Then, save and apply the updated policy.

```
apiVersion: network.openshift.io/v1
kind: EgressNetworkPolicy
metadata:
  name: ldap-firewall
spec:
  egress:
  - type: Allow
    to:
      dnsName: bluepages.ibm.com
  - type: Allow
    to:
      cidrSelector:  9.30.192.0/24
  - type: Deny
    to:
      cidrSelector: 0.0.0.0/0
  podSelector:
    matchLabels:
      app: platform-auth-service
  policyType:
  - Egress
```



Custom search base support for LDAP group and user entity in SCIM group and user APIs

You can use custom search base for LDAP group and user entities in SCIM group APIs. For now, the custom search base is supported only through APIs, and not from your product UI.

The structure of the LDAP server is organized as a tree hierarchy. The leaves of the tree represent an individual user account or a group with a common name (cn) and other attributes. The classification of the LDAP tree is as follows:

- The root directory structure of the LDAP server is the Base DN, which is the distinguished name of the search base. It is further classified into subclasses such as country (c), domain component (dc), and organization name (o). For example, dc=abc,dc=com.
- The subtree of the LDAP server is Organizational Unit (ou) that you can use for a group search in a specific search base.

The custom search is useful in a scenario when you have multiple organizations in your LDAP server. By using the custom search base, you can isolate each organization in separate namespaces, and search the LDAP group and user under the organizations.

See the following notes:

- The custom search base specifies the subtree of the LDAP server for the search call for an entity type. The subtree overrides the base DN in search operations. For example, if the base DN is **o=ibm,c=us** and the search base is **ou=iUsers,o=ibm,c=us**, then all search calls are made under the **ou=iUsers,o=ibm,c=us** subtree. Multiple search bases can be configured for the same entity type.
- By using a custom search base for LDAP user entity in SCIM user APIs, you can configure search bases per LDAP connection. The corresponding search bases are used over base DN for the user search.

Enabling a custom search base

The **LDAP_GROUP_SEARCHBASE_LIST** and **LDAP_USER_SEARCHBASE_LIST** parameters define the list of custom search bases for LDAP groups and users. The data type must be a list. And, it is an optional parameter. To enable a custom search base, add the parameters with the list of search bases. See the following examples:

```
"LDAP_GROUP_SEARCHBASE_LIST":
["OU=searchbase1,DC=ibmtest,DC=com","OU=searchbase2,DC=ibmtest,DC=com","OU=searchbase3,DC=ibmtest,DC=com"]
```

```
"LDAP_USER_SEARCHBASE_LIST":
["OU=searchbase1,DC=ibmtest,DC=com","OU=searchbase2,DC=ibmtest,DC=com","OU=searchbase3,DC=ibmtest,DC=com"]
```

▶ The following API shows how to enable a custom search base:

To use the API, you need the host details and the base64-encoded password for the **"LDAP_BINDPASSWORD"** parameter. For more information, see Registering an LDAP connection by using IdP V3 API.

The following curl command is an example of adding a custom search base for an LDAP group entity while you create an LDAP connection:

```
curl -k -X POST 'https://<cluster_address>/idprovider/v3/auth/idsource/'
--header "Authorization: bearer $ACCESS_TOKEN" \
--header 'Content-Type: application/json'
-d
'{
```

```
 "LDAP_ID": "msad",
 "LDAP_URL": "ldap://corp.abc.com:389",
 "LDAP_BASEDN": "DC=ibmtest,DC=com",
 "LDAP_BINDDN": "CN=Administrator,cn=Users,DC=ibmtest,DC=com",
 "LDAP_BINDPASSWORD": "password in base64 encoded",
 "LDAP_TYPE": "Microsoft Active Directory",
 "LDAP_USERFILTER": "(&(sAMAccountName=%v)(objectclass=person))",
 "LDAP_GROUPFILTER": "(&(cn=%v)(objectcategory=group))",
 "LDAP_USERIDMAP": "user:sAMAccountName",
 "LDAP_GROUPIDMAP":"*:cn",
 "LDAP_GROUPMEMBERIDMAP": "memberOf:member"
 "LDAP_GROUP_SEARCHBASE_LIST":
["OU=searchbase1,DC=ibmtest,DC=com","OU=searchbase2,DC=ibmtest,DC=com","OU=searchbase3,DC=ibmtest,DC=com"]
}'
```

The following curl command is an example of adding a custom search base for an LDAP user entity while you create an LDAP connection:

```
curl -k -X POST 'https://<cluster_address>/idprovider/v3/auth/idsource/'
--header "Authorization: bearer $ACCESS_TOKEN" \
--header 'Content-Type: application/json'
-d
'{
 "LDAP_ID": "msad",
 "LDAP_URL": "ldap://corp.abc.com:389",
 "LDAP_BASEDN": "DC=ibmtest,DC=com",
 "LDAP_BINDDN": "CN=Administrator,cn=Users,DC=ibmtest,DC=com",
 "LDAP_BINDPASSWORD": "password in base64 encoded",
 "LDAP_TYPE": "Microsoft Active Directory",
 "LDAP_USERFILTER": "(&(sAMAccountName=%v)(objectclass=person))",
 "LDAP_GROUPFILTER": "(&(cn=%v)(objectcategory=group))",
 "LDAP_USERIDMAP": "user:sAMAccountName",
 "LDAP_GROUPIDMAP":"*:cn",
 "LDAP_GROUPMEMBERIDMAP": "memberOf:member"
 "LDAP_USER_SEARCHBASE_LIST":
["OU=searchbase1,DC=ibmtest,DC=com","OU=searchbase2,DC=ibmtest,DC=com","OU=searchbase3,DC=ibmtest,DC=com"]
}'
```

You can also enable the custom search base for LDAP group or LDAP user while you update the existing LDAP directory. For more information, see Updating an LDAP connection by using IdP V3 API.

Using realName as a query filter

You can use the **realmName** parameter in SCIM APIs to filter user and group queries.

When you use the **/identity/v3/idsource** API, the **realmName** parameter shows the IdP connection name. See the following example:

```
"urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User": {
        "realmName": "openLDAP"
}
```

You can filter user and group queries based on the **realmName**.

Get the RealmName for IdP

Use the following API to get the realmName.

See these API parameters:

- The protocol values can be **ldap** for LDAP servers, **oauth** for OpenShift, and **saml** for SAML and OIDC.
- If you have multiple LDAP servers, replace **[0]** with the LDAP server sequence number. Use 0 for the first LDAP server, 1 for the second LDAP server, and so on.

```
curl -k -X "Authorization: Bearer $ACCESS_TOKEN" "https://<cp-console>/idprovider/v3/auth/idsource?
protocol=ldap" | jq -r .idp | jq -r '.[0].idp_config.name'
```

The following output is an example:

```
OutPut: openLDAP
```

Use the realmName to query users and groups

Use the realmName that you get from the **https://<cp-console>/idprovider/v3/auth/idsource?protocol=<protocol-value>** API to run a filter on user and group queries.

- For SCIM users query, the filter name must be equal to `urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User:realmName` or `realmName`. See the following example:

  ```
  https://<cp-console>/idmgmt/identity/api/v1/scim/users/?
  filter=urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User:realmName eq "openLDAP"
  ```

  Or

  ```
  https://<cp-console>/idmgmt/identity/api/v1/scim/users/?filter=realmName  eq "openLDAP"
  ```

- For SCIM groups query, the filter name must be equal to `urn:ietf:params:scim:schemas:extension:ibmcp:2.0:Group:realmName` or `realmName`. See the following example:

  ```
  https://<cp-console>/idmgmt/identity/api/v1/scim/groups/?
  filter=urn:ietf:params:scim:schemas:extension:ibmcp:2.0:Group:realmName eq "openLDAP"
  ```

  Or

  ```
  https://<cp-console>/idmgmt/identity/api/v1/scim/groups/?filter=realmName  eq "openLDAP"
  ```

Note: The only supported operator for realmName is `equal` or `eq`. You can use any other filter with the `realmName` by using `and` or `or` operator.

See the following example:

```
https://<cp-console>/idmgmt/identity/api/v1/scim/users/?
filter=urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User:realmName eq "openLDAP" and displayName eq
"icpuser1"
https://<cp-console>/idmgmt/identity/api/v1/scim/users/?
filter=urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User:realmName eq "openLDAP" or displayName eq
"icpuser1"
```

Limitations

The use of a realmName filter has the following limitations:

- The SCIM query returns all users for an identity provider. You must set the pagination to query identity providers with many users.
- For OpenShift, the groups are not returned when you run a query by using SCIM.
- You cannot run a query on OIDC users by using SCIM.
- For SAML with LDAP dependency, the SCIM query returns the LDAP connection name as realmName.

Enabling LDAP Nested Search

Nested search enables the Cloud Pak users to onboard the users or groups that belong to Nested hierarchy in the LDAP tree.

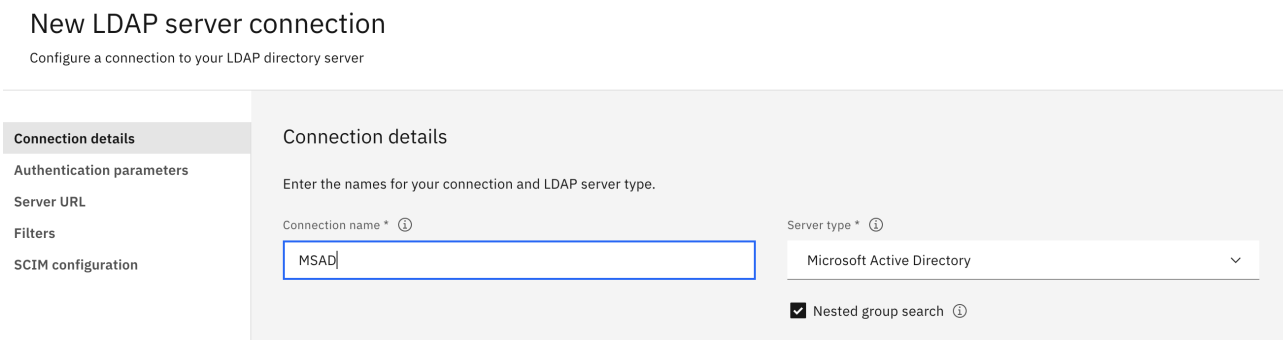
You can enable the nested search for the following:

- Microsoft Active Directory (MSAD) server
- Tivoli Directory Server (TDS) and Security Directory Server (SDS)

IMPORTANT: Nested Search can be an expensive operation. If the Nested search is enabled, it can affect the response time.

Nested search for MSAD

You can enable Nested search for Microsoft Active Directory by using the console in the following scenarios:



- Creating the MSAD connection
- Editing connection for existing MSAD

Enabling Nested search for MSAD while creating the connection

1. Log on to the console by using the URL and enter the username and password.

   Note: The console can be Platform UI or Common UI. For more information, see Accessing your cluster by using the console.

2. From the navigation menu, click **Identity and access** > **Identity providers**.
3. Click **Create Connection**. The LDAP connection page is displayed.
4. Select the Server type as `Microsoft Active Directory`. The **Nested group search** option is enabled.
5. Select the **Nested group search** to enable the nested search for the Microsoft Active Directory.

Enabling Nested search for existing MSAD connection

1. Log on to the console by using the URL and enter the username and password.

   Note: The console can be Platform UI or Common UI. For more information, see Accessing your cluster by using the console.

2. From the navigation menu, click **Identity and access** > **Identity providers**.
3. In the **Identity providers** page, the name of the MSAD connection is displayed. Select the MSAD connection name to edit and click **Edit connection**. The **Edit your LDAP connection** page is displayed.
4. Select the **Nested group search** option to enable the nested search for an existing Microsoft Active Directory server.
5. Click **Save**.

Nested search support for Tivoli Directory Server (TDS) and Security Directory Server (SDS)

For now, TDS and SDS nested search can only be configured using APIs, not from the product UI. You can enable nested search for Tivoli Directory Server (TDS) and Security Directory Server (SDS) by two ways:

- **TDS or SDS recommended way:** From IBM Cloud Pak foundational services version 3.19.9, 3.22, and later, you can enable nested search for TDS/SDS by creating nested group data as per TDS or SDS recommendations.
- **Recursive method:** From IBM Cloud Pak foundational services version 3.19.9 and 3.23, IM supports recursive method to enable nested search for TDS/SDS if LDAP nested group data set up is not created as per TDS or SDS recommendations.

IMPORTANT: It is mandatory to use the TDS or SDS recommended way method to enable nested search for TDS/SDS when you have created the LDAP nested group data set up as per TDS or SDS recommendations. In this case, if you use the recursive method, nested group functionality might not work properly.

IMPORTANT: It is mandatory to use the recursive method to enable nested search for TDS/SDS when you have not created the LDAP nested group data set up as per TDS or SDS recommendations. In this case, if you use the TDS or SDS recommended way method, nested group functionality might not work properly.

Tivoli Directory Server (TDS) and Security Directory Server (SDS) recommended way to create Nested group

IMPORTANT: The IBM Cloud Pak foundational services IM will be retrieving the Nested Group members only if data has been created with the TDS or SDS recommended format.

In IBM TDS/SDS LDAP server, a nested group is created by adding the **`ibm-nestedGroup`** object class in the group schema. And, the nested child groups must be added using **`ibm-memberGroup`** attributes.

The **`ibm-nestedGroup`** and **`ibm-memberGroup`** attributes must be present in the nested group schema as following:

```
dn: cn=TeamStaff,cn=platform,ou=cloud,ou=isl,ou=groups,dc=ibm,dc=com
cn: TeamStaff
objectClass: groupOfUniqueNames
objectClass: top
objectclass: ibm-nestedGroup
ibm-memberGroup: cn=TeamDoctors,cn=platform,ou=cloud,ou=isl,ou=groups,dc=ibm,dc=com
ibm-memberGroup: cn=Coaches,cn=platform,ou=cloud,ou=isl,ou=groups,dc=ibm,dc=com
```

IM uses operational attribute that is provided by TDS/SDS LDAP to query aggregate group membership as following. Ensure that LDAP data is created as per the TDS or SDS recommended format.

- **`ibm-allMembers`**: For a given group entry, the **`ibm-allMembers`** operational attribute returns all nested members.
- **`ibm-allGroups`**: For a given user entry, the **`ibm-allGroups`** returns all nested groups.

Note:

- If your data for nested groups is set up as per the TDS recommended way, IBM Cloud Pak foundational services IM will be able to use the **ibm-allMembers** attribute, and the **ibm-allMembers** attribute will return all nested members for a group, and **ibm-allGroups** attribute will return all nested groups for a user.
- If your data for nested group is not set up as per the TDS recommended way, Nested search feature will not work as expected, means, when IBM Cloud Pak foundational services IM uses the **ibm-allMembers** attribute, the **ibm-allMembers** attribute will only return all first-level members for a group, and **ibm-allGroups** attribute will return only the parent groups for a user.

Enabling Nested search feature in TDS/SDS recommended way by using SCIM API

The following parameters are used in directory management API to enable nested search in TDS/SDS recommended way:

- The **LDAP_NESTEDSEARCH** parameter in the directory management API is used to support the nested search feature in SCIM APIs. Set the **LDAP_NESTEDSEARCH** parameter to **true** to enable nested search option for TDS/SDS.
- From IBM Cloud Pak foundational services version 3.19.9 and 3.23,**LDAP_TDS_NESTEDCONFIG** parameter is introduced in directory management API. The value of this parameter is used to determine that which method (TDS/SDS recommended way or recursive method) is used to enable nested search for TDS/SDS.
    - If this parameter is set as **true**, the TDS/SDS recommended method will be used for nested search. However, make sure that to use TDS/SDS recommended method, you must create the LDAP nested group data set up as per TDS or SDS recommendations.
    - If this parameter is set as **false**, the recursive method logic will be used for nested search. Note that if you have not created the LDAP nested group data set up as per TDS or SDS recommendations, you need to use recursive method to enable nested search for TDS/SDS.
    - If the parameter is not provided, its default value will be considered as **false**, that means by default, recursive method is used to enable nested search.

Note: To use the directory management APIs, you need to get the host details. To get the host details, see Getting host details. And, use the base64-encoded password for the **"LDAP_BINDPASSWORD"** parameter. To encode the password, use the following command:

```
echo -n <password> | base64

Following is an example output:
```cmd {: pre}
```

UGFzc3cwcmQ=

```
#### Enabling nested search in TDS/SDS recommended way while creating LDAP connection by using the Directory management API

The following API shows how to enable the nested search option in TDS/SDS recommended way while creating an LDAP connection by using the Directory management API.

    "LDAP_GROUPMEMBERIDMAP":"groupOfUniqueNames:uniquemember",
    "LDAP_NESTEDSEARCH": "true",
```

```
    "LDAP_TDS_NESTEDCONFIG": "true"
  }'
```

Recursive approach to enable nested search for TDS/SDS

You might have LDAP directories for years and your data set up for nested search might not be as per Tivoli Directory Server (TDS) and Security Directory Server (SDS) recommendations. In such case, from IBM Cloud Pak foundational services version 3.19.9, 3.23, and later, IM supports recursive approach to enable nested search. It is mandatory to use the recursive method for nested search when you have not created the LDAP nested group data set up as per TDS or SDS recommendations. Otherwise, nested group functionality might not work properly.

Enabling recursive method to support nested search for TDS/SDS by using SCIM API

The following parameters are used in directory management API to enable recursive method/logic to support nested search for TDS/SDS:

- **`LDAP_NESTEDSEARCH`** : The **`LDAP_NESTEDSEARCH`** parameter in the Directory management API is used to support the nested search feature in SCIM APIs. Set the **`LDAP_NESTEDSEARCH`** parameter to **`true`** to enable recursive logic for nested search in TDS/SDS.
- **`LDAP_TDS_NESTEDCONFIG`**: From IBM Cloud Pak foundational services version 3.19.9 and 3.23,**`LDAP_TDS_NESTEDCONFIG`** parameter is introduced in directory management API. The value of this parameter is used to determine that which method (TDS/SDS recommended way or recursive method) is used to enable nested search for TDS/SDS.
  - If this parameter is set as **`true`**, the TDS/SDS recommended method will be used for nested search. However, make sure that to use TDS/SDS recommended method, you must create the LDAP nested group data set up as per TDS or SDS recommendations.
  - If this parameter is set as **`false`**, the recursive method logic will be used for nested search. Note that if you have not created the LDAP nested group data set up as per TDS or SDS recommendations, you need to use recursive method to enable nested search for TDS/SDS.
  - If the parameter is not provided, its default value will be considered as **`false`**,that means by default, recursive method is used to enable nested search.

Note:

- For SCIM group API, IM returns only first level members (users and groups) for any groups.
- For SCIM users API, IM returns all nested groups of any users.
- To use the directory management APIs, you need to get the host details. To get the host details, see Getting host details. And, use the base64-encoded password for the **`"LDAP_BINDPASSWORD"`** parameter. To encode the password, use the following command:

  ```
  echo -n <password> | base64
  ```

  Following is an example output:

  ```
  UGFzc3cwcmQ=
  ```

Enabling recursive logic to support nested search for TDS/SDS while creating an LDAP connection

    "LDAP_USERIDMAP":"*:uid",
    "LDAP_GROUPIDMAP":"*:cn",
    "LDAP_GROUPMEMBERIDMAP":"groupOfUniqueNames:uniquemember",
    "LDAP_NESTEDSEARCH": "true",
    "LDAP_TDS_NESTEDCONFIG": "false"
  }'
```

Changing LDAP cache settings

Changing the Lightweight Directory Access Protocol (LDAP) cache settings that are used for authentication in IBM Cloud Pak® for AIOps.

The LDAP cache setting parameters are listed in the following tables. For more information, see LDAP User Registry (ldapRegistry).

Note: Specify a positive integer followed by a unit of time, which can be hours (h), minutes (m), seconds (s), or milliseconds (ms). For example, specify 500 milliseconds as 500ms. You can include multiple values in a single entry. For example, 1s500ms is equivalent to 1.5 seconds. This note is applicable only to the `LDAP_ATTR_CACHE_TIMEOUT` and `LDAP_SEARCH_CACHE_TIMEOUT` parameters.

Table 1. LDAP attribute cache properties

Parameter	Description	Default value
`LDAP_ATTR_CACHE_ENABLED`	Enable or disable LDAP attribute cache.	true
`LDAP_ATTR_CACHE_SIZE`	Number of entities that can be stored in the cache.	2000
`LDAP_ATTR_CACHE_SIZELIMIT`	Maximum number of attributes per LDAP entity that are cached.	2000
`LDAP_ATTR_CACHE_TIMEOUT`	Maximum time that the contents of the LDAP attribute cache are available. When the specified time elapses, the LDAP attribute cache is cleared.	1200s

Table 2. LDAP search results cache properties

Parameter	Description	Default value
`LDAP_SEARCH_CACHE_ENABLED`	Enable or disable LDAP search results cache.	true
`LDAP_SEARCH_CACHE_SIZE`	Number of search results that are stored in the cache.	2000
`LDAP_SEARCH_CACHE_SIZELIMIT`	Maximum number of results that can be cached for a single LDAP search.	2000
`LDAP_SEARCH_CACHE_TIMEOUT`	Maximum time that the contents of the search results cache are available. When the specified time elapses, the search results cache is cleared.	1200s

Changing the parameter values by using kubectl

To change the parameter values, complete the following steps:

1. Install the Kubernetes CLI (kubectl) tool.
2. Edit the `platform-auth-idp` ConfigMap.

   ```
   kubectl -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

3. Change the following attribute values as required:
   - `LDAP_ATTR_CACHE_ENABLED`
   - `LDAP_ATTR_CACHE_SIZE`
   - `LDAP_ATTR_CACHE_SIZELIMIT`
   - `LDAP_ATTR_CACHE_TIMEOUT`
   - `LDAP_SEARCH_CACHE_ENABLED`
   - `LDAP_SEARCH_CACHE_SIZE`
   - `LDAP_SEARCH_CACHE_SIZELIMIT`
   - `LDAP_SEARCH_CACHE_TIMEOUT`
4. Save and close the ConfigMap.
5. Restart the `platform-auth-service` pods

   ```
   kubectl -n <your-foundational-services-namespace> delete pod -l k8s-app=platform-auth-service
   ```

6. Wait for some time. Then, check the status of the `platform-auth-service` pods. The status must show as `4/4 Running` for all the pods.

```
kubectl -n <your-foundational-services-namespace> get pods | grep platform-auth-service
```

Changing the parameter values by using the console

1. Log in to the Red Hat® OpenShift® Container Platform console as a user with cluster administrator access.
2. From the navigation menu, click **Workloads** > **Config Maps.**
3. Search for `platform-auth-idp`.
4. Click **...** > **Edit Config Map**.
5. Change the following attribute values as required:
   - `LDAP_ATTR_CACHE_ENABLED`
   - `LDAP_ATTR_CACHE_SIZE`
   - `LDAP_ATTR_CACHE_SIZELIMIT`
   - `LDAP_ATTR_CACHE_TIMEOUT`
   - `LDAP_SEARCH_CACHE_ENABLED`
   - `LDAP_SEARCH_CACHE_SIZE`
   - `LDAP_SEARCH_CACHE_SIZELIMIT`
   - `LDAP_SEARCH_CACHE_TIMEOUT`
6. Click **Save**.
7. From the navigation menu, click **Workloads > Deployments**.
8. Locate `platform-auth-service`.
9. Click **...** > **Edit Deployment**. A window for editing displays.
10. Click **Save** without making any change. This step is to reload the `platform-auth-service` pods with the latest ConfigMap values.
11. Click `platform-auth-service`.
12. Wait for some time. Then, check the status of the `platform-auth-service` pods in the **Pods** pane. The status of all the pods must show as `4/4` under the **Ready** field name.

Changing LDAP search settings

Changing the Lightweight Directory Access Protocol (LDAP) search settings in IBM Cloud Pak® for AIOps.

Configure attributes consideration for LDAP search

By default, IBM Cloud Pak for AIOps searches for users and groups on both the common name (CN) and identifier (ID) attributes as configured in the LDAP connection settings. Examples of ID attributes are `uid`, `sAMAccountName`, and `emailAddress`.

This behavior can be changed by setting the following configuration parameters:

The following two attributes are used for the search:

- `LDAP_SEARCH_CN_ATTR_ONLY` - Search by CN only. Default value is `false`.
- `LDAP_SEARCH_ID_ATTR_ONLY`- Search by ID only. Default value is `false`.

To use only the CN attribute for searching users or groups, set `LDAP_SEARCH_CN_ATTR_ONLY` value to `true`. To use only the ID attribute for searching users or groups, set `LDAP_SEARCH_ID_ATTR_ONLY` value to `true`.

Following are the steps to change the values of the LDAP search config parameters:

Changing the attribute values by using kubectl

To change the values, complete the following steps:

1. Install the `kubectl` CLI.

2. Edit the `platform-auth-idp` ConfigMap.

   ```
   kubectl -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

   Set the following attribute values as required to `true` or `false`.

   - `LDAP_SEARCH_CN_ATTR_ONLY`
   - `LDAP_SEARCH_ID_ATTR_ONLY`

   Note: Set only one value to `true`.

3. Save and close the ConfigMap.

4. Restart the `platform-auth-service` pods

   ```
   kubectl -n <your-foundational-services-namespace> delete pod -l k8s-app=platform-auth-service
   ```

5. Wait for some time. Then, check the status of the **platform-auth-service** pods. The status must show as **4/4 Running** for all the pods.

```
kubectl -n <your-foundational-services-namespace> get pods | grep platform-auth-service
```

Changing the attribute values by using the console

1. Log in to the Red Hat® OpenShift® Container Platform console as a user with cluster administrator access.
2. From the navigation menu, click **Workloads** > **Config Maps.**
3. Search for **platform-auth-idp**.
4. Click **...** > **Edit Config Map**.
5. Change either of the following attribute values to **true**, as required:
   - **LDAP_SEARCH_CN_ATTR_ONLY**
   - **LDAP_SEARCH_ID_ATTR_ONLY**

   Note: Set only one value to **true**.
6. Click **Save**.
7. From the navigation menu, click **Workloads > Deployments**.
8. Locate **platform-auth-service**.
9. Click **...** > **Edit Deployment**. A window for editing displays.
10. Click **Save** without making any change. This step is to reload the **platform-auth-service** pods with the latest ConfigMap values.
11. Click **platform-auth-service**.
12. Wait for some time. Then, check the status of the **platform-auth-service** pods in the **Pods** pane. The status of all the pods must show as **4/4** under the **Ready** field name.

Changing the LDAP search size limit and time limit values

Following are the LDAP search limit configuration parameters:

- **LDAP_SEARCH_SIZE_LIMIT**: Default value is "50". Range of values is 50 - 100.
- **LDAP_SEARCH_TIME_LIMIT**: Default value is "5". Range of values is 5 - 50.

Changing the values by using kubectl

To change the values, complete the following steps:

1. Set up the **kubectl** CLI. For more information, see Install tools.
2. Edit the **platform-auth-idp** ConfigMap.

   ```
   kubectl -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

   Change the following values as required:

   - **LDAP_SEARCH_SIZE_LIMIT**
   - **LDAP_SEARCH_TIME_LIMIT**
3. Save and close the ConfigMap.
4. Restart the **platform-auth-service** pods

   ```
   kubectl -n <your-foundational-services-namespace> delete pod -l k8s-app=platform-auth-service
   ```
5. Wait for some time. Then, check the status of the **platform-auth-service** pods. The status must show as **4/4 Running** for all the pods.

   ```
   kubectl -n <your-foundational-services-namespace> get pods | grep platform-auth-service
   ```

Changing the values by using the console

1. Log in to the console as a user with cluster administrator access.
2. From the navigation menu, click **Workloads** > **Config Maps.**
3. Search for **platform-auth-idp**.
4. Click **...** > **Edit Config Map**.
5. Change the following attribute values, as required:

- `LDAP_SEARCH_SIZE_LIMIT`
- `LDAP_SEARCH_TIME_LIMIT`

6. Click **Submit**.
7. From the navigation menu, click **Workloads > Deployments**.
8. Locate `platform-auth-service`.
9. Click **...** > **Edit Deployment**. A window for editing displays.
10. Click **Submit** without making any change. This step is to reload the `platform-auth-service` pods with the latest ConfigMap values.
11. Click `platform-auth-service`.
12. Wait for some time. Then, check the status of the `platform-auth-service` pods in the **Pods** pane. The status of all the pods must show as `4/4` under the **Ready** field name.

Change LDAP search wild characters usage

Following is the LDAP search wild characters configuration parameter:

- `LDAP_SEARCH_EXCLUDE_WILDCARD_CHARS`: Default value is "false".

In IBM Cloud Pak for AIOps, wild characters such as asterisk are used in the search string to match the substring value of the LDAP server attribute.

Set `LDAP_SEARCH_EXCLUDE_WILDCARD_CHARS` value to `true` to exclude wild characters (*) in the search string and to match the exact value of the LDAP server attribute.

Following is the default search string:

```
(|(&(cn=*<searchstring>*)(objectclass=person))(&(uid=*<searchstring>*)(objectclass=person)))
```

Following is the search string when the `LDAP_SEARCH_EXCLUDE_WILDCARD_CHARS` is set to `true`:

```
(|(&(cn=<searchstring>)(objectclass=person))(&(uid=<searchstring>)(objectclass=person)))
```

To change the wild characters usage in the search string, complete the following steps:

Changing the wild characters configuration parameter by using kubectl

To change the values, complete the following steps:

1. Install the Kubernetes CLI (kubectl) tool.
2. Edit the `platform-auth-idp` ConfigMap.

   ```
   kubectl -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

   Change the following value as required:

   - `LDAP_SEARCH_EXCLUDE_WILDCARD_CHARS`
3. Save and close the ConfigMap.
4. Restart the `platform-auth-service` pods

   ```
   kubectl -n <your-foundational-services-namespace> delete pod -l k8s-app=platform-auth-service
   ```
5. Wait for some time. Then, check the status of the `platform-auth-service` pods. The status must show as `4/4 Running` for all the pods.

   ```
   kubectl -n <your-foundational-services-namespace> get pods | grep platform-auth-service
   ```

Changing the wild characters configuration parameter by using the console

1. Log in to the Red Hat® OpenShift® Container Platform console as a user with cluster administrator access.
2. From the navigation menu, click **Configuration** > **Config Maps.**
3. Search for `platform-auth-idp`.
4. Click **...** > **Edit Config Map**.
5. Change the following value, as required:
   - `LDAP_SEARCH_EXCLUDE_WILDCARD_CHARS`
6. Click **Save**.
7. From the navigation menu, click **Workloads > Deployments**.
8. Locate `platform-auth-service`.
9. Click **...** > **Edit**. A window for editing displays.
10. Click **Save** without making any change. This step is to reload the `platform-auth-service` pods with the latest ConfigMap values.
11. Click `platform-auth-service`.
12. Wait for some time. Then, check the status of the `platform-auth-service` pods in the *Pods* pane. The status of all the pods must show as `4/4` under the **Ready** field name.

Changing SCIM LDAP search limit settings

You can change the SCIM LDAP search limits settings in IBM Cloud Pak® for AIOps.

Following are the SCIM LDAP search limit description and configuration parameters:

- **`SCIM_LDAP_SEARCH_SIZE_LIMIT`**: It limits the number of entries that can be returned in the SCIM user/group API call. The default value is 4500. There is no limitation for the value, you can set any value based on the number of entries that is expected to return from the LDAP. When the LDAP returns the entries more than its configured value, it displays **`Size Limit Exceeded`** error.

  Note: Consider the LDAP maximum page size value while tuning the **`SCIM_LDAP_SEARCH_SIZE_LIMIT`** parameter. For now, IM SCIM does not fully support the LDAP pagination.

- **`SCIM_LDAP_SEARCH_TIME_LIMIT`**: It limits the maximum wait time for the SCIM users/groups search API call. The default value is 10 seconds and this value is configurable. If the wait time is greater than 10 seconds or the configured value, it displays **`Time Limit Exceeded`** error. It is a client-side restriction. The LDAP server can also provide a limit on the search time.

  Note: If the configured value of the **`SCIM_LDAP_SEARCH_TIME_LIMIT`** is greater than 30 seconds, increase the OpenShift Platform Container route ingress level timeout.

  It can be adjusted by using the following annotations:

  ```
  oc annotate route cp-console -n <your-foundational-services-namespace> --overwrite
  haproxy.router.openshift.io/timeout=60s
  ```

Changing the values by using the console

1. Log in to the OpenShift Container console as a user with cluster administrator access.
2. From the navigation menu, click **Workloads** > **Config Maps.**
3. Search for **`platform-auth-idp`**.
4. Click **...** > **Edit Config Map**.
5. Change the following attribute values, as required:
   - **`SCIM_LDAP_SEARCH_SIZE_LIMIT`**
   - **`SCIM_LDAP_SEARCH_TIME_LIMIT`**
6. Click **Submit**.
7. From the navigation menu, click **Workloads > Deployments**.
8. Locate **`platform-auth-service`**.
9. Click **...** > **Edit Deployment**. A window for editing displays.
10. Click **Submit** without making any change. This step is to reload the **`platform-auth-service`** pods with the latest ConfigMap values.
11. Click **`platform-auth-service`**.
12. Wait for some time. Then, check the status of the **`platform-auth-service`** pods in the **Pods** pane. The status of all the pods must show as **`4/4`** under the **Ready** field name.

Adding custom SCIM attributes

You can add custom SCIM user and group attributes.

The new attributes must be defined in the extended SCIM user schema (urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User). They must follow the SCIM specification of attribute properties, including name, type, multiValued, description, required, caseExact, mutability, returned, and uniqueness. For more information, see Resource Schema Representation.

Following table provides the payload of the attributes.

Table 1. Custom attribute payload

Subattribute field name	Mandatory or not	Default value	Allowed value
schemaId	Yes	NA	urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User or urn:ietf:params:scim:schemasibmcp:2.0:User; urn:ietf:params:scim:schemas:extension:ibmcp:2.0:Group or urn:ietf:params:scim:schemasibmcp:2.0:Group
screenName	Yes	NA	Any alphanumeric characters between 2 and 30 characters in length; may contain space
name	Yes	NA	Any alphanumeric characters between 2 and 30 characters in length
description	No	NA	NA
isSensitive	No	false	false

Subattribute field name	Mandatory or not	Default value	Allowed value
type	Yes	string	string, complex
multiValued	No	false	true, false
required	No	false	true, false
caseExact	No	false	false
mutability	No	readWrite	readWrite
returned	No	default	default
uniqueness	No	none	none

Important: The SchemaIds urn:ietf:params:scim:schemasibmcp:2.0:User and urn:ietf:params:scim:schemasibmcp:2.0:Group might be deprecated in a future release. Hence, use the SchemaId urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User or urn:ietf:params:scim:schemas:extension:ibmcp:2.0:Group when you create any custom SCIM attributes.

See these notes:

- For each attribute, you must provide the mandatory subattribute as described in Table 1. Otherwise, the POST API operation returns an error.
- `schemaId` is a mandatory field and its value must be `urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User` or `urn:ietf:params:scim:schemasibmcp:2.0:User` for user, and `urn:ietf:params:scim:schemas:extension:ibmcp:2.0:Group` or `urn:ietf:params:scim:schemasibmcp:2.0:Group` for group.
- For each attribute, it is ideal to add the nonmandatory subattribute fields with values in the payload. Otherwise, the default values are added as described in the Table 1.
- Attribute key and name must have the same value.
- IM supports only default values for these subattributes: isSensitive, caseExact, mutability, returned, and uniqueness. If you provide custom values, then IM changes the values of these subattributes to their default values and then creates the custom SCIM attribute.

Add custom SCIM attributes

Use the `POST` operation with the `idmgmt/identity/api/v2/scim/attributes` API to add one or more custom SCIM attributes in the users and groups section.

Before you use the API, create these environment variables to use with the APIs.

- Console route. For more information about how to get the console route, see Getting the console URL.

  ```
  export CP_CONSOLE_URL=$CP_CONSOLE_URL_ROUTE
  ```

- Access token. For more information, see Preparing to run component or management API commands.

  1. Run the following command to get all authentication tokens. Then, copy the access token from the output.

     ```
     curl -k -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" -d
     "grant_type=password&username=admin&password=admin&scope=openid"
     https://$CP_CONSOLE_URL/idprovider/v1/auth/identitytoken
     ```

  2. Create an environment variable for the access token.

     ```
     export ACCESS_TOKEN= <Access-token>
     ```

Add custom SCIM attribute for users

Run the following curl command to add custom attribute only for users:

```
curl -k -X POST \
  -H "Authorization: Bearer $ACCESS_TOKEN" \
  -H "content-type: application/json" \
  "https://$CP_CONSOLE_URL/idmgmt/identity/api/v2/scim/attributes" \
  -d '{
      "user": {
        "userAttribute1": {
            "schemaId": "urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User",
            "screenName": "userAttribute1",
            "isSensitive": false,
            "name" : "userAttribute1",
            "type" : "string",
            "multiValued" : false,
            "description" : "Custom User Attribute 1",
            "required" : true,
            "caseExact" : false,
            "mutability" : "readWrite",
            "returned" : "default",
            "uniqueness" : "none"
          }
```

```
      }
   }'
```

Add custom SCIM attribute for groups

Run the following curl command to add custom attribute only for groups:

```
curl -k -X POST \
  -H "Authorization: Bearer $ACCESS_TOKEN" \
  -H "content-type: application/json" \
  "https://$CP_CONSOLE_URL/idmgmt/identity/api/v2/scim/attributes" \
  -d '{
        "group": {
            "groupAttribute1": {
              "schemaId": "urn:ietf:params:scim:schemas:extension:ibmcp:2.0:Group",
              "screenName": "groupAttribute1",
              "isSensitive": false,
              "name" : "groupAttribute1",
              "type" : "string",
              "multiValued" : false,
              "description" : "Custom Group Attribute 1",
              "required" : true,
              "caseExact" : false,
              "mutability" : "readWrite",
              "returned" : "default",
              "uniqueness" : "none"
            }
        }
      }'
```

Add custom SCIM attribute for users and groups

Run the following curl command to add custom attribute for both users and groups:

```
curl -k -X POST \
  -H "Authorization: Bearer $ACCESS_TOKEN" \
  -H "content-type: application/json" \
  "https://$CP_CONSOLE_URL/idmgmt/identity/api/v2/scim/attributes" \
  -d '{
      "user": {
        "userAttribute1": {
          "schemaId": "urn:ietf:params:scim:schemas:extension:ibmcp:2.0:User",
          "screenName": "userAttribute1",
          "isSensitive": false,
          "name" : "userAttribute1",
          "type" : "string",
          "multiValued" : false,
          "description" : "Custom User Attribute 1",
          "required" : true,
          "caseExact" : false,
          "mutability" : "readWrite",
          "returned" : "default",
          "uniqueness" : "none"
           }
        },
        "group": {
            "groupAttribute1": {
              "schemaId": "urn:ietf:params:scim:schemas:extension:ibmcp:2.0:Group",
              "screenName": "groupAttribute1",
              "isSensitive": false,
              "name" : "groupAttribute1",
              "type" : "string",
              "multiValued" : false,
              "description" : "Custom Group Attribute 1",
              "required" : true,
              "caseExact" : false,
              "mutability" : "readWrite",
              "returned" : "default",
              "uniqueness" : "none"
            }
        }
      }'
```

Updating a custom SCIM attribute

Use the **PUT** operation with the **idmgmt/identity/api/v2/scim/attributes/<resourceType>/<attributekey>** API to modify a custom SCIM attribute in the users and groups section.

Update user attribute

To modify a user attribute, use the **idmgmt/identity/api/v2/scim/attributes/users/<attributekey>** API.

- To get the user **attributekey** value, use the following command:

```
curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Content-Type:
application/json" "https://$CP_CONSOLE_URL:443/idmgmt/identity/api/v2/scim/attributes/users"
```

- To modify the user attribute, use the following curl command:

```
curl -k -X PUT \
  -H "Authorization: Bearer $ACCESS_TOKEN" \
  -H "content-type: application/json" \
  "https://$CP_CONSOLE_URL/idmgmt/identity/api/v2/scim/attributes/user/<attributekey>" \
  -d '{
          "schemaId": "urn:ietf:params:scim:schemasibmcp:2.0:User",
          "screenName": "userAttribute1",
          "isSensitive": false,
          "name" : "userAttribute1",
          "type" : "string",
          "multiValued" : false,
          "description" : "Custom User Attribute 1",
          "required" : true,
          "caseExact" : false,
          "mutability" : "readWrite",
          "returned" : "default",
          "uniqueness" : "none"

      }
```

Update group attribute

To modify a group attribute, use the **idmgmt/identity/api/v2/scim/attributes/group/<attributekey>** API.

- To get the group **attributekey** value, use the following command:

```
curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Content-Type:
application/json" "https://$CP_CONSOLE_URL:443/idmgmt/identity/api/v2/scim/attributes/group"
```

- To modify the group attribute, use the following curl command:

```
curl -k -X PUT \
  -H "Authorization: Bearer $ACCESS_TOKEN" \
  -H "content-type: application/json" \
  "https://$CP_CONSOLE_URL/idmgmt/identity/api/v2/scim/attributes/group/<attributekey>" \
  -d '{
          "schemaId": "urn:ietf:params:scim:schemasibmcp:2.0:Group",
          "screenName": "groupAttribute1",
          "isSensitive": false,
          "name" : "groupAttribute1",
          "type" : "string",
          "multiValued" : false,
          "description" : "Custom Group Attribute 1",
          "required" : true,
          "caseExact" : false,
          "mutability" : "readWrite",
          "returned" : "default",
          "uniqueness" : "none"

      }'
```

Deleting a custom SCIM attribute

Use the **DELETE** operation with the **idmgmt/identity/api/v2/scim/attributes/<resourceType>/<attributekey>** API to delete a custom SCIM attribute in the users and groups section.

Delete a user attribute

Use the **idmgmt/identity/api/v2/scim/attributes/users/<attributekey>** API.

Use the following curl command:

```
curl -k -X DELETE \
  -H "Authorization: Bearer $ACCESS_TOKEN" \
  -H "content-type: application/json" \
  "https://$CP_CONSOLE_URL/idmgmt/identity/api/v2/scim/attributes/user/<attributekey>"
```

Delete a group attribute

Use the **idmgmt/identity/api/v2/scim/attributes/group/<attributekey>** API.

Use the following curl command:

```
curl -k -X DELETE \
  -H "Authorization: Bearer $ACCESS_TOKEN" \
  -H "content-type: application/json" \
  "https://$CP_CONSOLE_URL/idmgmt/identity/api/v2/scim/attributes/group/<attributekey>"
```

Updating SCIM LDAP attributes mapping

You can update the SCIM LDAP attributes mapping.

To support the SCIM APIs for a configured LDAP connection in IBM Cloud Pak foundational services, you can update **SCIM_LDAP_ATTRIBUTES_MAPPING** data in the following ways:

- By using SCIM configuration for LDAP connection. For more information, see SCIM configuration by using IBM Cloud Pak for AIOps UI.
- By using the **attributemapping** API (available for IBM Cloud Pak foundational services version 3.11.0 or later)

Note: Use of the configmap to update the SCIM LDAP attributes mapping is not supported and removed from the foundational services version 4.8.

Updating with `attributemapping` API

To use the **attributemapping** API, you must add an authorization header to your request. You need to add an access token to the authorization header. To obtain the access token, see Preparing to run component or management API commands.

Procedure

Note: The **members** and **objectClass** attributes do not consider the custom SCIM attribute values. Use LDAP filter values for these attributes to map the data.

1. Check the existing attribute mappings by using the following API call:

   ```
   curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Content-Type:
   application/json" "https://$BCS_URL:443/idmgmt/identity/api/v1/scim/attributemappings"
   ```

   The response resembles the following code:

   ```
   [{"idp_id":"default","idp_type":"ldap","user":
   {"id":"dn","userName":"uid","principalName":"uid","displayName":"cn","givenName":"cn","familyName":"sn"
   ,"fullName":"cn","externalId":"dn","emails":"mail","created":"createTimestamp","lastModified":"modifyTi
   mestamp","phoneNumbers":[{"value":"mobile","type":"mobile"},
   {"value":"telephoneNumber","type":"work"}],"objectClass":"person","groups":"memberOf"},"group":
   {"id":"dn","name":"cn","principalName":"cn","displayName":"cn","externalId":"dn","created":"createTimes
   tamp","lastModified":"modifyTimestamp","objectClass":"groupOfUniqueNames","members":"uniqueMember"}},
   ```

2. Create the attribute mappings with your mapping data by using the following API call:

   Note: If you already have the attribute mappings, do not create another attribute mapping. You can skip this step.

   ```
   export DATA='{"idp_id":"test","idp_type":"ldap","user":
   {"id_test":"dn","userName":"uid","principalName":"uid","displayName":"cn","givenName":"cn","familyName"
   :"sn","fullName":"cn","externalId":"dn","phoneNumbers":[{"value":"mobile","type":"mobile"},
   {"value":"telephoneNumber","type":"work"}],"objectClass":"person","groups":"memberOf"},"group":
   {"id":"dn","name":"cn","principalName":"cn","displayName":"cn","externalId":"dn","created":"createTimes
   tamp","lastModified":"modifyTimestamp","objectClass":"groupOfUniqueNames","members":"uniqueMember"}}'
   ```

   The sample curl command resembles the following code:

   ```
   curl -sk -X POST --header "Authorization: Bearer $ACCESS_TOKEN" --header "Content-Type:
   application/json" -d $DATA "https://$BCS_URL:443/idmgmt/identity/api/v1/scim/attributemappings"
   ```

   The response resembles the following code:

   ```
   {"idp_id":"test","idp_type":"ldap","user":
   {"id_test":"dn","userName":"uid","principalName":"uid","displayName":"cn","givenName":"cn","familyName"
   :"sn","fullName":"cn","externalId":"dn","phoneNumbers":[{"value":"mobile","type":"mobile"},
   {"value":"telephoneNumber","type":"work"}],"objectClass":"person","groups":"memberOf"},"group":
   {"id":"dn","name":"cn","principalName":"cn","displayName":"cn","externalId":"dn","created":"createTimes
   tamp","lastModified":"modifyTimestamp","objectClass":"groupOfUniqueNames","members":"uniqueMember"}}
   ```

3. Update the existing attribute mappings data with your mapping data by using the following API call:

   ```
   export DATA='{"idp_id":"$IDP_ID","idp_type":"ldap","user":
   {"id_test":"dn","userName":"uid","principalName":"uid","displayName":"cn","givenName":"cn","familyName"
   :"sn","fullName":"cn","externalId":"dn","phoneNumbers":[{"value":"mobile","type":"mobile"},
   ```

```
{"value":"telephoneNumber","type":"work"}],"objectClass":"person","groups":"memberOf"}},"group":
{"id":"dn","name":"cn","principalName":"cn","displayName":"cn","externalId":"dn","created":"createTimes
tamp","lastModified":"modifyTimestamp","objectClass":"groupOfUniqueNames","members":"uniqueMember"}'
```

The sample curl command resembles the following code:

```
curl -sk -X PUT --header "Authorization: Bearer $ACCESS_TOKEN" --header "Content-Type:
application/json" -d $DATA "https://$BCS_URL:443/idmgmt/identity/api/v1/scim/attributemappings/$IDP_ID"
```

The response resembles the following code:

```
{"idp_id":"test","idp_type":"ldap","user":
{"id_test":"dn","userName":"uid","principalName":"uid","displayName":"cn","givenName":"cn","familyName"
:"sn","fullName":"cn","externalId":"dn","phoneNumbers":[{"value":"mobile","type":"mobile"},
{"value":"telephoneNumber","type":"work"}],"objectClass":"person","groups":"memberOf"},"group":
{"id":"dn","name":"cn","principalName":"cn","displayName":"cn","externalId":"dn","created":"createTimes
tamp","lastModified":"modifyTimestamp","objectClass":"groupOfUniqueNames","members":"uniqueMember"}}
```

4. Delete the existing attribute mappings by using the following API call:

```
curl -sk -X DELETE --header "Authorization: Bearer $ACCESS_TOKEN" \
--header "Content-Type: application/json" \
"https://$BCS_URL:443/idmgmt/identity/api/v1/scim/attributemappings/$IDP_ID"
```

The response resembles the following code:

```
{"count":1}
```

Note: By default, the LDAP connection configuration considers the following mapping values for SCIM APIs.

Table 1. LDAP connection attributes

LDAP connection attributes	SCIM object	SCIM attributes
LDAP_USERIDMAP	user	userName
LDAP_USERFILTER	user	objectClass
LDAP_GROUPIDMAP	group	name
LDAP_GROUPFILTER	group	objectClass
LDAP_GROUPMEMBERIDMAP	group	members

Note: If you have multiple expressions in the LDAP connection attributes configuration, the first configuration value is considered.

LDAP attributes

For information about LDAP attributes, you can use the **ldapsearch** tool or any LDAP browser such as **Apache Directory Studio**.

Installing the ldapsearch tool

On Ubuntu, run the following command:

```
sudo apt-get install ldap-utils
```

On Red Hat® Enterprise Linux®, run the following command:

```
sudo yum install openldap-clients
```

The following examples show the ldapsearch tool command structure and an example output.

User

Command:

```
ldapsearch -x -H <LDAP_URL> -b <LDAP_BASEDN> -D <LDAP_BINDDN> -W -s sub "(sAMAccountName=pavann)" "*" "+"
```

Output:

```
# extended LDIF
#
# LDAPv3
# base <DC=ibmtest,DC=com> with scope subtree
# filter: (sAMAccountName=pava)
# requesting: * +
#

# Tom Northwood, Users, ibmtest.com

IBM Cloud attributes

To search IBM Cloud users in SCIM, custom attributes can be defined as shown in the following code example. By default, these attributes are not defined.

```
"IBMCloud" = {
    "user": {
        "id": "userId",
        "userName": "userId",
        "principalName": "userId",
        "displayName": "firstName",
        "emails": "email",
        "familyName": "lastName",
        "givenName": "firstName",
        "externalId": "userId"
    }
};
```

Enhancing SCIM group and user API performance

Enhanced SCIM group API performance

By default, foundational services supports the LDAP query filter size limit to up to 5000. You can run a query on a bulk of group members by using a single LDAP search. If you have a more number of members in a group, it is advised to increase the LDAP query filter size limit to at least 5000 for the configured LDAP to get the benefit from the enhanced performance of the group API calls.

Follow the tuning guidelines for the CPU and memory for the following observations, if you have a large number of members in a group:

Note: The values that are provided in the following observations and tuning guidelines are the estimated values. These values might also depend on the other environmental factors such as overall load, cluster health, network.

- A Group of approximately 21k members with concurrent access to 10 users, requires around 1500m of CPU and 1500Mi of memory, and 1 replica for the small profile.
- If the number of concurrent accesses increases, you need to increase the number of replicas as well. For example, the same 21k members for concurrent access to 20 users, require around 3 replicas with the 1500m of CPU and 1500Mi of memory for the small profile.

- If you have more members in the group, use the large profile instead of the small profile. For example, the large profile for a group of 87K members with the concurrent access to 10 users, needs around 3 replicas with 2550m of CPU and 2850Mi of memory.

Enhanced SCIM user API performance

IM has the following configuration parameters for SCIM users search API:

- **`SCIM_AUTH_CACHE_MAX_SIZE`**: It indicates the maximum number of tokens that are stored in the cache. The default value is 1000. If you have multiple concurrent calls, it is recommended to tune this value.
- **`SCIM_AUTH_CACHE_TTL_VALUE`**: It indicates the TTL value in seconds of each token that is stored in the cache. The default value is 60 seconds. If you have a long-running process that simultaneously calls the SCIM API for more than 60 seconds, it is recommended to tune this value.

These SCIM configured parameters improve the overall response time to avoid the repeated authorization calls.

Changing the configured SCIM attributes by using the console

1. Log in to the Red Hat® OpenShift® Container Platform console as a user with cluster administrator access.
2. From the navigation menu, click **Workloads** > **Config Maps.**
3. Search for **`platform-auth-idp`**.
4. Click **...** > **Edit Config Map**.
5. Change the following attribute values to **`true`**, as required:
   - **`SCIM_AUTH_CACHE_MAX_SIZE`**
   - **`SCIM_AUTH_CACHE_TTL_VALUE`**
6. Click **Save**.
7. From the navigation menu, click **Workloads > Deployments**.
8. Locate **`platform-auth-service`**.
9. Click **...** > **Edit Deployment**. A window for editing displays.
10. Click **Save** without making any change. This step is to reload the **`platform-auth-service`** pods with the latest ConfigMap values.
11. Click **`platform-auth-service`**.
12. Wait for some time. Then, check the status of the **`platform-auth-service`** pods in the **Pods** pane. The status of all the pods must show as **`4/4`** under the **Ready** field name.

Changing the configured SCIM attributes by using CLI

1. Log in to your infrastructure node by using the **`oc login`** command.
2. Edit the **`platform-auth-idp`** configmap.

   ```
   oc -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

3. Change the following SCIM configured attributes parameter to a higher value:
   - **`SCIM_AUTH_CACHE_MAX_SIZE`**
   - **`SCIM_AUTH_CACHE_TTL_VALUE`**
4. Save the changes.
5. Restart the **`platform-auth-service`** pods by deleting the pods.
   1. Get the **`platform-auth-service`** pod names.

      ```
      oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
      ```

   2. Delete the **`platform-auth-service`** pod.

      ```
      oc -n <your-foundational-services-namespace> delete pods <pod-name>
      ```

Wait for some time and then check the status of the **`platform-auth-service`** pods. The status of all **`platform-auth-service`** pods must show as **`Running`**.

```
oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
```

Custom Group filter support in SCIM User API

You can use the LDAP Group filter value when you query for a group of SCIM users.

For example, User1 is part of four groups - **icptest1**, **icptest2**, **isvtest1** and **isvtest2** and you set this value **"(&(cn=%v)(cn=*icptest*)(objectclass=person))"** in the LDAP Group filter while you create the LDAP connection. When you query User1 through the SCIM API, the User1 has only **icptest1** and **icptest2** groups in the **group** section of the SCIM response.

SCIM pagination support for LDAP server

From the foundational services version 3.19.9, 3.21, and later, the server-side pagination is supported for the LDAP. The pagination feature in the LDAP server allows you to access the large results sets when there is a server-side administrative limit to the number of entries returned from a query.

The supported LDAP types in your product cluster enforce the page size limits upon the results that are returned from the LDAP in the SCIM user/group API call. The supported LDAP types in your product cluster with their corresponding default page size limit:

LDAP types with their corrresponding default page size limit

LDAP type	Default page size
IBM Tivoli Directory Server	20000
IBM Lotus Domino	20000
IBM SecureWay Directory Server	20000
Novell eDirectory	500
Sun Java™ System Directory Server	2000
Netscape Directory Server	5000
Microsoft Active Directory	1000
Custom	4500

For example, in Microsoft Active Directory, the default page size limit is 1000. It means, the default number of entries that are returned in a single request is, 1000. If you send the request to retrieve more than 1000 entries, the LDAP server returns the **LDAP_SIZELIMIT_EXCEEDED** error. To avoid the **LDAP_SIZELIMIT_EXCEEDED** error in the foundational services version 3.20 and earlier, the entry request in your query should be less than or equal to 1000.

Similarly, for other LDAPs server, if the number of entries in your request exceeds the default page size limit of the LDAP server, the server displays the **LDAP_SIZELIMIT_EXCEEDED** error. To overcome this page size limit of LDAP server, the SCIM pagination option is introduced with the foundational services version 3.19.9, 3.21, and later. The pagination option for LDAP server is applicable for the SCIM APIs. This option enables you to retrieve the result of your query even if your LDAP entry request is beyond the default page size limit of the LDAP server.

Enabling pagination option for LDAP server

By default, the SCIM pagination option for the LDAP server is disabled. You can enable the pagination option by using the Identity Provider V3 API. For now, you can enable pagination option through the APIs only.

The Identity Provider V3 API contains following parameters to support the server-side pagination option for LDAP:

- **LDAP_PAGINGSEARCH**: If the LDAP_PAGINGSEARCH parameter is set as "false", it indicates that the pagination option is disabled. Set this parameter to "true" to enable the pagination option.
- **LDAP_PAGING_SIZE**: It is a numeric field that defines the page size of the LDAP type. You can set the number as per your requirement. It is an optional field. If you do not provide the value to the **LDAP_PAGING_SIZE** parameter, the default page size of the LDAP server will be considered as a request in the API query. For example, when the LDAP type is Microsoft Active Directory (MSAD) and you do not provide the **LDAP_PAGING_SIZE** value in the API, then 1000 (default page size) value will be considered as a request in the API. Also, the **LDAP_PAGING_SIZE** value should not exceed the default server side page limit or the maximum configured value for the respective LDAP type.

See the following notes:

- The IM supports LDAP user and group search through SCIM APIs and LDAP APIs. However, the pagination option for the LDAP server is applicable for the SCIM APIs only.
- You can configure the server-side pagination option for each LDAP type.
- **LDAP_PAGINGSEARCH** and **LDAP_PAGING_SIZE** parameters are optional in the Identity Provider V3 API. Include these parameters in the API as per your requirement.

Procedure

The following example to enable the pagination and set the page size while creating an LDAP connection through Identity Provider V3 API:

Before you begin: Ensure that you are informed about the other LDAP configuration parameters that are used in the Identity Provider V3 APIs. For more information, see LDAP authentication, LDAP filters and Default LDAP filters by LDAP type.

Prerequisites: The LDAP server must have **bind dn** and **bind password**, otherwise you might get **InsufficientAccessRightsError** while performing the SCIM APIs query. You must use the admin **bind dn** and **bind password** while configuring the LDAP connection. If you use the non-admin **bind dn** and **bind password**, enable the non-admin page search option in the underlying LDAP server. For example, in IBM Tivoli Directory Server, the conf file attribute, **ibm-slapdPagedResAllowNonAdmin**(boolean) should be enabled. This file attribute decides whether the non-admin binds are allowed to perform page search.

The sample curl command to create an LDAP connection:

```
curl -k -X POST 'https://cp-console.apps.mycluster.mydomain.fyre.ibm.com/idprovider/v3/auth/idsource/' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
  "name": "openldap",
  "description": "",
  "protocol": "ldap",
  "type": "Custom",
  "idp_config": {
        "ldap_id": "openldap",
        "ldap_realm": "REALM",
        "ldap_url": "ldap://9.30.253.13:389",
        "ldap_host": "9.30.253.13",
        "ldap_port": "389",
        "ldap_protocol": "ldap",
        "ldap_basedn": "dc=ibm,dc=com",
        "ldap_binddn": "cn=admin,dc=ibm,dc=com",
        "ldap_bindpassword": "UGFzc3cwcmQ=",
        "ldap_type": "Custom",
        "ldap_ignorecase": "false",
        "ldap_userfilter": "(&(uid=%v)(objectclass=person))",
        "ldap_useridmap": "*:uid",
        "ldap_groupfilter": "(&(cn=%v)(objectclass=groupOfUniqueNames))",
        "ldap_groupidmap": "*:cn",
        "ldap_groupmemberidmap": "groupOfUniqueNames:uniqueMember",
        "ldap_nestedsearch": "false",
        "ldap_pagingsearch": "false"
        }
}'
```

To use the Identity Provider APIs for LDAP connection, you need to get the host details, and the base64-encoded password for the **"LDAP_BINDPASSWORD"** parameter. For more information, see Creating an LDAP connection.

By using Identity Provider APIs, you can also enable pagination option and set the page size while updating the existing LDAP directory. For more information, see Update an LDAP directory.

Changing LDAP contextPool settings

Change the contextPool settings to suit your Lightweight Directory Access Protocol (LDAP) server load.

The LDAP contextPool parameters are listed in the following tables. For more information, see LDAP User Registry (ldapRegistry).

Note: Specify a positive integer followed by a unit of time, which can be hours (h), minutes (m), seconds (s), or milliseconds (ms). For example, specify 500 milliseconds as 500ms. You can include multiple values in a single entry. For example, 1s500ms is equivalent to 1.5 seconds. This note is applicable only to the `LDAP_CTX_POOL_TIMEOUT` and `LDAP_CTX_POOL_WAITTIME` parameters. Also, the `LDAP_CTX_POOL_TIMEOUT` must be set lesser than the idle timeout on a firewall (or backend server) for it to be effective.

Table 1. LDAP contextPool parameter properties

Parameter	Description	Default value
`LDAP_CTX_POOL_INITSIZE`	An integer value that determines the initial size of the context pool. Set this value based on the load on the repository.	10
`LDAP_CTX_POOL_MAXSIZE`	An integer value that defines the maximum context pool size. Set this value based on the maximum load on the repository.	50
`LDAP_CTX_POOL_PREFERREDSIZE`	Maximum number of attributes per LDAP entity that are cached.	10
`LDAP_CTX_POOL_TIMEOUT`	The duration after which the context pool times out.	30s
`LDAP_CTX_POOL_WAITTIME`	The time interval that the request waits until the context pool checks again if an idle context instance is available in the pool when the number of context instances reaches the maximum pool size.	60s

Changing the parameter values by using kubectl

To change the parameter values, complete the following steps:

1. Install the Kubernetes CLI (kubectl) tool.
2. Edit the `platform-auth-idp` ConfigMap.

   ```
   kubectl -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

3. Change the following attribute values as required:
   - `LDAP_CTX_POOL_INITSIZE`
   - `LDAP_CTX_POOL_MAXSIZE`
   - `LDAP_CTX_POOL_PREFERREDSIZE`
   - `LDAP_CTX_POOL_TIMEOUT`
   - `LDAP_CTX_POOL_WAITTIME`
4. Save and close the ConfigMap.
5. Restart the `platform-auth-service` pods

   ```
   kubectl -n <your-foundational-services-namespace> delete pod -l k8s-app=platform-auth-service
   ```

6. Wait for some time. Then, check the status of the `platform-auth-service` pods. The status must show as `4/4 Running` for all the pods.

   ```
   kubectl -n ibm-common-services get pods | grep platform-auth-service
   ```

Changing the parameter values by using the console

Complete the following steps:

1. Log in to the Red Hat® OpenShift® Container Platform console as a user with cluster administrator access.
2. From the navigation menu, click **Workloads** > **Config Maps.**
3. Search for `platform-auth-idp`.
4. Click **...** > **Edit Config Map**.
5. Change the following attribute values as required:
   - `LDAP_CTX_POOL_INITSIZE`
   - `LDAP_CTX_POOL_MAXSIZE`
   - `LDAP_CTX_POOL_PREFERREDSIZE`
   - `LDAP_CTX_POOL_TIMEOUT`
   - `LDAP_CTX_POOL_WAITTIME`
6. Click **Save**.
7. From the navigation menu, click **Workloads > Deployments**.

8. Locate **platform-auth-service**.
9. Click **...** > **Edit Deployment**. A window for editing displays.
10. Click **Save** without making any change. This step is to reload the **platform-auth-service** pods with the latest ConfigMap values.
11. Click **platform-auth-service**.
12. Wait for some time. Then, check the status of the **platform-auth-service** pods in the **Pods** pane. The status of all the pods must show as **4/4** under the **Ready** field name.

Cluster configurations

Learn to configure your cluster.

- Allowing limited users to log in by using only LDAP
- Updating cp-console hostname and TLS secret
- Changing the cluster administrator access credentials
- Adding a logout redirect URL
- Configuring access and identity token validity
- Changing the security role mappings refresh time interval that is used during authorization
- Changing LDAP search cache variable values
- Using a proxy server for outbound traffic
- Changing LDAP contextPool settings

Allowing limited users to log in by using only LDAP

You might have scenarios where you want to provide a strict subset of accounts the ability to authenticate by using an LDAP server that is configured in your Identity Management (IM) instance.

For example, when you configure a SAML connection to use an existing LDAP connection as its identity provider (IdP), you cannot use that LDAP for IM authentication. This behavior is the default and is implemented to enforce multi-factor authentication across all account logins. You might still need to allow a subset of nonpersonal accounts or functional IDs to authenticate directly with the LDAP server despite this broader implementation. Or, perhaps you need to block some or all use of LDAP for authentication with IM, but do not want to change the user and group filters that are already set on the configurations in your LDAP connections.

In such situations, you can use the ID source update API to set an allowlist of users on one or more LDAP configurations in your cluster. You can do so by adding an **ldap_allowlist** in the **idp_config** of the LDAP configuration. The field is optional.

ldap_allowlist field settings

The following table describes the parameter values that are in the **ldap_allowlist** field.

Table 1. ldap_allowlist field settings

Value type	Syntax	Description
An array with one or more string values	`"ldap_allowlist": [ "user1", "user2", "user3" ]`	Allows only these listed accounts to use LDAP authentication through the identity management (IM) service
Empty array	`"ldap_allowlist": []`	Deny all - blocks all attempts to use LDAP authentication through IM
No field present	NA	Default behavior - allows all attempts to use LDAP authentication through IM

Behavior on the IBM Cloud Pak console

If the **PREFERRED_LOGIN** field in the **platform-auth-idp** configmap has a nonempty value, the field must contain "LDAP", or else users cannot log in with LDAP. This requirement applies even in cases where an allowlist is defined for an LDAP connection.

When PREFERRED_LOGIN is set to a value that allows LDAP authentication, the enterprise LDAP login option is available to you on your IBM Cloud Pak console. Setting a nonempty allowlist on an LDAP connection that is being used as an IdP for a SAML connection adds the enterprise LDAP login option to the console if it was not already present. Then, the console no longer automatically redirects to the login page of your SAML provider: users from the allowlist can authenticate by using LDAP instead.

Behavior of ldap_allowlist with multiple LDAPs

If multiple LDAP servers are configured with IM, you can define an **ldap_allowlist** field on one or more of those configurations. When a user tries to log in to IM by using their LDAP credentials, IM checks whether allowlists are set on any of the configured LDAP servers. IM assumes that

user or account names between the configured LDAP servers are unique. So, if any allowlists are set, IM checks whether the provided username is present in any of those allowlists. If present, IM allows the authentication to continue.

You must be careful when you add allowlists, especially when you use multiple LDAPs in IM. For example, if you add an allowlist on one LDAP and no allowlist on a second LDAP, then only the usernames from the allowlist of the first LDAP can authenticate with IM by using LDAP. Users from the second LDAP cannot use the LDAP authentication option because the second LDAP doesn't have an allowlist.

Also, if a username from the allowlist of the first LDAP exists in other LDAPs, even if the username is of a different user or account identity (for example, another person), IM allows the username to log in by using the other LDAP.

Adding ldap_allowlist field to the LDAP configuration

Use the **/idprovider/v3/auth/idsource** APIs to update the LDAP server with the **ldap_allowlist** field. Before you begin, make sure you have the following ready:

- An account with sufficient permissions to interact with the **idsource** APIs, **curl** commands, or any other means of making **HTTP**/**HTTPS** requests.
- **jq** installed, if you want to make it easier to read responses and construct requests.

Define an **ldap_allowlist** by following these steps. The steps work from a terminal that uses a POSIX-compliant shell. For example, **bash**.

1. Get the LDAP server information
2. Add the **ldap_allowlist** field
3. Update the LDAP configuration

Get the LDAP server information

Get the ID of the LDAP server.

1. Obtain an access token from IM. See Preparing to run component or management API commands.
2. Define the following environment variables:
   - access token

     ```
     export access_token=<access_token_value>
     ```

   - LDAP server name of the users that you want to add in the **ldap_allowlist** field

     ```
     export LDAP_NAME=<ldap_name>
     ```

   - **cp-console** domain name

     ```
     export CP_CONSOLE_DOMAIN=<domain_name>
     ```

3. Get the LDAP server details. If you are using **jq**, see Using jq with the commands.

   ```
   curl \
     --location \
     --request GET \
     --insecure \
     --silent \
     --header 'Content-Type: application/json' \
     --header 'Accept: application/json' \
     --header "Authorization: Bearer ${access_token}" \
     --get \
     -d "name=${LDAP_NAME}" \
     -d 'protocol=ldap' \
     "https://${CP_CONSOLE_DOMAIN}/idprovider/v3/auth/idsource"
   ```

   The response looks something like the following response. Note the **uid** value from the response. The **uid** value is used in the API call to update the LDAP connection configuration.

   ```
   {
     "idp": [
       {
         "name": "example_ldap",
         "description": "An example LDAP",
         "protocol": "ldap",
         "type": "IBM Tivoli Directory Server",
         "idp_config": {
           "ldap_id": "example_ldap",
           "ldap_realm": "REALM",
           "ldap_url": "ldap://ldap.example.com:389",
           "ldap_host": "ldap.example.com",
           "ldap_port": "389",
           "ldap_protocol": "ldap",
           "ldap_basedn": "o=example.com",
   ```

```
        "ldap_binddn": "",
        "ldap_bindpassword": "",
        "ldap_type": "IBM Tivoli Directory Server",
        "ldap_ignorecase": "false",
        "ldap_userfilter": "(&(uid=%v)(objectclass=ePerson))",
        "ldap_useridmap": "*:uid",
        "ldap_groupfilter": "(&(cn=%v)(objectclass=groupOfUniqueNames))",
        "ldap_groupidmap": "*:cn",
        "ldap_groupmemberidmap": "groupOfUniqueNames:uniqueMember",
        "ldap_nestedsearch": "false",
        "ldap_pagingsearch": "false"
      },
      "uid": "917a0ac9-9cf0-49aa-9313-53aa5b9e87ec"
    }
  ]
}
```

4. Define environment variables for the UID and JSON response.

   - UID

     ```
     export uid=<ldap_uid_from_previous_command>
     ```

   - JSON response

     ```
     export json_response=<response_from_previous_command>
     ```

5. Write the JSON response to a file so that you can edit the response and submit an update request.

   ```
   echo "${json_response}" > ldap.json
   ```

Add the ldap_allowlist field

Add the **ldap_allowlist** field in the **ldap.json** file that you created in the earlier section.

You must add the **ldap_allowlist** field to the **idp_config** field and set it to an array value.

Important: Remove the **uid** field from the **ldap.json** file. **PUT** requests do not accept payloads if the **uid** is present. If you used **jq** filter in the previous section, the command automatically removes the **uid** field.

After you add the **ldap_allowlist** field and remove the **uid**, the **ldap.json** file content must resemble the following payload. The **"ldap_allowlist"** array must have your list of account names:

```
{
  "name": "example_ldap",
  "description": "An example LDAP",
  "protocol": "ldap",
  "type": "IBM Tivoli Directory Server",
  "idp_config": {
    "ldap_id": "example_ldap",
    "ldap_realm": "REALM",
    "ldap_url": "ldap://ldap.example.com:389",
    "ldap_host": "ldap.example.com",
    "ldap_port": "389",
    "ldap_protocol": "ldap",
    "ldap_basedn": "o=example.com",
    "ldap_binddn": "",
    "ldap_bindpassword": "",
    "ldap_type": "IBM Tivoli Directory Server",
    "ldap_ignorecase": "false",
    "ldap_userfilter": "(&(uid=%v)(objectclass=ePerson))",
    "ldap_useridmap": "*:uid",
    "ldap_groupfilter": "(&(cn=%v)(objectclass=groupOfUniqueNames))",
    "ldap_groupidmap": "*:cn",
    "ldap_groupmemberidmap": "groupOfUniqueNames:uniqueMember",
    "ldap_nestedsearch": "false",
    "ldap_pagingsearch": "false",
    "ldap_allowlist": [ "ldap_user1", "ldap_user2", "ldap_user_etc"]
  }
}
```

Update the LDAP configuration

Update the LDAP connection configuration by using the PUT method on the idsource API.

```
curl \
  --location \
  --request PUT \
  --insecure \
  --silent \
  --header "Authorization: Bearer ${access_token}" \
```

```
  --header 'Content-Type: application/json' \
  --header 'Accept: application/json' \
  -d @ldap.json \
  "https://${CP_CONSOLE_DOMAIN}/idprovider/v3/auth/idsource/${uid}"
```

Using jq with the commands

If you are using `jq`, you can pipe the JSON response into it when you run the curl commands.

1. Get the LDAP server details. The following command is the same as the curl command run in step 4, but stored as an array.

   ```
   curl_command=(
     curl
     --location
     --request GET
     --insecure
     --silent
     --header 'Content-Type: application/json'
     --header 'Accept: application/json'
     --header "Authorization: Bearer ${access_token}"
     --get
     -d "name=${LDAP_NAME}"
     -d 'protocol=ldap'
     "https://${CP_CONSOLE_DOMAIN}/idprovider/v3/auth/idsource"
   )
   ```

2. Read `uid` and LDAP idsource JSON into variables in your shell.

   Note: The following example command assumes that the query parameters are specific enough to narrow the results down to a single LDAP entry.

   ```
   IFS='|' read -r uid json_response <<< "$("${curl_command[@]}" | jq -r -c -M '.idp[] | [.uid, (. | del(.uid))] | "\(.[0])|\(.[1])"')"
   ```

3. Confirm that the variables were set properly.

   ```
   echo "UID: ${uid}"
   echo "JSON response: ${json_response}"
   ```

4. Write the JSON response to a file to edit and submit for update request.

   ```
   echo "${json_response}" > ldap.json
   ```

Next, create the `ldap_allowlist` field and update the LDAP configuration.

Updating cp-console hostname and TLS secret

You can update the cp-console hostname with the custom hostname and certificates using one of the following methods:

- Updating cp-console hostname and TLS using the script
- Updating cp-console hostname using the `ibmcloud-cluster-info` configmap (no TLS certificate update required)

Note: These instructions are for changing only the cp-console route hostname and certificates. This procedure is not applicable for the cpd route, zenservice CR, or Platform UI. Run the following command to verify whether the cp-console exists in the cluster:

```
oc get route | grep cp-console
```

If cp-console exists in the cluster, the following routes are displayed in the response:

```
cp-console              cp-console-ibm-common-services.apps.fidelitytest.cp.fyre.ibm.com   /
common-web-ui                 3000                    reencrypt/Redirect     None
id-mgmt                 cp-console-ibm-common-services.apps.fidelitytest.cp.fyre.ibm.com   /idmgmt/
platform-identity-management   4500                    reencrypt/Redirect     None
platform-auth           cp-console-ibm-common-services.apps.fidelitytest.cp.fyre.ibm.com   /v1/auth/
platform-identity-provider     4300                    reencrypt/Redirect     None
platform-id-provider    cp-console-ibm-common-services.apps.fidelitytest.cp.fyre.ibm.com   /idprovider/
platform-identity-provider     4300                    reencrypt/Redirect     None
platform-login          cp-console-ibm-common-services.apps.fidelitytest.cp.fyre.ibm.com   /login
platform-identity-provider     4300                    reencrypt/Redirect     None
platform-oidc           cp-console-ibm-common-services.apps.fidelitytest.cp.fyre.ibm.com   /oidc
platform-auth-service          9443                    reencrypt/Redirect     None
saml-ui-callback        cp-console-ibm-common-services.apps.fidelitytest.cp.fyre.ibm.com
/ibm/saml20/defaultSP/acs   platform-auth-service          9443                    reencrypt/Redirect
None
social-login-callback   cp-console-ibm-common-services.apps.fidelitytest.cp.fyre.ibm.com   /ibm/api/social-
login       platform-auth-service          9443                    reencrypt/Redirect     None
```

This procedure is applicable only for the cluster with the cp-console route.

You can refer to the following sections to restore SAML and revert the updates:

- Restore SAML
- Reverting the updates

Updating cp-console hostname using the script

You can update the **cp-console** hostname and certificates using the **cs-onprem-tenant-config.sh** script. Ensure that you complete the prerequisites before you run the script.

Prerequisites

Keep your new hostname and certificates ready.

- Create the custom hostname. If you modify the default Red Hat® OpenShift® Container Platform domain, ensure that the new hostname can resolve to the Red Hat® OpenShift® Container Platform router from inside and outside the Red Hat® OpenShift® Container Platform cluster.
- Optional: If you are updating the TLS secret, provide new certificates in an unencrypted PEM format. Place the certificates in the **installer_scripts** directory. For more information, see Download and extract the installer scripts for your CASE bundle.

  Note: This step is applicable only if you need to update the certificates. If the certificates change or expire, you must provide new certificates and run the script again to create a secret by using the new certificates.

  - **ca.crt**: Contains the intermediate CA signer certificates and the CA root signer certificate. The file must start with the intermediate CA certificates in order that to lead the root CA.
  - **tls.crt**: Contains only the route server certificate.

    Note: The route server certificate passes the TLS verification for the route hostname.
  - **tls.key**: Contains the private key of the route server certificate.

  See the following example of PEM encoding that uses header and footer lines for each certificate and private key.

```
-----BEGIN CERTIFICATE-----
(encoded set of characters)
-----END CERTIFICATE-----

-----BEGIN PRIVATE KEY-----
(encoded set of characters)
-----END PRIVATE KEY-----
```

Procedure

Complete the following steps to change the cp-console hostname and certificates of the **cp-console** route.

1. Create a **cs-onprem-tenant-config.yaml** file with the following configmap definition. In the **data** section, provide your custom hostname. If you are providing new certificates to update the TLS secret, do not change the name of the **custom_host_certificate_secret** secret in the configmap.

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: cs-onprem-tenant-config
  namespace: <your-foundational-services-namespace>
labels:
  cs_onprem_tenant_config: "true"
data:
  ##comment out or remove this setting if not changing the hostname
  custom_hostname: <your-custom-hostname>
  ##comment out or remove this setting if not changing the certificates
  custom_host_certificate_secret: custom-tls-secret
```

   The following is the sample custom hostname:

```
cp-testcustomhn.apps.o1-849902.cp.fyre.ibm.com
```

   Note: You need to update the **custom_hostname:** parameter with the URL that includes the domain name and new custom hostname without **https://** protocol.

2. Create the **cs-onprem-tenant-config** configmap.

```
oc apply -f cs-onprem-tenant-config.yaml
```

3. If your cluster topology has a separate namespace for all operators, identify that namespace and set it as the default namespace. You need to update the **$csNamespace** and **$map_to_common_service_namespace** in the script.

    1. Get the namespace where you deployed the foundational services.

        ```
        oc get csv -A | grep common-service-operator
        ```

        The following is the sample output:

        ```
        cp4itest                                            ibm-common-service-operator.v4.11.0
        IBM Cloud Pak foundational services    4.11.0            ibm-common-service-operator.v4.10.0
        Succeeded
        ```

        cp4itest is the namespace where foundational services is deployed and **v4.11.0** is the CASE version

    2. Set the project with the default foundational services namespace.

        ```
        oc project <your-foundational-services-namespace>
        ```

        The following is the sample command:

        ```
        oc project cp4itest
        ```

4. Download and extract the installer scripts for your CASE bundle. To find your CASE version, see IBM: Product CASE to Application Version and search for the installed foundational services version to find the related CASE version.

    ```
    export CASE_VERSION=<your foundational service operator version>
    ```

    ```
    wget https://github.com/IBM/cloud-pak/raw/master/repo/case/ibm-cp-common-services/${CASE_VERSION}/ibm-cp-common-services-${CASE_VERSION}.tgz
    ```

    ```
    tar -xvzf ibm-cp-common-services-$CASE_VERSION.tgz
    ```

    ```
    cd ibm-cp-common-services/inventory/ibmCommonServiceOperatorSetup/installer_scripts
    ```

    Replace **CASE_VERSION** with the foundational services version. To get the operator version, run the following command:

    ```
    oc get csv | grep "<your-foundational-services-namespace>"
    ```

5. Set the following environmental variables in the **cs-onprem-tenant-config.sh** script. To update the script, you can use the text editor or run one of the following commands in a system editor:

    ```
    vi cs-onprem-tenant-config.sh
    ```

    ```
    sudo nano cs-onprem-tenant-config.sh
    ```

    - **$csNamespace** - Set the operator namespace of the foundational services. The operator namespace is the control namespace where foundational services is deployed.
    - **$map_to_common_service_namespace** - Set the operand namespace of the foundational services where **platform-auth-service-xxx** pod is running.

    Note: If the operators and operands are in the same namespace, set **$map_to_common_service_namespace** and **$csNamespace** with **<your-foundational-services-namespace>**.

6. If you are providing new certificates for TLS secret, place the **tls.key**, **tls.crt**, and **ca.crt** files in the **installer_scripts** directory. Run the script to create the TLS secret with the required certificate files.

    To change the hostname and use the selfsigned certificate, see Prerequisites to prepare your **cert** and **tls** files.

7. Run the script from the operator namespace.

    ```
    ./cs-onprem-tenant-config.sh
    ```

    If you see the following error, it means that you did not provide the new certificate files for TLS secret in the **installer_scripts** directory. To resolve the issue, place the certificate files and run the script again.

    ```
    tls.key is not present in current directory, pls keep tls.key, tls.crt and ca.crt files in current directory
    ```

    The script completes the following tasks:

    - Uses namespaces from the **common_service_maps** configmap that is in the **kube-public** namespace. The common_service_maps ` configmap has all the namespaces in a tenant.
    - Creates a TLS secret if you provided new certificate files.
    - If your cluster topology has a separate namespace for all operators, the script runs the **iam-custom-hostname** job in that namespace.

- Update the custom hostname in all applicable identity management (IM) components.

8. Restart the Zen operator pod.

   ```
   oc get pod -n <your-foundational-services-namespace> | grep ibm-zen-operator

   oc delete pod -n <your-foundational-services-namespace> <ibm-zen-operator-pod-name>
   ```

9. Restart the **usermgmt** pods.

   1. Get the **usermgmt** pod names.

      ```
      oc get pods |grep usermgmt
      ```

   2. Delete the **usermgmt** pods.

      ```
      oc delete pod <usermgmt-pod-name>
      ```

10. Wait until the Zen operator and **usermgmt** pods restart. Ensure that the pods are in the ready and running status.

```
oc get pods -n <your-foundational-services-namespace> | grep ibm-zen-operator
oc get pods -n <your-foundational-services-namespace>|grep usermgmt
```

Updating cp-console hostname using the `ibmcloud-cluster-info` configmap (no TLS certificate update required)

You can update the **cp-console** hostname with the wildcard certificate using the **ibmcloud-cluster-info** configmap. You cannot change the **cp-console** hostname that is not configured with the wildcard certificate and **cp-console** domain name.

The following is the sample wildcard certificate:

An example of wildcard certificate

Note: You cannot update the TLS using the **ibmcloud-cluster-info** configmap. To update the TLS, see Updating cp-console hostname using the script.

Complete the following steps to update the custom hostname with the **ibmcloud-cluster-info** configmap:

1. Update the **cluster_address** and **cluster_endpoint** parameters in the **ibmcloud-cluster-info** configmap.

   ```
   oc edit cm ibmcloud-cluster-info -n cpfs-data
   ```

   The following is the sample **ibmcloud-cluster-info** configmap:

   ```
   apiVersion: v1
   data:
     cluster_address: <hostname>-cpfs-data.apps.ocp415-qb.cp.fyre.ibm.com.
     cluster_endpoint: https://<hostname>-cpfs-data.apps.ocp415-qb.cp.fyre.ibm.com
     cluster_kube_apiserver_host: api.ocp415-qb.cp.fyre.ibm.com
     cluster_kube_apiserver_port: "6443"
     cluster_name: mycluster
     cluster_router_http_port: "80"
     cluster_router_https_port: "443"
     im_idmgmt_endpoint: https://platform-identity-management.cpfs-data.svc:4500
     im_idprovider_endpoint: https://platform-identity-provider.cpfs-data.svc:4300
     proxy_address: cp-proxy-cpfs-data.apps.ocp415-qb.cp.fyre.ibm.com
   kind: ConfigMap
   ```

   Replace **<hostname>** with the custom hostname.

2. Wait for the IM pods to restart.

   ```
   platform-auth-service-xxx
   platform-identity-management-xxx
   platform-identity-provider-xxx
   ```

3. Restart Zen pods with the following label:

   ```
   name=ibm-zen-operator
   component=usermgmt
   ```

   1. Get the **usermgmt** pod names.

      ```
      oc get pods |grep usermgmt
      ```

   2. Delete the **usermgmt** pods.

      ```
      oc delete pod <usermgmt-pod-name>
      ```

You can login to **cp-console** and **cpd** with the updated hostname after the restart of the Zen pods.

Result

After you run the script, the **cp-console** route is updated with the new hostname. You can also see the new certificates, if applicable, in your browser when you access the **cp-console** URL.

Restore SAML

After you change the certificate, the Security Assertion Markup Language (SAML) connection breaks. You must update the SAML metadata with the new certificate information to restore the connection. For more information, see Identity and access management migration.

Reverting the updates

If you need to revert to the previous hostname and certificate, repeat the steps in Procedure by using the previous hostname.

To revert to the default name for **cp-console**, complete the following steps:

1. Update the **cs-onprem-tenant-config** ConfigMap to set the default name in the **custom_hostname** parameter.

```
oc -n <your-foundational-services-namespace> edit configmap cs-onprem-tenant-config
```

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: cs-onprem-tenant-config
  namespace: $csNamespace
labels:
  cs_onprem_tenant_config: "true"
data:
  ##comment out or remove this setting if not changing the hostname
  custom_hostname: <Default hostname>
  ##comment out or remove this setting if not changing the certificates
  custom_host_certificate_secret: custom-tls-secret
```

2. Run the script again.

```
./cs-onprem-tenant-config.sh
```

3. To restore the default certificates, delete the **cp-console** route.

```
oc get route -n <your-foundational-services-namespace>
```

```
oc delete route cp-console  -n <your-foundational-services-namespace>
```

Changing the Cloud Pak administrator access credentials

You can update the administrator username and password.

Note: **cpadmin** is the default admin user name.

Before you begin

- Install the OpenShift client.
- Ensure that you must have **administrator** access to update the administrator username and password.

Supported languages

You can change the default administrator username **cpadmin** to a custom username. The username can be in the following languages:

Table 1. Supported languages

Language	Language code
Brazilian Portuguese	pt_br
English	en
French	fr
German	de
Italian	it

Language	Language code
Japanese	ja
Korean	ko
Chinese Simplified	zh_CN
Chinese Traditional	zh_TW
Spanish	es

Changing the administrator username

Complete the following steps to rename a default admin user in Platform UI:

1. Review the current admin and password.

```
oc -n <your-foundational-services-namespace> get secret platform-auth-idp-credentials -o yaml | grep
admin |xargs -l  bash -c 'echo -n "$0  " ; echo "$1" | base64 -d && echo'
```

   The sample output:

```
admin_password:  IRXkjnsZg8nUUK8S2BBVFJeIOW0wVrhD
admin_username:  cpadmin
```

2. Get the access token. For more information, see Preparing to run API commands.

3. Run the following CURL command to update default admin username:

```
curl -X PUT 'https://cp-
console.apps.mycluster.mydomain.fyre.ibm.com/idmgmt/identity/api/v1/users/defaultAdmin' \
    --header 'Content-Type: application/json' \
    --header 'Accept: application/json' \
    --header "Authorization: Bearer $ACCESS_TOKEN" \
    -d "{\"username\": \"${new_admin_username}\"}" \
    --insecure
```

4. Restart the **platform-identity-provider** and **platform-auth-service** pods by deleting them.

   1. Get the **platform-identity-provider** pod name and **platform-auth-service** pod name .

```
oc get pods -n <your-foundational-services-namespace> | grep platform-identity-provider
```

```
oc get pods -n <your-foundational-services-namespace> | grep platform-auth-service
```

   2. Delete the **platform-identity-provider** pod and **platform-auth-service** pod.

```
oc delete pod <platform-identity-management-pod-name> -n <your-foundational-services-namespace>
```

```
oc delete pod <platform-auth-service-pod-name> -n <your-foundational-services-namespace>
```

5. After the pods restart, login to **cp-console** to test whether the default username has changed.

```
oc get routes -n <your-foundational-services-namespace> |grep -i cp-console
```

Changing the administrator password

The administrator password is stored in a Kubernetes Secret.

Complete the following steps to change the administrator password in Platform UI:

1. Review the current admin and password.

```
oc -n <your-foundational-services-namespace> get secret platform-auth-idp-credentials -o yaml | grep
admin |xargs -l  bash -c 'echo -n "$0  " ; echo "$1" | base64 -d && echo'
```

   The sample output:

```
admin_password:  IRXkjnsZg8nUUK8S2BBVFJeIOW0wVrhD
admin_username:  admin
```

2. Update the **admin_password** field in the **platform-auth-idp-credentials** secret with the new password.

   - In the namespace where foundational services is installed, edit the **platform-auth-idp-credentials** secret:

```
oc edit secret platform-auth-idp-credentials -n "${SERVICES_NAMESPACE}"
```

   Where, **{SERVICES_NAMESPACE}** is the namespace name where foundational services is installed.

- Search for `admin_password` value in `platform-auth-idp-credentials` secret and replace it with the new password. The new password must be `base64-encoded` password.

3. Restart the `platform-auth-service`, `platform-identity-provider`,`platform-identity-management`, and `usermgmt` pods by deleting them.

    1. Delete the `platform-auth-service` pod.

        - Get the `platform-auth-service` pod name.

          ```
          oc get pods -n <your-foundational-services-namespace> | grep platform-auth-service
          ```

        - Delete the `platform-auth-service` pod.

          ```
          oc delete pod <platform-auth-service-pod-name> -n <your-foundational-services-namespace>
          ```

    2. Delete the `platform-identity-provider` pod.

        - Get the `platform-identity-provider` pod name.

          ```
          oc get pods -n <your-foundational-services-namespace> | grep platform-identity-provider
          ```

        - Delete the `platform-identity-provider` pod.

          ```
          oc delete pod <platform-identity-provider-pod-name> -n <your-foundational-services-namespace>
          ```

    3. Delete the `platform-identity-management` pod.

        - Get the `platform-identity-management` pod name.

          ```
          oc get pods -n <your-foundational-services-namespace> | grep platform-identity-management
          ```

        - Delete the `platform-identity-management` pod.

          ```
          oc delete pod <platform-identity-management-pod-name> -n <your-foundational-services-namespace>
          ```

    4. Delete the `usermgmt` pod.

        - Get the `usermgmt` pod name.

          ```
          oc get pods -n <your-foundational-services-namespace> | grep usermgmt-<pod name>
          ```

        - Delete the `usermgmt` pod.

          ```
          oc delete pod <usermgmt-pod-name> -n <your-foundational-services-namespace>
          ```

After the pod restart, login to `cp-console` to test whether the password has changed.

```
oc get routes -n <your-foundational-services-namespace> |grep -i cp-console
```

The password must follow the defined password rules.

Password rules

Password rules are optional, regular expressions (regex) that are used to set and validate managed password values within a namespace. The `update-secret` command checks password rules before changing the values in the secret. It validates if rules exist on the namespace that the secret is in, and that the secret data element name change contains `pass` or `pwd` in any case combination.

Note: You can use the following regex expressions from the command line. Ensure that you wrap the expressions in single quotation marks:

Table 2. List of rules for Regex expressions

Rule	Regex
Min length 10	`^.{10,}`
Max length 10	`^.{0,10}$`
Length range	`^.{10,20}$`
Require lower	`.*[a-z].*`
Require upper	`.*[A-Z].*`
Require num	`.*[0-9].*`
Require spec	`.*[!@#$%^&*].*`

Customizing the cluster access URL

Customize the Uniform Resource Locator (URL) that you use to log in to IBM Cloud Pak for AIOps console.

- Supported customization formats
- Customize the cluster access URL
  - Customize the cluster access URL with `oc` command

Supported customization formats

The following customization formats are supported:

- `https://<Public IP>:8443/console`
- `https://<Public IP>:8443/console/`
- `https://<Private IP>:8443/console/`
- `https://<Private IP>:custom-port/console/`
- `https://<host name>:8443/console`
- `https://<host name>:custom-port/console`
- `https://localhost:8443/console`
- `https://localhost:<custom port>/console`
- `https://<Regex host name>:8443/console`
- `https://<Regex IP>:8443/console`
- `https://<Regex host name>:<custom port>/console`
- `https://<Regex IP>:<custom port>/console`
- `https://<Regex host name>:<Regex port>/console`
- `https://<Regex IP>:<Regex Port>/console`

Required user type or access level: Administrator

Customize the cluster access URL with `oc` command

Complete the following tasks on the boot node of your cluster.

1. Log in to the boot node as a user with root permissions.
2. Set up the OpenShift client (oc).
3. Copy the content that is in the **`registration-json`** configmap into the file **`registration.yaml`**.

   ```
   oc get cm registration-json -n <your-foundational-services-namespace> -o yaml > registration.yaml
   ```

   The **`registration.yaml`** file content resembles the following code:

   ```
   apiVersion: v1
   data:
     platform-oidc-registration.json: |
       {
       "token_endpoint_auth_method":"client_secret_basic",
       "client_id": "d2a00fc99163f85169ac7c6de758bad1",
       "client_secret": "01661d22bd0b2025fd87e26e994a4894",
       "scope":"openid profile email",
       "grant_types":[
          "authorization_code",
          "client_credentials",
          "password",
          "implicit",
          "refresh_token",
          "urn:ietf:params:oauth:grant-type:jwt-bearer"
       ],
       "response_types":[
          "code",
          "token",
          "id_token token"
       ],
       "application_type":"web",
       "subject_type":"public",
       "post_logout_redirect_uris":[

   "https://10.10.25.213:8443/console/logout","https://9.37.239.32:8443/console/logout","https://mycluster
   .icp:8443/console/logout"    ],
       "introspect_tokens":true,
       "trusted_uri_prefixes":[
          "https://10.10.25.213:8443","https://9.37.239.32:8443","https://mycluster.icp:8443"    ],
       "redirect_uris":[

   "https://10.10.25.213:8443/auth/liberty/callback","https://9.37.239.32:8443/auth/liberty/callback","htt
   ps://mycluster.icp:8443/auth/liberty/callback","https://mycluster.icp:8443/oidc/endpoint/OP"    ]
   ```

```
    }
kind: ConfigMap
metadata:
  creationTimestamp: 2018-06-06T11:53:21Z
  name: registration-json
  namespace: <your-foundational-services-namespace>
  resourceVersion: "1255"
  selfLink: /api/v1/namespaces/<your-foundational-services-namespace>/configmaps/registration-json
  uid: 3620b003-6980-11e8-9420-fa163ea0dafe
```

4. Create a **platform-oidc-registration.json** file. Place the file in the **<installation directory>/cluster/cfc-components/** folder.

5. Copy the content that is in the **data:** section of the **registration.yaml** file into the **platform-oidc-registration.json** file. The **platform-oidc-registration.json** file content resembles the following code:

```
{
 "token_endpoint_auth_method":"client_secret_basic",
 "client_id": "d2a00fc99163f85169ac7c6de758bad1",
 "client_secret": "01661d22bd0b2025fd87e26e994a4894",
 "scope":"openid profile email",
 "grant_types":[
    "authorization_code",
    "client_credentials",
    "password",
    "implicit",
    "refresh_token",
    "urn:ietf:params:oauth:grant-type:jwt-bearer"
 ],
 "response_types":[
    "code",
    "token",
    "id_token token"
 ],
 "application_type":"web",
 "subject_type":"public",
 "post_logout_redirect_uris":[

"https://10.10.25.213:8443/console/logout","https://9.37.239.32:8443/console/logout","https://mycluster
.icp:8443/console/logout"    ],
 "preauthorized_scope":"openid profile email general",
 "introspect_tokens":true,
 "trusted_uri_prefixes":[
    "https://10.10.25.213:8443","https://9.37.239.32:8443","https://mycluster.icp:8443"    ],
 "redirect_uris":[
 "https://10.10.25.213:8443/auth/liberty/callback","https://9.37.239.32:8443/auth/liberty/callback","ht
tps://mycluster.icp:8443/auth/liberty/callback","https://mycluster.icp:8443/oidc/endpoint/OP"    ]
 }
```

6. Add the following piece of code to the **platform-oidc-registration.json** file:

```
"allow_regexp_redirects":"true",
```

   The updated code resembles the following text:

```
{
 "token_endpoint_auth_method":"client_secret_basic",
 "client_id": "d2a00fc99163f85169ac7c6de758bad1",
 "client_secret": "01661d22bd0b2025fd87e26e994a4894",
 "scope":"openid profile email",
 "allow_regexp_redirects":"true",                                    <==========
 "grant_types":[
    "authorization_code",
    "client_credentials",
    "password",
    "implicit",
    "refresh_token",
    "urn:ietf:params:oauth:grant-type:jwt-bearer"
    ...
```

7. Add your custom URIs in the **"redirect_uris"** section of the **platform-oidc-registration.json** file. See Supported customization formats for the types of URIs that you can add.

```
"<regexp>:https://<custom IP address or host name>:<custom port>/auth/liberty/callback",
```

   Where, you add **<regexp>:** only if you are using a regex in the custom URI.

   Consider the following example URIs that you want to use to access the cluster:

   - Use the master node IP address and any port that starts with **84**. You would then add **"regexp:https://<master node IP address>:84!d!d/auth/liberty/callback"**.

- Use the host name `example.abc.com` and port `4002`. You would then add `"https://example.abc.com:4002/auth/liberty/callback"`.
- Use a variable host name and a dynamic port assignment. You would then add `"regexp:https://example.[a-z]*.com:[0-9]*/auth/liberty/callback"`.

If you added the example custom URIs, the updated code resembles the following text:

```
...
"application_type":"web",
"subject_type":"public",
"post_logout_redirect_uris":[

"https://10.10.25.213:8443/console/logout","https://9.37.239.32:8443/console/logout","https://mycluster
.icp:8443/console/logout"    ],
"preauthorized_scope":"openid profile email general",
"introspect_tokens":true,
"trusted_uri_prefixes":[
   "https://10.10.25.213:8443","https://9.37.239.32:8443","https://mycluster.icp:8443"    ],
"redirect_uris":[
   "regexp:https://10.10.25.213:84!d!d/auth/liberty/callback",       <==========
   "https://example.abc.com:4002/auth/liberty/callback",         <==========
   "regexp:https://example.[a-z]*.com:[0-9]*/auth/liberty/callback",          <==========

"https://10.10.25.213:8443/auth/liberty/callback","https://9.37.239.32:8443/auth/liberty/callback","htt
ps://mycluster.icp:8443/auth/liberty/callback","https://mycluster.icp:8443/oidc/endpoint/OP"    ]
}
```

8. Save and exit the file.
9. Save the client ID, client secret, and access IP to the following variables:
   1. Save the client secret:

      ```
      OAUTH2_CLIENT_REGISTRATION_SECRET=$(oc -n <your-foundational-services-namespace> get secret
      platform-oidc-credentials -o "jsonpath={.data.OAUTH2_CLIENT_REGISTRATION_SECRET}" | base64 --
      decode)
      ```

   2. Save the client ID:

      ```
      WLP_CLIENT_ID=$(oc -n <your-foundational-services-namespace> get secret platform-oidc-credentials
      -o "jsonpath={.data.WLP_CLIENT_ID}" | base64 --decode)
      ```

   3. Save the access IP:

      ```
      FIP=<master node IP address>
      ```

10. Apply the changes that you made to the `platform-oidc-registration.json` file.

    ```
    curl -kvv -X PUT -u oauthadmin:$OAUTH2_CLIENT_REGISTRATION_SECRET -H "Content-Type: application/json" -
    d @<installation directory>/cluster/cfc-components/platform-oidc-registration.json
    https://$FIP:8443/oidc/endpoint/OP/registration/$WLP_CLIENT_ID
    ```

11. Update the `registration-json` configmap with the custom URIs. Make the same changes that you made to the `platform-oidc-registration.json`.
12. Open the `registration-json` configmap for editing.

    ```
    oc edit cm registration-json -n <your-foundational-services-namespace>
    ```

13. Add the following piece of code:

    ```
    "allow_regexp_redirects":"true",
    ```

14. Add the custom URIs. If you added the example custom URIs, you would then add the following piece of code:

    ```
    "redirect_uris":[
    "regexp:https://10.10.25.213:84!d!d/auth/liberty/callback",
    "https://example.abc.com:4002/auth/liberty/callback",
    "regexp:https://example.[a-z]*.com:[0-9]*/auth/liberty/callback",
    ```

Adding a logout redirect URL

You can add a logout redirect URL that is displayed after you log out of the Red Hat® OpenShift® Container Platform console.

For more information, see Red Hat® OpenShift® Container Platform documentation.

- For Red Hat® OpenShift® Container Platform version 4.4, see Configuring the web console in OpenShift Container Platform.

- For Red Hat® OpenShift® Container Platform version 4.3, see Configuring the web console in OpenShift Container Platform.

Complete these steps to add a logout redirect URL:

1. Update the Console resource.
2. Update the platform-oidc-registration.json file.

Update the Console resource

Complete these steps to add a logout redirect URL in the **Console** resource:

1. Get the IBM Cloud Pak foundational services URL.

   ```
   oc get route -n <your-foundational-services-namespace> cp-console -o=jsonpath={.spec.host}
   ```

   Following is a sample output:

   ```
   cp-console.apps.hcp.darumtech.net[root@2test-inf ~]
   ```

2. Get the Red Hat® OpenShift® Container Platform console URL.

   ```
   oc get route -n openshift-console console -o jsonpath={.spec.host}
   ```

   Following is a sample output:

   ```
   console-openshift-console.apps.hcp.darumtech.net[root@2test-inf ~]
   ```

3. Add the redirect URLs in the OpenShift console resource.

   1. Open the resource for editing.

      ```
      oc edit console cluster
      ```

      Following is a sample content of the **Console** resource:

      ```
      apiVersion: config.openshift.io/v1
      kind: Console
      metadata:
        annotations:
          release.openshift.io/create-only: "true"
        creationTimestamp: "2020-03-25T15:34:01Z"
        generation: 6
        name: cluster
        resourceVersion: "9119030"
        selfLink: /apis/config.openshift.io/v1/consoles/cluster
        uid: ab896f97-ad65-456e-806b-1f7fbe879345
      spec: {}
      status:
        consoleURL: https://console-openshift-console.apps.hcp.darumtech.net
      ```

   2. Add the logout redirect URL in the **spec** section by using the IBM Cloud Pak foundational services URL and the Red Hat® OpenShift® Container Platform console URL values. Following is the syntax of the logout redirect URL:

      ```
      https://<{{site.data.keyword.cs}} URL>/idprovider/v1/auth/logout?
      login_url=https://<{{site.data.keyword.ocp}} console URL>
      ```

      Following would be the example logout redirect URL:

      ```
      https://cp-console.apps.hcp.darumtech.net/idprovider/v1/auth/logout?login_url=https://console-
      openshift-console.apps.hcp.darumtech.net
      ```

      You would add this redirect URL as shown in the following piece of code:

      ```
      spec:
        authentication:                 <===== Add this section
          logoutRedirect:               <===== Add the logout redirect URL
      ```

      Following is a sample of the updated **Console** resource:

      ```
        apiVersion: config.openshift.io/v1
        kind: Console
        metadata:
          annotations:
            release.openshift.io/create-only: "true"
          creationTimestamp: "2020-03-25T15:34:01Z"
          generation: 6
          name: cluster
          resourceVersion: "9119030"
          selfLink: /apis/config.openshift.io/v1/consoles/cluster
          uid: ab896f97-ad65-456e-806b-1f7fbe879345
      ```

```
  spec:
    authentication:
      logoutRedirect: https://cp-console.apps.hcp.darumtech.net/idprovider/v1/auth/logout?
login_url=https://console-openshift-console.apps.hcp.darumtech.net
  status:
    consoleURL: https://console-openshift-console.apps.hcp.darumtech.net
```

Update the platform-oidc-registration.json file

You must add the Red Hat® OpenShift® Container Platform console URL in the platform-oidc-registration.json in the **"redirect_uris"** section.

Configuring access and identity token validity

Change the default setting of the access token and identity token validity.

By default, the access token and identity (ID) token are valid for 12 hours after you sign out of the console or close your browser. You can change this default value as required.

Follow these steps to change the token validity:

1. Edit the **platform-auth-idp** configmap.

   ```
   oc -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

   The file content resembles the following code:

   ```
   # Please edit the following object. Lines beginning with a '#' will be ignored,
   # and an empty file will abort the edit. If an error occurs while saving this file will be
   # reopened with the relevant failures.
   #
   apiVersion: v1
   data:
     AUDIT_ENABLED_IDMGMT: "false"
     AUDIT_ENABLED_IDPROVIDER: "false"
     BASE_AUTH_URL: /v1
     BASE_OIDC_URL: https://127.0.0.1:8443/idauth/oidc/endpoint/OP
     CLUSTER_NAME: mycluster
     HTTP_ONLY: "true"
     IDENTITY_AUTH_DIRECTORY_URL: http://127.0.0.1:3100
     IDENTITY_PROVIDER_URL: http://127.0.0.1:4300
     IDTOKEN_LIFETIME: 12h
     JOURNAL_PATH: /run/systemd/journal
     MASTER_HOST: mycluster.icp
     NODE_ENV: production
     OAUTH2DB_DB_PORT: "3306"
     OIDC_ISSUER_URL: https://mycluster.icp:8443/oidc/endpoint/OP
     SESSION_TIMEOUT: "43200"
     logrotate: |-
       /var/log/audit/*.log {
         su nobody root
       .
       .
       .
   ```

2. Update the values of the **SESSION_TIMEOUT** and **IDTOKEN_LIFETIME** parameters.

   - The **SESSION_TIMEOUT** parameter sets the access token validity, the default value of which is **43200** seconds. Specify a positive integer followed by a unit of time, which can be hours (h), minutes (m), or seconds (s). For example, specify 30 seconds as 30s. You can include multiple values in a single entry. For example, 1m30s is equivalent to 90 seconds.
   - The **IDTOKEN_LIFETIME** parameter sets the ID token validity, the default value of which is **12** hours. Specify a positive integer followed by a unit of time, which can be hours (h), minutes (m), or seconds (s). For example, **14h** or **60000s**. You cannot include multiple values in a single entry. For example, you cannot add **1h30m**.

   After you update and save the changes, you see the following message:

   ```
   configmap "platform-auth-idp" edited
   ```

3. Restart the **platform-auth-service** pod.

   1. Get the **platform-auth-service** pod ID.

      ```
      oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
      ```

      Following is a sample output of the command:

      ```
      platform-auth-service-t6sfm     4/4     Running     0     1d
      ```

2. Delete the **platform-auth-service** pod.

   ```
   oc -n <your-foundational-services-namespace> delete pod platform-auth-service-t6sfm
   ```

   After the pod is deleted, you see the following message:

   ```
   pod "platform-auth-service-t6sfm" deleted
   ```

   Wait for a few minutes for the pod to restart.

3. Verify the status of the pod.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service-t6sfm
   ```

   The pod gets a new ID after restart.

   ```
   platform-auth-service-5267t                  1/4       Running     0          4m
   ```

Changing the security role mappings refresh time interval that is used during authorization

Change the security role mappings refresh time interval that is used during authorization.

By default, the security role mappings refresh time interval is set to 10 minutes. You can change this default value as required.

Follow these steps to change the time interval:

1. Edit the **platform-auth-idp** configmap.

   ```
   oc -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

2. Update the value of the **PDP_REDIS_CACHE_DEFAULT_TTL** parameter, as required. Specify the value in seconds. The default value is **600** seconds.

   After you update and save the changes, you see the following message:

   ```
   configmap "platform-auth-idp" edited
   ```

3. Restart all **platform-identity-management** pods by deleting them.

   ```
   oc -n <your-foundational-services-namespace> delete pod -l k8s-app=platform-identity-management
   ```

   Wait for a few minutes for the pod to restart.

4. Verify the status of the pods.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep platform-identity-management-pdp
   ```

   The status of all the pods must show as **1/1 Running**.

Changing LDAP search cache variable values

Change the default values of the Lightweight Directory Access Protocol (LDAP) search cache variables.

You can change the values of the following variables:

Table 1. LDAP cache parameters

Variable	Default value	Description
LDAP_SEARCH_CACHE_TIMEOUT	1200 seconds	The maximum time that the contents of the search results cache are available.
LDAP_SEARCH_CACHE_ENABLED	true	A Boolean value to indicate that the search results must be cached or not.
LDAP_SEARCH_CACHE_SIZE	2000	The number of search results that are stored in the cache.
LDAP_SEARCH_CACHE_SIZELIMIT	2000	The maximum number of results that can be cached for a single LDAP search.
LDAP_ATTR_CACHE_SIZE	2000	The number of entities that can be stored in the cache.
LDAP_ATTR_CACHE_TIMEOUT	1200 seconds	The maximum time that the contents of the LDAP attribute cache are available.
LDAP_ATTR_CACHE_SIZELIMIT	2000	The maximum number of attributes per LDAP entity that are cached.
LDAP_ATTR_CACHE_ENABLED	true	A Boolean value to indicate that the entities must be cached or not.

For more information, see LDAP User Registry (ldapRegistry).

Follow these steps to change the variable values:

1. Edit the **platform-auth-idp** configmap.

   ```
   oc -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

   The file content resembles the following code:

   ```
   # Please edit the following object. Lines beginning with a '#' will be ignored,
   # and an empty file will abort the edit. If an error occurs while saving this file will be
   # reopened with the relevant failures.
   #
   apiVersion: v1
   data:
     AUDIT_DETAIL: "false"
     AUDIT_ENABLED_IDMGMT: "false"
     AUDIT_ENABLED_IDPROVIDER: "false"
     .
     .
     LDAP_ATTR_CACHE_ENABLED: "true"
     LDAP_ATTR_CACHE_SIZE: "2000"
     LDAP_ATTR_CACHE_SIZELIMIT: "2000"
     LDAP_ATTR_CACHE_TIMEOUT: 1200s
     LDAP_SEARCH_CACHE_ENABLED: "true"
     LDAP_SEARCH_CACHE_SIZE: "2000"
     LDAP_SEARCH_CACHE_SIZELIMIT: "2000"
     LDAP_SEARCH_CACHE_TIMEOUT: 1200s
     LDAP_SEARCH_CN_ATTR_ONLY: "false"
     LDAP_SEARCH_ID_ATTR_ONLY: "false"
     LDAP_SEARCH_SIZE_LIMIT: "50"
     LDAP_SEARCH_TIME_LIMIT: "5"
     MASTER_HOST: mycluster.icp
     NODE_ENV: production
     .
     .
   "/tmp/kubectl-edit-i5ta2.yaml" 60L, 2204C
   ```

2. Change the LDAP variable values, as required, and save the ConfigMap.

   After you update and save the changes, you see the following message:

   ```
   configmap "platform-auth-idp" edited
   ```

3. Restart the **platform-identity-provider** pod.

   1. Get the **platform-identity-provider** pod ID.

      ```
      oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
      ```

      Following is a sample output of the command:

      ```
      platform-identity-provider-5b78f                          4/4     Running                3
      12d
      ```

   2. Delete the **platform-identity-provider** pod.

      ```
      oc -n <your-foundational-services-namespace> delete pod platform-identity-provider-5b78f
      ```

      After the pod is deleted, you see the following message:

      ```
      pod "platform-identity-provider-5b78f" deleted
      ```

      Wait for a few minutes for the pod to restart.

   3. Verify the status of the pod.

      ```
      oc -n <your-foundational-services-namespace> get pods | grep platform-identity-provider
      ```

      The pod gets a new ID after restart.

      ```
      platform-identity-provider-5267t               1/4       Running     0          4m
      ```

Using a proxy server for outbound traffic

Use a forward proxy to communicate with your external identity provider.

Forward proxy servers isolate the network and provide a control point for outbound requests. The egress traffic is routed through the proxy server, and the proxy server sends it to the destination, which can be an external service outside the firewall. The proxy server also performs the same actions for any response that comes back from the destination. You can configure authentication requirement for the proxy server.

You can use a proxy server only if you are using OpenID Connect (OIDC) to connect your IBM Cloud Pak® with your identity provider (IdP).

Configuring the proxy server

Configure your proxy server to manage traffic for specific namespaces.

The identity management (IM) service uses the following parameters from the proxy configuration to add the proxy settings to IM applications:

- **`_userdefined_http_proxy`:** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be HTTP.
- **`_userdefined_https_proxy`:** A proxy URL to use for creating HTTPS connections outside the cluster. The URL scheme must be either HTTP or HTTPS.

IBM Cloud Pak requirements

Your IBM Cloud Pak must meet the following requirements:

- IBM Cloud Pak foundational services 4.2 or higher must be installed.
- Your IBM Cloud Pak and the Zen service must be installed.
- The IBM Cloud Pak for Data command-line interface (**`cpd-cli`**) and resource specification injection (RSI) must be configured. For more information, see Customizing pod specifications with resource specification injection.
- You must install and enable RSI for the namespace where foundational services are installed.

After you complete the requirements, you can inject the proxy configuration parameters into the IM application through RSI configuration.

1. Create a file named **`cpfs-im-proxy-envs.json`** in the RSI configuration directory, which is usually located under the **`cpd-cli`** as **`cpd-cli-workspace/olm-utils-workspace/work/rsi`**. The **`cpfs-im-proxy-envs.json`** file must contain the following lines. Replace the parameter values as applicable to your environment. Authentication credentials are optional.

   ```
   [ {
       "name":  "_userdefined_http_proxy",
       "value": "http://<username>:<password>@<ip>:<port>"
   }, {
       "name":  "_userdefined_https_proxy",
       "value": "http://<username>:<password>@<ip>:<port>"
   } ]
   ```

2. Run the following RSI patch for IM applications. Replace **`$cs-data-ns`** with your foundational services data plane namespace.

   ```
   ./cpd-cli manage create-rsi-patch     --cpd_instance_ns=$cs-data-ns     --patch_name="cpfs-im-authsvc-proxy"     --description="add proxy settings to im authsvc"     --patch_type=rsi_pod_env_var     --patch_spec=/tmp/work/rsi/cpfs-im-proxy-envs.json     --spec_format=set-env     --selector=app.kubernetes.io/instance:platform-auth-service --skip_apply=false --state=active
   ```

   ```
   ./cpd-cli manage create-rsi-patch     --cpd_instance_ns=$cs-data-ns     --patch_name="cpfs-im-providersvc-proxy"     --description="add proxy settings to im providersvc"     --patch_type=rsi_pod_env_var     --patch_spec=/tmp/work/rsi/cpfs-im-proxy-envs.json     --spec_format=set-env  --selector=app.kubernetes.io/instance:platform-identity-provider --skip_apply=false --state=active
   ```

3. Check the new **`platform-auth-service`** and **`platform-identity-provider`** pods to make sure that the proxy values are set as applicable to your environment. If you don't find your environment values despite successfully running the **`cpd-cli`** command, restart the **`platform-auth-service`** and **`platform-identity-provider`** pods and reverify whether the values are set.

4. Configure the public OIDC IdP and log in as you usually do.

Rolling back the RSI proxy configuration from IM applications

To roll back the proxy configuration, first make sure that the RSI injection was successfully completed.

Then, run these commands to deactivate the patch and remove it. Replace **`$cs-data-ns`** with your foundational services data plane namespace.

```
./cpd-cli manage create-rsi-patch     --cpd_instance_ns=$cs-data-ns     --patch_name="cpfs-im-authsvc-proxy"
--description="add proxy settings to im authsvc"     --patch_type=rsi_pod_env_var     --
patch_spec=/tmp/work/rsi/cpfs-im-proxy-envs.json     --spec_format=set-env     --
selector=app.kubernetes.io/instance:platform-auth-service --skip_apply=false --state=inactive
```

```
./cpd-cli manage delete-rsi-patch \
    --cpd_instance_ns=$cs-data-ns \
    --patch_name="cpfs-im-authsvc-proxy"
```

```
./cpd-cli manage create-rsi-patch     --cpd_instance_ns=$cs-data-ns     --patch_name="cpfs-im-providersvc-
proxy"     --description="add proxy settings to im providersvc"     --patch_type=rsi_pod_env_var     --
patch_spec=/tmp/work/rsi/cpfs-im-proxy-envs.json     --spec_format=set-env  --
selector=app.kubernetes.io/instance:platform-identity-provider --skip_apply=false --state=inactive
```

```
./cpd-cli manage delete-rsi-patch \
    --cpd_instance_ns=$cs-data-ns \
    --patch_name="cpfs-im-providersvc-proxy"
```

IM sample configuration

Learn how OKTA-IM integration and AZURE-IM integration help in managing the authentication and authorization for the resources.

- SCIM configuration by using IBM Cloud Pak for AIOps UI
- IBM Cloud Pak SCIM OKTA integration
- IBM Cloud Pak SCIM AZURE AD integration
- IBM Cloud Pak JIT support for SCIM OKTA and Azure Active Directory
- Integrating SAML with Azure Active Directory

SCIM configuration by using IBM Cloud Pak for AIOps UI

In IBM Cloud Pak for AIOps UI, you can configure SCIM by selecting the attributes (User and Group attributes) to map the Identity provider (Idp) attributes to the SCIM attributes.

Note: If you want to add custom SCIM attributes, see Adding custom SCIM attributes.

To configure SCIM, complete the following steps:

Pre-requisite: Install the cluster. Once the cluster is installed, the admin username, password, and the URL are displayed.

1. Log in to the console by using the URL and enter the username and password.

   Note: The console can be Platform UI or Common UI.

2. From the navigation menu, click **Identity and access** > **Identity providers**.

3. Click **Create Connection**. The **New LDAP server connection** page is displayed.

4. Select **SCIM configuration**.

5. Click **New attribute** in the SCIM configuration page. The attribute types- **User attribute** and **Group attribute** are displayed.

6. Select **User attribute** and complete the following:

   - Select the attribute from the **Attribute** drop-down.
   - Provide an Idp attribute to map the Idp attribute to the SCIM attribute.

7. Select **Group attribute** and complete the following:

   - Select the attribute from the **Attribute** drop-down.
   - Provide an Idp attribute to map the Idp attribute to the SCIM attribute.

   Similarly, you can create another **User attribute** and **Group attribute** by clicking **New attribute**.

   See the following notes:

   - The attributes in the **Attribute** drop-down are divided into two categories- simple attribute and complex attribute. For example, **Name** is a complex attribute because when you select the **Name** attribute from the drop-down, the **New component attribute** option is displayed. Click **New component attribute** to select the component attribute from the drop-down. These component attributes can be **familyName**, **givenName**, **userType**, and so on. And, **id** is a simple attribute because it does not have any component attribute.

   - If no SCIM attributes mappings are added, the default mapping happens. If you define a custom SCIM attributes mapping, the default mapping will not work and SCIM user search will return only those field values that you have added to the mapping list. Therefore, in such cases, perform the attribute mapping for others SCIM attributes in SCIM configuration section.

8. Click **Create** to update the identity provider.

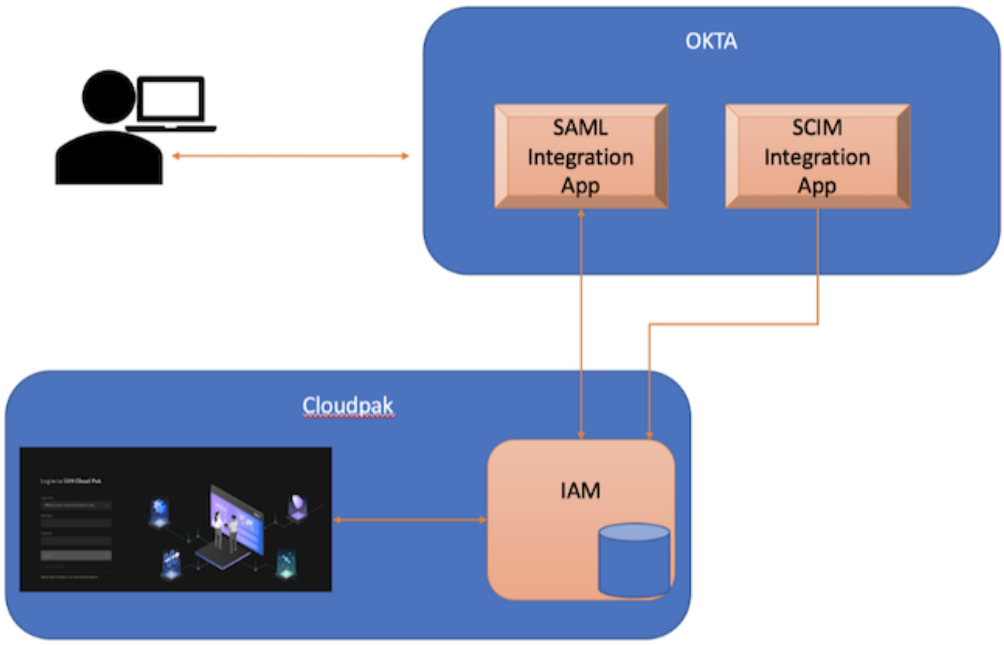
Editing the SCIM configuration

To edit the SCIM configuration, complete the following steps:

1. In the **Identity Providers** page, a list of SCIM configurations is displayed.
2. Select the name of SCIM configuration to edit and click **Edit connection**. **Edit LDAP connection** dialog box is displayed.
3. In **Edit your LDAP connection** dialog box, click **Edit**. It displays the LDAP connection page that contains SCIM configuration.

   You can edit the SCIM configuration by the following ways:

   - Select **New attribute**, if you want to add new attributes to the SCIM configuration.
   - Delete any existing attribute. For each attribute, there is a **Delete** option in the UI.
   - Change the value of the Idp attribute of any existing attribute.
4. Click **Save**.



See the following notes:

- The `Group filter` and `Group member ID map` filters do not consider the custom SCIM attribute values. Use LDAP filter values for `Group filter` and `Group member ID map` attributes to map the data. For more information about LDAP filters, see LDAP filters.
- The SCIM users and groups API for LDAP is dependent on the attribute mapping list. You must provide a proper attribute mapping for all the SCIM user and group attributes. If the SCIM attributes mapping is not proper then SCIM API might not be able to fetch users or group details or some attributes might miss in the SCIM users or groups response.

IBM Cloud Pak SCIM Okta integration

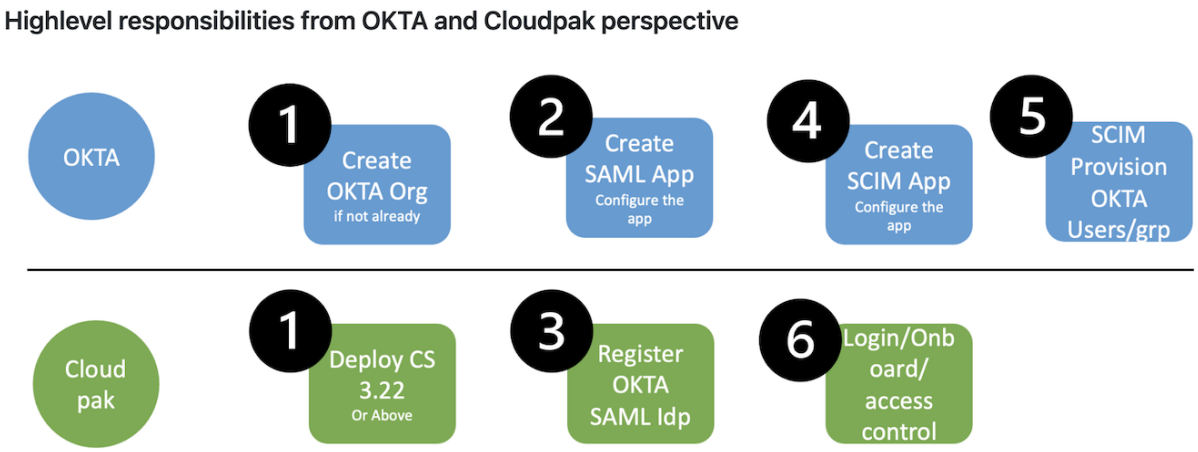
You can use SCIM for OKTA-IM integration to manage your IBM Cloud Pak® users and groups. The OKTA-IM integration also helps in managing the authentication and authorization of the resources.

Okta is an enterprise-grade, identity management service that is built for the cloud. However, it is compatible with many on-premises applications. With Okta-IM integration, the organization can manage employees' access to any application or device. Okta is a cloud-based, SaaS-delivered Identity Management (IM) service that provides enterprise-grade identity lifecycle management capabilities to the developers and organizations.

Configuration required for OKTA integration by using SAML SSO and SCIM

See the following notes:

- Use the following process until an IBM-specific application is published in the Okta Integration Network (OIN) catalog.



- You can create a free Okta dev org by signing up on the OKTA Dev portal. Both personal and official accounts are accepted. Once you create a dev account, you can log in to the dev account to get the main Okta dashboard.

See the following prerequisites:

- You must have a valid active OKTA account and org.
- The cp-console route must be displayed with the trusted certificate.
- The cp-console route must be publicly accessible over an internet unless Okta is deployed in a private tenant.

Follow these steps to create an application:

1. Create an Okta Org, if you don't have one. And, deploy the foundational services version 4.x.
2. Create a SAML app and configure the app at Okta. For more information, see Configure Cloud Pak as SAML service provider (SP) at OKTA.
3. Register Okta SAML IdP at your Cloud Pak. For more information, see Configure OKTA as SAML IdP at Cloud Pak.
4. Create a SCIM app. Configure the app at Okta. For more information, see Configure SCIM integration with Cloud Pak SCIM Server.
5. Provision SCIM for Okta users and groups. For more information, see Manage users and Manage groups.
6. Log in or onboard to the Cloud Pak.

Primarily, the following main configurations are required to get OKTA-SCIM integration to work with your Cloud Pak along with SAML SSO.

- Configure Cloud Pak as SAML service provider (SP) at OKTA
- Configure OKTA as SAML IdP at Cloud Pak
- Configure SCIM integration with Cloud Pak SCIM Server

Configuring Cloud Pak as SAML SP at Okta and configuring Okta as SAML IdP at Cloud Pak are performed to make the e2e SSO to work. And, configuring SCIM integration with Cloud Pak SCIM server is performed to enable SCIM provisioning.

Configure Cloud Pak as SAML service provider (SP) at OKTA

Before you begin: You must have the SP **Cloud Pak CommonServices IM liberty** SAML metadata. For more information, see SAML metadata export by using samlmetadata API.

Steps

1. Log in to the OKTA org. You see the Okta dashboard.
2. From the navigation menu, click **Applications** > **Applications**. You see the **Applications** page.
3. Click **Create App Integration**.
4. Select **SAML 2.0**.
5. Click **Next**.
6. Provide the App name.
7. Click **Next**.
8. Fill all the required details for the SAML configuration.

- **Single sign-on URL:** Get ACS URL from the Liberty SAML metadata. For example, https://cpconsole/ibm/saml20/defaultSP/acs. To get the `cpconsoleroute`, see Getting host details.
- **Audience URI (SP Entity ID):** Get Entity ID from Liberty SAML metadata. For example, https://cpconsole/ibm/saml20/defaultSP. To get the `cpconsoleroute`, see Getting host details.
- **Name ID format:** EmailAddress
- **Application Username:** Okta username

9. Update the **Attribute Statements (optional)** section. It allows Okta to send the attributes in SAML response to Cloud Pak. **Important:** Even though the section name indicates **(optional)**, you must provide at least one SAML attribute. Otherwise, the SAML configuration fails.

   Following are the default **User** attributes:

   - Name: **uid**, Name format: **Basic**, Value: **user.email**
   - Name: **firstName**, Name format: **Basic**, Value: **user.firstName**
   - Name: **lastName**, Name format: **Basic**, Value: **user.last.Name**
   - Name: **emailAddress**, Name format: **Basic**, Value: **user.email**

   The following are the default **Group** attributes:

   - Name: **groups**, Name format: **Basic**, Filter: **Equals** (it can be adopted based on the groupName), Value: **groupName** (groupName should be the Okta groupName)

     Note: While registering the Okta IdP, you can use the same default keys of the **Name** field (uid, firstName, lastName, emailAddress, groups) to specify the values in the `token_attribute_mappings` section. In case you customized the attributes keys, use the customized keys only to specify the values in the `token_attribute_mappings` section. For more information, see SAML attributes statements. The following is an example mapping of the use of default attribute keys to specify the values in `token_attribute_mappings` section:

```
"token_attribute_mappings": {
            "sub": "uid",
            "given_name": "firstName",
            "family_name": "lastName",
            "groups": "groups",
            "email": "emailAddress",
            "first_name": "firstName",
            "last_name": "lastName"
}
```

10. Click **Preview the SAML Assertion** to reconfirm whether the SP metadata is configured correctly.
11. Click **Next** and select an option to specify whether you are a customer or partner.
12. Click **Finish**. You see the **Sign on** tab page.
13. In the **SAML Setup** section, click **View SAML setup instructions**. You then see a page with instructions to configure SAML with your application.
14. From the **Optional** section, copy the IdP metadata and save it to a file named `idp-metadata-xml.xml`.

After you copy the IdP metadata, assign the SAML application to the user or group who need to log in at the Cloud Pak end.

Note: This is a mandatory procedure for the user to be able to log in.

1. From the navigation menu, click **Applications** > **Applications**. You see the **Applications** page.
2. Select the application and users or groups that you want to assign to the application.

If you want to assign existing LDAP users or group to the App, follow the procedure to first integrate OKTA Agent to LDAP Server. Once it is done, the LDAP entities can be imported to OKTA and used for assignment.

Configure Okta as SAML IdP at Cloud Pak

Use the IdP V3 API to register OKTA as SAML IdP. For now, the Okta registration is not supported through UI. Therefore, you need to perform the registration by using API only. However, the process remains the same. For more information about the IdP v3 usage, see IdP V3 registration with Okta.

With the registration IdP v3 API, the required Oauth client is also created. This Oauth client is used for configuring SCIM server Oauth authentication from Okta.

Note: Provide the `redirect_uri` for `oauthClient` registration.

Upon successful registration, you get `clientId` and `clientSecret` name. From the `clientSecret`, both the `clientId` and `clientSecret` can be retrieved.

To be concluded, the IdP v3 Okta registration does the following:

- Register Okta as SAML IdP
- Register Okta to Liberty `oauthClient` while returning the client credentials.

See the following prerequisites:

- Download the `idp-metadata-xml` from Okta.
- Encode the `idp-metadata-xml` content as base64. For example, `cat idp-metadata-xml |base64`.
- You need to pass the `redirect_uri` for OKTA oauth client creation along with IdP V3 registration.

Getting the `redirect_uri`

Based on the environment (a standard org, an EMEA org, and an Okta Preview org), the `redirect_uri` can be one of the following:

- https://system-admin.okta.com/admin/app/cpc/${appName}/oauth/callback
- https://system-admin.okta-emea.com/admin/app/cpc/${appName}/oauth/callback
- https://system-admin.oktapreview.com/admin/app/cpc/${appName}/oauth/callback

Note: Replace the **${appName}** with the variable name for your application instance. If you don't know the variable name for application instance, you can find it as part of the App Embed link from the browser by opening the embed link, or you can also check the **Name** attribute for the application at the `/Apps API` endpoint.

For example, if the URL embedded link is https://dev-68798908-admin.okta.com/admin/app/dev-68798908_iamsaml_3/instance/0oa6vnyhkm86B4xha5d7/#tab-general, the **${appName}** will be **dev-68798908_iamsaml_3** and the `redirect_uri` is, "redirect_uri": [https://system-admin.okta.com/admin/app/cpc/dev-68798908_iamsaml_3/oauth/callback].

Steps

1. Use the IdP V3 API to register OKTA as SAML IdP.

   The sample for OKTA registration as SAML IdP :

```
curl --location --request POST 'https://cpconsoleroute/idprovider/v3/auth/idsource' \
--header 'Authorization: Bearer $accessToken' \
--header 'Content-Type: application/json' \
--data-raw
'{
   "name": "OKTASAML",
   "description": "OKTASAML",
   "protocol": "saml",
   "type": "okta",
   "idp_config":{
      "token_attribute_mappings": {
        "sub": "uid",
        "given_name": "firstName",
        "family_name": "lastName",
        "groups": "groups",
        "email": "emailAddress"
        "first_name": "firstName",
        "last_name": "lastName"
   },
     "idp_metadata": "Base64-encoded-metadata"
   },
   "jit": false,
   "scim_config":{
      "redirect_url": [
        "okta_redirect_url"
      ],
      "scim_attribute_mappings": {
          "user":{
            "principalName": "userName",
            "name":{
              "givenName": "givenName",
              "familyName": "familyName"
            },
            "displayName": "displayName",
            "emails": [
              {
                 "value": "emails",
                 "type": "home"
               }
               ],
               "id": "id",
               "userName": "userName"
             },
             "group": {
                 "principalName": "displayName",
                 "displayName": "displayName",
                 "id": "displayName"
```

```
            }
          }
    }
 }'
```

2. Upon successful registration, you might get the status similar to the following:

```
{
   "status": "success",
   "message": "Identity provider {OKTASAML} is successfully registered with unique identifier :
defaultSP, oktaclient created with clientId: lgz9i024740cyuc0vl6eh3g7f6mv2b1f , client secret: okta-
oidcclient-secret"
}
```

   The error message resembles the following:

```
401 "error": "Insufficient user permission for role : rolename"
400 "error": "schema error:schema validation error followed by error"
400 "error": "duplicate : Idp with protocol=saml is already created"
500 "error": "Other errors"
```

   token_attribute_mappings: `token_attribute_mappings` is a custom mapping that user can provide based on the SAML attribute mapping that is configured at Okta. User must modify the value, not the key, based on the Okta SAML attribute configuration. For more information about attributes, see Step 9 in Configure Cloud Pak as SAML service provider (SP) at OKTA.

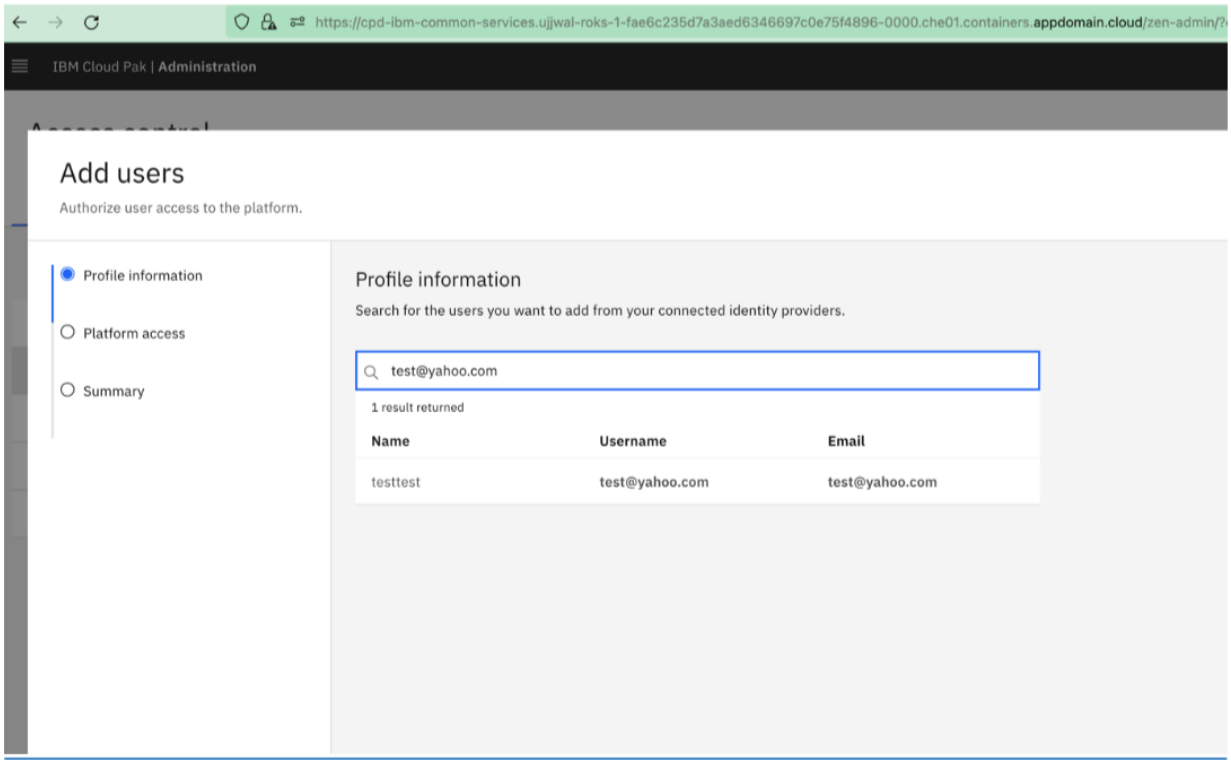
   scim_attribute_mappings: Provide the mapping attributes as in the CURL command. The defined mapping is used in the filter query, creating attributes and the response to be sent.

Note: You can get the client credential details from the secret that was created. These client credential details are sent back as a response.

To get the Oauth client credentials:

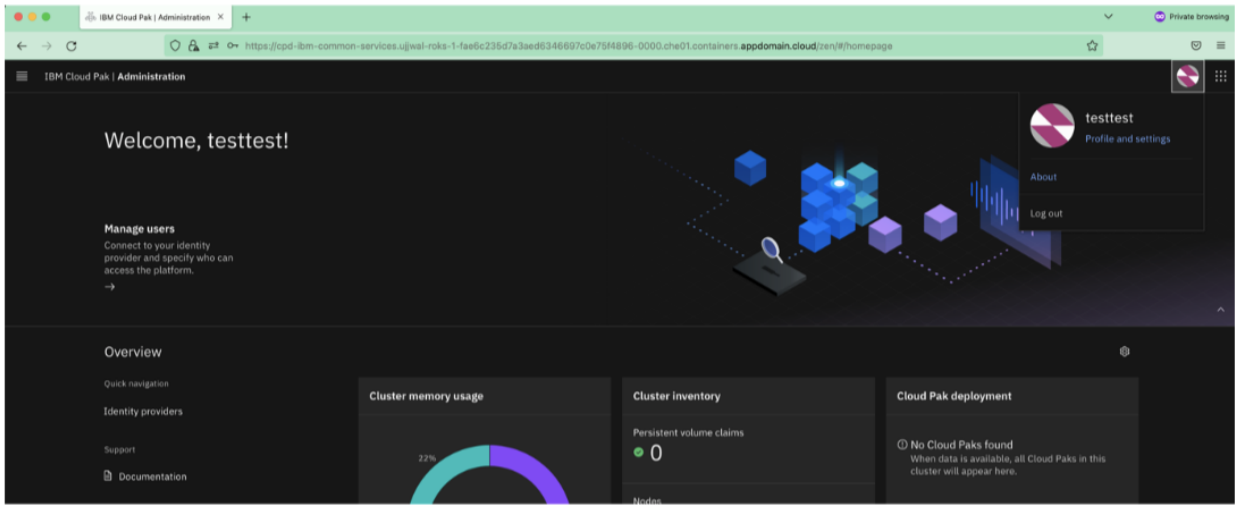
1. Log in to the OpenShift Container Platform by using `oc` CLI.
2. Run the following commands:

```
oc get secrets/okta-oidcclient-secret --template={{.data.CLIENT_ID}} | base64 --decode
```



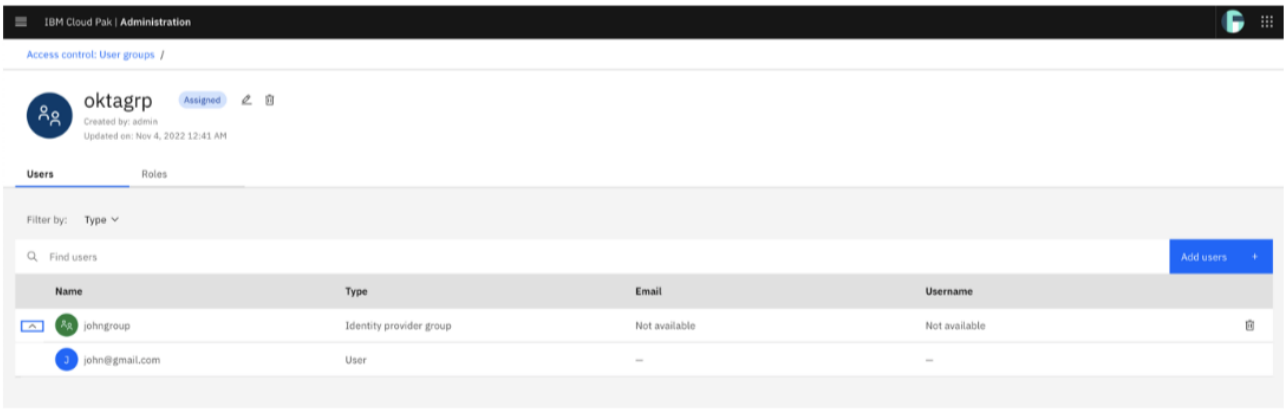
```
oc get secrets/okta-oidcclient-secret --template={{.data.CLIENT_SECRET}} | base64 --decode
```

Once the registration is done, the SAML configuration can be validated by login through the cp-console directly. The default role is **Viewer**.

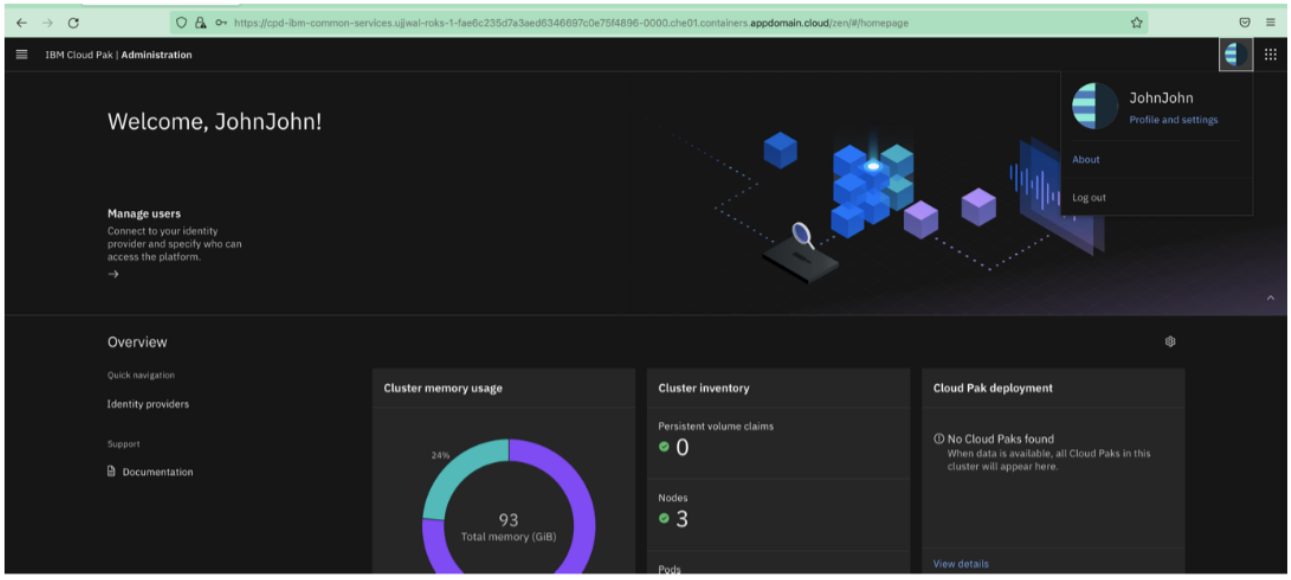


For Platform UI SAML login, you need to first complete the OKTA SCIM integration so that the provisioned user or group can be onboarded at Platform UI end. If you have not already completed the SCIM Integration and provisioned for the users and groups, then complete the steps that are mentioned in Configure SCIM integration with Cloud Pak SCIM server before you proceed further.

To log in to the Platform UI console, follow these steps:



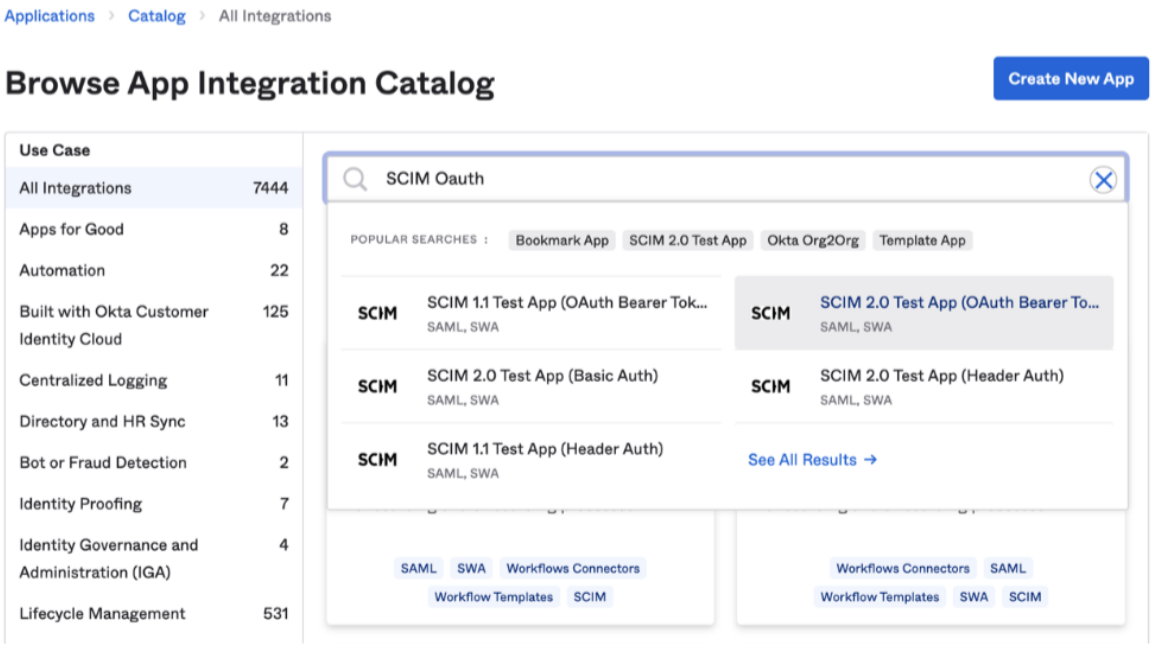
1. Onboard the user to Platform UI from the IM Scim Server. For example, **test@yahoo.com**, a user that was provisioned from OKTA to IM SCIMServer. For more information, see steps that are mentioned in Configure SCIM integration with Cloud Pak SCIM server.



2. Once the user is onboarded, login to the Platform UI console with that user.

3. Similarly, the provisioned group can also be onboarded to the Platform UI console from the IM ScimServer.

Member of the group can log in to the Platform UI console.

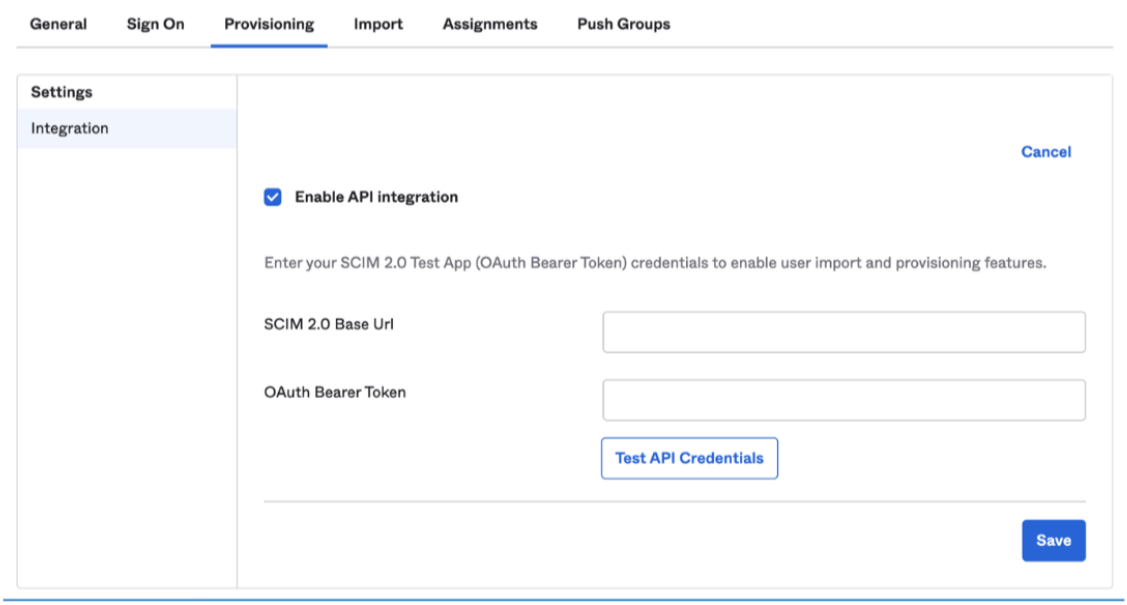


Configure SCIM integration with Cloud Pak SCIM server

Note: You can follow this configuration process until the IM SCIM App is published to the OIN catalog. Later, you can use the proper Oauth configurations with clientID and clientSecret with the IBM Specific Integration App that was created as a part of IdP V3 registration in Configure Okta as SAML IdP at Cloud Pak.

Steps

1. Go to Okta dashboard.
2. Go to **Applications** > **Applications**. The **Application** page appears.
3. Select **Browse App Catalog**. The **Browse App Integration Catalog** page appears.
4. In the search tab, type **SCIM 2.0 Oauth**. Then, select **SCIM 2.0 Test App (OAuth Bearer Token)** from the displayed options.



5. Select **Add Integration**.
6. Click **Next**. Then, click **Done**. Ignore the SSO configuration part. Leave it as it is.
7. Go to **Provisioning** > **Integration**.
8. Select **Enable API Integration**.
9. Update the following details:
    - **SCIM 2.0 Base URL**: https://cpconsoleroute/idmgmt/identity/api/v1/scim

Note: To get `cpconsoleroute` from cluster, see Getting the host details.

- **OAuth Bearer token**: Update the accessToken as Oauth Bearer Token. To get the OAuth Bearer Token from cluster:
    - Log in to the OpenShift Container Platform cluster by using `oc` CLI.
    - Run the following commands:

```
oc get secrets/platform-auth-scim-credentials --template={{.data.scim_admin_password}} |
base64 --decode
```

```
curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" -d
"grant_type=password&username=scimadmin&password=passwordfromabove&scope=openid"
https://cpconsoleroute/idprovider/v1/auth/identitytoken --insecure
```

10. Test the API credential.

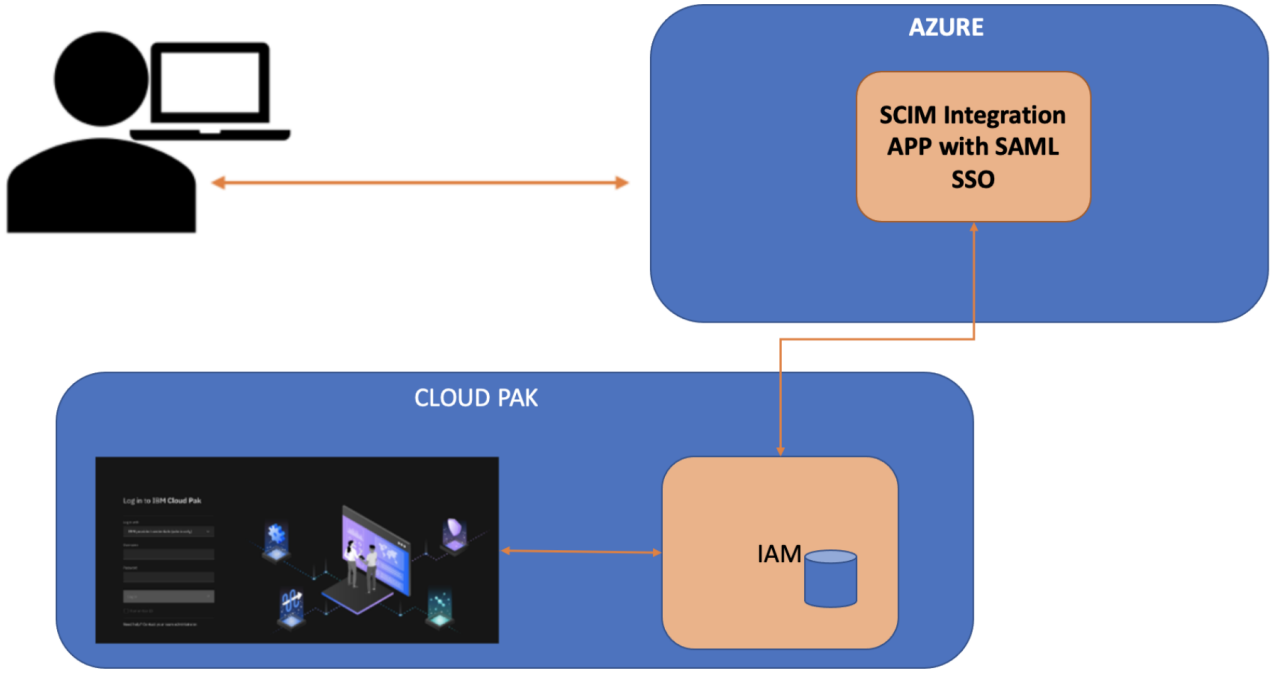
    See the following notes:

    - It is expected that this validation might fail if you are trying for the first time as the Okta requires at least one user to be returned when the Okta validates the token. Therefore, it is advisable to manually create a user or run the runscope before you test the API credentials.
    - **accessToken** in the following CURL command is the same as the value retrieved from OAuth Bearer token in Step 9 in Configure SCIM integration with Cloud Pak SCIM server.

- Create a user manually.

```
curl --location --request POST 'https://cpconsoleroute/idmgmt/identity/api/v1/scim/users' \
--header 'Authorization: Bearer ${accessToken}' \
--header 'Content-Type: application/json' \
--data-raw '{
  "schemas": ["urn:ietf:params:scim:schemas:core:2.0:User"],
  "userName": "Dummy",
  "name":
  {
    "givenName": "Dummy",
    "middleName": "",
    "familyName": "Dummy"
  },
  "emails":
  [{
    "primary": true,
    "value": "Dummy@ibm.com",
    "type": "work"
  }],
    "displayName": "Dummy",
    "externalId": "Dummy",
    "groups": [],
    "active": true
  }'
```

- To run the RunScope, see Scope of tests.



11. Once the token is verified, follow the process to start provisioning for Managing users and Managing groups.

Note: If you want to provision existing LDAP users or groups to the App, follow the procedure to first integrate OKTA Agent to LDAP Server. Once it is done, the LDAP entities can be imported to Okta and used for the assignment.

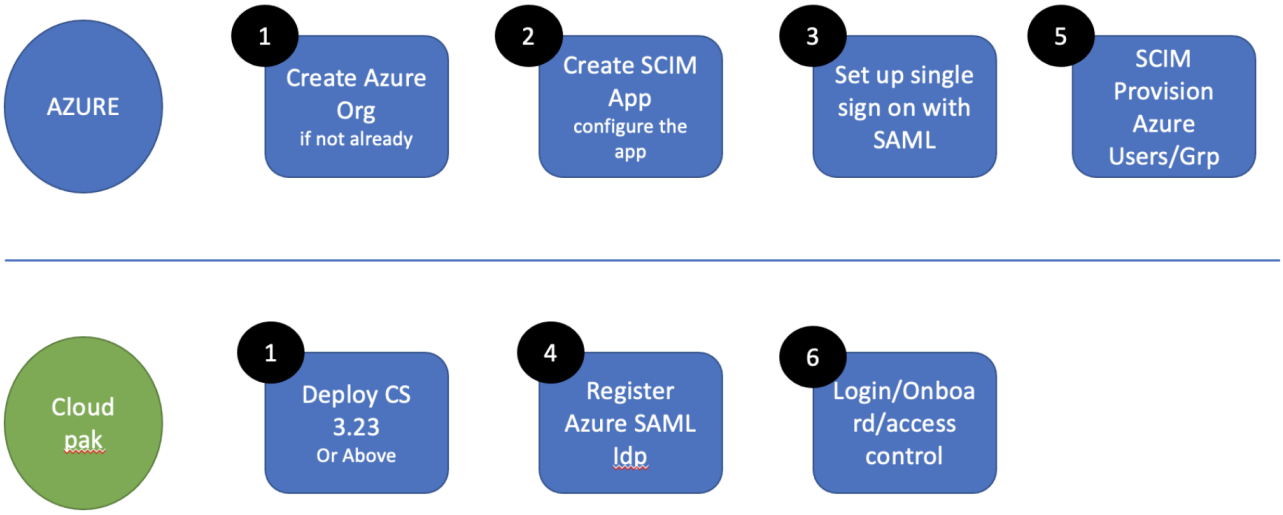
IBM Cloud Pak SCIM Azure AD integration

From foundational services version 3.19.9, 3.23, and later, Cloud Pak can use the Azure-IM integration by using SCIM to manage the users and groups at the CloudPak end. The Azure-IM integration will also help in managing the authentication and authorization for the resources.

Azure Active Directory (Azure AD) is an enterprise identity service that provides single sign-on, multifactor authentication, and conditional access to protect against cybersecurity attacks.

Configuration required for Azure integration using SSO/SAML and SCIM

See the following notes:



- Follow this process until you have the IBM Specific app published in Azure AD application gallery.
- You can create free Azure dev org by signing up to Azure Dev portal. Both personal and official accounts are accepted. Once dev account is created, you can login to the dev account to get the Azure main dashboard.

See the following prerequisites:

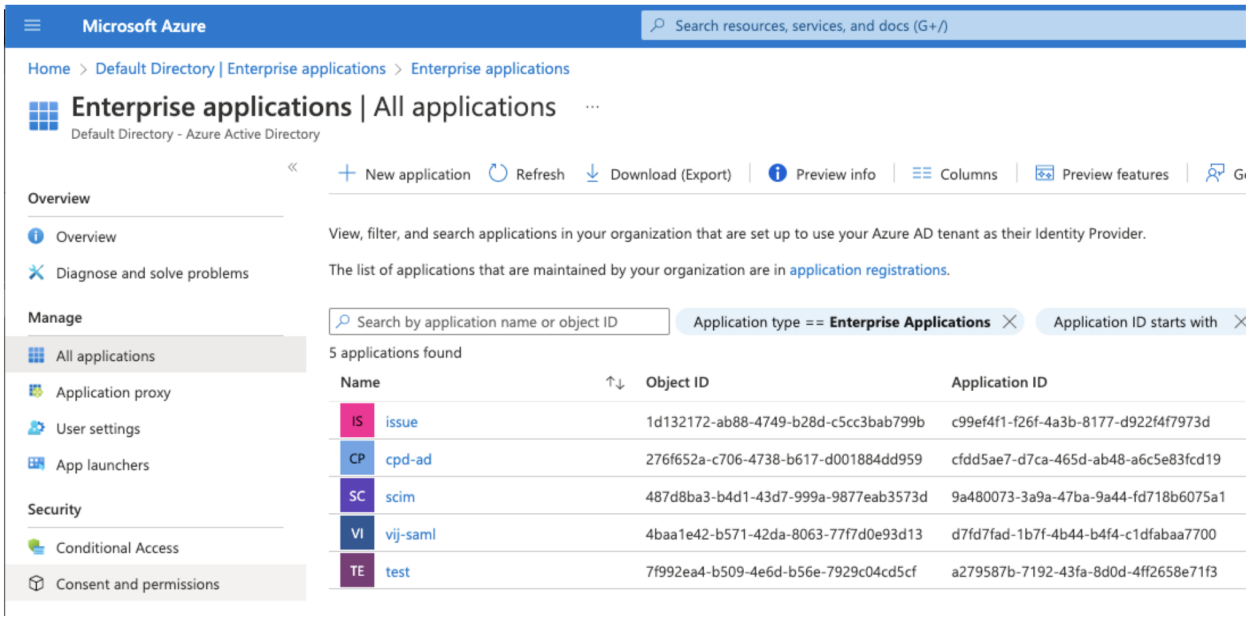
- Cloud Pak must have foundational services version 3.19.9, 3.23, or later.
- You must have a valid active Azure account and org.
- CP console route must be displayed with the trusted certificate.
- CP console route must be publicly accessible over an internet unless Azure is deployed into private tenant.

Follow the steps in sequence:

1. Create Azure Org if you have not created the Azure Org. And, deploy the foundational services version 3.19.9, 3.23, and later.
2. Create the SCIM app and configure the app at Azure. For more information, see Configure CloudPak as SAML service provider (SP) at Azure.
3. Set up single-sign-on with SAML.
4. Register Azure SAML IdP at Cloud Pak. For more information, see Configure Azure as SAML IdP at CloudPak.
5. Perform SCIM provisioning for Azure users and groups. For more information, see Manage users and Manage groups.
6. Login or onboard to the Cloud Pak.

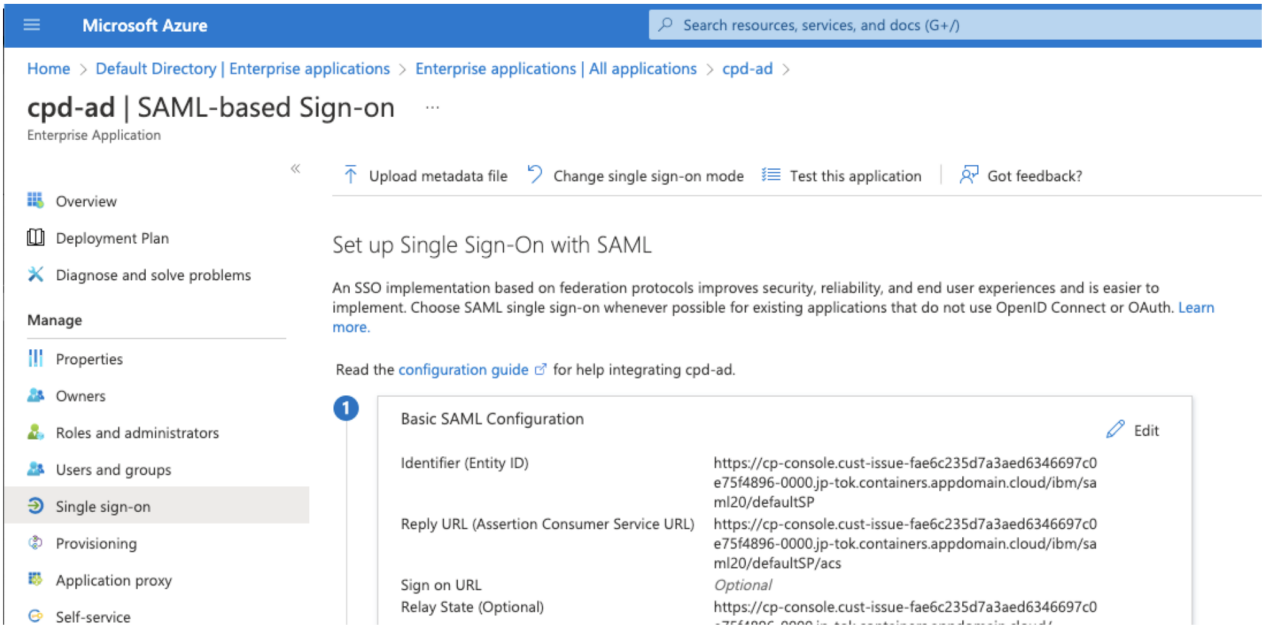
Primarily, the following main configurations are required to get Azure SCIM Integration working with CloudPak along with SAML SSO.

- Configure Cloud Pak as SAML service provider (SP) at Azure
- Configure Azure as SAML IdP at Cloud Pak
- Configure SCIM Integration with Cloud Pak SCIM Server



Configuring Cloud Pak as SAML SP at Azure and configuring Azure as SAML IdP at Cloud Pak are performed to make the e2e SSO work. And, configuring SCIM integration with CloudPak SCIM server is performed to enable SCIM provisioning.

Configure Cloud Pak as SAML service provider (SP) at Azure



Before you begin: You must have the SP, **CloudPak CommonServices IM liberty** SAML metadata. You can use the **`samlmetadata`** API to get the SAML metadata. For more information, see SAML metadata export by using samlmetadata API.

Steps

1. Create a custom FreeStyle enterprise application. Complete the following steps:
    1. Login to Azure org.
    2. Select **Microsoft Entra ID** in the **`Azure Services`** section.
    3. Click **+ Add** and select **Enterprise application**.
    4. Click **+ Create your own application** and enter the name of your app in the **`Input name`** section.
    5. Select **Integrate any other application you don't find in the gallery (Non-gallery)** and click **Create**.
2. Select your enterprise application from the list in the **Enterprise applications** page.

3. Click **Get started** in the **Set up single sign on** to configure single sign-on method for your enterprise application.
4. Click **SAML** in the **`Single sign-on`** page.
5. Select **Upload metadata file** option and upload the SP metadata file and click **Add**.

6. Confirm the **Attributes & Claims** names and values.

   The default **User** attributes:

   - Name: **http://schemas.xmlsoap.org/ws/2005/05/identity/claims/name**, Type: **SAML**, Value: **userprincipalname**
   - Name: **http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname**, Type: **SAML**, Value: **user.givenname**
   - Name: **http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname**, Type: **SAML**, Value: **user.surname**
   - Name: **http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress**, Type: **SAML**, Value: **user.mail**

   The default **Group** attributes:

   - Name: **http://schemas.microsoft.com/ws/2008/06/identity/claims/groups**, Type: **SAML**, Filter: **Equals** (it can be adopted based on the groupName), Value: **groupName** (groupName should be the Azure groupName and it should be any of the following: None, All groups, Security groups, Directory roles, Groups assigned to the application)

   Note: While registering the Azure IdP, you can use the same default keys of the **Name** field to specify the values in the **`token_attribute_mappings`** section. The values allows Azure to send the attributes in SAML response to Cloud Pak. In case, you have customized the attributes keys, use the customized keys only to specify the values in the **`token_attribute_mappings`** section. For more information, see SAML authentication with Azure Active Directory. For example, if you are using the default attributes keys to specify the values in **`token_attribute_mappings`** section:

```
"token_attribute_mappings": {
   "sub": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/name",
   "given_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
   "family_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname",
   "groups": "http://schemas.microsoft.com/ws/2008/06/identity/claims/groups",
   "email": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress",
   "first_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
   "last_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname"
}
```

7. Once the metadata is saved, go to the SAML certificate section and download **Federation Metadata XML** and save as **`idp-metadata-xml.xml`**.
8. Click **Test this application**.
9. Verify the login by clicking **Test single sign-on with cpd-ad** section.
10. Go to SCIM app and assign the user and/or group who are required to login at Cloud Pak end. To assign the user and/or group:

    - Under **Manage** section, select **Enterprise applications** from the menu. The **Enterprise applications** page appears.
    - Select **Assign users and groups**. Then, select the users and groups that you want to assign.

If you want to assign existing LDAP users or group to the App, use Azure Active Directory (Azure AD) to create a domain in Azure and link the Azure AD to an on-premises AD domain. For more information, see Integrate on-premises AD with Azure. After this, the LDAP entities can be imported to Azure and it can be used for assignment.

Configure Azure as SAML IdP at Cloud Pak

Use the IdP V3 API to register Azure as SAML IdP. For now, the Azure registration is not supported through UI. Therefore, you need to perform the registration using API only. However, the process remains the same. For more information about the IdP v3 usage, see IdP V3 registration with Azure.

With the registration IdP v3 API, the required Oauth client is also created. This Oauth client will be used for configuring SCIM server Oauth authentication from Azure.

Note: Provide the **`redirect_uri`** for **`oauthClient`** registration.

Upon successful registration, you will get **`clientId`** and **`clientSecret`** name. From the **`clientSecret`**, both the **`clientId`** and **`clientSecret`** can be retrieved.

To be concluded, the IdP v3 Azure registration does the following:

- Register Azure as SAML IdP.
- Register Azure to Liberty **`oauthClient`** while returning the client credentials.

See the following prerequisites:

- Download the **`idp-metadata-xml`** from Azure as mentioned in step 7 in Configuring Cloud Pak as SAML service provider (SP) at Azure.
- Encode the **`idp-metadata-xml`** content as base64. For example, **`cat idp-metadata-xml |base64`**.
- You need to pass the **`redirect_uri`** for Azure Oauth client creation along with IdP V3 registration.

Steps

1. Use the IdP V3 API to register Azure as SAML IdP.

   The following sample for Azure registration as SAML IdP. To get **`accessToken`**, see Get access token by using cpclient_credentials.

```
curl --location --request POST 'https://cpconsoleroute/idprovider/v3/auth/idsource' \
--header 'Authorization: Bearer $accessToken' \
--header 'Content-Type: application/json' \
--data-raw
'{
   "name": "AzureSAML",
   "description": "AzureSAML",
   "protocol": "saml",
   "type": "azuread",
   "idp_config":
    {
      "token_attribute_mappings": {
        "sub": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/name",
        "given_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
        "family_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname",
        "groups": "http://schemas.microsoft.com/ws/2008/06/identity/claims/groups",
        "email": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress"
        "first_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
        "last_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname"
    },
      "idp_metadata": "Base64-encoded-metadata"
    },
    "jit": false,
    "scim_config":
    {
      "redirect_url": ["azure_redirect_url"],
        "scim_attribute_mappings": {
          "user":
          {
            "principalName": "userName",
            "name":
            {
              "givenName": "givenName",
              "familyName": "familyName"
            },
            "displayName": "displayName",
            "emails":
            [
            {
              "value": "emails",
              "type": "home"
            }
            ],
```

```
            "id": "id",
            "userName": "userName"
            },
            "group":
            {
             "principalName": "displayName",
             "id": "displayName"
             "displayName": "displayName"
            }
          }
      }
}'
```

2. Upon successful registration, you might get the status similar to the following:

```
{
   "status": "success",
   "message": "Identity provider {AzureSAML} is successfully registered with unique identifier :
defaultSP, azureadclient created with clientId: yx3a5pwtdrmn0sf8ockyf97dg55lswo7 , client secret:
azuread-oidcclient-secret"
}
```

   The error message resembles the following:

```
401 "error": "Insufficient user permission for role : rolename"
400 "error": "schema error:schema validation error followed by error"
400 "error": "duplicate : Idp with protocol=saml is already created"
500 "error": "Other errors"
```

   token_attribute_mappings: `token_attribute_mappings` is a custom mapping that user can provide based on the SAML attribute mapping that is configured at Azure. User should modify the values, not the key, based on the Azure SAML attribute configuration. For more information about attributes, see Step 6 in Configure CloudPak as SAML service provider (SP) at Azure.

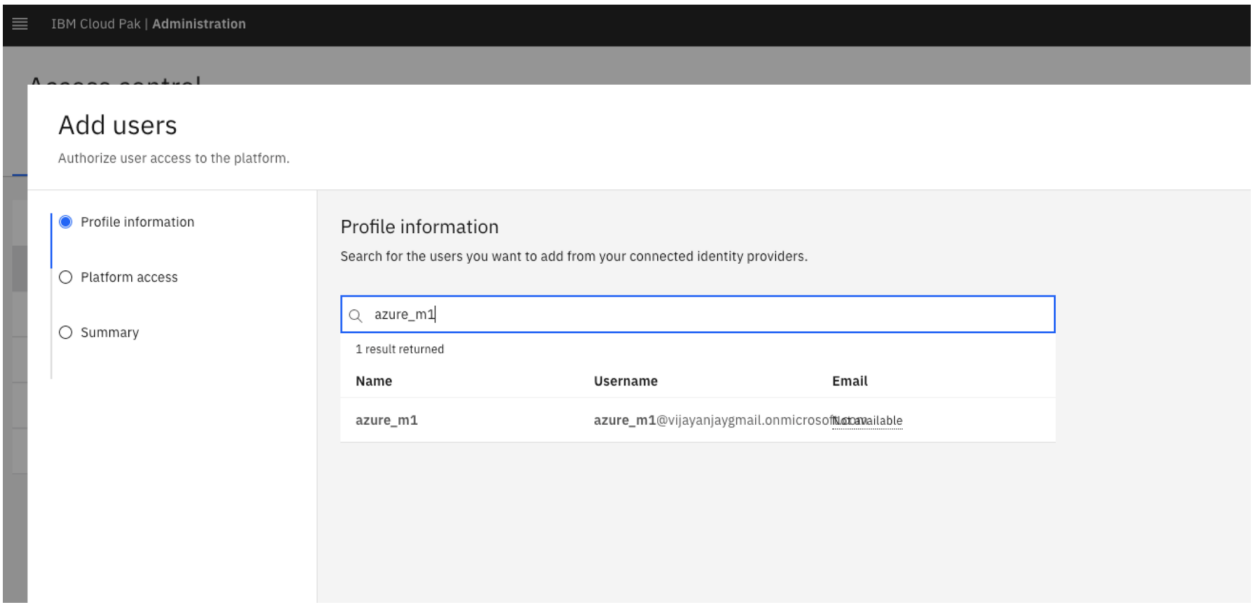
   scim_attribute_mappings: Provide the mapping attributes as in the CURL command. The defined mapping will be used in filter query, creating attributes and the response that is to be sent.

   Note: You can get the client credential details from the secret that has been created. This client credential details are sent back as a response.

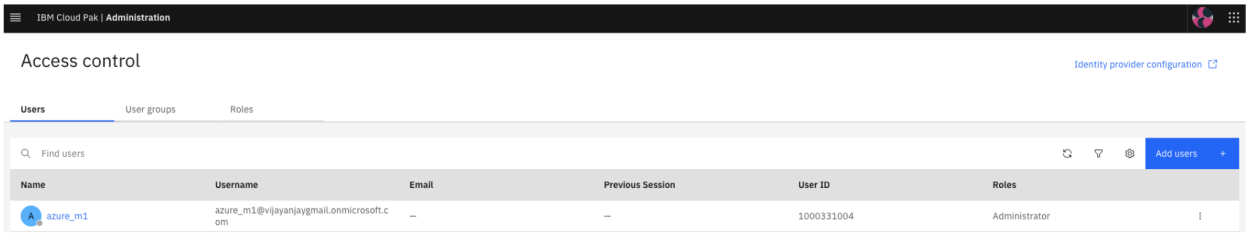
To get the Oauth client credentials:

- Login to the OpenShift Container platform by using `oc` CLI.
- Run the following commands:

```
oc get secrets/azuread-oidcclient-secret --template={{.data.CLIENT_ID} | base64 -D
```

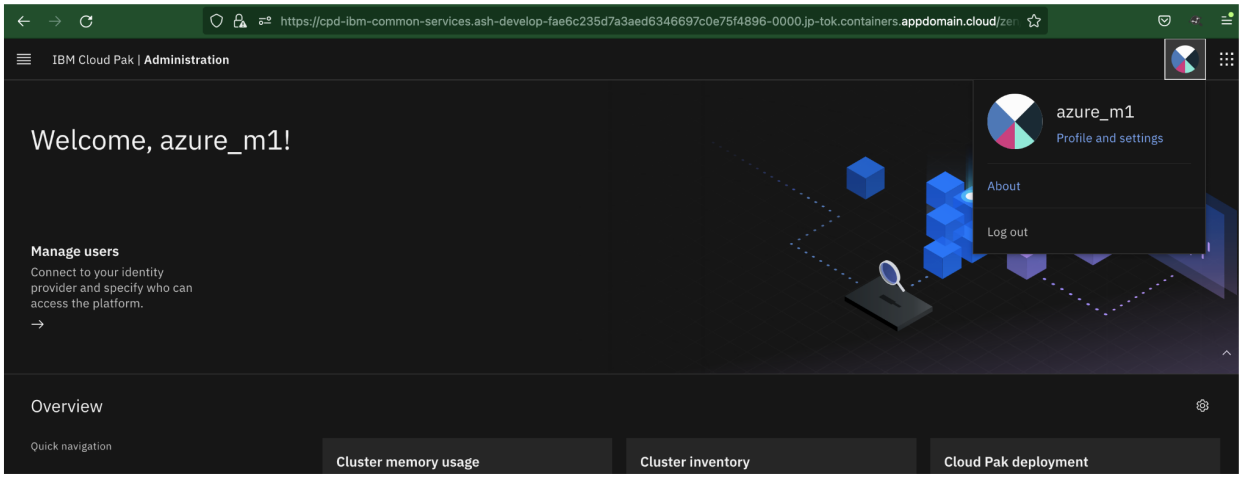


```
oc get secrets/azuread-oidcclient-secret --template={{.data.CLIENT_SECRET}} | base64 -D
```



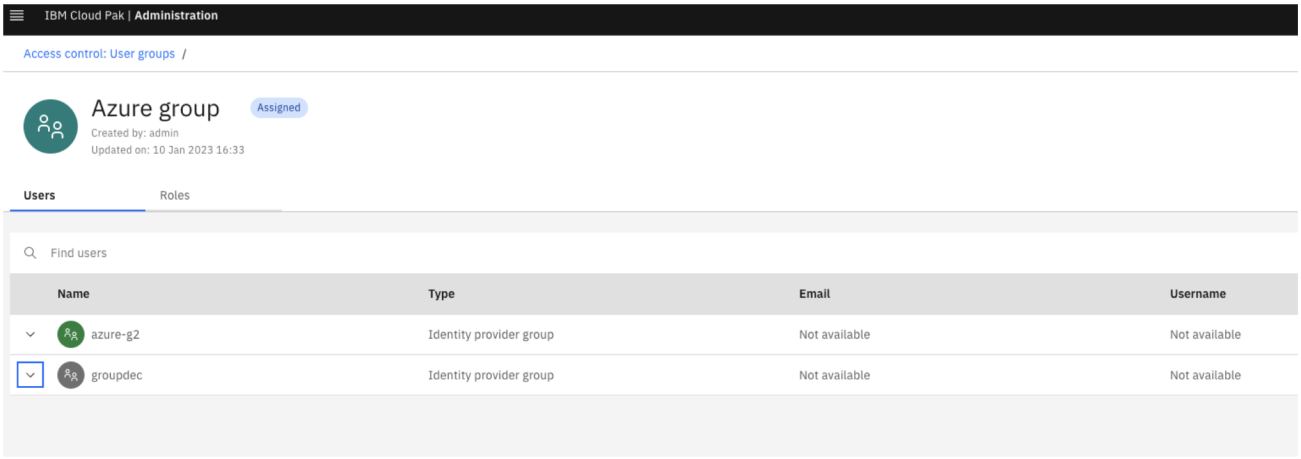
Once the registration is done, the SAML configuration can be validated by login through the cp-console directly. The default role will be **Viewer**.

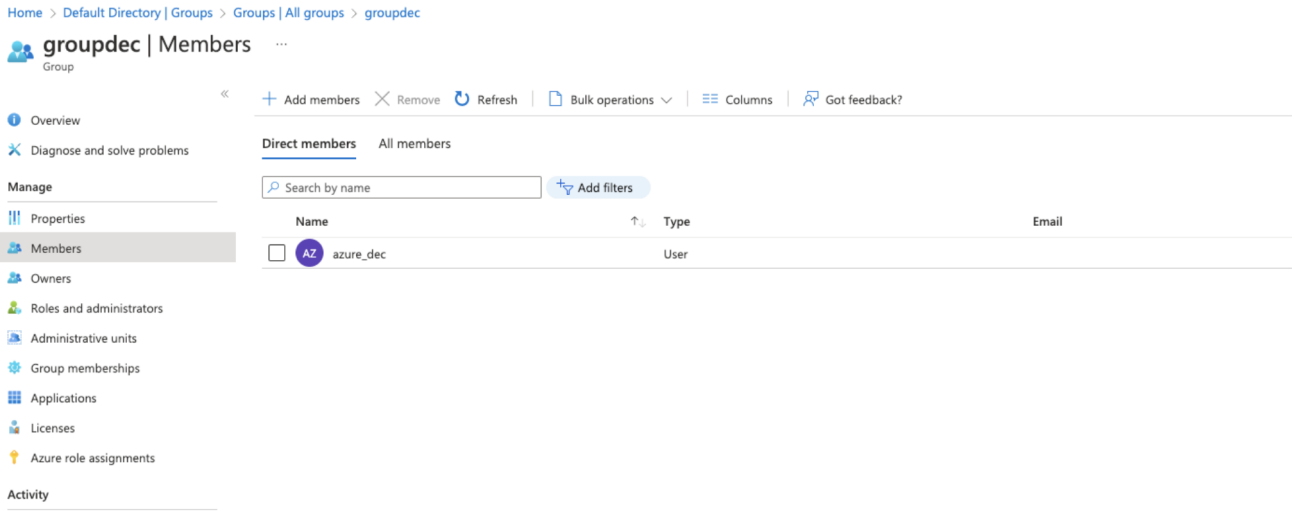
For Platform UI SAML login, you need to first complete the Azure SCIM integration so that the provisioned user or group can be onboarded at Platform UI end. If you have not already completed the SCIM Integration and provisioned required for the users and groups, then complete the steps that are mentioned in Configure SCIM integration with CloudPak SCIM server before you proceed further.



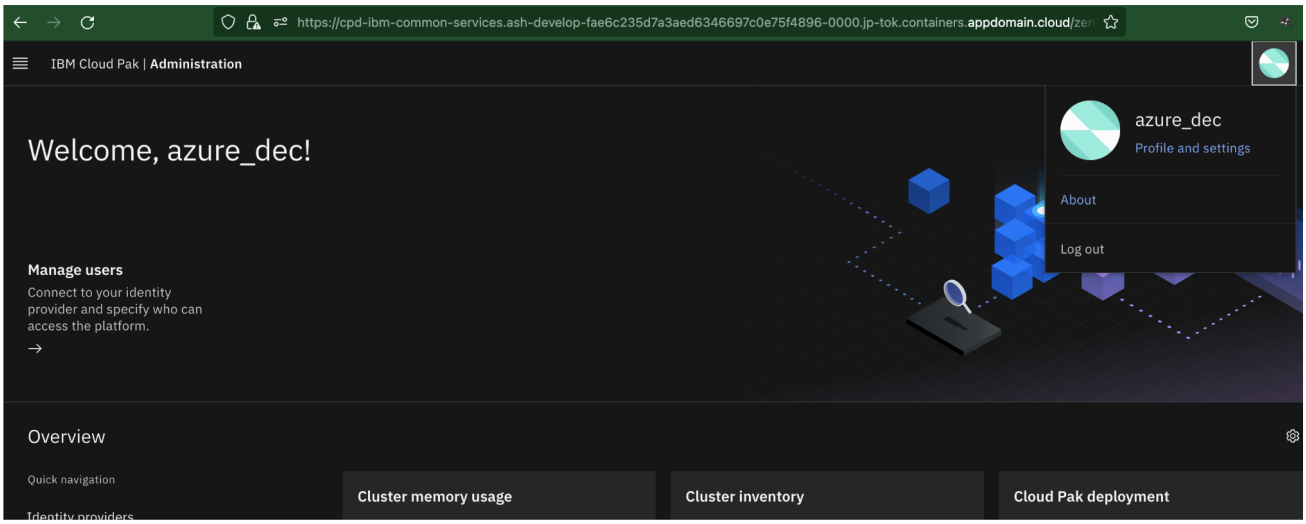
To login Platform UI console, follow these steps:

1. Onboard the user to Platform UI from the IM ScimServer. For example, **azure_m1@vijayanjaygmail.onmicrosoft.com**, a user that has been provisioned from Azure to IM SCIMServer. For more information, see steps that are mentioned in Configure SCIM integration with Cloud Pak SCIM server.





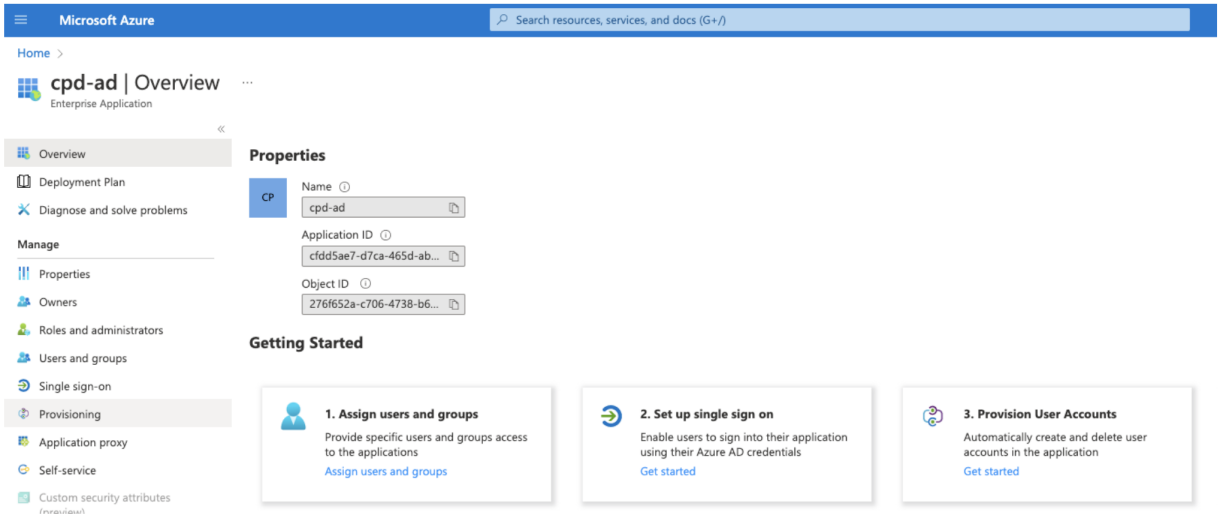
2. Once the user is onboarded, login to the Platform UI console with that user.



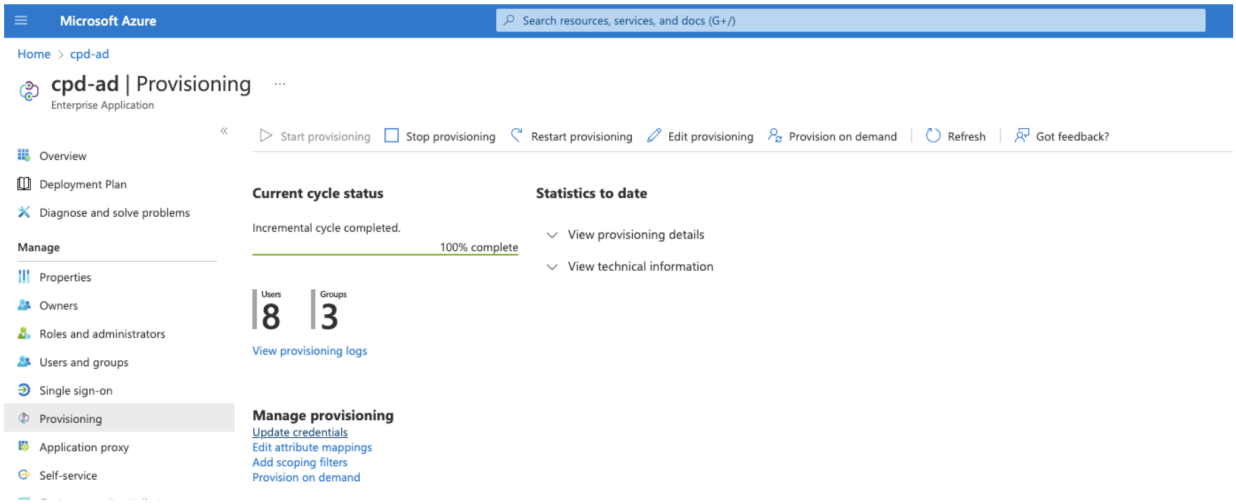
3. Similarly, the provisioned group can also onboarded to Platform UI console from the IM ScimServer.

Azure_dec is the member which is available inside **groupdec**.

Member of the groups can login to the Platform UI console.

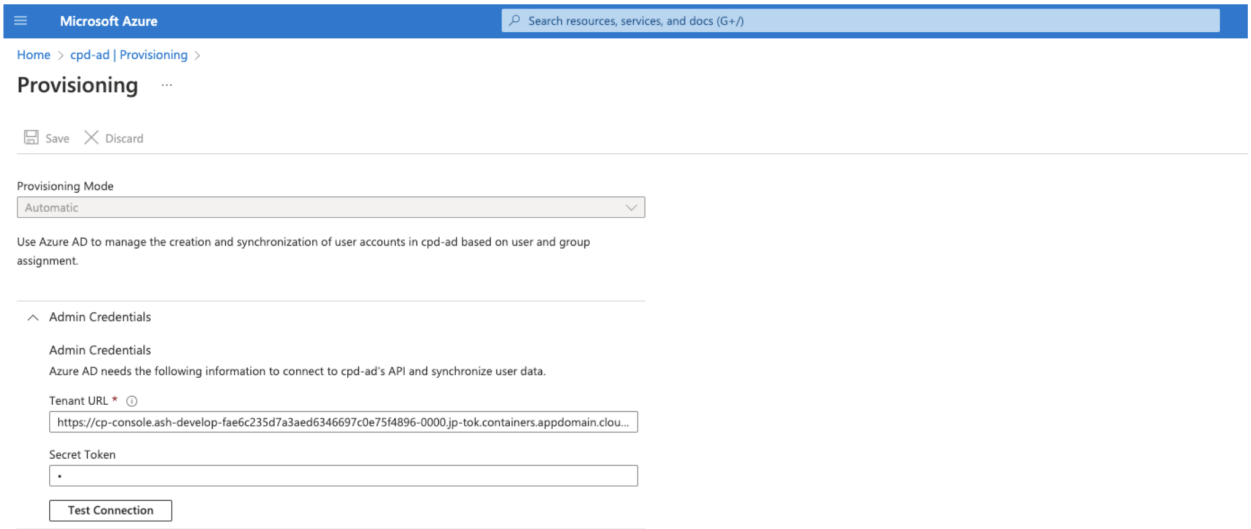


Configure SCIM integration with CloudPak SCIM server



Note: You can follow this configuration process until the IM SCIM App is published to Azure AD app gallery. Later, you can use the proper Oauth configurations with clientID and clientSecret with the IBM Specific Integration App that has been created as a part of IdP V3 registration in Configure Azure as SAML IdP at Cloud Pak.

Steps



1. Go to Azure Active Directory dashboard .
2. Under **Manage** section, select **Enterprise applications** from the menu. The **Enterprise applications** page appears.
3. Select the enterprise application from the list that is displayed on **Enterprise applications** page. Then, select **Provisioning** from the navigation menu.

4. Click **Update credentials** under **Manage provisioning**.

5. In **Provisioning** page, under **Admin Credentials**, provide **Tenant URL** and **Secret Token**.

- **Tenant URL**: https://cpconsoleroute/idmgmt/identity/api/v1/scim

Note: To get `cpconsoleroute` from cluster, see Getting the host details.

- **Secret token**: Update the Secret Token as Oauth Bearer Token. To get the OAuth Bearer Token from cluster:
  - Login to OpenShift Container Platform cluster using `oc` CLI.
  - Run the following commands:

```
oc get secrets/platform-auth-scim-credentials --template={{.data.scim_admin_password}} |
base64 -D
```

```
curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" -d
"grant_type=password&username=scimadmin&password=passwordfromabove&scope=openid"
https://cpconsoleroute/idprovider/v1/auth/identitytoken --insecure
```

6. Click **Test Connection** to test API Credential. For more information, see Validate a SCIM endpoint.
7. Once the token is verified, follow the process to start provisioning for Managing users and Managing groups.

If you want to provision existing LDAP users or group to the app, follow the step to integrate on-premise AD with Azure.

IBM Cloud Pak foundational services JIT support for SCIM OKTA and Azure Active Directory

You can configure just-in-time (JIT) with Security Assertion Markup Language (SAML) only for OKTA and Azure AD identity providers (IdPs). JIT supports both user and group attributes. You can also use System for Cross-domain Identity Management (SCIM) APIs with attribute mappings. You must correctly configure these attributes at the IdP and service provider (SP). For the attribute-mapping values for IdP and SP, see SAML attribute mappings of IdP and SP.

When you enable JIT, you can use SCIM operations to search users and groups after the user logs in at least once by using SAML IdP. You can then enable their access to the IBM Cloud Pak console.

To enable the access for users and groups before you enable JIT, see Granting access to capabilities within an IBM Cloud Pak.

Configure SAML at IdP and SP ends:

- Configuring SAML at IdP end
- Configuring SAML at SP end

Configuring SAML at IdP end

If you are using the OKTA template application to configure SAML, see Configure Cloud Pak as SAML SP at OKTA. You can provide the attribute mappings in the **Attribute Statements (optional)** section in the application.

Important: Even though the section name indicates **(optional)**, you must provide at least one SAML attribute. Otherwise, the SAML configuration fails.

Configure the SAML IdP attributes such as Name, Name format, and Value at IdP.

Note: The SAML IdP attributes are the user-defined values. You can update these values based on your requirements.

The following table is an example for SAML IdP attributes:

Table 1. Example of SAML IdP attributes

Name	Name format	Value
uid	Basic	user.email
firstName	Basic	user.firstName
lastName	Basic	user.lastName
emailAddress	Basic	user.email
groups	Basic	Matches regex

Configuring SAML at SP end

To register OKTA as SAML IdP, you can either use the console or use the IdP V3 APIs. For more information, see Registering the SAML clients using IdP V3.

Note: It is not necessary to specify `redirect_url` for SAML with OKTA or Azure AD types when JIT is enabled.

IAM supports the following SAML SP attributes for user and group entities:

Table 2. IAM-supported SAML SP attributes

Name	Description
sub	Unique ID
given_name	First name of the user
family_name	Family name of the user
groups	Group name of the user
email	Email ID of the user

The values of the SAML SP attributes must be the same as the user-defined values for SAML IdP attributes.

The following table includes the mapping of the SAML attributes of IdP and SP:

Table 3. SAML attribute mappings of IdP and SP

SAML SP attribute	SAML IdP attribute	Description
sub	uid	Unique ID
given_name	firstName	First name of the user
family_name	lastName	Family name of the user
groups	groups	Group name of the user
email	emailAddress	Email ID of the user

Note: Table 3. SAML attribute mappings of IdP and SP includes the attribute mapping based on Example of SAML IdP attributes and IAM-supported SAML SP attributes tables.

See the following prerequisites:

1. Download the IdP metadata-xml file from the OKTA-SAML integration application. For more information, see IBM Cloud Pak SCIM Okta integration. You can save the file as **`idp-metadata-xml.xml`**.
2. Encode the IdP metadata-xml file content as base64. See the following example:

   ```
   cat idp-metadata-xml.xml | base64 --decode
   ```

   Following is a sample payload of IdP V3 registration for OKTA with JIT enabled. The example payload is based on attributes from Example of SAML IdP attributes:

   ```
   {
       "name": "OKTASAML",
       "description": "OKTASAML",
       "protocol": "saml",
       "type": "okta",
       "idp_config": {
           "token_attribute_mappings": {
               "sub": "uid",
               "given_name": "firstName",
               "family_name": "lastName",
               "groups": "groups",
               "email": "emailAddress"
           },
           "idp_metadata": "base64 idp metadata"
       },
       "jit": true,
       "scim_config": {
         "scim_attribute_mappings": {
           "user": {
             "principalName": "userName",
             "name": {
               "givenName": "givenName",
               "familyName": "familyName"
             },
             "displayName": "displayName",
             "emails": [
               {
                 "value": "emails",
                 "type": "home"
               }
             ],
             "id": "id",
             "userName": "userName"
           },
           "group": {
             "principalName": "displayName",
             "id": "displayName"
           }
   ```

```
        }
      }
    }
```

3. Ensure that the values of **`token_attribute_mappings`** such as sub, given_name, family_name, groups, and email are same as the SAML IdP attributes that are configured at **Attribute Statements (optional)** section in OKTA IdP.

   Note: It is mandatory to specify the **`principalName`** for user and groups.

4. The **`scim_attribute_mappings`** is an optional attribute. If you specify the values for **`scim_config.scim_attribute_mappings`**, ensure that the values are the same as the matching attributes that are configured at OKTA IdP.

   If you do not specify the values for **`scim_config.scim_attribute_mappings`**, IAM defaults to the following SCIM attribute mappings for users and groups:

   - SCIM attribute mappings for user:

     ```
     {
        "id": "sub",
        "userName": "sub",
        "principalName": "sub",
        "displayName": "firstName",
        "emails": [
            {
            "value": "email",
            "type": "primary"
            }],
        "familyName": "lastName",
        "givenName": "firstName",
        "externalId": "sub"
     }
     ```

   - SCIM attribute mappings for groups:

     ```
     {
        "id" : "_id",
        "displayName" : "_id",
        "groupName" : "_id",
        "principalName" : "_id",
     }
     ```

     Restriction: Ensure that you manually remove the user or group from your IBM Cloud Pak when you remove the user or group from OKTA.

Integrating IBM Cloud Pak SAML with Azure Active Directory

Learn how to integrate the IBM Cloud Pak® SAML with Azure Active Directory.

IBM Cloud Pak foundational services provides single sign-on (SSO) to IBM Cloud Paks and to workloads that run on the IBM Cloud Paks.

The SAML authentication flow supports automated onboarding by just-in-time (JIT) provisioning of users. You can configure SSO with Azure Active Directory, and grant user access to Cloud Pak Platform based on user's group membership from Azure Active Directory. After you complete the configuration, users who belong to an Azure Active Directory group are granted access to the IBM Cloud Pak.

To integrate the SAML with Azure Active Directory, complete the following steps:

- Prerequisites
- Configuring SSO with Azure Active Directory
- Configuring Azure as SAML IdP at IBM Cloud Pak®
- Configuring JIT support for Azure Active Directory integration

Prerequisites

To complete the configuration, you must meet the following requirements:

- Subscribe to Microsoft Azure.
- Be able to run `oc` or `kubectl` commands with admin access to the Red Hat® OpenShift® Container Platform cluster.
- Install foundational services with your IBM Cloud Pak.
- Grant a user administrator access to your IBM Cloud Pak.

Configuring SSO with Azure Active Directory

Complete the steps in the following sections to configure SSO with Azure Active Directory.

Retrieve the SAML metadata file from your IBM Cloud Pak

Complete these steps to download the SAML metadata file:

1. Retrieve your IBM Cloud Pak login URL by checking the foundational services route. For example, by using the following command:

   ```
   oc get route -n <your-foundational-services-namespace>
   ```

2. Log in to your IBM Cloud Pak console as an admin user.
3. Click **Identity providers** > **New connection**.
4. Select **SAML 2.0**.
5. On the **New SAML connection** page, click **Download metadata**.

Configure your Azure Active Directory application with SAML SSO

Complete the following tasks in the Microsoft Azure portal.

Create your own Azure Active Directory application. Add users and groups to your application. Set up SSO

Create your own Azure Active Directory application

1. Log in to the Microsoft Azure portal.

2. From the Azure menu, select **Azure Active Directory**.
3. From the navigation menu, select **Enterprise applications**.
4. Create you application.
    1. Click **Create your own application**.
    2. Enter the name of your application.
    3. Select the **Integrate any other application you don't find in the gallery (Non-gallery)** option.
    4. Click **Create** and wait a few seconds. The Overview page of your application opens.

Add users and groups to your application

1. On the Overview page, select the **1. Assign users and groups** tile from the Getting started section.
2. Click **Add user/group**.
3. On the Add assignment page, under Users and groups, click **None selected**. The list of users and groups opens in a **Users and groups** window.
4. Select the users and groups that you want to add to your application from the list, and click **Select**.
5. On the Add assignment page, click **Assign**.
6. Go back to your application overview.

Set up SSO

1. On the Overview page, select the **2. Set up single sign on** tile from the Getting started section.
2. Choose **SAML**.
3. Provide basic SAML configuration.
    1. On the Set up Single Sing-On with SAML page, click **Upload metadata file**.
    2. Select the SAML metadata file that you downloaded in the Retrieve the SAML metadata file section.
    3. Click **Add**.
       After you upload the metadata file, the Basic SAML configuration window opens. The following fields are automatically filled from the metadata file: Identifier, Reply URL, and Logout Url.
    4. Click **Save**, and go back to the **Set up Single Sing-On with SAML** page.
4. Configure group claim.
    1. On the Single Sing-On with SAML page, under **Attributes and Claims**, click **Edit**.
    2. Click **Add a group claim**. For more information, see Configure group claims for applications with Azure Active Directory in Microsoft documentation.
       Note: If an existing application expects to consume group information by using claims, Azure Active Directory can be configured with different claim formats.
    3. Select **Groups assigned to the application** as the groups that should be returned in the claim, and click **Save**.
5. Configure the SAML signing certificate. On the Single Sing-On with SAML page, under SAML Signing Certificate, click **Download** to save the **Federation Metadata XML** to your local drive.

Upload the Federation Metadata XML configuration to your IBM Cloud Pak

Complete these steps from your IBM Cloud Pak console:

1. Log in to your console as an admin user.
2. Click **Identity providers**.
3. Click the SAML connection that you created in Retrieve the SAML metadata file from your IBM Cloud Pak section.
4. Click **Token attribute mapping**.
5. Update the token attribute-mapping fields from the Azure Active Directory Federation Metadata XML file that you downloaded in the Set up SSO section.
6. Click **Create**.
7. From the **Workloads** page, restart all pods with `platform-` and `usermgmt-` in their name.

Test SAML login from the IBM Cloud Pak

1. To get your IBM Cloud Pak console URL, run the following command:

   ```
   oc get route -n <your-foundational-services-namespace>
   ```

2. Copy the URL and paste it into your browser.
3. On the login screen, select **Enterprise SAML**. Use your Microsoft email to log in, for example, user@cloudpak.onmicrosoft.com. You can log in. However, your view of the Administration panel is limited. When you click at your profile avatar, you see that you have a viewer access role.

Grant an admin role

Use the Zen console to assign the admin role to users.

Grant access to capabilities within an IBM Cloud Pak

You can customize access and grant users access to capabilities within the IBM Cloud Pak. Each capability can have a granular access control policy to control who can access different resources or APIs.

You can grant access to Cloud Pak Platform to users. By default, Cloud Pak Platform comes with two roles:

- User - Basic role that gives minimal access to the platform.
- Administrator - Admin role that gives access to the entire Cloud Pak Platform.

The user needs a User role to access the IBM Cloud Pak capabilities.

Complete the following steps to grant a User role for Cloud Pak Platform. The procedure is based on APIs.

1. Set the project to the namespace where foundational services pods are running. Use the namespace where **platform-auth-service-xxxx** pod is running.

   ```
   oc project <your-foundational-services-namespace>
   ```

2. Export the **CPHOST**, **ZENHOST**, **USERNAME**, and **PASSWORD** environment variables.

   ```
   export CPHOST=https://$(oc get route cp-console -o jsonpath="{.spec.host}")
   export ZENHOST=https://$(oc get route cpd -o jsonpath="{.spec.host}")
   export USERNAME=`oc get secret platform-auth-idp-credentials -o json | jq -r .data.admin_username|
   base64 -d`
   export PASSWORD=`oc get secret platform-auth-idp-credentials -o json | jq -r .data.admin_password|
   base64 -d`
   ```

3. Get the IBM Cloud Pak access token for the admin user with the following command:

   ```
   IAM_TOKEN=$(curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" -d
   "grant_type=password&username=${USERNAME}&password=${PASSWORD}&scope=openid"
   "${CPHOST}/idprovider/v1/auth/identitytoken" 2> /dev/null | jq -r ".access_token")
   ```

4. Extract and set the **$ZENTOKEN** value from the **$IAMTOKEN** value that you got from the previous step.

   ```
   ZENTOKEN=$(curl -k -X GET "${ZENHOST}/v1/preauth/validateAuth" --header "username: ${USERNAME}" --
   header "iam-token: ${IAM_TOKEN}" 2> /dev/null | jq -r '.accessToken')
   ```

5. Create a user group with the role that you want to assign to the user.

   ```
   curl -k -s -X POST "${ZENHOST}/usermgmt/v2/groups" --header 'Content-Type: application/json' --header
   'Accept: application/json' --header "Authorization: Bearer ${ZENTOKEN}" -d '{"name":
   "azuregroup","description": "Group default Azure group","role_identifiers": ["zen_user_role"]}'
   ```

   Note: To create an admin group, specify **"zen_administrator_role"** in the role identifiers field.

   Verify that the group is listed, and get the group ID:

   ```
   curl -k -s -X GET "${ZENHOST}/usermgmt/v2/groups" --header 'Content-Type: application/json' --header
   'Accept: application/json' --header "Authorization: Bearer ${ZENTOKEN}" | jq -r
   ```

   Save the Azure group ID, you will need it in the next step.

   Note: Azure SAML response contains the IDs or names of all groups to which a user belongs. You can check the Azure group ID or group name in the Microsoft Azure portal. Go to the **Groups** page, and find the **Object Id** or group name of the specific group.

6. Add the Azure group to the **LDAP**, **SAML**, or **OIDC** user group. You can specify the group ID or group name of the **LDAP**, **SAML**, or **OIDC** user group in the **"idp_groups"** parameter.

   ```
   curl -k -s -X POST "${ZENHOST}/usermgmt/v2/groups/<azuregroup_ID>/members" --header 'Content-Type:
   application/json' --header 'Accept: application/json' --header "Authorization: Bearer ${ZENTOKEN}" -d
   '{"idp_groups": ["group ID or group name of the user group"]}'
   ```

   In the command, the **<azuregroup_ID>** is the Azure group ID that you got in the previous step.

   Configuration is completed.

7. Verify whether the user who is a member of the Azure group can log in to Cloud Pak Platform with proper permissions. Open Cloud Pak Platform in your browser by using the URL of $CPHOST.

Configuring Azure as SAML IdP at CloudPak

To configure azure as SAML IdP, see Configure Azure as SAML IdP at CloudPak.

Configuring JIT support for Azure Active Directory integration

To configure JIT support for Azure Active Directory integration, see IBM Cloud Pak JIT support for SCIM OKTA and Azure AD.

IM common service EDB PostgreSQL database backup and restore

EDB PostgreSQL is a database that is used with the Identity Management (IM) service.

Learn how to back up, restore, and troubleshoot EDB PostgreSQL database.

- Backing up EDB PostgreSQL database
- Restoring EDB PostgreSQL database
- Backing up and restoring the common services EDB PostgreSQL database using pg_dump

Backing up common services EDB PostgreSQL database

Set the EDB backup deployment to store the Identity Management (IM) data in the **common-service-db** backup resources.

Prerequisites

- Download the CASE package and extract the **installer-scripts** directory. For more information, see Downloading scripts for additional configuration from specific version CASE bundle.
- Set up any Amazon S3-compatible storage. For example, you can create a bucket in IBM Cloud Object Storage. For more information, see IBM Cloud Object Storage.
- When you add a service credential to the bucket, include the hash-based message authentication code (HMAC). For more information, see Service credentials. From the **Cloud Object Storage** navigation menu, gather the following information:
  - **access key id**, which can be found on the **Service credentials** page that is associated with the bucket.
  - **secret access key**, which can be found on the **Service credentials** page that is associated with the bucket.
  - **bucket name**, which can be found on the **Buckets** page.
  - **bucket region**, which can be found on the **Buckets** page.
  - **root directory name**, which is the path in the bucket where you want to store the backups.
  - **s3 URL**, which is the endpoint URL of the bucket.

    Note: The endpoint URL must start with **http://** or **https://**.
- Set up Velero on the new cluster. For more information, see Create the backup resources section. If the cluster being backed up or restored to uses s390x for architecture, any velero CLI commands must be run on an alternate cluster that does not use s390x and has **oc** access to the original (usually using **oc login**). Velero CLI does not yet support s390x.
- If the Velero or OADP is not configured in your cluster, you can backup the EDB PostgreSQL database using **pg_dump** CLI method. For more information, see Back up EDB database using **pg_dump** CLI method.

Back up EDB database (common-service-db)

Complete the following steps to back up EDB database for IM:

1. Get the common-service-db backup resources.

```
wget https://raw.githubusercontent.com/IBM/ibm-common-service-operator/scripts-adopter/velero/schedule/common-service-db/cs-db-backup-deployment.yaml
wget https://raw.githubusercontent.com/IBM/ibm-common-service-operator/scripts-adopter/velero/schedule/common-service-db/cs-db-backup-pvc.yaml
wget https://raw.githubusercontent.com/IBM/ibm-common-service-operator/scripts-adopter/velero/schedule/common-service-db/cs-db-br-script-cm.yaml
wget https://raw.githubusercontent.com/IBM/ibm-common-service-operator/scripts-adopter/velero/schedule/common-service-db/cs-db-role.yaml
wget https://raw.githubusercontent.com/IBM/ibm-common-service-operator/scripts-adopter/velero/schedule/common-service-db/cs-db-rolebinding.yaml
```

```
wget https://raw.githubusercontent.com/IBM/ibm-common-service-operator/scripts-adopter/velero/schedule/common-service-db/cs-db-sa.yaml
```

2. Update the backup files.
   - Replace `<cs-db namespace>` with the namespace where `common-service-db` instance is running.
   - Replace the `<storage class>` with the storage class that the current IM deployment uses.
3. Add the PVC to the cluster.

   ```
   oc apply -f cs-db-backup-pvc.yaml
   ```

4. Add the `cs-db-br-script-cm.yaml` to the correct namespace

   ```
   oc apply -f cs-db-br-script-cm.yaml
   ```

5. Give the common-service-db backup necessary permissions

   ```
   oc apply -f cs-db-sa.yaml
   ```

   ```
   oc apply -f cs-db-role.yaml
   ```

   ```
   oc apply -f cs-db-rolebinding.yaml
   ```

6. Add the deployment to the cluster.

   ```
   oc apply -f cs-db-backup-deployment.yaml
   ```

Restoring EDB PostgreSQL database

Deploy the EDB PostgreSQL database backup deployment to restore the Identity Management (IM) data from the **`common-service-db`** backup resources.

Prerequisites

- Download the CASE package and extract the **`installer-scripts`** directory. For more information, see Downloading scripts for additional configuration from specific version CASE bundle.
- Set up any Amazon S3-compatible storage. For example, you can create a bucket in IBM Cloud Object Storage. For more information, see IBM Cloud Object Storage.
- When you add a service credential to the bucket, include the hash-based message authentication code (HMAC). For more information, see Service credentials. From the **Cloud Object Storage** navigation menu, gather the following information:
  - **`access key id`**, which can be found on the **Service credentials** page that is associated with the bucket.
  - **`secret access key`**, which can be found on the **Service credentials** page that is associated with the bucket.
  - **`bucket name`**, which can be found on the **Buckets** page.
  - **`bucket region`**, which can be found on the **Buckets** page.
  - **`root directory name`**, which is the path in the bucket where you want to store the backups.
  - **`s3 URL`**, which is the endpoint URL of the bucket.

    Note: The endpoint URL must start with **`http://`** or **`https://`**.
- Set up Velero on the new cluster. For more information, see Create the backup resources section.

If the cluster being backed up or restored to uses s390x for architecture, any velero CLI commands must be run on an alternate cluster that does not use s390x and has **`oc`** access to the original (usually using **`oc login`**). Velero CLI does not yet support s390x.

- If the Velero or OADP is not configured in your cluster, you can restore the EDB PostgreSQL database using **`pg_restore`** CLI method. For more information, see Restore EDB database using **`pg_restore`** CLI method.

Restore EDB PostgreSQL database (common-service-db)

Complete the following steps to restore IM data from **`common-service-db`** backup resources.

1. Get the restore object.

```
wget https://raw.githubusercontent.com/IBM/ibm-common-service-operator/scripts-adopter/velero/restore/restore-cs-db.yaml
```

2. Substitute the **__BACKUP_NAME__** with the name of the backup resource that you created previously.

   ```
   vi restore-cs-db.yaml
   ```

3. Restore the **cs-db** data.

   ```
   oc apply -f restore-cs-db.yaml
   ```

4. Check restore progress. Proceed with the next step after restore process is complete.

   ```
   velero restore get
   ```

5. Check logs of the velero restore to verify that the data was restored.

   ```
   velero restore logs restore-zen5-data
   ```

Troubleshooting restoring EDB PostgreSQL database

If the logs or the data indicate that the restore was not successful, complete the following steps:

1. Get the restore job:

   ```
   wget https://raw.githubusercontent.com/IBM/ibm-common-service-operator/scripts-adopter/velero/restore/common-service-db/cs-db-restore-job.yaml
   ```

2. Replace **<cs-db namespace>** with the namespace where common-service-db instance is running.

3. Delete the existing cs-db-backup deployment and cs-db-backup pod.

   ```
   oc delete deploy cs-db-backup -n <namespace>
   ```

4. Run the restore job.

   ```
   oc apply -f cs-db-restore-job.yaml
   ```

Adding users for console access

When you add a user to the platform for accessing the IBM Cloud Pak for AIOps console and tools, a user profile (or record) is created for the user.

This user profile lists the user's roles and permissions. The user can also now access the Cloud Pak for AIOps console.

All users that are added to the platform are also automatically included within a default *All users* group. This group is used to give all users access to the Cloud Pak for AIOps console and common features, such as their profile and settings. You cannot edit or delete this group.

You can add a user to the platform in the following ways:

- You can give a user from a connected LDAP service access by directly assigning that user a role.
- You can include a user from a connected LDAP service into a user group. When you add a user to a user group, the platform automatically assigns the user each role that is assigned to the group.
- You can give all members of an LDAP group access to the platform by adding that LDAP group to a user group.

Important:

- You cannot create a user from the **Access control** page of your cluster Cloud Pak for AIOps console. You can use the **Access control** page to add only an existing LDAP user to your cluster.
- You must use the configured identity provider (LDAP) to manage users that are added from that provider system. For instance, to change or reset the password for a user, you must complete that change in your configured provider system. You cannot change or reset a user password with the Cloud Pak for AIOps console.

  To see your configured identity providers, navigate to **Administration** > **Identity providers** in the Cloud Pak for AIOps console.

Before you begin

- **Required permissions**: To manage access to the Cloud Pak for AIOps console, you must have one of the following permissions:
  - **Administer platform**

    - **Manage users**
- Connect to an LDAP service. You need to connect to an LDAP service as an identity provider to create the users that you want to add IBM Cloud Pak for AIOps.
    - To configure an LDAP connection, you must be an Administrator with permissions to manage users. For more information, see Configuring an LDAP connection.
    - Any user that needs access to IBM Cloud Pak® for AIOps must exist in your LDAP service with their `user name` and `email` attributes set. If these attributes are not set for a user, you might not be able to find and add the user to IBM Cloud Pak® for AIOps.
- **Required information for creating a user**: You need at least one of the following types of information about a user from your connected LDAP service to add the user to IBM Cloud Pak for AIOps:
    - Full name: If you use this information when adding a user, you must enter the name exactly as it is specified in the LDAP service.
    - Username: This value maps to the field that you specified for the **User search field** in the LDAP configuration
    - Email address: If you use this information when adding a user, enter the email address exactly as it is specified in the LDAP service.
- **User groups**: You can create user groups to simplify the process of managing large groups of users. User groups make it easier to manage a large number of users with similar access requirements.

  By default, an All users group is included. As the name suggests, all users are automatically included in this group. The group is used to give all platform users access to the console and common features, such as their profile and settings. You cannot edit or delete this group.

  For more information, see Managing user groups.

Procedure

To give users access to the console:

1. Log in to the IBM Cloud Pak for AIOps console as an administrator with permissions to manage users.
2. From the navigation menu, select **Administration** > **Access control**.
3. From the *Users* tab, click **Add user**.
4. Search for the user's profile information by entering one of the following details about the user:
    - Full name
    - Username
    - Email

   Limitations:
    - You cannot select a specific LDAP service to use for adding users. All connected LDAP services are searched for the specified user ID, username, or email.
    - You cannot use an external lookup service for finding and adding users from the LDAP service to IBM Cloud Pak for AIOps.
    - You need to know the user ID, user name, or email of a user within the connected LDAP service to find and add that user.
5. Click **Next**.
6. Set the platform access permissions for the user. Privileges on the platform are controlled by permissions. Users are granted permissions through role assignment. Users can be assigned roles directly or inherit roles from user groups that they are included within. Users within a user group inherit all roles and permissions that associated with the user group.

   Select either of the options to set permissions for the user:
    - **Assign roles directly**

      Select this option to directly assign one or more existing roles or create a role for the user.
        - Optional. Create a new role to assign to the user. For more information about existing roles and permissions, or about creating a role, see Roles and permissions.
        - Select the checkbox for each role that you want to assign to the user. If you created a new role for the user, you must still select the checkbox for that role.
        - Click **Next**.
    - **Add to user group**

      Select this option to add a user to an existing user group or groups. For more information about user groups, including how to create a group, see Managing user groups.
        - Select the checkbox for each user group or groups that you want to include the user within.
        - Click **Next**.

7. Review the *Summary* of the user profile, user groups, roles, and access. When finished, click **Add**.

What to do next

- Edit the user details and roles, such as to add more roles or to add the user to a user group. When you are editing a user, you can complete the following changes:
    - View, add, and remove roles
    - View, add, and remove permissions
    - Add the user to a user group
    - Remove the user from a group
    - Change the user full name
    - Change the user email
    - Delete the user from IBM Cloud Pak for AIOps

  You can also add a user group, such as to add and manage roles for all users that you include in the group.
- Login as the newly added user

  As a user directly added from the LDAP service or from an added user group, log in to the console and verify that the expected roles and permissions exist.

  Upon login, either your *Home* page or the *Administrator panel* is displayed. Users with an administrator role view the *Administrator panel* upon login, while all other users view their *Home* page. From the main navigation menu, browse through your available tools and pages to ensure that you can view the correct data and complete the tasks for your assigned permissions.

Managing user groups

You can create user groups to simplify the process of managing large groups of users.

User groups make it easier to manage a large number of users with similar access requirements. For example, if you know that 20 different users are going to collaborate on a project and they all need the same role, you can add them to a group that is assigned that role. If a member of the group leaves the company, you can remove the user from the group, rather than looking for all of the assets that the user has access to.

Before you begin

- **Required permissions**: To manage groups, you must have one of the following permissions:
    - **Administer platform**
    - **Manage groups**

About this task

You can create and edit groups from the **User groups** tab of the **Access control** page.

Important:

- You can either create assigned groups or dynamic groups
    - If you select the assigned option, you can select the users you want to include.
    - If you select the dynamic option, you can create attribute-based rules to determine which users are automatically added to the group.
- By default, an **All users** group is included. As the name suggests, all users are automatically included in this group. The group is used to give all platform users access to the console. You cannot edit or delete this group.

Procedure

You can create an user group with one of the following methods:

- Creating an user group with the **Assigned** option
- Creating an user group with the **Dynamic** option

Creating an user group with the Assigned option

1. Log in to the console.
2. From the navigation menu, select **Administration** > **Access control**.

3. Open the **User groups** tab.
4. Click **New user group**.
5. Enter a name and, optionally, a description for the role.
6. Under Membership type, select **Assigned**.

   Note: With assigned membership, you select the users that you want to add to the group.
7. Click **Next**.
8. Specify the users to include in the group. The available options depend on whether the environment is connected to use an identity provider for authentication, such as an LDAP server.

   - **Existing users** - Find and add existing platform users.
   - **Identity provider users** - Find and add a user from a connected identity provider, such as an LDAP server.
   - **Identity provider groups** - Find and add a user group from a connected identity provider, such as an LDAP server. If IM integration is enabled, choose this option.

   After you find the user or group, select the user or group to add them to the new user group. Repeat this action to add more users or groups.

   Notes:

   - When searching for a user, you can search by the user's name, email, or username.
   - If you have the **Manage users** permission and you do not see the user that you want to add to the group, first create the user.
   - If you add users from an LDAP group, the users might not immediately be added to the user group. If you do not see a user within the group, log in to the console as that user. Upon login, the Platform UI detects that the user belongs to an LDAP group and creates the user profile. User profiles for LDAP group users are created only when the users log in to the console.
9. Click **Next**.
10. Select one or more roles that you want to assign to this group.
11. Click **Next**.
12. Review the summary. If the values are correct, click **Create**.

Creating an user group with the Dynamic option

1. Log in to the console.
2. From the navigation menu, select **Administration** > **Access control**.
3. Open the **User groups** tab.
4. Click **New user group**.
5. Enter a name for the user group. You can optionally include a description for the role.
6. Select **Dynamic** in the **Membership type** section.

   Note: You can create attribute-based rules to determine which users are automatically added to the group with dynamic membership.
7. Click **Next**.
8. Define the rule in **Membership rule** to add the users automatically in the group based on the attributes that are assigned to the users on the identity provider.

   1. Select one of the following conditions:

      - Select **All conditions (AND)** to include the users with all the specified attribute, operator, and values.
      - Select **Any conditions (OR)** to include the users with a minimum of one specified attribute, operator, and values.
   2. Select the **Attribute** and **Operator** from the drop-down list and enter the value based on the identity provider for the defined conditions in the **Value** field.

      - **Attribute:** Select **Location**, **Nationality**, **Organization**, or **User type**.
      - **Operator:** Select **Equal**, **Not equal**, **Match**, or **Not match**.
      - **Value:** Enter the value based on the identity provider for the defined conditions.

      If you need to add more than one conditions, click **Add conditions**.
9. Click **Next**.
10. Select at least one role to assign to the new user group. For example, you can assign **Administrator** and/or **User** to the user group. Alternatively, you can **create a new role** and assign the new role you created.

11. Click **Next**.
12. Review the summary. If the values are correct, click **Create**.

Results

You can now use the group to give users access to various assets on the platform.

Viewing your user group assignment as a user

You can see what user groups you are included within from your user profile:

1. Log in to the IBM Cloud Pak for AIOps console and click your avatar in the upper right of the toolbar.
2. Click **Profile and settings**.
3. Click the **User groups** tab.

The groups that you are associated with are listed in the table.

Roles and permissions

For accessing and completing actions with IBM Cloud Pak® for AIOps, users require specific roles and permissions. Review the different available roles, permissions, and the associated actions that users can complete with the roles and permissions. These roles and permissions help you get your users set up to begin day to day operations.

- Predefined roles
- Creating a role
- Permissions
  - AI models
  - Applications (Resource management)
  - Basic operations
  - Incidents
  - Integrations
  - Operational policies
  - Platform administration
  - Profiles
  - Runbooks
  - Secure tunnel
  - Service instances
  - Topology administration
  - User administration
- Viewing your permissions
- Adding users
- Assigning roles and permissions to users
- Red Hat OpenShift Container Platform roles

Predefined roles

A role defines the permissions that a user or group has. You can edit the roles that are available by default roles or create roles if the default set of permissions for a role does not align with your business needs.

The following roles are available by default:

- Administrator
- Automation Administrator
- Automation Analyst
- Automation Developer (AIOps Developer role)
- Automation Operator
- Service Administrator
- User

Notes:

- **Service Administrator**: Users with the *Service Administrator* role do not have permission to add or update a role, or view the details of a user's assign role. If a user with the Service Administrator role selects to view details about a role when viewing details about a user group, a 401 error page is instead displayed.

- **Automation Analyst** and **User**: These predefined roles are available by default but do not include any permissions for completing actions within IBM Cloud Pak for AIOps.

  These default roles are used within the IBM® Automation family of offerings, which includes IBM Cloud Pak for AIOps, however, these roles are not used within IBM Cloud Pak for AIOps. If more IBM Cloud Paks are installed, these roles can have permissions for completing actions within tools for those other IBM Cloud Paks.

  As these roles do not include or provide any permissions within IBM Cloud Pak for AIOps, do not assign the roles to users within IBM Cloud Pak for AIOps.

- Not all permissions are associated with a predefined role. A user with with a permission to manage roles, such as the Administer platform permission, can assign permissions to a role when needed.

Default user

The default user (`admin`) is automatically assigned the following roles when the roles are added to the platform:

- Administrator

Creating a role

If the existing default roles are not sufficient for your needs, you can create a role for your users. In addition, when you are adding a user, you can choose to create a role for that user instead of assigning an existing role.

The settings for creating a role are the same regardless of the path you select to create the role.

To directly create a role, complete the following steps:

1. Log in to the console as an administrator with permissions to manage users.

   Required permissions: To manage access to the Cloud Pak for AIOps console, you must have one of the following permissions:

   - **Administer platform**
   - **Manage platform roles**
2. From the main navigation, click **Administration** > **Access control**.
3. Select the **Roles** tab and click **New role**.
4. Enter the details for the new role:

   - Name - Enter a distinctive and descriptive name for the role.
   - Description - Enter an optional description for the role to define the role, such as to identify the objective or responsibilities for users with the role.
5. Click **Next**.
6. Select the permissions for the role. You can use the *Find permissions* search field to find and filter the list of permissions.
7. Click **Next**.
8. Review the details for the role and click **Create**.

AI models permissions

The following table describes the actions that are associated with each permission.

Table: AI models permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Manage AI models	(1)			X	X	X
View AI models status	(2)		X	X	X	X

1. Manage AI models

   Users with this permission can complete the following actions:

   - Gather and prepare AI training data
   - Train AI models
   - Deploy AI models

2. View AI models status

   Users with this permission can complete the following actions:

   - View AI model status

Applications (Resource management) permissions

The following table describes the actions that are associated with each permission.

Table: Resource management permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Assign criticalities and disruption costs	(1)			X	X	X
Manage applications	(2)		X	X	X	X
Manage resource group templates	(3)			X	X	X
Manage topology comments	(4)	X	X	X	X	X
View topologies	(5)	X	X	X	X	X

1. Assign criticalities and disruption costs

   Users with this permission can assign criticalities to applications, resource groups, and resources. Users with this permission can complete the following actions:

   - Assign criticalities
2. Manage applications

   Users with this permission can manage applications and related settings. Users with this permission can complete the following actions:

   - View applications and resources
   - Create applications
   - Edit applications
   - Delete applications
3. Manage resource group templates

   Users with this permission can manage templates that define how resources are organized into resource groups. Users with this permission can complete the following actions:

   - View resource group templates
   - Create resource group templates
   - Edit resource group templates
   - Delete resource group templates
4. Manage topology comments

   Users with this permission can manage comments on resources included in a topology. Users with this permission can complete the following actions:

   - View topology comments
   - Create topology comments
5. View topologies

   Users with this permission can view application topologies. Users with this permission can complete the following actions:

   - View topologies

Basic operations permissions

The following table describes the actions that are associated with each permission.

Table: Basic operations permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Administer AIOps Insights	(1)			X	X	X
Perform basic operations tasks	(2)	X	X	X	X	X

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Use AIOps Insights	(3)	X	X	X	X	X

1. Administer AIOps Insights

   Users with this permission can Administer the AIOps Insights dashboard. Users with this permission can complete the following actions:

   - Use AIOps insights
   - Manage scopes (collections of resources to monitor)
2. Perform basic operations tasks

   Users with this permission can perform basic operations tasks involving applications, resources, alerts, incidents, and runbooks. Users with this permission can complete the following actions:

   - View applications
   - View resources
   - View alerts
   - View incidents
   - Assign incidents
   - Change state of incidents
   - Resolve incidents
   - View published runbooks
   - Run published runbooks
   - View operational policies
3. Use AIOps Insights

   Use the AIOps Insights dashboard to view productivity metrics such as mean time to restore, incident activity, noise reduction, and runbook usage.

   - Use AIOps Insights

Incidents permissions

The following table describes the actions that are associated with each permission.

Table: Integrations permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Resolve all incidents	(1)			X	X	
Update all incidents	(2)			X	X	

1. Resolve all incidents

   Users with this permission can resolve all incidents regardless of assignment. Users with this permission can complete the following actions:

   - Resolve incident
2. Update all incidents

   Users with this permission can assign and change the status of all incidents regardless of assignment. Users with this permission can complete the following actions:

   - Assign incident
   - Change status of incident

Integrations permissions

The following table describes the actions that are associated with each permission.

Table: Integrations permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Manage integrations	(1)			X	X	X
View integrations	(2)		X	X	X	X

1. Manage integrations

   Users with this permission can manage integrations to infrastructure, log, event, source code, and chat management tools. Users with this permission can complete the following actions:

   - View integrations
   - Create integrations
   - Edit integrations
   - Delete integrations
2. View integrations

   Users with this permission can view integrations to infrastructure, log, event, source code, and chat management tools. Users with this permission can complete the following actions:

   - View integrations

Operational policies permissions

This permission is required for viewing policy-related information that can be displayed within the details for an application incident.

Attention: To access **Automations** in the main navigation menu, the *Use runbooks* permission is required in conjunction with the Operational policy roles. For more information, see Runbook permissions.

The following table describes the actions that are associated with each permission.

Table: Operational policies permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Delete operational policies	(1)	X		X	X	X
Edit operational policies	(2)	X		X	X	X
View operational policies	(3)	X	X	X	X	X

1. Delete operational policies

   Users with this permission can delete policies for promoting alerts to incidents. Users with this permission can complete the following actions:

   - Delete operational policies
2. Edit operational policies

   Users with this permission can edit policies for promoting alerts to incidents. Users with this permission can complete the following actions:

   - Edit operational policies
3. View operational policies

   Users with this permission can view policies for promoting alerts to incidents. User with this permission can complete the following actions:

   - View operational policies

Platform administration permissions

Permissions in this category enable an administrator to configure, customize, monitor, and manage the platform.

Only the Administer platform permission is associated with a predefined role (Adminstrator). This permission includes all other platform administration permissions.

The following table describes the actions that are associated with each permission.

Table: Platform administration permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Administer platform	(1)					X
Manage configurations	(2)					

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Manage platform health	(3)					
View platform health	(4)					

1. Administer platform

   This permission offers the most comprehensive set of actions for managing and monitoring the platform. Users with this permission have elevated privileges and can grant or revoke all permissions, including other administrative permissions. Users with this permission can complete the same actions as users that have the following permissions:

   - Manage configurations (Administer platform)
   - Manage platform health (Administer platform)
   - Manage platform roles (User administration)
   - Manage users (User administration)
   - Manage user groups (User administration)
   - Manage service instances (Service instances)
2. Manage configurations

   Users with this permission can customize the platform, integrate the platform with other applications, and enable connections to unsupported data sources. Users with this permission can access the Customizations page, the Configurations page, and the JDBC drivers tab on the Platform connections page. Some actions require specific services to be installed. Users with this permission can complete the following actions:

   - Configure connection to SMTP server

     Note: Requires Watson Studio or Watson Knowledge Catalog. An SMTP connection enables the platform to send emails.
   - Configure integration with IBM Guardium appliances

     Note: Requires Watson Knowledge Catalog. Use IBM Guardium to audit access to sensitive data on remote databases.
   - Configure connections to Hadoop clusters

     Note: Requires Execution Engine for Apache Hadoop.
   - Customize branding
   - Enable and disable home page cards
   - Enable and disable default support links
   - Add and delete custom support links
   - Enable and disable guided tours
   - Import JDBC drivers

     Note: Requires the common core services. JDBC drivers enable users to connect to unsupported data sources.
3. Manage platform health

   Users with this permission can monitor resource use, set quotas and alerts, manage workloads to maintain the health of the platform, and gather diagnostic data when problems occur. Users with this permission can access the Monitoring page and the Diagnostics page. Users with this permission can complete the following actions:

   - Monitor workloads and resource use

     Note: Workloads include active runtimes and jobs. Resources include memory and vCPU use across services, instances, and environments.
   - Stop any runtime environment

     Note: Environments are hardware and software configurations defined for running analytical assets or jobs.
   - View pod status, details, and logs

     Note: Services are composed of Kubernetes pods. A pod is an instance of a process that runs on the cluster.
   - Restart pods
   - View platform quotas and service quotas

Note: A quota specifies the maximum amount of memory or vCPU that the platform or a service should use.

- View event history and alerts
- Set and edit platform resource quotas
- Set and edit individual service resource quotas
- Create and run diagnostics jobs

  Note: A diagnostic job gathers information that can be used for troubleshooting problems.

- Delete diagnostics jobs

4. View platform health

   Users with this permission can monitor resource use and workloads across the platform to gauge the health of the platform. Users with this permission have read-only access to the Monitoring page. Users with this permission can complete the following actions:

   - Monitor workloads and resource use

     Note: Workloads include active runtimes and jobs. Resources include memory and vCPU use across services, instances, and environments.

   - View pod status, details, and logs

     Note: Services are composed of Kubernetes pods. A pod is an instance of a process that runs on the cluster.

   - View platform quotas and service quotas

     Note: A quota specifies the maximum amount of memory or vCPU that the platform or a service should use.

   - View event history and alerts

Profiles permissions

The following table describes the actions that are associated with each permission.

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Manage profiles	(1)					X

1. Manage profiles.

   Users with this permission can control the visibility and content of incidents, alerts, applications/services, resource groups, and resources. Users with this permission can complete the following actions:

   - View, create, edit, and delete profiles
   - View, create, edit, and delete restriction filters
   - View, create, edit, and delete access control policies

   With restriction and redaction filters, you can configure the following conditions for user access:

   - Limit the access that a user or user group has to see alerts
   - Limit the access that a user or user group has to see incidents
   - Limit the access that a user or user group has to see topology or inventory

Runbooks permissions

The following table describes the actions that are associated with each permission.

Table: Runbooks permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Administer runbooks and runbook application	(1)			X	X	X
Author and manage runbooks	(2)			X	X	X
Author runbooks	(3)	X		X	X	X
Use runbooks	(4)	X	X	X	X	X

1. Administer runbooks and runbook application

Users with this permission can complete the following actions:

- View draft and published runbooks
- Run draft and published runbooks
- Create draft runbooks
- Edit draft runbooks
- Approve draft runbooks
- Delete draft and published runbooks
- Edit integrations
- Edit global settings
- Edit group ownership

2. Author and manage runbooks

   Users with this permission can complete the following actions:

   - View draft and published runbooks
   - Run draft and published runbooks
   - Create draft runbooks
   - Edit draft runbooks
   - Approve draft runbooks
   - Delete draft and published runbooks

3. Author runbooks

   Users with this permission can complete the following actions:

   - View draft and published runbooks
   - Run draft and published runbooks
   - Create draft runbooks
   - Edit draft runbooks

4. Use runbooks

   Users with this permission can complete the following actions:

   - View published runbooks
   - Run published runbooks

Secure tunnel permissions

The following table describes the actions that are associated with each permission.

Table: Secure tunnel permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Install tunnel connectors	(1)			X	X	X
Manage tunnel applications	(2)			X	X	X
Manage tunnel connections	(3)			X	X	X
Manage tunnel templates	(4)			X	X	X
Renew certificates	(5)			X	X	X
View tunnel audit logs	(6)			X	X	X

1. Install tunnel connectors

   Users with this permission can install tunnel connectors on remote clusters or hosts. Users with this permission can complete the following actions:

   - Install tunnel connectors

2. Manage tunnel applications

   Users with this permission can manage application traffic at the address or port level. Users with this permission can complete the following actions:

   - View application mappings
   - Create application mappings
   - Edit application mappings
   - Delete application mappings

3. Manage tunnel connections

   Users with this permission can manage connections to remote clusters or hosts. Users with this permission can complete the following actions:

   - View tunnel connections
   - Create tunnel connections
   - Edit tunnel connections
   - Delete tunnel connections
4. Manage tunnel templates

   Users with this permission can manage templates that simplify the creation of tunnel connections. Users with this permission can complete the following actions:

   - View tunnel templates
   - Create tunnel templates
   - Edit tunnel templates
   - Delete tunnel templates
5. Renew certificates

   Users with this permission can renew certificates for tunnel connections. Users with this permission can complete the following actions:

   - Renew certificates for tunnel connections.
6. View tunnel audit logs

   Users with this permission can view a history of user-driven operations and tunnel connection events. Users with this permission can complete the following actions:

   - View tunnel audit logs

Service instances permissions

The service instance permissions are included through the underlying IBM Cloud Pak foundational services that is installed with IBM Cloud Pak for AIOps. These permissions are not used within IBM Cloud Pak® for AIOps:

- Create service instances
- Manage service instances

If more IBM Cloud Paks are installed, these permissions can be required for completing actions within tools for those other IBM Cloud Paks.

As these permissions are not used within IBM Cloud Pak for AIOps, do not assign the permissions to any roles that you create unless they are required for use with another installed IBM Cloud Pak.

Topology administration permissions

The following table describes the actions that are associated with each permission.

Table: Topology administration permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Manage advanced topology settings	(1)			X	X	X
Manage topology presentation	(2)			X	X	X
Manage topology rules	(3)			X	X	X
Manage topology tools	(4)			X	X	X

1. Manage advanced topology settings

   Users with this permission can define global preferences for creating and using topologies. Users with this permission can complete the following actions:

   - View advanced topology settings
   - Edit advanced topology settings
2. Manage topology presentation

   Users with this permission can define how topologies are presented to end users. Users with this permission can complete the following actions:

   - View topology presentation settings

- Create topology presentation settings
- Edit topology presentation settings
- Delete topology presentation settings

3. Manage topology rules

   Users with this permission can define how resources are processed to enable event correlation, tagging of resources, and the creation of end-to-end topologies. Users with this permission can complete the following actions:

   - View topology rules
   - Create topology rules
   - Edit topology rules
   - Delete topology rules

4. Manage topology tools

   Users with this permission can define custom actions for resources that are included within topologies. Users with this permission can complete the following actions:

   - View topology tools
   - Create topology tools
   - Edit topology tools
   - Delete topology tools

User administration permissions

User administration permissions enable an administrator to manage users, groups, and roles. These permissions apply to the platform. Service instances and workspaces such as projects, catalogs, and deployment spaces have their own access controls.

The following table describes the actions that are associated with each permission.

Table: User administration permissions

Permissions	Actions	Automation Developer	Automation Operator	Service Administrator	Automation Administrator	Administrator
Manage platform roles	(1)					
Manage user groups	(2)			X		
Manage users	(3)			X		

1. Manage platform roles

   Users with the *Manage platform roles* permission can access the Roles tab on the Access control page to modify platform roles or create custom roles. Roles determine the permissions that a user or user group has. This permission does not apply to service instances or assets, such as projects, catalogs, and deployment spaces. Users with this permission can complete the following actions:

   - Create platform roles
   - Edit platform roles
   - Delete platform roles

2. Manage user groups

   Users with the *Manager user groups* permission can access the User groups tab on the Access control page to manage user groups. User groups make it easier to manage the roles (and permissions) of users with similar access requirements. Users with this permission can complete the following actions:

   - Create user groups
   - Edit user groups
   - Delete user groups
   - Assign roles to user groups
   - Remove roles from user groups

3. Manage users

   Users with the *Manager users* permission can access the Users tab on the Access control page, and can onboard users to the platform. Users with this permission can complete the following actions:

   - Add users
   - Edit user profiles
   - Assign roles to users
   - Remove roles from users
   - Remove users

What permissions do I have?

You can see what permissions you have from your profile. Your permissions are determined by the roles that are assigned to you.

To see what roles are assigned to you:

1. Log in to the IBM Cloud Pak for AIOps console and click your avatar in the upper right of the toolbar.
2. Click **Profile and settings**.
3. Click the **Roles** tab.

The permissions that are associated with your role (or roles) are listed in the **Enabled permissions** column.

Adding users

To add users, you need to have an external LDAP server set up for creating user profiles and authentication. When a user record is included within the LDAP server, you can add the user account within the IBM Cloud Pak for AIOps console. You can add a user directly or as part of an LDAP group. For more information, see Adding users.

Assigning roles and permissions

When you add a user or group, you must specify the role and permissions that they have. These roles and permissions can be granted to users through a combination of the Cloud Pak for AIOps console and an external LDAP server for managing user authentication.

Red Hat OpenShift Container Platform roles

To add and manage users and roles for accessing and using the Red Hat OpenShift Container Platform web console, you need to use the Red Hat role-based access control (RBAC). For more information, see the Red Hat OpenShift topic Using RBAC to define and apply permissions.

Profiles

Profiles can be assigned to user groups to control the visibility of incidents, alerts, applications, resource groups, and resources to those users. These profiles can combine restriction filters with redaction policies to form the final redaction criteria that is applied to a user group.

A profile can be a *Group* profile or a *Base* profile. By default, there is always a **Base** profile which applies to all users. You can use this profile to assign restriction filters and redaction policies to all users. You can use one or more **Group** profiles to assign restriction filters and redaction policies to specific groups of users. *Group* profiles can augment or override the settings in the *Base* profile. The Base profile should be configured to show the minimum set of entities or properties that users in the system can see, so that the filter and policies should be aiming to remove everything from the views, while the group profiles aim to add things back into the views. A profile can be enabled, even when the underlying filters and policies are disabled.

Restriction filters control the visibility of incidents, alerts, applications, resource groups, and resources. These filters are assigned to users through profiles. You can use restriction filters to control how information is distributed to your users. Restriction filtering works by enabling you to specify that under certain situations, users should only see particular alerts, incidents, applications, resource groups or resources based on particular conditions.

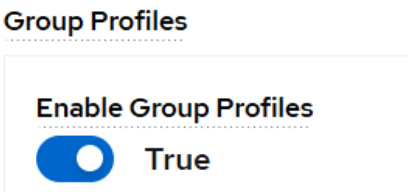
Notes:

- Restriction filters do not hide resources in topology graph visualisations, so a combination of filter and redaction is required to make sure that no data is exposed.
- If no filter or policy shows it might be due to none being available for that data type.

To create and apply a restriction filter, you need to create a filter from either the *Incidents*, *Alerts*, or *Resource management* (application, resource, resource group) page and save the filter as a restriction filter. After creating a restriction filter, you can then include it in the Base profile or an appropriate group profile. For more information, see Creating restriction filters.

Redaction policies work alongside filtering and allow you to specify the visibility and content of the properties of incidents, alerts, applications, resource groups, and resources, and are assigned to users through profiles. The policies are defined using Rego, a programming language created specifically for redaction policies, which allows you to manipulate the end result output either by hiding or showing all the properties or reacting or modifying particular properties. For more information, see Creating redaction policies.

If you need to create or manage a user group before applying any profile, see Managing user groups.



- Prerequisites
- Creating a group profile
- Viewing a profile
- Enabling or disabling a profile

- Editing a profile
- Duplicating a profle
- Deleting a profile

Prerequisites

To work with profiles, and their associated restriction filters and redaction policies, you must possess an administrative user account with the **Manage profiles** role. For more information, see Roles and permissions.

Note: In the installation resource you are using you need to set the *Enable Group Profiles* radio button to *True*.

Creating a group profile

1. From the main navigation menu, go to **Administration** > **Profiles**.

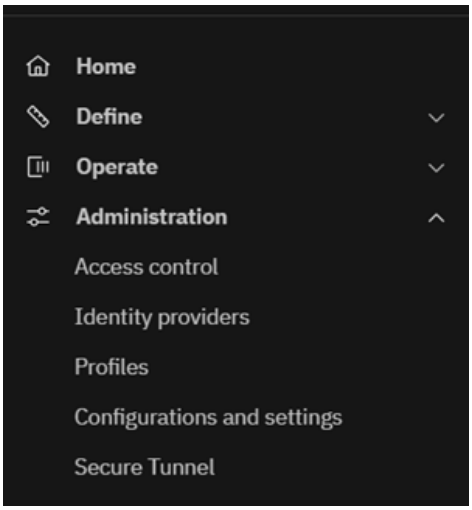


Figure. Profiles list

By default, the **Profiles** tab for the **Profiles** page is displayed.

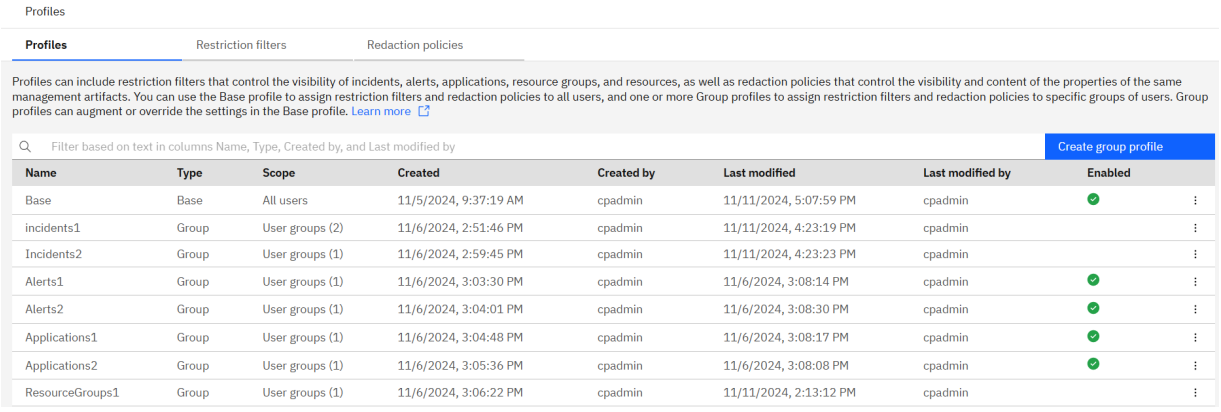

Figure. Profiles list

2. Click **Create group profile**. The options for creating a **New profile** are displayed.

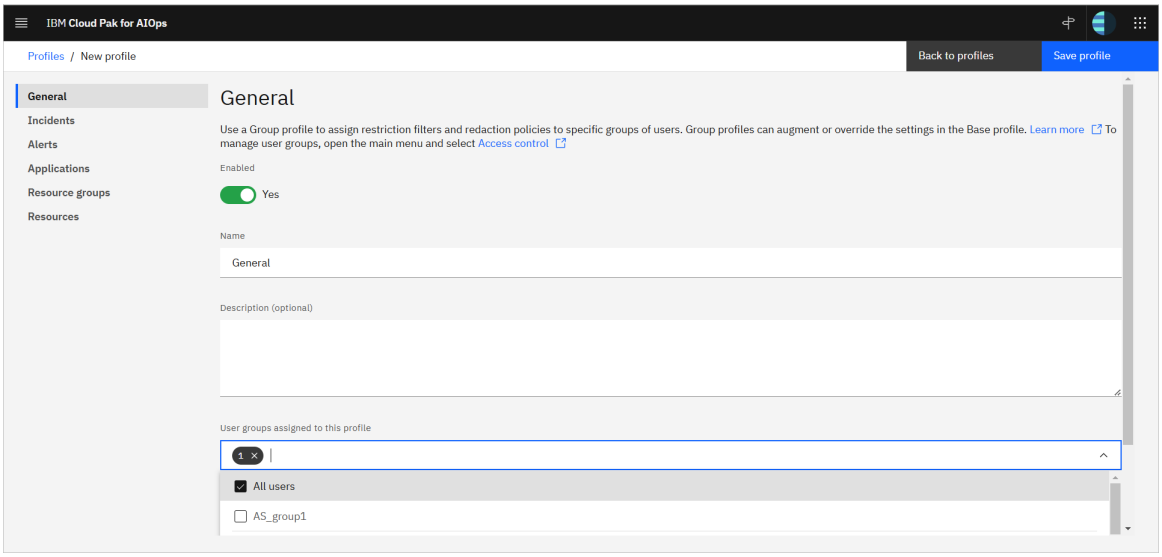

Figure. New profile creation

3. On the **General** details page, enter the following details:
    - Select whether to enable the profile by switching the value of **Enabled** from **No** to **Yes**. You can enable or disable a profile later as needed.
    - Enter a **Name** for the profile.
    - Enter a **Description (optional)** for the profile
    - Select the **User groups assigned to this profile**. Selected user groups display in a **User group** list.
4. Click through each of the following pages to select any required restriction filters or redaction policies to control the visibility of properites and content:
    - **Incidents**
    - **Alerts**
    - **Applications**
    - **Resource groups**
    - **Resources**
    - To control visibility, select a **Restriction filter**. For example, on the **Incidents** page, this selection is in the section **Visibility of Incidents**. The selection is in a similar section on each page.

      After selecting the filter, switch the toggle to enable the filter.

      Note: If you need to create a restriction filter, you must go to the console page for that feature to create the filter. For more information, see Creating restriction filters. Ensure that you save the filter as a restriction filter.

      To view general details for a selected restriction filter, click the *Information* icon. The following details are displayed for the filter:

        - Name
        - Created (date)
        - Created by
        - Last modified (date)
        - Last modified by
    - To control visibility and content, select a **Redaction policy**. For example, on the **Incidents** page, this selection is in the section **Visibility and content of Incident properties**. The selection is in a similar section on each page.

      After selecting the filter, switch the toggle to enable the policy. Once a filter/policy has been selected from the list the toggle automatically switches to *on* but it can be set to *off* if required.

      Notes:

        - If you need to edit the selected policy, click the **Edit selected redaction policy** icon.
        - If you need to create a redaction policy, complete one of the following actions:
            - Click the **Add new redaction policy** icon.

- Select a policy and click the **Duplicate selected redaction policy** icon.

For more information about creating and editing redaction policies, see Creating redaction policies. Redaction policies must be authored in the Rego language.

To view general details for a selected restriction filter, click the *Information* icon. The following details are displayed for the filter:

- Name
- Created (date)
- Created by
- Last modified (date)
- Last modified by

5. Click **Save profile**. Your new profile is saved and you are returned to the **Profiles** page. The new profile is now included in the list of existing profiles.

Viewing a profile

To view an existing group profile or the base profile, go to the **Profiles** page in the UI:

1. From the main navigation menu, go to **Administration** > **Profiles**. By default, the **Profiles** tab for the page is displayed. This tab lists the existing profiles and the following general details for those profiles:
   - **Name**:
   - **Type**:
   - **Scope**:
   - **Created**:
   - **Created by**:
   - **Last modified**:
   - **Last modified by**:
   - **Enabled**:
2. (Optional) If needed, you can filter the list of profiles to help you find a specific profile.

Enabling or disabling a profile

1. From the main navigation menu, go to **Administration** > **Profiles**. By default, the **Profiles** tab for the page is displayed. This tab lists the existing profiles.
2. Find the profile that you want to enable or disable. If needed, you can filter the list of profiles to help you find a specific profile.
3. For that profile, click the *Options* (3-dot) menu and click either **Enable** or **Disable**.

   A dialog requesting you to confirm your choice is displayed. This dialog indicates the number of affected user groups for changes to the selected profile. Click **Enable profile** or **Disable profile** to confirm your choice.

Editing a profile

1. From the main navigation menu, go to **Administration** > **Profiles**. By default, the **Profiles** tab for the page is displayed. This tab lists the existing profiles.
2. Find the profile that you want to edit. If needed, you can filter the list of profiles to help you find a specific profile.
3. For that profile, click the *Options* (3-dot) menu and click **Edit selected**.
4. Complete any required changes and click **Save profile**. For details on the available settings, see Creating a group profile.

   Note: If you want to edit the **Base** profile, the available settings to edit are the same as a group profile.

Duplicating a profle

1. From the main navigation menu, go to **Administration** > **Profiles**. By default, the **Profiles** tab for the page is displayed. This tab lists the existing profiles.
2. Find the profile that you want to duplicate. If needed, you can filter the list of profiles to help you find a specific profile.

   Note: You cannot duplicate the **Base** profile.
3. For that profile, click the *Options* (3-dot) menu and click **Duplicate**.
4. Enter or select the required settings for the profile and click **Save profile**. For details on the available settings, see Creating a group profile.

Deleting a profile

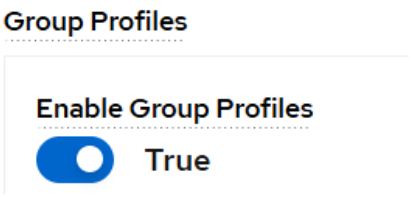
1. From the main navigation menu, go to **Administration** > **Profiles**. By default, the **Profiles** tab for the page is displayed. This tab lists the existing profiles.
2. Find the profile that you want to delete. If needed, you can filter the list of profiles to help you find a specific profile.
3. For that profile, click the *Options* (3-dot) menu and click **Delete**.

   A dialog requesting you to confirm the deletion is displayed. Click **Delete** to confirm and delete the profile.

Restriction filters

Restriction filters control the visibility of incidents, alerts, applications, resource groups, and resources. These filters are assigned to users through profiles. When creating the filter the name must be unique to the system, including normal filters, and then if editing the filter the name cannot be changed.

You can use restriction filters to control how information is distributed to your users. Restriction filtering works by enabling you to specify that under certain situations, the users should only see particular alerts, incidents, applications, resource groups or resources based on particular conditions.



To create and apply a restriction filter, you need to create a filter from either the *Incidents*, *Alerts*, or *Resource management* (application, resource, resource group) page and save the filter as a restriction filter. After creating a restriction filter, you can include it in the Base profile (applied to all users) or an appropriate group profile (applied to specified user groups).

- Prerequisites
- Creating a restriction filter
- Viewing restriction filters
- Editing restriction filters

Prerequisites

To work with profiles, and their associated restriction filters and redaction policies, you must possess an administrative user account with the **Manage profiles** role. For more information, see Roles and permissions.

Note: In the installation resource you are using you need to set the *Enable Group Profiles* radio button to *True*.

Creating a restriction filter

1. Go to the appropriate UI page for the filter that you want to create:
   - For an incident-related filter, go to the **Operate** > **Incidents** page.
   - For an alert related filter, go to the **Operate** > **Alerts** page.
   - For an application, resource group, or resource-related filter, go to the **Operate** > **Resource management** page.
2. Follow the steps for creating a new filter, but save the filter as a restriction filter. For details on creating a filter see:
   - For an incident-related filter, see Searching and filtering incidents.
   - For an alert related filter, see Searching and filtering alerts.
   - For an application, resource group, or resource related filter, see Resource management: Searching and filtering.
3. When you have finished selecting your options for the filter, click the three dots icon next to the Filter conditions. From the options that are listed, click **Save as new restriction filter**.

   The following images show where to find the *Save as new restriction filter* option for creating a filter from each of the **Incidents**, **Alerts**, **Resource management** pages.

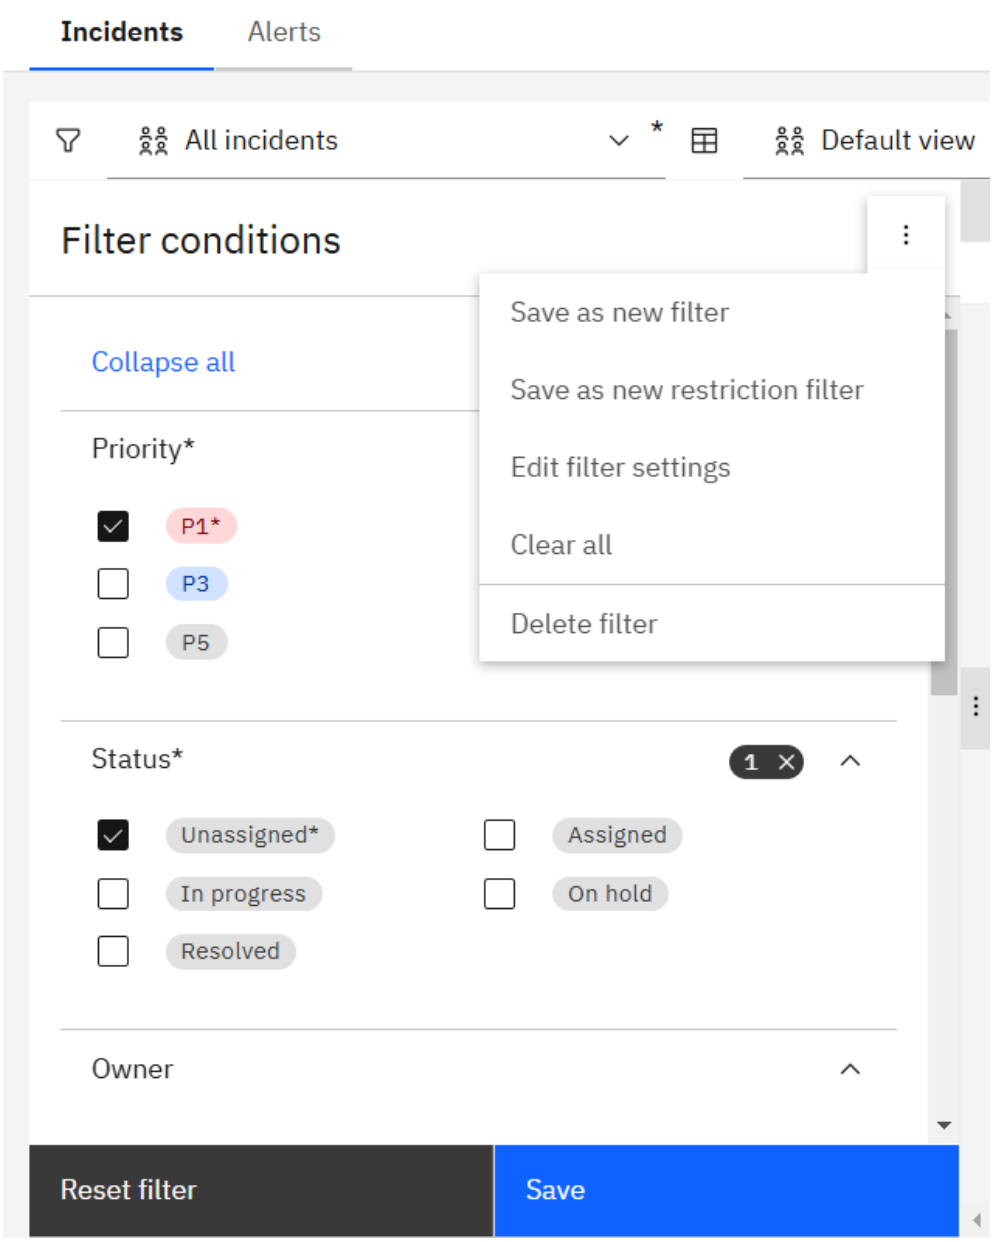


Figure. Example showing filters being applied for incidents

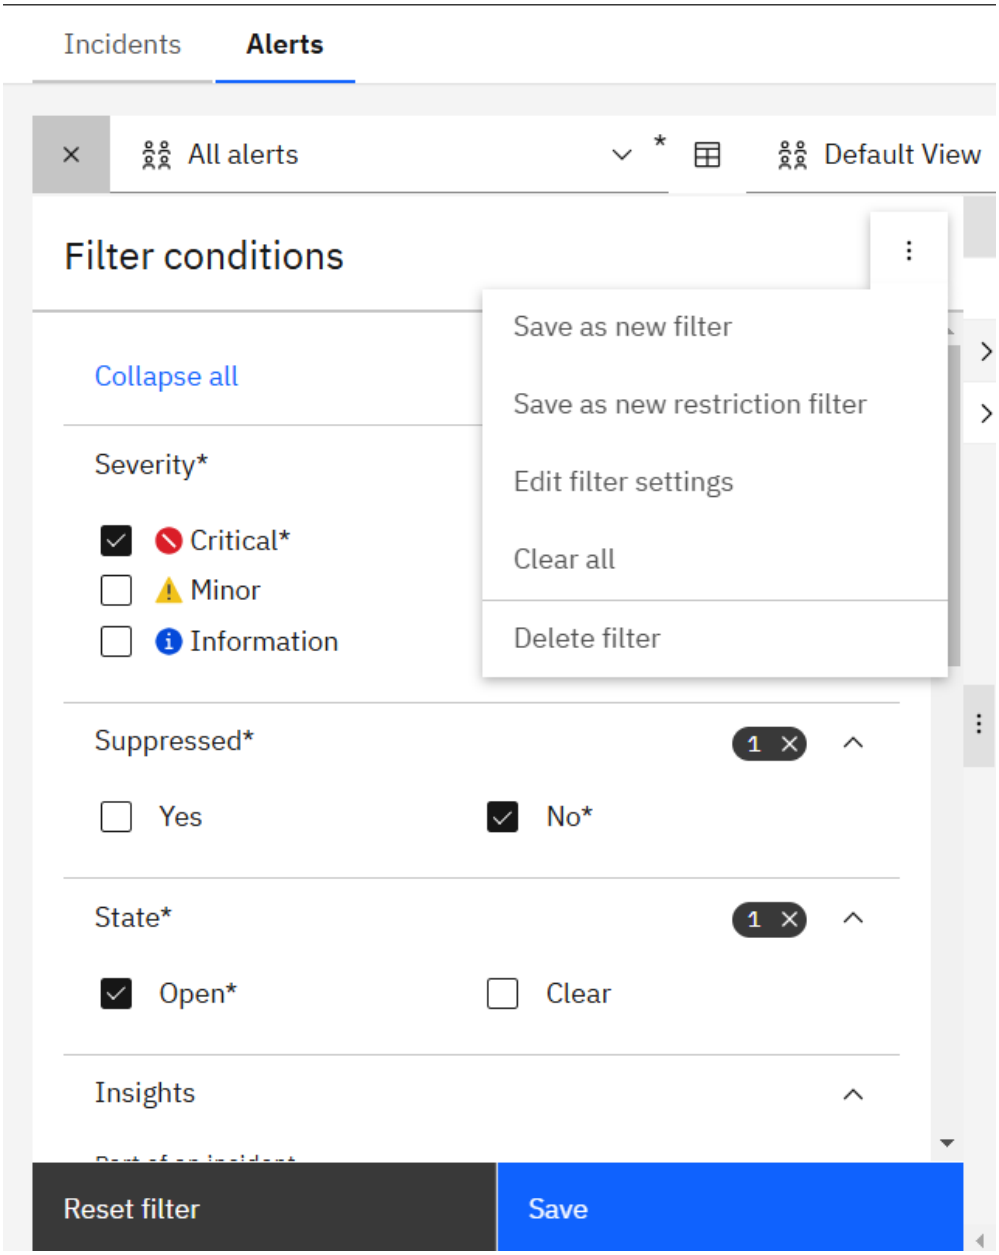

Figure. Example showing filters being applied for alerts

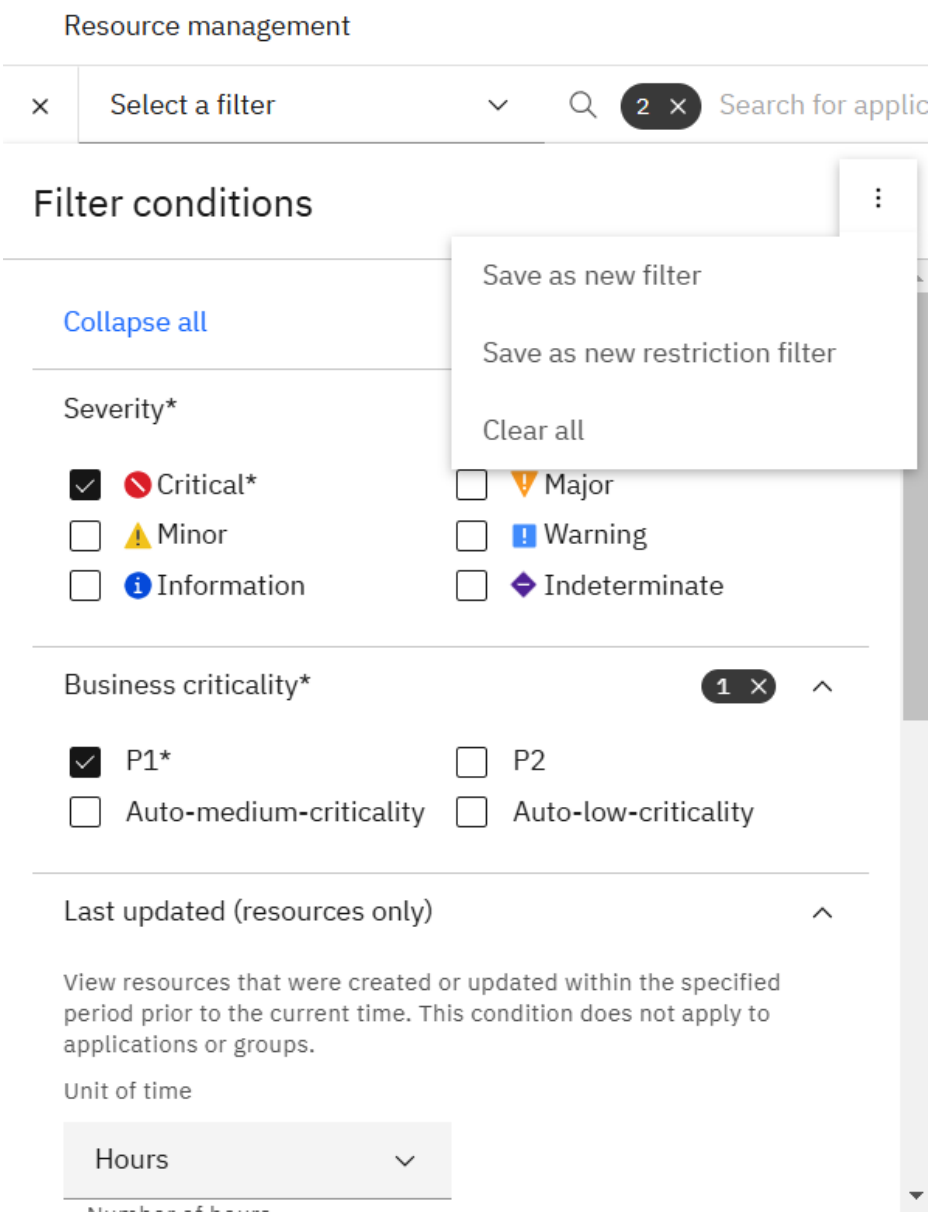

Figure. Example showing filters being applied for resource management

4. On the **Save as new restriction filter** dialog, complete the following settings:

   - Enter the name and description for the filter.
   - Select any user groups that need to be assigned the filter. For instance, assign the filter to any groups that are assigned *Manage Profiles* permission and responsible for creating and managing access control profiles.

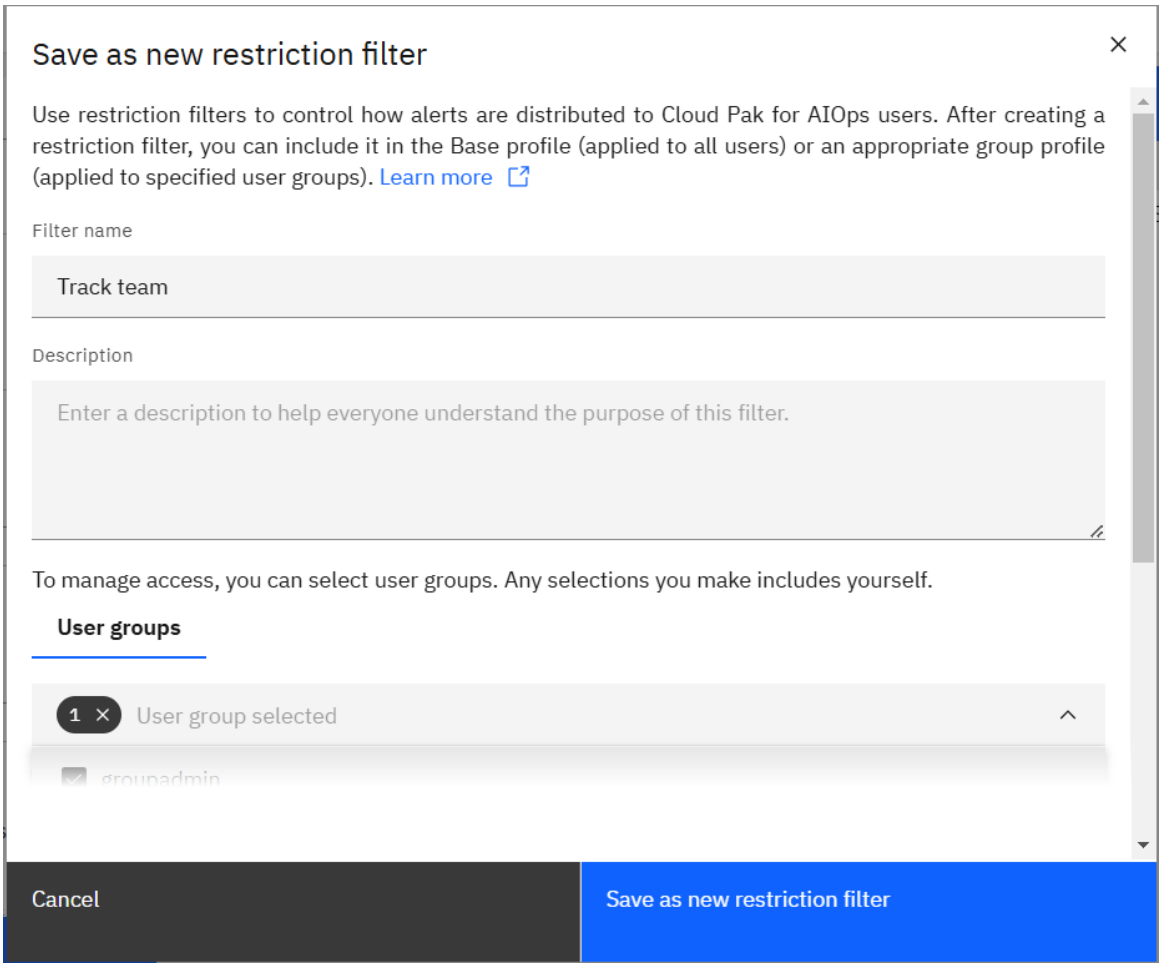

Figure. Save new restriction filter dialog

5. When you have finished entering and selecting the details for the filter, click **Save as new restriction filter**.

   Your new filter is created and listed on the **Restriction filters** tab of the **Administration** > **Profiles** page.

6. From the **Restriction filters** tab, click the **Profiles** tab and apply your created filter to a profile. For more information, see Managing profiles.

Viewing restriction filters

To view restriction filters go to the **Administration** > **Profiles** page. Then, click the **Restriction filters** tab. The list of existing filters is displayed, with the following details for each filter:

- Name
- Data types
- Created (date)
- Created by
- Last modified (date)
- Last modified by

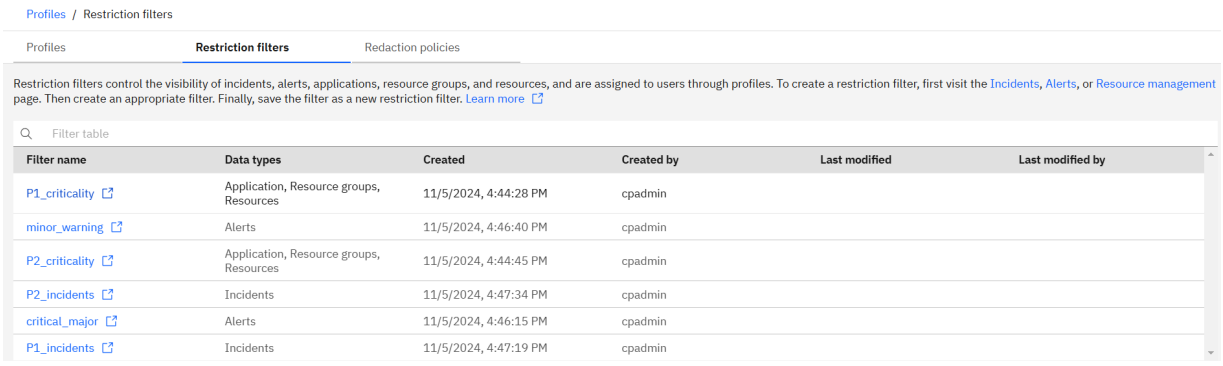

Figure. Restriction filters list

Editing restriction filters

1. From the main navigation menu, go to **Administration** > **Profiles**. By default, the **Profiles** tab for the page is displayed.
2. Click the **Restriction filters** tab. The list of existing filters is displayed, with the following details for each filter:

- Name
- Data types
- Created (date)
- Created by
- Last modified (date)
- Last modified by

3. Find the filter that you want to edit. If needed, you can filter the list to help you find a specific filter.
4. For that restriction filter, click the value for the **Filter name**. The corresponding **Incidents**, **Alerts**, or **Resource management** page for editing the filter opens.
5. Click the Filter icon to open the filter side panel. Complete any required changes and click **Save**. profile**. For details on the available settings, see the appropriate documentation:
    - For an incident-related filter, see Searching and filtering incidents.
    - For an alert related filter, see Searching and filtering alerts.
    - For an application, resource group, or resource-related filter, see Resource management: Searching and filtering.

Redaction policies

You can use redaction policies to hide, show, and change the properties (fields) of management artifacts such as incidents, alerts, applications, resource groups, and resources to users.

Redaction policies work alongside filtering to define the access control of data for your users. You can create, edit and duplicate direct from the profile definitions. If you need to hide or show management artifacts, as opposed to the properties of management artifacts, use restriction filters For more information, see Creating restriction filters.

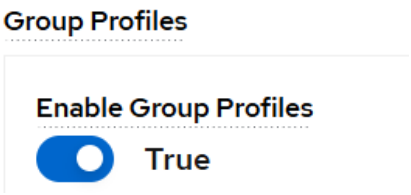
Base policies are the most redactive policies, comprising the minimum set of properties every user in the system is allowed to see. Group policies act as a way of additionally including extra properties for certain users. If a user has multiple group profiles assigned with different policies then the end JSON they see will be the combination of all policies. If the base policy option is disabled it might be due to no base policy being currently enabled.

Redaction policies must be authored using Rego, a programming language created specifically for policy-based control of IT environments. You can author your policies to manipulate the end result output either by hiding or showing all the properties or reacting or modifying particular properties.

For authoring a redaction policy in the Rego policy language, you can use the authoring tools that are included with the console **Profiles** page. These authoring tools include syntax checking and linting capabilities to help you create your policy source. For linting error notifications in the line number margin appear with details of the error.

Redaction policies are implemented using Open Policy Agent, which is an Apache v2.0 licensed CNCF project. You can use existing Open Policy Agent documentation to help you author your own policies. For more information, see the Open Policy Agent documentation.

Note: If a custom tool or styling is being applied using specific properties, you must ensure these are included in the final payload and not redacted, as otherwise the UI will not work.



You can apply a created redaction policy to all users, or specific user groups through a profile. To apply a policy to all users, apply the policy to the *Base* profile. To apply a policy to one or more specific user groups, use a *Group* profile. For more information, see Managing profiles.

- Prerequisites
- Creating a redaction policy
    - testing a policy
- Viewing a redaction policy
- Editing a redaction policy
- Duplicating a redaction policy
- Deleting a redaction policy

Prerequisites

To work with profiles, and their associated restriction filters and redaction policies, you must possess an administrative user account with the **Manage profiles** role. For more information, see Roles and permissions.

Note: In the installation resource you are using you need to set the *Enable Group Profiles* radio button to *True*.

Creating a redaction policy

You can create duplicate, edit, and delete redaction policies from the console **Profiles** page.

1. Go to the **Administration** > **Profiles** page. Then, click the **Redaction policies** tab. The list of existing policies is displayed.

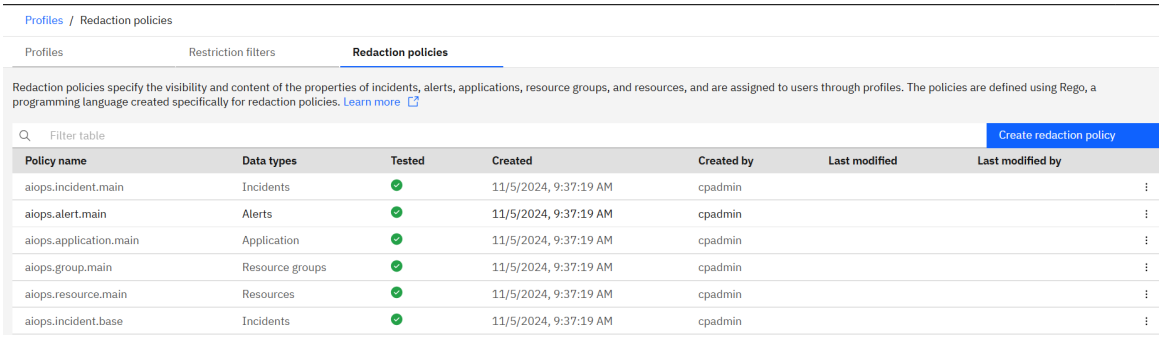


Figure. Redaction policy tab

2. Click **Create redaction policy**. The options and authoring tools for creating a **New redaction policy** are displayed. From this page, you can author your policy source, apply it to a particular data type, test it, and save it.

You can also reach this page when creating or editing a profile.

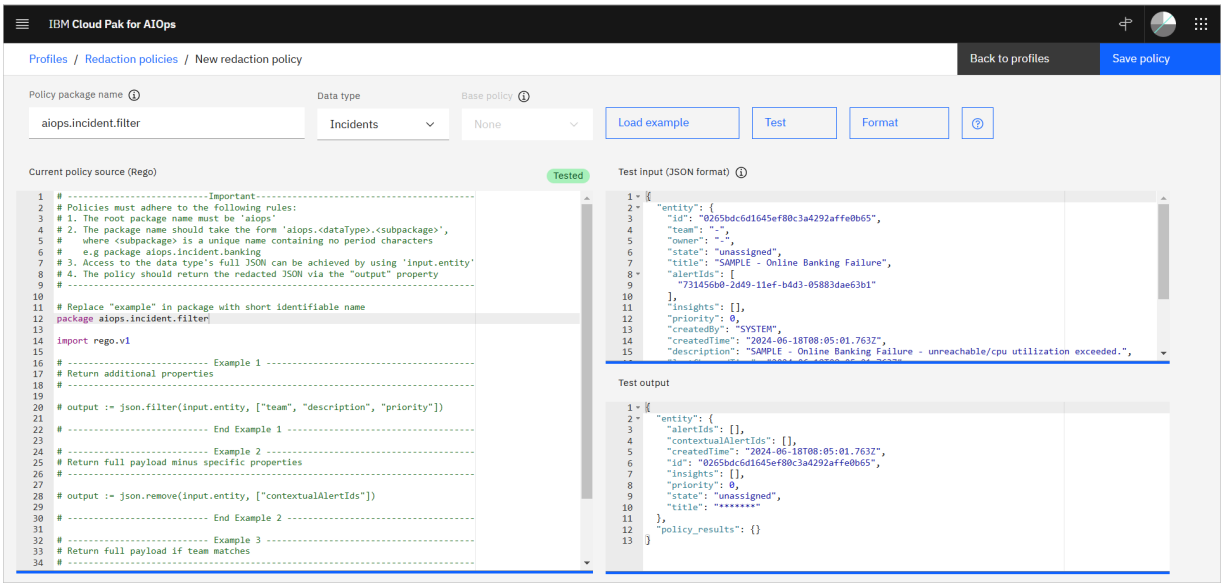

Figure. Redaction policy creation

3. Enter or select the following mandatory details for the policy:

   - **Policy package name**: The name must be in the form **`aiops.<data_type>.<policy_name>`**, where **`<data_type`** is either **`incident`**, **`alert`**, **`application`**, **`group`**, or **`resource`**. For example, **`aiops.resource.myPolicy`**.

     The value for the *Policy package name* must match the value for the package name that is include in the policy source.

   - **Data type**: Select the type of management artifact that the policy affects. The value can be **`Incidents`**, **`Alerts`**, **`Applications`**, **`Resource groups`**, or **`Resources`**.

     Note: If the redaction policy editor is opened when you are creating or editing a profile, you are not be able to change the data type.

- **Base policy**: Select a base policy when the current policy will be included in a *Group* profile, and there will be a corresponding policy in the *Base* profile. The base policy source will be displayed above the current policy source.

  When you run a test, the test is run against the base policy and the current policy. If a base policy is not selected, tests are run against the current policy alone.

  When testing with a base policy the output includes a section called *policy_results*, which shows the individual contributions from each policy.

4. (Optional) Click **Load example** to load an example policy and companion test data to view how a policy and test input can be structured.

   To test the example, click **Test**. The *Test* button will only be clickable once the policy has been given a valid package name. You can then view the results in the **Test output** area.

   Note: For a test policy the entity JSON should be placed under the entity as this will match the input format in the policy.

5. Author your policy source within the **Current policy source (Rego)** area.

   For examples of how to define different filter conditions, see Example redaction policies.

6. Click **Format** to properly indent each line of your policy source. A red error will show at the top of the file if formatting is required.

7. Test your policy source. To test a policy load representative test data. You can include the JSON representation of an incident, alert, application, resource group, or resource.

   When you have your input data entered within the **Test input (JSON format)** area, click **Test**. Review the results in the **Test output** area.

   Note: If a base policy is selected, the base policy and the current policy are included in tests. To exclude the base policy from tests, set **Base policy** to *None*.

   The following examples show how to get test data for existing management artifacts:

   Example: Getting incident test data:

   1. Open the main menu and select **Operate** > **Incidents**.
   2. Open an appropriate incident.
   3. Click **View raw**.
   4. Copy the JSON code to the clipboard.
   5. In the Test input field of the redaction policy editor, include the JSON representation of the incident as an entity, for example:

      ```
      {
       "entity": {
         "id": "12345678-0005-2024-0920-025539000001",
         "state": "unassigned",
         …
        }
      }
      ```

   Example: Getting alert test data:

   1. Open the main menu and select **Operate** > **Alerts**.
   2. Open an appropriate alert.
   3. In the Alert details panel, select the **Raw view**.
   4. Copy the JSON code to the clipboard.
   5. In the Test input field of the redaction policy editor, include the JSON representation of the alert as an entity, for example:

      ```
      {
      "entity": {
        "acknowledged": false,
        "deduplicationKey": "12345678-0005-2024-0920-025539000020",
        …
       }
      }
      ```

   Example: Getting application, resource groups, or resources test data:

   1. Open the main menu and select **Operate** > **Resource management**.
   2. On the Resource management page, select the **Applications** tab, **Resource groups** tab, or **Resources** tab.

3. Locate an appropriate application/service, resource group, or resource and click More details.
4. In the details window, set **Show JSON** to On.
5. Copy the JSON code to the clipboard.
6. In the Test input field of the redaction policy editor, include the JSON representation of the application/service, resource group, or resource as an entity, for example:

```
{
 "entity": {
   "_id": "rSRqQX6NTVywShGIjhm-Kg",
   "businessCriticality": "Tier 1",
   …
  }
}
```

8. When completed and tested, click **Save policy**.

   Your new policy is created and listed on the **Redaction policy** tab of the **Administration** > **Profiles** page.

9. From the **Redaction policies** tab, click the **Profiles** tab and apply your created policy to one or more profiles. For more information, see Managing profiles.

Tips: If a policy is not working as expected, complete the following actions:

- Leverage the test capabilities included in the redaction policy editor.
- Ensure that the policy is selected and enabled in the appropriate profiles.
- Ensure that the relevant profiles are enabled.
- If a policy is included in one or more group profiles, ensure that the profiles include the appropriate user groups.

Viewing redaction policies

To view restriction filters go to the **Administration** > **Profiles** page. Then, click the **Redaction policies** tab. The list of existing policies is displayed, with the following details for each policy:

- Policy Name
- Data types
- Tested
- Created (date)
- Created by
- Last modified (date)
- Last modified by

Editing a redaction policy

It is important to note that the main policy should never be modified unless done with the help of support. The main policy is responsible for combining all policies together. It also ensures that the required properties are always included, and should not be removed as they are used by the UI to render screens correctly.

1. From the main navigation menu, go to **Administration** > **Profiles**. Click the **Redaction policies** tab.
2. Find the policy that you want to edit. If needed, you can filter the list of policies to help you find a specific policy.
3. For that policy, click the *Options* (3-dot) menu and click **Edit selected**.
4. Complete any required changes and click **Save policy**.

Duplicating a redaction policy

1. From the main navigation menu, go to **Administration** > **Profiles**. Click the **Redaction policies** tab.
2. Find the policy that you want to duplicate. If needed, you can filter the list of policies to help you find a specific policy.
3. For that policy, click the *Options* (3-dot) menu and click **Duplicate**.
4. Change the policy as needed and click **Save profile**.

Deleting a redaction policy

1. From the main navigation menu, go to **Administration** > **Profiles**. Click the **Redaction policies** tab.

2. Find the policy that you want to delete. If needed, you can filter the list of policies to help you find a specific policy.
3. For that policy, click the *Options* (3-dot) menu and click **Delete**.

   A dialog requesting you to confirm the deletion is displayed. Click **Delete** to confirm and delete the policy.

   Note: You cannot delete a policy if is being used in the profile.

Example redaction policies

The following code samples shows the various different ways to define code filters in Rego:

Full JSON example

```
{
        "entity": {
          "_id": "imSB3oo-RcWqjFhX-55Qag",
          "name": "delaware10-le4-cs29.na.test.lab",
          "tags": [
                "1.3.6.1.4.1.9.1.217",

          "entityDiscoveryTime": "2019-07-19T15:04:42.000Z"
        }
  }
```

Equals filter example

```
output := input.entity if {
        input.entity.cdmType == 2
}
```

Is not equal filter example

```
output := input.entity if {
        not input.entity.cdmType == 2
}
```

Contains filter example

```
output := input.entity if {
        contains(input.entity.name, "ware")
}
```

Does not contain filter example

```
output := input.entity if {
        not contains(input.entity.name, "ware")
}
```

Starts with filter example

```
output := input.entity if {
        startswith(input.entity.name, "del")
}
```

Ends with filter example

```
output := input.entity if {
        endswith(input.entity.name, ".lab")
}
```

Empty filter example

```
output := input.entity if {
        not input.entity.cdmType
}
```

Is not empty filter example

```
output := input.entity if {
        input.entity.cdmType
}
```

Matches filter example

```
output := input.entity if {
        regex.match(`^delaware`, input.entity.name)
}
```

Does not match filter example

```
output := input.entity if {
        not regex.match(`^delaware`, input.entity.name)
}
```

Check value matches a value in a set filter example

Requires knowing the criticalities to allow

```
output := input.entity if {
        input.entity.businessCriticality in ["Gold", "Silver", "Bronze"]
}
```

Includes any filter example

Check a list of provided types

```
output := input.entity if {
        some type in input.entity.entityTypes
        type in ["host", "otherType", "otherType2"]
}
```

Includes all filter example

```
output := input.entity if {
        every type in input.entity.entityTypes {
                type in ["host", "switch"]
        }
}
```

Complex combination

```
output := input.entity if {
        # When dealing with a host
        "host" in input.entity.entityTypes

        # Must start with del to show properties
        startswith(input.entity.name, "del")

        # Must include the tag "joe@ibm.com"
        some type in input.entity.tags
```

```
        type in ["joe@ibm.com"]
}
```

Complex definition to handle many different types

```
output := input.entity if {
        # When dealing with a host
        "host" in input.entity.entityTypes

        # Must start with del to show properties
        startswith(input.entity.name, "del")

        # Must include the tag "joe@ibm.com"
        some type in input.entity.tags
        type in ["joe@ibm.com"]
} else := input.entity if {
        # When dealing with a people
        "people" in input.entity.entityTypes

        # Must start with del to show properties
        startswith(input.entity.team, "uk_")
} else := input.entity if {
        # When dealing with a vms
        "vm" in input.entity.entityTypes

        # Must start with del to show properties
        regex.match(`^delaware`, input.entity.name)
}
```

Setting your preferences

You can customize the console to work for you.

You can customize your:

- Home page
- Profile photo

Customizing the contents of your home page

You can customize the cards that are displayed on your home page and the links that are displayed in the **Quick navigation** section.

To customize your home page:

Click the **Settings** icon:

- To customize the cards on your home page:
    1. Select **Personalize cards**:
        - You can add new cards from the list of **Available cards**.
        - You can drag the cards in the **Overview** section to reorder them.
    2. Click **Save and close**.
- To customize the links in the **Quick navigation**:
    1. Select **Personalize navigation**:
        - You can select up to 10 links from the **Add links** list.
        - You can drag the links in the **Quick navigation** section to reorder them.
    2. Click **Save and close**.

Changing your profile photo

Your profile photo is displayed next to projects that you create, notifications about actions that you've taken, and more. Your profile photo can make it easier for your coworkers to identify content that you contributed to.

To change your profile photo:

1. Click your avatar in the toolbar.
2. Click **Profile and settings**.

3. Click the **Replace photo** icon next to the current image.
4. Browse for or drag and drop the image that you want to use. The image can be up to 1 MB and must be a JPG or PNG file.
5. Click **Save**.

You might need to refresh your browser for the change to take effect.

Secret rotation

Find out about the secure operation of the following operators, and the procedure you must follow if you update secrets that are owned or used by these operators.

- Issue Resolution Core operator secret usage
- Issue Resolution Lifecycle operator secret usage

Issue Resolution Core operator secret usage

Find out about the secure operation of the **`Issue Resolution Core`** operator.

Secrets owned by the Issue Resolution Core operator

The **`Issue Resolution Core`** operator's secrets are created automatically when IBM Cloud Pak® for AIOps is installed. Alternatively, you can manually create some or all of these secrets before IBM Cloud Pak for AIOps is installed, with values of your own choosing. If these secrets exist before IBM Cloud Pak for AIOps is installed, then they are not modified (although new properties might be added).

The following table describes the secrets that the **`Issue Resolution Core`** operator owns. These secrets contain credentials, encryption keys, and other secrets. Some values can be changed after installation, which might necessitate restarting pods that have access to these secrets, or require additional steps to run. Details are provided in the table.

Table 1. Secrets that belong to the Issue Resolution Core operator

Secret	Property	Type	Purpose	Rotation	Example commands
`aiops-ir-core-cem-users-secret`	**`clientid`**	hex15	OAuth client id	Change the secret. **`aiops-akora-ui`**, **`aiops-ir-core-cem-users`**, **`aiops-ir-core-esarchiving`**, **`aiops-ir-core-ncodl-api`**, **`aiops-ir-core-rba-rbs`** and **`aiops-ir-core-usercfg`** will restart automatically.	**`oc set data secret aiops-ir-core-cem-users-secret --from-literal=clientid=$(openssl rand --hex 15)`**
`aiops-ir-core-cem-users-secret`	**`clientsecret`**	hex15	OAuth client secret	Change the secret. **`aiops-akora-ui`**, **`aiops-ir-core-cem-users`**, **`aiops-ir-core-esarchiving`**, **`aiops-ir-core-ncodl-api`**, **`aiops-ir-core-rba-rbs`** and **`aiops-ir-core-usercfg`** will restart automatically.	**`oc set data secret aiops-ir-core-cem-users-secret --from-literal=clientsecret=$(openssl rand --hex 15)`**
`aiops-ir-core-cem-users-secret`	**`oidcclientid`**	hex15	Not used in AIOps	May be changed without effect.	
`aiops-ir-core-cem-users-secret`	**`oidcclientsecret`**	hex15	Not used in AIOps	May be changed without effect.	

Secret	Property	Type	Purpose	Rotation	Example commands
`aiops-ir-core-cem-users-secret`	`password`	hex15	Basic auth for `https://aiops-ir-core-cem-users:6002`	Change the secret. `aiops-akora-ui`, `aiops-ir-core-cem-users`, `aiops-ir-core-esarchiving`, `aiops-ir-core-ncodl-api`, `aiops-ir-core-rba-rbs` and `aiops-ir-core-usercfg` will restart automatically.	`oc set data secret aiops-ir-core-cem-users-secret --from-literal=password=$(openssl rand --hex 15)`
`aiops-ir-core-cem-users-secret`	`username`	hex15	Basic auth for `https://aiops-ir-core-cem-users:6002`	Change the secret. `aiops-akora-ui`, `aiops-ir-core-cem-users`, `aiops-ir-core-esarchiving`, `aiops-ir-core-ncodl-api`, `aiops-ir-core-rba-rbs` and `aiops-ir-core-usercfg` will restart automatically.	`oc set data secret aiops-ir-core-cem-users-secret --from-literal=username=$(openssl rand --hex 15)`
`aiops-ir-core-couchdb`	`admin_password`	hex15	Basic auth for `https://aiops-ir-core-couchdb-api`	Change the secret and restart `c-example-couchdbcluster-m`.	`oc set data secret aiops-ir-core-couchdb --from-literal=admin_password=$(openssl rand --hex 15) && oc delete pod -l app.kubernetes.io/component=couchdb`
`aiops-ir-core-couchdb`	`couchdb_auth_secret`	hex15	Internal CouchDB use	Change the secret and restart `c-example-couchdbcluster-m`.	`oc set data secret aiops-ir-core-couchdb --from-literal=couchdb_auth_secret=$(openssl rand --hex 15) && oc delete pod -l app.kubernetes.io/component=couchdb`
`aiops-ir-core-couchdb`	`csrf_secret`	hex15	Internal CouchDB use	Change the secret and restart `c-example-couchdbcluster-m`.	`oc set data secret aiops-ir-core-couchdb --from-literal=csrf_secret=$(openssl rand --hex 15) && oc delete pod -l app.kubernetes.io/component=couchdb`
`aiops-ir-core-couchdb`	`erlang_cookie`	hex15	Internal CouchDB use	Change the secret and restart `c-example-couchdbcluster-m`.	`oc set data secret aiops-ir-core-couchdb --from-literal=erlang_cookie=$(openssl rand --hex 15) && oc delete pod -l app.kubernetes.io/component=couchdb`
`aiops-ir-core-couchdb`	`ibm_password`	hex15	Internal CouchDB use	Change the secret and restart `c-example-couchdbcluster-m`.	`oc set data secret aiops-ir-core-couchdb --from-literal=ibm_password=$(openssl rand --hex 15) && oc delete pod -l app.kubernetes.io/component=couchdb`
`aiops-ir-core-model-secret`	`hkeyname`	ts	Identifier for `hkeyvalue` value	See Key rotation.	
`aiops-ir-core-model-secret`	`hkeyvalue`	hex16	HMAC key for sensitive data in CouchDB	See Key rotation.	
`aiops-ir-core-model-secret`	`oldhkeys`	hex16	Previous HMAC keys for sensitive data in CouchDB	See Key rotation.	
`aiops-ir-core-model-secret`	`keyname`	ts	Identifier for `keyvalue` value	See Key rotation.	
`aiops-ir-core-model-secret`	`keyvalue`	hex32	Encryption key for sensitive data in CouchDB	See Key rotation.	

Secret	Property	Type	Purpose	Rotation	Example commands
`aiops-ir-core-model-secret`	`oldkeys`	hex32	Previous encryption keys for sensitive data in CouchDB	See Key rotation.	
`aiops-ir-core-ncodl-api-secret`	`password`	hex15	Basic auth for `https://aiops-ir-core-ncodl-api:10011`	Change the secret and restart `cp4waiops-metricsprocessor`. `aiops-ir-core-ncodl-api` will restart automatically.	`oc set data secret aiops-ir-core-ncodl-api-secret --from-literal=password=$(openssl rand --hex 15) && oc delete pod -l connector.aiops.ibm.com/name=cp4waiops-metricsprocessor`
`aiops-ir-core-ncodl-api-secret`	`username`	hex15	Basic auth for `https://aiops-ir-core-ncodl-api:10011`	Change the secret and restart `cp4waiops-metricsprocessor`. `aiops-ir-core-ncodl-api` will restart automatically.	`oc set data secret aiops-ir-core-ncodl-api-secret --from-literal=username=$(openssl rand --hex 15) && oc delete pod -l connector.aiops.ibm.com/name=cp4waiops-metricsprocessor`
`aiops-ir-core-ncodl-std-secret`	`password`	hex15	Basic auth for `https://aiops-ir-core-ncodl-std:10011`	Change the secret and restart `aimanager-aio-ai-platform-api-server`, `aimanager-aio-change-risk`, `aimanager-aio-chatops-orchestrator`, `aimanager-aio-chatops-slack-integrator`, `aimanager-aio-chatops-teams-integrator`, `aimanager-aio-controller`, `aimanager-aio-cr-api`, `aimanager-aio-log-anomaly-detector`, `aimanager-aio-log-anomaly-feedback-learning`, `aimanager-aio-oob-recommended-actions`, `aimanager-aio-similar-incidents-service`. `aiops-ir-analytics-probablecause`, `aiops-ir-core-api`, `aiops-ir-core-ncodl-api`, `aiops-ir-core-ncodl-if`, `aiops-ir-core-ncodl-jobmgr`, `aiops-ir-core-ncodl-std` and `aiops-ir-core-rba-as` will restart automatically.	`oc set data secret aiops-ir-core-ncodl-std-secret --from-literal=password=$(openssl rand --hex 15) && oc delete pod -l app.kubernetes.io/component=ai-platform-api-server && oc delete pod -l app.kubernetes.io/component=change-risk && oc delete pod -l app.kubernetes.io/component=chatops-orchestrator && oc delete pod -l app.kubernetes.io/component=chatops-slack-integrator && oc delete pod -l app.kubernetes.io/component=chatops-teams-integrator && oc delete pod -l app.kubernetes.io/component=controller,app.kubernetes.io/name=aio && oc delete pod -l app.kubernetes.io/component=cr-api && oc delete pod -l app.kubernetes.io/component=log-anomaly-detector && oc delete pod -l app.kubernetes.io/component=log-anomaly-feedback-learning && oc delete pod -l app.kubernetes.io/component=oob-recommended-actions && oc delete pod -l app.kubernetes.io/component=similar-incidents-service`
`aiops-ir-core-ncodl-std-secret`	`username`	fixed	Basic auth for `https://aiops-ir-core-ncodl-std:10011`	The user name is `system`, this should not be changed and is included for future flexibility.	
`aiops-ir-core-omni-secret`	`OMNIBUS_PROBE_PASSWORD`	hex15	Probe password for ObjectServer	See ObjectServer passwords.	
`aiops-ir-core-omni-secret`	`OMNIBUS_ROOT_PASSWORD`	hex15	Root password for ObjectServer	See ObjectServer passwords.	
`aiops-ir-core-postgresql`	`caCertificate`	x509	Root CA certificate for PostgreSQL	This value must be copied from `<instance>-edb-secret`.	

Secret	Property	Type	Purpose	Rotation	Example commands
aiops-ir-core-postgresql	**dbname**	fixed	Name of event database in PostgreSQL	The database name is **aiops_irb**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql	**host**	hostname	Service name of PostgreSQL cluster	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql	**password**	hex15	Password for PostgreSQL event runtime user	Change. **aiops-ir-core-ncodl-jobmgr** and **aiops-ir-core-ncodl-std** will restart automatically.	**oc set data secret aiops-ir-core-postgresql --from-literal=password=$(openssl rand --hex 15)**
aiops-ir-core-postgresql	**port**	port	Port for PostgreSQL cluster service	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql	**schema**	fixed	Name of event schema in PostgreSQL	The schema name is **aiops_irb**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql	**username**	fixed	Name of PostgreSQL event runtime user	The user name is **aiops_irb**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql-admin	**caCertificate**	x509	Root CA certificate for PostgreSQL	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-admin	**dbname**	fixed	Name of event database in PostgreSQL	The database name is **aiops_irb**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql-admin	**host**	hostname	Service name of PostgreSQL cluster	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-admin	**password**	hex15	Password for PostgreSQL event admin user	Change the secret. No pod restarts are required.	**oc set data secret aiops-ir-core-postgresql-admin --from-literal=password=$(openssl rand --hex 15)**
aiops-ir-core-postgresql-admin	**port**	port	Port for PostgreSQL cluster service	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-admin	**schema**	fixed	Name of event schema in PostgreSQL	The schema name is **aiops_irb**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql-admin	**username**	fixed	Name of PostgreSQL event admin user	The user name is **aiops_irb_admin**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql-uc	**caCertificate**	x509	Root CA certificate for PostgreSQL	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-uc	**dbname**	fixed	Name of event database in PostgreSQL	The database name is **aiops_irbuc**, this should not be changed and is included for future flexibility.	

Secret	Property	Type	Purpose	Rotation	Example commands
aiops-ir-core-postgresql-uc	**host**	hostname	Service name of PostgreSQL cluster	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-uc	**password**	hex15	Password for PostgreSQL event runtime user	Change. **aiops-ir-core-usercfg** will restart automatically.	**oc set data secret aiops-ir-core-postgresql-uc --from-literal=password=$(openssl rand --hex 15)**
aiops-ir-core-postgresql-uc	**port**	port	Port for PostgreSQL cluster service	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-uc	**schema**	fixed	Name of event schema in PostgreSQL	The schema name is **aiops_irbuc**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql-uc	**username**	fixed	Name of PostgreSQL event runtime user	The user name is **aiops_irbuc**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql-uc-admin	**caCertificate**	x509	Root CA certificate for PostgreSQL	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-uc-admin	**dbname**	fixed	Name of event database in PostgreSQL	The database name is **aiops_irbuc**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql-uc-admin	**host**	hostname	Service name of PostgreSQL cluster	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-uc-admin	**password**	hex15	Password for PostgreSQL event admin user	Change the secret. No pod restarts are required.	**oc set data secret aiops-ir-core-postgresql-uc-admin --from-literal=password=$(openssl rand --hex 15)**
aiops-ir-core-postgresql-uc-admin	**port**	port	Port for PostgreSQL cluster service	This value must be copied from **<instance>-edb-secret**.	
aiops-ir-core-postgresql-uc-admin	**schema**	fixed	Name of event schema in PostgreSQL	The schema name is **aiops_irbuc**, this should not be changed and is included for future flexibility.	
aiops-ir-core-postgresql-uc-admin	**username**	fixed	Name of PostgreSQL event admin user	The user name is **aiops_irbuc_admin**, this should not be changed and is included for future flexibility.	
aiops-ir-core-rba-devops-secret	**password**	hex15	Basic auth for **https://aiops-ir-core-rba-as:3080** and **https://aiops-ir-core-rba-rbs:3005**	Change the secret and restart **cp4waiops-metricsprocessor**. **aiops-ir-core-rba-as** and **aiops-ir-core-rba-rbs** will restart automatically.	**oc set data secret aiops-ir-core-rba-devops-secret --from-literal=password=$(openssl rand --hex 15) && oc delete pod -l connector.aiops.ibm.com/name=cp4waiops-metricsprocessor**
aiops-ir-core-rba-devops-secret	**username**	hex15	Basic auth for **https://aiops-ir-core-rba-as:3080** and **https://aiops-ir-core-rba-rbs:3005**	Change the secret and restart **cp4waiops-metricsprocessor**. **aiops-ir-core-rba-as** and **aiops-ir-core-rba-rbs** will restart automatically.	**oc set data secret aiops-ir-core-rba-devops-secret --from-literal=username=$(openssl rand --hex 15) && oc delete pod -l connector.aiops.ibm.com/name=cp4waiops-metricsprocessor**

Secret	Property	Type	Purpose	Rotation	Example commands
`aiops-ir-core-rba-jwt-secret`	`secret`	hex15	Key used to sign runbook JSON web tokens	Change the secret and restart `aiops-akora-ui`, `aiops-ir-core-rba-as`, `aiops-ir-core-rba-rbs`, `connector-orchestrator`.	`oc set data secret aiops-ir-core-rba-jwt-secret --from-literal=secret=$(openssl rand --hex 15) && oc delete pod -l app.kubernetes.io/component=aiops-aiops-akora-ui && oc delete pod -l app.kubernetes.io/component=rba-as && oc delete pod -l app.kubernetes.io/component=rba-rbs && oc delete pod -l app=connector-orchestrator`
`aiops-ir-core-usercfg-creds`	`password`	hex15	Basic auth for `https://aiops-ir-core-usercfg:10011`	Change the secret. `aiops-ir-core-ncodl-api` and `aiops-ir-core-usercfg` will restart automatically.	`oc set data secret aiops-ir-core-usercfg-creds --from-literal=password=$(openssl rand --hex 15)`
`aiops-ir-core-usercfg-creds`	`username`	hex15	Basic auth for `https://aiops-ir-core-usercfg:10011`	Change the secret. `aiops-ir-core-ncodl-api` and `aiops-ir-core-usercfg` will restart automatically.	`oc set data secret aiops-ir-core-usercfg-creds --from-literal=username=$(openssl rand --hex 15)`

Where `<instance>` is the name of your IBM Cloud Pak for AIOps instance, for example `ibm-cp-aiops`.

The `Type` for each secret in the table has one of the following entries:

- hex15, hex16, hex32 - 15, 16, or 32-byte number encoded in hexadecimal (30, 32 or 64 hex digits).
- ts - timestamp value that is used as an identifier for another value. The timestamp is not significant and alternative strings can be used. Some restrictions on the characters might exist. ASCII alphanumeric characters are recommended.
- fixed - do not change this value. The value is included in a secret for future flexibility.
- x509 - an X.509 certificate
- hostname - the DNS hostname of a service.
- port - a TCP port number

Secrets that are used by the Issue Resolution Core operator

The following table describes secrets that are owned by another operator but that are used by the Issue Resolution Core operator. The table shows the Issue Resolution Core components that need to be restarted if these secrets are rotated.

Table 2. Secrets that are used by the Issue Resolution Core operator

Secret	Owner	Purpose	Automatically restarted
`aiops-topology-cassandra-auth-secret`	`asm-operator`	Cassandra contact details	`aiops-ir-core-archiving`, `aiops-ir-core-esarchiving`
`<instance>-couchdb-secret`	`ibm-aiops-orchestrator`	CouchDB contact details	`aiops-ir-core-cem-users`, `aiops-ir-core-rba-as`, `aiops-ir-core-rba-rbs`
`<instance>-es-aiops-user-connection-secret`	`ibm-aiops-orchestrator`	Elasticsearch contact details	`aiops-ir-core-datarouting`, `aiops-ir-core-ncodl-api`
`<instance>-kafka-secret`	`ibm-aiops-orchestrator`	Kafka contact details	`aiops-ir-core-api`, `aiops-ir-core-archiving`, `aiops-ir-core-datarouting`, `aiops-ir-core-esarchiving`, `aiops-ir-core-ncodl-if`, `aiops-ir-core-ncodl-jobmgr`, `aiops-ir-core-ncodl-std`, `aiops-ir-core-rba-rbs`
`<instance>-redis-secret`	`ibm-aiops-orchestrator`	Redis contact details	`aiops-ir-core-cem-users`, `aiops-ir-core-esarchiving`, `aiops-ir-core-rba-rbs`
`internal-nginx-svc-tls`	`ibm-zen-operator`	Trusted CA for Zen	`aiops-ir-core-cem-users`
`internal-tls`	`ibm-zen-operator`	Trusted CA for Zen	`aiops-ir-core-cem-users`
`zen-service-broker-secret`	`ibm-zen-operator`	Token for accessing Zen API	`aiops-ir-core-cem-users`

Where `<instance>` is the name of your IBM Cloud Pak for AIOps instance, for example `ibm-cp-aiops`.

Key rotation

Warning: The secret `aiops-ir-core-model-secret` contains an encryption key and a HMAC key that is used to protect sensitive data that is stored in CouchDB. Care must be taken when rotating these keys since data that is protected with previous keys cannot be recovered if the keys

are lost.

Replacement values for **keyvalue** must be 16 bytes and in hexadecimal format (32 digits). Replacement values for **hkeyvalue** must be 32 bytes and in hexadecimal format (64 digits).

Each key has an associated identifier. Encrypted data is stored along with the identifier of the key that was used to protect it. The identifier must be changed when and only when the key is changed. When the operator creates a new key, it uses the current time as the identifier (for example **2022-06-13T10:58:10Z**). This is a convention but other string formats may be used. If another format is used, there might be some restrictions on the characters that can be used. ASCII alphanumeric characters are recommended.

When rotating keys, all old (key, identifier) pairs must be stored in the **oldhkeys** and **oldkeys** properties so that data that is protected with the old keys can be used. The current key is always used when data is stored or modified. The following examples show the use of the old keys' properties.

1. Secret created by the operator.

```
{
  "hkeyname": "2022-06-13T10:58:10Z",
  "hkeyvalue": "2905c99e41fd6594de9e8632382da185eec94cea545cbd96082552274a454d2b",
  "keyname": "2022-06-13T10:58:10Z",
  "keyvalue": "5cc068f45904c0ff998213941684790e"
}
```

2. Secret after the first rotation.

   The identifiers **myfirsthkey** and **myfirstkey** were used. Time based could have been used.

```
{
  "hkeyname": "myfirsthkey",
  "hkeyvalue": "7539eb64abdae09a500659ca0593140babd00046b175c3a83e3ed28f8d79daca",
  "oldhkeys": "{\"keys\":[{\"name\":\"2022-06-
13T10:58:10Z\",\"value\":\"2905c99e41fd6594de9e8632382da185eec94cea545cbd96082552274a454d2b\"}]}",
  "keyname": "myfirstkey",
  "keyvalue": "211812c9750778c0175bca4a11cc1e3b",
  "oldkeys": "{\"keys\":[{\"name\":\"2022-06-
13T10:58:10Z\",\"value\":\"5cc068f45904c0ff998213941684790e\"}]}"
}
```

3. Secret after the second rotation.

   The identifiers **mysecondhkey** and **mysecondkey** were used. Time based could have been used.

```
{
  "hkeyname": "mysecondhkey",
  "hkeyvalue": "07a290a68d6ff7eb45b7febbfd8c5079da5ee40c068f2e1bb87293c22c39b712",
  "oldhkeys": "{\"keys\":[{\"name\":\"2022-06-
13T10:58:10Z\",\"value\":\"2905c99e41fd6594de9e8632382da185eec94cea545cbd96082552274a454d2b\"},
{\"name\":\"myfirsthkey\",\"value\":\"7539eb64abdae09a500659ca0593140babd00046b175c3a83e3ed28f8d79daca\
"}]}",
  "keyname": "mysecondkey",
  "keyvalue": "f01b36adba59c50841a1444cee8eb09e",
  "oldkeys": "{\"keys\":[{\"name\":\"2022-06-
13T10:58:10Z\",\"value\":\"5cc068f45904c0ff998213941684790e\"},
{\"name\":\"myfirstkey\",\"value\":\"211812c9750778c0175bca4a11cc1e3b\"}]}"
}
```

   If the **oldhkeys** and **oldkeys** properties exist, they must hold the JSON representation of an object with a single property (the name does not matter, this example used **keys**) that has an array of objects. Each of the inner objects has a **name** and a **value** property holding the identifier and value of a previous key.

```
oc delete pod -l app.kubernetes.io/component=rba-as && oc delete pod -l
app.kubernetes.io/component=rba-rbs
```

ObjectServer passwords

Use the following steps to change the ObjectServer password. Ensure that you retain a copy of the original password until these steps are complete.

1. Run the following command to obtain the current passwords from the **aiops-ir-core-omni-secret** secret.

   For example:

```
oc get secret aiops-ir-core-omni-secret -o json | jq -r '.data.OMNIBUS_PROBE_PASSWORD|@base64d'`
oc get secret aiops-ir-core-omni-secret -o json | jq -r '.data.OMNIBUS_ROOT_PASSWORD|@base64d'`
```

2. Open a session on the primary ObjectServer pod.

```
oc rsh aiops-ir-core-ncoprimary-0
```

3. Log in to the OMNIbus query tool **nco_sql**, and supply the root password when prompted.

   ```
   $NCHOME/omnibus/bin/nco_sql -u root -s AGG_P_C
   ```

4. If you want to change the root password, enter the following command.

   ```
   alter user 'root' set password '<NEWPASSWORD>';
   go
   ```

   Where **<NEWPASSWORD>** is the password that you want to set.

5. If you also want to change the probe password, enter the following command.

   ```
   alter user 'probe' set password '<PROBE_PASSWORD>';
   go
   ```

   Where **<PROBE_PASSWORD>** is the password that you want to set.

6. Test the new root password by entering **quit** to leave the SQL prompt, and then log in again and supply the new root password when prompted.

   ```
   $NCHOME/omnibus/bin/nco_sql -u root -s AGG_P_C
   ```

7. Exit the **oc rsh** session.

8. Wait for 60 seconds to ensure that the password updates have been transferred to the backup ObjectServer.

9. Remote shell into the backup ObjectServer, and test the new root password.

   ```
   oc rsh -c objserv aiops-ir-core-ncobackup-0`
   ```

10. Log in to the OMNIbus query tool **nco_sql**, and supply the root password when prompted.

    ```
    $NCHOME/omnibus/bin/nco_sql -u root -s AGG_B_C
    ```

11. Exit the **oc rsh** session.

12. Update the **aiops-ir-core-omni-secret** with one or more new passwords.

    For example,

    ```
    oc set data secret aiops-ir-core-omni-secret --from-literal=OMNIBUS_PROBE_PASSWORD=<PROBE_PASSWORD>
    oc set data secret aiops-ir-core-omni-secret --from-literal=OMNIBUS_ROOT_PASSWORD=<NEWPASSWORD>
    ```

    Where

    - **<NEWPASSWORD>** is the new root password
    - **<PROBE_PASSWORD>** is the new probe password

13. If you changed the root password, run the following command to restart **aiops-ir-core-ncodl-if**

    ```
    oc delete pod -l app.kubernetes.io/component=ncodl-if
    ```

Issue Resolution Lifecycle operator secret usage

Find out about the secure operation of the **Issue Resolution Lifecycle** operator.

Secrets owned by the Issue Resolution Lifecycle operator

The **Issue Resolution Lifecycle** operator's secrets are created automatically when IBM Cloud Pak® for AIOps is installed. Alternatively, you can manually create some or all of these secrets before IBM Cloud Pak for AIOps is installed, with values of your own choosing. If these secrets exist before IBM Cloud Pak for AIOps is installed, then they are not modified (although new properties might be added).

The following table describes the secrets that the **Issue Resolution Lifecycle** operator owns. These secrets contain credentials, encryption keys, and other secrets. Some values can be changed after installation, which might necessitate restarting pods that have access to these secrets, or require additional steps to run. Details are provided in the table.

Table 1. Secrets that belong to the Issue Resolution Lifecycle operator

Secret	Property	Type	Purpose	Rotation	Example commands

Secret	Property	Type	Purpose	Rotation	Example commands
`aiops-ir-lifecycle-flink-admin-user`	`password`	hex15	Basic auth for `https://aiops-ir-lifecycle-flink-api:9081`	Change the secret. `aiops-ir-lifecycle-flink` will restart automatically.	`oc set data secret aiops-ir-lifecycle-flink-admin-user --from-literal=password=$(openssl rand --hex 15)`
`aiops-ir-lifecycle-flink-admin-user`	`username`	fixed	Basic auth for `https://aiops-ir-lifecycle-flink-api:9081`	The user name is flink-admin, this should not be changed and is included for future flexibility.	
`aiops-ir-lifecycle-flink-internal-keystore`	`password`	hex15	Password used for key store within pods.	Change the secret. `aiops-ir-lifecycle-flink` and `aiops-ir-lifecycle-flink-taskmanager` will restart automatically.	`oc set data secret aiops-ir-lifecycle-flink-internal-keystore --from-literal=password=$(openssl rand --hex 15)`
`aiops-ir-lifecycle-flink-internal-truststore`	`password`	hex15	Password used for trust store within pods.	Change the secret. `aiops-ir-lifecycle-flink` and `aiops-ir-lifecycle-flink-taskmanager` will restart automatically.	`oc set data secret aiops-ir-lifecycle-flink-internal-truststore --from-literal=password=$(openssl rand --hex 15)`
`aiops-ir-lifecycle-flink-rest-keystore`	`password`	hex15	Password used for key store within pods.	Change the secret. `aiops-ir-lifecycle-flink` and `aiops-ir-lifecycle-flink-taskmanager` will restart automatically.	`oc set data secret aiops-ir-lifecycle-flink-rest-keystore --from-literal=password=$(openssl rand --hex 15)`
`aiops-ir-lifecycle-flink-rest-truststore`	`password`	hex15	Password used for trust store within pods.	Change the secret. `aiops-ir-lifecycle-flink` and `aiops-ir-lifecycle-flink-taskmanager` will restart automatically.	`oc set data secret aiops-ir-lifecycle-flink-rest-truststore --from-literal=password=$(openssl rand --hex 15)`
`aiops-ir-lifecycle-flink-truststore`	`password`	hex15	Password used for trust store within pods.	Change the secret. `aiops-ir-lifecycle-flink` and `aiops-ir-lifecycle-flink-taskmanager` will restart automatically.	`oc set data secret aiops-ir-lifecycle-flink-truststore --from-literal=password=$(openssl rand --hex 15)`
`aiops-ir-lifecycle-policy-registry-svc`	`password`	hex15	Basic authentication for `https://aiops-ir-lifecycle-policy-registry-svc:5601`	Change the secret. - Restart `cp4waiops-metricsprocessor`. - `aiops-ir-lifecycle-policy-registry-svc` restarts automatically.	`oc set data secret aiops-ir-lifecycle-policy-registry-svc --from-literal=password=$(openssl rand -hex 15) && oc delete pod -l connector.aiops.ibm.com/name=cp4waiops-metricsprocessor`
`aiops-ir-lifecycle-policy-registry-svc`	`username`	fixed	Basic authentication for `https://aiops-ir-lifecycle-policy-registry-svc:5601`	The username is `system` and must not be changed. It is included for future flexibility.	

The `Type` for each secret in the table has one of the following entries:

- hex15 - 15-byte number encoded in hexadecimal (30 hex digits).
- fixed - do not change this value. The value is included in a secret for future flexibility.

Secrets that are used by the Issue Resolution Lifecycle operator

The following table describes secrets that are owned by another operator but that are used by the Issue Resolution Lifecycle operator. The table shows the Issue Resolution Lifecycle components that are automatically restarted if these secrets are rotated, no manual component restarts are required.

Table 2. Secrets that are used by the Issue Resolution Lifecycle operator

Secret	Owner	Purpose	Automatically restarted
`aimanager-ibm-minio-access-secret`	`AIManager/aimanager`	Credentials for Minio S3 storage	`aiops-ir-lifecycle-flink`, `aiops-ir-lifecycle-flink-taskmanager`
`aiops-ir-analytics-ai-datalayer-system-secret`	`AIOpsAnalyticsOrchestrator`	Credentials for AI datalayer	`aiops-ir-lifecycle-flink`, `aiops-ir-lifecycle-flink-taskmanager`
`aiops-topology-asm-credentials`	`ASM/aiops-topology`	Credentials for `https://aiops-topology-topology.aiops.svc:8080`	`aiops-ir-lifecycle-flink`, `aiops-ir-lifecycle-flink-taskmanager`
`aiops-topology-cassandra-auth-secret`	`ASM/aiops-topology`	Credentials for Cassandra	`aiops-ir-lifecycle-flink-taskmanager`, `aiops-ir-lifecycle-policy-registry-svc`
`cp4waiops-cartridge-es-auth`	`Installation`	Credentials for Elasticsearch	`aiops-ir-lifecycle-flink`, `aiops-ir-lifecycle-flink-taskmanager`
`iaf-system-elasticsearch-es-ss-cacert-kp`	`Certificate/iaf-system-elasticsearch-es-ss-ca`	CA certificate for Elasticsearch	`aiops-ir-lifecycle-flink`, `aiops-ir-lifecycle-flink-taskmanager`
`<instance>-es-aiops-user-connection-secret`	`Installation`	Binding secret for Elasticsearch	`aiops-ir-lifecycle-datarouting`, `aiops-ir-lifecycle-policy-registry-svc`
`<instance>-kafka-secret`	`Installation`	Binding secret for Kafka	`aiops-ir-lifecycle-datarouting`, `aiops-ir-lifecycle-flink`, `aiops-ir-lifecycle-flink-taskmanager`, `aiops-ir-lifecycle-policy-registry-svc`
`zen-service-broker-secret`	`ibm-zen-operator`	Token for accessing Zen API	`aiops-ir-lifecycle-flink`, `aiops-ir-lifecycle-flink-taskmanager`

Where `<instance>` is the name of your IBM Cloud Pak for AIOps instance, for example `ibm-cp-aiops`.

Administering CouchDB data storage

Manage disk space used by runbook executions to avoid outages when the available disk space has been exhausted.

You can offload and delete historic runbook executions to reduce database footprint and increase database performance. Offloaded runbook executions are deleted from the production database and stored on a file system instead to preserve them for future audit purposes. They can be stored either in JSON or HTML format. A script for offloading runbook executions is included in the product and can be run by using the fully automated sample runbook **Example: Automatically reduce amount of data in runbook data stores**. Running this fully automated runbook has the negative side effect that the API key (which is contained in the parameters of the fully automated runbook) is stored and can be viewed within the runbook execution details. This description shows how you can avoid this limitation and still use the script that is available at the core of the fully automated runbook.

Runbook executions can be offloaded to store them somewhere else, in a different format (JSON or HTML), or to reduce the amount of data stored in the database. This is especially important if either the database is getting short of disk space, or a performance degradation that is caused by too much data is becoming noticeable. It is also a good practice to regularly offload runbook executions that exceed a certain age and are therefore no longer required on the production system.

When you offload and delete runbook execution records, the referenced action execution records are included in the offloading output and deleted as well. However, additional action execution records might remain for runbook executions that were already deleted separately, or were executed outside of a runbook context. You can use the following instructions on how to offload and delete those action execution records. Make sure to delete the action execution records only after the runbook execution records for the same time frame have been offloaded and deleted. Otherwise, the runbook execution records contain broken links to action execution records that have been deleted already.

Note:

- Once runbook executions are offloaded and deleted, they are no longer accessible from the runbook history page and are not reflected in the aggregated statistics of their runbook anymore.
- The size of the database does not shrink immediately after the runbook executions have been deleted, but only after the next CouchDB database compaction has been performed by CouchDB itself.

It is recommended to set up a scheduled task that offloads runbook execution data is regularly. For your planning you should consider the following aspects:

- What is the maximum size of the persistent volume that hosts the database where the runbook execution data is stored? For example, 20 GB.
- What is the average size of a single runbook execution in your environment? For simple runbooks, you can assume a value of about 15 KB per runbook execution.
- How many runbooks are executed per day?

Create an initial schedule for offloading the runbooks based on these values, allowing some buffer for days with higher load. Observe the behavior for some time, and tune the frequency of the scheduled task or the parameters of the runbook to match your needs.

The offloading script must run on a Linux system that meets the following requirements:

- Network access to the OpenShift or Linux® cluster where IBM Cloud Pak® for AIOps is installed.
- The `curl` tool must be installed.
- The `jq` tool must be installed. Starting with RHEL 8.0, `jq` can be installed by using the AppStream repository. On earlier RHEL versions, `jq` can be installed by following the instructions on https://stedolan.github.io/jq/.
- Some free disk space must exist to store copies of the offloaded runbook executions. See the FOLDER parameter for more information.
- The `base64` encoding tool must be installed.

The offloading script requires several environment variables to be set:

- API: The Runbook API URL as described in Automation (runbook) API. For example, set the value of the API parameter to `https://cpd-cp4waiops.apps.mycomp.com/aiops/api/story-manager/rba/v1`.
- APIKEY_NAME: The user ID that you used to log in when creating an API key. As described in Accessing APIs, section *Get access token by using your API key*, step *Generate your platform API key*.
- APIKEY_PW: The API key password that you created when following the instructions in Accessing APIs, section *Get access token by using your API key*, step *Generate your platform API key*.
- FOLDER: The fully qualified path name of an existing directory on the Linux system that will be used for storing the offloaded runbooks.
- MODE: Used to specify a format for the offloaded runbook executions. You can choose between `html` and `json`.
- DELETE: Whether to delete the offloaded runbook executions from the runbook database after successful offload. Recommended to be set to `false` while performing early tests, but set to `true` once you are ready to delete documents and reduce the size of the database.
- OLDER_THAN_MONTHS: A number of months to specify the timeframe for offloading runbook executions. Only runbook executions older than the specified number of months are offloaded. If you set this value to `0` then all runbook executions that were created before today will be offloaded. You can set this parameter to `-1` and instead use the parameters AFTER and BEFORE if you need to have more granular control on the time period.
- AFTER: Only offload execution records that are started after this timestamp. You can specify a date like `2022-03-31` or a timestamp in the moment.js format, for example, `2022-03-31T12:59:59`. If you want to use this parameter, the parameter OLDER_THAN_MONTHS must be set to the empty string.
- BEFORE: Only offload execution records that are started before this timestamp. You can specify a date like `2022-04-04` or a timestamp in the moment.js format, for example, `2022-04-04T12:59:59`. If you want to use this parameter, the parameter OLDER_THAN_MONTHS must be set to the empty string.

1. One-time set up to create the script

1. Create an API key as described in Accessing APIs, section *Get access token by using your API key*, step *Generate your platform API key*.
2. If it does not exist already, create the SSH integration as described in Creating SSH integrations. You do not need to define a jumpserver and you do not need to copy the SSH key to any target system for the purpose of this procedure.
3. Load the sample runbooks as described in Load and reset example runbooks.
4. Switch to the **Actions** tab.
5. Select the action **Example: Reduce amount of data in runbook data stores** and click **Edit**.
6. Copy the content of the **Script** field to the clipboard.
7. Log in to the Linux system and change to the directory where you want the script to be stored.
8. Create a file called "offloadRunbookExecutions.sh" and paste the content of the clipboard into this file.
9. Make the file "offloadRunbookExecutions.sh" executable, for example, run the following command:

   ```
   chmod a+x offloadRunbookExecutions.sh
   ```

10. Create a file called "offload.config" and paste the following content into this file:

    ```
    export API="https://cpd-cp4waiops.apps.mycomp.com/aiops/api/story-manager/rba/v1"
    export APIKEY_NAME="<api_key_user_id>"
    export APIKEY_PW="<api_key_password>"
    export FOLDER=$(pwd)
    ```

```
export MODE=json
export DELETE=false
export OLDER_THAN_MONTHS=-1
export AFTER="2022-03-01"
export BEFORE="2022-04-13T12:00:00"
#export CURL_OPTIONS="-k"
```

11. Adjust the values of the environment variables as needed (see the variable descriptions listed earlier) and save the file.

2. Test the script

1. Run the following command to load the environment variables into the current shell environment:

   ```
   . ./offload.config
   ```

2. Run the script:

   ```
   ./offloadRunbookExecutions.sh
   ```

3. If the action fails and you see the error **`curl: \(60\) SSL certificate problem: self-signed certificate in certificate chain`**, you can either replace the IBM Netcool Operations Insight server certificate with a trusted certificate, or enable the environment variable **`CURL\_OPTIONS="-k"`** to ignore the certificate errors.

4. If the action fails and you see the following error:

   ```
   ARBD0420E: Could not fetch list of runbook instances:
   curl: (22) The requested URL returned error: 500 Internal Server Error
   ```

   Then reduce the length of the time interval for offloading execution records (for example, by increasing the value of OLDER_THAN_MONTHS) and try again.

5. Review the results that were created by the script. If needed adjust the environment variables and repeat the procedure until you are fine with the results.

3. Schedule the script

1. Convert this script command to the format that is expected by your scheduling tool, and set up a schedule to regularly offload the runbook data.

2. Make sure that the DELETE environment variable is set to true once you are finished with the testing of the script and the schedule, and when you are ready to delete the offloaded runbook execution instances from the database.

Offloading and deleting remaining action execution records

Once you have deleted the runbook execution records for a particular time frame you should also check if there are remaining action execution records (also called action instances) for that time frame, and delete them as well.

Step 1: Prepare and verify the API URL and the credentials Adjust the values of the environment variables as needed (see the variable descriptions listed earlier) and run the following commands:

```
export API="https://cpd-cp4waiops.apps.mycomp.com/aiops/api/story-manager/rba/v1"
export APIKEY_NAME="<api_key_user_id>"
export APIKEY_PW="<api_key_password>"
export CURL_AUTHENTICATION=$(echo -n "${APIKEY_NAME}:${APIKEY_PW}" | base64 -w 0 | echo "Authorization:
ZenApiKey $(cat -)")
export CURL_OPTIONS="-ks"
curl "${CURL_OPTIONS}" -H "${CURL_AUTHENTICATION}" "${API}/status"
```

The command should run without any authentication errors, and the output should look similar to this (for the purpose of this task, you can ignore the value of the "connection" property, in particular any potential "errors" and "warnings" within the respective properties):

```
{"rbs":0,"as":0,"db":0,"connection":{"AWX":0,"IMPACT":2,"SCRIPT":0,"GITHUB":2},"errors":[],"warnings":[]}
```

Step 2: Get the remaining action execution records Adjust the "to" time stamp in the following command and run it to retrieve a list of the records that were created up to that date, and store their IDs in an environment variable:

```
curl "${CURL_OPTIONS}" -H "${CURL_AUTHENTICATION}" "${API}/actioninstances?from=2010-01-01&to=2022-12-01" >
actionInstances.json
export ACTION_INST_IDS=`cat actionInstances.json | jq '.[]' | jq -r '.[]._actionInstanceId'`
```

The records in **`actionInstances.json`** do not contain the actual output of each action. If you want to preserve the output for each of the actions, run the following command:

```
for actionInstId in ${ACTION_INST_IDS}; do echo "Getting details for ${actionInstId}"; curlOutput=$(curl -X
GET "${CURL_OPTIONS}" -H "${CURL_AUTHENTICATION}" "${API}/actioninstances/${actionInstId}" >
```

```
${actionInstId}.json); if (test ${#curlOutput} -gt 0); then echo ${curlOutput}; fi; done
```

Store the each of these action execution record files as appropriate.

Step 3: Delete the remaining action execution records Run the following command to delete the records:

```
for actionInstId in ${ACTION_INST_IDS}; do echo "Deleting ${actionInstId}"; curlOutput=$(curl -X DELETE
"${CURL_OPTIONS}" -H "${CURL_AUTHENTICATION}" "${API}/actioninstances/${actionInstId}"); if (test
${#curlOutput} -gt 0); then echo ${curlOutput}; fi; done
```

Restricting the number of alerts returned by the data layer to the Alert Viewer

By default, the data layer returns all the alerts that match the filter in the Alert Viewer. If this has the potential to cause performance issues on the backend, you can restrict the number of alerts to be returned by the data layer.

Note: When increasing this limit an increase to CPU and memory resources may also be required.

Edit the **aiops-ui-configurations** ConfigMap with your required values. You can perform this task from the command line or the console UI.

Command line

1. Run the command:

   ```
   oc edit cm aiops-ui-configurations
   ```

2. Add the following line under the **data** section:

   ```
   IR_UI_MAX_ALERT_FETCH_LIMIT: "x"
   ```

   Where "x" equals the number of alerts that are returned by the data layer.

3. Save your changes to the ConfigMap file.

Red Hat OpenShift Container console

1. Log in to the Red Hat OpenShift Container console as a user with cluster administrator access.
2. From the navigation menu, click **Workloads > Config Maps**.
3. Search for **aiops-ui-configurations**.
4. Click **... > Edit Config Map**.
5. Add the following line under the **data** section:

   ```
   IR_UI_MAX_ALERT_FETCH_LIMIT: "x"
   ```

   Where "x" equals the number of alerts that are returned by the data layer.

6. Click **Submit** and wait for the **aiops-akora-ui pod** to restart.

Example

```
# Please edit the object below. Lines beginning with a '#' will be ignored,
# and an empty file will abort the edit. If an error occurs while saving this file will be
# reopened with the relevant failures.
#
apiVersion: v1
data:
  IR_UI_MAX_ALERT_FETCH_LIMIT: "5"
  cacertVersion: "41802278"
  prerequisiteCheck: Complete
  productVersion: 4.5.0
  zenVersion: 5.1.1
kind: ConfigMap
metadata:

```

A message on the Alert Viewer indicates when the list has been configured to limit the number of alerts displayed.

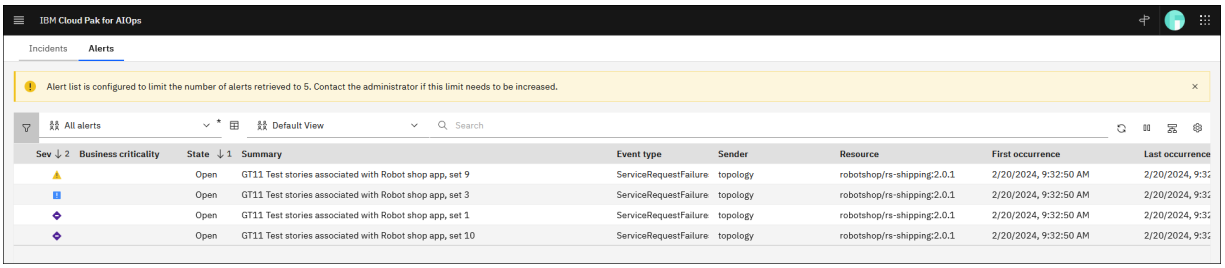

Figure. Alert Viewer

Disabling additional alert count queries from the Alert Viewer

You can disable alert count queries in the Alert Viewer in order to reduce the load on Postgres. The `IR_UI_ALERT_MAX_ROWS_ENABLED` environment variable is set to `true` by default. If disabled, the **Total matched** and **Total active** alert counts are not shown on the modal that is launched from the information icon at the bottom of the table.

Edit the `aiops-ui-configurations` configmap with your required value. You can perform this task from the command line or the console UI.

Command line

1. Run the command:

   ```
   oc edit cm aiops-ui-configurations
   ```

2. Add the following lines under **apiVersion: v1**:

   ```
   data:
     IR_UI_ALERT_MAX_ROWS_ENABLED: "false"
   ```

   Example (after adding):

   ```
   apiVersion: v1
   data:
     IR_UI_ALERT_MAX_ROWS_ENABLED: "false"
   kind: ConfigMap
   metadata:
   ```

3. Save your changes to the configmap file.

Red Hat OpenShift Container console

1. Log in to the Red Hat OpenShift Container console as a user with cluster administrator access.
2. From the navigation menu, click **Workloads > Config Maps**.
3. Search for `aiops-ui-configurations`.
4. Click **... > Edit Config Map**.
5. Add the following line under **apiVersion: v1**:

```
data:
   IR_UI_ALERT_MAX_ROWS_ENABLED: "false"
```

6. Click **Submit** and wait for the **aiops-akora-ui pod** to restart.

The alert count information in the Alert Viewer is now displayed without the **Total matched** and **Total active** alert counts.

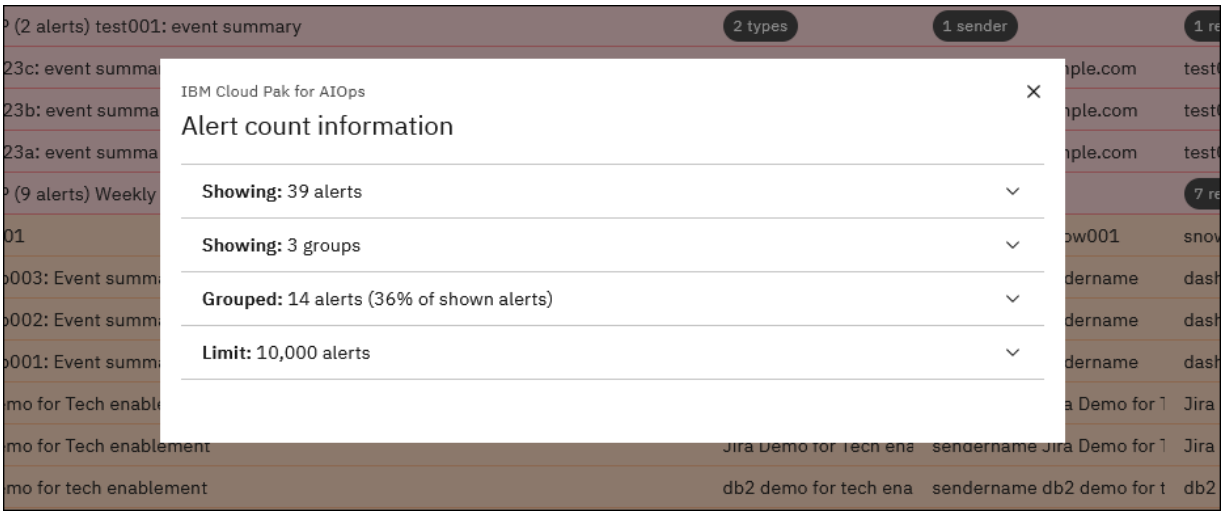

Figure. Alert count

Updating usage data collection preferences

To assist in the development of IBM Cloud Pak for AIOps, daily aggregated usage data is collected to analyse how IBM Cloud Pak for AIOps is used. The collection of usage data is enabled or disabled when you install or upgrade to IBM Cloud Pak for AIOps 4.7.1, but can be changed at any time.

This usage data is collected by the **cp4waiops-metricsprocessor** pod, and is sent to and stored in IBM controlled GDPR-compliant systems. The collection of usage data is enabled by default, but can be disabled. For transparency, the **cp4waiops-metricsprocessor** pod's logs will contain all of the information that is collected. The usage data that is collected is all numeric, or is about the deployment type and platform. It does not include email addresses, passwords, or specific details. Only the following data is collected:

- Current number of applications
- Current number of alerts (all severities aggregated)
- Current number of incidents (all priorities aggregated)
- Current number of policies (includes predefined and user created)
- Current number of runbooks executed since install
- Current number of integrations of each type (For example, ServiceNow, Instana, Falcon Logscale)
- Secure tunnel enablement: whether *connection* (which controls whether you can create a secure tunnel) is enabled in the *Installation* custom resource
- Deployment type: base deployment or extended deployment
- Deployment platform: Red Hat® OpenShift® Container Platform or Linux®

Disabling the collection of usage data

1. Set environment variables.

```
export CUSTOMER_NAME=<your company name>
export CUSTOMER_ICN=<your IBM Customer Number>
export CUSTOMER_ENVIRONMENT=<Set to `trial`, `poc`, or `production`>
export PROJECT_CP4AIOPS=<the project where IBM Cloud Pak for AIOps is deployed, usually cp4aiops>
```

2. Disable usage data collection.

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-
literal=customerName=${CUSTOMER_NAME} --from-literal=customerICN=${CUSTOMER_ICN} --from-
literal=environment=${CUSTOMER_ENVIRONMENT} --from-literal=enableCollection=false
```

3. Find the name of the metricsprocessor pod by running the following command:

```
oc get pods -n ${PROJECT_CP4AIOPS} | grep cp4waiops-metricsprocessor
```

Example output:

```
cp4waiops-metricsprocessor-f4dc776d-7pwlm                          1/1     Running     0
19h
```

4. Restart the metricsprocessor pod by running the following command:

   ```
   oc delete pod <metrics_processor_pod> -n ${PROJECT_CP4AIOPS}
   ```

   Where **<metrics_processor_pod>** is the pod returned by the previous step.

Enabling the collection of usage data

1. Set environment variables.

   ```
   export CUSTOMER_NAME=<your company name>
   export CUSTOMER_ICN=<your IBM Customer Number>
   export CUSTOMER_ENVIRONMENT=<Set to `trial`, `poc`, or `production`>
   ```

2. Configure the usage data with your customer details.

   ```
   oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-
   literal=customerName=${CUSTOMER_NAME} --from-literal=customerICN=${CUSTOMER_ICN} --from-
   literal=environment=${CUSTOMER_ENVIRONMENT}
   ```

3. If you have a firewall enabled, ensure that outbound traffic to https://api.segment.io is allowed.

4. Find the name of the metricsprocessor pod by running the following command:

   ```
   oc get pods -n ${PROJECT_CP4AIOPS} | grep cp4waiops-metricsprocessor
   ```

   Example output:

   ```
   cp4waiops-metricsprocessor-f4dc776d-7pwlm                          1/1     Running     0
   19h
   ```

5. Restart the metricsprocessor pod by running the following command:

   ```
   oc delete pod <metricsprocessor_pod> -n ${PROJECT_CP4AIOPS}
   ```

   Where **<metricsprocessor_pod>** is the pod returned by the previous step.

Clearing out topology data without reinstalling

You can clear all topology data without having to reinstall your system.

Before you begin

Ensure you have all the required administrator or management permissions to perform administration tasks.

Also ensure that you have the information specific to your deployment to hand, such as your specific release name prefix and namespace; (you will be setting these variables in step three, after stopping the observer jobs and backing up any required configuration settings).

About this task

To clear all topology data without having to reinstall your system, you perform the following sequence of steps:

1. Stop all observer jobs from running to ensure no new data is received until the old data has been removed.
2. Back up any configurations if required.
3. Set the environment variables manually. This will help with the pre- and post-validation of the topology and inventory databases.
4. Pre-validate the topology and inventory databases to confirm that the data to be removed is present.
5. Run the script to clean the topology and inventory databases.
6. Post-validate to confirm that the data has been removed from the topology and inventory databases.
7. Scale up the topology pods to restart the system and any configured observer jobs.

To clear topology data

1. Stop all observer jobs.

   a. Expand **Define**, click **Integrations**, click the **Manage observer jobs** tab, then click **Configure, schedule, and manage observer jobs**. The Observer jobs page is displayed.

   b. Ensure that no observer jobs are running or are scheduled to run.

2. Back up IBM Cloud Pak for AIOps configurations if required. For more information, see Backing up and restoring UI topology configuration data in the IBM Netcool Operations Insight documentation.

3. Set the required environment variables. These will be specific to your deployment.

   a. Set the release and namespace as required (as in the following examples):

```
export release=aiops
export NAMESPACE=cp4aiops
```

   b. Set the following variables:

```
export POSTGRES_PASS=$(oc get secret $release-topology-postgres-user -o jsonpath='{.data.password}' |
base64 -d)
export POSTGRES_USER=$(oc get secret $release-topology-postgres-user -o jsonpath='{.data.username}' |
base64 -d)
export INVENTORY_DB=$(oc get asmformation $release-topology -o
jsonpath='{.spec.helmValues.global.postgres.dbname}')

export INVENTORY_SCHEMA=$(oc get asmformation $release-topology -o
jsonpath='{.spec.helmValues.global.postgres.schema}')
export CASSANDRA_PASS=$(oc get secret $release-topology-cassandra-auth-secret -o
jsonpath='{.data.password}' | base64 -d)
export CASSANDRA_USER=$(oc get secret $release-topology-cassandra-auth-secret -o
jsonpath='{.data.username}' | base64 -d)
export installation=$(oc get installation.orchestrator.aiops.ibm.com -o jsonpath="
{.items[0].metadata.name}")
export POSTGRES_POD=$(oc get clusters.postgresql.k8s.enterprisedb.io $installation-edb-postgres --
namespace $NAMESPACE -o jsonpath="{.status['currentPrimary']}")
```

4. Pre-validate the topology and inventory databases to confirm the presence of the data to be cleared.

   a. Use the following command to verify that the topology database has the janusgraph keyspace:

```
oc exec $release-topology-cassandra-0 -- bash -c "echo 'SELECT * FROM system_schema.keyspaces;exit'
|cqlsh --ssl -u '$CASSANDRA_USER' -p '$CASSANDRA_PASS'"
```

   The following example output indicates that the janusgraph keyspace is present in the topology (Cassandra) database:

```
| keyspace_name | durable_writes | replication
|
| ------------- | -------------- | ------------------------------------------------------------------------
----------------- |
|         aiops |           True | {'class': 'org.apache.cassandra.locator.NetworkTopologyStrategy',
'datacenter1': '1'} |
|        x_in_y |           True | {'class': 'org.apache.cassandra.locator.NetworkTopologyStrategy',
'datacenter1': '1'} |
|    janusgraph |           True |   {'class': 'org.apache.cassandra.locator.SimpleStrategy',
'replication_factor': '1'} |
|   system_auth |           True |   {'class': 'org.apache.cassandra.locator.SimpleStrategy',
'replication_factor': '1'} |
```

   b. Use the following command to verify that the inventory database contains data (under types, edges and other tables).

```
oc exec -it $POSTGRES_POD -- /bin/bash -c 'export PGPASSWORD='$POSTGRES_PASS'; psql --host localhost --
username '$POSTGRES_USER' --dbname '$INVENTORY_DB' --command "select * from types"'
```

   The following example output shows that data is present in the inventory (postgres) database:

```
|  id |               type | description |
| --- | ------------------ | ----------- |
|   1 | undergroundStation |             |
|   2 |        railStation |             |
|   5 | interchangeStation |             |
|  31 |      completeGroup |             |
|  32 |                TFL |             |
| 550 |  waiopsApplication |             |
| 552 |             server |             |
| 553 |                 vm |             |
| 554 |           database |             |
```

5. Clear out the topology and inventory databases.

   Important: Make a note of the current scaling of the following core services that access the topology and search databases before you configure and run the script:

```
$release-topology-inventory
$release-topology-topology
$release-topology-layout
```

```
$release-topology-merge
$release-topology-status
```

The following command provides the current scaling of core services:

```
oc get pods --field-selector=status.phase=Running --no-headers=true --output=custom-
columns="CNAME:.metadata.ownerReferences[0].name" | grep $release-topology | uniq --count
```

Remember that the `$release` prefix for the topology services will be specific to your scenario, for example `aiops-`.

a. Scale down the core services which access the storage.

```
oc scale deploy $release-topology-inventory --replicas=0
oc scale deploy $release-topology-topology --replicas=0
oc scale deploy $release-topology-layout --replicas=0
oc scale deploy $release-topology-merge --replicas=0
oc scale deploy $release-topology-status --replicas=0
```

b. Drop the topology janusgraph keyspace.

```
oc exec $release-topology-cassandra-0 -- bash -c "echo 'DROP KEYSPACE janusgraph;exit' |cqlsh --ssl -u
'$CASSANDRA_USER' -p '$CASSANDRA_PASS'"
```

c. Finally, clear out the inventory data

```
oc exec -it $POSTGRES_POD -- /bin/bash -c 'export PGPASSWORD='$POSTGRES_PASS'; psql --host localhost --
username '$POSTGRES_USER' --dbname '$INVENTORY_DB' --command "CREATE FUNCTION
pg_temp.clear_inventory(inventory_schema text) RETURNS void AS \
\$\$ \
    DECLARE \
        statements CURSOR FOR \
        SELECT schemaname, tablename \
        FROM pg_tables \
        WHERE schemaname = FORMAT('\''%s'\'',inventory_schema) \
        AND NOT tablename IN ('\''flyway_schema_history'\'','\''spatial_ref_sys'\'' ); \
    BEGIN \
        FOR stmt IN statements LOOP \
            EXECUTE '\''TRUNCATE TABLE '\'' || string_agg(format('\''%I.%I'\'', stmt.schemaname,
stmt.tablename), '\'', '\'') || '\'' CASCADE;'\''; \
        END LOOP; \
    END; \
\$\$ \
LANGUAGE plpgsql;" --command "SELECT pg_temp.clear_inventory('\'''$INVENTORY_SCHEMA''\'');"'
```

6. Post-validate to confirm that the data has been removed from the topology and inventory databases.

   a. Use the following command to verify that the topology database **no longer** has the `janusgraph` keyspace:

   ```
   oc exec $release-topology-cassandra-0 -- bash -c "echo 'SELECT * FROM system_schema.keyspaces;exit'
   |cqlsh --ssl -u '$CASSANDRA_USER' -p '$CASSANDRA_PASS'"
   ```

   The following example output indicates that the janusgraph keyspace is **no longer** present in the topology (Cassandra) database:

   ```
   | keyspace_name | durable_writes | replication
   |
   | ------------- | -------------- | ------------------------------------------------------------------------
   ----------------- |
   |         aiops |           True | {'class': 'org.apache.cassandra.locator.NetworkTopologyStrategy',
   'datacenter1': '1'} |
   |        x_in_y |           True | {'class': 'org.apache.cassandra.locator.NetworkTopologyStrategy',
   'datacenter1': '1'} |
   |   system_auth |           True |   {'class': 'org.apache.cassandra.locator.SimpleStrategy',
   'replication_factor': '1'} |
   ```

   b. Use the following command to verify that the inventory database contains **no** data.

   ```
   oc exec -it $POSTGRES_POD -- /bin/bash -c 'export PGPASSWORD='$POSTGRES_PASS'; psql --host localhost --
   username '$POSTGRES_USER' --dbname aiops_topology --command "select * from types"'
   ```

   The following example output shows that **no** data is present in the inventory (postgres) database:

   ```
   | id | type | description |
   | -- | ---- | ----------- |

   (0 rows)
   ```

7. Scale up the pods to the same state as before you cleared out the data.

   Note: The number of replicas can be found using the command mentioned in the **Important** note in Step 5.

   ```
   oc scale deploy $release-topology-inventory --replicas=<number_of_replicas>
   oc scale deploy $release-topology-topology --replicas=<number_of_replicas>
   ```

```
oc scale deploy $release-topology-layout --replicas=<number_of_replicas>
oc scale deploy $release-topology-merge --replicas=<number_of_replicas>
oc scale deploy $release-topology-status --replicas=<number_of_replicas>
```

Setting the idle session timeout

You can adjust the idle session timeout for IBM Cloud Pak for AIOps in accordance with your security and compliance requirements. If a user leaves their session idle in a web browser for the specified length of time, the user is automatically logged out of the IBM Cloud Pak for AIOps console.

Before you begin

If you have an installation of IBM Cloud Pak for AIOps on Red Hat® OpenShift®, then you must have one of the following roles:

- Red Hat OpenShift cluster administrator.
- Red Hat OpenShift project administrator on the project (namespace) where IBM Cloud Pak for AIOps is installed.

About this task

By default, IBM Cloud Pak for AIOps logs users out of the Cloud Pak for AIOps console after 12 hours. You can edit the **product-configmap** to adjust the following session timeout settings:

- The length of time until a user's session expires (TOKEN_EXPIRY_TIME). When the user leaves their session idle for the specified length of time, the user is automatically logged out of the web client. The default is 12 hours.

  If you set **TOKEN_EXPIRY_TIME: "1"**, a user's session will expire after 1 hour of inactivity. If you set **TOKEN_EXPIRY_TIME: "0.5"**, a user's session will expire after 30 minutes of inactivity. You are recommended to set the value between 0.1 and 1.

- The length of time that a user has to refresh their session (TOKEN_REFRESH_PERIOD). The default is 12 hours. You are recommended to set the value between 1 and 24.

  If you set **TOKEN_REFRESH_PERIOD: "1"** and the user's session does not expire, the user's session is automatically refreshed during this 60 minute period. The session is extended based on the value that is set for the **TOKEN_EXPIRY_TIME** parameter. However, after the token refresh period passes, the user must log back into the web client when their current session expires.

  If you don't want to allow users to extend their sessions, set the value of the **TOKEN_REFRESH_PERIOD** parameter to a value less than the value of the **TOKEN_EXPIRY_TIME** parameter.

For example, the following configuration shows potential values for these settings:

```
TOKEN_EXPIRY_TIME: "0.5"
TOKEN_REFRESH_PERIOD: "2"
```

If a user starts work at 8 AM and logs in to the console, the user must be active in the web session within 30 minutes for their token to be refreshed. If the user stops using the Cloud Pak for AIOps console at 8:10 and attempts to use the console again until 8:41, the user must re-authenticate to the console because their session expired.

However, if the user remains active in their session and their token refreshes at 9:59 AM, their session lasts until 10:29 AM. When the session expires at 10:29, the user must re-authenticate to the console because the token refresh period expired.

Procedure

1. Change to the project where IBM Cloud Pak for AIOps is deployed:

   If you have an installation of IBM Cloud Pak for AIOps on Red Hat OpenShift, log in to your cluster and then run the following command:

   ```
   oc project <project>
   ```

   Where **<project>** is the namespace (project) that IBM Cloud Pak for AIOps is deployed in.

   If you have an installation of IBM Cloud Pak for AIOps on Linux, log in to a control plane node and then run the following command:

   ```
   oc project aiops
   ```

2. Run the following command to edit the **product-configmap** file:

   ```
   oc edit configmap product-configmap
   ```

3. Add an entry for the **TOKEN_EXPIRY_TIME** parameter to the data section of the **product-configmap** file. For example:

```
data:
  ...
  TOKEN_EXPIRY_TIME: "1"
  ...
```

4. Add an entry for the **TOKEN_REFRESH_PERIOD** parameter to the data section of the **product-configmap** file. For example:

```
data:
  ...
  TOKEN_REFRESH_PERIOD: "1"
  ...
```

5. Save your changes to the **product-configmap** file.
6. Restart the **usermgmt** pods for the changes to take effect. To restart the pods, run the following command:

```
oc delete pod -l component=usermgmt
```

Configuring probable cause

The probable cause capability identifies the alert with the greatest probability of being the cause of the alert group, by using a combination of text classification and analysis of the topological information within the alerts.

You can configure how the system classifies alerts and performs probable cause scoring by changing the default values in the API.

Changing default settings of probable cause

Edit MIME Customization APIs in Swagger to change settings.

- Add keywords
- Update keywords
- Set severity
- Update severity
- Other

Next steps

Access Mime Customization APIs with your Platform UI authentication token or API keys. Include the Platform UI access token in the authorization header of your API calls.

For more information on the available API and related Swagger documentation, see APIs.

Nonproduction features (Technology preview)

IBM Cloud Pak® for AIOps can include components and features for nonproduction use only as technology previews. As licensee of IBM Cloud Pak for AIOps, you can use these components and features only as part of your internal development and test environment for internal nonproduction use. Components and features that are available for nonproduction use are not to be relied on in a production environment.

Features available for nonproduction use:

- Visualizing analytics with IBM Cognos Analytics

  IBM Cloud Pak for AIOps supports an integration with IBM Cognos® Analytics. This integration provides you with additional tools to create custom dashboards and reports to visualize and analyze your IBM Cloud Pak for AIOps data. When you set up this integration, you can open IBM Cognos Analytics from the Cloud Pak for AIOps console and begin using IBM Cognos Analytics dashboards to build visualizations of your IBM Cloud Pak for AIOps data, such as alert and topology data.

- Incident (Story) prioritization from persistence analysis and golden signals extraction

  Incident prioritization uses the golden signal policy and the alert suppression policy to filter out incidents when the observed alerts contain a golden signal and are not suppressed. The policy suppresses alerts that do not need attention.

- Deploy to single ROSA cluster configured across multiple AWS Zones

You can install IBM Cloud Pak for AIOps on Red Hat OpenShift Service on AWS (ROSA). When you are installing, you can follow any of the main installation options for installing IBM Cloud Pak® for AIOps, but for installing on Red Hat OpenShift Service on AWS, you do need to complete some additional and replacement steps. For more information, see Installing IBM Cloud Pak for AIOps on Red Hat OpenShift Service on AWS (ROSA).

- Multi-zone high availability and disaster recovery (HADR)

  Install IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HADR) for better resilience. IBM Cloud Pak for AIOps is starting to implement multi-zone availability, as provided by the Red Hat OpenShift Container Platform.

  Installing on a cluster that spans multiple availability zones improves resiliency by enabling the distribution of services across nodes in different zones in the cluster. If a zone becomes unavailable, then the remaining services in the other zones are still able to service requests, and disruption is lessened.

- New data collection functionality for Dynatrace integration

  This new Dynatrace integration allows for the collection of both metric and event data together, which is new as previously you could only collection metric data when setting up a Dynatrace integration. This new Dynatrace integration does not allow for historic data collection, and the following should be adhered to if you select to run Dynatrace in remote mode:

  1. Podman must be installed to execute the remote deployment script with a recommended minimum version of 4.4.1.
  2. Read and write access are required for the folder where the remote deployment script will be executed and the script also must have execution permissions in order to be run.
  3. No more than one remote deployment script should be executed per host.

- Metric anomaly detection shape correlation algorithm

  The shape correlation algorithm establishes correlation between metrics of similar shape or pattern. To enable this feature, create a scope-based policy on the **`alert.sender.sourceId`** field.

Operator cluster service versions (CSVs)

Learn about the operator cluster service versions (CSVs) that are installed for IBM Cloud Pak® for AIOps.

The following table lists the CSVs that are installed for IBM Cloud Pak for AIOps.

Table 1. Operators

NAME	DISPLAY	VERSION
aimanager-operator.v4.7.1	IBM AIOps AI Manager	4.7.1
aiopsedge-operator.v4.7.1	IBM AIOps Edge	4.7.1
asm-operator.v4.7.1	IBM Netcool Agile Service Manager	4.7.1
cloud-native-postgresql.v1.18.13	EDB Postgres for Kubernetes	1.18.13
ibm-aiops-ir-ai.v4.7.1	IBM Watson AIOps Issue Resolution AI & Analytics	4.7.1
ibm-aiops-ir-core.v4.7.1	IBM Watson AIOps Issue Resolution Core	4.7.1
ibm-aiops-ir-lifecycle.v4.7.1	IBM Cloud Pak for Watson AIOps Lifecycle	4.7.1
ibm-aiops-orchestrator.v4.7.1	IBM Cloud Pak for AIOps	4.7.1
ibm-appconnect.v12.3.0	IBM App Connect	12.3.0
ibm-automation-elastic.v1.3.16	IBM Elastic	1.3.16
ibm-cert-manager-operator.v4.2.9	IBM Cert Manager	4.2.9
ibm-common-service-operator.v4.6.7	IBM Cloud Pak foundational services	4.6.7
ibm-commonui-operator.v4.4.6	Ibm Common UI	4.4.6
ibm-events-operator.v5.0.1	IBM Events Operator	5.0.1
ibm-iam-operator.v4.5.6	IBM IM Operator	4.5.6
ibm-opencontent-flink.v2.0.5	IBM OpenContent Flink Operator	2.0.5
ibm-redis-cp.v1.2.2	ibm-redis-cp-controller	1.2.2
ibm-secure-tunnel-operator.v4.7.1	IBM Secure Tunnel	4.7.1
ibm-watson-aiops-ui-operator.v4.7.1	IBM AIOps UI	4.7.1

NAME	DISPLAY	VERSION
ibm-zen-operator.v5.1.9	IBM Zen Service	5.1.9
operand-deployment-lifecycle-manager.v4.3.6	Operand Deployment Lifecycle Manager	4.3.6

Note: Deployments of IBM Cloud Pak for AIOps on Linux do not have IBM App Connect, IBM Elastic, or IBM Secure Tunnel. Deployments of IBM Cloud Pak for AIOps on Linux also have:

Table 2. Additional operators for deployments of IBM Cloud Pak for AIOps on Linux

NAME	DISPLAY	VERSION
ibm-elasticsearch-operator.v1.1.2346	IBM OpenContent Elasticsearch	1.1.2346

You can view a list of CSVs and subscriptions by running the following commands:

```
oc get csv
oc get sub
```

Permissions (IBM Cloud Pak for AIOps)

Alert and Event schemas

See the following tables to understand Cloud Pak for AIOps alert and event properties.

Cloud Pak for AIOps Alert schema

An alert is a mutable record of something that has happened over a certain period of time. It indicates an anomalous condition.

Cloud Pak for AIOps alert property	Description	Example
id	A system-generated unique id for the alert.	1a2a6787-59ad-4acd-bd0d-46c1ddfd8e06
state	The current state of this alert.	Open
eventCount	The count of events that have contributed to this alert.	2
acknowledged	Flag indicating alert acknowledgement.	false
team	Team with responsibility for the alert.	Db2 admin group
owner	Individual with responsibility for the alert.	user123

Cloud Pak for AIOps alert property	Description	Example
deduplicationKey	The key that uniquely identifies the anomalous condition that this alert represents.	{hostname=users-db.myapp.example.com, name=users-db.myapp.example.com, service=users-db.myapp.example.com, type=Service}-High query timeout count:++:Database query timeout-
signature	An id which uniquely identifies an anomalous condition on a resource. This may be used to identify historic alerts which refer to the same condition on the same resource.	{hostname=users-db.myapp.example.com, name=users-db.myapp.example.com, service=users-db.myapp.example.com, type=Service}-High query timeout count:++:Database query timeout-
firstOccurrenceTime	The time at which the anomalous condition was first detected, in millisecond granularity. Format: yyyy-mm-ddThh:mm:ss.sssZ (ISO8601)	2022-06-14 3:14:10.862
lastOccurrenceTime	The time at which the anomalous condition was last detected, in millisecond granularity. Format: yyyy-mm-ddThh:mm:ss.sssZ (ISO8601)	2022-06-14 3:14:10.862
lastStateChangeTime	The time in millisecond granularity for which the alert was last updated.	2022-06-14 3:14:10.862
summary	A human-readable description of the event.	Fan failure detected on server1.example.com.
langId	ISO 639-3 encoding if not specifed assumption is eng.	eng
severity	Indicates the alert severity level, which indicates how the perceived capability of the managed object has been affected.	5 - Major
sender	Identifies the resource which sent this alert. This may be the resource that is the subject of the event, or it may be some external system which is monitoring the subject.	{"service":"DemoMon","name":"hyper.example.com","type":"Netcool/OMNIbus"}
resource	Identifies the resource that is the subject of this alert. This is made up of multiple fields that describe the resource. There are a set of standard fields which should be used where applicable, but additional fields may be set. **Tip:** If (when querying the topology service APIs for resource data) the optional parameter **`_include_status_severity`** is set to **`true`**, the **`_hasStatus`** field will reflect the maximum and most severe severity of all of the status records related to the resource, for example **`"_hasStatus": "critical"`**.	{"service":"hyper.example.com","name":"hyper.example.com","hostname":"hyper.example.com", "type":"Service"}
expirySeconds	The number of seconds before the event should automatically expire. A value of zero indicates that there is no expiration.	0

Cloud Pak for AIOps alert property	Description	Example
links	An optional array of links to external systems which provide addition information or control over the event, or its subject. This may include a management console for the subject resource, or a page containing further event information from the source monitoring system. Each link should be in the form of a fully qualified URL.	[{"url":"`https://fan-controller.example.com/?fanId=1234`","linkType": "webpage","name":"management-console", "description":"Fan controller management console"}]
details	Additional properties that describe the alert. **Note:** You can include custom fields in the `details` object. Their values must be of type string.	{"additionalProp1":"string","additionalProp2":"string", "additionalProp3":"string"}
insights	An array of insights associated with the alert with one or more other entities or groupings.	insights.topology, insights.runbook, insights.scopeGroup
relatedIncidentIds	The set of incident id's that this alert is a member of either as a trigger or related context.	["related-incident-2","related-incident-1","related-incident-3"]

Cloud Pak for AIOps Event schema

An event is an immutable record of something happening at a certain time point. It may or may not indicate an anomalous condition.

Cloud Pak for AIOps event property	Description	Example
id	A system-generated unique id for the event.	1a2a6787-59ad-4acd-bd0d-46c1ddfd8e06
occurrenceTime	The time at which this event occurred.	6/15/2022, 3:14:10 PM
summary	A human-readable description of the event.	Fan failure detected on server1.example.com.
severity	Indicates the event severity level, which indicates how the perceived capability of the managed object has been affected.	5 - Major
sender	Identifies the resource which sent this event. This may be the resource that is the subject of the event, or it may be some external system which is monitoring the subject.	{"service":"DemoMon", "name": "hyper.example.com","type":"Netcool/OMNIbus"}
resource	Identifies the resource that is the subject of this event. This is made up of multiple fields that describe the resource. There are a set of standard fields which should be used where applicable, but additional fields may be set. **Tip:** If (when querying the topology service APIs for resource data) the optional parameter `_include_status_severity` is set to `true`, the `_hasStatus` field will reflect the maximum and most severe severity of all of the status records related to the resource, for example `"_hasStatus": "critical"`.	{"service":"hyper.example.com","name": "hyper.example.com","hostname":"hyper.example.com", "type":"Service"} . For additional fields in property, see Resource property.

Cloud Pak for AIOps event property	Description	Example
expirySeconds	The number of seconds before the event should automatically expire. A value of zero indicates that there is no expiration.	0
links	An optional array of links to external systems which provide addition information or control over the event, or its subject. This may include a management console for the subject resource, or a page containing further event information from the source monitoring system. Each link should be in the form of a fully qualified URL.	[{"url":"`https://fan-controller.example.com/?fanId=1234`","linkType": "webpage","name":"management-console", "description":"Fan controller management console"}] . For additional fields in property, see Links property.
details	Additional properties that describe the event. **Note:** You can include custom fields in the `details` object. Their values must be of type string.	{"additionalProp1":"string","additionalProp2": "string", "additionalProp3":"string"}
insights	An array of insights associated with the event with one or more other entities or groupings.	insights.topology, insights.runbook, insights.scopeGroup. . For additional fields in property, see Insights property.
type	Values in an object that indicate the type of an event, such as a problem event or a resolution event, and the classification of an event.	{ "classification":":++:CEASelfMonitoring", "eventType":"problem"}. For additional fields in property, see EventType properties.

Alerts and Events schema fields

On this page, find fields that can be included in an Event or Alert schema in IBM Cloud Pak for AIOps for these properties:

- EventType
- Insights
- Links
- Resource

Note: format type used is Open API v3 definition.

EventType property schema

```
EventType:
      description: >
        The classification of the event, i.e. a description of what happened.
      type: object
      properties:
        eventType:
          description: >
            String description of whether the event is a problem
            or resolution event.
          type: string
          enum:
            - problem
            - resolution
          default: problem
        classification:
          description: >
            Description of the type of the event. E.g. Utilization, System
            status, Threshold breach
```

```
          type: string
          example: Utilization
        condition:
          description: >
            The condition/status or threshold causing the event. E.g. Down, 95%,
            Unavailable
          type: string
          example: "> 30 seconds"
```

Insights property schema

```
Insight:
      description: >
        Represents an insight reference to one or more other entities provided
        by a specified source that is related to associated element.
      type: object
      properties:
        id:
          description: >
            The unique identifier for this specific relationship, used to
            identify other related entities. Entities with the same insight
            id will participate in the same insight (i.e. this may act as a
            correlation key).
          type: string
          example: 98aa5f81-7da7-4063-bd66-dccaf59097d1
        type:
          description: The type of insight being described
          type: string
          example: ibm.com/causal-alert-relationship
        source:
          description: The source of the insight information
          type: string
          example: ibm.com/causal-correlation/temporal
        details:
          description: >
            Additional details about this insight. The schema of this object
            depends on the insight type.
          type: object
          $ref: "#/components/schemas/InsightDetails"

    AssociatedChange:
      type: object
      properties:
        link:
          type: string
          description: The URL to the associated change in source system.

    Conversation:
      type: object
      properties:
        link:
          type: string
          description: The URL to the conversation in source system.

    Grouping:
      type: object
      properties:
        policyId:
          type: string
          description: The id of the policy that creates the grouping.
        groupDetails:
          type: object
          description: >
            Details or links on group and/or to explain the reasons for the
            grouping.
    Runbook:
      type: object
      additionalProperties: false
      required:
        - policyId
        - runbookId
        - isAutomated
      properties:
        policyId:
          type: string
          description: The id of the policy that connected this insight.
        runbookId:
          type: string
          format: uuid
          description: The ID of the runbook
        runbookVersion:
          type: integer
```

```
          minimum: 1
          description: Optional. Defines whether a fixed version of a runbook should be linked. If, not
specified latest version is used.
        order:
          type: integer
          minimum: 1
          description: Optional. Order for runbook actions. Defines in which order runbooks should be
executed.
        isAutomated:
          type: boolean
          description: Defines whether or not the connected Runbook will be automatically executed, once the
policy matches.
        mappings:
          type: array
          description: In order to execute a runbook all required runbook parameters need to be filled out.
If the incident wants to define the values based on the policy or on its own attributes a suitable mapping
has to be created. This is required if automatically triggered execution is desired.
          items:
            type: object
            additionalProperties: false
            properties:
              mappingType:
                type: string
                description: Choose how a parameter is mapped. 'parameter' means using a field/property from
the Incident. 'fixed' means the same value will always be used. 'useDefault' will use the default from the
runbook. 'runtime' leave entry up to the operator.
                enum:
                  - parameter
                  - fixed
                  - useDefault
                  - runtime
              runbookParameterName:
                type: string
                description: The name of the runbook parameter as valued is mapped to.
              parameterValue:
                type: string
                description: The value put into the runbook for the parameter. Depending on the
'mappingType' this value is optional (useDefault), represents the name of an incident parameter (parameter)
or is the value to be put in (fixed).

    Seasonality:
      type: object
      properties:
        policyId:
          type: string
          description: >
            The id of the policy that relates to the seasonality insight.
        seasonalDetails:
          type: object
          description: >
            Details or links on seasonality and/or to explain the reasons for
            the grouping.
    SimiliarIncident:
      type: object
      properties:
        incidentid:
          type: string
          description: id of incident that it related to
        link:
          type: string
          description: The URL to the incident in source system.
        distance:
          description: this should be a double but open API does not seem to like it  :-(
          type: integer

    SimilarIncidents:
      description: >
        Represents a list of similar historical tickets, based on query
        submitted to the service. It also includes a list of recommended
        actions that are extracted from resolutions, which can be highlighted
        with help of their offset information.
      type: object
      properties:
        similar_incidents:
          description: The list of similar incients for the query.
          type: array
          items:
            $ref: "./similar_incidents.schema.yaml#/components/schemas/SimilarIncidentItem"
        recommended_actions:
          description: The list of extracted actions from resolutions in related incidents.
          type: array
          items:
```

```
            $ref: "./similar_incidents.schema.yaml#/components/schemas/RecommendedActionItem"

    AlertResolutions:
      description: Represents a list of resolution links for current alert.
      type: object
      properties:
        shortDescription:
          type: string
          description: Short description of the log anomaly alert.
        description:
          type: string
          description: Description about the current log anomaly alert.
        category:
          type: string
          description: Detected error category.
        subCategory:
          type: string
          description: Detected error sub category.
        resolutionLinks:
          type: array
          description: A list of resolution url links for current alert.
          items:
            type: object
            properties:
              url:
                type: string
                description: URL link for the resolution.
              title:
                type: string
                description: Title for the resolution.
              content:
                type: string
                description: Content excerpt for the resolution.

    AssociatedAlertTemplates:
      description: >
        Represents the error template info for explainable purpose.
      type: object
      properties:
        error_template_list:
          type: array
          items:
            type: string
          description: A list of error template
        error_count_vector:
          type: array
          items:
            type: integer
          description: Count vector corresponding to error template list.
        significant_message_code:
          type: string
          description: Message code for the significant error template.
        type_window:
          type: string
          description: Indicates the window type, e.g., "liberty_twas"

    TopologicalGroup:
      description: >
        Signifies that one of the resources that this entity pertains to is a member
        of a resource group. The id of the insight is the id of the resource group
        within the topology store.
      type: object
      properties:
        name:
          type: string
          description: Human readable name of the resource group
        tags:
          description: A list of any tags assigned to the resource group
          type: array
          items:
            type: string
        entityTypes:
          description: >
            An array of group types that pertain to this group, ex. AiopsApplication which
            signifies this resource group represents an application.
          type: array
          items:
            type: string

    TopologicalResource:
      description: >
        Signifies that this entity pertains to a specific resource within the topology.
```

```
      The id of this insight will be set to the unique id of the resource within the topology.
    type: object
    properties:
      name:
        type: string
        description: Human readable name of the resource
      compositeOfIds:
        type: string
        description: >
          If this resource is a composite resource, contains a comma
          separated list of id's of composed resources.
      compositeId:
        type: string
        description: id of the compositeId

  ProbableCauseRanking:
    type: object
    description: the ranking of alerts in the group
    properties:
      id:
        type: string
        description: in the alert it is the correlationId or the eventId if in the incident
      rank:
        type: integer
        description: the rank of the alert

  IncidentTopology:
    type: object
    description: >
      details of the group id where incident topology is stored.  The incident topology is
      generated by probable cause component
    properties:
      id:
        type: string
        description: asm group id
      time:
        type: integer
        description: time in ms when the last resource in the asm group was added

  Union:
    type: object
    description: >
      Represents a union of insights of a particular type across entities. The
      union is uniquely identified by the id field of the insight.
    properties:
      subsumedUnions:
        type: array
        description: >
          An array of ids of previous union insights which were subsumed by
          this one, due to a new entity occurring that joined them.
        items:
          type: string
          description: The id of a subsumed union insight

  ProposedIncident:
    type: object
    description: >
      Represent a suggested incident to create for this alert.
    properties:
      policyId:
        type: string
        description: The id of the policy that proposes this incident.
      delay:
        type: integer
        description: Suggested hold-off delay in seconds before creating the incident.

  ChatOpsIntegrators:
    type: object
    description: >
      An array of configured integrators for a given incident to hold integrator specific details.
    properties:
      id:
        type: string
        description: Unique id for this integrator
      channel_name:
        type: string

          type: string
          example: Dallas 10
        accessScope:
          type: string
          description: The project or namespace the resource is part of
          example: default
        connectionId:
          type: string
          description: >-
            Configuration unique identifier of the integration this event
            came from.
          example: 'f5aa7fa9-92eb-4bec-942c-37eb3e3e9601'
```

Resource schemas

For more information about IBM Cloud Pak® for AIOps resource properties, see the following table.

Table. Resource schemas

Cloud Pak for AIOps resource property	Description	Type	Example
type	The type of the resource	string	host
name	The name of the resource	string	myhost.example.com
sourceId	The ID that the resource is known by in the source system	string	`7045b61d-e59c-4270-b525-545d55ecd06e`
hostname	The hostname of the resource	string	myhost.example.com
ipAddress	The IP address of the resource	string	9.123.123.1
service	The name of the service that the resource is serving	string	mobile-app
port	The port that is the subject of this event	string or integer	`ssh` or `22`
interface	The interface that is the subject of this event	string	eth0
application	The application that is the subject of this event	string	mobile-app-1
controller	The controller that is the subject of this event	string	controller1
component	The component that is the subject of this event	string	database
cluster	The cluster that is the subject of this event	string	staging-cluster
location	The location of the resource	string	Dallas 10
accessScope	The project or namespace that the resource is part of	string	default
connectionId	The unique identifier of the integration that this event came from	string	`f5aa7fa9-92eb-4bec-942c-37eb3e3e9601`
scopeId	The scope identifier value for this event from the originating system	string	myhost.example.com:location01

You can also define more resource properties for resources that are not included in the table. Added properties with valid JSON are stored and available, but special knowledge or handling of them is not included.

EventType schemas

EventType schemas indicate whether an event is a problem or a resolution and how it is classified. For more information about IBM Cloud Pak® for AIOps EventType properties, see the following table.

Cloud Pak for AIOps resource property	Description	Type	Example
eventType	Describes whether the event is a problem or resolution event. The only possible values that can be set are `problem` or `resolution`.	string	`problem`, `resolution`
classification	Describes the type of the event. This property is used to determine the golden signals for an alert.	string	`system status`, `threshold breach`, `utilization`
condition	Provides context to the type of the event and states the condition, status, or threshold that caused the event.	string	`> 30 seconds`, `95%`, `Down`, `Unavailable`

Normalized Mapping Rules

To help you map event data from incoming data sources review the following event schemas and samples.

- Kafka integration normalized event schema
  - Normalized PagerDuty events sample
  - Normalized IBM Netcool Operations Insight events sample
- PagerDuty normalized mapping rules
  - Sample PagerDuty event
- IBM Netcool Operations Insight normalized mapping rules
  - Sample IBM Netcool Operations Insight event

IBM Cloud Pak for AIOps troubleshooting

Learn how to isolate and resolve problems with IBM Cloud Pak® for AIOps.

Verify that your issues are not related to operating system requirements, such as disk, memory, and CPU capacities. For more information, see Planning.

Additionally, you can see whether the problem is documented in Known issues and limitations.

To potentially avoid problems, run routine health checks to analyze your system for potential issues. For more information about health check options for IBM Cloud Pak for AIOps, see Health checks and monitoring.

If you need direct help from IBM Support, see the Support.

Troubleshooting topics

- Install and upgrade
- Clusters and nodes
- Integrations
- AI model management
- ChatOps
- Topology
- Troubleshooting Identity Management (IM) issues
- Troubleshooting certificates
- Secure Tunnel
- Alert management
- Runbook Automation
- Infrastructure Automation

Troubleshooting installation and upgrade

Learn how to isolate and resolve problems with installing and upgrading IBM Cloud Pak for AIOps.

Known issues and limitations

In addition to the common problems and solutions that are listed, review the installation related known issues for potential issues that you might encounter during installation. For more information, see Known issues and limitations.

Troubleshooting tips

- General troubleshooting tips (Console)
- General troubleshooting tips (CLI)
- Troubleshooting storage
- Recovering IBM Cloud Pak for AIOps after a cluster restart

Note: If you have an aborted or stalled installation, uninstall any installed or partially installed components and restart the installation. For more information about uninstalling, see the following topics:

- Uninstalling IBM Cloud Pak for AIOps on Linux
- Uninstalling IBM Cloud Pak for AIOps on OpenShift

Installation issues

- Installation fails to proceed when creating the IBM Cloud Pak for AIOps custom resource
- The AI manager operator does not progress past `Reconciling`, and the Cassandra setup pod is stuck
- "Application is not available" message is displayed intermittently
- Installation on Linux fails with network connectivity errors when using `aiopsctl` to install on vSphere VMs
- Installation on Linux: deployment is unstable after cluster restart
- Installation on Linux: unable to log in to IBM Cloud Pak for AIOps

Upgrade issues

- After upgrade, policies do not process alerts due to problem with the `aiops-ir-lifecycle-create-policies-job`
- After upgrade, a metric integration goes into a failed state
- After upgrade, alerts are not visible in the UI
- Navigation menu items disappear after an upgrade
- Upgrade does not complete because the lifecycletrigger component is stuck

Issues common to installation and upgrade

- Offline install or upgrade throws 'invalid character' error
- Offline install or upgrade stuck because the 'oc ibm-pak generate mirror-manifests' command fails with 'no space left on device'

General troubleshooting

General troubleshooting tips (Console)

1. From the Red Hat® OpenShift® console, go to **Workloads** > **Pods**.
2. Select the project that IBM Cloud Pak for AIOps is installed in from the drop-down menu to view the status of all the pods in this project.
3. If you want to see the status and details for one of the pods, click the pod that you want to investigate.
4. If you want to see the logs for the pod, click **Logs**.

General troubleshooting tips (CLI)

- To find out the status of all the pods in a project, run the following command:

  ```
  oc get pods -n <project>
  ```

  Where **<project>** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.

- To see the status of a particular pod, run the following command:

  ```
  oc get pods | grep <pod_name>
  ```

  Where **<pod_name>** is the pod that you want to see status for.

- To see a pod's logs, run the following command:

  ```
  oc logs -f <pod_name> -n <project>
  ```

  Where

  - **<pod_name>** is the pod that you want to see status for.
  - **<project>** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.

Troubleshooting storage

Storage that is associated with persistent volumes claims (PVCs) reaches capacity. This issue can occur as storage requests and resources fluctuate over time.

Solution: If storage fills up, increase the size of the PVC. For more information about increasing the size of a PVC, see Storage class requirements.

Recovering IBM Cloud Pak for AIOps after a cluster restart

After a Red Hat® OpenShift® Container Platform cluster restart, your IBM Cloud Pak for AIOps deployment has not come up successfully.

Use the following steps to help you to identify any problems.

1. Run the following command and then check that all of the OpenShift nodes come back up, and that they all report a *STATUS* of **`Ready`**.

   ```
   oc get nodes
   ```

   If all of the OpenShift nodes have not come back up, then see the *Updating clusters* and *Troubleshooting* sections in the OpenShift documentation for guidance.

2. Run the following command and then check that the IBM Cloud Pak for AIOps pods all have a *STATUS* OF **`Running`** or **`Completed`**.

   ```
   oc get pods -n <project>
   ```

   Where **`<project>`** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.

3. Check the logs of any pods that did not report a *STATUS* of **`Running`** or **`Completed`** in steps 2 and 3 to see whether you can identify a cause.

   ```
   oc logs -f <failed_pod_name> -n <project>
   ```

   Where

   - **`<project>`** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.
   - **`<failed_pod_name>`** is a failed pod name, as returned in steps 2 and 3.

Solution: Restart any failed pods with the following command:

```
oc delete pod <failed_pod_name> -n <project>
```

Where

- **`<project>`** is the project (namespace) where IBM Cloud Pak for AIOps is deployed.
- **`<failed_pod_name>`** is the pod name as returned in steps 2 and 3.

Troubleshooting installation

Installation not proceeding after creating the IBM Cloud Pak for AIOps custom resource

When you are installing, the installation is not proceeding as expected after you create an instance of the IBM Cloud Pak for AIOps custom resource. For instance, after you create the instance, the installation process appears to be stalled, however no pods in the namespace and cluster display show errors.

This stalling of the installation process can be due to an issue with the Operator Lifecycle Manager (OLM), which causes the expected ClusterServiceVersion (CSV) for some operator subscriptions to not be found. For example, installPlan instances for the **`aimanager-operator`**, **`connector-utilities-operator`**, and other operators can be found, but without a reference to the required ClusterServiceVersion (CSV) YAML. While the operators can be created within your defined namespace, if the ClusterServiceVersion (CSV) cannot be found, the operators cannot be managed. If this issue occurs, the overall installation cannot proceed correctly.

Solution: Delete any operator subscription that does not have an associated ClusterServiceVersion (CSV) YAML and has an unresolved subscription. The installation process should re-create the associated operator and generate a new installPlan. If a new installPlan is not generated, repeat the process to delete the operator subscription and try again.

The AI manager operator does not progress past `Reconciling`, and the Cassandra setup pod is stuck

When installing, the AI Manager operator remains in **Phase: Reconciling**. The **`aiops-ir-analytics-cassandra-setup`** pod is in Crashloopbackoff state, and its log has the following error:

```
ERROR [2023-06-13 09:57:44,010] com.ibm.itsm.analytics.metric.service.cassandra.SessionManager: Cassandra not available.
```

Solution: Use the following steps to reset the Cassandra admin password, and delete the **`aiops-ir-analytics-cassandra-setup`** and **`aiops-ir-core-archiving-setup`** jobs.

1. Run the following command to switch to your IBM Cloud Pak for AIOps project.

```
oc project <project>
```

Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deploying in.

2. Reset the Cassandra admin password.

```
oc rsh aiops-topology-cassandra-0 bash -c 'python3 -u /opt/ibm/change-superuser.pyc --initial --user
admin --password $(cat /opt/ibm/cassandra_auth/password) --replication-factor
$CASSANDRA_AUTH_REPLICATION_FACTOR'
```

3. Delete the **aiops-ir-analytics-cassandra-setup** job, if it does not own any pods.

    1. Check if there are any pods belonging to the **aiops-ir-analytics-cassandra-setup** job.

    ```
    oc get pod -l app.kubernetes.io/managed-by=aiops-analytics-
    operator,app.kubernetes.io/component=cassandra-setup
    ```

    2. If no pods are returned, then delete the **aiops-ir-analytics-cassandra-setup** job.

    ```
    oc delete job -l app.kubernetes.io/managed-by=aiops-analytics-
    operator,app.kubernetes.io/component=cassandra-setup
    ```

4. Delete the **aiops-ir-core-archiving-setup** job, if it does not own any pods.

    1. Check if there are any pods belonging to the **aiops-ir-core-archiving-setup** job.

    ```
    oc get pod -l app.kubernetes.io/managed-by=ir-core-operator,app.kubernetes.io/component=archiving-
    setup
    ```

    2. If no pods are returned, then delete the **aiops-ir-core-archiving-setup** job.

    ```
    oc delete job -l app.kubernetes.io/managed-by=ir-core-
    operator,app.kubernetes.io/component=archiving-setup
    ```

"Application is not available" message is displayed intermittently.

This is caused by a defect in some versions of Red Hat OpenShift. For more information, see OpenShift 4 - Intermittent 503 from all routes or timeouts when calling to backends directly when **allow-from-openshift-ingress** network policy is applied in the Red Hat OpenShift documentation.

Solution: Upgrade to a supported version of Red Hat OpenShift. For more information, see Supported Red Hat OpenShift versions.

Installation on Linux fails with network connectivity errors when using `aiopsctl` to install on vSphere VMs

The **aiopsctl** script installs the Kubernetes distribution **k3s**. When **k3s** is installed on a VMWare vSphere virtual machine (VM), routing across ClusterIPs does not work. The creation of the subscriptions for **Cert Manager** and the **Licensing Service** fail with errors similar to the following because they cannot reach the catalog:

```
- message: 'failed to populate resolver cache from source ibm-aiops-catalog/olm:
      failed to list bundles: rpc error: code = Unavailable desc = connection error:
      desc = "transport: Error while dialing: dial tcp: lookup ibm-aiops-catalog.olm.svc
      on 10.43.0.10:53: read udp 10.42.1.2:41727->10.43.0.10:53: i/o timeout"'
```

This problem is caused by a known kernel issue with Red Hat® Enterprise Linux® on vSphere. To fix the problem, run the following command on each of your nodes:

```
ethtool -K flannel.1 tx-checksum-ip-generic off
```

For more information, see k3s support

Installation on Linux: deployment is unstable after cluster restart

After a cluster restart, one of IBM Cloud Pak for AIOps's components, **zookeeper**, cannot start due to issues around DNS resolution causing it to misidentify its assigned cluster IP address.

Running the following command shows that **iaf-system-kafka-0** and some other pods failed:

```
kubectl get pods
```

Running the following command shows errors in the **zookeeper** logs:

```
kubectl logs -l app.kubernetes.io/name=zookeeper --tail -1
```

Example errors:

```
2024-06-17 20:57:26,674 ERROR Couldn't bind to iaf-system-zookeeper-0.iaf-system-zookeeper-
nodes.aiops.svc/10.42.1.53:2888 (org.apache.zookeeper.server.quorum.Leader) [QuorumPeer[myid=1]
(plain=127.0.0.1:12181)(secure=[0:0:0:0:0:0:0:0]:2181)]
```

```
java.net.BindException: Cannot assign requested address
java.net.SocketException: Unresolved address
```

Solution: Run the following command to restart the **zookeeper** pods, and then wait a few minutes for the system to recover:

```
kubectl delete pods -l app.kubernetes.io/name=zookeeper
```

Installation on Linux: unable to log in to IBM Cloud Pak for AIOps

If you have a deployment of IBM Cloud Pak for AIOps on Linux and your Domain Name System (DNS) does not provide resolution for the **cp-console** hostname on all of your nodes, then you may not be able to log in to the Cloud Pak for AIOps console.

Run the following command from the control plane node to view the **platform-identity-provider** pod logs:

```
oc logs deployment/platform-identity-provider -n aiops
```

Example output where **cp-console** is not resolved:

```
{"name":"platform-identity-provider","hostname":"platform-identity-provider-79855f988-
zqp2z","pid":1,"level":50,"err":{"message":"getaddrinfo ENOTFOUND cp-console-
aiops.example.com","name":"Error","stack":"Error: getaddrinfo ENOTFOUND cp-console-aiops.example.com\n    at
GetAddrInfoReqWrap.onlookup [as oncomplete] (node:dns:107:26)","code":"ENOTFOUND"},"msg":"getaddrinfo
ENOTFOUND cp-console-aiops.example.com","time":"2025-03-24T20:10:31.696Z","v":0}
```

Solution: Use one of the following options to resolve this issue:

Option 1: Configure DNS records to resolve the hosts for accessing the Cloud Pak for AIOps console, and ensure that the DNS is used by all of the nodes in the cluster. For more information, see DNS requirements.

Option 2: Configure CoreDNS to provide DNS resolution within the cluster. Use the following steps:

1. Run the following command to create a ConfigMap with a custom configuration for the CoreDNS server:

   ```
   oc apply -f - <<EOF
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: coredns-custom
     namespace: kube-system
   data:
     default.server: |
       cp-console-aiops.<example.com> {
           hosts {
                 <load_balancer_ip> cp-console-aiops.<example.com>
                 fallthrough
           }
       }
   EOF
   ```

   Where:

   - **<example.com>** is your hostname
   - **<load_balancer_ip>** is the IP address of your load balancer
2. Run the following command to apply the configuration:

   ```
   oc -n kube-system rollout restart deployment coredns
   ```

Troubleshooting upgrade

After upgrade, policies do not process alerts due to problem with the aiops-ir-lifecycle-create-policies-job

This issue can occur if there is a problem connecting to Cassandra during upgrade. The **aiops-ir-lifecycle-create-policies-job** reports successful completion even it was unable to connect to Cassandra and run some of its policy-related queries. After upgrade policies do not process alerts, and error messages similar to the following are present in the **aiops-ir-lifecycle-create-policies-job's** log:

```
"name":"installdefaultpolicies","hostname":"aiops-ir-lifecycle-create-policies-job-
c8k7t","pid":42,"level":40,"err":{"message":"All host(s) tried for query failed.
```

```
"name":"installdefaultpolicies","hostname":"aiops-ir-lifecycle-create-policies-job-
c8k7t","pid":42,"level":50,"msg":"Failed to update policy with content
```

Solution: Restart the **aiops-ir-lifecycle-create-policies-job** by running the following command:

```
oc delete job aiops-ir-lifecycle-create-policies-job
```

After upgrade, a metric integration goes into a failed state

After upgrade a metric integration pod goes into a failed state waiting for a missing secret volume, because the secret **aiopsedge-postgres-edb-secret** does not yet exist. The upgrade process should create this secret after a few hours, or you can use the following solution to create it immediately and restore functionality.

Solution: Run the following command to update the **aiopsedge** custom resource with the postgres access secret if it is not set.

```
# Set environment variables
NAMESPACE=<project>
AIOPS_INSTALL_NAME=$(oc get install -n $NAMESPACE -o jsonpath='{.items[*].metadata.name}')
AIOPSEDGE_NAME=$(oc get aiopsedge -n $NAMESPACE -o jsonpath='{.items[*].metadata.name}')
EDB_POSTGRESS_SECRET=$AIOPS_INSTALL_NAME-edb-secret

# Check if spec.postgres.accessSecret is set
CURRENT_SECRET=$(oc get aiopsedge $AIOPSEDGE_NAME -n $NAMESPACE -o jsonpath='{.spec.postgres.accessSecret}')

# Patch the aiopsedge custom resource
if [[ "${CURRENT_SECRET}" != "${EDB_POSTGRESS_SECRET}" ]]; then
    oc patch aiopsedge $AIOPSEDGE_NAME -n $NAMESPACE --type='json' -p="[{'op': 'replace', 'path':
'/spec/postgres/accessSecret', 'value': '$EDB_POSTGRESS_SECRET'}]"
else
    echo "Postgres access secret name already set to $CURRENT_SECRET in $AIOPSEDGE_NAME resource."
fi

# Restart the Edge operator manager pod to force a reconcile:
oc scale deployment/aiopsedge-operator-controller-manager -n $NAMESPACE --replicas=0
oc scale deployment/aiopsedge-operator-controller-manager -n $NAMESPACE --replicas=2
```

Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in, usually **cp4aiops**.

After upgrade, alerts are not visible in the UI

1. Run the following command to view the LifecycleTrigger job.

   ```
   oc get LifecycleTrigger aiops -o yaml
   ```

2. Check the **status** section of the returned YAML.

   Example **status** section:

   ```
   status:
     conditions:
     - lastTransitionTime: "2024-04-15T10:12:44Z"
       message: Job '5e569b68014d9a669574096001ce51e6' in state 'RESTARTING'
       observedGeneration: 2
       reason: NotReady
       status: "False"
       type: LifecycleTriggerReady
     jobs:
     - jid: 5e569b68014d9a669574096001ce51e6
       startTime: "2024-04-13T20:22:17Z"
       state: RESTARTING
     savepoints:
     - path: s3://aiops-ir-lifecycle/savepoints/savepoint-d9c1a5-95d27a6574b4
       time: "2024-04-13T20:10:56Z"
     - lifecycleVersion: 4.5.1
       namespace: aiops
       path: s3://aiops-ir-lifecycle/savepoints/savepoint-d9c1a5-40e97c1c5bdd
       time: "2024-04-13T20:15:22Z"
     - lifecycleVersion: 4.5.1
       namespace: aiops
       path: s3://aiops-ir-lifecycle/savepoints/savepoint-d9c1a5-40e97c1c5bdd-upgraded
       time: "2024-04-13T20:21:53Z"
     - lifecycleVersion: 4.5.1
       namespace: aiops
       path: s3://aiops-ir-lifecycle/savepoints/savepoint-5e569b-6d60d2f35ca8
       time: "2024-04-13T20:23:20Z"
   ```

   Check to see if:

   - the **conditions** section has **Job <...> in state 'RESTARTING'**.
   - the **savepoints** section has an entry with a path that ends with **-upgraded**, which follows an entry with the same path without this suffix.
   - the two entries that are described above are followed by at least one more entry. This check is important.

Solution: If all of the above checks are true, then you can remediate this problem with the following steps.

1. Note the value of **jid** in the status block (**5e569b68014d9a669574096001ce51e6** in the example above) and export it as an environment variable.

   ```
   export JOB_ID=<jid>
   ```

2. Run the following command to cancel the LifecycleTrigger job that is restarting.

   ```
   oc patch LifecycleTrigger aiops --type json --patch '[{"op":"add","path":"/spec/cancelJobs","value":["'${JOB_ID}'"]}]'
   ```

3. Check the LifecycleTrigger YAML again.

   ```
   oc get LifecycleTrigger aiops -o yaml
   ```

   After about a minute the **status.jobs** section should have two entries:

   - The first entry has the old job ID and the state will change to CANCELLED.
   - the second entry has a new job ID and the state should eventually settle at RUNNING.

Navigation menu items disappear after an upgrade

You might notice an issue where navigation menu items in IBM Cloud Pak for AIOps console disappear when you upgrade .

To determine if you are encountering this issue, run the following command:

```
kubectl logs -l component=zen-core-api
```

The output can resemble the following example:

```
time="2024-07-18 13:46:00" level=error msg=GetNavExtensions func=zen-core-api/source/apis/internal_extensions/nav.GetNavItemsWrapper file="/go/src/zen-core-api/source/apis/internal_extensions/nav/get_nav_items.go:124" exception="circular dependency or dangling node found in aiops-nav-menuitem-alerts_page,aiops-connectors-nav,aiops-nav-menuitem-metric_search,aiops-insights-nav,aiops-nav-menuitem-incidents_page,aiops-aimodel-nav,aiops-nav-menuitem-resource_management,aiops-nav-menuitem-automations"
```

Solution: If you see the preceding error, then use the following step to resolve the menu items disappear issue:

1. Delete the **aiops-baseui-frontdoor-ext** resource:

   ```
   oc delete zenextension aiops-baseui-frontdoor-ext
   ```

   The output can resemble the following example:

   ```
   zenextension.zen.cpd.ibm.com "aiops-baseui-frontdoor-ext" deleted
   ```

Upgrade does not complete because the lifecycletrigger component is stuck

After upgrade, the lifecycletrigger component has a status of *Not Ready*, and the phase does not progress past *Updating*, as in the following example:

```
  componentstatus:
    issueresolutioncore: Ready
    flinkdeployment: Ready
    baseui: Ready
    aimanager: Ready
    kafka: Ready
    aiopsanalyticsorchestrator: Ready
    aiopsedge: Ready
    tunnel: Ready
    rediscp: Ready
    commonservice: Ready
    lifecycleservice: Ready
    lifecycletrigger: Not Ready
    zenservice: Ready
    cluster: Ready
    asm: Ready
    elasticsearch: Ready
    aiopsui: Ready
  imagePullSecret: Global
  licenseacceptance: Accepted
  phase: Updating
```

Solution: Cancel and resubmit the lifecyle job.

1. Check whether the lifecycle job is stuck restarting.

```
oc get irlct aiops -o jsonpath="{.status.jobs[0].state}"
```

2. If the previous step returned a value of *RESTARTING*, then run the following command to restart the lifecycle job from the latest savepoints.

```
oc patch irlct aiops --type=json --patch="[{\"op\":\"add\",\"path\":\"/spec/cancelJobs\",\"value\":$(oc get irlct aiops -o jsonpath='{"["}{range .status.jobs[*]}{"\""}{.jid}{"\","}{end}{"]"}'|sed 's/,]/]/')}]"
```

Issues that are common to installation and upgrade

Offline install or upgrade throws 'invalid character' error

When doing an offline install or upgrade, running the **`oc ibm-pak generate mirror-manifests <..>`** command throws an error similar to the following:

```
Error: failed to load the catalog FBC at cp.stg.icr.io/cp/ <...> invalid character '<' in string escape code
```

Solution: You must have **`IBM Catalog Management Plug-in for IBM Cloud Pak`** (**`ibm-pak-plugin`**) v1.10 or higher installed. Run the following commands to ensure that **`ibm-pak-plugin`** is at the required level.

1. Check which version of **`ibm-pak-plugin`** you have installed.

   Run the following command on your bastion host, portable compute device, or connected compute device if you are using a portable storage device.

   ```
   oc ibm-pak --version
   ```

   Example output:

   ```
   oc ibm-pak --version
   v1.11.0
   ```

2. If the **`ibm-pak-plugin`** version is lower than v1.10.0, then you must download and install the most recent version.

   Follow the steps for your installation approach:

   - Bastion host: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.
   - Portable device: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.

Offline install or upgrade stuck because the 'oc ibm-pak generate mirror-manifests' command fails with 'no space left on device'

The **`oc ibm-pak generate mirror-manifests $CASE_NAME $TARGET_REGISTRY --version $CASE_VERSION`** command fails with a message similar to the following in **`$IBMPAK_HOME/.ibm-pak/logs/oc-ibm_pak.log`**:

```
write /tmp/render-unpack-4002583241/var/lib/rpm/Packages: no space left on device
```

Solution: The default temporary directory does not have enough space to run the **`ibm-pak`** tool. You must set the **`TMPDIR`** environment variable to a different directory with more space before running the **`oc ibm-pak generate mirror-manifests`** command.

```
TMPDIR=<new_temp_dir> oc ibm-pak generate mirror-manifests ${CASE_NAME} ${TARGET_REGISTRY} --version ${CASE_VERSION}
```

Where **`<new_temp_dir>`** is the path for a directory with more space.

Troubleshooting clusters and nodes

Learn how to isolate and resolve problems that involve cluster and node failures.

- Temporal grouping policies not created after training historic events
- Illegal reflective access operation in Jobmanager pod log
- Kafka pods fail to restart
- Cloud Pak for AIOps console not accessible after shutdown of backup cluster
- Log anomaly detection Kafka intermittent Issue, as Log anomaly detector abruptly stops making predictions
- EDB Postgres cluster failure
- Postgres EDB database crashes
- CouchDB pod reports a permission error when draining a node

- Kafka broker pods are unhealthy because Kafka PVCs are full
- Deployment on Linux: unable to access Cloud Pak for AIOps console
- Deployment on Linux: API server down after cluster restart

Temporal grouping policies not created after training historic events

Groups of related alerts that occur together (temporal groups) are not correlated automatically by the system. This issue can occur when temporal grouping policies are not created automatically due to communication issues between the aiops-ir-core-archiving pod and some Kafka topics.

Solution: Complete the following steps:

1. Run the following command, while logged in as an admin user in the project (namespace) where IBM Cloud Pak® for AIOps is running:

   ```
   kubectl logs $(kubectl get pods|grep aiops-ir-core-archiving|grep -v setup|awk '{print $1}') | grep
   "lib-rdkafka status"| tail -1
   ```

   Example command output:

   ```
   {
   "name": "client.kafka",
   "hostname": "aiops-ir-core-archiving-5dfd8fdcc5-l52g8",
   "pid": 20,
   "level": 30,
   "brokerStates": {
      "0": "UP",
      "-1": "UP"
   },
   "partitionStates": {
      "cp4waiops-cartridge.irdatalayer.replay.alerts.0": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.1": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.2": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.3": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.4": "UP",
      "cp4waiops-cartridge.irdatalayer.replay.alerts.5": "UP"
   },
   "msg": "lib-rdkafka status",
   "time": "2021-10-19T11:00:49.852Z",
   "v": 0
   }
   ```

2. If any of the broker or partition states are not up, restart the aiops-ir-core-archiving pod with the following command:

   ```
   kubectl delete pod $(kubectl get pods|grep aiops-ir-core-archiving|grep -v setup|awk '{print $1}')
   ```

Illegal reflective access operation in Jobmanager pod log

Reports of illegal reflective access operation.

```
WARNING: An illegal reflective access operation has occurred
WARNING: Illegal reflective access by
org.apache.flink.shaded.akka.org.jboss.netty.util.internal.ByteBufferUtil (file:/opt/flink/lib/flink-
dist_2.11-1.13.2.jar) to method java.nio.DirectByteBuffer.cleaner()
WARNING: Please consider reporting this to the maintainers of
org.apache.flink.shaded.akka.org.jboss.netty.util.internal.ByteBufferUtil
WARNING: Use --illegal-access=warn to enable warnings of further illegal reflective access operations
WARNING: All illegal access operations will be denied in a future release
```

This warning is reported when the Flink library is run by Java 11. For more information, see https://issues.apache.org/jira/browse/FLINK-17524

Solution: No action required. This warning message can be ignored and does not impact functionality.

Kafka pods fail to restart

Kafka pods fail to start when a worker node goes down, as in the following example:

```
evtmanager-kafka-0                                    1/2     Running            55
15h
evtmanager-kafka-1                                    2/2     Running            0
16h
evtmanager-kafka-2                                    1/2     Running            0
15h
evtmanager-kafka-3                                    1/2     Running            0
15h
evtmanager-kafka-4                                    1/2     Running            0
15h
```

```
evtmanager-kafka-5                                    2/2     Running            0
15h
evtmanager-zookeeper-0                                1/1     Running            0
16h
evtmanager-zookeeper-1                                1/1     Running            0
15h
evtmanager-zookeeper-2                                1/1     Running            0
15h
```

If the worker node where the Kafka pods are located goes down, the Kafka pods might fail to restart on another node.

Solution: Restart all zookeeper and Kafka pods:

```
oc delete pod {evtmanager-zookeeper-0} {evtmanager-zookeeper-1} {evtmanager-zookeeper-n} {evtmanager-kafka-
0} {evtmanager-kafka-1} {evtmanager-kafka-n}
```

Cloud Pak for AIOps console not accessible after shutdown of backup cluster

Unable to access the IBM Cloud Pak for AIOps console on the backup cluster after a systematic shut down and start up of the backup cluster. The following error message is displayed:

```
"Document was encrypted with unknown key '<namespace>-<release name>-<timestamp>'"
```

Solution: Find and then delete the required databases through the API.

1. First, run the following command to retrieve the hostname:

   ```
   oc get route couchdb-georedundancy
   ```

   For this scenario, use the hostname `couchdb-georedundancy-geonoi.apps.geo01primary.myibm.com`.

2. Run the two `SECRET_NAME` commands to retrieve the `username` and `password` that are required to retrieve the database names.

   For Username:

   ```
   SECRET_NAME=$(oc get secret | grep couchdb-secret | awk '{ print $1 }'); kubectl get secret
   ${SECRET_NAME} -o json | grep "username" | cut -d : -f2 | cut -d '"' -f2 | base64 -d
   username
   ```

   For Password:

   ```
   SECRET_NAME=$(oc get secret | grep couchdb-secret | awk '{ print $1 }'); kubectl get secret
   ${SECRET_NAME} -o json | grep "password" | cut -d : -f2 | cut -d '"' -f2 | base64 -d
   password
   ```

3. Use the `hostname`, `username`, and `password` obtained in the previous steps to run the command to retrieve the database names:

   ```
   curl -sk -u "username:password" https://couchdb-georedundancy-
   geonoi.apps.geo01primary.myibm.com/_all_dbs | jq "."
   ```

   Example output:

   ```
   [
   "_global_changes",
   "_replicator",
   "_users",
   "collabopsuser",
   "emailrecipients",
   "genericproperties",
   "icp-63666439356237652d336263372d343030362d613461382d6137336137396337313235535-rba-as",
   "icp-63666439356237652d336263372d343030362d613461382d6137336137396337313235535-rba-rbs",
   "integration",
   "noi-drdb",
   "noi-osregdb",
   "normalizercfd95b7e-3bc7-4006-a4a8-a73a79c71255",
   "osb-map",
   "otc_omaas_broker",
   "rba-pdoc",
   "schedule",
   "tenant",
   "trainingjob"
   ]
   ```

   The relevant database name here is **collabopsuser**.

4. Run the following command to delete the database:

   ```
   curl -sk -u "root:netcool" -X DELETE "https://couchdb-georedundancy-
   geonoi.apps.geo01primary.myibm.com/${DATABASE_NAME}"
   ```

Where **DATABASE_NAME** = **collabopsuser**

5. Restart the **cem-users** pod to recreate the database:

```
oc get pods |grep cem-users
<cem_users_pod_name>

oc delete pod <cem_users_pod_name>
```

6. You can confirm the database is created by running the curl command from step 3:

```
curl -sk -u "username:password" https://couchdb-georedundancy-
geonoi.apps.geo01primary.myibm.com/_all_dbs | jq "."
```

LAD Kafka intermittent Issue, as Log anomaly detector abruptly stops making predictions

The log anomaly detector abruptly stops making predictions.

On checking the anomaly pod logs, you see error messages related to Kafka, and due to these intermittent issues, log anomaly stops consuming data from the windowed logs topic, even when there are continuous windows generated from the data preprocessing component.

An example of such an error in the logs is as follows:

```
[2022-03-19 14:28:34,233] [logprophet.logs.watson_aiops] [ERROR] An error has occurred while processing
message in batch mode. Error: 'NoneType' object is not iterable
[2022-03-19 14:28:34,234] [app.anomaly_detector.service_controller] [ERROR] Consumer failed with unhandled
exception : 'NoneType' object is not iterable
```

Solution: There is a two-step process to resume the flow:

1. Clear the windowed logs topic content. This step is required to clear any old data that is not yet consumed by the log anomaly detector. If you do not clear this data, when LAD is ready to make predictions, it will try to generate events for old data showing a lag. So, you need to disable the data flow, and clear data from windowed logs.
    - Disable data flow from data integration
    - Clear the windowed logs topic using following command

      ```
      oc edit kt cp4waiops-cartridge-windowed-logs-1000-1000
      ```

    - Set **retention.ms** to **1**.
    - Wait for a few minutes, and once the data is cleared and no more windows are generated, reset the 'retention.ms' to the original value
    - Enable the data flow in the data integration
2. Once the data is cleared using the above steps, restart the anomaly pod logs with the following command:

```
oc get po | grep anomaly
oc delete pod <anomaly-pod>
```

EDB Postgres cluster failure

Run the following command on your cluster:

```
oc get clusters.postgresql.k8s.enterprisedb.io <installation_name>-edb-postgres -n <namespace>
```

Where:

- **<installation_name>** is the name of your IBM Cloud Pak for AIOps instance, for example **ibm-cp-aiops**.
- **<namespace>** is the namespace that IBM Cloud Pak for AIOps is deployed in.

If the cluster *STATUS* does not show **Cluster in healthy state** and the *READY* count is 0, then the EDB Postgres cluster has failed.

EDB Postgres is a component that is used by IBM Cloud Pak for AIOps. A defect in EDB Postgres 1.18.6 and lower can cause the EDB Postgres cluster to fail. If the pod that hosts the primary instance of EDB Postgres is deleted and there is not a healthy EDB Postgres replica instance available to promote, then the EDB Postgres operator may not reschedule the pod hosting the primary instance.

Solution: If you encounter this problem, then you must contact IBM Support who can help you to determine and bring up the primary EDB Postgres node.

Postgres EDB database crashes

After a failure of one of the Postgres EDB replicas, a new replica is unable to come up, and the failed replica remains.

Solution: Delete the failed replica and its persistent volume claim (PVC) if the replica failure is due to a synchronization problem.

1. Run the following command to find all Postgres instances that are not running:

   ```
   export PROJECT_CP4AIOPS=<project>
   oc get pod -n $PROJECT_CP4AIOPS -l "k8s.enterprisedb.io/podRole=instance" | grep -vE "Running"
   ```

   Where **<project>** is the project (namespace) where IBM Cloud Pak for AIOps is deployed, usually **cp4aiops**.

   Example output where **zen-metastore-edb-1** has failed:

   ```
   oc get pod -n cpaiops -l "k8s.enterprisedb.io/podRole=instance" | grep -vE "Running"

   NAMESPACE NAME                   READY   STATUS             RESTARTS         AGE
   aiops     zen-metastore-edb-1    0/1     CrashLoopBackOff   904 (36s ago)    7d1h
   ```

2. Examine the logs for the failed replica to see whether the non-primary replicas are not synchronized with the WAL logs in the primary replica.

   ```
   oc logs -n "${PROJECT_CP4AIOPS}" <failed_replica>
   ```

   Where **<failed_replica>** is the failed replica returned in step 1, for example **zen-metastore-edb-1**.

   Look for entries similar to the following examples:

   ```
   pg_rewind: servers diverged at WAL location 5/6606A4E0 on timeline 1
   pg_rewind: error: could not open file
   \"/var/lib/postgresql/data/pgdata/pg_wal/000000010000000500000068\": No such file or directory
   pg_rewind: fatal: could not read WAL record at 5/68000028
   ```

   ```
   {"level":"info","ts":1677595436.8679705,"logger":"postgres","msg":"record","logging_pod":"ibm-cp-aiops-
   edb-postgres-1","record":{"log_time":"2023-02-28 14:43:56.867
   UTC","user_name":"streaming_replica","process_id":"90988","connection_from":"10.254.24.22:32852","sessi
   on_id":"63fe132c.1636c","session_line_num":"1","command_tag":"idle","session_start_time":"2023-02-28
   14:43:56
   UTC","virtual_transaction_id":"13/0","transaction_id":"0","error_severity":"ERROR","sql_state_code":"58
   P01","message":"requested WAL segment 0000000300000002000000A0 has already been
   removed","query":"START_REPLICATION 2/A0000000 TIMELINE 2","application_name":"ibm-cp-aiops-edb-
   postgres-2","backend_type":"walsender"}}
   ```

3. Check that the failed replica is not the primary replica.

   Run the following command, and check that the failed replica identified in step 1 is not listed in the **PRIMARY** column for any of the Postgres clusters.

   ```
   oc get clusters.postgresql.k8s.enterprisedb.io -n $PROJECT_CP4AIOPS
   ```

   Example output:

   ```
   oc get clusters.postgresql.k8s.enterprisedb.io -n cp4aiops
   NAME                        AGE   INSTANCES   READY   STATUS                     PRIMARY
   common-service-db           23h   1           1       Cluster in healthy state   common-service-db-1
   ibm-cp-aiops-edb-postgres   23h   1           1       Cluster in healthy state   ibm-cp-aiops-edb-
   postgres-1
   zen-metastore-edb           23h   2           2       Cluster in healthy state   zen-metastore-edb-2
   ```

4. Delete the failed replica and its PVC.

   Run the following command if the failed replica is not the primary and the logs for the failed replica showed errors similar to the example output in step 2. Otherwise, contact IBM Support.

   ```
   oc delete pod,pvc zen-metastore-edb-1 -n "${PROJECT_CP4AIOPS}"
   ```

   Where **<failed_replica>** is the failed replica returned in step 1, for example **zen-metastore-edb-1**.

CouchDB pod reports a permission error when draining a node

The **CouchDB** pod's log reports a permission error similar to the following example:

```
[error] 2022-12-02T01:24:20.726024Z couchdb@c-example-couchdbcluster-m-0.c-example-couchdbcluster-m
<0.13913.7> -------- Could not open file /data/db/shards/00000000-7fffffff/_users.1669801403.couch:
permission denied
```

Note: After a restore into a new namespace, similar symptoms can be seen. For more information about the solution for this scenario, see Restore fails with CouchDB pod in CrashLoopBackOff.

The way that Kubernetes mounts persistent volumes can cause this problem.

Solution: Delete the **CouchDB** pods that are not ready. When the replacement pods are created, the persistent volumes are mounted correctly.

1. Find the names of your **couchdb** pods.

   ```
   oc get pods -l app.kubernetes.io/name=IssueResolutionCoreCouchDB -n <namespace>
   ```

   Where **<namespace>** is the namespace that IBM Cloud Pak for AIOps is deployed in.

2. Delete all the **couchdb** pods that the previous step showed as not ready.

   ```
   oc delete pod <couchdb-pod> -n <namespace>
   ```

   Where:

   - **<namespace>** is the namespace that IBM Cloud Pak for AIOps is deployed in.
   - **<couchdb-pod>** is a couchdb pod that is not ready.

Kafka broker pods are unhealthy because Kafka PVCs are full

When the Kafka broker pods are unhealthy due to insufficient storage, the Events operator is unable to expand the PVCs.

Solution: Check whether the Kafka broker pods have storage available, and expand the storage available to Kafka if they do not.

1. Check the state of the Kafka broker pods:

   ```
   export AIOPS_NAMESPACE=<project>
   oc get pod -n "${AIOPS_NAMESPACE}" -l app.kubernetes.io/name=kafka
   ```

   Where **<project>** is the namespace (project) that IBM Cloud Pak for AIOps is deployed.

   Example output:

   ```
   iaf-system-kafka-0                                                1/1     Running                 0
   5d21h
   iaf-system-kafka-1                                                0/1     CreateContainerError    0
   95m
   iaf-system-kafka-2                                                0/1     CreateContainerError    1
   (2d18h ago)     5d21h
   ```

2. If the broker pods are in a *CreateContainerError* state, check the logs for errors:

   ```
   oc logs -n "${AIOPS_NAMESPACE}" iaf-system-kafka-1
   ```

   Example output:

   ```
   Warning  Failed          5m40s (x13 over 89m)  kubelet  Error: relabel failed
   /var/lib/kubelet/pods/37e6519a-b372-429d-b5f5-9aaf5b12fd37/volumes/kubernetes.io~csi/pvc-ff53e966-fee1-
   41e2-9448-b0eeac2e49c6/mount: lsetxattr /var/lib/kubelet/pods/37e6519a-b372-429d-b5f5-
   9aaf5b12fd37/volumes/kubernetes.io~csi/pvc-ff53e966-fee1-41e2-9448-b0eeac2e49c6/mount/kafka-log1/.lock:
   no space left on device
   ```

   Do not proceed with the rest of these troubleshooting steps if the error is not related to disk space.

3. Adjust the Kafka storage size in the CustomResource:

   ```
   oc patch kafka/iaf-system -n "${AIOPS_NAMESPACE}" --type merge -p '{"spec":{"kafka":{"storage":
   {"size":"<size>Gi"}}}}'
   ```

   Where **<size>** is the increased storage size that you require for the Kafka PVCs.

4. Increase the Kafka PVCs:

   ```
   for p in $(oc get pvc -l app.kubernetes.io/name=kafka -n "${AIOPS_NAMESPACE}" -o
   jsonpath='{.items[*].metadata.name}'); do oc patch pvc $p -n "${AIOPS_NAMESPACE}" --type merge -p
   '{"spec":{"resources":{"requests":{"storage":"<size>Gi"}}}}' ; done
   ```

   Where **<size>** is the same value that was used in the previous command.

   Note : The time required for this command to run depends on the number of PVCs and the amount of data that is stored in each one.

Deployment on Linux: unable to access Cloud Pak for AIOps console

The pods in the IBM Cloud Pak for AIOps cluster are in a *Running* state, but the user interface is not accessible.

Solution: When you installed IBM Cloud Pak for AIOps, you used an existing load balancer or configured a new one of your choice. For more information, see Load balancing. The load balancer is the entry point for accessing deployments of IBM Cloud Pak for AIOps on Linux. Problems with your load balancer can prevent access to the Cloud Pak for AIOps console. Check the load balancer status and logs for problems, and restart the load balancer if it is not running.

Deployment on Linux: API server is down after a cluster restart

After restarting the Linux cluster, all requests to the Kubernetes API server such as **`oc get pod`** and **`aiopsctl status`** fail, as in the following example output:

```
$ oc get pod -n aiops
E0903 08:55:39.586644    1287 memcache.go:265] couldn't get current server API group list: the server is
currently unable to handle the request
E0903 08:55:39.589138    1287 memcache.go:265] couldn't get current server API group list: the server is
currently unable to handle the request
E0903 08:55:39.592133    1287 memcache.go:265] couldn't get current server API group list: the server is
currently unable to handle the request
E0903 08:55:39.594610    1287 memcache.go:265] couldn't get current server API group list: the server is
currently unable to handle the request
E0903 08:55:39.597172    1287 memcache.go:265] couldn't get current server API group list: the server is
currently unable to handle the request
Error from server (ServiceUnavailable): the server is currently unable to handle the request

$ aiopsctl status
o- [03 Sep 24 08:58 PDT] Getting cluster status
[ERROR] Failed to get cluster status apiserver not ready
```

Solution: Run the following steps to confirm that the problem is due to the Kubernetes API server being down, and to rectify this.

1. Check the control plane nodes.

    1. On each control plane node, run the following command to assess the platform state. Affected deployments have a state of *activating*.

        ```
        systemctl status k3s.service
        ```

        Example output for a deployment affected by this issue:

        ```
        $ systemctl status k3s.service

        k3s.service - Lightweight Kubernetes    Loaded: loaded (/etc/systemd/system/k3s.service; enabled;
        vendor preset: enabled)    Active: activating (start) since Mon 2024-09-09 05:10:30 PDT; 6s ago
        ```

    2. On each control plane node, run the following command to check the platform logs:

        ```
        journalctl -xeu k3s.service
        ```

        Example output for a deployment affected by this issue:

        ```
        Sep 09 05:11:28 control-plane-2.acme.com k3s[50701]: {"level":"warn","ts":"2024-09-
        09T05:11:28.735466-0700","caller":"rafthttp/http.go:413","msg":"failed to find remote peer in
        cluster","local-member-id":"8c10b42dfa5ffc54","rem>
        Sep 09 05:11:28 control-plane-2.acme.com k3s[50701]: {"level":"warn","ts":"2024-09-
        09T05:11:28.828015-0700","caller":"rafthttp/http.go:413","msg":"failed to find remote peer in
        cluster","local-member-id":"8c10b42dfa5ffc54","rem>
        Sep 09 05:11:28 control-plane-2.acme.com k3s[50701]: {"level":"warn","ts":"2024-09-
        09T05:11:28.834347-0700","caller":"rafthttp/http.go:145","msg":"failed to process Raft
        message","local-member-id":"8c10b42dfa5ffc54","error":"ra>
        ```

    If your deployment is affected, continue with the following steps.

2. Stop **`k3s`** on the primary control plane node:

    ```
    systemctl stop k3s
    ```

    Note: The primary control plane is the first control plane attached to the cluster. This is the value of CONTROL_PLANE_NODE in your aiops_var.sh environment variables file. The non-primary control plane nodes are the nodes in the ADDITIONAL_CONTROL_PLANE_NODES array in your aiops_var.sh environment variables file.

3. Run a cluster reset on the primary control plane node to soft reset **`etcd`**.

```
k3s server --cluster-reset
```

4. Stop k3s on the non-primary control plane nodes.

   ```
   systemctl stop k3s
   ```

5. Back up the **etcd** data directory on each non-primary control plane node.

   ```
   cp -r <data_directory> <backup_directory>
   ```

   Where

   - **<data_directory>** is: **/var/lib/rancher/k3s/server/db** if you are not using a custom platform directory, or **PLATFORM_STORAGE_PATH** in aiops_var.sh if you are using a custom platform directory
   - **<backup_directory>** is a directory where you want to store the backup.

6. Delete the **etcd** data directory on each non-primary control plane node.

   Important: Do not delete the platform data directory on the primary control plane node.

   ```
   rm -rf <data_directory>
   ```

   Where **<data_directory>** is **/var/lib/rancher/k3s/server/db** if you are not using a custom platform directory, or **PLATFORM_STORAGE_PATH** in aiops_var.sh if you are using a custom platform directory.

7. Run the following command on the primary control plane node, and then on each of the non-primary control plane nodes:

   ```
   systemctl start k3s
   ```

Troubleshooting integrations

Review frequently encountered issues with creating and managing outgoing and incoming integrations.

- Multiple integrations
- Integrations page
- Metrics integrations
- Instana
- Kafka
- Netcool
- ServiceNow
- Splunk
- IBM Tivoli Netcool/Impact

Multiple integrations

- Integrations do not initialize

Integrations do not initialize

If an integration gets stuck in a state that is not running, there may be an issue with the secrets being created.

To check this log in to openshift and check the pods. For example, the netcool integration has the following issue:

```
NAME                                                              READY   STATUS              RESTARTS
AGE
netcool-conn-cfe182e0-d7eb-42f6-9677-fb86b180bd0f-8bd546cbvv5km   0/1     ContainerCreating   0
27m
```

If you describe the pod **oc describe pod netcool-conn-cfe182e0-d7eb-42f6-9677-fb86b180bd0f-8bd546cbvv5km** and you see a mount error in the events log such as the following:

```
34s (x20 over 25m)          Warning   FailedMount                       Pod/netcool-conn-cfe182e0-d7eb-42f6-
9677-fb86b180bd0f-8bd546cbvv5km             MountVolume.SetUp failed for volume "grpc-bridge-service-
binding" : secret "connector-cfe182e0-d7eb-42f6-9677-fb86b180bd0f" not found
```

you can conclude that the secrets failed to create. The way to fix this is to use the following command:

```
oc get pods | grep connector-manager
```

Then delete the connector-manager pods and restart it. On restarting it, the secrets are re-created for all integrations.

Integrations page

On viewing the Integrations page, you might encounter the following issues:

- Deleting an integration does not remove the PVC for the integration
- Error displays when you activate Kafka, Humio, Splunk, Mezmo, ELK, PagerDuty, ServiceNow integrations
- Integrations on the Integrations page show a red 'Unknown' status
- Integrations UI pod in CrashLoopBackOff for the Integrations page
- Integrations page becomes unresponsive after some time or shows an error
- Incorrect integration status on the Integrations page
- The integration keeps showing *Error* or *Retrying* and integration pod is stuck in *Pending*
- Ansible Automation Controller integration not running due to prohibited egress

Deleting an integration does not remove the PVC for the integration

For StatefulSet type integrations, when the integration is deleted the Persistent Volume Claim (PVC) resource for the integration is not automatically deleted. You must manually delete the resource with the Red Hat OpenShift **oc** CLI or with the Red Hat OpenShift UI.

This behavior occurs because the StatefulSet PVC is created by specifying the **volumeClaimTemplate**, but the created PVC is not automatically deleted by Red Hat OpenShift when the StatefulSet resource is deleted.

To delete a PVC resource with the Red Hat OpenShift **oc** CLI, complete the following steps:

1. Get the list of PVC resources for your current integrations:

   ```
   oc get pvc | grep 'conn'
   ```

2. Select the PVC resource that you want to delete and record the name.

3. Delete the PVC resource:

   ```
   oc delete pvc <pvc-name>
   ```

   Where **<pvc-name>** is the name of the PVC resource that you want to delete.

Error displays when you activate Kafka, Humio, Splunk, Mezmo, ELK, PagerDuty, ServiceNow integrations

When you activate a Kafka, Falcon LogScale, Splunk, Mezmo, ELK, PagerDuty, ServiceNow integration in the console, an error can occur when the required Flink task slots to run the integration are not available. When this error occurs, the following message is displayed:

```
Failure: Not enough task slots to activate the connection.
```

This error occurs as there is a finite number of Flink task slots to use for creating integrations to remote resources. The error message displays the number of slots that are needed to support the current active integration set, along with the total number of slots available.

Solution: To activate the integration, you must either reduce the number of slots that are needed by this (or another) integration, or allocate more slots. To decrease the number of slots needed by a integration, consider reducing the "base parallelism" or "logs per second" value for the integration. This reduced value decreases the rate at which data flows through the integration, making more slots available to other integrations. To allocate more slots, see Increasing data streaming capacity.

Integrations on the Integrations page show a red 'Unknown' status

All integrations are showing red 'Unknown' integration status and data is not flowing after creating a new integration, such as a Mezmo integration. For the new integration if you enable 'Data collection', you can see that the data is not flowing, and the integration shows the same red 'Unknown' status in the Data collection status field instead of the expected 'Running' status. The common cause for this is unstable Kafka in the background.

Solution: If this issue occurs, restart the bridge and operator pod.

Integrations UI pod in CrashLoopBackOff for the Integrations page

You can encounter an intermittent issue that causes the Integrations page to fail and become unavailable for viewing.

Solution: If the page does not automatically recover, you can increase the timeout setting for the **aimanager-aio-controller** deployment to help prevent the issue. To increase this setting, edit the **aimanager-aio-controller** deployment (**liveliness** and **healthcheck** probe) and set it to a longer timeout of say 15 seconds, up from the default 5 seconds. This change can stop the **Connections-ui** pod from going into CrashLoopBackOff.

1. Check the **aimanager-aio-controller**

   ```
   oc get pods | grep aio-controller
   aimanager-aio-controller-6d9f68d5f5-8dkk9                         1/1     Running     0
   27h
   ```

2. Edit the **aimanager-aio-controller**'s deployment

   ```
   oc edit deployment aimanager-aio-controller
   ```

3. Edit these 2 variables (**timeoutSeconds**) for both the **livenessProbe** and the **readinessProbe** to 15 seconds:

```
livenessProbe
- timeoutSeconds
readinessProbe
- timeoutSeconds
```

Integrations page becomes unresponsive after some time or shows an error

If you are using IBM Cloud Pak for AIOps, you might encounter an unresponsive Integrations page around 24 hours after you install your cluster. The integrations page might take a long time to load and then display no integrations despite configuring them earlier. Another symptom of this problem is that you might fail to create an integration and see the following error:

```
Failed submitting creating request
```

Solution: To ensure the Integrations page works normally, delete the **aimanager-aio-controller** pod:

```
for n in $(oc get pods |grep aimanager-aio-controller |awk '{print $1}')
do
oc delete pod $n
done
```

Within one to two minutes of running the script, the pod will automatically restart and the Integrations page will work as usual.

Incorrect integration status on the Integrations page

You might encounter an incorrect integration status for all gRPC integrations (Instana, Netcool, AppDynamics, Dynatrace, AWS CloudWatch, Splunk, Zabbix, and New Relic) on the Integrations page. The integration status might appear as *Unknown* when it must be *Running*. The incorrect status might be the result of the pod connector-bridge being in CrashLoopBackOff state and restarting multiple times due to an unstable Kafka integration.

Solution: If this issue occurs, check the Kafka and zookeeper pods for any restarts. Kafka integration becomes unstable and restarts when the PVC used for Kafka is full. Review the current capacity of the PVC and increase the capacity as needed to resolve the issue. For more information about adjusting the size of the PVC, see Increasing Kafka PVC.

The integration keeps showing *Error* or *Retrying* and integration pod is stuck in *Pending*

On the Integrations UI page, an integration keeps showing *Error* or *Retrying* and the integration pod is stuck in *Pending*. This issue occurs because the Persistent Volume Claim (PVC) is requesting a volume from a storage provider that does not support the **ReadWriteOnce** (RWO) access mode.

Solution: You can use either one of the following methods to unblock the stuck integration pod:

- Change the default storage class

Or

- Re-create the Persistent Volume Claim with a different storage class

Method 1: Change the default storage class. Review the default storage class in the cluster and change to a storage class that supports **ReadWriteOnce** (RWO) access mode, such as file storage types.

Note: This method should resolve integration PVC issues but since it changes the global default storage class type in the cluster, it might also affect other workloads that rely on the default storage class settings when requesting a volume.

1. Run the following command to determine which is the current default storage class.

   ```
   oc get storageclass
   ```

2. Note the name of the default storage class **(default)**.

3. Change the default storage class to one that supports the **ReadWriteOnce** (RWO) access mode like file storages. The following command sets the **storageclass.kubernetes.io/is-default-class** annotation to **true** on the new storage class and sets the annotation to **false** on the old storage class. (Change the **<new-default-storageclass-name>** and **<old-default-storageclass-name>** with the actual storage class names in your cluster.)

   ```
   oc patch storageclass <old-default-storageclass-name> -p '{"metadata": {"annotations":
   {"storageclass.kubernetes.io/is-default-class":"false"}}}'
   oc patch storageclass <new-default-storageclass-name> -p '{"metadata": {"annotations":
   {"storageclass.kubernetes.io/is-default-class":"true"}}}'
   ```

4. Verify that the default storage class is updated by running

   ```
   oc get storageclass
   ```

5. Log in to the Cloud Pak for AIOps console and navigate to the **Integrations** page.

6. Delete the existing integration, then reinstall it.

7. Verify that the integration enters a *Running* state.

Method 2: Re-create the Persistent Volume Claim with a different storage class. Delete the existing PVC and re-create a new one with the same name that uses a storage class that supports the **`ReadWriteOnce`** (RWO) access mode.

Note: This method updates only a single integration instance. Repeat this step for all integrations unable to request a persistent volume, due to the incorrect storage class type.

1. Get the PVC name of the integration. You can list all PVCs by using **`oc get pvc`**. Look for the one that is still in *Pending* state with your integration name.

2. Delete the existing PVC and re-create a new one with the same name. Review the following sample command as reference. Update the **`<connector-pvc-name>`** with the PVC name from the previous step and set **`<storage-class-name>`** with the storage class that supports the required **`ReadWriteMan`** (RWX) access mode.

```
# Set the PVC name
CONNECTOR_PVC_NAME=<connector-pvc-name>

# Set new storage class
STORAGE_CLASS=<new-storage-class>

CONNECTOR_APP=$(oc get pvc $CONNECTOR_PVC_NAME -o jsonpath='{.metadata.labels.app}')
CONNECTOR_ID=$(oc get pvc $CONNECTOR_PVC_NAME -o jsonpath='{.metadata.labels.instance}')
PVC_SIZE=$(oc get pvc $CONNECTOR_PVC_NAME -o jsonpath='{.spec.resources.requests.storage}')

oc delete pvc $CONNECTOR_PVC_NAME && \
cat << EOF | tee >(oc apply -f -) | cat
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
    name: $CONNECTOR_PVC_NAME
    labels:
        app: $CONNECTOR_APP
        app.kubernetes.io/instance: aiopsedge
        app.kubernetes.io/managed-by: aiopsedge-operator
        app.kubernetes.io/name: ibm-aiops-edge
        app.kubernetes.io/part-of: ibm-aiops-edge

    storageClassName: $STORAGE_CLASS
```

```
    volumeMode: Filesystem
EOF
```

3. Verify that the integration pod transitions to **Running** state.
4. If necessary, repeat the steps above on any other integration that is producing the same problem.

Metrics integrations

If you are creating, or have, a metrics integration, you might encounter the following issue:

Metrics connection is unable to pull further historical data when historical mode is completed

When a metrics integration (for example Dynatrace, Appdynamics, Zabbix, New Relic, Splunk, or AWS) has completed its historical data pulling, historical mode can never be restarted again even if the connection configuration is edited or updated from the UI to specify a different start date, end date or a different set of metrics.

Solution: If you need to pull historical data again for another set of metrics or different dates, you can create a new connection.

Instana integrations

If you are creating, or have, an Instana integration, you might encounter the following issues:

- integration is unable to update the metric list in the UI
- IBM Cloud Pak for AIOps cannot close some alerts when an Instana integration exists
- After a repair of Instana, alerts in the Instana application do not associate with the corresponding IBM Cloud Pak for AIOps application
- Due to an out-of-memory error the Instana integration pod keeps restarting when retrieving data from Instana

integration is unable to update the metric list in the UI

The Instana integration UI page displays a list of metrics from Instana that are updated when the Instana integration pod runs. Some Instana hosts can have many technology plug-ins installed, which collect many built-in and custom metrics. These metrics can cause the Instana integration to exceed the allowed message limit when the integration sends an update to the UI. If this limit is exceeded, the Instana integration pod logs the following message:

```
0000004d Connector     I   UI configuration patch exceeds the safe message limit, skip sending configuration patch. The metrics list in the UI could not be updated with the actual list of technologies and metrics. Please configure more filter patterns to reduce the number of metrics to query.
```

The integration logs each technology plug-in and the number of metrics that are included or filtered.

Solution: Apply additional filter patterns in the Instana configmap for the integration to exclude when querying the metric list from Instana.

1. Get the Instana pod logs to determine which technology plug-in contains many metrics

   ```
   oc logs $(oc get pod | grep 'instana-conn' | awk '{print $1}') | grep -e "Plugin \'.*\' \(.*\)"
   ```

   The following example log indicates that a **aceMessageFlow** technology plug-in that contains a large list of metrics, and that is a candidate to filter.

   Tip: Look for any technology plug-ins that contain more than 100 metrics.

   ```
   0000004d InstanaInstan I Plugin 'ACE Message Flow' (aceMessageFlow) metrics: 2,666 included, 0 filtered.
   ```

2. Determine the available metrics names by technology from the Instana API or from your Instana administrator. To use the Instana API, you can use a command similar to the following sample command, which queries **aceMessageFlow** metrics:

   ```
   INSTANA_ENDPOINT=<your Instana host>
   INSTANA_TOKEN=<your Instana API token>
   curl --request GET -s  --url ${INSTANA_ENDPOINT}/api/infrastructure-monitoring/catalog/metrics/aceMessageFlow \
   --header "authorization: apiToken ${INSTANA_TOKEN}" \
   | jq 'group_by(.pluginId)[]|  {(.[0].pluginId): [.[] | .metricId] | sort}'
   ```

3. Create a pattern to filter metrics from the output of the previous command. For example, **flowNodes\\..*** to filter all metrics with **flowNodes.** prefix.
4. Get the Instana integration configmap name to add the filter pattern from the previous step.

   Note: If multiple Instana integrations exist, select the configmap with the UID that matches the pod name.

   ```
   oc get configmap | grep instana-connector
   ```

5. Extract the **exclude-filter-patterns** from the configmap. This command saves the content of the configmap into the local file:

```
oc extract configmap/ibm-grpc-instana-connector-d59eea9f-501d-4bd1-b3a3-6f98b49b0930 --keys=exclude-filter-patterns --to=.
```

6. Edit the local **exclude-filter-patterns** file to add the metric pattern in addition to the default ones that are defined in the **filters** array.

   Note: To escape a slash **** character, you must use double ****. For example:

   ```
   {"filters":["fs\\./dev/.*","fs_mount\\./.*","metrics\\.counters\\..*\\..*\\..*","(.*\\.)?metrics\\.gauges\\..*\\..*\\..*","metrics\\.meters\\..*","(.*\\.)?metrics\\.timers\\..*","prometheus\\.metrics.*","flowNodes\\..*"]}
   ```

7. Apply the change to the configmap:

   ```
   oc set data configmap/ibm-grpc-instana-connector-d59eea9f-501d-4bd1-b3a3-6f98b49b0930 --from-file=exclude-filter-patterns
   ```

8. Verify that the new filter pattern is loaded by the pod, and that the number of metrics that are filtered for the technology plug-in is changed.

   ```
   oc logs $(oc get pod | grep 'instana-conn' | awk '{print $1}') | grep 'Loaded filter patterns from ConfigMap'
   ```

9. Verify that the Instana integration can send an update to the UI successfully:

   ```
   oc logs $(oc get pod | grep 'instana-conn' | awk '{print $1}') | grep -e 'Status message .* write with configuration patch .* successful.'
   ```

10. In the *Edit Instana integration* UI page, the list of technologies and metrics list is now updated.

IBM Cloud Pak for AIOps cannot close some alerts when an Instana integration exists

When an integration with Instana exists, IBM Cloud Pak for AIOps might not be able to close some alerts. Instead, you might need to check the status for the associated event within the Instana UI and clear the alert manually.

Solution: To find the alert URL for clearing the alert, complete the following actions:

1. From the IBM Cloud Pak for AIOps console, open the *Incidents and alerts* tool.
2. Select the alert in the table to display the Alert details side panel for that alert. The Information section is open by default in the side panel.
3. Copy the URL from links and Paste the URL into your browser.
4. If you are an Instana authorized user, you see the associated event in the Instana UI.

If the event is not active and has "end-time" for the event in the Instana UI, clear the alert:

1. Click *Alert* to see the alert details.
2. Click *Clear Alert* to clear the alert.

After a repair of Instana, alerts in the Instana application do not associate with the corresponding IBM Cloud Pak for AIOps application

When you restart Instana post repair, alerts in the Instana application do not map with the corresponding application in IBM Cloud Pak for AIOps. The reason is that Instana creates new identifiers for the resources on its application on restarting, without updating the topology in IBM Cloud Pak for AIOps. As a result, the IDs of the resources do not match leading to the disassociation of alerts.

Solution: To map the alerts, you must complete the following steps:

1. Clean up the application in Instana.
2. Re-create the application after a few minutes.

To clean up and recreate applications in Instana, see Getting started with Instana.

Due to an out-of-memory error the Instana integration pod keeps restarting when retrieving data from Instana

When the Instana integration receives a large amount of data from one or more Instana APIs while the integration is observing many resources, and there is insufficient memory to process this large amount of data, an out of memory error can occur.

Solution: If this error occurs, you can apply custom memory settings to allocate more memory to the Instana integration pod by increasing the memory limit setting. This allocation can only be done post-installation as the integration must exist before applying the custom setting. To apply custom resource settings, follow the steps to patch the Instana integration:

Prerequisite: Ensure you have the **yq** and **jq** packages installed on your system before running the commands below. To get installation instructions for these packages, refer to the documentation or website for **yq** and **jq**.

1. From a command line, change to your IBM Cloud Pak for AIOps project (namespace):

   ```
   namespace=<aiops-namespace>
   oc project $namespace
   ```

2. Get the display name for the Instana integration you would like to increase resources for from the command line:

   ```
   oc get connectorconfiguration
   ```

3. Set the required variables:

   ```
   connectionname=<instana-connection-name>
   connconfig=$(oc get connectorconfiguration --no-headers | grep $connectionname | awk '{print $1}')
   connconfiguid=$(oc get connectorconfiguration $connconfig -o jsonpath='{.metadata.uid}')
   gitappname=$(oc get gitapp -l connectors.aiops.ibm.com/connection-id==$connconfiguid --no-headers | awk
   '{print $1}')
   ```

   Note: Update the `connectionname` variable with your Instana display name from the command above.

4. Run this command to create a variable with a patch specification for the Instana integration. This will apply only to one Instana integration at a time. This command should not have an output. Copy this command directly from the documentation and do not paste it into a text editor because this can affect the format.

   ```
   jsonpatch=$(yq -o json <<EOF
       patch: |-
         apiVersion: apps/v1
         kind: Deployment
         metadata:
           name: ibm-grpc-instana-connector
         spec:
           template:
             spec:
               containers:
               - name: ibm-grpc-instana-connector
                 resources:
                   requests:
                     memory: 1536Mi
                     ephemeral-storage: 2Gi
                   limits:
                     memory: 8Gi
                     ephemeral-storage: 4Gi
       target:
         group: apps
         kind: Deployment
         name: ibm-grpc-instana-connector
         version: v1
   EOF
   )
   ```

5. Run the following command to apply the custom resource setting that you created in the previous step:

   ```
   oc get gitapp $gitappname  -n $namespace -o json | jq ".spec.components[0].kustomization.patches +=
   [$jsonpatch]" | oc apply -f -
   ```

   Note: If you see an error message when running this command that states there was a configuration conflict, try running the command a second time.

6. It takes a moment for the changes to show in the integration pod.

Note: If the memory limit is not updated for the Instana integration pod after a few minutes, run `oc get gitapp $gitappname` and check to see if there are any errors. If there is an error stating that the YAML is invalid, run the command below to revert the patch and go through all steps again. The cause of this error is that the format of the commands may have been altered by a text editor and should be copied directly from the documentation and run directly in the terminal.

Revert the custom resource settings to default resource settings:

To revert from custom to default resource settings, run the following command:

```
oc patch gitapp $gitappname -n $namespace --type='json' -p="[{'op': 'remove', 'path':
'/spec/components/0/kustomization/patches'}]"
```

Kafka integrations

If you are creating, or have, a Kafka integration, you might encounter the following issues:

- Kafka events not displayed in IBM Cloud Pak for AIOps
- After copying log data into a Kafka cluster, verify that the data is imported into Elasticsearch

Kafka events not displayed in IBM Cloud Pak for AIOps

You cannot see Kafka events in IBM Cloud Pak for AIOps after successfully creating a Kafka integration. This failure occurs when the Kafka key or message violates the format requirements. The `MismatchedInputException` error in the task manager pod log indicates this formatting error.

Solution: To ensure that the Kafka events display in IBM Cloud Pak for AIOps, check whether the following conditions are met:

1. The key in Kafka payload is null.

   Note: The key is determined by Kafka producer. Most producer tools use null object as key unless the producer is programmed to assign value.

2. The message in Kafka payload is a JSON message that satisfies the following requirements:

   - Exists in the format of the selected data source.
   - Contains sufficient data for the mapping.

After copying log data into a Kafka cluster, verify that the data is imported into Elasticsearch

To publish log data, you can copy it into a Kafka cluster. For more information, see Copying log data into the Kafka cluster. Then, you can check whether the log data is imported into Elasticsearch.

Solution: Verify that the log data is imported into Elasticsearch by getting shell access to the `ai-platform-api-server` pod. Run the following commands from the namespace where IBM Cloud Pak for AIOps is installed:

```
oc exec -it $(oc get pods | grep ai-platform-api-server | awk '{print $1}') -- /bin/bash
```

Example:

```
curl -X GET -u $ES_USERNAME:$ES_PASSWORD $ES_URL/_cat/indices -k | sort
```

Example output:

```
% Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100  4710  100  4710    0     0  28373      0 --:--:-- --:--:-- --:--:-- 28373

Netcool integrations

If you are creating, or have, a Netcool integration, you might encounter the following issues:

- Runbook automation pod "rba-rbs" crashes during an alert burst, for example, while connecting to Netcool
- ObjectServer alerts missing in IBM Cloud Pak for AIOps due to `No object found with id` error in the data layer
- Setting values for mandatory fields for events sent to the embedded ObjectServer
- Events from IBM Tivoli Netcool/OMNIbus are not updated in Alert Viewer
- Test connection fails in the Netcool connector UI configuration page
- Fresh alerts are missing in Alert Viewer

Runbook automation pod "rba-rbs" crashes during an alert burst, for example, while connecting to Netcool

The "rba-rbs" pod crashes and gets restarted automatically, and most of the fully automated runbooks that are associated with the new alerts are not run. This restart behavior might be observed multiple times until all the events from the event burst have been ingested, and the system reaches its regular state of operation again.

Solution: During an event burst like the one that occurs when connecting to a Netcool server, all enabled policies are evaluated, and for the matching events, the associated fully automated runbooks are started. If many matching events exist, these events might result in a high load of concurrent runbook invocations that the runbook service rba-rbs is not able to handle. The system recovers automatically. However, some runbooks will not be run during the burst.

ObjectServer alerts missing in IBM Cloud Pak for AIOps due to a `No object found with id` error in the data layer

If a new alert is rejected by the data layer, subsequent update alerts may be rejected by the data layer with the error: **`No object found with id`** being found in the **`cp4waiops-cartridge.irdatalayer.errors`** Kafka topic.

Solution: The **`AIOpsAlertId`** column must be cleared so that when its updates reach the connector, the data will be perceived as a fresh alert by IBM Cloud Pak for AIOps.

To do this, use the following steps:

1. Disable the connector's data collection (this will trigger the gateway to shut down).
2. Go to the connector pod, remove the gateway cache file and SAF file under the following directory:

   `/bindings/netcool-connector/omnibus/var/G_CONNECTOR`

3. In the ObjectServer:
   1. Rectify the data columns that had resulted in wrongly mapped values.
   2. Clear the **`AIOpsAlertId`** column of the alert.
4. Enable the connector's data collection.

When processing the next update event to that alert, the connector will see an empty **`AIOpsAlertId`** and will generate **`"type": "update"`** in the northbound CloudEvent payload.

Setting values for mandatory fields for events sent to the embedded ObjectServer

If you are manually inserting events into the embedded ObjectServer using **`nco_sql`**, you must set values for the following fields so that the events can be processed correctly:

- **`Node`**
- **`AlertKey`**
- **`AlertGroup`**
- **`Manager`**

Note: This is only a concern if you are creating an event manually using an insert statement. All IBM Netcool Operations Insight probes will set all required columns.

Events from IBM Tivoli Netcool/OMNIbus are not updated in Alert Viewer

You might notice an issue where events from IBM Tivoli Netcool/OMNIbus reach Cloud Pak for AIOps, but the updates are not reflected in the Alert Viewer. The reason for this issue is that the Netcool connector might have restarted. The connector restart causes existing alerts in Cloud Pak for AIOps to dissociate from the origin alerts in the ObjectServer.

Solution: Upgrade Cloud Pak for AIOps to version 4.5.1 or newer. After the upgrade, the new alerts are not impacted by the Netcool connector restart.

Test connection fails in the Netcool connector UI configuration page

You might notice that the test connection fails in the Netcool connector UI configuration page.

Solution: Use the following steps to diagnose and resolve the connection failure.

1. Set the IBM Netcool Operations Insight ObjectServer log message level to **`debug`**. This can be done by updating the **`MessageLevel`** property in the **`$OMNIHOME/etc/{ObjectServer_name}.props`** file on the Netcool host. **`ObjectServer_name`** is the name of IBM Netcool Operations Insight ObjectServer.

2. Click **test connection** in the Netcool UI. Check if the IBM Netcool Operations Insight ObjectServer login attempt is received.

   - If no log in attempt is seen in the IBM Netcool Operations Insight ObjectServer log, check whether the IBM Netcool Operations Insight ObjectServer host IP that is resolved on Cloud Pak for AIOps matches the IBM Netcool Operations Insight ObjectServer host IP.

- If a log in attempt is seen but rejected by the OS authentication, check the Transport Layer Security (TLS) certificate, especially the Common Name (CN) value, which must match the fully qualified domain name (FDQN) of the server.

3. If the Connection manager is down or not responsive to the request to connect to the IBM Netcool Operations Insight ObjectServer, then restart the Connection manager pod.

4. For an on-premises IBM Netcool Operations Insight ObjectServer integration, you might notice these issues:

   - If the CN value in the TLS certificate does not match the host server FQDN, create a TLS certificate that contains the host FQDN.
   - If a firewall restriction exists on the IBM Netcool Operations Insight ObjectServer port, then update the firewall rules to unblock the port.

Fresh alerts are missing in Alert Viewer

You might notice an issue where the most recent alerts are not showing in Alert Viewer. You need to inspect the data in different stages of the pipeline to diagnose the problem.

When an alert is missing, you can scan the north-bound Kafka topics for the alert message. The following example shows the direction of the north-bound data flow:

Netcool connector -> **`cp4waiops-cartridge.lifecycle.input.alerts`** [topic] -> **`cp4waiops-cartridge.irdatalayer.requests.alerts`** [topic] -> Alert Viewer

Where:

- **`[topic]`** refers to a Kafka topic.
- **`cp4waiops-cartridge.lifecycle.input.alerts`** is a Kafka topic where all the new alerts are collected.
- **`cp4waiops-cartridge.irdatalayer.requests.alerts`** is a Kafka topic. **`cp4waiops-cartridge.irdatalayer.requests.alerts`** is one of the outcomes by the lifecycle.

Solution: Use the following steps to diagnose and resolve the missing alerts issue.

Note: Download and extract the **`Ext_IAFKafkaTools.tar.gz`** file located in Download Ext_IAFKafkaTools.tar.gz. After you extract the **`Ext_IAFKafkaTools.tar.gz`** file, follow the steps in the **`README.txt`** file.

1. Check whether an alert message appears in the **`cp4waiops-cartridge.irdatalayer.errors`** topic. Look for the alert message and run the following command.

   ```
   consumer.sh | grep <pattern>
   ```

   Inspect the cause of the error in the message.

2. Check whether the alert message appears in the **`cp4waiops-cartridge.lifecycle.input.alerts`** topic.

   The following example shows an alert message with **`type: update`**.

   ```
   {"tenantid":"cfd95b7e-3bc7-4006-a4a8-a73a79c71255","requestid":"b6079c67-8b2c-4a84-ae1d-9e50df05bfa1","requestTime":"2024-04-16T03:23:37.443484418Z","type":"update","entityType":"alert","entity":{"insights":[{"details":{"lastProcessedEventOccurrenceTime":"2024-04-16T03:23:33Z"},"id":"event-occurrence","type":"[aiops.ibm.com/insight-type/deduplication-details](https://aiops.ibm.com/insight-type/deduplication-details)"}],"deduplicationKey":"{hostname=null, name=null}-UserLogoutSessionEvent-","eventCount":84341,"state":"open","id":"9e96637d-15cf-4618-bdf7-ef97e6016128","type":{"classification":"UserLogoutSessionEvent","eventType":"problem"},"lastOccurrenceTime":"2024-04-16T03:23:33.000Z"}}
   ```

3. If a new alert message appears in **`cp4waiops-cartridge.lifecycle.input.alerts`** and fulfills the positive criteria of **`type: create`**, check whether the message is delivered to **`cp4waiops-cartridge.irdatalayer.requests.alerts`**.

   If the message is not found in the **`requests.alerts`** topic, the message is either blocked or rejected by the lifecycle process or not yet consumed from the **`input.alerts`** topic.

4. If the message passes through **`cp4waiops-cartridge.irdatalayer.requests.alerts`**, and is not reflected in the Alert Viewer, check the data layer process.

5. Restart the pod of the processes that are not working based on the error in the message. The pods that might need a restart depending on the error can be **`Grpc server`**, **`Life cycle processor`**, and **`Kafka broker`**.

6. If Kafka topics storage limitation is an issue, update the Kafka storage size.

ServiceNow integrations

Incidents aren't created

Incidents might not be created for various reasons.

Solution: Complete the following checks to help ensure that incidents can be created.

1. Validate the ServiceNow URL and credentials. Go to the ServiceNow integration page, select the integration, and select **Test connection**. If the test fails, check that the URL and credentials are correct.
2. Make sure that the versions of Cloud Pak for AIOps and the IBM ServiceNow marketplace applications are compatible. For more information about which version of Cloud Pak for AIOps is in use, see Prerequisites in Creating a ServiceNow integration.
3. Make sure that a policy is configured to use the existing ServiceNow connection. For more information about creating policies, see Promote alerts to an incident.
4. Make sure that the ServiceNow integration user has the correct permissions. For more information, see Managing roles.
5. Incident tables can have business rules that prevent incident creation. Check business rules and change them so that they don't affect incident tables.

Splunk integrations

If you are creating, or have, a Splunk integration, you might encounter the following issues while creating or editing the integration:

- All fields in the Splunk form reset if edited while loading metrics
- Splunk integrations that are created before upgrade fail to update after upgrade

All fields in the Splunk form reset if edited while loading metrics

If you edit the fields in the Splunk form while the metrics are loading in the integration console, then you cannot save the changes made to the form.

Solution: To avoid this issue, do not modify the fields in the Splunk form while metrics are loading. If you do so, then redo the changes after the metrics are loaded to save the edits.

Splunk integrations that are created before upgrade fail to update after upgrade

On upgrading from 3.5.0, you might not be able to enable or disable log or metric data flows on Splunk integrations that were created before upgrade. This issue can occur intermittently.

Solution: When this issue occurs, you can refresh the console and try again after some time. Alternatively, you can create a new integration and later delete the Splunk integration that was defined before upgrade.

IBM Tivoli Netcool/Impact integrations

If you are creating, or have, a IBM Tivoli Netcool/Impact integration, you might encounter the following issues:

- IBM Tivoli Netcool/Impact integration status shows "Retrying"
- IBM Tivoli Netcool/Impact stops sending data to widgets in a JazzSM dashboard
- AIOps data source in IBM Tivoli Netcool/Impact is missing required headers

IBM Tivoli Netcool/Impact integration status shows "Retrying"

After Creating IBM Tivoli Netcool/Impact integrations, you might see a **Connection Orchestration** status of "Done", but the **IBM Tivoli Netcool/Impact integration** shows an error with a status of "Retrying".

The reason for this error might be a locked IBM Tivoli Netcool/Impact file that is preventing the creation of the IBM Cloud Pak for AIOps data model in IBM Tivoli Netcool/Impact. If this is the issue, the **`impactserver-errors`** logs in IBM Tivoli Netcool/Impact will display an error similar to the following:

```
   30 Jun 2023 03:27:21,137 ERROR [DataModelUIResource] File etc/NCIP_datasourcelist is locked by user:
root.
```

Solution: Locate and delete a file called **`<servername>_versioncontrol.locks`** in IBM Tivoli Netcool/Impact and restart the IBM Tivoli Netcool/Impact server and GUI.

1. Log in to the IBM Tivoli Netcool/Impact host and navigate to the **`$IMPACT_HOME/etc`** directory. Locate a file called **`<servername>_versioncontrol.locks`**. For example, **`NCIP_versioncontrol.locks`**.

2. Delete the file.

3. Restart the Impact server and GUI:

   ```
   $IMPACT_HOME/bin/stopImpactServer.sh
   $IMPACT_HOME/bin/stopGUIServer.sh

   $IMPACT_HOME/bin/startImpactServer.sh
   $IMPACT_HOME/bin/startGUIServer.sh
   ```

The status of the **IBM Tivoli Netcool/Impact integration** should switch to **Running** in Cloud Pak for AIOps.

IBM Tivoli Netcool/Impact stops sending data to widgets in a JazzSM dashboard

After Creating IBM Tivoli Netcool/Impact integrations, the IBM Tivoli Netcool/Impact server stops sending data to widgets in a JazzSM dashboard. The widget will report an **ATKRST132E** or **404** error code.

Solution: Re-create the parameter files for the AIOPS_HandleAction and AIOPS_ExecJS Impact policies.

For more information, refer to the troubleshooting article Netcool/Impact datasets for DASH stop working after deploying the AIOps to Impact integration.

AIOps data source in IBM Tivoli Netcool/Impact is missing required headers

When an integration is made to IBM Tivoli Netcool/Impact, a RESTful data source is created in Netcool/Impact during the initialization stage.

However, the data source may be missing one or more fields including required headers. Attempting to edit or delete such a data source will fail with an error message:

```
Error : Version Control System failed. Check system error logs for further details
```

Solution:

To remedy this, you can add the required connection details and header values using the Netcool/Impact GUI.

1. Log into the Netcool/Impact GUI. Open the **Data Model** tab and make a note of the data source name. For example, **AIOps-impact-e92b7669-8809-4cc2-ab3c-5cbdf0db1534**
2. Open an SSH terminal to the primary Netcool/Impact server.
3. Change to the **etc** directory of the application:

   ```
   cd /opt/IBM/tivoli/impact/etc
   ```

4. Locate the data source file with the .ds extension. For example, **NCI_AIOps-impact-e92b7669-8809-4cc2-ab3c-5cbdf0db1534.ds**

   Note: If the file does not exist, create an empty file with the name of the missing data source.

5. Use the **svn add** command to manually add the file to version control:

   ```
   /opt/IBM/tivoli/impact/platform/linux/svn/bin/svn add NCI_AIOps-impact-e92b7669-8809-4cc2-ab3c-5cbdf0db1534.ds
   ```

6. Use the **svn commit** command to check in the file:

   ```
   /opt/IBM/tivoli/impact/platform/linux/svn/bin/svn commit -m "manual commit" NCI_AIOps-impact-e92b7669-8809-4cc2-ab3c-5cbdf0db1534.ds
   ```

7. Log in to the Impact GUI **Data Model** tab. Open the AIOPs data source.
8. Enter the following values in the connection details fields:

Field Name	Value
Host Name	**<HOSTNAME>**
Resource Path	/aiops
Port	443
Use HTTTPS	Enabled

   Replace **<HOSTNAME>** with the Cloud Pak for AIOps hostname. For example, **cpd-aiops.apps.clustername.cp.ibm.com**.

9. In **Request Headers**, add the following headers:

Header	Value
x-tenant-id	**cfd95b7e-3bc7-4006-a4a8-a73a79c71255**
Content-Type	**application/json;charset=utf-8**
Authorization	**ZenApiKey <KEY>**

   In the **Authorization** field, replace **<KEY>** with the API key. Follow the procedure from Configuring a connection in IBM Tivoli Netcool/Impact for IBM Cloud Pak for AIOps to retrieve the key.

   Note: In Netcool/Impact 7.1.0.32, you can hide the values by declaring the request headers as a protected header instead.

10. In the **Proxy Settings** tab, set the **Proxy Port** to **8080** and select **No Authentication** as the **Authentication Method**.

    Note: The **Password** field is ignored.

11. Save the data source. Click **Test Connection** to confirm the connection works.

Ansible Automation Controller integration not running due to prohibited egress

After configuring an Ansible Automation Controller integration, the integration reports *Not running*, and no Ansible templates are shown in the *Automation Actions* table.

Use the following steps to check whether the failure is due to prohibited egress:

1. Run the following commands to view the RBA Automation Service pod logs, and check whether responses are being received from Ansible:

   ```
   export AIOPS_NAMESPACE=<AIOps installation namespace>
   oc logs -l app.kubernetes.io/component=rba-as -n ${AIOPS_NAMESPACE}
   ```

   Example output if responses are not being received from Ansible:

   ```
   Error: awxp/requestAwx.requestAwx: Request to Ansible failed... Request was not responded after 5
   seconds
   ```

2. Run the following commands to attempt to connect to the Ansible instance from the RBA Automation Service pod:

   ```
   export AIOPS_NAMESPACE=<AIOps installation namespace>
   oc exec $(oc get pod -l app.kubernetes.io/component=rba-as -n ${AIOPS_NAMESPACE} -o
   jsonpath='{.items[0].metadata.name}') -c rba-as -n ${AIOPS_NAMESPACE} -it -- /bin/bash

   # An interactive shell inside the container will open
   curl -k -vvv <Your Ansible host>
   ```

Solution: If responses are not received from Ansible and you cannot connect to Ansible, then create a NetworkPolicy that allows egress from the RBA service pods. Run the following commands:

```
export AIOPS_NAMESPACE=<AIOps installation namespace>

cat << EOF | oc apply -f -
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: aiops-rba-rbs-egress
  namespace: ${AIOPS_NAMESPACE}
spec:
  egress:
  - {}
  podSelector:
    matchLabels:
      app.kubernetes.io/component: rba-rbs
  policyTypes:
  - Egress
EOF

cat << EOF | oc apply -f -
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: aiops-rba-as-egress
  namespace: ${AIOPS_NAMESPACE}
spec:
  egress:
  - {}
  podSelector:
    matchLabels:
      app.kubernetes.io/component: rba-as
  policyTypes:
  - Egress
EOF
```

Troubleshooting Secure Tunnel

Learn how to isolate and resolve problems with Secure Tunnel.

- Secure Tunnel connector is not running after restart with Podman
- fuser hangs when Secure Tunnel install script is launched
- When creating a Secure Tunnel connection, the status remains in pending for a long time
- Slack is unable to verify the secure tunnel URL
- Secure Tunnel connector pod in crash loop state after installation on OpenShift Container Platform cluster

Secure Tunnel connector is not running after a restart with Podman

This issue can occur when you install the Secure Tunnel connector to a host machine on which Podman is installed. When the host machine is rebooted and the Secure Tunnel connector is checked by using the **`podman ps -a`** command, the Secure Tunnel connector container does not display **`running`** status.

If this issue occurs, the **`podman-restart`** service must be activated by using the **`systemctl`** command:

```
systemctl start podman-restart
systemctl enable podman-restart
```

After entering the command, check **`podman-restart`** worked by using the following command:

```
systemctl status podman-restart
```

If the Connector is still not running, try restarting the host machine.

fuser hangs when Secure Tunnel install script is launched

After launching the Secure Tunnel install script, fuser hangs and you see something that resembles this

```
Checking whether docker or podman is installed ...
docker found.
Starting docker engine...
fuser found.
```

This issue can occur when fuser is having trouble finding a specific available port and so the execution stalls.

Solution: This issue rarely happens but should you encounter it edit the **`install-connector.sh`** and add a timeout in the fuser command.

Change **`PortCheck=$(fuser $HEALTHY_PORT/tcp 2>/dev/null)`** to **`PortCheck=$(timeout 2 fuser $HEALTHY_PORT/tcp 2>/dev/null)`**. This change can resolve the issue.

When creating a Secure Tunnel connection, the status remains in pending for a long time

When you use the **Custom** method to create a Secure Tunnel connection, the **Status** of the connection is stuck in **Pending** for a long time. This also occurs when you create a secure tunnel connection that uses a shortcut (for example, ChatOps, VMware or OpenStack).

This issue can occur when the **`tls secret`** was not created by the CertManager but the tunnel connection is waiting for it.

Solution: In most cases, re-creating the connection resolves the problem. If that does not work, you need to run the following command to restart the **IBM Cert Manager** and re-create the certificate CR to resolve this problem. Replace the namespace used here, **`cp4aiops`**, with your own namespace.

1. Find the namespace that IBM Cert Manager is deployed in.

   ```
   oc get pod -A | grep cert-manager-controller | awk '{print $1}'
   ```

2. Export environment variables:

   ```
   export CERT_MGR_NAMESPACE=<cert_namespace>
   export CONNECTION_NAME=<conn_name>
   ```

   Where:

   - **`<cert_namespace>`** is the namespace that IBM Cert Manager is deployed in.
   - **`<conn_name>`** is the name of the tunnel connection

3. Run the following commandL:

   ```
   for NAME in $(oc -n ${CERT_MGR_NAMESPACE} get pod --no-headers | grep cert-manager | awk '{print $1}')
   do
       oc -n ${CERT_MGR_NAMESPACE} delete pod ${NAME}
   done
   CONNECTION_ID=`oc -n cp4aiops get TunnelConnection ${CONNECTION_NAME} -o=jsonpath={.status.id}`
   oc -n cp4aiops delete certificates.certmanager.k8s.io sre-tunnel-${CONNECTION_ID}-server-cert
   oc -n cp4aiops delete certificates.certmanager.k8s.io sre-tunnel-${CONNECTION_ID}-connector-cert
   oc -n cp4aiops delete certificates.certmanager.k8s.io sre-tunnel-${CONNECTION_ID}-api-cert
   ```

Slack is unable to verify the secure tunnel URL

You can encounter an issue with Slack being unable to verify the secure tunnel URL after you set up a ChatOps secure tunnel connection. This issue can occur even when the Secure Tunnel UI shows that the installation was successful.

This issue can occur if you enabled the Egress Network policy with the **enableEgressNetworkPolicy: true** when you install the Secure Tunnel.

You can use the following command to check whether the egress network policy is enabled. If the egress network policy is enabled the output should be **true**.

```
oc -n <the namespace of the aiops> get Tunnel sre-tunnel -o=jsonpath='{.spec.enableEgressNetworkPolicy}'
```

Solution: Use the following YAML code to help you create an egress network policy in your IBM Cloud Pak for AIOps project (namespace) to allow Secure Tunnel access to the **ibm-nginx** gateway.

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: chatopstunnel-egress-ibm-nginx
  namespace: <the namespace of the aiops>
spec:
  podSelector:
    matchLabels:
      app.kubernetes.io/instance: sre-tunnel
      app.kubernetes.io/managed-by: tunnel
      app.kubernetes.io/name: sre-tunnel-chatopstunnel.app
      tunnel_connection_name: chatopstunnel
  egress:
    - to:
        - podSelector:
            matchLabels:
              app.kubernetes.io/component: ibm-nginx
              icpdsupport/app: gateway
              component: ibm-nginx
  policyTypes:
    - Egress
```

Secure Tunnel connector pod in crash loop state after installation on OpenShift Container Platform cluster

You might notice an issue where the Secure Tunnel connector pods stay in a crash loop state. The pod logs might show proxy related errors.

This issue can occur when the Secure Tunnel connector is installed on a cluster within an air-gapped (offline) environment that does not have outbound network access.

Solution: For the Secure Tunnel connector that is installed within the air-gapped (offline) environment, create a network connection with the Secure Tunnel server by using an HTTP proxy. You can create the connection by completing the following steps:

1. From a command line, go to the **tunnel-connector-install-scripts** directory.
2. Open the **tunnel-connector.yaml** file by using the following command:

   ```
   vi tunnel-connector.yaml
   ```

   When you open the YAML file, it can resemble the following example YAML file:

   ```
   apiVersion: v1
   kind: Secret
   metadata:
     labels:
       app.kubernetes.io/name: sre-tunnel-df012501eede4b02.secret
       app.kubernetes.io/managed-by: tunnel
       app.kubernetes.io/instance: sre-tunnel
       tunnel-network-name: woprod-test
       tunnel_connection_name: woprod-test
       tunnel_connection_id: "df012501eede4b02"
     name: sre-tunnel-df012501eede4b02-config
   data:
     config_connector.yaml: |
       <base64 encoded data>
   type: Opaque
   ```

3. Decode the **<base64 encoded data>** of the YAML file by using the following command:

   ```
   echo <base64 encoded data> | base64 -d
   ```

   Where **<base64 encoded data>** is the encoded data from the YAML file.

4. Update the **websocket_http_proxy** and **websocket_https_proxy** properties that are found in the decoded data.

   ```
   websocket_http_proxy: <http proxy endpoint>
   websocket_https_proxy: <https proxy endpoint>
   ```

Where

- `<http proxy endpoint>` is the HTTP proxy endpoint. This proxy is used by the tunnel connector to create a nonencrypted network web socket connection with the tunnel server. For example, the value can be `proxy.example.ibm.com:3128`.
- `<https proxy endpoint>` is the HTTPS proxy endpoint. This proxy is used by the tunnel connector to create an encrypted network web socket connection with the tunnel server. For example, the value can be `proxysecure.example.ibm.com:3128`.

5. Encode the data by using the following command.

```
echo '<decoded data>' | base64
```

Where `<decoded data>` is the decoded data with the two modified properties.

6. Add the Base64 encoded data to the `<base64 encoded data>`.

```
cat <<EOF | oc -n <namespace> apply -f -
apiVersion: v1
kind: Secret
metadata:
  labels:
    app.kubernetes.io/name: sre-tunnel-df012501eede4b02.secret
    app.kubernetes.io/managed-by: tunnel
    app.kubernetes.io/instance: sre-tunnel
    tunnel-network-name: woprod-test
    tunnel_connection_name: woprod-test
    tunnel_connection_id: "df012501eede4b02"
  name: sre-tunnel-df012501eede4b02-config
data:
  config_connector.yaml: |
    <base64 encoded data>

type: Opaque
EOF
```

Where

- `<base64 encoded data>` is the Base64 encoded data.
- `<namespace>` is the namespace where Secure Tunnel connector is installed.

7. Restart the Secure Tunnel connector pods by using the following command:

```
oc delete pod <secure-tunnel-connector-pod> -n <namespace>
```

Where

- `<secure-tunnel-connector-pod>` is the name of the Secure Tunnel connector pod.
- `<namespace>` is the namespace where Secure Tunnel connector is installed.

Troubleshooting AI model management

Learn how to isolate and resolve problems with AI model training.

- Larger data sets are taking a long time to train
- Log anomaly detection training is taking longer than expected
- Network issues with Elasticsearch
- Network issues with Spark
- Training encounters insufficient resources
- Training reports failure but process completes
- Log anomaly detection model deployment fails with error undefined
- Ingested raw logs are not available
- Statistical baseline reference can require manual reset
- How to stop a precheck job
- Evaluation of historical metric data gives inconsistent results
- Model training considers less historical data in a data quality check
- Deployed model status in a metric anomaly or temporal grouping training algorithm is changed to pending
- Model version deployment reports failure despite being successfully deployed
- The Alert suppression XinY policies tile does not appear in AI model management
- Related events training can fail when when you are processing a high alert count
- Ticketing integration missing from list of integrations
- Metric anomaly detection training fails after an extended time period

Larger data sets are taking a long time to train

If your data sets are large, it can take a long time for AI training to complete. For example, when you run log anomaly training a large log data set might take a full day to train.

By default, two training pods are assigned to handle training jobs. This number of pods is sufficient to complete training within acceptable time periods if your data sets are not too large. However, larger data sets can take a considerable amount of time to train based on two training pods that are running in parallel.

Solution: To speed up training, you must increase the number of training pods that are dedicated to training. The default value is two pods, regardless of the type of training definition that you are running.

A limit applies to the number of training pods that can be dedicated to training. Before you increase the number of training pods that are dedicated to training, it is important for you to be aware of these limits.

Each additional training pod requires approximately the following extra resources:

- 2.5 CPU cores
- 2 - 16 GBytes of memory, depending on the AI type that is trained.

Complete the following steps:

1. Log in to your cluster.
2. Go to the target IBM Cloud Pak for AIOps namespace.
3. Find the training resource quota by running the following command:

   ```
   oc get resourcequota | grep training
   ```

4. Edit the resource quota by running `oc edit resourcequota <name of resource quota found in step 3>`. Also, edit the `spec.hard.pods` field with the number of pods you want to dedicate to training simultaneously. Ensure that you have the needed resources as described in the Before you begin section.
5. Save the edit by typing `:wq` or `:x`. After a few minutes, the changes are automatically applied to your cluster, and you can start training.

Log anomaly detection training is taking longer than expected

Log anomaly detection training is taking longer than expected. Currently, log training times are on the order of 860 log records per second. This number is significantly slower than the 25,000 log records per second that is expected in enterprise environments. Log training time is proportional to the volume of log data passed through the training system.

This issue can occur as the training rate is constrained by the current system architecture.

Solution: This issue has no simple resolution. Depending on the data you are training, the following actions might have some impact on training times:

- Increase the number of training pods that are dedicated to training, as described in the **Solution** section of Larger data sets are taking a long time to train.
- Decrease the sampling size used for the training.

Network issues with Elasticsearch

The IBM Cloud Pak for AIOps IBM Cloud Pak for AIOps console is generating lots of network errors.

This issue occurs when Elasticsearch is in an unhealthy state. It occurs most likely due to issues with Elasticsearch connectivity.

Solution: Try to get more information on potential Elasticsearch issues by examining the AI Platform pod logs. Check to see whether any error logs associated with Elasticsearch connectivity exists.

1. Log in to your cluster by running the `oc login` command. You must be an administrator user within the project (namespace) where IBM Cloud Pak for AIOps is installed.

   ```
   oc login -u <username> -p <password>
   ```

   For more information, see Logging in to the OpenShift CLI.

2. Display the logs and look for error logs associated with Elasticsearch connectivity.

   ```
   oc logs $(oc get pods | grep ai-platform-api-server| awk '{print $1}')
   ```

Network issues with Spark

The AI platform has problems either launching training jobs, or reporting ongoing training status for the temporal grouping AI algorithm. As a result, you encounter errors on the Manage AI algorithms page.

This issue can occur as training jobs for the temporal grouping AI algorithm are orchestrated by the internal component Spark. When there are issues with launching training jobs or training status is not being displayed, it indicates that Spark is in an unhealthy state.

Solution: Try to get more information on potential Spark issues by examining the AI Platform pod logs.

Proceed as follows:

1. Log in to your cluster by running the **`oc login`** command. You must be an administrator user within the project (namespace) where IBM Cloud Pak for AIOps is installed.

   ```
   oc login -u <username> -p <password>
   ```

   For more information, see Logging in to the OpenShift CLI.

2. Display the logs and look for error logs associated with Spark.

   ```
   oc logs $(oc get pods | grep ai-platform-api-server| awk '{print $1}')
   ```

Training encounters insufficient resources

Training an AI algorithm returns an insufficient resources exception. The reason for this exception is that internal components within the training process were unable to locate a node with sufficient CPU or memory requirements to satisfy the training run.

Solution: The solution is to reduce the number of CPU and memory requests. Usually memory is the bottleneck so if you are unsure of what to do, a good option is to initially reduce memory by half.

1. Find the custom resource of the algorithm for which you want to alter the default resource requirements by running the following command:

   ```
   oc get algorithms
   ```

2. On running the command, custom resources containing all the algorithm specifications are displayed as follows:

   ```
   oc get algorithms
   ```

   ```
   NAME                AGE
   change-risk         46h
   log-anomaly         46h
   similar-incidents   46h
   ```

3. Edit the specific algorithm by running the following command:

   ```
   oc edit algorithm <name>
   ```

4. Decode the *spec.manifestBase64* field. Once decoded, you see a *resources* field that is defined as follows:

   ```
   resources:
       requests:
           cpu: 2
           memory: 4Gi
       limits:
           cpu: 2
           memory: 4Gi
   ```

   Note: You can edit requests and limits (make sure that **limits=requests** for training algorithms), re-encode to base64, and then replace the *manifestBase64* field in the CR with this newly encoded manifest.

5. Save the changes, and proceed with your training.

Training reports failure but process completes

An AI algorithm training run has completed, but the IBM Cloud Pak for AIOps console shows that the training has failed. No concrete model was generated during the training run.

The reason for this failure might be insufficient data or a misconfiguration in the range of the data set. Failure does not mean that the training failed; it just means that no value was obtained from the training run and consequently no model was produced.

Solution: Examine the data sources for the training, examine the training configuration, make any necessary changes, and launch the training again.

Log anomaly detection model deployment fails with error undefined

When you are training the log anomaly detection algorithm with historical data and you attempt to deploy the AI model, you might encounter an issue where the model deployment fails with an **`Error: undefined`** error in the UI.

Solution: As a workaround when this issue occurs, restart all **cp4waiops-eventprocessor** pods, which can cause the model deployment to complete successfully. To restart the pods, run the following command, which deletes the current instance of the pods and creates and starts a new instance of the pods.

```
oc delete po cp4waiops-eventprocessor-eve-29ee-ep-jobmanager-0 cp4waiops-eventprocessor-eve-29ee-ep-jobmanager-1 cp4waiops-eventprocessor-eve-29ee-ep-taskmanager-0 cp4waiops-eventprocessor-eve-29ee-ep-taskmanager-1
```

Note: If you installed IBM Cloud Pak for AIOps with a larger production deployment sizing, you need to specify any additional **cp4waiops-eventprocessor** pods that exist when you run the preceding command.

Ingested raw logs are not available immediately

Ingested raw logs are not available immediately for "Log anomaly detection - natural language" model training after the import is complete. Raw logs are not available for review in the "Preview log" section of the ChatOps Alert Viewer.

This issue can occur as additional time is required to store normalized logs in Elasticsearch after they are ingested. The amount of time can be reduced by allocating more Flink tasks to the Flink job that stores the normalized logs.

Solution: To resolve this issue, complete the following steps:

1. The environment variables that control the number of Flink tasks that are used to move logs to Elasticsearch are located in the Kubernetes deployment for aimanager-aio-controller. Edit this deployment: oc edit deployment aimanager-aio-controller
2. Find the environment variables by searching for "LOGS_JOB2_BASE_PARALLELISM". Change the value of LOGS_JOB2_BASE_PARALLELISM and LOGS_JOB2_NUM_PARTITIONS from their default values of 2 to something higher. Consider doubling the value to see whether it has the wanted effect.
3. Save the yaml and wait for the pods to restart. You can verify that the pods have restarted by monitoring the output of: oc get pods | grep aimanager-aio-controller
4. Stop the data flow for all logs integrations. It is important that there are no active logs integrations, as this is how the controller knows that it is OK to stop the Flink job, which copies the logs to Elasticsearch.
5. Restart the data flow for all logs integrations.

The Flink job restarts by using a higher number of tasks. It copies the logs to Elasticsearch more quickly.

Be careful not to allocate a higher parallelism than you have Flink task slots available. The number of tasks that you need can be calculated by adding the following values:

- sum of base_parallelism from all defined integrations, as defined in the Integration UI
- value of LOGS_JOB3_BASE_PARALLELISM multiplied by the number of logs type defined integrations (for example, Mezmo, Falcon Logscale, Splunk, and so on)
- value of LOGS_JOB2_BASE_PARALLELISM
- value of LOGS_JOB4_BASE_PARALLELISM

If you need additional task manager slots, you can add a task manager by Increasing data streaming capacity.

Statistical baseline reference can require manual reset

There is a chance that infrequently occurring anomalies are learned as normal behavior and they might not be detected anymore. For instance, if interval for the infrequently occurring anomalies do not exceed the predefined threshold of 0.15, the interval is not tagged as biased and the reference values are updated and the anomaly is learned as normal behavior. If this occurs, you need to reset the learning by resetting the reference of the statistical baseline with the following steps.

Select the instructions for your deployment architecture.

Deployments on Red Hat® OpenShift® Container Platform:

1. Open a terminal and log in to your cluster:

   ```
   oc login <server> -u <cluster username> -p <cluster pass>
   ```

2. Open another terminal and run port-forwarding for Elasticsearch

   ```
   while true; do oc port-forward $(oc get po | grep iaf-system-elasticsearch-es-aiops-0 | awk '{print $1}') 9200; done
   ```

3. Get the Elasticsearch credentials:

   ```
   export username=$(oc get secret iaf-system-elasticsearch-es-default-user -o jsonpath="{.data.username}"|base64 -d);
   export password=$(oc get secret iaf-system-elasticsearch-es-default-user -o jsonpath="{.data.password}"|base64 -d);
   ```

4. Reset the statistical baseline reference:

```
curl -u $username:$password -XDELETE https://localhost:9200/1000-1000-reference_oob --insecure | sort
```

Deployments on Linux

1. SSH into a control plane node or the loadbalancer VM on your Linux® deployment, and then switch to the namespace where IBM Cloud Pak for AIOps is installed.
2. Run the following command to switch to your IBM Cloud Pak for AIOps project.

   ```
   export PROJECT_CP4AIOPS=<project>
   ```

   Where **<project>** is the namespace (project) that IBM Cloud Pak for AIOps is deployed in.
3. Reset the statistical baseline reference:

   ```
   export ELASTIC_SET="$(oc get statefulset -l app.kubernetes.io/managed-by=ibm-elasticsearch -o
   jsonpath='{.items[0].metadata.name}')"
   oc exec "statefulset/${ELASTIC_SET}" -- curl -XDELETE -k --fail "http://127.0.0.1:19200/1000-1000-
   reference_oob"
   ```

How to stop a precheck job

The workaround is to stop the precheck job manually using Openshift CLI commands, delete the training definition, recreate the training definition, and relaunch the training configuration with the correct details.

There are two methods to do this. The first is recommended as it limits mistakes and there is less risk of making training off sync with data in the Elasticsearch database, but the models are deleted if you use this method, whereas with the second method that is listed they will not, so it's preferable to use the second method if you want to conserve the models in question.

Method 1: Stop the precheck job and delete the training definition to start afresh

1. Retrieve the precheck job in the IBM Cloud Pak for AIOps namespace, or a different namespace that it is installed under:

   ```
   oc get jobs | grep precheck
   ```
2. Delete the precheck job in order to stop the precheck run:

   ```
   oc delete job <job-name>
   ```
3. Delete the training definition using the delete button on the console.
4. Re-create the training definition with the correct configurations required for the training algorithm, for example date range or scheduling.
5. Run the training as usual.

Method 2: Stop precheck job and clean up Elasticsearch data

1. Retrieve the precheck job in the IBM Cloud Pak for AIOps namespace, or a different namespace that it is installed under:

   ```
   oc get jobs | grep precheck
   ```
2. Delete the precheck job in order to stop the precheck run:

   ```
   oc delete job <job-name>
   ```
3. Retrieve the AI Platform pod name in the IBM Cloud Pak for AIOps namespace or different namespace that it is installed under:

   ```
   oc get pod | grep api-server
   ```
4. Enter inside the pod:

   ```
   oc rsh <pod-name> # Example: oc rsh aimanager-aio-ai-platform-api-server-55d5b59bd4-jk7nz
   ```
5. Verify the latest precheck run and retrieve the '_id' required for cleanup:

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/precheckrun/_search?pretty=true" -H 'Content-Type:
   application/json' -d '{"query": {"match_all": {}},"size": 1,"sort": [{"timestamp": {"order":
   "desc"}}]}'
   ```

   Example:

   ```
   "_id":
   "log_anomaly_detection_configurationv3"
   ```
6. Use the '_id' and version specified in the ID to delete the precheck respective run entries in elasticsearch:

   ```
   curl -k -u <username>:<password> -X POST $ES_URL/precheckrun/_delete_by_query" -H 'Content-Type:
   application/json' -d '{"query": {"term": {"_id": <ID retrieved from previous step>}}}'
   ```

Example:

```
curl -k -u <username>:<password> -X POST $ES_URL/precheckrun/_delete_by_query" -H 'Content-Type:
application/json' -d '{"query": {"term": {"_id": "log_anomaly_detection_configurationv3"}}}'

curl -k -u <username>:<password> -X POST $ES_URL/precheckstatus/_delete_by_query" -H 'Content-Type:
application/json' -d '{"query": {"term": {"precheckRunVersion": <version retrieved from previous
step>}}}'
```

Example:

```
curl -k -u <username>:<password> -X POST $ES_URL/precheckstatus/_delete_by_query" -H 'Content-Type:
application/json' -d '{"query": {"term": {"precheckRunVersion": "v3"}}}'
```

7. Update the training definition document to decrement the precheck run version:

```
curl -k -u <username>:<password> -X POST
$ES_URL/trainingdefinition/_update/log_anomaly_detection_configuration" -H 'Content-Type:
application/json' -d '{"doc": {"precheckRunVersion": <decremented version>}}'
```

Example:

```
curl -k -u <username>:<password> -X POST
$ES_URL/trainingdefinition/_update/log_anomaly_detection_configuration" -H 'Content-Type:
application/json' -d '{"doc": {"precheckRunVersion": "v2"}}'
```

8. Make your changes to the training configuration, for example to the date range or scheduling.
9. Run the training as usual.

Evaluation of historical metric data gives inconsistent results

Sending historical metric data for training – such as in a product demonstration – you see inconsistent outcomes in the IBM Cloud Pak for AIOps console metric anomaly results.

At inference (metric evaluation) time, it takes a short amount of time to load analytics models into memory. This delay might lead to some metric data being left out of an evaluation.

Solution: Send in one datapoint, for each individual metric, to allow the model to be loaded. Then, send remaining data after a short interval, 30 - 60 seconds later.

Model training considers less historical data in a data quality check

Less data is included in a data quality check if you select **Training** first instead of running a precheck and training separately.

If you select **Training** to run both a data quality check and training sequentially, you might notice this problem. This situation occurs only when some integrations are moved into live data after the training completes, and the training dates are changed to check historical data from another integration source.

Solution: Run the precheck and training separately. Start the data quality precheck, and after the precheck is complete, run the training after.

Deployed model status in a metric anomaly or temporal grouping training algorithm is changed to pending

A temporal grouping or a metric anomaly detection algorithm is in a pending state although the model was previously trained and deployed with success.

Solution: To resolve this issue, complete the following steps:

1. Run the `oc -n <namespace> rsh <aimanager-aio-ai-platform-api-server-*>` command.
2. Delete all versions of the `metric_anomaly_detection_configuration` or `temporal_grouping_configuration` training algorithms in the `trainingrun` index. Search the index by running the following command:

   ```
   ./elastic.sh -X GET -E trainingrun/_search\?pretty=true&size=1000
   ```

3. Identify all the documents that are related to your `metric_anomaly_detection_configuration` or `temporal_grouping_configuration` training algorithms. The `_id` field of the documents is `metric_anomaly_detection_configurationv<version>` or `temporal_grouping_configurationv<version>`, where `<version>` is the version of the training run.
4. Delete the training run documents:

```
./elastic.sh -X DELETE -E trainingrun/_doc/metric_anomaly_detection_configurationv1
./elastic.sh -X DELETE -E trainingrun/_doc/metric_anomaly_detection_configurationv2
[..]
```

or

```
./elastic.sh -X DELETE -E trainingrun/_doc/temporal_grouping_configurationv1
./elastic.sh -X DELETE -E trainingrun/_doc/temporal_grouping_configurationv2
[..]
```

5. Delete the training definition to clean the UI:

```
./elastic.sh -X DELETE -E trainingdefinition/_doc/metric_anomaly_detection_configuration
```

or

```
./elastic.sh -X DELETE -E trainingdefinition/_doc/temporal_grouping_configuration
```

6. Now, you can train a new model.

Model version deployment reports failure despite being successfully deployed

When you deploy LAD model version manually, you might encounter an error message on your console that reports deployment failure. The error message reads that the failure occurs due to the version being already deployed.

This error arises due to the successful deployment of the model version in the background despite getting timed out.

Solution: Restart the data flow for all the integrations. To do so, first disable and then re-enable the data flow for all integrations.

The Alert suppression XinY policies tile does not appear in AI Model Management

In the IBM Cloud Pak for AIOps console, click **AI model management** and find the *Alert suppression XinY policies* tile. If this tile does not appear, an administrator or developer user needs to restart the `aimanager-aio-ai-platform-api-server` pod.

To restart the target pod, delete the pod so that a new pod automatically starts up:

1. Connect to your cluster with the `oc login` command.
2. Restart the `aimanager-aio-ai-platform-api-server` pod.

   ```
   oc delete pod/"$(oc get pod|grep aimanager-aio-ai-platform-api-server|awk '{print$1; exit}')"
   ```

   Successfully running this command produces output similar to the following example:

   ```
   pod "aimanager-aio-ai-platform-api-server-55c5d975c4-6qpwk" deleted
   ```

Related events training can fail when when you are processing a high alert count

When you are running related events training on a data set that includes a high number of alerts (approximately 11.5M or more alerts), the training can fail. When this failure occurs the Spark log includes thrown exceptions.

The spark log exceptions can resemble the following output:

```
24/02/23 10:16:01 ERROR TaskSetManager: Task 0 in stage 3215.0 failed 4 times; aborting job
24/02/23 10:16:01 INFO TaskSchedulerImpl: Removed TaskSet 3215.0, whose tasks have all completed, from pool
24/02/23 10:16:01 INFO DAGScheduler: Job 326 failed: $anonfun$withThreadLocalCaptured$1 at <unknown>:0, took
0.996638 s
24/02/23 10:16:01 INFO TaskSchedulerImpl: Cancelling stage 3215
24/02/23 10:16:01 INFO TaskSchedulerImpl: Killing all running tasks in stage 3215: Stage cancelled: Job
aborted due to stage failure: Task 0 in stage 3215.0 failed 4 times, most recent failure: Lost task 0.3 in
stage 3215.0 (TID 2975) (10.254.75.83 executor 0): org.apache.spark.SparkException: Checkpoint block
rdd_680_0 not found! Either the executor
that originally checkpointed this partition is no longer alive, or the original RDD is
unpersisted. If this problem persists, you may consider using `rdd.checkpoint()`
instead, which is slower than local checkpointing but more fault-tolerant.

        at org.apache.spark.rdd.RDD.iterator(RDD.scala:328)
```

Solution: As a workaround if this failure occurs, increase the spark worker memory limit and run the training again.

The spark worker memory limit can be modified by using the following command:

```
oc edit sts aiops-ir-analytics-spark-worker
```

The field that needs modification is the **memory** field as shown in the following example output:

```
resources:
  limits:
    memory: 8000Mi
```

Ticketing integration missing from list of integrations

If a ticketing integration is missing from the list of integrations in a training module such as Similar tickets or Change risk, you should update that integration. To do this, edit the integration and either update the existing description or add a new one, then save your changes. This action will trigger a resynchronization of the connector schema for that integration. After a few minutes, the updated integration should appear in the trainer **Integrations** table.

Metric anomaly detection training fails after an extended time period

Previously deployed metric anomaly detection training models stop running successfully.

An error similar to the following example appears in the Cassandra logs:

```
ERROR [ReadStage-2] 2024-10-22 11:53:22,943 StorageProxy.java:2175 - Scanned over 100001 tombstones during
query 'SELECT value FROM tararam.dt_metric_value WHERE token(t_uid, mr_id) >= token('cfd95b7e-3bc7-4006-
a4a8-a73a79c71255', 28f522d0-5c6a-3d8a-b867-8a449f3e5fa9) AND token(t_uid, mr_id) <= 515685720241936768
LIMIT 1000 ALLOW FILTERING' (last scanned row token was 4404220741919580179 and partion key was ((cfd95b7e-
3bc7-4006-a4a8-a73a79c71255, bab5050a-5780-3e92-b8b4-8baa00cbfe42), 2024-09-27T18:25:00.000Z)); query
aborted
```

Solution: Clear the already expired metric data and then restore the expiration interval to its original value.

1. Connect to the Cassandra database:

   ```
   Login the CQL for cassandra:
          export CASSANDRA_PASSWORD=$(oc get secret aiops-topology-cassandra-auth-secret --template=
   {{.data.password}} | base64 --decode);echo $CASSANDRA_PASSWORD
          oc exec -ti aiops-topology-cassandra-0 -- /opt/ibm/cassandra/bin/cqlsh -u admin -p <PASSWORD
   FROM PREVOUS> --ssl
   ```

2. Set the **gc_grace_seconds** period on the metric data table to 10 minutes:

   ```
   cqlsh> ALTER TABLE tararam.dt_metric_value WITH gc_grace_seconds=600;
   ```

3. Wait at least 10 minutes for the data to expire.
4. Then, set the table back to its original value:

   ```
   cqlsh> ALTER TABLE tararam.dt_metric_value WITH gc_grace_seconds=864000;
   ```

Troubleshooting alert management

Learn how to isolate and resolve problems with alert management.

- No alert or incident created when an event is sent
- No alert ranking with large installations
- Closed alerts are not being removed from Alert Viewer
- No alerts shown in Alert Viewer and "Unknown error" message is displayed
- Alert list ignores saved view sort order
- "Unknown error" message in Alert Viewer when you click the alert view without selecting the ID and Summary columns

No alert or incident created when an event is sent

Symptom A: An event is sent, but no alert is received by IBM Cloud Pak® for AIOps and no incident is created.

Running `waiops-mustgather.sh -V flink-jobs` using the must-gather tool, returns `"RESTARTING"` or `"FAILED"` under the entry `[FLINK = aiops-ir-lifecycle]`. For example:

```
[FLINK = cp4aiops]
{
  "jobs": []
}

[FLINK = aiops-ir-lifecycle]
{
  "jobs": [
    {
      "id": "4e442c7880239bede340e953e6b920b3",
      "status": "RESTARTING"
    }
  ]
}
```

This issue might be caused by a volume of event data that is too large for the given installation size and configured policy set. This can cause the policy engine to run out of available memory.

Solution: To resolve this issue, complete the following steps:

1. Evaluate the sizing of the installation compared to the current event load. If there is a miss-match, change the installed sizing, or the configured event sources.
2. Ensure that incident creation policies are only configured to raise incidents for alerts which require immediate resolution. Incidents are more resource intensive to process than alerts, so creating incidents for all alerts will require a larger sized installation.
3. After re-configuring the system, the policy engine may still be in a failure state as it tries to re-process the already-inserted events. It is possible to reset the policy engine so that it only processes new events using the must-gather tool:

   ```
   waiops-mustgather.sh -DR -C clear-lifecycle-state.sh
   ```

   NOTE: Resetting the policy engine will cause all policy state to be lost. This may result in events creating new alerts and incidents rather than being deduplicated into existing ones. It will also mean that any events inserted in the time between the failure and running this command will not be processed by the system.
4. Restart the `flink` pods:
   1. Search for the pods that match the string `aiops-ir-lifecycle-flink`
      This should return four pods.
   2. Right-click and **Delete** the pods.
      The pods should restart immediately.

Symptom B: An event is sent, but no alert is received by IBM Cloud Pak® for AIOps and no incident is created. The log of the lifecycle task manager pod contains the following error:

```
WARNING: Exception thrown during asynchronous load
java.util.concurrent.CompletionException: io.grpc.StatusRuntimeException: UNAVAILABLE: ssl exception
```

The issue might be a certificate mismatch between the lifecycle operator and the policy GRPC server, causing the connection to fail with SSL exceptions.

Solution: To resolve this issue, complete the following steps:

1. Run the following command to delete the certificate:

   ```
   oc delete secret aiops-ir-lifecycle-policy-grpc-clt-svc aiops-ir-lifecycle-policy-grpc-svc
   ```
2. Get the lifecycle-operator pod name:

   ```
   oc get pods |grep ir-lifecycle-operator-controller-manager
   ```
3. Restart the lifecycle operator:

   ```
   oc delete pod ir-lifecycle-operator-controller-manager-<lifecycle-operator-pod-name>
   ```

No alert ranking with large installations

On larger production scale installations of IBM Cloud Pak® for AIOps, no ranking of alerts is displayed in the Alert Viewer.

Solution: To resolve this issue, complete the following steps:

1. Run the following command to find the **classifier** and **probablecause** pods:

   ```
   oc get pods | egrep -i "classifier|probablecause"
   ```

   For example:

   ```
   oc get pods | egrep -i "classifier|probablecause"

   aiops-ir-analytics-classifier-6477fd7788-4rzwx                    1/1     Running     0
   aiops-ir-analytics-classifier-6477fd7788-8jd55                    1/1     Running     0
   aiops-ir-analytics-probablecause-5b89d56c44-b752h                 1/1     Running     1
   aiops-ir-analytics-probablecause-5b89d56c44-kpqcb                 1/1     Running     1
   ```

2. Restart the pods:

   ```
   oc delete pods aiops-ir-analytics-classifier-6477fd7788-4rzwx aiops-ir-analytics-classifier-6477fd7788-
   8jd55 aiops-ir-analytics-probablecause-5b89d56c44-b752h aiops-ir-analytics-probablecause-5b89d56c44-
   kpqcb
   ```

Closed alerts are not being removed from Alert Viewer

You might notice an issue where closed alerts are not being removed from the Alert Viewer.

If this issue occurs, you might see an error that is related to timeouts for requests to Postgres. This error can be similar to the following example:

```
[2023-12-12T17:30:30.022Z] ERROR: datalayer.postgres/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz:
Error detected on streaming query
    Error: Query timed out
        at Timeout._onTimeout (/app/lib/helpers/dbservice/lib/helpers/dbservice/postgres.js:178:20)
        at listOnTimeout (node:internal/timers:559:17)
        at processTimers (node:internal/timers:502:7)
[2023-12-12T17:30:30.022Z] ERROR: datalayer.postgres/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz:
Error detected on client connection. Ending query stream (reqid=13778660-9914-11ee-844d-e573891ebc4b)
    Error: Query timed out
        at Timeout._onTimeout (/app/lib/helpers/dbservice/lib/helpers/dbservice/postgres.js:178:20)
        at listOnTimeout (node:internal/timers:559:17)
        at processTimers (node:internal/timers:502:7)
[2023-12-12T17:30:30.024Z] ERROR: datalayer.postgres/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz:
Error detected on streaming query cursor
    Error: Connection terminated
        at Connection.<anonymous> (/app/node_modules/pg/lib/client.js:132:36)
        at Object.onceWrapper (node:events:627:28)
        at Connection.emit (node:events:525:35)
        at Socket.<anonymous> (/app/node_modules/pg/lib/connection.js:63:12)
        at Socket.emit (node:events:525:35)
        at TCP.<anonymous> (node:net:301:12)
```

This issue might be caused by the failure of the datalayer job manager. Since the job is not running, there is no automated process for clearing the closed alerts.

Solution: Use the following steps to resolve the closed alerts issue:

1. Determine the name of the datalayer job manager pod.

   ```
   oc get pod -l "app.kubernetes.io/component=ncodl-jobmgr"
   ```

   The output from the preceding command can look like the following example::

   ```
   [root@6c025b05c0a7 /]# oc get pod -l "app.kubernetes.io/component=ncodl-jobmgr"
   NAME                                        READY   STATUS    RESTARTS   AGE
   aiops-ir-core-ncodl-jobmgr-85458b4979-gqgj8   1/1     Running   0          5h11m
   ```

2. Use the pod name to describe the job manager pod. If the pod is in a crash loop or not scheduled status, use the following command to see the failure:

   ```
   oc describe pod <pod name>
   ```

   Where **<pod name>** is the name of the datalayer job manager pod.

   If the failure reason from describe command is not clear or the pod appears to be running fine then check the pod logs for potential run failure conditions. Use the following command to check the logs:

   ```
   oc logs <pod name>
   ```

   Where **<pod name>** is the name of the datalayer job manager pod.

You can, for example, search for "Alert delete job" in the logs. "Alert delete job" must be running. The logs for delete job are shown in the following example.

```
[2023-12-12T17:38:00.002Z]  INFO: datalayer.jobmgr/14 on aiops-ir-core-ncodl-jobmgr-7f4c64dcdd-d7xjz:
Running: Alert delete job [2023-12-12T17:38:30.120Z]  INFO: datalayer.jobmgr/14 on aiops-ir-core-ncodl-
jobmgr-7f4c64dcdd-d7xjz: Complete: Alert delete job
 metrics: {
   "fetched": 0,
   "deleted": 0,
   "failed": 0
 }
 --
 psql: [
   {
     "name": "deletes",
     "mean": 0,
     "min": 0,
     "max": 0
   },
   {
     "name": "relatedDeletes",
     "mean": 0,
     "min": 0,
     "max": 0
   }
 ]
```

3. Use the following command to check whether the postgres instance is **Running**:

   ```
   oc get pods | grep postgres
   ```

   The postgres pod name might be similar to **ibm-cp-watson-aiops-edb-postgres-***. The asterisk (*) represents multiple pods that might be running for postgres.

4. If the Postgres instance is running fine, then it is possible that the instance might be busy and overloaded. If you see the preceding error such as "timeouts on request Postgres" or if the Postgres instance is running fine, in both cases use the following script to manually purge and recover the system.

   ```
   #!/bin/bash

   EDBPOD=ibm-cp-watson-aiops-edb-postgres-1
   EBDSECRET=aiops-ir-core-postgresql

   # Get the credentials from required sec
   USERNAME=$(oc get secret ${EBDSECRET} -o=jsonpath='{.data.username}' | base64 -d)
   PASSWORD=$(oc get secret ${EBDSECRET} -o=jsonpath='{.data.password}' | base64 -d)
   DBNAME=$(oc get secret ${EBDSECRET} -o=jsonpath='{.data.dbname}' | base64 -d)
   SCHEMA=$(oc get secret ${EBDSECRET} -o=jsonpath='{.data.schema}' | base64 -d)

   # RSH into EDB container.
   oc rsh ${EDBPOD} psql -h localhost -p 5432 -U ${USERNAME} "dbname=${DBNAME} sslmode=require" -- <<EOF
   ${PASSWORD}

   DELETE FROM aiops_irb.alerts WHERE state=2;
   DELETE FROM aiops_irb.insights insight WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE
   insight.parentid = alert.alertid) AND NOT EXISTS(SELECT 1 FROM aiops_irb.stories story WHERE
   insight.parentid = story.storyid);
   DELETE FROM aiops_irb.links link WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE
   link.parentid = alert.alertid) AND NOT EXISTS(SELECT 1 FROM aiops_irb.stories story WHERE link.parentid
   = story.storyid);
   DELETE FROM aiops_irb.timeline timeline WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE
   timeline.parentid = alert.alertid) AND NOT EXISTS(SELECT 1 FROM aiops_irb.stories story WHERE
   timeline.parentid = story.storyid);
   DELETE FROM relationships relation WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE
   relation.childid = alert.alertid) AND NOT EXISTS(SELECT 1 FROM aiops_irb.stories story WHERE
   relation.parentid = story.storyid);
   DELETE FROM aiops_irb.alerts_details detail WHERE NOT EXISTS(SELECT 1 FROM aiops_irb.alerts alert WHERE
   detail.identifier = alert.identifier);
   EOF
   ```

   Where **EDBPOD** is the Postgres pod name that you obtained previously.

   The script deletes all closed alerts from the Alert Viewer. The job manager will also be able to remove the future closed alerts automatically.

   A sample output from successful execution of the script:

   ```
   Defaulted container "postgres" out of: postgres, bootstrap-controller (init)
   Password for user aiops_irb:
   DELETE 0
   ```

```
DELETE 0
DELETE 0
DELETE 0
DELETE 0
DELETE 0
```

The number after the **DELETE** keyword is the number of rows that are deleted.

"Unknown error" message in Alert Viewer and no alerts displayed

Symptom: No alerts are shown in the Cloud Pak for AIOps Alert Viewer and "Unknown error" message is displayed on the UI.

Cause: The problem might be that the number of alerts exceeds what the Alert Viewer can process. A production deployment of Cloud Pak for AIOps can process a standing alert count of up to 200,000 alerts, with a chosen subset displayed in the Alert Viewer. The precise number of alerts that can be shown depends on different permutations of variables that affect the performance of the Alert Viewer. For example, standing alert count, filtered alert count, and view used (such as simple columns with alert data, or complex columns with insights and custom user enriched columns).

Solution: At first (during deployment or creation of a new view), try excluding columns with insights or columns based on custom properties. You can then add these columns sequentially to better gauge how many alerts a view can handle. For more information, see Creating views.

You can also restrict the number of alerts that are returned by the data layer to the Alert Viewer. This can improve performance issues on the backend. For more information, see Restricting the number of alerts returned by the data layer to the Alert Viewer.

Alert list ignores saved view sort order

Symptom: The alerts table sort order you wanted to apply to it does not save as expected.

Cause: It might be related to a similar issue, which deals with editing the alert view and how it then does not show the correct configuration when launched for the first time. This is due to having to fetch users and groups before being able to show the right view configuration. This is being fixed now also, so should no longer be an issue in future releases.

Solution: If the original alert table sort order didn't save as expected, you have to apply the sort order again after the alerts table is loaded.

"Unknown error" message in Alert Viewer when you click the alert view without selecting the ID and Summary columns

Symptom: You may get the unknown error when you click the alert view without having selected the ID and SUMMARY columns.

Cause: This problem is because the view requires the ID and SUMMARY columns to be part of the view. If these columns are not included in the view then it will be unusable and the only way to delete that view will be by using the API.

Solution: Include the ID and SUMMARY columns in the alert view. If you do not and cannot then delete the unusable view that results, you will have to delete the view using the API.

Troubleshooting Runbook Automation

Learn how to isolate and resolve problems with Runbook Automation.

- SSH action output shows "Permission denied" error
- SSH automation action output for PowerShell shows garbled multi-byte characters
- Exported runbook includes password from referenced action in clear text (if any)
- Runbook approval request not visible

SSH action output shows "Permission denied" error

Symptom: When attempting to run an SSH action script on some Linux target system, an error such as **`bash: /tmp/tmp.gXO9WCs7Zy: Permission denied`** is displayed in the script output area.

Cause: In order to run an SSH script on a Linux target system, Runbook Automation writes a temporary script file to the **`/tmp`** directory of the target system, and executes it from there. So the user on the target system that is configured to run the SSH script remotely does not only need to have write access to the **`/tmp`** directory , but also the **`/tmp`** directory itself must not be mounted with the **`noexec`** property.

Solution: Mount the **`/tmp`** directory without the **`noexec`** property, and verify that scripts can be run from within **`/tmp`**. Then retry running the SSH action.

If using the `/tmp` directory with write and execute access is prohibited in your organization then you can configure `mktemp` to use a different directory, for example, by generally setting the target system user's `TMPDIR` environment variable to an alternative directory path. See Creating an SSH integration for more details on the requirements for target systems of SSH connections.

SSH automation action output for PowerShell shows garbled multi-byte characters

Symptom: When running a PowerShell script on a Windows target system that is expected to print multi-byte or other non-ASCII characters, these characters are not properly displayed. Instead, these characters are replaced with question marks.

Cause: Runbook Automation expects the script output to be returned in UTF-8 format, but PowerShell is not configured to use UTF-8 as the default console output encoding.

Solution: Add an instruction to your PowerShell script code to set the console output encoding to UTF-8. For example, start your script with the following command:

```
$OutputEncoding = [Console]::OutputEncoding = [Text.UTF8Encoding]::UTF8
```

See the Microsoft documentation for more details on character encoding in PowerShell.

Exported runbook includes password from referenced action in clear text (if any)

Symptom: If an HTTP action has parameters for basic authentication configured, and the action is referenced by a runbook, then exporting the runbook using the RBA API includes the password in clear text.

Cause: The exported runbook is intended to be self-contained, so when imported to the same or a different deployment, the runbook is usable again (which includes having the password available). However, there is no password encryption/decryption mechanism in place for this scenario.

Solution:

- Avoid specifying passwords within actions.
- Store the exported runbook file in a place that only persons with a need-to-know for the password(s) have access to.
- Encrypt the exported file manually.

Runbook approval request not visible

Symptom: When the approval flow is enabled, and a runbook has been previously published, then a new request for approval for an updated draft of the runbook is not visible in the runbook library table. The expected approval status is "Approval pending". Instead, the runbook continues to be marked as "Approved".

Cause: The runbook library table displays the data from the last published version of the runbook, or from the draft runbook if it has never been published before. Therefore, approval requests for new draft runbooks are visible, but not for runbooks that have been previously published.

Solution: As author of the change, notify the approver which runbook needs to be reviewed and approved. As approver, open the runbook in "edit" or "preview" mode to see the latest changes. Directly communicate with the author if changes are needed. Once the runbook is ready to be published, disable the approval flow temporarily, and publish the runbook.

Troubleshooting ChatOps

Learn how to isolate and resolve problems with ChatOps IBM Cloud Pak® for AIOps.

- Slack buttons are unresponsive
- Log preview dialog or View alerts dialog hangs intermittently in an incident in Slack or Microsoft Teams
- Alert and incidents do not appear in Slack
- Slack ChatOps integration is not working within an air-gapped (offline) environment
- Microsoft Teams ChatOps integration shows no response in the console
- During a ChatOps secure tunnel creation an 'installation failed' message displays
- Show more button does not work in Slack after an upgrade
- Links in ChatOps incident messages are invalid

Slack buttons are unresponsive

Unresponsive buttons might be caused by a number of issues. If you encounter this issue, try completing the following steps to find the cause of the problem:

1. **Ensure two-way communication is established:**

    1. **Test two-way communication:** Incoming incidents are proof that one-way communication from IBM Cloud Pak for AIOps to Slack is successful. To check two-way communication, tag the IBM Cloud Pak for AIOps bot in the Slack channel. It responds with "Hey there I'm up and running." If it doesn't, IBM Cloud Pak for AIOps might not be receiving any communication from Slack.
    2. **Verify endpoints:** If the IBM Cloud Pak for AIOps bot did not respond, it might be that Slack is trying to communicate with the wrong endpoints, or the endpoints are not publicly accessible. To make sure that the endpoints are correct, open up the slack api for the app and navigate to the app manifest. The `event_subscriptions` and `interactivity` urls should match the ones that are produced by the IBM Cloud Pak for AIOps slack configuration and should be verified by Slack. If they do match but Slack has not verified them, that means Slack cannot access the endpoints likely because they are private. Slack needs some kind of proxy to access the private endpoints. A secure tunnel can be used in scenarios like this. For more information, see Secure Tunnel.
2. **Check communication speed:** If there are no problems with the steps that are outlined above, then it is possible the communication between Slack and IBM Cloud Pak for AIOps is taking too long. If a button is clicked, Slack waits 3 seconds to receive a response. If it doesn't get one, the communication is rejected and the button click fails. This is a rare occurrence, but can happen if the network communication is too slow, or if something else is preventing communication from happening in a timely manner. Try reconnecting and reconfiguring the Slack integration. For more information, see Creating a Slack integration. Then, verify that the issue is resolved.

3. **Look for errors in the ChatOps pods:** If 2-way comms are successful, and network communication seems to be fine, try logging in to the cluster to look at the logs. Look at the `aimanager-aio-chatops-slack-integrator` and `aimanager-aio-chatops-orchestrator` pods for any unusual errors and then contact the L2 support team.

Log preview modal or View alerts modal hangs intermittently in an incident in Slack or Microsoft Teams

This issue might happen when the Log Anomaly detection is in a high load, and takes longer time than normal to respond. When it occurs, you might encounter the following :

- When you select **View alerts** in an incident in Slack or Microsoft Teams, it hangs with the `Loading ...` message.

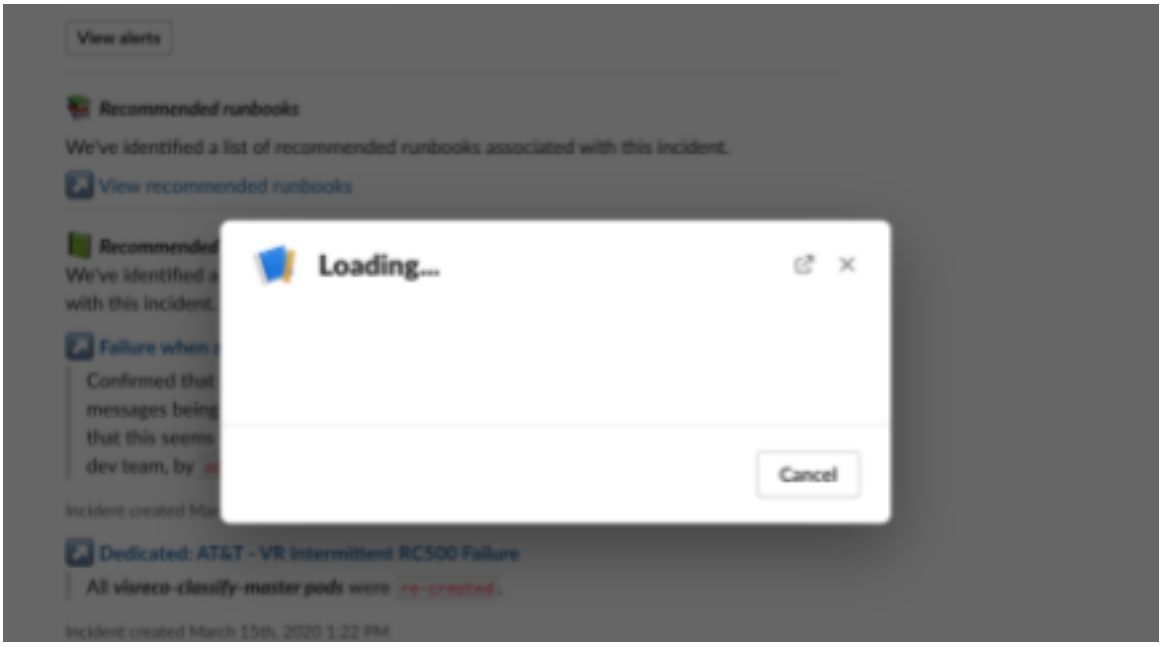

Figure. View alerts

- The **Log preview** dialog in Slack or Microsoft Teams hangs with the `Loading log data..` message.

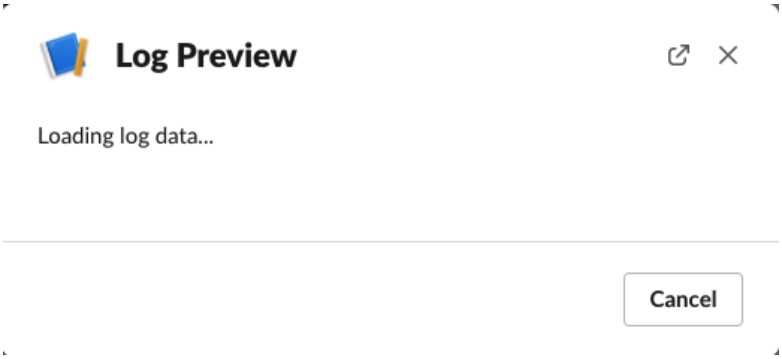

Figure. Log preview

- Checking the log results in something similar to this:

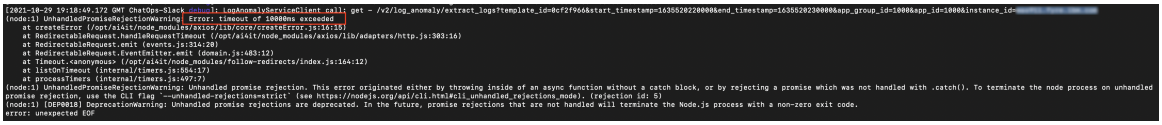

Figure. View log

Solution: close the **View alerts** dialog or the **Log preview** dialog in Slack or Microsoft Teams, and retry the operation.

Alerts and incidents not appearing in Slack

Alerts and incidents are showing up on IBM Cloud Pak for AIOps console but not in Slack ChatOps.

A number of causes can be considered when alerts are not showing up in Slack. Try one or more of the following to help resolve the problem.

1. Make sure that alerts and incidents are being created from events: alerts and incidents can be seen in the *Incidents and alerts* page in the IBM Cloud Pak for AIOps console. If events are flowing but no alerts or incidents are being created, review Troubleshooting alert management.
2. Double check channel IDs: if alerts and incidents are visible in the IBM Cloud Pak for AIOps console, make sure the channel IDs are correctly pasted in the ChatOps data integration form. Ensure the channel ID rather than the channel name is being used and make sure that no extra blank spaces are in the form field. Instructions for retrieving channel IDs can be found in the Configuring Slack applications for integration page.
3. Ensure that the Slack app is a channel member: to post incident messages, the IBM Cloud Pak for AIOps Slack app must be a channel member of the channel IDs being used. To add an application to a channel, tag the bot with the "@" symbol followed by the bot name.
4. Look for any visible errors in the **`chatops-slack-integrator`** logs. If the IDs are correct and the app is a channel member, look for error messages in the pod and contact the L2 support team.

Note: If the Slack app is not properly configured when an incident is initially created, that incident is not posted to Slack. Only when the app is successfully configured do new incidents, and updates to those incidents, get posted.

Slack ChatOps integration is not working within an air-gapped (offline) environment

If you create a Slack integration within an air-gapped (offline) environment, the integration might not work as expected. When you first create the Slack integration, the test of the integration (by clicking **Test connection to Slack.com.**) must be successful. If the test was successful, but the Slack integration is still not working, restart the Slack integrator pod to retrieve the latest integration information.

To restart the pod, complete the following steps:

1. From a command line, use the OpenShift CLI **`oc login`** command to log in to your cluster.
2. Switch to the project (namespace) where IBM Cloud Pak for AIOps is installed:

   ```
   oc project <project>
   ```

   Where **`<project>`** is the project (namespace) where IBM Cloud Pak for AIOps is installed.
3. Retrieve Slack integrator pod name:

   ```
   oc get pods | grep slack
   ```

   Record the name of the Slack integrator pod.
4. Delete the pod to cause the pod to restart:

   ```
   oc delete pod <slack integrator pod>
   ```

   Where **`<slack integrator pod>`** is the name of the pod name.

Microsoft Teams ChatOps integration shows no response in the console

If you have a Microsoft Teams ChatOps integration, you can encounter an issue the Microsoft Teams console shows no response through the integration. This issue can occur when you install and configure a Secure Tunnel for IBM Cloud Pak for AIOps on an on-premises Red Hat OpenShift Container Platform and configure a corresponding Secure Tunnel connecter for Microsoft Teams on a virtual machine (VM) that is accessible from a public network.

If you encounter this issue, complete the following steps:

1. Verify that the Secure Tunnel is working.

    1. Log in to the IBM Cloud Pak for AIOps console.
    2. Go to **Administration** > **Secure Tunnel**.
    3. Verify that the Secure Tunnel connection is configured and that the status is `Ready`.
    4. Click into the **Application mappings** column of your Secure Tunnel connection. Verify the URLs list in the **Application mapping address** column.

    Notes:

    - If the status is not `ready`, then check whether the Secure Tunnel Connector is installed and running. For more information about setting up the connector, see Install the Secure Tunnel Connector.
    - If your Secure Tunnel Connector is running, but you do not see the status as `Ready` for the connection, check the log messages from the Secure Tunnel Connector container.
        - If the log message indicates TLS errors, you might not have the correct Secure Tunnel Connector package. Verify that the installed package is correct. If necessary, download and install the correct package. For more information about installing the connector, see Install the Secure Tunnel Connector.
        - If the log message indicates a connecting error, check whether you can access the virtual machine (VM) where the Secure Tunnel Connector is installed from the Secure Tunnel pod.
2. Verify that the network between the Secure Tunnel and the VM on which Secure Tunnel Connector is installed is accessible.

    1. Log in to the Red Hat OpenShift Container Platform console where IBM Cloud Pak for AIOps is installed.
    2. Go to **Workloads** > **Pods**.
    3. Switch to the project (namespace) for IBM Cloud Pak for AIOps.
    4. Filter the pods to find the secure tunnel pod. For instance filter by `sre-tunnel-network`.
    5. Click listed pod. Then, click **Terminal**.
    6. Access the IP address of your VM by running a command similar to the following `curl` command on port `50443`:

        ```
        curl -k https://your.vm.external.host.com:50443
        ```

        - If you get any SSL error from the command, the error indicates that the network connection is working.
        - If you a message tht indicates `Connection refused` from the command, the message indicates that the network connection is not reachable. Contact your network administrator to fix the network connection.
3. Verify that the configuration of the Microsoft Azure Bot for the ChatOps integration is correct.

    1. Log in to the Microsoft Azure portal, and click **Bot services**. Then, click your Azure bot.
    2. Click **Configuration** under **Settings**.
    3. Check the `messaging endpoint` setting. Replace the `request URL` value with the `application mapping URL` from the Secure Tunnel connection. For more information about the settings for the connection, see Creating a Microsoft Teams connection.
    4. Attempt to send the message `@<bot_name> /waiops_welcome` in Microsoft Teams. If the connection still does not work, other issues might exist. contact your network administrator for assistance with investigating and fixing the network connection.
4. Verify that the network between the Microsoft Azure Bot and the VM on which the Secure Tunnel connector is installed is accessible:

    1. Log in to the terminal of the VM on which you installed the Secure Tunnel connector.
    2. Find the network interface (NIC) that is accessible from public network. You can use a command like `ip address` to find this interface. For example, if your network interface is `eth1`, listen to the port `12443` on that network interface by using the command `tcpdump -i eth1 port 12443`.
    3. Test the access to the `application mapping URL` of your Secure Tunnel connection from your device or from another device outside of your on-premise netowork. For example, run the following command, where `your.vm.external.host.com` is your VM host.

        ```
        curl -k -X POST
        https://your.vm.external.host.com:12443/aiops/aimanager/instances/1683613041902750/teams/api/messages
        ```

    4. Verify that there are outputs from the `tcpdump` command while you run the `curl` command.

        If you do not find any output from the `tcpdump` command, you might have firewalls or ACL restrictions that are blocking inbound traffic to the VM. Contact your network administrator to grant inbound traffic on port `12443` for the VM and retest the command.

During a ChatOps secure tunnel creation an 'installation failed' message displays

When you create a ChatOps integration and it fails, wait for a few minutes to see if the installation retries, and if it does not simply create the integration again.

Show more button does not work in Slack after an upgrade

You might notice an issue where the **Show more** button does not work in Slack after an IBM Cloud Pak for AIOps upgrade.

The reason for this issue is that the TLS certificate CA for ChatOps is updated through the upgrade, and the tunnel `ApplicationMapping` is still using the previous TLS certificate CA.

If you encounter this issue, use the following steps to restart the pod `sre-tunnel-controller-a-`. This restart causes the Secure tunnel controller pod to update the TLS certificate CA:

1. Get the name of the Secure tunnel controller pod:

   ```
   oc get pod | grep sre-tunnel-controller-a-
   ```

2. Restart the pod `sre-tunnel-controller-a-*`:

   ```
   oc delete pod <Secure tunnel controller pod>
   ```

   Where `Secure tunnel controller pod` is the name you extracted in the preceding step.

Links in ChatOps incident messages are invalid

In ChatOps incident messages for IBM Cloud Pak for AIOps 4.7.1, the following incident message links are invalid:

- On the *Associated automations* message, the **View associated automations** link is invalid.
- On the *Incident resources* message, the **View incident resource topology** link is invalid.

For IBM Cloud Pak for AIOps 4.7.1, go to the incident page to view the associated runbooks and resources.

Troubleshooting topology

Learn how to isolate and resolve problems with the Topology viewer and topology service.

To help you with troubleshooting topology issues, review the topology service logs. For more information, see Viewing the topology logs.

Common issues:

- Chrome extension display issues on Incident Topology page
- Error connecting topology services to Cassandra database
- Observer schedule toggle becomes disabled after saving the job
- File Observer fails due to hidden characters
- Kubernetes Observer job fails to restart after OOM
- Halt a Cassandra node for maintenance
- Topology observer job failure due to prohibited egress
- Topology viewer user interface crashes after the update manager is displayed

Chrome extension display issues on Incident Topology page

When displaying the details for a listed event in the Resolution Hub by using the Chrome browser, the resizing of the page might cause screen errors. This is caused by the MEGA Secure Cloud Storage and Chat Chrome browser extension.

Solution: Remove the MEGA Secure Cloud Storage and Chat extension.

Error connecting topology services to Cassandra database

During startup, the topology service can attempt to connect to the Cassandra database before it is fully started, which causes an error, followed by a warning message similar to the following message:

```
WARN   [2022-02-28 11:01:36,748] [main] c.i.i.t.g.ConnectionManager -  failed to connect to storage back end sleeping before retrying.
```

This issue can occur when the topology service has started before the Cassandra database is fully ready.

Solution: You do not need to complete any workaround. The topology service tries to connect to the Cassandra database repeatedly. When the Cassandra database is up and running, the service can successfully connect.

Observer schedule toggle becomes disabled after saving the job

After editing and saving an observer job that includes scheduled jobs, the **Schedule request** toggle becomes disabled. However, the job remains scheduled and continues to run in the background.

This issue can occur when the **Schedule request** toggle fails to read the existing job schedule and erroneously reverts to its default setting of **Off**.

Solution: The job scheduling remains active and no workaround is required. To confirm the existing observer job schedule:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. On the *Add integration** page, click **Topology** in the *Category* list that is next to the list of all integrations.
5. Click the **configure, schedule, and manage other observer jobs** link in the description for the topology integration.
6. Select the observer.
7. Confirm that the job schedule remains active.

File Observer fails due to hidden characters

An error can occur when your File Observer input file contains hidden characters that interfere with the processing of the content.

```
The following lines numbers had problems, check the logs for details: 1
```

This issue can occur when a file appears compliant in content and format, but is in a UTF-8 Unicode (with BOM) file format (instead of the regular UTF-8 file format).

Solution: Change the file format. For example, you can create a new file from the source file by using the following command:

```
sed '1s/^\xEF\xBB\xBF//' < topology.txt > new.txt
```

Kubernetes Observer job fails to restart after OOM

Kubernetes Observer jobs with very large payloads can encounter an OOM (out-of-memory) error, after which they may fail to restart. The observer appears offline, but a health check fails to flag any errors.

Solution: Restart the observer if it appears as offline in the UI.

Halt a Cassandra node for maintenance

Sometimes you need to manually maintain the Cassandra server nodes. For example, you might need to halt one node for long enough to allow you to complete the required maintenance work or debug a problem.

The following steps suspend (halt) one Cassandra node while the other nodes still serve queries, which allows you to perform maintenance tasks without shutting down your production environment.

Note: To reduce the impact of pausing a Cassandra node on the performance of your remaining system resources, keep such maintenance periods to a minimum.

Halt the node

1. Edit the bootstrap configMap.

```
oc edit configmaps aiops-topology-cassandra-bootstrap-config
```

For example, if you want to halt node 0, you can set the following columns.

```
hostname_filter: aiops-topology-cassandra-0
running_mode: maintenance
```

2. Save and exit.

3. To restart the target node pod, you delete the pod so that the statefulSet will restart the pod automatically. Then it should be halted.

```
oc delete pod aiops-topology-cassandra-0
```

Debug the Cassandra server

After the node is restarted and halted, you should see that its state stays as `0/1 Running`. When the pod is in this mode, the Cassandra server is not automatically started in it. The `liveness` probe and `readiness` probe will not be activated for many days in this pod, allowing you to perform any maintenance that is required.

There are two methods to start the Cassandra server for debug purposes.

- You can go into the pod container to manually start the server.

```
oc exec -it aiops-topology-cassandra-0 -- bash
bash-4.4$ /opt/ibm/cassandra/bin/cassandra -fR > /tmp/server.log 2>&1 &
```

The server process will be started in the background and the log messages can be found in file **/tmp/server.log**.

- You can reuse the entry point script.

```
oc exec -it aiops-topology-cassandra-0 -- bash
bash-4.4$ export RUNNING_MODE=normal
bash-4.4$ /opt/ibm/start-cassandra.sh > /tmp/server.log 2>&1 &
```

Example maintenance task: Remove corrupt commit logs that are causing Cassandra to not start.

```
$ oc exec -it aiops-topology-cassandra-0 -- bash
bash-4.4$ rm -rf /opt/ibm/cassandra/data/commitlog/CommitLog-6-1682019553495.log
```

After performing the required maintenance, you can stop the manually started Cassandra server.

```
oc exec -it aiops-topology-cassandra-0 -- bash
bash-4.4$ nodetool stopdaemon
```

Note: You can also perform other actions, like fixing volumes or transforming the data files. Every time you restart the pod, it will be halted.

Return the node to normal

After you complete your manual work, you can edit the configMap and restart the pod to return it back to normal.

```
oc edit configmaps aiops-topology-cassandra-bootstrap-config
```

Set the running mode to normal.

```
hostname_filter: aiops-topology-cassandra-0
running_mode: normal
```

Restart normal operations

Finally, you can delete the pod again so it will revert to the normal node and continue to work in the cluster.

Topology observer job failure

When you attempt to run a topology observer, the job fails because no response is returned for the request to the corresponding external service.

Solution: Run the following commands to create a NetworkPolicy that allows egress from the topology observer pods:

```
export AIOPS_NAMESPACE=<AIOps installation namespace>

cat << EOF | oc apply -f -
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: aiops-observer-egress
  namespace: ${AIOPS_NAMESPACE}
spec:
  egress:
  - {}
  podSelector:
    matchLabels:
      app.kubernetes.io/instance: aiops-topology
  policyTypes:
  - Egress
EOF
```

Topology viewer user interface crashes after the update manager is displayed

The issue is that you cannot use the update manager feature in topology viewer.

The solution is to change your topology viewer user preferences to auto render changes on refresh, which prevents the update manager from appearing.

Viewing the topology logs

You can see all topology and observer logs by using the **oc logs** command.

About this task

All observers are deployed in pods. You can identify logs either by their names or their labels.

To increase or decrease the log levels for a specific observer to help investigate issues, you first use the **`oc get deployments`** command to display a list of all deployments. Then, use the **`oc edit deployment`** command to change the logging levels to, in this example, 'debug'. A log level of 'debug' logs all request or response operations to provide detailed diagnostic data.

Viewing logs

1. To list all pods and the labels that are applied to the pods, run the **`oc get pod --show-labels`** command.

   ```
   oc get pod --show-labels
   ```

   Sample output:

   ```
   deploy-test-ciscoaci-observer-8755fcc94-7cp7h      1/1       Running   0          2d
   app=ciscoaci-observer,chart=ciscoaci-observer,heritage=Tiller,pod-template-
   hash=431197750,release=deploy
   deploy-test-file-observer-76c5869d8b-tm7xj         1/1       Running   0          2d        app=file-
   observer,chart=file-observer,heritage=Tiller,pod-template-hash=3271425846,release=deploy-test
   deploy-test-rest-observer-789cd8699d-zb8vx         1/1       Running   0          2d        app=rest-
   observer,chart=rest-observer,heritage=Tiller,pod-template-hash=3457842558,release=deploy-test
   deploy-test-vmvcenter-observer-675bd88f5c-8kgnk    1/1       Running   0          2d
   app=vmvcenter-observer,chart=vmvcenter-observer,heritage=Tiller,pod-template-
   hash=2316844917,release=deploy-test
   ```

2. Display the logs by using either the pod names or labels. When you run the **`oc`** logs command, you must also specify the project (namespace).

   1. View logs for a specific pod:

      ```
      oc logs asm-layout-88bd88bdb-htjfp --namespace=netcool
      ```

   2. View logs by using the label:

      ```
      oc logs -l app=layout --namespace=netcool
      ```

Changing log levels to `debug`

Run the following command to change the debug level to **`DEBUG`**:

```
oc exec -it deploy-test-file-observer-76c5869d8b -- /opt/ibm/netcool/asm/bin/log-level.pyc --level DEBUG
```

Sample system output

```
Configured logging level for com.ibm to DEBUG
Response code: 200
```

Setting observer log levels

You can set the observer logging level to 'debug' (or a number of other levels) to troubleshoot in more detail.

About this task

To increase or decrease the log levels for a specific observer, you first obtain the observer's pod name, internal IP address, admin port and credentials. You then specify the required log level ('debug' in this example) before running the observer's load job and tailing the observer log.

Note: A log level of 'debug' logs all request or response operations to provide detailed diagnostic data.

The following task describes how to set the observer log levels to 'debug'. An OpenStack Observer example is provided.

Setting observer log levels to 'debug'

1. Obtain the observer pod name.

```
oc get pod | grep [observer name]
```

Example output:

```
[release name]-topology-[observer name]-observer-dd845b66c-vqs82                1/1     Running     0
106m
```

Note: The observer pod name is [release name]-topology-[observer name]-observer-dd845b66c-vqs82. The value of dd845b66c-vqs82 will vary depending on the pod name.

2. Use the observer pod name to obtain the observer's internal IP address.

```
oc describe pod [observer pod name] | grep IP
```

Example output:

```
IP: 10.254.21.131
IPs:
IP: 10.254.21.131
```

Note: Note down the IP address, which is the internal IP address.

3. Use the observer pod name to obtain the observer admin port.

```
oc describe pod [release-name]-topology-[observer name]-observer-dd845b66c-vqs82 | grep Ports
```

Example output:

```
Ports: 9082/TCP, 9083/TCP
Host Ports: 0/TCP, 0/TCP
```

Note: In this example 9083 is the admin port of the observer. (The port with the odd number as the last digit is always the admin port.)

4. Complete the following sub-steps.

   a. Obtain the base64 encoded string of `[username]:[password]`

   ```
   oc get secret | grep asm-credentials
   ```

   Example output:

   ```
   [release-name]-topology-asm-credentials                                    Opaque
   2      5d9h
   ```

   b. From the output above, run the following commands:

   ```
   oc get secret [release-name]-topology-asm-credentials --template={{.data.username}} | base64 -d

   oc get secret [release-name]-topology-asm-credentials --template={{.data.password}} | base64 -d
   ```

   Example commands and output:

   ```
   oc get secret aiops-topology-asm-credentials --template={{.data.username}} | base64 -d
   asm-netcool-user

   oc get secret aiops-topology-asm-credentials --template={{.data.password}} | base64 -d
   asmauto
   ```

   c. Encode to base64 format:

   ```
   echo "asm-netcool-user:asmauto" | base64
   ```

   Example output:

   ```
   YXNtLW5ldGNvb2wtdXNlcjphc21hdXRvCg==
   ```

5. Specify the DEBUG log level. Run the following command:

```
oc exec -it [observer pod name] -- curl -k -X POST --header 'Authorization: Basic [base64 encoded string of
username:password]' -d "logger=com.ibm.itsm.topology.observer.[observer name]&level=DEBUG" https://[internal
IP address]:[observer admin port]/tasks/log-level
```

- Replacing `[observer pod name]` and `[internal IP address]` in your environment. Note that `[observer name]` is the observer that is to be configured and [observer admin port] is the admin port of the observer.
- The `[base64 encoded string of username:password]` is the base64 encoded string of `[username]:[password]`.

OpenStack Observer example:

```
oc exec -it aiops-topology-openstack-observer-dd845b66c-vqs82 -- curl -k -X POST --header 'Authorization:
Basic YXNtLW5ldGNvb2wtdXNlcjphc21hdXRvCg==' -d
"logger=com.ibm.itsm.topology.observer.openstack&level=DEBUG" https://10.254.21.131:9083/tasks/log-level
```

The following prompt should be visible in the console:

```
Configured logging level for com.ibm.itsm.topology.observer.[observer name] to DEBUG
```

- In this example the package name `com.ibm.itsm.topology.observer.[observer name]` tells us that the observer package has been set to the DEBUG level.

6. Run the observer load job and tail the observer log.

```
oc logs -f [release name]-topology[-observer name]-observer-dd845b66c-vqs82
```

Note: If set successfully to DEBUG, the DEBUG messages are now recorded in the observer log.

Example log entry (for the OpenStack Observer):

```
DEBUG [2024-07-30 06:46:13,200] [pool-12-thread-1] c.i.i.t.o.o.OpenStackRESTSession - [iZx9pZr] -
getOpenStackClientAccessOrToken: Http Logging filter is 'false'
```

Defining classifier log settings

When viewing incidents on the Incident page, the topology can be viewed on the Overview tab, but is not available on the Topology tab.

About this task

Top alerts are displayed on the Overview tab, while more detailed information is used to render the information on the Topology tab.

To display the topology for an incident on the Topology tab, it uses the classifier for event classification for probable cause calculation. If these are not being recorded due to the level of log settings, the information is unavailable and the topology is not displayed. You must set additional properties to control the classifier logging.

You add (or edit) the following properties for the classifier deployment in both AI Manager and Event Manager

Note: Only the LOGGING_LEVEL property exists with a default setting of `INFO`. You must add the other settings to the classifier deployment manually.

- `0` = no logging set
- `10` = `debug`
- `20` = `information`
- `30` = `warning`
- `40` = `error`
- `50` = `critical`

Changing classifier log settings

1. Change the settings for the following log levels.

   a. For kafka:

   ```
   `KAFKA_LOGGING_LEVEL` = ???
   ```

   b. For file and console for other mime utils file:

   ```
   `LOGGING_LEVEL` = ???
   ```

2. Change the settings to define rotation and backup settings for the log files.

   a. For file rotation:

   ```
   `DEFAULT_LOGGING_FILE_SIZE` = ???
   ```

   b. For the number of history backups:

   ```
   `DEFAULT_LOGGING_FILE_BK_COUNT` = ???
   ```

   c. For the output format to console:

   ```
   `%(asctime)s.%(msecs)03d %(levelname)s %(module)s - %(funcName)s: %(message)s`
   ```

IM issues

Troubleshoot Identity Management (IM) issues.

- Login
- LDAP
- Pod issues
- OIDC
- API calls
- MongoDB to EDB PostgreSQL database migration

- EDB PostgreSQL cluster is down and the pod is in `Completed` status
- Enable debugging for user authentication issues

Login

Review frequently encountered login issues.

- Internal server error while login Platform UI by using SAML with LDAP dependency
- Cannot log in to the console by using the admin username
- Docker login results in unencrypted password warning
- Login too slow or times out, or invalid username or password error
- Cannot log in to the console by using OpenShift authentication
- Cannot log in to the console after reinstallation of foundational services
- Default admin cannot log in due to LDAP server issues
- Username shows as Undefined Undefined after login to CloudPak dashboard through SAML login
- Cannot login Platform UI with CloudPak administrator username
- Gateway timeout error while you log in to the console
- CWWKS1406E: Unable to load the login page and an invalid client error is displayed

Internal server error while login Platform UI by using SAML with LDAP dependency

Login error appears when you try to access the Platform UI by using SAML that is registered with LDAP.

Symptoms

When you use LDAP dependency with SAML authentication and try to access the Platform UI by using SAML, the login error appears and displays a message, **500 internal server error**.

If you access the Common UI console, the following errors are displayed in the **common-ui** container logs:

```
[2022-03-04T11:58:45.375] [ERROR] [webui-nav] [platform-auth-service] SAML enabled, but unable to get
idsource registrations to determine if ldap is enabled for the saml config - default to true Error:
    at Request.<anonymous> (/opt/ibm/platform-header/lib/server/request.js:115:34)

    'Content-Length: 57\n' +
```

```
    'Etag: W/"39-Iup4jU4k5A0rUB2wIQCJV1dX4gw"\n' +
    'Date: Fri, 04 Mar 2022 11:58:45 GMT\n' +
    'Connection: close\n' +
    '\n' +
    '{"error":"Insufficient user permission for role :Viewer"}\n'
}
```

Causes

Service-id permission returns **Viewer** role access.

Resolving the problem

Upgrade your current foundational services version to 3.16.0 version or later.

Cannot authenticate Kubeadmin user as CloudPakAdministrator by default

The **Kubeadmin** user does not get **CloudPakAdministrator** role by default after login.

Symptoms

After you log in as a **Kubeadmin** user in the Administration panel, it assigns you the **Viewer** role.

Causes

Bootstrap process is not successful during the IM service installation.

Resolving the problem

Restart the **platform-identity-management** pod by using the following command:

```
oc -n <your-foundational-services-namespace> delete pod -l app=platform-identity-management
```

Cannot log in to the console by using the admin username

After you set up an LDAP connection, you cannot log in to IBM Cloud Pak® for AIOps cluster console by using the default cluster administrator **admin** username.

Causes

There might be a user by the name **admin** in the LDAP directory that you configured in your cluster.

Resolving the problem

To resolve the problem, see Default admin cannot log in due to LDAP server issues.

If you still want to use the admin user from the LDAP, you can change the user name in IBM Cloud Pak for AIOps cluster. To change the username in IBM Cloud Pak for AIOps cluster, see Changing the cluster administrator username.

Docker login results in unencrypted password warning

After you log in to your private image registry with the Docker login command, a warning is displayed that indicates that your password is stored unencrypted.

Symptoms

A warning message is displayed when you log in to your private image registry with the following command:

```
docker login <cluster_CA_domain>:8500
```

In this command, **<cluster_CA_domain>** is the certificate authority (CA) domain that was set during installation.

The command output includes the following warning:

```
WARNING! Your password will be stored unencrypted in /root/.docker/config.json.
Configure a credential helper to remove this warning. See
https://docs.docker.com/engine/reference/commandline/login/#credentials-store
```

Causes

By default, Docker stores the login password unencrypted within the **/root/.docker/config.json** Docker configuration file. This is the default Docker behavior.

Resolving the problem

You can store your user credentials in an external credentials store instead of within the Docker configuration file. Storing your credentials in a credentials store is more secure than storing the credentials in the Docker configuration file. For more information, see the Docker community credentials store documentation.

Login too slow or times out, or invalid username or password error

After you set up an LDAP connection, you cannot log in to IBM Cloud Pak® for AIOps cluster console.

Symptoms

There are two symptoms for the same cause.

- When you try to log in, the login process might take a long time, or might time out.
- You might see the following error:

  ```
  Invalid user name or password
  ```

Cause

The login failure is due to an LDAP error when Liberty looks up groups for the user. By default, Liberty searches which groups the user is a member of. It then searches which groups these groups are a member of. The message log shows the following error:

```
An FFDC Incident has been created: "com.ibm.wsspi.security.wim.exception.WIMSystemException: CWIML4520E: The
LDAP operation could not be completed. The LDAP naming exception
javax.naming.NameNotFoundException: [LDAP: error code 32 - 0000208D: NameErr: DSID-03152973, problem 2001
(NO_OBJECT), data 0, best match of:
"
```

Resolving the problem

To resolve the issue, disable the **recursiveSearch** parameter in the LDAP **server.xml** file.

1. Log in to your boot node with the **oc login** command.
2. Edit the **platform-auth-idp** configmap.

   ```
   oc edit cm platform-auth-idp -n <your-foundational-services-namespace>
   ```

3. Change the **LDAP_RECURSIVE_SEARCH: "true"** parameter value to **LDAP_RECURSIVE_SEARCH: "false"**.
4. Save the changes.
5. Restart the **platform-auth-service** pods by deleting the pods.
   1. Get the **platform-auth-service** pod names.

      ```
      oc get pods -n <your-foundational-services-namespace> | grep platform-auth-service
      ```

   2. Delete the **platform-auth-service** pod.

```
oc delete pods <pod-name> -n <your-foundational-services-namespace>
```

Cannot log in to the console by using OpenShift authentication

If you are using OpenShift authentication, you cannot log in to the console after you install IBM Cloud Pak foundational services on an OpenShift cluster that is in any cloud environment.

Symptom

You see a **`400: Bad request - The request or response is invalid`** error.

Cause

The rolebinding collection failed due to identity-provider:4300 connection time-out in the **`oidclient-watcher`** pod.

Resolving the problem

To resolve the issue, restart the **`oidclient-watcher`** pod.

1. Log in to your infrastructure node with the **`oc login`** command.
2. Get the **`oidcclient-watcher`** pod name.

   ```
   oc get pods -n <your-foundational-services-namespace> | grep oidcclient
   ```

3. Delete the **`oidcclient-watcher`** pod

   ```
   oc delete pod -n <your-foundational-services-namespace> <oidcclient-watcher-pod-name>
   ```

Wait for the pod to restart.

You can log in after the **`oidclient-watcher`** pod restarts.

Cannot log in to the console after reinstallation of foundational services

After you uninstall IBM Cloud Pak foundational services and reinstall them on the same cluster, you cannot log in to the console with the default admin credentials.

Symptoms

You might see the following error:

```
CWOAU0038E: The client could not be verified. Either the client ID: t19ph7yimexir00h517actss98zbrg0m or client secret is incorrect.
```

Cause

After you uninstall the foundational services, if all the resources are not properly cleaned, reinstallation on the same cluster fails.

The cause of the failure might be either or both of the following reasons:

- There is a mismatch of the **`client_id`** and **`client_secret`** values in the cluster, which causes the console login to fail.
- The IM jobs are not completed or are completed with errors.

Resolving the problem

To resolve the issue, correct the **`client_id`** and **`client_secret`** values and restart all IM jobs.

1. Log in to your boot node with the **`oc login`** command.
2. Check whether the **`ibm-im-operator`** pod is running.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep ibm-iam-operator
   ```

3. Check whether all the auth pods are running without any errors. If you see errors, check the logs and resolve the issue.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep auth
   ```

4. Check the **client_id** and **client_secret** values in the **platform-oidc-credentials** secret and in the **registration-json** configmap.

   - Check the values in the **platform-oidc-credentials** secret:

     ```
     oc -n <your-foundational-services-namespace> get secret platform-oidc-credentials -o "jsonpath=
     {.data.WLP_CLIENT_ID}" | base64 --decode
     oc -n <your-foundational-services-namespace> get secret platform-oidc-credentials -o "jsonpath=
     {.data.WLP_CLIENT_SECRET}" | base64 --decode
     ```

   - Check the values in the **registration-json** configmap:

     ```
     oc -n <your-foundational-services-namespace> get cm registration-json -o "jsonpath=
     {.data['platform-oidc-registration\.json']}" > platform-oidc-registration.json
     cat platform-oidc-registration.json
     ```

5. If the values in the secret and configmap do not match, update the values in the **registration-json** configmap with the values from the **platform-oidc-credentials** secret. To edit the configmap, run the following command:

   ```
   oc -n <your-foundational-services-namespace> edit cm registration-json
   ```

   Replace the **client_id** and **client_secret** values, and save and exit the configmap.

6. Restart the following IM job.

   ```
   oc -n <your-foundational-services-namespace> delete job oidc-client-registration
   ```

7. Wait for some time and check the job status.

   ```
   oc -n <your-foundational-services-namespace> get jobs
   ```

   The status should show as **Completed**.

8. Restart the **common-web-ui** pods so that the **client_id** and **client_secret** get the correct values from the **platform-oidc-credentials** secret.

   1. Get the **common-web-ui** pod name.

      ```
      oc -n <your-foundational-services-namespace> get pods | grep common-web-ui
      ```

   2. Delete the pod.

      ```
      oc -n <your-foundational-services-namespace> delete <common-web-ui-pod-name>
      ```

9. Wait for sometime until the **common-web-ui** and **management-ingress** pods show the **Running** status. You can check the status by running the following command:

   ```
   oc -n <your-foundational-services-namespace> get pods | grep -e common-web-ui
   ```

After the pods are running, you can log in to the console with the default cpadmin credentials.

Default admin cannot log in due to LDAP server issues

The default admin user can no longer log in to your product cluster console.

You might see the following error in the **platform-auth-service** container of the **platform-auth-service** pod.

```
[ERROR   ] CWIML4537E: The login operation could not be completed. The specified principal name admin is not
found in the back-end repository.

com.ibm.wsspi.security.wim.exception.PasswordCheckFailedException: CWIML4537E: The login operation could not
be completed. The specified principal name admin is not found in the back-end repository.
        at com.ibm.ws.security.wim.ProfileManager.loginImpl(ProfileManager.java:1820)
        at [internal classes]
```
```## Causes

This issue can occur because of the following reasons:

- The LDAP parameters that you specified when you configured the LDAP connection might not be correct.
- LDAP server is inaccessible for some reason.
- LDAP configuration file is corrupted.
- A user who is named `admin` might exist in the LDAP directory. For this case, try this resolution, [Cannot
log in to the management console by using the admin username](../troubleshoot/ldap_admin.html).
```

```
## Resolving the problem {: #resolve}

As a temporary measure, you can remove the LDAP configuration file that is in the `platform-auth-service` container of the `platform-auth-service` pod so that the default admin user can log in to the cluster.

The LDAP configuration is stored in the `/config/configDropins/defaults/ldap-<LDAP_connection_name>.xml` and `federated.xml` files in the `platform-auth-service` container. To remove the incorrect LDAP configuration, you must delete the files or move them to another location. You can then log in to the console and set up the LDAP connection again with the correct parameters.

Removing the LDAP configuration file in the `platform-auth-service` container has no impact on the LDAP connection configuration. The users, groups, roles, and other resources are retained.

Complete the following steps to remove the LDAP configuration files.

1. SSH to your boot node and log in to cluster with `oc login` command.

2. Get the `platform-auth-service` pod names.

   ```cmd {: codeblock}
   oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
```

3. Access the shell inside the **platform-auth-service** container.

   ```
   oc -n <your-foundational-services-namespace> exec -it platform-auth--service-xxxxxx-yyyy -c platform-auth-service -- /bin/bash
   ```

4. Make a note of the LDAP settings file name that is located in the **/config/configDropins/defaults/** directory. For example, the file name is **ldap-openLDAP.xml** if your LDAP connection name is **openLDAP**.

5. Move the LDAP settings file **ldap-<LDAP_connection_name>.xml** and the **federated.xml** files out of the **/config/configDropins/defaults/** directory. For example, you can move the files to the **/config/configDropins/** directory.

   ```
   mv /config/configDropins/defaults/ldap-<LDAP_connection_name>.xml /config/configDropins/
   mv /config/configDropins/defaults/federated.xml /config/configDropins/
   ```

   Note: Instead of moving the files, you can delete the LDAP settings file, and **federated.xml** files from the **/config/configDropins/defaults/** directory. However, when you move the files, ensure that you have a backup of the configuration files, which can be used for troubleshooting.
   You can also correct the settings in the files and reuse it to set up the LDAP connection. If you are reusing the files, you must move the corrected files back into the **/config/configDropins/defaults/** directory.

   Exit from the container.

6. Perform steps 3 - 5 for all **platform-auth-service** pods.

7. Wait for a minute and then try log in as the default admin user.

8. Set up your LDAP connection with proper configuration parameters. For more information about setting up an LDAP connection, see Configuring LDAP connection.

   Note: You must identify the root cause of the issue and take the necessary actions to resolve it. After you resolve the issue, you can restart the **platform-auth-service** pod and then log in to the console as the admin user.

   You can also enable debugging for Liberty and collect logs. For more information, see Enable debugging for user authentication issues.

Username shows `Undefined Undefined` after login to CloudPak dashboard using SAML login option

Symptoms

When you use SAML login as option to login to the Cloudpak console, you might notice that the username is showing **Undefined Undefined** in the CloudPak dashboard page. You can observe this issue if you are using the foundational services version 3.20 and 3.21.

Causes

Migration from the IdP V2 to V3.

Resolving the problem
   ```

As per the SAML V3 schema, **given_name** and **family_name** are mapped to the **givenname** and **familyname** of IdP. You can update the V3 registration call to resolve this issue.

Steps

Get the V3 registration data

Note:

- The SAML UID that is supported is **defaultSP**. For more information, see Getting SAML registration by UID.
- Replace **base64-encoded-idp-xml** with actual base64 encoded **idp-metadata** that you have received in the GET call.
- Get the **cp-console-url** by using the command, **oc get routes**.

To get the existing SAML registration:

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster Master Host

Port number

Cluster Master API Port

Path

idprovider/v3/auth/idsource/defaultSP

Command

GET

Command output format

application/json

```
curl -k -X GET 'https://cp-console.apps.mycluster.mydomain.com/idprovider/v3/auth/idsource/defaultSP' --
header "Authorization: Bearer $ACCESS_TOKEN"
```

Update the V3 registration data by adding first_name and last_name under token_attribute_mappings

1. Copy the response that you get by using the curl command in Get the V3 registration data.
2. Remove the **uid** entry from the response, **"uid":"defaultSP"**.
3. Add the following attributes, **first_name** and **last_name** under the **token_attribute_mappings**.

```
"token_attribute_mappings": {
    "sub": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/name",
    "given_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
    "family_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname",
    "groups": "http://schemas.microsoft.com/ws/2008/06/identity/claims/groups",
    "email": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress",
    "first_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
    "last_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname"
}
```

4. Update the IdP V3 registration by adding the **token_attribute_mappings** payload as described in Step 3.

Note:

- Replace **base64-encoded-idp-xml** with actual base64 encoded **idp-metadata** that you have received in the GET call.
- Get the **cp-console-url** by using the command, **oc get routes**.

For example:

API version

1.0.0

API URI components

Scheme

HTTPS

Host IP

Cluster Master Host

Port number

Cluster Master API Port

Path

idprovider/v3/auth/idsource

Command

PUT

Command output format

application/json

```
curl -k -X PUT 'https://cp-console.apps.mycluster.mydomain.com/idprovider/v3/auth/idsource/defaultSP' \
--header 'Content-Type: application/json' \
--header "Authorization: Bearer $ACCESS_TOKEN"
--data-raw
'{
  "name": "w3id-sample-saml",
  "description": " this is plain saml testing",
  "protocol": "saml",
  "type": "default",
  "idp_config": {
    "token_attribute_mappings": {
    "sub": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/name",
    "given_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
    "family_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname",
    "groups": "http://schemas.microsoft.com/ws/2008/06/identity/claims/groups",
    "email": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress",
    "first_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/givenname",
    "last_name": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/surname"
    },
    "idp_metadata": "<base64-encoded-idp-xml>"
  },
  "jit": true
}'
```

Gateway timeout or blank page error while you log in to the console

Cannot log in to your IBM Cloud Pak foundational services or IBM Cloud Pak® console.

Symptoms

You might see a **`504 Gateway timeout`** error or blank page when you log in to the console.

Cause

IBM WebSphere Liberty has a limitation in their federated user registry mechanism where a problem in one registry affects all other registries in the cluster.

The foundational services Identity Management (IM) service uses Liberty federated registry. Hence, if you have multiple LDAP (Lightweight Directory Access Protocol) registries in your cluster, if any registry server is down, it impacts all other registries. You can't log in to your cluster. The issue might happen even if you have only one LDAP connection in your cluster.

Resolving the problem

If you find that all the IM pods are up and running, then follow these steps as a workaround to the issue:

1. Verify whether your LDAP registries are healthy and that you are able to reach the servers.
2. If there is a problem in any LDAP registry, disconnect the LDAP registry from your cluster by using either of the following ways:

- If other identity providers are configured in your cluster, a user with admin access can log in to the console and delete the connection from the navigation menu > **Identity and access** > **Identity providers** page.
- If you have the foundational services default **cpadmin** token, you can use the Deleting an LDAP connection by using IdP V3 API to remove the connection.

3. Restart the **platform-auth-service** pod.

```
oc get pod -n <your-foundational-services-namespace> | grep platform-auth
oc delete pod $platform-auth-pod
```

If the problem still persists, contact IBM Support.

LDAP

Review frequently encountered LDAP (Lightweight Directory Access Protocol) configuration issues.

- Enable debugging for user authentication issues
- Troubleshooting LDAP configuration
- Configuring LDAP over SSL
- Troubleshooting users and user groups search issues
- Timeout error while setting up an LDAP connection
- LDAP nested search for Microsoft Active Directory does not work correctly
- SAML with LDAP dependency using V2 API does not work correctly

Enable debugging for user authentication issues

Enable debugging for **platform-auth-service** Liberty to get trace logs for debugging user authentication issues.

Enable debug logs by using oc commands

Complete these steps to enable debug logging of platform-auth-service container pods by using the command-line interface:

1. Update the **platform-auth-idp** configmap. Then, save it.

```
oc edit cm platform-auth-idp -n <your-foundational-services-namespace>

LIBERTY_DEBUG_ENABLED: "false"   << true
LOG_LEVEL_AUTHSVC: info    << debug
LOG_LEVEL_IDMGMT: info     << debug
LOG_LEVEL_IDPROVIDER: info  << debug
```

   See the following notes:

   - **<your-foundational-service-namespace>** is the namespace where the platform-auth-service pods are deployed.
   - **LIBERTY_DEBUG_ENABLED** when set to **"true"**, enables the liberty container trace string to traceSpecification="com.ibm.ws.webcontainer*=all:com.ibm.wsspi.webcontainer*=all:HTTPChannel=all:GenericBNF=all:HTTPDispatcher=all".
   - **LOG_LEVEL** for the pods can be changed from **"info"** to **"debug"**
     - **LOG_LEVEL_AUTHSVC** is for the **platform-auth-service** pod
     - **LOG_LEVEL_IDMGMT** is for the **platform-identity-management** pod
     - **LOG_LEVEL_IDPROVIDER** is for the **platform-identity-provider** pod

2. Restart the **platform-auth-service**, **platform-identity-management**, and **platform-identity-provider** pod one at a time by deleting the pod. Wait for the pod to restart before you delete the next pod.

   1. Delete the pod.

```
oc delete pod -l component=<pod-name> -n <your-foundational-services-namespace>
```
```
   2. Check the pod status.
```
```
cmd {: codeblock}
oc get pods -A | grep platform
```

3. Wait for all containers and pods to start.

```
watch "oc get pods -n <your-foundational-services-namespace> | grep platform"
```

Enable debug logs by using the Red Hat® OpenShift® Container Platform console

Complete these steps to enable debug logging of identity management pods by using the Red Hat® OpenShift® Container Platform console:

1. Log in to the Red Hat® OpenShift® Container Platform console as a user with cluster administrator access.
2. From the navigation menu, click **Configuration** > **ConfigMaps.**
3. Search for **`platform-auth-idp`**, and select the configmap.
4. Click the YAML edit tab to open the configmap for editing.
5. Search for **`LIBERTY_DEBUG`** and update **`LIBERTY_DEBUG_ENABLED: "false"`** to **`LIBERTY_DEBUG_ENABLED: "true"`**.
6. Change the log levels of LOG_LEVEL_IDPROVIDER, LOG_LEVEL_AUTHSVC, LOG_LEVEL_IDMGMT**`from`**"info"**`to`**"debug"`.

```
LIBERTY_DEBUG_ENABLED: "false"     << true
LOG_LEVEL_AUTHSVC: info            << debug
LOG_LEVEL_IDMGMT: info             << debug
LOG_LEVEL_IDPROVIDER: info         << debug
```

7. Click **Save**.
8. From the navigation menu, click **Workloads** > **Pods**.
9. Delete the **`platform-auth-service`**, **`platform-identity-management`**, and **`platform-identity-provider`** pods to restart them. Delete the pods by clicking **...** > **Actions** > **Delete pod**.
10. Wait for some time. Then, check the status of the pods on the **Pods** pane. The status of all the pods must show as **`4/4`** under the **Ready** field name.

Collect identity management pod and liberty container logs, and foundational services configuration information

After you enable debugging, re-create the issue and collect debug logs. Then, share all the **`platform-auth-service`** pod logs with the support team.

The following **`MG-IAM-CSv4.sh`** script helps to collect the container and liberty logs, and foundational services configuration information.

Note: Before you run the script, define the **`NAMESPACE`** environment variable with the namespace where you deployed foundational services.

```
#!/bin/bash
################################################################################################
#Replace the NAMESPACE where platform-auth-service pods are running
#Collects description and container logs for all pods under the namespace
#Collect the liberty FFDC, logs, and default LDAP configuration from platform-auth-service container
#For the latest script Source  https://www.ibm.com/docs/en/cloud-paks/foundational-services/4.2?topic=ldap-
enable-debugging-user-authentication-issues
################################################################################################
# export LOGLIMIT="--tail=10000" # uncomment if you experience problems collecting large files
export NAMESPACE=<common-services-instance-Namesapce>
export AUTHMGDIR=AuthidpLogs-$(date '+%y%b%dT%H-%M-%S')
mkdir -p $AUTHMGDIR/$NAMESPACE

for pod in $(oc -n $NAMESPACE get pods -l component=platform-auth-service --no-headers -o custom-
columns=name:.metadata.name); do
  echo "===== $pod ====="
  LIBDIR="$AUTHMGDIR/$NAMESPACE/$pod-liberty"
  mkdir -p $LIBDIR
  echo "$pod collect liberty logs "
  oc -n $NAMESPACE cp $pod:/logs -c platform-auth-service $LIBDIR/logs
  echo "$pod collect liberty configuration  ====="
  oc -n $NAMESPACE cp $pod:/opt/ibm/wlp/usr/servers/defaultServer/ -c platform-auth-service
$LIBDIR/defaultserver
done

echo gathering info from namespace $NAMESPACE
oc get all,secrets,cm,events -n $NAMESPACE -o wide &> $AUTHMGDIR/$NAMESPACE/all-list.txt
oc get pods -n $NAMESPACE | awk 'NR>1{print "oc -n $NAMESPACE describe pod "$1" >
$AUTHMGDIR/$NAMESPACE/"$1"-describe.txt && echo described "$1"' | bash
oc get pods -n $NAMESPACE -o go-template='{{range $i := .items}}{{range $c := $i.spec.containers}}{{println
$i.metadata.name $c.name}}{{end}}{{end}}' > $AUTHMGDIR/$NAMESPACE/container-list.txt
awk '{print "oc -n $NAMESPACE logs "$1" -c "$2" $LOGLIMIT -p > $AUTHMGDIR/$NAMESPACE/"$1"_"$2"_previous.log
&& echo gathered previous logs of "$1"_"$2"' $AUTHMGDIR/$NAMESPACE/container-list.txt | bash
awk '{print "oc -n $NAMESPACE logs "$1" -c "$2" $LOGLIMIT > $AUTHMGDIR/$NAMESPACE/"$1"_"$2".log && echo
gathered logs of "$1"_"$2"' $AUTHMGDIR/$NAMESPACE/container-list.txt | bash
echo;echo
echo Replace case number TS123456
tar czf CaseTS123456-$AUTHMGDIR.tgz $AUTHMGDIR/
```

Send the logs to the support team

Complete these tasks after you collect the logs:

- Compress the logs and send them to support for analysis.

  ```
  tar czf $AUTHMGDIR.tgz $AUTHMGDIR
  ```

Note: When debug logging is enabled, excess logs are generated, which might affect the container resources. After you collect the debug logs, revert the log level values by editing the settings in the **platform-auth-idp** configmap. For the previous log level values, see parameter values.

Troubleshooting LDAP configuration

Use the **ldapsearch** command line tool to troubleshoot your LDAP (Lightweight Directory Access Protocol) configuration.

Install ldapsearch

Install the **ldapsearch** program.

On Ubuntu, run the following command:

```
sudo apt-get install ldap-utils
```

On Red Hat Enterprise Linux (RHEL), run the following command:

```
sudo yum install openldap-clients
```

Test LDAP connection

To test your LDAP connection, run the following command:

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" -w "<LDAP_BINDPASSWORD>" -s sub
```

Following are the parameter descriptions:

- **<LDAP_URL>** is the URL of the LDAP server. For example, **ldap://<LDAP server domain name or IP address>:<port>** or **ldaps://<LDAP server domain name>:<port>**. The default port number is 389 for LDAP protocol and 636 for LDAP over Secure Sockets Layer (LDAPS) protocol.
- **<LDAP_BASEDN>** is the LDAP distinguished name (DN) of the search base. For example, **dc=abc,dc=com**.
- **<LDAP_BINDDN>** is the LDAP user who is allowed to search the base DN. For example, **cn=admin,dc=abc,dc=com**.
- **<LDAP_BINDPASSWORD>** is the password of the user who is mentioned in the bind DN.

Example commands

```
ldapsearch -x -H "ldap://<hostname or IP address>:389" -b "o=abc.com" -s sub
```

```
ldapsearch -x -H "ldap://<hostname or IP address>:389" -b "dc=abc,dc=com" -D "cn=admin,dc=abc,dc=com" -w "password" -s sub
```

Validate LDAP filters

Create a search string based on the LDAP filters to retrieve data from your LDAP server. If the search results show one or more LDAP entries, then the LDAP filter configuration is correct. If the search results do not show any entry, then the LDAP filter is not correct or is not compatible with your LDAP server type.

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" -w "<LDAP_BINDPASSWORD>" -s sub "<Search string>"
```

Following are the parameter descriptions:

- **<LDAP_URL>** is the URL of the LDAP server. For example, **ldap://<LDAP server domain name or IP address>:<port>** or **ldaps://<LDAP server domain name>:<port>**. The default port number is 389 for LDAP protocol and 636 for LDAPS protocol.
- **<LDAP_BASEDN>** is the LDAP DN of the search base. For example, **dc=abc,dc=com**.
- **<LDAP_BINDDN>** is the LDAP user who is allowed to search the base DN. For example, **cn=admin,dc=abc,dc=com**.
- **<LDAP_BINDPASSWORD>** is the password of the user who is mentioned in the bind DN.
- **<search string>** is the search string that is used to search your LDAP server.

IBM Tivoli Directory Server LDAP filters

Table 1. IBM Tivoli Directory Server LDAP filters

Attribute name	Default value

Attribute name	Default value
Group filter	(&(cn=%v)(objectclass=groupOfUniqueNames))
Group ID map	*:cn
Group Member ID map	groupOfUniqueNames:uniqueMember
User filter	(&(emailAddress=%v)(objectclass=person))
User ID map	*:emailAddress

- Example command to validate group filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(cn=*)(objectclass=groupOfUniqueNames))"
```

- Example command to validate group ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=*)(cn=*))"
```

- Example command to validate group member ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=groupOfUniqueNames)(uniqueMember=*))"
```

- Example command to validate user filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(emailAddress=*)(objectclass=person))"
```

- Example command to validate user ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=*)(emailAddress=*))"
```

Microsoft Active Directory LDAP filters

Table 2. Microsoft Active Directory LDAP filters

Attribute name	Default value
Group filter	(&(cn=%v)(objectcategory=group))
Group ID map	*:cn
Group Member ID map	memberOf:member
User filter	(&(sAMAccountName=%v)(objectcategory=user))
User ID map	user:sAMAccountName

- Example command to validate group filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(cn=*)(objectcategory=group))"
```

- Example command to validate group ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectcategory=*)(cn=*))"
```

- Example command to validate group member ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectcategory=*)(member=*))"
```

- Example command to validate user filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(sAMAccountName=*)(objectcategory=user))"
```

- Example command to validate user ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectcategory=user)(sAMAccountName=*))"
```

Custom (OpenLDAP) server LDAP filters

Table 3. Custom (OpenLDAP) server LDAP filters

Attribute name	Default value
Group filter	(&(cn=%v)(objectclass=groupOfUniqueNames))
Group ID map	*:cn
Group Member ID map	groupOfUniqueNames:uniqueMember

Attribute name	Default value
User filter	(&(uid=%v)(objectclass=person))
User ID map	*:uid

- Example command to validate group filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(cn=*)(objectclass=groupOfUniqueNames))"
```

- Example command to validate group ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=*)(cn=*))"
```

- Example command to validate group member ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=groupOfUniqueNames)(uniqueMember=*))"
```

- Example command to validate user filter

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(uid=*)(objectclass=person))"
```

- Example command to validate user ID map

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" \
-w "<LDAP_BINDPASSWORD>" -s sub "(&(objectclass=*)(uid=*))"
```

Resolve common login issues

Unable to login to `cp-console` or `cpd` using LDAP authentication

The **`ClassCastException`** error is displayed if the **`ObjectClass`** or **`ObjectCategory`** attribute is not defined in the Liberty XML file. The following error is displayed in the logs of the **`auth-service`** pods:

```
Exception = java.lang.ClassCastException
Source = com.ibm.ws.security.oauth20.plugins.jose4j.OidcUserClaims
probeid = 178
Stack Dump = java.lang.ClassCastException: com.ibm.wsspi.security.wim.model.Entity incompatible with
com.ibm.wsspi.security.wim.model.PersonAccount
        at
com.ibm.ws.security.oauth20.plugins.jose4j.OidcUserClaims.getUserinfoFromRegistryMap(OidcUserClaims.java:136
)
        at
com.ibm.ws.security.oauth20.plugins.jose4j.OidcUserClaims.getUserinfoFromRegistry(OidcUserClaims.java:177)
        at
com.ibm.ws.security.openidconnect.web.OidcEndpointServices.getUserinfoFromRegistry(OidcEndpointServices.java

com.ibm.ws.security.openidconnect.web.OidcEndpointServices.handleOidcRequest(OidcEndpointServices.java:281)
        at
com.ibm.ws.security.openidconnect.web.OidcEndpointServlet.handleRequest(OidcEndpointServlet.java:111)
        at com.ibm.ws.security.openidconnect.web.OidcEndpointServlet.doPost(OidcEndpointServlet.java:69)
        at javax.servlet.http.HttpServlet.service(HttpServlet.java:707)
```

Resolving the issue

IM supports the LDAP Entity type configuration for LDAP User and Group entities to define the **`ObjectClass`** or **`ObjectCategory`** attributes automatically in the Liberty XML file.

For the existing LDAP connection, you need to restart the **`platform-auth-service`** pods to enable the **`LDAPEntityType`** configuration.

1. Get the **`platform-auth-service`** pod name.

   ```
   oc get pods -n <your-foundational-services-namespace> | grep platform-auth-service
   ```

2. Delete the **`platform-auth-service`** pod.

   ```
   oc delete pod <platform-auth-service-pod-name> -n <your-foundational-services-namespace>
   ```

The following is the sample Liberty XML file with the LDAP configuration:

```
<server>
    <featureManager>
        <feature>ldapRegistry-3.0</feature>
    </featureManager>
```

```
    <ldapRegistry id="SunOneLDAP" realm="REALM" host="[dd103bgpvip1165.virginia.ms.com]
(https://dd103bgpvip1165.virginia.ms.com/)" port="389"
            ignoreCase="false" baseDN="o=Morgan Stanley" bindDN="msfwid=2053167,ou=prodids,o=Morgan Stanley"
            bindPassword="{xor}OQ9mHBIlFQVoaGk4NSgK" ldapType="Sun Java System Directory Server"
recursiveSearch="true" sslEnabled="false"
            certificateMapMode="CERTIFICATE_FILTER" certificateFilter="uid=${SubjectCN}">
         <ldapEntityType name="PersonAccount">
               <objectClass>msperson</objectClass>
         </ldapEntityType>
         <!-- For Groups -->
        <ldapEntityType name="Group">
                <objectClass>msaclgroup</objectClass>
       </ldapEntityType>
        <iplanetFilters
            userFilter="(&amp;(objectClass=msperson)(uid=%v))"
            groupFilter="(&amp;(cn=%v)(objectclass=msaclgroup)(mseonid=24507))"
            userIdMap="*:uid"
            groupIdMap="*:cn"
            groupMemberIdMap="groupofuniquenames:uniquemember" />
            <ldapCache>
              <attributesCache size="2000" timeout="1200s" enabled="true" sizeLimit="2000"/>
              <searchResultsCache size="2000" timeout="1200s" enabled="true" resultsSizeLimit="2000"/>
            </ldapCache>
    </ldapRegistry>
</server>
```

Unable to log in as LDAP user after you configure an LDAP connection

You might not be able to log in as an LDAP user even when the connection test and the LDAP configuration are successful.

You see an error that indicates an **invalid username or password**.

You might see the following error in the log files of the **platform-auth-service** container:

```
CWIML4537E: The login operation could not be completed. The specified principal name XXXXXX is not found in
the back-end repository.
```

To identify the error, enable trace for Liberty service to know the exact error in First failure data capture (FFDC) logs. For more information, see Enable debugging for user authentication issues.

Following are the possible causes. A resolution is provided for each cause.

Cause 1 - Invalid `username` value is used when you logged in

The user name value is not the same as the **userIdMap** filter attribute value.

Resolution for cause 1

Ensure that you enter the correct user name. The user name must be the same as the **userIdMap** filter attribute value. The user name is case-sensitive.

Consider the following example:

LDAP user details on an LDAP server:

```
dn: uid=testuser,ou=people,dc=abc,dc=com
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: person
objectClass: top
cn: TestUser
givenName: TestUser
sn: SN
uid: testuser
userPassword: testuser
mail: testuser@abc.com
```

LDAP configuration:

```
User filter: (&(uid=%v)(objectclass=person))
User ID map: *:uid
```

If you use ***:uid** as the **userIdMap** filter, then you must use the **uid** value **testuser** as the user name when you log in.

Cause 2 - LDAP login user or Bind DN user is disabled or locked at the LDAP server

- The LDAP login user is disabled or locked at the LDAP server due to many unsuccessful login attempts.
- The **Bind DN** user is disabled or locked at LDAP server due to many unsuccessful login attempts.

Resolution for cause 2

- Use the `ldapsearch` tool to test the LDAP connection.
- Enable or unlock the LDAP login user or **Bind DN** user at the LDAP server.

Cause 3 - Invalid Password value is used to log in

- The LDAP user password might be wrong.
- The **Bind DN password** might contain some unsupported special characters.

Resolution for cause 3

- Enter the correct password and try logging in.
- If the **Bind DN password** has special characters, change the password and do not use special characters in the changed password.

Cause 4 - LDAP configuration might not be synchronized across all the pods in a high availability (HA) cluster

The login request might be going to a pod in an HA cluster that does not have the LDAP configuration.

Resolution for cause 4

Restart the `platform-auth-service` pod. If the issue is still not resolved, restart the `platform-auth-service`, `platform-identity-provider`, and `platform-identity-management` pods.

Cause 5 - LDAP connection issues due to various reasons

- The LDAP server is not reachable.
- You used the LDAP server hostname in the LDAP server URL, and the hostname is not reachable. This issue might be because the correct DNS server entries were not added during cluster installation.
- If LDAPS is used to configure the LDAP connection, following might be the possible causes:
  - An IP address is used instead of the LDAP server hostname in the LDAP server URL.
  - The LDAP server certificate is not imported into your cluster.
  - The LDAP server certificate does not match with the LDAP server hostname (or certificate SANs (Subject Alternative Names)).

Resolution for cause 5

- Test the LDAP connection by using the `ldapsearch` tool.
- Add the LDAP server hostname in the `/etc/hosts` file either on the master node or in the `platform-auth-service` container.
- For configuring an LDAPS connection, use the LDAP server hostname in the LDAP server URL and the LDAP server certificate is imported into your cluster. Followed all the required steps for Configuring LDAP over SSL.
- Change the hostname, or get a new certificate that matches with the LDAP server hostname or any one of the certificate SANs.

Cause 6 - External database connection failed in the `platform-auth-service` container

You can see external database connection failure errors in the logs of the `platform-auth-service` container.

Resolution for cause 6

Restart the `platform-auth-service` pod that is configured with the external database.

Resolve common issues with search users or groups

Unable to search users or groups while you create a team.

Cause

You used an invalid search string.

Resolution

You must use the value of the `cn` attribute or the user or group attribute such as `uid` or `emailaddress` that you used in the LDAP configuration.

Consider the following example:

LDAP user details on an LDAP server

```
dn: uid=testuser,ou=people,dc=abc,dc=com
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: person
objectClass: top
cn: TestUser
```

```
  givenName: TestUser
  sn: SN
  uid: testuser
  userPassword: testuser
  mail: testuser@abc.com
```

Following filters are used in the LDAP configuration:

- User filter: (&(uid=%v)(objectclass=person))
- User ID map: *:uid

The **userIdMap** that is used is ***:uid**.

The valid values that you can use to search for a user are as follows:

- TestUser (**cn** value)
- testuser (**uid** value)

Configuring LDAP over SSL

You can secure your Lightweight Directory Access Protocol (LDAP) connection by using SSL (Secure Sockets Layer).

If LDAP over SSL (LDAPS) is not automatically configured in your cluster, complete these steps to manually configure the LDAPS connection.

You must prepare your product cluster for connecting with your LDAPS directory.

Before you begin, you must import the public or private SSL certificate that you used for setting up your LDAPS directory.

Retrieving the SSL certificate

If you have the SSL certificate of your LDAP server, proceed with Encoding the SSL certificate.

If you do not have the SSL certificate of your LDAP server, use one of the following approaches to retrieve the SSL certificate:

Option 1: Using the `ldapsearch` command

Note: You need the **ldapsearch** program to run these commands. You can install it by running **apt install ldap-utils** on Ubuntu and **yum install openldap-clients** on Red Hat Enterprise Linux (RHEL).

1. Ensure that no SSL certificates are in the **/etc/openldap/cacerts** directory.
2. Run the following **ldapsearch** command to retrieve the certificate name:

   ```
   ldapsearch -H <LDAP server URL> -d 1  -b <searchbase> -D "" -s base "(<filter>)"
   ```

   Where,

   - **LDAP server URL** is your LDAP directory domain name, and port. Format: **ldaps://<LDAP server domain name or IP address>:<port>**.
   - **-d** is the debugging level.
   - **-b** is the search base.
   - **-D** is the bind DN. This parameter is optional.
   - **-s** is the scope of search.
   - **filter** is the LDAP filter. Default filter: **(objectClass=*)**.

   Sample command:

   ```
   ldapsearch -H ldaps://corp.example.com:636 -d 1  -b o=example.com -D "" -s base "(objectclass=*)"
   ```

   Sample output:

   ```
   ldap_url_parse_ext(ldaps://corp.example.com:636)
   ldap_create
   ldap_url_parse_ext(ldaps://corp.example.com:636/??base)
   ldap_sasl_bind
   ldap_send_initial_request
   ldap_new_connection 1 1 0
   ldap_int_open_connection
   ldap_connect_to_host: TCP corp.example.com:636
   ldap_new_socket: 3
   ldap_prepare_socket: 3
   ldap_connect_to_host: Trying 9.17.186.253:636
   ldap_pvt_connect: fd: 3 tm: -1 async: 0
   ```

```
attempting to connect:
connect success
TLS: certdb config: configDir='/etc/openldap' tokenDescription='ldap(0)' certPrefix='cacerts'
keyPrefix='cacerts' flags=readOnly
TLS: cannot open certdb '/etc/openldap', error -8018:Unknown PKCS #11 error.
TLS: could not get info about the CA certificate directory /etc/openldap/cacerts - error -5950:File not
found.
TLS: certificate [CN=DigiCert Global Root G2,OU=www.digicert.com,O=DigiCert Inc,C=US] is not valid -
error -8172:Peer's certificate issuer has been marked as not trusted by the user..
TLS: error: connect - force handshake failure: errno 2 - moznss error -8172
TLS: can't connect: TLS error -8172:Peer's certificate issuer has been marked as not trusted by the
user..
ldap_err2string
ldap_sasl_bind(SIMPLE): Can't contact LDAP server (-1)
```

The certificate information is in the **`TLS: certificate [CN=DigiCert Global Root G2,OU=www.digicert.com,O=DigiCert Inc,C=US] is not valid - error -8172:Peer's certificate issuer has been marked as not trusted by the user..`** section of the output.

3. Locate the certificate in your web browser, export it to a file in a PEM format, and save the PEM file with a **`.crt`** extension.

   Note: If you have multiple certificates, export each certificate to a file in a PEM format and save the PEM file with a **`.crt`** extension.

4. Copy the **`.crt`** file to the infrastructure node of your cluster.

Option 2: Using the `openssl` tool

1. Run the following command:

   ```
   openssl s_client -connect <ldap-server-host>:636 -showcerts > ldap_server_certs.pem
   ```

2. Edit the **`ldap_server_certs.pem`** file:

   1. Remove the unwanted lines.
   2. Retain the content between **`-----BEGIN CERTIFICATE-----`** and **`-----END CERTIFICATE-----`** lines.

   Note: Ensure that final **`ldap_server_certs.pem`** certificate file is a valid PEM format and no empty lines are there in-between.

Preparing for a single LDAPS connection

If you are configuring a single LDAPS connection, complete the steps in the Encoding the SSL certificate section.

Encoding the SSL certificate

Complete the following steps to encode the certificate in base64:

1. Log on to the infrastructure node of your cluster.

2. Convert the certificate into PEM format.

   ```
   openssl x509 -in <cert>.cer -outform PEM -out <convertedCert>.pem
   ```

   If your LDAP server uses chain certificates (root CA and intermediate certificates), convert each certificate into PEM format. Then, combine them into one file. Use the following command to combine the converted certificates.

   ```
   cat <convertedFirstCert.pem> <convertedSecondCert.pem> ..<converted_n_Cert.pem> >
   <convertedCombinedCert>.pem
   ```

3. Encode your certificate in base64.

   ```
   cat <LDAPS SSL certificate name>.pem | base64 -w 0
   ```

   The output resembles the following code:

   ```
   LS0tLS1CRUdJTiBDRVJUSUZJQ0FURS0tLS0tCk1JSUdDRENDQS9DZ
   0F3SUJBZ0lRS3k1dTZ0bDFObXdVaW03Ym8zeU1CekFOQmdrcWhraUc5
   ...
   lDOHg0OU9oZ1E9Ci0tLS0tRU5EIENFUlRJRklDQVRFLS0tLS0KDQo=
   ```

Next, proceed with Preparing your cluster.

Preparing for multiple LDAPS connections

If you are configuring multiple LDAPS connections, first check if you already have a certificate in the "data" > "certificate" section of **`platform-auth-ldaps-ca-cert`**. If you have a certificate, then complete the steps in the following sections:

- Retrieve the current certificate

- Encode the SSL certificate

If no certificate exists, then complete the steps in Encoding the SSL certificate.

Retrieve the current certificate

You can retrieve the certificate by using the Red Hat® OpenShift® Container Platform console or command line interface (CLI).

Option 1: Using the console

1. Log on to the Red Hat® OpenShift® Container Platform console as a cluster administrator.
2. From the navigation menu, click **Workloads** > **Secrets**.
3. Locate `platform-auth-ldaps-ca-cert` and click **...** > **Edit Secret**. A window for editing displays.
4. Copy the base64 encoded certificate value from "data" > "certificate" section.

   ```
   "data": {
    "certificate": "LS0tLS1...ASDFASDo="
   },
   ```

5. Convert the existing encoded certificate and save to a file.

   ```
   echo "<copied_cert_value>" | base64 --decode > existing_cert.pem
   ```

Option 2: using the CLI

1. Access the CLI of your infrastructure node. Install the Kubernetes CLI (kubectl). You need this tool to complete the following tasks.
2. Get the base64 certificate.

   ```
   kubectl -n <your-foundational-services-namespace> get secret platform-auth-ldaps-ca-cert -o "jsonpath=
   {.data['certificate']}" | base64 --decode > existing_cert.pem
   ```

Next, proceed with Encode the SSL certificate.

Encode the SSL certificate

Complete the following steps to encode the certificate in base64:

1. Log on to the infrastructure node of your cluster.
2. Convert the new certificate into PEM format.

   ```
   openssl x509 -in <cert>.cer -outform PEM -out <convertedCert>.pem
   ```

   If your LDAP server uses chain certificates (root CA and intermediate certificates), convert each certificate into PEM format. Then, combine them into one file. Use the following command to combine the converted certificates.

   ```
   cat <convertedFirstCert.pem> <convertedSecondCert.pem> ..<converted_n_Cert.pem> >
   <convertedCombinedCert>.pem
   ```

3. Add the existing certificate to the new certificate, or to the combined certificate if you use chain certificates.

   ```
   cat existing_cert.pem <new_cert.pem or convertedCombinedCert.pem> > final_combined_cert.pem
   ```

4. Encode your certificate in base64.

   ```
   cat <LDAPS SSL certificate name>.pem | base64 -w 0
   ```

   The output resembles the following code:

   ```
   LS0tLS1CRUdJTiBDRVJUSUZJQ0FURS0tLS0tCk1JSUdDRENDQS9DZ
   0F3SUJBZ0lRS3k1dTZ0bDFObXdVaW03Ym8zeU1CekFOQmdrcWhraUc5
   ...
   lDOHg0OU9oZ1E9Ci0tLS0tRU5EIENFUlRJRklDQVRFLS0tLS0KDQo=
   ```

Next, complete the steps in the Preparing your cluster section.

Preparing your cluster

You can prepare your cluster by using the Red Hat® OpenShift® Container Platform console or CLI.

Option 1: Using the console

1. Log on to the Red Hat® OpenShift® Container Platform console as a cluster administrator.

2. From the navigation menu, click **Workloads** > **Secrets**.
3. Locate `platform-auth-ldaps-ca-cert` and click **...** > **Edit Secret**. A window for editing displays.
4. Paste the base64 certificate in the following section:

   ```
   "data": {
    "certificate": ""
   },
   ```

   The updated section resembles the following text:

   ```
   "data": {
    "certificate": "LS0tLS1<very_long_base64_string>ASDFASDo="
   },
   ```

5. Click **Save**.
6. From the navigation menu, click **Workloads > Deployments**.
7. Locate `platform-auth-service`.
8. Click **...** > **Edit Deployment**. A window for editing displays.
9. Click **Save** without making any change. This step is to reload the `platform-auth-service` pods with the latest ConfigMap values.
10. Wait for a minute or two and then check whether the certificate is mounted on the pod.
    1. Get the `platform-auth-service` pods.

       ```
       kubectl -n <your-foundational-services-namespace> get pods | grep platform-auth-service
       ```

    2. Check whether the certificate is mounted on the pod.

       ```
       kubectl -n <your-foundational-services-namespace> exec -it platform-auth-service-<pod-id> -c
       platform-auth-service cat /opt/ibm/ldaps/ldaps-ca.crt
       ```

Option 2: Using the CLI

1. Access the CLI of your infrastructure node. You need `kubectl`, the Kubernetes command line tool to complete the following tasks. For more information about installing `kubectl`, see Install tools.
2. Copy the LDAPS CA certificate secret to a file:

   ```
   kubectl get secret platform-auth-ldaps-ca-cert -o yaml -n <your-foundational-services-namespace> >
   platform-auth-ldaps-ca-cert-secret.yaml
   ```

3. Copy and paste the base64 certificate to the `platform-auth-ldaps-ca-cert-secret.yaml` file.
4. Get the security service Deployment YAML file:

   ```
   kubectl -n <your-foundational-services-namespace> get deploy platform-auth-service -o yaml > platform-
   auth-service.yaml
   ```

5. Apply the changes:
   1. Run the following command to apply the `platform-auth-ldaps-ca-cert-secret.yaml` file:

      ```
      kubectl apply -f platform-auth-ldaps-ca-cert-secret.yaml
      ```

   2. Run the following command to apply the `platform-auth-service.yaml` file:

      ```
      kubectl apply -f platform-auth-service.yaml
      ```

Next, complete the steps in the Connecting to your LDAP directory section.

Troubleshooting users and user groups search issues

Verify or test search users and groups by using the `ldapsearch` command tool.

Search users

Use the following `ldapsearch` command:

```
ldapsearch -x -l <TIME_LIMIT> -z <SIZE_LIMIT> -H <LDAP_URL> -b <LDAP_BASEDN> -D <LDAP_BINDDN> -w
<LDAP_BINDPASSWORD> -s sub "<search query>"
```

See the following definitions:

- **<LDAP_URL>** is the Lightweight Directory Access Protocol (LDAP) server URL.
- **<LDAP_BASEDN>** is the LDAP Base DN.
- **<LDAP_BINDDN>** is the LDAP Bind DN.
- **<LDAP_BINDPASSWORD>** is the LDAP Bind DN password.
- **<TIME_LIMIT>** is the time limit in seconds for the search. Default value is 5 seconds.
- **<SIZE_LIMIT>** is the size limit for search. Default value is 50 entries.

In IBM Cloud Pak® for AIOps, the search string is based on the **cn** and **User ID map** attributes that are configured in the LDAP connection user filters.

For example, consider the following LDAP user filters configuration:

```
User filter: (&(uid=%v)(objectclass=person))
User ID map: *:uid
```

For the example configuration, following is the search query:

```
(|(&(cn=*<searchstring>*)(objectclass=person))(&(uid=*<searchstring>*)(objectclass=person)))
```

In the search query, user name or user ID value is the **<searchstring>**. For example, **John** or **robbie**.

Following is an example **ldapsearch** command:

```
ldapsearch -x -l 5 -z 50 -H "ldap://X.X.X.X:389" -b "dc=abc,dc=com" -D "cn=admin,dc=abc,dc=com" -w
'password' -s sub "(|(&(cn=*user*)(objectclass=person))(&(uid=*user*)(objectclass=person)))"
```

Here, the **<searchstring>** is **user**.

Following is a sample output:

```
# extended LDIF
#
# LDAPv3
# base <dc=abc,dc=com> with scope subtree
# filter: (|(&(cn=*user*)(objectclass=person))(&(uid=*user*)(objectclass=person)))
# requesting: ALL
#

# user1, Users, abc.com
dn: uid=user1,ou=Users,dc=abc,dc=com
cn: User One
objectClass: inetOrgPerson
objectClass: person
objectClass: top
sn: One
uid: user1
userPassword:: dXNlcjE=

# user2, Users, abc.com
dn: uid=user2,ou=Users,dc=abc,dc=com
cn: User Two
objectClass: inetOrgPerson
objectClass: person
objectClass: top
sn: Two
uid: user2
userPassword:: dXNlcjI=

# search result
search: 2
result: 0 Success

# numResponses: 3
# numEntries: 2
```

Search groups

Use the following **ldapsearch** command:

```
ldapsearch -x -l <TIME_LIMIT> -z <SIZE_LIMIT> -H <LDAP_URL> -b <LDAP_BASEDN> -D <LDAP_BINDDN> -w
<LDAP_BINDPASSWORD> -s sub "<search query>"
```

See the following list of definitions:

- **<LDAP_URL>** is the LDAP server URL.
- **<LDAP_BASEDN>** is the LDAP Base DN.
- **<LDAP_BINDDN>** is the LDAP Bind DN.
- **<LDAP_BINDPASSWORD>** is the LDAP Bind DN password.
- **<TIME_LIMIT>** is the time limit in seconds for the search. Default value is 5 seconds.
- **<SIZE_LIMIT>** is the size limit for search. Default value is 50 entries.

In IBM Cloud Pak for AIOps, the search string is based on the **cn** and **Group ID map** attributes that are configured in the LDAP connection group filters.

For example, consider the following LDAP group filters configuration:

```
Group filter: (&(cn=%v)(objectclass=groupOfUniqueNames))
Group ID map: *:cn
```

For the example configuration, following is the search query:

```
(&(cn=*<searchstring>*)(objectclass=groupOfUniqueNames))
```

In the search query, group name value is the **<searchstring>**. For example, **security** or **administrators**.

If the **Group ID map** attribute is different than **cn**, for example **gid**, then the following search query can be used:

```
(|(&(cn=*<searchstring>*)(objectclass=groupOfUniqueNames))(&(gid=*<searchstring>*)
(objectclass=groupOfUniqueNames)))
```

Here, the group name or **gid** value is the **<searchstring>**.

Following is an example **ldapsearch** command:

```
ldapsearch -x -l 50 -z 100 -H "ldap://X.X.X.X:389" -b "dc=abc,dc=com" -D "cn=admin,dc=abc,dc=com" -w
'password' -s sub "(&(cn=*gr*)(objectclass=groupOfUniqueNames))"
```

Here, the **<searchstring>** is **gr**.

Following is a sample output:

```
# extended LDIF
#
# LDAPv3
# base <dc=abc,dc=com> with scope subtree
# filter: (&(cn=*gr*)(objectclass=groupOfUniqueNames))
# requesting: ALL
#

# group1, Groups, abc.com
dn: cn=group1,ou=Groups,dc=abc,dc=com
cn: group1
objectClass: groupOfUniqueNames
objectClass: top
uniqueMember: cn=group2,ou=Groups,dc=abc,dc=com
uniqueMember: uid=user1,ou=Users,dc=abc,dc=com

# group2, Groups, abc.com
dn: cn=group2,ou=Groups,dc=abc,dc=com
cn: group2
objectClass: groupOfUniqueNames
objectClass: top
uniqueMember: uid=user2,ou=Users,dc=abc,dc=com

# search result
search: 2
result: 0 Success

# numResponses: 3
# numEntries: 2
```

Retrieve users from an LDAP group

Use the following **ldapsearch** command:

```
ldapsearch -x -H "<LDAP_URL>" -b "<LDAP_BASEDN>" -D "<LDAP_BINDDN>" -w "<LDAP_BINDPASSWORD>" -s sub "(cn=
<GROUP_NAME>)"
```

See the following list of definition:

- **<LDAP_URL>** is the LDAP server URL.
- **<LDAP_BASEDN>** is the LDAP Base DN.

- `<LDAP_BINDDN>` is the LDAP Bind DN.
- `<LDAP_BINDPASSWORD>` is the LDAP Bind DN password.
- `<GROUP_NAME>` is the group name.

Consider the following example command:

```
ldapsearch -x -H "ldap://X.X.X.X:389" -b "dc=abc,dc=com" -D "cn=admin,dc=abc,dc=com" -w 'password' -s sub "
(cn=group2)"
```

Following is a sample output:

```
# extended LDIF
#
# LDAPv3
# base <dc=abc,dc=com> with scope subtree
# filter: (cn=group2)
# requesting: ALL
#

# group2, Groups, abc.com
dn: cn=group2,ou=Groups,dc=abc,dc=com
cn: group2
objectClass: groupOfUniqueNames
objectClass: top
uniqueMember: uid=user2,ou=Users,dc=abc,dc=com

# search result
search: 2
result: 0 Success

# numResponses: 2
# numEntries: 1
```

Timeout error while setting up an LDAP connection

Cannot set up a connection with your LDAP server.

Symptoms

While setting up an LDAP connection, you might see a **`504 Gateway timeout`** error.

Cause

The connection needs more time than usual to be established.

Resolving the problem

To resolve the issue, increase the LDAP configuration timeout value in the **`platform-auth-idp`** configmap to a value in the range 25-60 seconds.

1. Log in to your infrastructure node by using the **`oc login`** command.
2. Edit the **`platform-auth-idp`** configmap.

   ```
   oc -n <your-foundational-services-namespace> edit configmap platform-auth-idp
   ```

3. Change the **`AUTH_SVC_LDAP_CONFIG_TIMEOUT: "25"`** parameter value to a higher value. For example, **`"45"`**. The value is in seconds.
4. Save the changes.
5. Restart the **`platform-auth-service`** pods by deleting the pods.
   1. Get the **`platform-auth-service`** pod names.

      ```
      oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
      ```

   2. Delete the **`platform-auth-service`** pod.

      ```
      oc -n <your-foundational-services-namespace> delete pods <pod-name>
      ```

Wait for some time and then check the status of the **`platform-auth-service`** pods. The status of all **`platform-auth-service`** pods must show as **`Running`**.

```
oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
```

Timeout error after enabling LDAP Nested search for Microsoft Active Directory

Once you enable Nested search option while searching the SCIM users or groups, the time taken for the SCIM API to response might be increased. As a result, sometimes you might see that the SCIM search returns empty or **504 Gateway timeout** error in the logs.

Symptoms

- **504 Gateway timeout** error is displayed.
- Or, you get no response.

Cause

- The connection needs more time than usual to search SCIM users or groups.
- You might be searching many SCIM users or groups in a single query after enabling the Nested search option.
- The underlying LDAP server has many nesting levels.

Resolving the problem

1. Increase the OCP (OpenShift Container Platform) route timeout by using the following code:

   ```
   oc -n <your-foundational-services-namespace> annotate route cp-console --overwrite
   haproxy.router.openshift.io/timeout=60s
   ```

2. Disable the Nested search if it is not required. LDAP Nested Search can be a very expensive operation and it can go worse if the nesting level increases.

Client registration failure in Platform UI console

Client registration fails in Platform UI console When you upgrade the foundational services version 3.22 or version 3.23 to foundational services version 4.x.x.

Symptoms

You might fail to register the client in Platform UI console in the following scenarios:

- When you upgrade the foundational services version 3.22 or version 3.23 to foundational services version 4.x.x and migrate more than one LDAP.
- When you have more than one LDAP before upgrading foundational services version 3.22 or version 3.23 to foundational services version 4.x.x.

Workaround

- Check the **platform-auth-service** pod configuration. You might see that some files have wrong entries. To check the pod configuration, run the following command:

  ```
  for i in $(oc get pod -l app.kubernetes.io/instance=platform-auth-service --no-headers|awk '{print
  $1}');do oc exec -it $i -- ls /config/configDropins/defaults/;done
  ```

  The sample output:

  ```
  Defaulted container "platform-auth-service" out of: platform-auth-service, init-mongodb (init)
  federated.xml  keystore.xml  ldap-cp4ba-prod-default-4776.xml
  ```

- Restart **platform-auth-service** pods.

  ```
  oc delete pod $(oc get pod -l name=platform-auth-service --no-headers|awk '{print $1}')
  ```

  Once the pod is deleted, wait for some time and then restart the **platform-auth-service** pods.

- Then, restart **platform-identity-provider** pods.

  ```
  oc delete pod $(oc get pod -l name=platform-identity-provider --no-headers|awk '{print $1}')
  ```

Once the pod is deleted, wait for some time and then restart the **platform-identity-provider** pods.

Intermittent login failure in Platform UI console

You might fail to login Platform UI console when you upgrade the foundational services version 3.22 or version 3.23 to foundational services version 4.x.x.

Symptoms

There might be intermittent login failure in Platform UI console when you upgrade the foundational services version 3.22 or version 3.23 to foundational services version 4.x.x and then configure the multiple LDAPs.

Workaround

- If you check the **platform-auth-service** pod configuration, you might see that only the **keystore.xml** file is in the pod. Also, some files might be missing in the pod. To check the pod configuration, run the following command:

  ```
  for i in $(oc get pod -l app.kubernetes.io/instance=platform-auth-service --no-headers|awk '{print $1}');do oc exec -it $i -- ls /config/configDropins/defaults/;done
  ```

- Restart **platform-auth-service** pods.

  ```
  oc delete pod $(oc get pod -l name=platform-auth-service --no-headers|awk '{print $1}')
  ```

  Once the pod is deleted, wait for some time and then restart the **platform-auth-service** pods.

LDAP nested search for Microsoft Active Directory does not work correctly

SCIM LDAP Nested search for Microsoft Active Directory is not working properly.

Symptoms

Not all users that match the search query are returned in the search result.

Run these queries to verify whether the nested search is returning correct results.

LDAP queries

- Run an LDAP query to search all nested users that belong to a group: **memberOf:1.2.840.113556.1.4.1941:=<group dn>**.
  - Use the following syntax:

    ```
    ldapsearch -x -H ldap://ip:389 -b <LDAP_BASEDN> -D <LDAP_BINDDN> -w <LDAP_BINDPASSWORD> -s sub "(&(memberOf:1.2.840.113556.1.4.1941:=<group dn>)(objectcategory=user))"
    ```

  - Following is a sample output:

    ```
    ldapsearch -x -H ldap://1.2.3.4:389 -b dc=ibm,dc=com -D cn=root -w password -s sub "(&(memberOf:1.2.840.113556.1.4.1941:=cn=Icpgroup1,cn=platform,ou=cloud,ou=isl,ou=groups,dc=ibm,dc=com)(objectcategory=user))"
    ```

- Run an LDAP query to search all nested groups that a user belongs to: **(member:1.2.840.113556.1.4.1941:<user dn>)**.
  - Use the following syntax:

    ```
    ldapsearch -x -H ldap://ip:389 -b <LDAP_BASEDN> -D <LDAP_BINDDN> -w <LDAP_BINDPASSWORD> -s sub "(&(member:1.2.840.113556.1.4.1941:<user dn>)(objectcategory=group))"
    ```

  - Here is a sample output:

    ```
    ldapsearch -x -H ldap://1.2.3.4:389 -b dc=ibm,dc=com -D cn=root -w password -s sub "(&(member:1.2.840.113556.1.4.1941:uid=icpuser1,ou=people,dc=ibm,dc=com)(objectcategory=group))"
    ```

SCIM queries

- Run a SCIM query to get all nested users that belong to a group.
  - Use the following API:

    ```
    curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Accept: application/json"
    "$BCS_URL/idmgmt/identity/api/v1/scim/groups/$GROUP_ID" | jq -r '.members'
    ```

  - See the following example result:

    ```
    curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Accept: application/json"
    "$BCS_URL/idmgmt/identity/api/v1/scim/groups/cn=Icpgroup1,cn=platform,ou=cloud,ou=isl,ou=groups,dc
    =ibm,dc=com" | jq -r '.members'
    ```

- Run a SCIM query to get all nested groups that a user belongs to.
  - Use the following API:

    ```
    curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Accept: application/json"
    "$BCS_URL/idmgmt/identity/api/v1/scim/users/$USER_ID" | jq -r '.groups'
    ```

  - See the following example result:

    ```
    curl -sk -X GET --header "Authorization: Bearer $ACCESS_TOKEN" --header "Accept: application/json"
    "$BCS_URL/idmgmt/identity/api/v1/scim/groups/uid=icpuser1,ou=people,dc=ibm,dc=com"  | jq -r
    '.groups'
    ```

Cause

Your LDAP directory setup might have problems, or your SCIM configuration might be wrong.

Resolving the problem

For LDAP query issues, check you LDAP directory data setup.

For SCIM query issues, see the available troubleshooting documents.

Pod issues

Troubleshoot security pod issues.

- platform-auth-service pod restarts multiple times
- Pods are not scheduled
- secret-watcher and security-onboarding pods fail to start
- Secret watcher pod shows CrashLoopBackOff status
- IM pods cannot be deployed when foundational services is configured with external EDB PostgreSQL
- The ibm-iam-operator pod fails because of cache sync failures

platform-auth-service pod restarts multiple times

The **platform-auth-service** pod restarts multiple times.

Symptoms

The **platform-auth-service** pod restarts multiple times. The **platform-auth-service** shows the following logs:

```
oc logs platform-auth-service -n <your-foundational-services-namespace> -c platform-auth-service

2019-02-12 18:18:12,170 WARN received SIGTERM indicating exit request
2019-02-12 18:18:12,170 INFO waiting for 01-wlp-platform-auth-service, 02-directory-service to die
2019-02-12 18:18:12,183 INFO stopped: 02-directory-service (terminated by SIGTERM)
[AUDIT   ] CWWKE0085I: The server defaultServer is stopping because the JVM is exiting.
[AUDIT   ] CWWKE1100I: Waiting for up to 30 seconds for the server to quiesce.
[AUDIT   ] CWWKT0017I: Web application removed (default_host): http://platform-auth-service-v9h8q:9080/oidc/
[AUDIT   ] CWWKT0017I: Web application removed (default_host): http://platform-auth-service-
v9h8q:9080/oauth2/
2019-02-12 18:18:15,385 INFO waiting for 01-wlp-platform-auth-service to die
```

```
2019-02-12 18:18:18,387 INFO waiting for 01-wlp-platform-auth-service to die
2019-02-12 18:18:21,390 INFO waiting for 01-wlp-platform-auth-service to die
2019-02-12 18:18:22,391 WARN killing '01-wlp-platform-auth-service' (9) with SIGKILL
2019-02-12 18:18:22,514 INFO stopped: 01-wlp-platform-auth-service (terminated by SIGKILL)
```

Causes

The **platform-auth-service** is using more resources than the configured limit. This issue is seen more often on Linux on IBM Z and LinuxONE platforms.

Resolving the problem

To resolve the issue, remove the resource limits.

1. Install the Kubernetes CLI (kubectl).
2. Edit the **platform-auth-service** daemonset.

   ```
   kubectl edit ds platform-auth-service -n <your-foundational-services-namespace>
   ```

3. Locate the following section:

   ```
       name: platform-auth-service
       ports:
       - containerPort: 8443
         hostPort: 8443
         name: http
         protocol: TCP
       readinessProbe:
         failureThreshold: 3
         httpGet:
           path: /
           port: 8443
           scheme: HTTPS
         periodSeconds: 10
         successThreshold: 1
         timeoutSeconds: 1
       resources:
         limits:
           cpu: "1"
           memory: 1Gi
         requests:
           cpu: 100m
           memory: 256Mi
   ```

4. Remove the **limits** section under the **resources** section. The **resources** section must look like the following piece of code after the change:

   ```
         resources:
           requests:
             cpu: 100m
             memory: 256Mi
   ```

5. Save the file and wait until all the **platform-auth-service** pods restart. The pods might take a few minutes to restart.

Pods are not scheduled

Security pods are not scheduled since the master nodes do not meet the required memory or CPU requirements.

If you are unable to log in to the console, check whether the following pods are scheduled:

```
platform-identity-provider-xxx
platform-identity-management-xxx
platform-auth-service-xxx
auth-apikeys-xxx
secret-watcher-xxx
security-onboarding-xxx
```

If any of these pods are not scheduled, get information about the pod's controller (daemonset, statefulset, deployment, and other components) and check whether the pod is not getting scheduled due to resource unavailability. Use the following command to get the information:

```
kubectl describe daemonset platform-auth-service -n <your-foundational-services-namespace>
```

The output has the information about memory and CPU requirements. If the resource requirement is not met, increase the master node's memory or CPU.

After you increase the resources, the pods are automatically scheduled.

secret-watcher and security-onboarding pods fail to start

During IBM Cloud Pak foundational services installation, the **secret-watcher** and **security-onboarding** pods fail to start.

Causes

The identity management (IM) pods are not ready.

To get the status of **secret-watcher** and **security-onboarding** pods, run the following command:

```
oc get pod -A | grep -e secret-watcher -e security-onboarding
```

After you run the command, you might get the following output. The **STATUS** in the sample output shows that the **secret-watcher** pod is running successfully and the **security-onboarding** pod is completed.

```
NAMESPACE                          NAME                                  READY   STATUS      RESTARTS   AGE
<your-foundational-services-namespace>           secret-watcher-5c79cb8969-7w4nw    1/1     Running     0
19h
<your-foundational-services-namespace>           security-onboarding-8kh8l          0/1     Completed   0
20h
```

For an instance, the **STATUS** of the pods can also display the error:

```
NAMESPACE              NAME                                READY     STATUS                          RESTARTS     AGE
<your-foundational-services-namespace>   secret-watcher-cccd54d9f-vdnn2    0/1
CreateContainerConfigError   0          20m
<your-foundational-services-namespace>   security-onboarding-btlhh         0/1
CreateContainerConfigError   0          20m
```

If you observe the error in the pod's status, you can run the following command to know the cause of the **CreateContainerConfigError** error. The following command display the list of events for the **security-onboarding** pod:

```
oc get event --namespace <your-foundational-services-namespace> --field-selector
involvedObject.name=security-onboarding-xxxx
```

After you run the command, you might get the following status that indicates that the "icp-serviceid-apikey-secret" key is missing due to which the pod is showing **CreateContainerConfigError** error. It indicates the issue with the **iam-onboarding** job.

```
108m    Warning  Failed      pod/security-onboarding-8kh8l  Error: secret "icp-serviceid-apikey-secret" not
found
```

Resolving the problem

Restart the **iam-onboarding** job to resolve the issue.

1. Log in to your boot node by running the **oc login** command.
2. Restart the **iam-onboarding** job.
    - Get the **iam-onboarding** job.

oc get job iam-onboarding

```
  * If the `iam-onboarding` doesn't exist, restart the IM operator.

  ``` {: codeblock}
 oc delete po -l name=ibm-iam-operator

* If the `iam-onboarding` job exists, restart the iam-onboarding job.

``` {: codeblock}
```

oc get job iam-onboarding -o json | jq 'del(.spec.selector)' | jq 'del(.spec.template.metadata.labels)' | kubectl replace --force -f -

Secret watcher pod shows CrashLoopBackOff status

The **secret-watcher** pod keeps crashing and shows a **CrashLoopBackOff** status.

Cause

There might be many Kubernetes secrets that are configured in the cluster. The current memory limit that is configured in the **secret-watcher** pod is not sufficient to manage the Kubernetes secrets. Kubernetes killed the pod due to less memory.

Resolving the problem

To resolve the issue, increase the resource memory limit to a value that is sufficient for the pod to manage all the Kubernetes secrets.

1. Log in to your boot node with the **oc login** command.
2. Check the number of Kubernetes secrets that are in the cluster.

   ```
   oc get secrets --all-namespaces | wc -l
   ```

3. Edit the **CommonService** custom resource.

   ```
   oc -n <your-foundational-services-namespace> edit CommonService common-service
   ```

4. Add the following piece of configuration under the **spec.services** section. Add the required memory limit in the **resources.limits.memory** section.

   ```
   spec:
     services:
     - name: ibm-im-operator
       spec:
         secretwatcher:
           resources:
             limits:
               memory: 220Mi
   ```

5. Save and exit the custom resource.

   Wait for some time and then check the **secret-watcher** pod status. The status must show as **1/1 Running** and the updated memory must show in the pod description.

6. Get the **secret-watcher** pod status and name.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep secret-watcher
   ```

7. Check the pod description.

   ```
   oc -n <your-foundational-services-namespace> describe pod <secret-watcher-pod-name>
   ```

OIDC issues

Troubleshoot OIDC related issues.

- OIDC client creation is not successful
- OIDC registration fails to update

OIDC client creation is not successful

There can be many reasons that why the OIDC client creation is not successful, however, the few obvious reasons are listed following:

- Invalid client CR
- Associated pod is not running properly
- Issue with the dependent services, such as **platform-auth-service** pod, etc.
- OIDC client watcher pod is not Out Of Memory (OOM) or not in the **crashloopback** state.

If you have verified that the client CR is valid, associated pods are running properly or dependent services are also running properly and still the OIDC client creation is still not successful then the possible reason might be that the **oidc-client-watcher** is not able to connect with **auth-service** endpoint properly. This might be because of not having the correct certificate entry at the **auth-service** end.

Confirming the certificate import issue if oidc-client-watcher pod is not able to connect with auth-service endpoint properly

The following symptoms might confirm whether there is certificate import issue:

- If no status is available in the client CR after the client CR is created
- Also, the **oidc-client-watcher** container might show the similar error:

  ```
  oc logs $oidcclient-watcher-xxx -f
  ```

Replace **oidcclient-watcher-xxx** with actual pod and instance names.

```
{"level":"error","ts":1669062335.0758603,"logger":"controller-runtime.controller","msg":"Reconciler
error","controller":"controller_oidc_client","request":"cap4ba-ns3/ibm-bts-oidc-client","error":"Error
occurred during create oidc client regstration".
```

Where, **request** name might vary.

In case you see this error, you can verify whether you are observing the error due to the certificate issue. If there are multiple **platform-auth-service** instances, you need to verify for all the instances by using the following command:

```
oc login
oc project $namespace
oc exec -it $platform-auth-service-xxx /bin/bash
cd /opt/ibm/wlp/output/defaultServer/resources/security
keytool -v -list -keystore key.jks -alias default -storepass insecurePass
```

Replace the **platform-auth-service-xxx** with the **platform-auth-service** instance names. And, provide the namespace where **common-services** are installed.

If you find the default alias entry that contains the following information as **Issuer** and **Owner**, it means that the certificate import is an issue.

```
Owner: OU=ISL, O=IBM India, L=BANGALORE, ST=KARNATAKA, C=IN
Issuer: EMAILADDRESS=test@test.local, CN=CFSSL TEST Root CA, O=CFSSL TEST, L=San Francisco, ST=California,
C=US
```

Note: If certificate import is the issue, see Steps to follow if certificate import is an issue. If certificate import is not the issue then there might be different reason that why the client creation is not happening and that needs to be checked.

Steps to follow if certificate import is an issue

1. Login to the cluster by using **oc** CLI.
2. Save the content of shell as **updateJKS.sh**.
3. Run the shell script as **updateJKS.sh $namespace**. Provide the namespace where **common-services** are installed.

```
oc project $1
for pod in $(oc get pod -o name | grep platform-auth-service);
do
  echo "Going to update jks for pod Name: ${pod}"
  oc exec -it ${pod} /bin/bash -c 'platform-auth-service' -- keytool -importkeystore -destkeystore
/opt/ibm/wlp/output/defaultServer/resources/security/key.jks -srckeystore /certs/generated/platformauth-
ks.p12 -srcstoretype pkcs12 -alias default -storepass insecurePass -srcstorepass insecurePass -noprompt
  echo  "Done"
done
```

Note: It is possible that after restart you might see the same issue so it is recommended to re-run the script.

OIDC registration fails to update

Symptoms

Before you register the OIDC clients by using IdP V3 API, you need to login into third party ID provider. And, then you can register the OIDC clients in the application. While registering, you use application url as cp-console url and redirect URL as **https://<cp-console-url>/ibm/api/social-login/redirect/<name of the oidc>**. However, you might face issue while opening the cp-console browser. When you click the configured ID provider name, you might not be redirected to the authentication page of that IdP.

Causes

Issue with configuring the OIDC XML files in multi-cluster environment.

Troubleshooting the issue

Restart all the replicas of **platform-auth-service** pod.

To restart the **platform-auth-service** pod:

1. Get the platform-auth-service pod ID.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep platform-auth-service
   ```

   Following is a sample output of the command:

   ```
   platform-auth-service-t6sfm          4/4     Running       0     1d
   ```

2. Delete the **platform-auth-service** pod.

   ```
   oc -n <your-foundational-services-namespace> delete pod pod-name
   ```

   Where, **pod-name** specifies the name of the **platform-auth-service** pod that you want to delete.

3. Once the pod is deleted, you might see a similar message:

   ```
   pod "pod-name" deleted
   ```

   Where, **pod-name** specifies the name of the **platform-auth-service** pod that has been deleted.

4. Verify the status of the **platform-auth-service** pod that has been deleted.

   ```
   oc -n <your-foundational-services-namespace> get pods | grep pod-name
   ```

   Where, **pod-name** specifies the name of the **platform-auth-service** pod that you want to verify whether the pod is deleted or not.

5. The **platform-auth-service** pod will restart. The pod gets new ID after the restart.

API call issues

Troubleshoot OIDC related issues.

- Cannot generate IAM access token through API for external OIDC and SAML users
- Unable to find and add the IDP users or user groups using the console

Error 403 as a response while calling `/iam-token/serviceids/` APIs

While calling **/iam-token/serviceids/** APIs, you get **403** as a response.

Causes

The deployment of the old version of the Cloud Pak might not be properly cleaned up while you upgrading the Cloud Pak version. To know the reason for getting **403** as a response while calling **/iam-token/serviceids/** APIs, enable **platform-auth-service** pod debug level traces and liberty traces by using the following steps:

1. Open **platform-auth-idp** configmap to edit it by using the following command:

   ```
   oc edit cm platform-auth-idp
   ```

   After you run this command, the editor view of the configmap is displayed.

2. In **platform-auth-service** container log:

   - Change the value of **LOG_LEVEL_AUTHSVC** parameter to **debug**.

   Note: By default, the value of **LOG_LEVEL_AUTHSVC** parameter is **warning** or **info**. Changing its value to **debug** provides you the exact cause of error **403** that you get while calling **/iam-token/serviceids/** APIs.

   - Change the value of **LIBERTY_DEBUG_ENABLED** parameter to **true** to view liberty debug traces.

You might see the following trace sample. The sample displays the error, **Authorization failed. User is not authorized**.

```
[12/8/22 17:29:46:580 UTC] 00000099 id=00000000 com.ibm.cloud.iam.core.ServiceIdCore
I filterServiceIdByUserNamespace crnNamespace namespace : cp4s
[12/8/22 17:29:46:580 UTC] 00000099 id=00000000 com.ibm.cloud.iam.core.ServiceIdCore
I filterServiceIdByUserNamespace User namespace : cert-manager
[12/8/22 17:29:46:580 UTC] 00000099 id=00000000 com.ibm.cloud.iam.core.ServiceIdCore
I filterServiceIdByUserNamespace User namespace : cp4s-sandbox
[12/8/22 17:29:46:580 UTC] 00000099 id=00000000 com.ibm.cloud.iam.core.ServiceIdCore
I filterServiceIdByUserNamespace User namespace : cp4sec
[12/8/22 17:29:46:580 UTC] 00000099 id=00000000 com.ibm.cloud.iam.core.ServiceIdCore
I filterServiceIdByUserNamespace User namespace : default
.
.
.
[12/8/22 17:29:46:588 UTC] 00000099 id=00000000 com.ibm.cloud.iam.core.ServiceIdCore
I filterServiceIdByUserNamespace User namespace : services
[12/8/22 17:29:46:588 UTC] 00000099 id=00000000 com.ibm.cloud.iam.serviceid.rest.ServiceidsApi
1 listServiceid
com.ibm.cloud.iam.exception.authorization.AuthorizationServiceException: BXNIM0500E: Authorization failed.
User is not authorized..
at com.ibm.cloud.iam.core.ServiceIdCore.filterServiceIdsByUserNamespace(ServiceIdCore.java:406)
at com.ibm.cloud.iam.core.ServiceIdCore.listServiceId(ServiceIdCore.java:353)
```

IMPORTANT: After performing the steps, restore the value of `LOG_LEVEL_AUTHSVC` and `LIBERTY_DEBUG_ENABLED` parameters value to its default values to prevent unintended adverse effects, including degraded performance and system instability.

Troubleshooting the issue

To troubleshoot the issue, restore the old namespace where Cloud Pak was deployed.

Cannot generate IAM access tokens through API for external OIDC and SAML users

An LDAP user can generate an IAM access token with API. You cannot generate the IAM access token through APIs for external OIDC and SAML users in the Platform UI.

For example:

Curl command to generate access token:

```
curl -k -X POST -H "Content-Type: application/x-www-form-urlencoded;charset=UTF-8" -
d "grant_type=password&username=alfredo.capparielloe@ie.ibm.com&password=*********&scope=openid" https://cp-
console.roks.ibm-stratus.com/idprovider/v1/auth/identitytoken
```

The sample output:

```
Failed to get access token, invalid token request parameters server_error
```

Causes

By default, IAM checks for the username in the LDAP backend repository to validate the user. The following error is displayed in the liberty logs if an LDAP identity provider is not configured in the Cloud Pak console.

```
com.ibm.wsspi.security.wim.exception.PasswordCheckFailedException: CWIML4537E: The login operation could not
be
completed. The specified principal name 270001635h is not found in the back-end repository.
```

To enable debugging for `platform-auth-service` liberty, see Enable debugging for user authentication issues.

Workaround

Follow these steps to obtain an access token from Platform UI:

1. Login to the Platform UI. For more information, see Accessing your cluster by using the console.
2. Open Developer tools in your web browser and click **Application** tab.
3. Go to the **Cookies** section and obtain the access token in the `ibm-private-cloud-session` cookie.
4. Use the obtained token to make an API call.

Troubleshooting certificates

Learn how to isolate and resolve problems with certificates.

- Expired certificate secrets fail to rotate

Expired certificate secrets fail to rotate

When a cluster is restored from a snapshot or rebooted after a long period of shutdown, the certificate manager might need to rotate many certificates at the same time. When the IBM Cert Manager is used, this can lead to the Cert Manager failing to rotate some secrets associated with the certificates.

Solution: Use the following commands to identify if any certificate secrets contain expired certificate data:

1. Set the project (namespace):

   ```
   oc project <namespace>
   ```

   Where **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.

2. Run the following script to check for expired certificate secrets:

   Note: The script requires version 4 of bash.

   ```
   convert_date () {
   local months=( Jan Feb Mar Apr May Jun Jul Aug Sep Oct Nov Dec )
   local i
   for (( i=0; i<11; i++ )); do
      [[ $2 = ${months[$i]} ]] && break
   done
   printf "%4d-%02d-%02d\n" $3 $(( i+1 )) $1
   }

   declare -A CERT_TO_EXPIRY

   for secret in $(oc get certificate -o jsonpath='{.items[*].spec.secretName}'); do CERT_TO_EXPIRY["$(oc
   get secret $secret -o jsonpath='{.metadata.name}')"]="$(oc get secret $secret -o go-template='{{index
   .data "ca.crt" | base64decode}}' | openssl x509 -text -noout | grep "Not After" | awk '{print $5 " " $4
   " " $7}')"; done

   NOW=$(date +%s)

   for secret in ${!CERT_TO_EXPIRY[@]}; do
   CERT_DATE=${CERT_TO_EXPIRY[$secret]}
   if [[ "$OSTYPE" == "linux-gnu"* ]]; then
      CERT_DATE_SEC=$(date -d "$(convert_date $CERT_DATE)" +%s)
   elif [[ "$OSTYPE" == "darwin"* ]]; then
      CERT_DATE_SEC=$(date -j -f "%Y-%m-%d" "$(convert_date $CERT_DATE)" +%s)
   fi
   if [ $CERT_DATE_SEC -lt $NOW ]; then echo "$secret expired on $CERT_DATE"; fi
   done
   ```

3. If no secret names are printed from running the preceding script, no action is required. If secret names are printed, check the state of the owning certificates using the following command:

   ```
   oc get certificates.cert-manager.io
   ```

   The output can resemble the following sample output:

   ```
   NAME                                        READY   SECRET
   AGE
   aiops-ibm-elasticsearch-tls-secret          True    aiops-ibm-elasticsearch-tls-secret
   4h2m
   aiops-installation-redis-client-cert        True    aiops-installation-redis-client-cert
   4h7m
   aiops-installation-redis-server-cert        True    aiops-installation-redis-server-cert
   4h7m
   ```

   If any certificates show as `False` in the **READY** column, contact IBM Support to resolve the Cert Manager failure. If all certificates show as `True` in the **READY** column, continue with the resolution steps.

4. Use the following script to force the certificate secrets to be rotated.

   Note: The script requires version 4 of bash.

```
convert_date () {
   local months=( Jan Feb Mar Apr May Jun Jul Aug Sep Oct Nov Dec )
   local i
   for (( i=0; i<11; i++ )); do
      [[ $2 = ${months[$i]} ]] && break
   done
   printf "%4d-%02d-%02d\n" $3 $(( i+1 )) $1
}

declare -A CERT_TO_EXPIRY

for secret in $(oc get certificate -o jsonpath='{.items[*].spec.secretName}'); do CERT_TO_EXPIRY["$(oc get
secret $secret -o jsonpath='{.metadata.name}')"]="$(oc get secret $secret -o go-template='{{index .data
"ca.crt" | base64decode}}' | openssl x509 -text -noout | grep "Not After" | awk '{print $5 " " $4 " "
$7}')"; done

NOW=$(date +%s)

for secret in ${!CERT_TO_EXPIRY[@]}; do
  CERT_DATE=${CERT_TO_EXPIRY[$secret]}
  if [[ "$OSTYPE" == "linux-gnu"* ]]; then
    CERT_DATE_SEC=$(date -d "$(convert_date $CERT_DATE)" +%s)
  elif [[ "$OSTYPE" == "darwin"* ]]; then
    CERT_DATE_SEC=$(date -j -f "%Y-%m-%d" "$(convert_date $CERT_DATE)" +%s)
  fi
  if [ $CERT_DATE_SEC -lt $NOW ]; then oc delete secret $secret; fi
done
```

Troubleshooting Infrastructure Automation

Review the details about frequently encountered issues that are related to Infrastructure Automation.

- Troubleshooting installing and uninstalling Infrastructure Automation
- Troubleshooting Infrastructure Management
- Troubleshooting Managed services

Troubleshooting installing and uninstalling Infrastructure Automation

Review frequently encountered issues related to installing, upgrading and uninstalling Infrastructure Automation.

Installation issues

- Database is stuck on retrying on Infrastructure Automation IMInstall Power Environment
- The **cam-tenant-api** pod is not in a ready state after installing the IAConfig CR
- Offline install or upgrade throws 'invalid character' error
- Offline install or upgrade stuck because the 'oc ibm-pak generate mirror-manifests' command fails with 'no space left on device'

Uninstall issues

- Uninstall fails to remove Infrastructure Management cleanly after deleting IAConfig instance
- Uninstall hangs when uninstalling Managed services

Troubleshooting installation

Database is stuck on retrying on Infrastructure Management IMInstall Power Environment

Sometimes when Infrastructure Management is deployed, the orchestrator pod fails to start properly with the following in the oc logs:

```
Cannot connect to the database!
Deployment status is
```

Check the postgresql pod to ensure it's running and listening. Then, verify the **vmdb_production** database was created by rushing into the postresql pod:

```
sh-4.4$ psql -U postgres
psql (10.19)
Type "help" for help.

postgres=# \l
                                  List of databases
      Name       |  Owner   | Encoding |  Collate   |   Ctype    |   Access privileges
-----------------+----------+----------+------------+------------+
 postgres        | postgres | UTF8     | en_US.utf8 | en_US.utf8 |
 template0       | postgres | UTF8     | en_US.utf8 | en_US.utf8 | =c/postgres          +
                 |          |          |            |            | postgres=CTc/postgres
 template1       | postgres | UTF8     | en_US.utf8 | en_US.utf8 | =c/postgres          +
                 |          |          |            |            | postgres=CTc/postgres
(3 rows)
```

Solution: If the **vmdb_production** database doesn't exist, like above, it is possible that a remnant postgresql.conf in the DATA directory is preventing the postgresql image from initializing the new database on boot.

You will need to check the DATA directory and either clean it manually or recreate the PVC/PV and check that it is empty.

You can always find the location of the DATA directory using the psql command below:

```
postgres=# show data_directory;
        data_directory
------------------------------
 /var/lib/pgsql/data/userdata
(1 row)
```

Ensure that the data directory is empty before the postgresql pod is restarted.

The `cam-tenant-api` pod is not in a ready state after installing the IAConfig CR

After you install Infrastructure Automation, you can encounter an error where the **cam-tenant-api** pod displays as running, but not in a ready state. When this error occurs, you can see the following message:

```
[ERROR] init-platform-security - >>>>>>>>>> Failed to configure Platform Security. Will retry in 60 seconds
<<<<<<<<<<< OperationalError: [object Object]
```

If this error occurs, delete the **cam-tenant-api** pod to cause the pod to restart and attempt to enter a ready state.

Offline install or upgrade throws 'invalid character' error.

When doing an offline install or upgrade, running the **oc ibm-pak generate mirror-manifests <..>** command throws an error similar to the following:

```
Error: failed to load the catalog FBC at cp.stg.icr.io/cp/ <...> invalid character '<' in string escape code
```

Solution: You must have **IBM Catalog Management Plug-in for IBM Cloud Pak** (**ibm-pak-plugin**) v1.10 or higher installed. Run the following commands to ensure that **ibm-pak-plugin** is at the required level.

1. Check which version of **ibm-pak-plugin** you have installed.

   Run the following command on your bastion host, portable compute device, or connected compute device if you are using a portable storage device.

   ```
   oc ibm-pak --version
   ```

   Example output:

   ```
   oc ibm-pak --version
   v1.11.0
   ```

2. If the **ibm-pak-plugin** version is lower than v1.10.0, then you must download and install the most recent version.

   Follow the steps for your installation approach:

   - Bastion host: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.
   - Portable device: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.

Offline install or upgrade stuck because the 'oc ibm-pak generate mirror-manifests' command fails with 'no space left on device'

The **oc ibm-pak generate mirror-manifests $IA_CASE_NAME $TARGET_REGISTRY --version $IA_CASE_VERSION** command fails with a message similar to the following in **$IBMPAK_HOME/.ibm-pak/logs/oc-ibm_pak.log**:

```
write /tmp/render-unpack-4002583241/var/lib/rpm/Packages: no space left on device
```

Solution: The default temporary directory does not have enough space to run the **ibm-pak** tool. You must set the **TMPDIR** environment variable to a different directory with more space before running the **oc ibm-pak generate mirror-manifests** command.

```
TMPDIR=<new_temp_dir> oc ibm-pak generate mirror-manifests $IA_CASE_NAME $TARGET_REGISTRY --version
$IA_CASE_VERSION
```

Where **<new_temp_dir>** is the path for a directory with more space.

Troubleshooting uninstall

Uninstall fails to remove Infrastructure Management cleanly after deleting IAConfig instance

After deleting Infrastructure Management IAConfig CR in the namespace to uninstall Infrastructure Management from Red Hat OpenShift Container Platform console, some of the Infrastructure Management pods were still there in the namespace. You can workaround the problem by deleting IMInstall custom resource from the Red Hat OpenShift Container Platform console. This will remove the pods from the namespace.

You should also delete the **clients.oidc.security.ibm.com** customer resource that was used by Infrastructure Management if it still exists. Then, You can uninstall the operators remaining on the namespace.

To delete IMInstall Custom Resource (CR), you need to edit the CR to remove the Finalizer. Save the CR. Then delete the IMInstall Custom Resource (CR). Run the following commands or perform the same from the Red Hat OpenShift Container Platform console.

1. Identify the CR name, for example, **im-iminstall**

   ```
   oc -n <project> get iminstall
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed.

2. Edit the statement "finalizers:" and the one below it. Save and exit.

   ```
   oc -n <project> edit iminstall im-iminstall
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

3. Delete the CR.

   ```
   oc -n <project> delete iminstall im-iminstall
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

After a few minutes, the Infrastructure Management pods should no longer exist. The clients.oidc.security.ibm.com Custom Resource (CR) could still exist, and to delete the CR, do the following steps,

1. Check if the CR exist.

   ```
   oc -n <project> get clients.oidc.security.ibm.com
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

2. If the CR exists, edit the CR. Delete the statement "finalizers:" and the one below. Save and exit.

   ```
   oc -n <project> edit clients.oidc.security.ibm.com ibm-infra-management-application-client
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

3. Delete the CR.

   ```
   oc -n <project> delete clients.oidc.security.ibm.com ibm-infra-management-application-client
   ```

   Where **<project>** is the project (namespace) where Infrastructure Automation is deployed

Uninstall hangs when uninstalling Managed services

The Infrastructure Automation uninstallation sometimes hangs when trying to delete the manageservice instance.

Describing the Managed services instance shows output similar to the following:

```
# oc describe manageservice cam
Name:         cam
Namespace:    cp4aiops
Labels:       operator.ibm.com/opreq-control=true
Annotations:  operator-sdk/primary-resource: /cam-services-sa-csb-patch-rb-pod
```

```
              operator-sdk/primary-resource-type: ClusterRoleBinding.rbac.authorization.k8s.io
API Version:  cam.management.ibm.com/v1alpha1
Kind:         ManageService
Metadata:
  Creation Timestamp:             2024-03-05T21:46:56Z
  Deletion Grace Period Seconds:  0
  Deletion Timestamp:             2024-04-15T01:11:29Z
  Finalizers:
    helm.sdk.operatorframework.io/uninstall-release
  Generation:         2
  Resource Version:   55077252
  UID:                87e6b8cf-3123-4914-bf64-a2b209cbe22d
```

Solution: Edit the Managed services instance to remove the finalizer entry.

1. Run the following command:

   ```
   oc edit ManageService cam
   ```

2. Delete the following lines, and then save your changes.

   ```
   Finalizers:
       helm.sdk.operatorframework.io/uninstall-release
   ```

- Troubleshooting Managed services

Support

If you need help with using IBM Cloud Pak® for AIOps, visit the IBM Support page.

Additionally, you can see whether the problem is documented in Known issues or in Troubleshooting.

Learn more about IBM Support from the following topics:

- Opening an IBM Support case
- Installing and running the MustGather tool (Linux)
- Installing the MustGather tool (Openshift)
- Installing the MustGather tool
- Running the MustGather tool

Collecting support information for IBM Cloud Pak for AIOps

Learn how to gather information that is needed and relevant to a problem before you open a case with IBM® Support. Additionally, learn how to open a meaningful support case with IBM Support for IBM Cloud Pak® for AIOps.

Before you open an IBM Support case

Check the troubleshooting and known issues sections

Before you contact IBM Support, review the following topics to check whether your problem is already reported and a workaround or solution exists:

- Troubleshooting and support
- Known issues

Collect support information with MustGather tools

If you cannot find a solution for your problem in the documentation, complete the following steps to use the MustGather tool and gather information from the cluster for opening an IBM Support case. The collected data facilitates more effective support.

- Data collection for IBM Support cases
- Infrastructure Automation data collection for IBM Support cases

Data collection for IBM Support cases

1. Ensure that you meet the prerequisites for running the MustGather tool for collecting data
   - Access to the cluster as a user with a cluster-admin role.
   - The Red Hat® OpenShift® Container Platform CLI (oc) installed. For more information, see Installing the Red Hat OpenShift CLI.
2. Download and install the MustGather tool
3. Run the MustGather tool

Infrastructure Automation data collection for IBM Support cases

1. Ensure that you meet the prerequisites for running the MustGather tool for collecting data
   - Access to the cluster as a user with a cluster-admin role.
   - The Red Hat® OpenShift® Container Platform CLI (oc) installed. For more information, see Installing the Red Hat OpenShift CLI.
2. Run the MustGather to collect data and logs

   Follow the instructions on the following IBM Support page to run the MustGather tool to collect the data and logs for IBM Cloud Pak for AIOps: Collecting Data: MustGather for IBM Cloud Pak for AIOps - Infrastructure Automation

Opening an IBM Support case

If you cannot find a solution to your problem in product documentation, open a support case with IBM Support. Complete the following steps

1. Go to the IBM Support site and click **Open a case**.
2. Log in with your IBM ID and password, and consent to the IBM Privacy Statement.
3. Enter the case details. Enter the meaningful title that summarizes your problem. Then, select the Product Manufacturer, Product, and Severity.

   Note: The case severity is based on the business impact of the problem. If you set the case severity as 1, you need to have 24x7 availability to work with IBM Support on this issue.
4. Provide the detailed description of your problem. A detailed description can help IBM Support understand your problem more accurately and thus provide solutions or answers more quickly. The following information is crucial:
   - Product version
   - Platform
   - Red Hat OpenShift Container Platform version
   - Virtualization platform (VMWARE, Azure, AWS, IBM Cloud)
   - High Availability (HA)
   - Steps to reproduce the issue
5. Optional: Upload the `.tar.gz` file with the results of the diagnostic scan. For more information, see Collecting support information.

   Note: If you encounter problems with uploading the file, see Uploading a file during case creation.
6. Select the language preferences and click **Submit a case**.

Installing and running the MustGather tool (IBM Cloud Pak for AIOps on Linux)

Learn about installing and running the MustGather tool for IBM Cloud Pak for AIOps on Linux.

Installing and running the MustGather tool

The MustGather tool is used for troubleshooting and support purposes. It collects data and logs about a deployment of IBM Cloud Pak for AIOps. To install and run the latest version of the MustGather tool, run the following command on the control plane node:

```
aiopsctl mustgather
```

Advanced configuration

You can also supply parameters to the MustGather tool. For more information, see Running the MustGather tool. In the example code blocks in the MustGather topics, replace **waiops-mustgather.sh** with **aiopsctl mustgather** for a deployment of IBM Cloud Pak for AIOps on Linux.

There are additional options available for deployments of IBM Cloud Pak for AIOps on Linux. Run the following command to seee usage:

```
aiopsctl mustgather -h
```

Example output:

```
root@acme-server:~# aiopsctl mustgather -h
Run the AIOps MustGather script to collect server information for support

Usage:
  aiopsctl mustgather [flags]

Flags:
  -a, --alias string     MustGather configuration alias
  -f, --force-install    Force MustGather to be reinstalled
  -h, --help             help for mustgather
  -o, --options string   Additional options that will be supplied to the MustGather script
  -u, --update           Check for MustGather updates

Global Flags:
      --accept-license     Accept the license
  -c, --config string      Config file location (default "~/.aiopsctl.yaml")
  -l, --log-file string    Log filename, set to stdout to print to console
      --show-secrets       Allow the display of secrets in output
  -v, --verbose            Verbose logging
      --wait-timeout int   Wait timeout for services to come ready in minutes (default 180)
```

Installing the IBM Cloud Pak for AIOps MustGather tool (IBM Cloud Pak for AIOps on Red Hat OpenShift)

You must download and install the MustGather tool before you can run any commands for the tool. You must download the installation package for the MustGather tool from IBM Support. You can download the package to any machine that has valid access to the target cluster for running **oc** commands.

Important: This MustGather tool gathers data for IBM Cloud Pak® for AIOps deployments. For gathering data for Infrastructure Automation, see Infrastructure Automation data collection for IBM Support cases.

Procedure

Complete either of the following steps to download the tool:

- Download the (**waiops-mustgather-<version>.tar.gz**) package at the end of the following IBM Support page:

  Collecting Data: MustGather for IBM Cloud Pak for AIOps

- Open a command-line terminal and use the following command to download the package:

  ```
  wget https://www.ibm.com/support/pages/system/files/inline-files/waiops-mustgather-<version>.tar.gz
  ```

  Where **<version>** is the version of the MustGather tool. Refer to the preceding IBM Support page to determine the latest available version. For v.1.16.6, the command is:

  ```
  wget https://www.ibm.com/support/pages/system/files/inline-files/waiops-mustgather-v1.16.6.tar.gz
  ```

Important:

- Unpack the downloaded **waiops-mustgather-<version>.tar.gz** package in its own directory. Ensure that the directory is not shared with any other files or directories.
- Keep the MustGather tool up to date. By default the tool can run a **new-version-check** automatically. To disable this check, include the **-M** option when you run the MustGather tool to gather data. If you want to directly check for, and download, the latest version run the following command

  ```
  waiops-mustgather.sh -UD
  ```

MustGather tool use cases

Learn how to run the tool, and learn about the different use cases and command options that are available for use with the tool. For more information, see:

- Running the MustGather tool
- Data collection modes
- Advanced tips for using the MustGather tool

IBM Cloud Pak for AIOps MustGather tool

Learn how to use the IBM Cloud Pak® for AIOps MustGather tool to gather information that is needed and relevant to a problem before you open a case with IBM Support.

Important: This MustGather tool gathers data for IBM Cloud Pak for AIOps deployments. For gathering data for Infrastructure Automation, see Infrastructure Automation data collection for IBM Support cases.

The IBM Cloud Pak for AIOps MustGather tool is a wrapper for running `oc` commands. With this tool, you can complete data collection tasks and view analytics on the gathered data. After you run the tool to gather data, upload the output data file that is under your `/tmp` (or another directory if you used the ``-o` option) to the IBM Support website.

The tool generates a report that shows critical data about the status and health of the cluster and installation. This report allows the user view an overview of their cluster to help spot and solve multiple problems. The report can provide basic cluster analysis to identify cluster node resource utilization, warnings, and problematic resources. The report can also provide incident analysis, such as to identify whether Pod A is in CrashLoopBackOff.

The tool supports data collection for the following types of data:

Data type collection mode

Data type	Collection mode
`oc get` and `oc describe` (or `kubectl`) commands	This data is collected through the primary data collection modes.
Pod logs	This data is collected through the primary data collection modes.
Application logs within pods	This data collection is supported by the CPFILES secondary data collection mode.
Command output for commands that run through pods	This data collection is supported by the MANUALCOLLECT secondary data collection mode.
Command output that run on client machines (custom script)	This data collection is supported by the CMDEXEC secondary data collection mode.
Logs or command output that run on individual cluster nodes, such as journal, systemctl, iptables	This data collection is supported by the CLUSTERNODES secondary data collection mode.

Command syntax

```
waiops-mustgather.sh -[a|b|c|l] [-k resourname] [-z modules] [-d] [-L numlines] [-C cmdexec-file:cmdexec-env] [-E cmdexec-envvar] [-T timeout-value] [-m manual-collection-param] [-n manual-collection-envvar] [-j objname] [-w manual-collection-exec-timeout] [-e extra-namespaces:extra-resources] [-x product-version/path-to-config-file] [-A compliance-param] [-P plugins] [-Z plugins-envvar] [-Q plugins-timeout] [-F cpfiles-param] [-K] [-V view-only-module] [-y] [-J] [-p] [-t] [-g] [-f] [-R] [-S] [-s] [-u node-admin-username] [-i path-to-sshkey] [-o output-directory] [-G filename-regex:pattern] [-W primary-mode-var] [-N] [-I] [-X] [-Y] [-U] [-M] [-D] [-v] [-h]
```

- For details about the command options, see Data collection modes for the IBM Cloud Pak for AIOps MustGather tool.
- For details about running a custom script with the tool, see Run a custom script to complete corrective actions

Running the tool

- Primary use cases
- Additional use cases
- Miscellaneous use cases

Primary use cases

- Installation related problems
- Application related problems

- IBM Cloud Pak for AIOps related problems
- Log anomaly detection related problems
- Metric anomaly detection related problems
- Lifecycle related problems
- Datalayer related problems
- ChatOps related problems
- Healthcheck related problems

Installation related problems

To gather data for installation related problems, run the following command:

```
waiops-mustgather.sh -O install
```

The alias **-O install** is expanded to **-cypDfd** that uses the primary comprehensive (**-c**) mode and clusternode (**d**) mode to cause the tool to gather data for installation related problems.

To gather data for general non-installation related problems, run the following command:

```
waiops-mustgather.sh -O general
```

The alias **-O general** is expanded to **-cypDf** that is used to gather data for common problems.

Overall operation related problems

To gather data for overall IBM Cloud Pak for AIOps operation related problems, run the following command:

```
waiops-mustgather.sh -O aimgr
```

To gather raw data for IBM Cloud Pak for AIOps from its various data sources, such as Kafka, Flink, ElasticSearch and Postgres, run the following command:

```
waiops-mustgather.sh -O aimgr-data
```

To learn more about what aliases are available, use the command **waiops-mustgather.sh -O .listalias**

Important: The ALIAS mode (**-O xxx**) is used to expand an alias into a predefined command. If there is a need to change or add any option, you need to revert to the conventional way of running the MustGather tool by providing all the options or flags manually. For example, if a secret YAML is needed, you need to use **-cypDfS** (plus any other options or flags).

Log anomaly detection related problems

To gather data for log anomaly related problems, run the following command:

```
waiops-mustgather.sh -O lad
```

Metric anomaly detection related problems

To gather data for metric anomaly related problems, run the following command:

```
waiops-mustgather.sh -O mad
```

Lifecycle related problems

To gather data for Lifecycle related problems, run the following command:

```
waiops-mustgather.sh -O lifecycle
```

Datalayer related problems

To gather data for Datalayer related problems, run the following command:

```
waiops-mustgather.sh -O datalayer
```

ChatOps related problems

To gather data for ChatOps related problems, run the following command:

```
waiops-mustgather.sh -O chatops
```

Healthcheck related problems

Use the healtcheck option to gather data to check whether your installation was successful or to analyze how IBM Cloud Pak for AIOps is running.

For more information about using this option, see Running the MustGather Healthcheck.

Additional use cases

- Run script to complete corrective actions
- Run baseline data collection
- Pod specific data collection
- Product specific data collection
- Installation verification
- Copying pod files and directories
- Complex command

Run a custom script to complete corrective actions

If you want to complete a **corrective action**, such as to delete a pod to restart it, you can write a script and run the following command to run the script:

```
waiops-mustgather.sh -C <script>
waiops-mustgather.sh -R -C <script>
```

Where **<script>** is the script that contains the corrective action to run.

The preceding command will only run your script. To perform data collection before running the script, you can opt for any of the primary modes."

Notes: If needed, you can run the secondary data collection modes **MANUALCOLLECT**, **EXTRA**, **CPFILES** within your custom script.

The following examples show how to trigger the MANUALCOLLECT, EXTRA, and CPFILES modes:

- To make sure the correction actions are successful, you can trigger MANUALCOLLECT to collect some data within the script

  ```
  echo "ALL##NS4PROD=aimanager##pod##teams######" >> $CMD_EXEC_RESULT_MCCFG_FILE
  ```

- You can also trigger EXTRA mode to collect namespace data within the script

  ```
  echo "openshift-insights" > $CMD_EXEC_RESULT_EXTRANS_FILE
  ```

- If you need to copy some files from some pods to make sure your script ran successfully:

  ```
  echo "NS4PROD=aimanager##^iaf-system-kafka####/opt/kafka/config/log4j.properties" >>
  $CMD_EXEC_RESULT_CPFILES_FILE
  ```

For an example custom script and some of the variables and functions that you can include within it, see Example: custom script.

Run baseline data collection

To run a baseline data collection, use any of the primary data collection modes, such as **-cypDf**, for example:

```
waiops-mustgather.sh -cypf -C <script> -e <namespace> -F 'NS4PROD=<prodname>,<podname-regex>,<container-
name>,<filename>'
```

With the preceding command, you can run a baseline data collection that is followed by running a corrective action through a custom script. You can also check the result of the corrective action by using the **-e** option where **<namespace>** is the namespace where the custom script runs. You can also opt to copy files from the restarted pod through the **-F** option.

Notes:

- Only **-c** is the primary data collection mode. Other options are supported, but should be used together.
- If you want to run another round of data collection after your custom script runs, use a secondary data collection mode (other than **clusternodes** or **cmdexec**).

Pod specific data collection

If you have to run commands on a specific pod, but you do not know the full name of the pod, such when you know only the UUID portion, you can use the **manualcollect** mode:

```
waiops-mustgather.sh -R -m ps-out:[configfile]
```

Example (**<configfile>**):

```
@ TAG##NAMESPACE##OBJTYPE##OBJNAME##CONTAINER##EXECPREP##EXECCMD
ps-out##NS4PROD=aimanager##pod##^cp4waiops-postgres-keeper######hostname;ps -ef
```

The podname is a regex. The tool determines the full name of the pod automatically.

```
[OUTPUT - found in file 4-MANUALCOLLECT/<namespace>/<podname>.bash.exec]
cp4waiops-postgres-keeper-0
UID          PID    PPID  C STIME TTY          TIME CMD
stolon         1       0  1 Nov09 ?        02:09:11 stolon-keeper --data-dir /stolon-data
stolon        29       1  0 Nov09 ?        00:00:00 [create-template] <defunct>
```

```
stolon        54       1  0 Nov09 ?        00:15:06 postgres -D /stolon-data/postgres -c
unix_socket_directories=/tmp
stolon        59      54  0 Nov09 ?        00:00:09 postgres: checkpointer
stolon        60      54  0 Nov09 ?        00:00:10 postgres: background writer
stolon        61      54  0 Nov09 ?        00:01:00 postgres: walwriter
stolon        62      54  0 Nov09 ?        00:00:19 postgres: autovacuum launcher
stolon        63      54  0 Nov09 ?        00:02:47 postgres: stats collector
stolon        64      54  0 Nov09 ?        00:00:00 postgres: logical replication launcher
stolon   2905619      54  0 05:39 ?        00:00:00 postgres: cp4aiops cp4aiops 10.254.12.46(50562) idle
stolon   2906589      54  0 05:43 ?        00:00:00 postgres: cp4aiops cp4aiops 10.254.12.46(53384) idle
stolon   2918996       0  0 06:34 ?        00:00:00 bash -c hostname;ps -ef
stolon   2919006 2918996  0 06:34 ?        00:00:00 ps -ef
```

Product specific data collection

If you need to collect product-specific data, you can run the *plugins* secondary collection mode:

```
waiops-mustgather.sh -P aimanager
```

Installation verification

If you just want to check whether an installation is successful:

```
waiops-mustgather.sh -x X -DR
```

The preceding command scans the product namespaces for missing resources or objects based on the configuration file that is specified in the **<MUSTGATHER-DIR>/missingobj/config/missingobj-waiops-<prodver>.cfg** file.

Copying pod files and directories

If you need to copy files from a pod, you can run a command similar to the following command:

```
waiops-mustgather.sh -F 'NS4PROD=aimanager##aimanager-aio-log-anomaly-detector-####/opt/ai4it/*.log*'
```

The preceding command copies files and directories that match the filename wildcard of **/opt/ai4it/*.log*** from pods that match regex **aimanager-aio-log-anomaly-detector-** in the auto-resolved IBM Cloud Pak for AIOps namespace.

Complex command

If needed, you can run a more complex command:

```
waiops-mustgather.sh -aypf -e ibm-common-services,cs-control,openshift-operators -P aimanager -G
'ALL:error|fail|exception|login' -C /tmp/test.sh -E 'TEST1=uname -a##TEST2=date' -m cqlsh:manualcollect.csv
-n 'SQL="describe tables"' -F spark
```

Miscellaneous use cases

- Scale down the MustGather data collection

Scale down the MustGather data collection

If the cluster that you are working on is slow or throttles a lot, you can scale down the MustGather through the *selective* primary collection mode:

```
waiops-mustgather.sh -Xy -k deployments,sts,pods,jobs,pvc
```

The preceding command disables custom data collection (**-X**), enables YAML collection (**-y**) and runs the MustGather tool with the *selective* primary collection mode (**-k**) to collect data on resources such as **deployments**, **statefulsets**, **pods**, **jobs**, and **pvc**.

Command help

If you need help with running the MustGather tool, you can use the tool **help** command when you run the tool to view more details about the command:

```
waiops-mustgather.sh -h
```

Running the MustGather Healthcheck

You can run the IBM Cloud Pak for AIOps MustGather tool with a healthcheck option to gather data to check whether your installation was successful or to analyze how IBM Cloud Pak for AIOps is running.

Important: Ensure that your installed version of the tool is **v1.17.6** or newer. Some healthcheck data is only gathered with version **v1.17.6** and newer.

To gather data for healthcheck related problems, run the following command:

```
waiops-mustgather.sh -O healthcheck
```

This option gathers the following data for checking the current health of your IBM Cloud Pak for AIOps deployment and Red Hat OpenShift Container Platform cluster:

The healthcheck gathers the following data:

1. Node status, CPU utilization, and memory utilization
2. Red Hat OpenShift etcd status
3. Cluster service version (CSV) phase for IBM Cloud Pak for AIOps CSVs
4. CustomResourceDefinitions (CRDs) phase/status and version for IBM Cloud Pak for AIOps projects
5. Persistent volumes and persistent volume claims (PVC) status
6. Deployments, statefulsets, pods, daemonsets, and jobs statuses
7. Key missing resources
8. Basic compliance check results

After the tool finishes gathering data, review the **0-README-FIRST/SUMMARY.log** log file.

Node status, CPU utilization, and memory utilization

For the list of all nodes in the cluster with their respective status, CPU utilization, and memory utilization, review the **HEALTH REPORT OF NODES** section of the log.

This report shows the total CPU and MEMORY available in the cluster, and the CPU and memory request and limit of individual nodes. This report also indicates a warning when the CPU or memory utlization exceeds 95%.

The following log example shows a node health report for a IBM Cloud Pak for AIOps deployment:

```
================================================
HEALTH REPORT OF NODES
================================================

Cluster service version (CSV) phase for IBM Cloud Pak for AIOps CSVs

For a report that lists the cluster service versions (CSVs) for a IBM Cloud Pak for AIOps project (namespace), including the CSV phase, review the **STATUS REPORT OF CLUSTER SERVICE VERSION (namespace = <namespace>)** section of the log, where **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.

This report lists the version and phase for each CSV. Within the report check the **PHASE** column and value for each CSV. The value should be **Succeeded**.

The following log example shows a cluster service version status report for a IBM Cloud Pak for AIOps deployment:

```
==================================================
STATUS REPORT OF CLUSTER SERVICE VERSION (namespace = cp4aiops)
==================================================
NAME                                        DISPLAY                                        VERSION

CustomResourceDefinitions (CRDs) phase/status and version

For a report that lists all important CustomResourceDefinitions (CRDs) for a IBM Cloud Pak for AIOps project (namespace), including the CRD phase/status and version, review the **STATUS REPORT OF AIOPS PRODUCT COMPONENTS** section of the log.

This report shows the version, phase/status, and any error for each key CRD. Within the report check the **VERSION** column for each CRD:

- The string value **<none>** indicates that no version details are available. This value is not a cause for alarm.
- The string value **N/A** indicates that the MustGather tool is unable to detect the CRD. The healthcheck option for the MustGather scans for a predefined list of CRDs, if a CRD is installed, but shows as **N/A**, further investigation is required as there might be a problem with that component.

The following log example shows a product components status report for a IBM Cloud Pak for AIOps deployment:

```
================================================
STATUS REPORT OF WAIOPS PRODUCT COMPONENTS
================================================
KIND                                    NAME                        NAMESPACE                VERSION

Persistent volumes and Persistent volume claims (PVC) status

For node disk status (disk utilization details), Persistent volume status, and Persistent volume claims status, review the following sections of the log:

- `STATUS REPORT OF PERSISTENTVOLUMECLAIMS (namespace = <namespace>)`
- `PVC UTILIZATION REPORT (namespace = <namespace>)`

The PVC utilization report lists all PVCs and their respective **`df -h`** output. The report also shows a warning if the disk utilization is over 95% or if the **`df -h`** output is not available for a PVC.

Note: **`<namespace>`** is the project (namespace) where IBM Cloud Pak for AIOps is installed.

The following log example shows a PERSISTENTVOLUMECLAIMS report for a IBM Cloud Pak for AIOps deployment:

```
=====================================================
STATUS REPORT OF PERSISTENTVOLUMECLAIMS (namespace = cp4waiops)
=====================================================
[Sun Nov 12 20:54:41 PST 2023] [cp4waiops] All PVCs seem to be operating fine!
>>> [TOTAL OK] [cp4waiops] Bound (pvc) = 40
>>> [TOTAL PVC] = 40
```

The following log example shows a PVC utilization report for a IBM Cloud Pak for AIOps deployment:

```
=====================================================
PVC UTILIZATION REPORT (namespace = cp4waiops)
=====================================================

Deployments, statefulsets, pods, daemonsets, and jobs statuses

For deployment, statefulset, pod, daemonsets, and job statuses, review the **HEALTH REPORT OF NAMESPACE = <namespace>** section of the log, where **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.

This resource analysis report includes a simple analysis of the total resources (deployments, statefulsets, daemonsetspods, pods, and jobs) that are running properly and not running properly. The report identifies any of these resources that are problematic. For problematic pods, the report shows the events for the pods.

The following log example shows a project (namespace) health report of namespace for a IBM Cloud Pak for AIOps deployment:

```
================================================
HEALTH REPORT OF NAMESPACE = cp4waiops
================================================
[Sun Nov 12 20:53:38 PST 2023] [analyzeOcAll] Analyzing 'oc get all -o wide -n cp4waiops' => /tmp/mg/waiops-
modules-12112023-205309/PROD_NAMESPACES/cp4waiops/oc_all.out
[Sun Nov 12 20:53:38 PST 2023] [analyzeOcAll] Analyzing DEPLOYMENTS [cp4waiops]
>>> [TOTAL OK] [cp4waiops] Deployment = 84
>>> [TOTAL DEPLOYMENT] = 84

[Sun Nov 12 20:53:41 PST 2023] [analyzeOcAll] Analyzing STATEFULESETS [cp4waiops]
>>> [TOTAL OK] [cp4waiops] Statefulset = 14
>>> [TOTAL STATEFULSET] = 14

[Sun Nov 12 20:53:41 PST 2023] [analyzeOcAll] Analyzing DAEMONSET [cp4waiops]
>>> [cp4waiops] There is no 'daemonset' found!
>>> [TOTAL DAEMONSET] = 0

[Sun Nov 12 20:53:41 PST 2023] [analyzeOcAll] Analyzing PODS [cp4waiops]
>>> [TOTAL OK] [cp4waiops] Running = 166 / Completed = 20
>>> [TOTAL POD] = 186

[Sun Nov 12 20:53:46 PST 2023] [analyzeOcAll] Analyzing JOBS [cp4waiops]
COUNT  JOB                                                                    READY      DURATION   STATUS
1      aimanager-aio-curator-job-28281060                                     0/1        34d        NOK
>>> [TOTAL OK] [cp4waiops] Job = 40
>>> [TOTAL NOK] [cp4waiops] Job = 1
>>> [TOTAL JOB] = 41
```

Key missing resources

For the list of missing resources, review the **REPORT OF MISSING OBJECTS (PROD_VER=<version>)** section of the log, where **<version>** is the version of IBM Cloud Pak for AIOps that is installed.

This report includes the results of a scan for the resources that are expected to exist after a successful installation. The list of resources that are scanned is configurable, and can include any resource type (deployments, statefulsets, pods, strimzipodset, and more).

When reviewing the results, review the **[SCAN RESULT]** and **[SCAN SUMMARY]** sections for details. The results list:

- Any missing resources and their expected count.
- Resources that exist, but have mismatched counts, such as when 2 are expected, but only 1 exists

For any **[Objects Not Matched]** section for a context in the report, the section lists resources that are found, but are not configured in the scan as needed or critical resources. These results are not cause for concern.

The following log example shows a missing objects report for a IBM Cloud Pak for AIOps deployment:

```
================================================
REPORT OF MISSING OBJECTS (PROD_GROUP = cp4aiops@ibm-cp-aiops / PROD_VER = 4.4.0)
================================================
NOTE(1): Please be as accurate as possible with the regex of OBJNAME. Otherwise, an object is considered
found as long as there is at least one instance!
NOTE(2): The algorithm is based on matching 'oc get' returned object name against AWK regular expression
defined by 'OBJNAME'!
NOTE(3): For missing object with label [Count condition OK], it is likely to be either optional or deleted
job pod. To investigate further!

Data collection modes for the IBM Cloud Pak for AIOps MustGather tool

Learn more about the different commands that you can use with the IBM Cloud Pak® for AIOps MustGather tool to gather information for opening a case with IBM® Support.

There are 2 sets of data collection modes (primary and secondary). The MustGather tool has multiple (6) primary collection modes and multiple advanced modes for collecting specific sets of data.

Rules:

- Users can select zero or one primary mode.
- User can select zero, some or all secondary modes.
- User can combine one primary mode with zero, some or all secondary modes.

- Secondary modes can run independently without any primary mode
- The secondary modes selected (independently, or with any primary mode) are run with the following precedence: `clusternodes` > `cmdexec` > `manualcollect` > `extra` > `missingobj` > `compliance` > `plugins` > `cpfiles` > `snapshots`

Example commands:

```
waiops-mustgather.sh -aypD -C /tmp/cmdexec.input -m /tmp/manualcollect.csv -e cp4aiops
```

Since a primary mode `-a` is selected, all data collection that is configured for the *all* primary mode is run first. Then the data collection for the secondary modes are run in the sequence of `cmdexec` > `manualcollect` > `extra`.

```
waiops-mustgather.sh -C /tmp/cmdexec.input -m /tmp/manualcollect.csv -e cp4aiops
```

Since no primary mode is selected, the secondary modes are run in the sequence `cmdexec` > `manualcollect` > `extra`.

Primary modes

Primary mode options

Option	Description
`-a`	All mode, which gets all data (data volume is high).
`-c`	Comprehensive mode, which gets comprehensive data (data volume is moderate).
`-b`	Basic mode, which gets basic data (data volume is OK).
`-l`	Limited mode, which gets limited data (data volume is low).
`-k`	Selective mode, which gets data for selective resources (separate resources with comma), for example, pods,deployment,secrets (data volume is varied). To get cluster-wide (all-namespaces) data for namespace-scoped resource, such as a pod, you can use the special keyword `allns` (`pod/allns`,`ingress`,`cm/allns`). `allns` data is available in the `CLUSTER_DATA` directory. `namespaced` data is available in the `PROD_NAMESPACES` directory.
`-z`	Module mode, which gets data based on predefined modules separated by comma (clusterinfo productinfo storage networking installation csv pvcusage nodeinfo) (data volume is varied). To list all available modules, use `-z .listmodules`.

Secondary modes

Clusternode modes

Clusternode mode options

Option	Description
`-d`	Gets logs and data from all cluster nodes by using `oc debug` or SSH (if `-i` or `-u` is used).
`-l`	Number of lines of journal to collect from cluster nodes. The default is `2000`.

cmdexec mode

cmdexec mode options

Option	Description
`-C`	`[script file]##[environment file]` Where `[environment file]` is optional. The format of `[environment file]` is `KEY=VALUE`, which is similar to the variable definition format in shell script.
`-E`	Environment variable for the `cmdexec` script. For example, `'VAR1=VAL1##VAR2=VAL2##...'` - Enclose the entire input string with single quotation marks. For example `'VAR1=hello##VAR2=uname -a'`
`-T`	Timeout value for `cmdexec [-C]`. The default is `5m`. For example, `10s` where `s`=second; `m`=minute; `h`=hour.

Manualcollect mode

Manualcollect mode options

Option	Description
`-m`	`<manual-collection-param>` = `[TAGS]:input file` for the `getManualCollection()` function where `TAGS` is optional. The default is all config lines. - Separate multiple tags with a comma.
`-n`	Environment variables for the `manualcollect` `EXECCMD` command. For example, `TAG1~>VAR1=VAL1##VAR2=VAL2^^TAG2~>VAR1=VAL1...` - Use the symbol `^^` to separate environment variables for different tags. - Use the symbol `~>` to define an environment variable for a tag. Use the symbol `##` to separate multiple environment variables. - Enclose the entire input string with single quotation marks and each value with double quotation marks. For example, `VAR1="hello"##VAR2="uname -a"`.

Option	Description
`-j`	Provided string `[tag:<objname>##tag:<objname>##...]` is used to substitute the `OBJNAME` keyword under the `OBJNAME` column that is based on the `tagname` in the manual collect input configuration file, such as `tag1=pod-abc##tag2=pod-xyz`.
`-w`	Timeout value for `manualcollect [-m]`. The default is `5m`. For example, `10s` where `s`=second; `m`=minute; `h`=hour.

Extra namespace mode

Extra namespace mode options

Option	Description
`-e`	Get data for extra namespaces (`oc get all,pvc,configmap,secret,serviceaccount`, `oc describe`, `oc logs`) - Separate namespaces with a comma (`,`)

The `[:extra-resouces]` is optional and is a file that can be used to specify additional resource types, such as catalog sources, operand configs, and more). Specify one resource type per line in the file.

Missing object mode

Missing object mode options

Option	Description
`-x`	- Product version to use for `getMissingObj` function, such `-x 3.2.0` or `-x X` to auto-detect. Defaults to the product version that is detected by tool if a version is not provided Or - The absolute path for an input config file, such as `-x /tmp/myfile.cfg` for the `getMissingObj` function to use.

Compliance mode

Compliance mode options

Option	Description
`-A`	`<compliance-param> = TAGS:[input file for the getCompliance() function]` where `input file` is defaulted to `compliance/<prod-version>/compliance.cfg` (use keyword `ALL` to select all config lines. Separate multiple tags with a comma) [EXPERIMENTAL]

plugins mode

Plugins mode options

Option	Description
`-P`	Product plugin `[supported=aimanager]:action [supported=data fix]`. The default action is `data`. For example, `aimanager` or `aimanager:data` or `aimanager:fix`. - Separate plugins with a comma (`,`).
`-Z`	Environment variables for the plugins script. For example, `VAR1=VAL1##VAR2=VAL2##...` - Enclose the entire input string with single quotation marks. For example, `VAR1=hello##VAR2=uname -a`.
`-Q`	Timeout value for plugins `[-P]` The default is `15m`. For example, `10s` where `s`=second; `m`=minute; `h`=hour.

cpfiles mode

cpfiles mode options

Option	Description
`-F`	Copy files in a pod. `cpfiles-param` = `TAGS` or `NAMESPACE##PODNAME##CONTAINER##FILES` where multiple `TAGS` can be delimited by `@@`. `CONTAINER` is optional and `FILES` can be delimited by a colon. - `-F aimanager` refers to `cpfiles/cpfiles-<prodname>-<version>.cfg` and copies all the files configured as `TAG=aimanager`. `-F NS4PROD=aimanager##iaf-system-kafka-0####/tmp/abc.txt` is the manual command to copy a file.

Notes:

- You can use keyword `NS4PROD=<prodname>` to obtain namespace for those products automatically.
- You can use asterisk(`*`), square brackets(`[]`), question mark(`?`), and curly braces(`{}`) wildcards in `FILES`.
- Since the `tar` (needed by `oc cp`) command might not be available in the target pod or container, use this option only for text files (`oc exec/cat` is used as a secondary option).

Snapshots mode

Snapshots mode options

Option	Description
`-K`	Complete snapshots comparison.

View mode

View mode options

Option	Description
`-V`	`<view-only-module>` is a script that can be created under the `<mustgather-install-dir>/config/view/<PRODUCT_VERSION>` (precedence) or `<mustgather-install-dir>/view` directory. You can use `-V .listviews` to list down all available modules and their descriptions.

Supporting Options

Supporting options

Option	Description
`-y`	Collect YAML output (`oc get -o yaml`).
`-J`	Collect JSON output (`oc get -o json`).
`-p`	Collect logs for the previous instance of the container in a pod if it exists
`-t`	Do not collect `oc describe`.
`-g`	Do not collect pod logs (`oc logs` and `oc logs -p`).
`-f`	Collect PVC usage data (`df -h`) - Available only with options `-a`, `-c`, `-b`, `-l`, `-z` (productinfo/storage/pvcusage), `-k` (pvc) and `-e`.
`-R`	Enable report-on-screen where SUMMARY.log is printed on display.
`-S`	Explicitly collect YAML output of secret objects.
`-s`	Use SSH to collect logs and data from all cluster nodes without a common admin username across the cluster.
`-u`	Provide the admin username to used to SSH to all cluster nodes for data collection purpose. A passwordless SSH is needed for this option.
`-i`	Set the path to the SSH key. This path is needed for clusters on a cloud (experimental).
`-o`	Set the output directory. The default directory is `/tmp`.
`-G`	Use a filename regex and pattern, that is delimited by a colon, to run a grep operation. This option is applicable to pod logs, events, cpfiles, and node-related data files. - Separate patterns with double asperands (`@@`). - Separate `FILENAME_REGEX:PATTERNS` key value pairs with double hashes (`##`). - Use the keyword `ALL` as the filename regex as an instruction to run `grep` for all detected files. - Use a tilde (~) to run a piping grep. For example, `grep A <file>` | `grep B` | `grep C`. - To escape, use a tilde (~) with a backward slash (\) for the literal value. There is no need to escape by using a colon (`:`). For example, `ALL:error@@failure` or `^aimanager:error~fail` or `^aimanager:error##ALL:failure` or `ALL:error\~fail##ALL:error\/fail`
`-W`	Set global environment variable that all primary data collection modes can use for further processing. For example, `-W 'VAR1=123##VAR2=456##VAR3=789'`; this option delimits multiple variables with the `##` characters. All variables are suffixed with the string `PRIMODE_` when used internally (`VAR1` > `PRIMODE_VAR1`).
`-N`	Turn on data collection for problematic non-product namespaces. Data collection for problematic Red Hat OpenShift namespaces is always enabled.
`-I`	Enable incident reporting (experimental).
`-X`	Turn off custom data collection.
`-Y`	Auto-answer `YES` to question prompts.
`-U`	Check for updates.
`-M`	Turn of the automatic new version check and download for the tool.
`-D`	Turn on Debug mode.
`-v`	View the version details.
`-h`	View the tool help details.

Advanced tips for using the IBM Cloud Pak for AIOps MustGather tool

Learn more about advanced techniques that you can use with the IBM Cloud Pak® for AIOps MustGather tool to gather information for opening a case with IBM® Support.

Tip: Use manual collection mode to run commands

If you need to run `oc exec` commands on pods, you can use the manual collection (`MANUALCOLLECT`) mode. This mode can be configured to complete specific tasks, such as to "get all Elasticsearch indexes".

The MustGather Tool does include some default task configurations. For more information, review the **manualcollect/<version>/mc.cfg** file within the MustGather tool installation package.

Example command:

```
# ./waiops-mustgather.sh -R -m aimgr-indices:mc.cfg
```

Example output:

```
================================================
[MANUALCOLLECT] OUTPUT OF EXECCMD
================================================

[CFGLINE = lifecycle-policy##cp4waiops##pod##^aiops-ir-lifecycle-policy-registry-svc-######curl -u$(cat
$SYSTEMAUTH_BINDING_DIR/username):$(cat $SYSTEMAUTH_BINDING_DIR/password)
http://localhost:$PORT/policyregistry.ibm-netcool-prod.aiops.io/v1alpha/system/cfd95b7e-3bc7-4006-a4a8-
a73a79c71255]

[FILE = /tmp/waiops-manualcollect-07112022-190154/4-MANUALCOLLECT/TAG=lifecycle-policy/cp4waiops/aiops-ir-
lifecycle-policy-registry-svc-7587b88cdb-rk594.bash.exec]

[POD = aiops-ir-lifecycle-policy-registry-svc-7587b88cdb-rk594]

Defaulted container "aiops-ir-lifecycle-policy-registry-svc" out of: aiops-ir-lifecycle-policy-registry-svc,
policyregistry-checkdb (init)

  },
...
```

Tip: Use `CPFILES` to copy files from pods

If you need to copy specific files from pods, you can use the **CPFILES** option.

For example, the following command uses the MustGather tool to pull the **/conf/redis/redis.conf** file from all pods that match regex expression **^c-example-redis-m-**. This example uses the following parameters:

- **NS4PROD=** is a special keyword that instructs the tool to auto-resolve the namespace for product **aimanager**.
- **keyword** and **regex** (avoid hardcoding) are used to allow the configuration to be used across different environments without the need to reconfigure.

Example command:

```
[file cpfiles/cpfiles-waiops-320.cfg in the package]
test##NS4PROD=aimanager##^c-example-redis-m-####/conf/redis/redis.conf
```

Example output:

```
# pwd
/tmp/waiops-cpfiles-01042022-173635/8-CPFILES/waiops32
# ls -l c-example-redis-m-0/
total 56
-rw-r--r-- 1 root root 51281 Apr  1 17:36 '^conf^redis^redis.conf'
-rw-r--r-- 1 root root    78 Apr  1 17:36 '^conf^redis^redis.conf.ls'
# ls -l c-example-redis-m-1
total 56
-rw-r--r-- 1 root root 51306 Apr  1 17:36 '^conf^redis^redis.conf'
-rw-r--r-- 1 root root    78 Apr  1 17:36 '^conf^redis^redis.conf.ls'
# ls -l c-example-redis-m-2
total 56
-rw-r--r-- 1 root root 51306 Apr  1 17:36 '^conf^redis^redis.conf'
-rw-r--r-- 1 root root    78 Apr  1 17:36 '^conf^redis^redis.conf.ls'
```

Tip: Run custom scripts with the MustGather tool

You can run your own script with the MustGather Tool, such as for completing corrective actions before the tool collects data. After completing the custom script actions, the tool then proceeds with the data collection.

- Custom script variable
- Custom script functions
- Example Command
- Example script
- Example script functions
- Example script results

Custom script variable

The following tables list some of the variables that you can include within a custom script:

Custom script variables

Variable	Description
`$OC_CMD`	The system command used to collect data. You can use either an `oc` or `kubectl` command.
`$OC_WHOAMI`	The current user.
`$AWK`	The `AWK` used in the tool, which can be either `awk` or `gawk` (preferred).
`$OLDIFS`	The original IFS.
`$PRODUCT_VERSION`	The product version detected during runtime (on site).
`$MUSTGATHER_DIRNAME`	The directory name where the MustGather tool is installed.
`$OUTDIR`	The directory where the output data is written.
`$PROD_NAMESPACES_REFFILE`	The product-to-namespace mapping reference file (Do not change).
`$PROD_NAMESPACES_UNIQUE_REFFILE`	The unique product namespaces reference file (Do not change).
`$PROD_NAMESPACES_INVALID_STR`	A constant string value that represents the failed `getNamespaceToProdMapping()` function.
`$CMD_EXEC_OUTPUT_DIR`	The directory where the output of `CMDEXEC` is written to.
`$CMD_EXEC_PRODUCT_NSFILE`	A copy of the original product namespaces reference file that needs to be used by the inherited `getNamespaceToProdMapping()` function.
`$CMD_EXEC_RESULT_MCCFG_FILE`	A file that the custom script can write to for running the *MANUALCOLLECT* secondary mode.
`$CMD_EXEC_RESULT_EXTRANS_FILE`	A file that the custom script can write to for running the *EXTRA* (namespace) secondary mode.
`$CMD_EXEC_RESULT_CPFILES_FILE`	A file that the custom script can write to for running the *CPFILES* secondary mode.

Custom script functions

The following tables list some of the functions that you can include within a custom script:

Custom script functions

Functions	Description

Functions	Description
`getProdToNamespacesMapping()`	A function to retrieve product namespace through provided product name. **Syntax:** `getProdToNamespacesMapping <product-name> $CMD_EXEC_PRODUCT_NSFILE` **Returns:** - Product namespaces of the given product name or `PROD_NAMESPACES_INVALID_STR`. - Return status `0` for successful execution and `1` for a failed execution. Product namespaces: - `aimanager` = IBM Cloud Pak for AIOps - `noihybrid` = IBM Netcool Operations Insight (hybrid) - `ics` = IBM Cloud Pak foundational services
`getNamespaceToProdMapping()`	A function to retrieve product name through provided product namespace. **Syntax:** `getNamespaceToProdMapping <product-namespace> $CMD_EXEC_PRODUCT_NSFILE` **Returns:** Product name of the given product namespace.
`getResourceInstances()`	A function to retrieve a list of resource instances. **Syntax:** `getResourceInstances <resource type> <resource name regex> <resource namespace>` Where `<resource namespace>` is optional and defaults to `-all-namespaces`. **Returns:** - A list of resources that match the provided details or a blank string if the command fails or no resource is detected. - Return status `0` for successful execution and `1` for a failed execution.
`getUniqueProdNamespaces()`	A function to retrieve a list of unique product namespaces. **Syntax:** `getUniqueProdNamespaces $CMD_EXEC_PRODUCT_NSFILE` **Returns:** A list of unique product namespaces or blank string if failed.
`checkUserPriv()`	A function to check whether the current user has privilege to complete specific actions (verb) on a specific resource in a specific namespace. **Syntax** `checkUserPriv <verb> <resource type> <resource namespace>` **Returns:** `0` to indicate the user has the required privileges and `1` to indicate that user does not have the required privilege. `<verb>` reference: Kubernetes API Concepts.
`isPodOk()`	A function to determine whether a pod is in `RUNNING` state and all its containers are up. **Syntax:** `isPodOk <namespace> <podname>` **Returns:** `0` for an OK pod and `1` for a pod that is not OK.
`isPodLineOk()`	A function to determine whether a pod is in RUNNING state and all its containers are up. **Syntax:** `isPodLineOk <'oc get –no-headers' output of the pod>` **Returns:** `0` for an OK pod and `1` for an pod that is not OK.

Example Command

```
waiops-mustgather.sh -R -C /tmp/elite.sh##/tmp/env.in -Y
```

The previous command uses an environment variable file `/tmp/env.in` to pass in variables into the script.

```
POD=teams
CMD=date > /tmp/date.out
```

Example script

The following code shows an example custom script:

```
NOI_NAMESPACE=$(getProdToNamespacesMapping noi $CMD_EXEC_PRODUCT_NSFILE)

if [ ${#NOI_NAMESPACE} -gt 0 ]
then
  echo "[$(date)] Detected namespace = [$NOI_NAMESPACE]"

  IMPACTGUI_POD=$(getResourceInstances pod impactgui $NOI_NAMESPACE)

  if [ ${#IMPACTGUI_POD} -gt 0 ]
  then
    echo "[$(date)] Detected IMPACT GUI pod = [$IMPACTGUI_POD]"
    oc delete pod -n $NOI_NAMESPACE $IMPACTGUI_POD

    WAITFORPOD=0

    while [ $WAITFORPOD -eq 0 ]
    do
      if isPodOk "$NOI_NAMESPACE" "$IMPACTGUI_POD"
      then
        OUTFILE=$($OC_CMD exec -n $NOI_NAMESPACE $IMPACTGUI_POD --
/opt/IBM/tivoli/impact/bin/nci_collect_logs | grep 'Netcool/Impact log file is' | $AWK '{ print $7 }')
```

```
        if [ ${#OUTFILE} -gt 0 ]
        then
          echo "[$(date)] Creating COLLECTLOG timestamp file..."
          echo "ALL##$NOI_NAMESPACE##pod##$(getResourceInstances pod impactgui $NOI_NAMESPACE)####touch
/tmp/collectlog" > $CMD_EXEC_RESULT_MCCFG_FILE

          echo "[$(date)] Detected IMPACT GUI logfile = [$OUTFILE]"
          echo "$NOI_NAMESPACE##$IMPACTGUI_POD####$OUTFILE" > $CMD_EXEC_RESULT_CPFILES_FILE

          WAITFORPOD=1
        else
          echo "[$(date)] Unable to locate IMPACT GUI logfiles!"
          exit 1
        fi
      else
        echo "[$(date)] IMPACT GUI pod is not running!"
        sleep 5
      fi
    done
  else
    echo "[$(date)] Unable to locate IMPACT GUI pod!"
    exit 1
  fi
else
  echo "[$(date)] Unable to determine NOI namespace!"
  exit 1
fi
```

Example script functions

When you are creating your custom script, you can use the following functions:

- The function **getProdToNamespacesMapping** can be used in any **CMDEXEC** script to obtain product namespaces:

  ```
  NS=$(getProdToNamespacesMapping aimanager $CMD_EXEC_PRODUCT_NSFILE)
  echo "NAMESPACE=$NS"
  ```

- The Function **getResourceInstances** can be used in any **CMDEXEC** script to obtain resource instances based on a provided regex expression such to complete a corrective action:

  ```
  for MYPOD in $(getResourceInstances pod $POD $NS)
  do
  MYCMD="oc exec $MYPOD -n $NS -- bash -c '$CMD'"
  echo $MYCMD
  eval $MYCMD
  done
  ```

- The **MANUALCOLLECT** mode can be used to collect data within the script, such as to ensure that the correction actions are successful:

  ```
  echo "ALL##NS4PROD=aimanager##pod##teams####" >> $CMD_EXEC_RESULT_MCCFG_FILE
  ```

- The **EXTRA** mode can be used to collect namespace data within the script:

  ```
  echo "openshift-insights" > $CMD_EXEC_RESULT_EXTRANS_FILE
  ```

- The **CPFILES** option can be used to copy files from pods to verify that your script ran successfully:

  ```
  echo "NS4PROD=aimanager##^iaf-system-kafka####/opt/kafka/config/log4j.properties" >>
  $CMD_EXEC_RESULT_CPFILES_FILE
  ```

Example script results

- When the command **date > /tmp/date.out** runs in the pod:

  ```
  oc exec -it
  ```

  Output:

  ```
  aimanager-aio-chatops-teams-integrator-545bc7d4d-9w8fp -- bash -c 'ls -l /tmp; cat /tmp/date.out'
  Defaulted container "chatops-teams-integrator" out of: chatops-teams-integrator, controller-is-ready
  (init)
  total 12
  -rw-r--r--. 1 default root  29 Apr  2 01:00 date.out
  -rwx------. 1 root    root 701 Sep 14  2021 ks-script-vzv5jj6c
  -rwx------. 1 root    root 291 Sep 14  2021 ks-script-y5xeen0d
  Sat Apr  2 01:00:25 UTC 2022
  ```

- Through **MANUALCOLLECT**, the data of the pod that matched the regex **teams** is collected. You can verify this by running the following commands:

  1. Print the working directory:

```
# pwd
```

Output:

```
/tmp/waiops-cmdexec-01042022-175950/4-MANUALCOLLECT/TAG=ALL/waiops32
```

2. List the directory files:

```
# ls -l
```

Output:

```
total 4
-rw-r--r-- 1 root root 180 Apr  1 18:00 oc_pod-aimanager-aio-chatops-teams-integrator-545bc7d4d-
9w8fp.out
drwxr-xr-x 2 root root 164 Apr  1 18:00 pod
```

3. List the pods files:

```
total 12
-rw-r--r-- 1 root root 1551 Apr  1 18:00 aimanager-aio-chatops-teams-integrator-545bc7d4d-
9w8fp~chatops-teams-integrator.log
-rw-r--r-- 1 root root 7315 Apr  1 18:00 aimanager-aio-chatops-teams-integrator-545bc7d4d-
9w8fp.desc
```

- Through the **EXTRA** mode, data about the namespace **openshift-insights** is collected. You can verify this by running the following commands:

1. Print the working directory:

```
# pwd
```

Output:

```
/tmp/waiops-cmdexec-01042022-175950/5-EXTRA/openshift-insights
```

2. List the directory files:

```
# ls -l
```

Output:

```
total 28
drwxr-xr-x 2 root root  132 Apr  1 18:00 configmaps
drwxr-xr-x 2 root root   36 Apr  1 18:00 deployment.apps
-rw-r--r-- 1 root root 1738 Apr  1 18:00 oc_all.out
-rw-r--r-- 1 root root  194 Apr  1 18:00 oc_configmaps.out
-rw-r--r-- 1 root root  328 Apr  1 18:00 oc_pod_scc.out
-rw-r--r-- 1 root root   52 Apr  1 18:00 oc_pvc.out
-rw-r--r-- 1 root root 1427 Apr  1 18:00 oc_secrets.out
-rw-r--r-- 1 root root  155 Apr  1 18:00 oc_serviceaccounts.out
drwxr-xr-x 2 root root  117 Apr  1 18:00 pod
drwxr-xr-x 2 root root   35 Apr  1 18:00 pvc
drwxr-xr-x 2 root root   86 Apr  1 18:00 replicaset.apps
drwxr-xr-x 2 root root 4096 Apr  1 18:00 secrets
drwxr-xr-x 2 root root   26 Apr  1 18:00 service
drwxr-xr-x 2 root root  107 Apr  1 18:00 serviceaccounts
```

- Through CPFILES, the file **/opt/kafka/config/log4j.properties** is copied from the pods that matches the regex expression **^iaf-system-kafka**. You can verify this by running the following commands:

1. Print the working directory:

```
# pwd
```

Output:

```
/tmp/waiops-cmdexec-01042022-175950/8-CPFILES/waiops32/iaf-system-kafka-0
```

2. List the directory files:

```
# ls -l
```

Output:

```
total 12
-rw-r--r-- 1 root root 4674 Apr  1 18:00 '^opt^kafka^config^log4j.properties'
-rw-r--r-- 1 root root   77 Apr  1 18:00 '^opt^kafka^config^log4j.properties.ls'
```

3. View the first lines of the file to verify the file contents:

```
# head ^opt^kafka^config^log4j.properties
```

Output:

```
# Licensed to the Apache Software Foundation (ASF) under one or more
# contributor license agreements.  See the NOTICE file distributed with

Security bulletins and fixes

Stay informed about known security vulnerabilities and fixes for IBM Cloud Pak® for AIOps by subscribing to the security bulletins and by reviewing the list of fixed security-related vulnerabilities.

- Security bulletins
- Fixed security-related vulnerabilities in version 4.7.1
- Fixed security-related vulnerabilities in previous versions

Security bulletins

Subscribe to IBM Cloud Pak for AIOps notifications by following these steps:

1. Go to the IBM Support site.
2. Scroll to the **Support basics** section. Then, click the **Notification settings** card.
3. Log in to IBM with your IBM ID and password to continue.
4. Enter **IBM Cloud Pak for AIOps** in the **Product lookup** field. Click **Subscribe**.
5. In the **Select document types** page, select **Security bulletin** and **Fixes** > **Security Vulnerability (Sec/Int)**. You can also select any other document types that you need to keep informed about.
6. Click **Submit**.
7. To configure how you receive notifications, click **Delivery preferences** in the banner at the beginning of the page. Edit your settings as needed.

Fixed security-related vulnerabilities in version 4.7.1

Review the following tables, which lists the fixed reported security-related vulnerabilities with IBM Cloud Pak for AIOps, and any included IBM or third-party software.

Table. Fixed Common Vulnerabilities and Exposures in Version 4.7.1

CVE-ID	Issue	Description
CVE-2021-35937	RPM Project RPM privilege escalation	RPM Project RPM could allow a local authenticated attacker to gain elevated privileges on the system, caused by a TOCTOU race in checks for unsafe symlinks. An attacker could exploit this vulnerability to bypass the checks that were introduced in response to CVE-2017-7500 and CVE-2017-7501 and gain root privileges on the system.
CVE-2021-35938	RPM Project RPM privilege escalation	RPM Project RPM could allow a local authenticated attacker to gain elevated privileges on the system, caused by a symbolic link when setting the desired permissions and credentials after installing a file. An attacker could exploit this vulnerability to exchange the original file with a symbolic link to a security-critical file and gain elevated privileges on the system.
CVE-2021-35939	RPM Project RPM privilege escalation	RPM Project RPM could allow a local authenticated attacker to gain elevated privileges on the system, caused by the failure to perform checks for unsafe symlinks for intermediary directories. An attacker could exploit this vulnerability to gain root privileges on the system.
CVE-2021-46984	Linux Kernel information disclosure	Linux Kernel could allow a local attacker to obtain sensitive information, caused by an out-of-bounds read flaw when preempted. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2021-47097	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds read flaw in elantech_change_report_id(). By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.

CVE-ID	Issue	Description
CVE-2021-47101	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an uninit-value flaw in asix_mdio_read(). By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2021-47287		
CVE-2021-47289	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a null pointer dereference in ACPI. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2021-47321	Linux kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free in calling del_timer_sync() of watchdog. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2021-47338		
CVE-2021-47352	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by not properly validate the length of data provided by an untrusted device in the virtio-net driver. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2021-47383	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by an out-of-bound vmalloc access flaw in imageblit. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2021-47384	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw when driver read tmp value sufficient for (tmp & 0x08) && (!(tmp & 0x80)) && ((tmp & 0x7) == ((tmp >> 4) & 0x7)) from device. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2021-47385		
CVE-2021-47386		
CVE-2021-47393	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw with return non-zero value when fan current state is enforced from sysfs. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2021-47412		
CVE-2021-47432	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an integer overflows related to the radix tree code. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2021-47441	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bounds memory accesses flaw when thermal state transition statistics are enabled (CONFIG_THERMAL_STATISTICS=y). By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2021-47497	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a shift-out-of-bound (UBSAN) flaw with byte size cells. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2022-48619	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in the input_set_capability() function when an event code is outside the bitmap. By sending a specially crafted request, a local attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2022-48754		
CVE-2022-48760	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw related to memory-access ordering on SMP systems. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2022-48804	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by a transient integer underflow in the array_index_nospec function. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2022-48836	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a wrong endpoint type issue in the usb_submit_urb() function. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2022-48866		
CVE-2023-5981	GNU GnuTLS information disclosure	GNU GnuTLS could allow a remote attacker to obtain sensitive information, caused by a timing sidechannel issue during RSA-PSK key exchange. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information, and use this information to launch further attacks against the affected system.

CVE-ID	Issue	Description
CVE-2023-6004	libssh command execution	libssh could allow a local authenticated attacker to execute arbitrary commands on the system, caused by a flaw in the ProxyCommand handling. By sending a specially crafted request using hostname in expanded proxycommand, an attacker could exploit this vulnerability to execute arbitrary commands on the system.
CVE-2023-6040	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by an out-of-bounds access flaw during the creation of a new netfilter table. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2023-6918	libssh denial of service	libssh is vulnerable to a denial of service, caused by an unchecked return value flaw for the abstract layer for message digest (MD) operations. By sending a specially crafted request, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-7008	systemd man-in-the-middle	systemd is vulnerable to a man-in-the-middle attack, caused by a flaw with able to accept records of DNSSEC-signed domains even when they have no signature. An attacker could exploit this vulnerability to launch a man-in-the-middle attack and gain access to the communication channel between endpoints to manipulate records.
CVE-2023-7104	SQLite SQLite3 buffer overflow	SQLite SQLite3 is vulnerable to a heap-based buffer overflow, caused by improper bounds checking by the sessionReadRecord function in ext/session/sqlite3session.c. By sending a specially crafted request, a remote authenticated attacker could overflow a buffer and execute arbitrary code on the system.
CVE-2023-28322	cURL libcurl security bypass	cURL libcurl could allow a remote attacker to bypass security restrictions, caused by a flaw in the logic for a reused handle when it is (expected to be) changed from a PUT to a POST.. By sending a specially crafted request, an attacker could exploit this vulnerability to cause application to misbehave and either send off the wrong data or use memory after free or similar in the second transfer.
CVE-2023-38546	cURL libcurl security bypass	cURL libcurl could allow a remote attacker to bypass security restrictions, caused by a flaw in the curl_easy_duphandle function if a transfer has cookies enabled when the handle is duplicated. By sending a specially crafted request, an attacker could exploit this vulnerability to insert cookies at will into a running program.
CVE-2023-39326	Golang Go information disclosure	Golang Go could allow a remote attacker to obtain sensitive information, caused by a flaw in the net/http package. By sending a specially crafted HTTP request, an attacker could exploit this vulnerability to read many more bytes from the network than are in the body, and use this information to launch further attacks against the affected system.
CVE-2023-45284	Golang Go weak security	Golang Go could provide weaker than expected security, caused by the failure to correctly detect reserved device names in some cases by the IsLocal function in the filepath package. An attacker could exploit this vulnerability to report "COM1", and reserved names "COM" and "LPT" followed by superscript 1, 2, or 3 as local.
CVE-2023-46218	cURL libcurl security bypass	cURL libcurl could allow a remote attacker to bypass security restrictions, caused by a mixed case flaw when curl is built without PSL support. By sending a specially crafted request, an attacker could exploit this vulnerability to allow a HTTP server to set "super cookies" in curl.
CVE-2023-52428	Connect2id Nimbus-JOSE-JWT denial of service	Connect2id Nimbus-JOSE-JWT is vulnerable to a denial of service, caused by improper validation of user requests by the PasswordBasedDecrypter (PBKDF2) component. By sending a specially crafted request using a large JWE p2c header, a remote attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52470	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference in radeon_crtc_init(). A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52476	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a panic can occur when a vsyscall is made while LBR sampling is active. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2023-52478	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by a race condition in the hidpp_connect_event() function. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or crash the system.
CVE-2023-52522	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in neigh_periodic_work() function. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52605	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference check. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52683	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a overflow in the lpit_update_residency() function. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52817	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference when the smc_rreg pointer is NULL. An attacker could exploit this vulnerability to cause a denial of service.
CVE-2023-52840	Input: synaptics-rmi4 - fix use after free in rmi_unregister_function()	In the Linux kernel, the following vulnerability has been resolved: Input: synaptics-rmi4 - fix use after free in rmi_unregister_function() The put_device() calls rmi_release_function() which frees "fn" so the dereference on the next line "fn->num_of_irqs" is a use after free. Move the put_device() to the end to fix this.
CVE-2024-0553	GnuTLS information disclosure	GnuTLS could allow a remote attacker to obtain sensitive information. By perform a timing side-channel attack in the RSA-PSK key exchange, a remote attacker could exploit this vulnerability to obtain sensitive information.

CVE-ID	Issue	Description
CVE-2024-1737	ISC BIND denial of service	ISC BIND is vulnerable to a denial of service, caused by an error when content is being added or updated in resolver caches and authoritative zone databases that hold significant numbers of RRs for the same hostname (of any RTYPE). By processing queries, a remote attacker could exploit this vulnerability to cause the database to slow down.
CVE-2024-1975	ISC BIND denial of service	ISC BIND is vulnerable to a denial of service, caused by an error if a server hosts a zone containing a "KEY" Resource Record, or a resolver DNSSEC-validates a "KEY" Resource Record from a DNSSEC-signed domain in cache. By sending a stream of SIG(0) signed requests, a remote attacker could exploit this vulnerability to exhaust all available CPU resources.
CVE-2024-2961	GNU C Library code execution	GNU C Library could allow a remote attacker to execute arbitrary code on the system, caused by an out-of-bounds write in the ISO-2022-CN-EXT plugin. By sending specially crafted input, an attacker could exploit this vulnerability to overwrite critical data structures and execute arbitrary code on the system or cause the application to crash.
CVE-2024-5742	GNU Nano privilege escalation	GNU Nano could allow a local authenticated attacker to gain elevated privileges on the system. By using an insecure temporary file, an attacker could exploit this vulnerability to escalate privileges through a malicious symlink.
CVE-2024-6119	OpenSSL denial of service	OpenSSL is vulnerable to a denial of service, caused by an error when performing certificate name checks (e.g., TLS clients checking server certificates). By sending a specially crafted request, a remote attacker could exploit this vulnerability to read an invalid memory address resulting in abnormal termination of the application process.
CVE-2024-8260	Styra Open Policy Agent (OPA) seurity bypass	Styra Open Policy Agent (OPA) could allow a local authenticated attacker to bypass security restrictions, caused by a SMB force-authentication . By sending a specially crafted request, an attacker could exploit this vulnerability to pass an arbitrary SMB share instead of a Rego file as an argument to OPA CLI or to one of the OPA Go library's functions.
CVE-2024-21529	Node.js dset module code execution	Node.js dset module could allow a remote attacker to execute arbitrary code on the system, caused by a prototype pollution flaw in the dset function. By adding or modifying properties of Object.prototype using a **proto** or constructor payload, an attacker could exploit this vulnerability to execute arbitrary code or cause a denial of service condition on the system.
CVE-2024-21534	CVE-2024-21534	Versions of the package jsonpath-plus before 10.0.0 are vulnerable to Remote Code Execution (RCE) due to improper input sanitization. An attacker can execute aribitrary code on the system by exploiting the unsafe default usage of vm in Node. **Note:** The unsafe behavior is still available after applying the fix but it is not turned on by default.
CVE-2024-22020	Node.js code execution	Node.js could allow a remote attacker to execute arbitrary code on the system. By embedding non-network imports in data URLs, an attacker could exploit this vulnerability to bypass network import restrictions and execute arbitrary code on the system.
CVE-2024-23848	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free in cec_queue_msg_fh. A local attacker could exploit this vulnerability to cause the system to crash.
CVE-2024-25062	GNOME libxml2 denial of service	GNOME libxml2 is vulnerable to a denial of service, caused by a use-after-free flaw in the xmlValidatePopElement() function. By persuading a victim to open a specially crafted content, a remote attacker could exploit this vulnerability to cause the application to crash.
CVE-2024-25710	Apache Commons Compress denial of service	Apache Commons Compress is vulnerable to a denial of service, caused by an infinite loop flaw. By persuading a victim to open a specially crafted DUMP file, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-26308	Apache Commons Compress denial of service	Apache Commons Compress is vulnerable to a denial of service, caused by an out of memory error. By persuading a victim to open a specially crafted Pack200 file, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-26595	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference in error path. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26600	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference for SRP. A local attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26645	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by the lack of visibility when inserting an element into tracing_map. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26649	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference when load rlc firmware. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26665	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service caused by out-of-bounds access when building IPv6 PMTU. By sending a specially crafted request, a remote attacker could exploit this vulnerability to a denial of service condition.
CVE-2024-26717	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference flaw in the i2c-hid-of of HID. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.

CVE-ID	Issue	Description
CVE-2024-26720	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by divide-by-zero in Wb_dirty_limits(),. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-26769	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a deadlock flaw on delete association path. By ending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-26855	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference in ice_bridge_setlink() of net: ice. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to a denial of service condition.
CVE-2024-26880	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw when caling the resume method. By ending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-26894	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by a memory leak in the acpi_processor_power_exit() function. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2024-26923	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by a garbage collector racing flaw against connect(). By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-26939	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw with attempting to free a still active i915 VMA object when parking a GT believed to be idle. By ending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-27013	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw when illegal packet received by tun dev. By ending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-27042	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an out-of-bounds access flaw in drivers/gpu/drm/amd/amdgpu/amdgpu_discovery.c. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-28182	nghttp2 denial of service	nghttp2 is vulnerable to a denial of service, caused by a memory exhaustion flaw due to flood of CONTINUATION frames in the HTTP/2 protocol stack. By sending a specially crafted request, a remote attacker could exploit this vulnerability to cause excessive CPU usage, and results in a denial of service condition.
CVE-2024-28834	GnuTLS information disclosure	GnuTLS could allow a remote authenticated attacker to obtain sensitive information, caused by a flaw in the ECDSA code. By utilize Minerva attack techniques, an attacker could exploit this vulnerability to obtain private key information, and use this information to launch further attacks against the affected system.
CVE-2024-29131	Apache Commons Configuration code execution	Apache Commons Configuration could allow a remote attacker to execute arbitrary code on the system, caused by an out-of-bounds write vulnerability. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-29133	Apache Commons Configuration code execution	Apache Commons Configuration could allow a remote attacker to execute arbitrary code on the system, caused by an out-of-bounds write vulnerability. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-33599	glibc netgroup cache buffer overflow	glibc is vulnerable to a stack-based buffer overflow, caused by improper bounds checking when the Name Service Cache Daemon's (nscd) fixed size cache is exhausted by client requests. By sending a subsequent client request, a remote attacker could exploit this vulnerability to overflow a buffer and execute arbitrary code on the system.
CVE-2024-33600	glibc netgroup cache denial of service	glibc is vulnerable to a denial of service, caused by a NULL pointer dereference when the Name Service Cache Daemon's (nscd) cache fails to add a not-found netgroup response to the cache. A remote attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-33601	glibc netgroup cache denial of service	glibc is vulnerable to a denial of service, caused by a memory allocation failure when the Name Service Cache Daemon's (nscd) netgroup cache uses the xmalloc or xrealloc functions. A local attacker could exploit this vulnerability to terminate the daemon.
CVE-2024-33602	glibc netgroup cache denial of service	glibc is vulnerable to a denial of service, caused by a memory corruption by the Name Service Cache Daemon's (nscd) netgroup cache when the NSS callback fails to store all strings in the provided buffer. A local attacker could exploit this vulnerability to corrupt memory and cause a denial of service.
CVE-2024-35809	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by drain runtime-idle callbacks before driver removal. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-35877	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in VM_PAT Handling In COW Mappings. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-35884	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Udp. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.

CVE-ID	Issue	Description
CVE-2024-35944	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a memcpy() Run-Time Warning yn Dg_dispatch_as_host(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-35989	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a Kernel oops flaw during rmmod on single-CPU platforms. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-36883	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an out-of-bounds access in ops_init. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-36901	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL sereference in Ip6_output(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-36902	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL dereference In Fib6_rule_action(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-36920	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in scsi: mpi3mr. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-36939	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw with handle error of rpc_proc_register() in nfs_net_init(). By ending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-36953	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw with not handling gracefully when check for non-NULL vCPU in vgic_v2_parse_attr(). By ending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-37356	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by a shift-out-of-bounds in dctcp_update_alpha(). By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-38558	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw with overwriting ct original tuple for ICMPv6. By ending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-38559	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an out-of-bounds read flaw when using kstrtouint. By ending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-38570	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by Glock Use-After-Free on Unmount. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-38581	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by a use-after-free in drivers/gpu/drm/amd/amdgpu/amdgpu_mes.c. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-38619	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Usb-Storage: Alauda. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-38809	VMware Tanzu Spring Framework denial of service	VMware Tanzu Spring Framework is vulnerable to a denial of service, caused by improper input validation. By sending a specially crafted HTTP request containing ETags from "If-Match" or "If-None-Match" request headers, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-38816	VMware Tanzu Spring Security information disclosure	VMware Tanzu Spring Security could allow a remote attacker to obtain sensitive information, caused by a path traversal attack in applications serving static resources through the functional web frameworks WebMvc.fn or WebFlux.fn. By sending specially crafted HTTP requests, an attacker could exploit this vulnerability to obtain any file on the file system that is also accessible to the process in which the Spring application is running.
CVE-2024-39331	GNU Emacs code execution	GNU Emacs could allow a remote attacker to execute arbitrary code on the system, caused by a code injection flaw in org-link-expand-abbrev in lisp/ol.el. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-39471	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an out-of-bounds read in sdma_v4_0.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-39499	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by speculation leaks by sanitizing event in event_deliver() of vmci_event.c . A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-39501	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a race condition in core.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-39506	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer handling path in lio_vf_rep_copy_packet In lio_vf_rep_copy_packet(). A local authenticated attacker could exploit this vulnerability to cause a denial of service.

CVE-ID	Issue	Description
CVE-2024-39705	Natural Language Toolkit (NLTK) code execution	Natural Language Toolkit (NLTK) could allow a remote attacker to execute arbitrary code on the system, caused by a flaw when an untrusted packages have pickled Python code, and the integrated data package download functionality is used. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-40901	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by out-of-bounds access when using test_bit() in mpt3sas_base.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40904	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by CPU lockup due to excessive log messages. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40911	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL pointer dereference in util.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40912	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by deadlock in ieee80211_sta_ps_deliver_wakeup() in sta_info.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40929	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an out-of-bound access in iwlwifi/mvm/scan.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40931	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Mptcp. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40941	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in iwlwifi/mvm/fw.c . A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40954	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free in sock.c . A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40958	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a use-after-free in net_namespace.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40959	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a Null pointer dereference xfrm6_get_saddr() ip6_dst_idev(). A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40960	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a NULL Dereference in Rt6_probe(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40972	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in ext4. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40977	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by potential Hung Tasks During Chip Recovery in Wifi: Mt76: Mt7921. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40978	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Scsi: Qedi. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40988	drm/radeon: fix UBSAN warning in kv_dpm.c	In the Linux kernel, the following vulnerability has been resolved: drm/radeon: fix UBSAN warning in kv_dpm.c Adds bounds check for sumo_vid_mapping_entry.
CVE-2024-40989	KVM: arm64: Disassociate vcpus from redistributor region on teardown	In the Linux kernel, the following vulnerability has been resolved: KVM: arm64: Disassociate vcpus from redistributor region on teardown When tearing down a redistributor region, make sure we don't have any dangling pointer to that region stored in a vcpu.
CVE-2024-40995	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an infinite loop in Tcf_idr_check_alloc(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40997	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a memory leak on CPU EPP Exit. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-40998	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by uninitialized Ratelimit_state->Lock Access in __ext4_fill_super(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41005	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a race condition in netpoll_owner_active. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-41007	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Tcp. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41008	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in the handling and lifecycle of vm->task_info object. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.

CVE-ID	Issue	Description
CVE-2024-41012	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by improper locking flaw when fcntl/close race is detected. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-41013	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by an out-of-bound read flaw when accessing the fixed members. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2024-41014	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by the lack of verification of the space occupied by fixed members of xlog_op_header in the xlog_recover_process_data.. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2024-41023	Linux Kernel information disclosure	Linux Kernel could allow a local authenticated attacker to obtain sensitive information, caused by a task_struct reference leak flaw. By sending a specially crafted request, an attacker could exploit this vulnerability to obtain sensitive information or cause a denial of service condition.
CVE-2024-41035	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a duplicate endpoint bug in the usb_parse_endpoint() function. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-41038	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a buffer overrun when processing V2 alg headers. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-41039	Linux Kernel buffer overflow	Linux Kernel is vulnerable to a stack-based buffer overflow, caused by improper bounds checking by the wmfw header. By sending a specially crafted request, a local authenticated attacker could overflow a buffer and execute arbitrary code on the system.
CVE-2024-41040	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by a use-after-free flaw when resolving a clash. By sending a specially crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system.
CVE-2024-41041	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw related to set SOCK_RCU_FREE earlier in udp_lib_get_port(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-41044	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by an error related to ppp_async_encode() in ppp_generic.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41055	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by Null pointer dereference in mmzone.h. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41056	firmware: cs_dsp: Use strnlen() on name fields in V1 wmfw files	In the Linux kernel, the following vulnerability has been resolved: firmware: cs_dsp: Use strnlen() on name fields in V1 wmfw files Use strnlen() instead of strlen() on the algorithm and coefficient name string arrays in V1 wmfw files. In V1 wmfw files the name is a NUL-terminated string in a fixed-size array. cs_dsp should protect against overrunning the array if the NUL terminator is missing.
CVE-2024-41060	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by Null pointer dereference in radeon_gem.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41064	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Powerpc/Eeh. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41071	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Wifi: Mac80211. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41076	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in NFSv4. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41090	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by missing check against the validity of the frame length in the tap_get_user_xdp() path. By sending a specially crafted request, a local attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-41091	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by missing check against the validity of the frame length in the tun_xdp_one() path. By sending a specially crafted request, a local attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-41097	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Usb: Atm: Cxacru. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-41110	Moby authz zero length regression	Moby is an open-source project created by Docker for software containerization. A security vulnerability has been detected in certain versions of Docker Engine, which could allow an attacker to bypass authorization plugins (AuthZ) under specific circumstances. The base likelihood of this being exploited is low. Using a specially-crafted API request, an Engine API client could make the daemon forward the request or response to an authorization plugin without the body. In certain circumstances, the authorization plugin may allow a request which it would have otherwise denied if the body had been forwarded to it. A security issue was discovered In 2018, where an attacker could bypass AuthZ plugins using a specially crafted API request.

CVE-ID	Issue	Description
CVE-2024-41128	Action Dispatch has possible ReDoS vulnerability in query parameter filtering	Action Pack is a framework for handling and responding to web requests. Starting in version 3.1.0 and prior to versions 6.1.7.9, 7.0.8.5, 7.1.4.1, and 7.2.1.1, there is a possible ReDoS vulnerability in the query parameter filtering routines of Action Dispatch. Carefully crafted query parameters can cause query parameter filtering to take an unexpected amount of time, possibly resulting in a DoS vulnerability. All users running an affected release should either upgrade to version 6.1.7.9, 7.0.8.
CVE-2024-42084	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in ftruncate. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-42090	Linux Kernel denial of service pinctrl: fix deadlock in create_pinctrl() when handling -EPROBE_DEFER	Linux Kernel is vulnerable to a denial of service, caused by deadlock in create_pinctrl() when handling -EPROBE_DEFER. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-42094		
CVE-2024-42096		
CVE-2024-42114	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a lack of proper range validation by NL80211_ATTR_TXQ_QUANTUM in nl80211.c. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-42124	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a flaw in Scsi: Qedf. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-42131	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by integer overflow in dirty throttling logic. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-42152	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by memory leak in nvmet. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-42154	Linux Kernel information disclosure	Linux Kernel information disclosure
CVE-2024-42228	Linux Kernel code execution	Linux Kernel could allow a local authenticated attacker to execute arbitrary code on the system, caused by reusing uninitialized data when calling amdgpu_vce_cs_reloc in drm/amdgpu. By sending a specially-crafted request, an attacker could exploit this vulnerability to execute arbitrary code on the system or or cause a denial of service condition..
CVE-2024-42237	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by improperly validating payload length in cs_dsp_load() and cs_dsp_coeff_load(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-42238	Linux Kernel buffer overflow	Linux Kernel is vulnerable to a buffer overflow, caused by improper bounds checking in cs_dsp_power_up(). By sending a specially crafted request, a remote attacker could overflow to cause a denial of service.
CVE-2024-42240	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by infinite loop in x86/bhi. By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-42246	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by connection failure in xs_tcp_setup_socket. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-42265	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by the failure to protect the fetch of ->fd[fd] in do_dup2() from mispredictions. A local authenticated attacker could exploit this vulnerability to cause a denial of service.
CVE-2024-42322		
CVE-2024-43788	Webpack and Rspack cross-site scripting	Webpack and Rspack are vulnerable to cross-site scripting, caused by improper validation of user-supplied input. A remote authenticated attacker could exploit this vulnerability to inject malicious script into a Web page which would be executed in a victim's Web browser within the security context of the hosting Web site, once the page is viewed. An attacker could use this vulnerability to steal the victim's cookie-based authentication credentials.

CVE-ID	Issue	Description
CVE-2024-43798	Chisel AUTH environment variable not respected in server entrypoint	Chisel is a fast TCP/UDP tunnel, transported over HTTP, secured via SSH. The Chisel server doesn't ever read the documented `AUTH` environment variable used to set credentials, which allows any unauthenticated user to connect, even if credentials were set. Anyone running the Chisel server that is using the `AUTH` environment variable to specify credentials to authenticate against is affected by this vulnerability. Chisel is often used to provide an entrypoint to a private network, which means services that are gated by Chisel may be affected. Additionally, Chisel is often used for exposing services to the internet. An attacker could MITM requests by connecting to a Chisel server and requesting to forward traffic from a remote port. This issue has been addressed in release version 1.10.0.
CVE-2024-43830		
CVE-2024-43871	Linux Kernel denial of service	Linux Kernel is vulnerable to a denial of service, caused by a memory leakage when using driver API devm_free_percpu(). By sending a specially crafted request, a local authenticated attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-45614	Puma HTTP request smuggling	Puma is vulnerable to HTTP request smuggling, caused by improper parsing of the HTTP X-Forwarded-For header. By sending a specially crafted HTTP(S) X-Forwarded-For header, an attacker could exploit this vulnerability to poison the web cache, bypass web application firewall protection, and conduct XSS attacks.
CVE-2024-45801	DOMPurify code execution	DOMPurify could allow a remote attacker to execute arbitrary code on the system, caused by a prototype pollution flaw in depth check. By adding or modifying properties of Object.prototype using a **proto** or constructor payload, an attacker could exploit this vulnerability to execute arbitrary code or cause a denial of service condition on the system.
CVE-2024-47875		
CVE-2024-47887	rails denial of service	railsis vulnerable to a denial of service, caused by a regular expression denial of service (ReDoS) flaw in HTTP Token authentication in Action Controller. By sending a specially crafted regex input, a remote attacker could exploit this vulnerability to cause a denial of service condition.
CVE-2024-47888	rails denial of service	Action Text brings rich text content and editing to Rails. Starting in version 6.0.0 and prior to versions 6.1.7.9, 7.0.8.5, 7.1.4.1, and 7.2.1.1, there is a possible ReDoS vulnerability in the `plain_text_for_blockquote_node helper` in Action Text. Carefully crafted text can cause the `plain_text_for_blockquote_node` helper to take an unexpected amount of time, possibly resulting in a DoS vulnerability. All users running an affected release should either upgrade to versions 6.1.7.9, 7.0.8.5, 7.
CVE-2024-47889	rails denial of service	railsis vulnerable to a denial of service, caused by a regular expression denial of service (ReDoS) flaw in block_format in Action Mailer. By sending a specially crafted regex input, a remote attacker could exploit this vulnerability to cause a denial of service condition.

Fixed security-related vulnerabilities in previous versions

Review the following documentation, which includes the list of fixed reported security-related vulnerabilities in previous versions of IBM Cloud Pak for AIOps:

- Fixed security-related vulnerabilities in version 4.7.0
- Fixed security-related vulnerabilities in version 4.6.1
- Fixed security-related vulnerabilities in version 4.6.0
- Fixed security-related vulnerabilities in version 4.5.1
- Fixed security-related vulnerabilities in version 4.5.0
- Fixed security-related vulnerabilities in version 4.4.1
- Fixed security-related vulnerabilities in version 4.4.0
- Fixed security-related vulnerabilities in version 4.3.0
- Fixed security-related vulnerabilities in version 4.2.1
- Fixed security-related vulnerabilities in version 4.2.0
- Fixed security-related vulnerabilities in version 4.1.2
- Fixed security-related vulnerabilities in version 4.1.1
- Fixed security-related vulnerabilities in version 4.1.0

Fixed Support originated issues in IBM Cloud Pak for AIOps 4.7.1

Review the following list of fixed issues that were reported through IBM Support cases.

Fixed Support originated issues

Fixed install and upgrade issues

Fixed issue	Problem description
Installing - Incorrect registry configuration can break mirroring for offline installs	TBD
ELK Integration	TBD
Instana connector - List of services entity type metrics is not retrieved	Integration does not query all pages with the API
Netcool Connector - Mis-matched events between Netcool and Cloud Pak for AIOps	The integration connector thread stops running, while the pod still runs with an *Unknown* status being shown in the UI.
Netcool Connector - Performance issue with queries (mapping JSON payload)	TBD
Netcool connector - Missing alerts and parsing issues	TBD
Netcool Connector - Missing alerts	TBD
Netcool Connector - PVC capacity overflow	TBD
Netcool Connector - PVC capacity Overflow	TBD
event filtering	TBD
event filtering not working	TBD
cp4waiops-eventprocessor-eve-29ee-ep-taskmanager pods continuously restarting	TBD
Infrastructure Automation - Synchronization with Azure cloud provider does not work	TBD
Infrastructure Automation - Service provisioning stopped working	TBD
Messaging keystore password with special characters fails appliance setup	TBD
Infrastructure Automation - Memcached pod failed as certificate as expired	IBM Cloud Pak for AIOps is up and running but Infrastructure Automation is down, with the login page showing `504 Gateway Time-out`.
Incorrect ServiceMonitor resource crashes monitoring	When Red Hat OpenShift is configured for user monitoring to fetch metrics, the Prometheus monitoring ended in a CrashLoopBackOff. This issue is related to a reported Red Hat issue: https://issues.redhat.com/browse/OCPBUGS-23252.
Temporal and Seasonality trainings failed when there were 0 alerts in the database	When 0 alerts are in the database, training failed and models were not created. As a workaround, verify that you have at least three months of historical event data so the algorithm can learn alert patterns and discover groups.

Fixed Support originated issues in previous versions

Review the following documentation, which includes the list of fixed Support originated issues in previous versions of IBM Cloud Pak for AIOps:

- Fixed Support originated issues in version 4.6.1
- Fixed Support originated issues in version 4.6.0

Fixed security vulnerabilities

For the list of fixed security-related vulnerabilities, see Security bulletins and fixes.

Known issues and limitations

Glossary

This glossary provides terms and definitions for IBM Cloud Pak® for AIOps.

The following cross-references are used in this glossary:

- *See* refers you from a nonpreferred term to the preferred term or from an abbreviation to the spelled-out form.
- *See also* refers you to a related or contrasting term.

While IBM values the use of inclusive language, terms that are outside of IBM's direct influence are sometimes required for the sake of maintaining user understanding. As other industry leaders join IBM in embracing the use of inclusive language, IBM will continue to update the documentation to reflect those changes.

A

accelerator

A set of assets that enable customers to understand core concepts and implement solutions.

AI model

In a machine learning context, a set of functions and algorithms that are trained and tested on a data set to provide predictions or decisions. See also training definition training definition.

alert

A record of an event indicating a fault in the managed environment.

anomaly

A deviation from the expected baseline behaviors.

application

One or more computer programs or software components that provide a function in direct support of a specific business process or processes.

application mapping

Used to expose the on-premises IBM Cloud Pak for AIOps instance to the public cloud. After the application mapping is created, IBM Cloud Pak for AIOps can be accessed from Slack.

auto-remediation

The process of resolving an issue with minimal or no human intervention.

B

boot node

The OpenShift cluster node that is used for running installation, configuration, node scaling, and cluster updates.

C

capability

The core functions of a service. For example, the XYZ service provides "monitoring" capability.

CD

See continuous delivery.

change risk

The risk associated with implementing any type of change, whether it is to code, configurations, or data. See also risk score.

CI

See continuous integration.

connector

The means by which a data source is connected to a product or service. See also integration.

continuous delivery (CD)

A software development practice that employs techniques such as continuous testing, continuous integration, and continuous deployment so that new features and fixes are packaged and deployed rapidly and at low risk to test environments and then to customers.

continuous integration (CI)

A software development practice where members of a team integrate their work frequently so that there are multiple integrations each day. Integrations are verified by an automated build to detect integration errors as quickly as possible.

coverage

A qualitative determination of the AI's ability to produce insights from your incoming data flow as a result of it's training. See also training definition.

CRD

See custom resource definition.

custom resource

An instance of a custom resource definition. See also custom resource definition.

custom resource definition (CRD)

A customizable YAML file that defines a logically related group of objects in a cluster. Custom resource definitions enable a custom resource to be used like any native Kubernetes object in the cluster. See also custom resource.

D

data set

Data that is extracted and organized from data streams. Data sets serve as inputs for pipelines to train, retrain, or tune models.

data stream

A set of processes that convert extracted data into a normalized data set.

E

edge

The relationship, or link, between resources. See also hop, seed.

error

The fault in an event that causes a failure.

event

A change in state of a service or system.

F

failure

The surfacing of an error to the user.

fault

An error in the internal state of a component in a system.

field mapping

The assignment of values from one integration type to a standard set of values. When one maps source fields, one replaces or supplements those values with new or different values.

H

hop

A step along a single edge from one resource to another. See also edge, seed.

I

incident

An unplanned interruption that causes, may cause, or reduces the quality of an IT service. See also incident.

integration

Any independent application that provides additional capabilities to an IBM service or base product. See also connector.

issue

A cause or potential cause of one or more recurring or similar tickets or incidents.

L

log

Data output from an application or service that describes a transaction or state occurring in that application or service.

M

mean time between failures (MTBF)

The average time between failures.

mean time to failure (MTTF)

The average amount of time before a system lapses into a failed state.

mean time to detect (MTTD)

The average amount of time it takes to identify a failure.

mean time to resolve (MTTR)

The total time period from the start of a failure to when the failure resolves and operations resume.

O

observer

A service that extracts resource information and provides topology data for integrations and localization and blast radius information for events published to ChatOps integrations.

observer job

An automated scheduled task that retrieves topological details for a target system.

operand

The service component used by an operator to perform actions.

operator

A system design that simulates user behavior by linking a controller to custom resources, simulating the act of observing differences in states then acting on them.

P

pipeline

A set of iterative processes that transforms data into insights. For example, retraining pipelines take additional training data sets and improves existing models based on new insights.

proactive channel

A ChatOps channel that is used for change risk notifications. See also reactive channel.

probable cause

A rank-based indicator of causal likelihood that is based on the analysis of alerts and associated topology within the context of an incident.

problem

See issue.

R

reactive channel

A ChatOps channel that is used for outgoing incidents and alerts. See also proactive channel.

resource

A physical or logical component that can be provisioned or reserved for an application or service instance. Examples of resources can include storage, processors, memory, clusters, and VMs.

risk score

A value derived to describe risk across several dimensions associated with change. See also change risk.

RPO (Recovery point objective)

The application loss tolerance, such as the amount of data that can be lost before significant harm to the application occurs.

RTA (Recovery Time Actual)

The actual time that is required for an application to recover completely.

RTO (Recovery Time Objective)

The time that an application can be down without causing significant damage. RTA should be less than RTO.

S

secure tunnel

A feature to package TCP requests and responses, encrypt them with HTTPS, and transport the payloads between IBM Cloud Pak for AIOps and Slack. With Secure Tunnel, you can integrate IBM Cloud Pak for AIOps with Slack without creating firewall rules and policies.

seed

A single resource that serves as the starting point of a topology. Once defined, the topology view is expanded one hop at a time. See also edge, hop.

service

In IBM Cloud Pak solutions, a set of capabilities that provide functionality to a product.

service catalog

A curated repository of services that users can discover and instantiate for use within their organization's applications.

incident

A collection of insights derived from different data sources (logs, events, and alerts) that represent the products' determination of an incident. Incidents build understanding and drive remediation.

T

ticket

A formal record of identified issues or requests that are created against an item and assigned to appropriate users to resolve those issues or complete the requests.

topology

An arrangement of specific, interconnected assets and resources within a network or application.

topology template

A defined topology pattern that is used to dynamically generate topologies based on matching conditions from previously established topologies in the topology database.

training definition

The established model that serves as the baseline for your data to be measured against. For example, your AI model for log anomalies acts as the training definition for all of your log anomaly integrations. See also AI model, coverage.

tunnel worker

Server side of a TCP-over-HTTPS tunnel. It is developed based on OSS project, and is installed in the IBM Cloud Pak for AIOps cluster.

tunnel connection

Used to manage IBM Cloud Pak for AIOps instance that you want to expose. If you want to expose on-premises IBM Cloud Pak for AIOps for Slack integration, first you need to create a tunnel connection.

tunnel connector

Client side of a TCP-over-HTTPS tunnel. It is developed based on OSS project, and can be installed in an OpenShift cluster. Ensure that the OpenShift cluster can be accessed from the public network, and the cluster domain certificate is signed.
