About this DSM Configuration Guide.....	xxxvii
<b>Part 1. QRadar DSM installation and log source management.....</b>	<b>1</b>
Chapter 1. Event collection from third-party devices.....	3
Adding a DSM.....	4
Chapter 2. Introduction to log source management.....	5
Adding a log source.....	5
Adding a log source by using the <b>Log Sources</b> icon.....	7
Adding bulk log sources.....	8
Adding bulk log sources by using the Log Sources icon.....	9
Editing bulk log sources.....	10
Editing bulk log sources by using the Log Sources icon.....	11
Adding a log source parsing order.....	11
QRadar DSM installations and log source management FAQ.....	12
Testing log sources.....	12
Protocols available for testing.....	12
Log source groups.....	13
Creating a log source group.....	13
Copying and removing log sources.....	14
Removing a log source group.....	14
Chapter 3. Gateway log source.....	15
Log source identifier pattern.....	16
Chapter 4. Log source extensions.....	19
Examples of log source extensions on QRadar Support Forums .....	19
Patterns in log source extension documents.....	20
Match groups .....	20
Matcher (matcher).....	21
JSON matcher (json-matcher).....	26
LEEF matcher (leef-matcher).....	30
CEF matcher (cef-matcher).....	31
Name Value Pair matcher (namevaluepair-matcher).....	31
Generic List matcher (genericlist-matcher).....	33
XML Matcher (xml-matcher).....	34
Multi-event modifier (event-match-multiple).....	35
Single-event modifier (event-match-single).....	35
Extension document template.....	36
Creating a log source extensions document to get data into QRadar.....	38
Common regular expressions .....	39
Building regular expression patterns .....	40
Uploading extension documents to QRadar.....	42
Examples of parsing issues.....	42
Chapter 5. Manage log source extensions.....	45
Adding a log source extension.....	45
Chapter 6. Threat use cases by log source type.....	47

Chapter 7. Troubleshooting DSMs.....	59
<b>Part 2. QRadar protocol configuration.....</b>	<b>63</b>
Chapter 8. Undocumented protocols.....	65
Configuring an undocumented protocol.....	65
Chapter 9. Protocol configuration options.....	67
Akamai Kona REST API protocol configuration options.....	67
Alibaba Cloud Object Storage protocol configuration options.....	69
Alibaba Cloud Simple Log Service protocol configuration options.....	71
Alibaba Cloud Simple Log Service protocol workflow.....	73
Amazon AWS S3 REST API protocol configuration options.....	76
Amazon Web Services protocol configuration options.....	83
Apache Kafka protocol configuration options.....	96
Configuring Apache Kafka to enable Client Authentication.....	102
Configuring Apache Kafka to enable SASL Authentication.....	105
Troubleshooting Apache Kafka .....	107
Blue Coat Web Security Service REST API protocol configuration options.....	108
Centrify Redrock REST API protocol configuration options.....	108
Cisco Duo protocol configuration options.....	110
Cisco Duo protocol workflow.....	112
Cisco Firepower eStreamer protocol configuration options.....	115
Cisco NSEL protocol configuration options.....	116
EMC VMware protocol configuration options.....	117
Forwarded protocol configuration options.....	117
Google Cloud Pub/Sub protocol configuration options.....	117
Configuring Google Cloud Pub/Sub to integrate with QRadar.....	120
Adding a Google Cloud Pub/Sub log source in QRadar.....	121
Google G Suite Activity Reports REST API protocol options.....	122
Google G Suite Activity Reports REST API protocol FAQ.....	123
HCL BigFix SOAP protocol configuration options (formerly known as IBM BigFix).....	124
HTTP Receiver protocol configuration options.....	125
Setting up certificate-based authentication for HTTP Receiver.....	131
IBM Cloud Object Storage protocol configuration options.....	132
IBM Fiberlink REST API protocol configuration options.....	134
IBM Security Randori REST API protocol configuration options.....	136
IBM Security Randori REST API protocol workflow.....	138
IBM Security QRadar EDR REST API protocol configuration options.....	141
IBM Security QRadar EDR REST API protocol workflow.....	143
IBM Security Verify Event Service protocol configuration options.....	144
JDBC protocol configuration options.....	147
JDBC - SiteProtector protocol configuration options.....	152
Juniper Networks NSM protocol configuration options.....	154
Juniper Security Binary Log Collector protocol configuration options.....	155
Log File protocol configuration options.....	155
Microsoft Azure Event Hubs protocol configuration options.....	160
Configuring Microsoft Azure Event Hubs to communicate with QRadar.....	166
Configuring VNet Flow Logs on the Microsoft Azure portal.....	168
Troubleshooting Microsoft Azure Event Hubs protocol.....	169
Microsoft Defender for Endpoint SIEM REST API protocol configuration options.....	176
Microsoft DHCP protocol configuration options.....	179
Microsoft Exchange protocol configuration options.....	181
Microsoft Graph Security API protocol configuration options.....	184
Configuring Microsoft Graph Security API to communicate with QRadar.....	187

Migrating Microsoft Defender for Endpoint REST API log sources to Microsoft Graph	188
Security API log sources.....	188
Microsoft IIS protocol configuration options.....	189
Microsoft Security Event Log protocol configuration options.....	191
Microsoft Security Event Log over MSRPC protocol.....	191
MQ protocol configuration options.....	192
Office 365 Message Trace REST API protocol configuration options.....	194
Troubleshooting the Office 365 Message Trace REST API protocol.....	196
Office 365 REST API protocol configuration options.....	200
Creating self-signed certificates and keys for Office 365 REST API protocol.....	201
Uploading a self-signed certificate to Azure portal.....	202
Okta REST API protocol configuration options.....	202
OPSEC/LEA protocol configuration options.....	203
Oracle Database Listener protocol configuration options.....	205
PCAP Syslog Combination protocol configuration options.....	207
RabbitMQ protocol configuration options.....	209
Copy the server certificate.....	210
SDEE protocol configuration options.....	210
Seculert Protection REST API protocol configuration options.....	211
Seculert Protection REST API protocol workflow.....	214
SMB Tail protocol configuration options.....	216
SNMPv2 protocol configuration options.....	219
SNMPv3 protocol configuration options.....	220
Sophos Enterprise Console JDBC protocol configuration options.....	221
Sophos Central protocol configuration options.....	223
Sourcefire Defense Center eStreamer protocol options.....	224
Syslog Redirect protocol overview.....	224
TCP Multiline Syslog protocol configuration options.....	226
TLS Syslog protocol configuration options.....	231
Multiple log sources over TLS Syslog.....	237
UDP multiline syslog protocol configuration options.....	237
VMware vCloud Director protocol configuration options.....	240
 Chapter 10. Universal Cloud REST API protocol.....	243
Workflow.....	245
Workflow Parameter Values.....	246
State.....	246
Actions.....	247
Abort.....	247
Add.....	248
CallEndpoint.....	248
ClearStatus.....	255
Copy.....	255
Create JWTAccessToken.....	255
Delete.....	256
DoWhile.....	257
ForEach.....	257
FormatDate.....	258
GenerateHMAC.....	258
If/ElseIf/Else.....	259
Initialize.....	260
Log.....	261
Merge.....	261
ParseDate.....	262
PostEvent.....	262
PostEvents.....	263
RegexCapture.....	264
Set.....	265

SetStatus.....	266
Sleep.....	266
Split.....	266
While.....	267
XPathQuery.....	268
JPPath.....	268
Basic selection.....	268
Query.....	269
Arithmetic operations in JSON elements.....	271
Functions in JPath expressions.....	272
Command line testing tool.....	273
Chapter 11. Protocols that support Certificate Management.....	275
<b>Part 3. DSMs.....</b>	<b>277</b>
Chapter 12. 3Com Switch 8800.....	279
Configuring your 3COM Switch 8800 .....	280
Chapter 13. AhnLab Policy Center.....	281
Chapter 14. Akamai Kona.....	283
Configure an Akamai Kona log source by using the HTTP Receiver protocol.....	283
Configure an Akamai Kona log source by using the Akamai Kona REST API protocol.....	284
Configuring Akamai Kona to communicate with QRadar.....	286
Creating an event map for Akamai Kona events.....	286
Modifying the event map for Akamai Kona.....	287
Akamai Kona sample event messages.....	288
Chapter 15. Alibaba ActionTrail.....	291
Alibaba ActionTrail sample event message.....	291
Chapter 16. Amazon.....	293
Amazon AWS Application Load Balancer Access Logs.....	293
Amazon AWS Application Load Balancer Access Logs DSM specifications.....	293
Publishing flow logs to an S3 bucket.....	294
Create an SQS queue and configure S3 ObjectCreated notifications.....	294
Amazon AWS S3 REST API log source parameters for Amazon AWS Application Load Balancer Access Logs.....	304
Amazon AWS Application Load Balancer Access Logs sample event message.....	305
Amazon AWS CloudTrail.....	305
Configuring an Amazon AWS CloudTrail log source by using the Amazon AWS S3 REST API protocol.....	307
Configuring an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol.....	326
Configuring an Amazon AWS CloudTrail log source that uses Amazon Security Lake.....	339
Amazon AWS CloudTrail sample event messages.....	339
AWS Config.....	340
Enabling AWS Config logs.....	341
Configuring an Amazon AWS Config log source by using the Amazon AWS S3 REST API protocol.....	342
Amazon AWS Elastic Kubernetes Service.....	359
Amazon AWS Elastic Kubernetes Service DSM specifications.....	360
Configuring Amazon Elastic Kubernetes Service to communicate with QRadar.....	360
Configuring security credentials for your AWS user account.....	361
Amazon Web Services log source parameters for Amazon AWS Elastic Kubernetes Service... 361	361
Amazon AWS Elastic Kubernetes Service sample event messages.....	364

Amazon AWS Network Firewall.....	366
Amazon AWS Network Firewall DSM specifications.....	366
Create an SQS queue and configure S3 ObjectCreated notifications.....	367
Amazon AWS S3 REST API log source parameters for Amazon AWS Network Firewall.....	375
AWS Network Firewall sample event messages.....	376
Amazon AWS Route 53.....	377
Amazon AWS Route 53 DSM specifications.....	377
Configuring an Amazon AWS Route 53 log source by using the Amazon Web Services protocol and CloudWatch logs.....	378
Configuring an Amazon AWS Route 53 log source by using an S3 bucket with an SQS queue.....	386
Configuring an Amazon AWS Route 53 log source by using an S3 bucket with a directory prefix.....	399
Configuring an Amazon Route 53 log source that uses Amazon Security Lake.....	405
Amazon AWS Route 53 sample event messages.....	406
Amazon AWS Security Hub.....	407
Amazon AWS Security Hub DSM specifications.....	408
Creating an EventBridge rule for sending events.....	408
Creating an Identity and Access (IAM) user in the AWS Management Console.....	409
Amazon Web Services log source parameters for Amazon AWS Security Hub.....	409
Amazon AWS Security Hub sample event message.....	409
Amazon AWS WAF.....	410
Amazon AWS WAF DSM specifications.....	410
Configuring Amazon AWS WAF to communicate with QRadar.....	411
Configuring security credentials for your AWS user account.....	412
Amazon AWS S3 REST API log source parameters for Amazon AWS WAF.....	412
Amazon AWS WAF sample event messages.....	413
Amazon CloudFront.....	414
Configuring an Amazon CloudFront log source by using the Amazon Web Services protocol.....	415
Amazon CloudFront sample event message.....	421
Configuring security credentials for your AWS user account.....	421
Amazon GuardDuty.....	422
Configuring an Amazon GuardDuty log source by using the Amazon Web Services protocol.....	422
Creating an EventBridge rule for sending events.....	425
Creating an Identity and Access (IAM) user in the AWS Management Console.....	426
Configuring an Amazon GuardDuty log source by using the Amazon AWS S3 REST API protocol.....	426
Configuring an Amazon GuardDuty log source that uses Amazon Security Lake.....	429
Create an SQS queue and configure S3 ObjectCreated notifications.....	430
Configuring Amazon GuardDuty to forward events to an AWS S3 Bucket.....	439
Adding an Amazon GuardDuty log source on the QRadar Console using an SQS queue.....	439
Amazon GuardDuty sample event messages.....	443
Amazon VPC Flow Logs.....	445
Amazon VPC Flow Logs specifications.....	449
Publishing flow logs to an S3 bucket.....	449
Create the SQS queue that is used to receive ObjectCreated notifications.....	450
Configuring security credentials for your AWS user account.....	450
AWS Verified Access.....	450
AWS Verified Access DSM specifications.....	451
Configuring an AWS Verified Access log source by using the Amazon AWS S3 REST API protocol.....	451
Chapter 17. Ambiron TrustWave ipAngel .....	471
Chapter 18. APC UPS.....	473
Configuring your APC UPS to forward syslog events.....	474
APC UPS sample event messages.....	474
Chapter 19. Apache HTTP Server.....	475

Configuring Apache HTTP Server with syslog.....	475
Syslog log source parameters for Apache HTTP Server.....	476
Configuring Apache HTTP Server with syslog-ng.....	476
Syslog log source parameters for Apache HTTP Server.....	477
Apache HTTP Server sample event messages.....	478
 Chapter 20. Apple Mac OS X.....	479
Apple Mac OS X DSM specifications.....	479
Syslog log source parameters for Apple Mac OS X.....	479
Configuring syslog on your Apple Mac OS X.....	480
Apple Mac OS X sample event message.....	482
 Chapter 21. Application Security DbProtect.....	483
Installing the DbProtect LEEF Relay Module.....	484
Configuring the DbProtect LEEF Relay.....	484
Configuring DbProtect alerts.....	485
 Chapter 22. Arbor Networks.....	487
Arbor Networks Peakflow SP.....	487
Supported event types for Arbor Networks Peakflow SP .....	488
Configuring a remote syslog in Arbor Networks Peakflow SP.....	488
Configuring global notifications settings for alerts in Arbor Networks Peakflow SP.....	488
Configuring alert notification rules in Arbor Networks Peakflow SP.....	489
Syslog log source parameters for Arbor Networks Peakflow SP.....	489
Arbor Networks Pravail.....	490
Configuring your Arbor Networks Pravail system to send events to IBM QRadar.....	491
Arbor Networks Pravail sample event message.....	492
 Chapter 23. Arpeggio SIFT-IT.....	493
Configuring a SIFT-IT agent.....	493
Syslog log source parameters for Arpeggio SIFT-IT.....	494
Additional information.....	494
 Chapter 24. Array Networks SSL VPN.....	497
Syslog log source parameters for Array Networks SSL VPN.....	497
 Chapter 25. Aruba Networks.....	499
Aruba ClearPass Policy Manager.....	499
Configuring Aruba ClearPass Policy Manager to communicate with QRadar.....	500
TCP Multiline Syslog log source parameters for Aruba ClearPass Policy Manager.....	509
Aruba ClearPass Policy Manager sample event message.....	511
Aruba Introspect.....	511
Configuring Aruba Introspect to communicate with QRadar.....	513
Aruba Mobility Controllers.....	514
Configuring your Aruba Mobility Controller.....	514
Syslog log source parameters for Aruba Mobility Controllers.....	515
Aruba Mobility Controllers sample event messages.....	515
 Chapter 26. Avaya VPN Gateway.....	517
Avaya VPN Gateway DSM integration process.....	517
Configuring your Avaya VPN Gateway system for communication with IBM QRadar.....	518
Syslog log source parameters for Avaya VPN Gateway.....	518
Avaya VPN Gateway sample event messages.....	518
 Chapter 27. BalaBit IT Security.....	521
BalaBit IT Security for Microsoft Windows Events.....	521
Configuring the Syslog-ng Agent event source.....	521
Configuring a syslog destination.....	522

Restarting the Syslog- <i>ng</i> Agent service.....	523
Syslog log source parameters for BalaBit IT Security for Microsoft Windows Events.....	523
BalaBit IT Security for Microsoft ISA or TMG Events.....	523
Configure the BalaBit Syslog- <i>ng</i> Agent.....	524
Configuring the BalaBit Syslog- <i>ng</i> Agent file source.....	524
Configuring a BalaBit Syslog- <i>ng</i> Agent syslog destination.....	525
Filtering the log file for comment lines.....	525
Configuring a BalaBit Syslog- <i>ng</i> PE Relay.....	526
Syslog log source parameters for BalaBit IT Security for Microsoft ISA or TMG Events.....	527
 Chapter 28. Barracuda.....	529
Barracuda Spam & Virus Firewall.....	529
Configuring syslog event forwarding.....	529
Syslog log source parameters for Barracuda Spam Firewall.....	529
Barracuda Spam and Virus Firewall sample event messages.....	530
Barracuda Web Application Firewall.....	531
Configuring Barracuda Web Application Firewall to send syslog events to QRadar.....	532
Configuring Barracuda Web Application Firewall to send syslog events to QRadar for devices that do not support LEEF .....	532
Barracuda Web Filter.....	533
Configuring syslog event forwarding.....	534
Syslog log source parameters for Barracuda Web Filter.....	534
Barracuda Web Filter sample event message.....	534
 Chapter 29. BeyondTrust Privilege Management for Unix, Linux and Networked Devices.....	537
Syslog log source parameters for BeyondTrust Privilege Management for Unix, Linux and Networked Devices.....	537
TLS Syslog log source parameters for BeyondTrust Privilege Management for Unix, Linux and Networked Devices.....	538
Configuring BeyondTrust Privilege Management for Unix, Linux and Networked Devices to communicate with QRadar.....	538
BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM specifications..	540
BeyondTrust Privilege Management for Unix, Linux and Networked Devices sample event message.....	541
 Chapter 30. BlueCat Networks Adonis.....	543
Supported event types.....	543
Event type format.....	543
Configuring BlueCat Adonis.....	543
Syslog log source parameters for BlueCat Networks Adonis.....	544
 Chapter 31. Blue Coat.....	545
Blue Coat SG.....	545
Creating a custom event format.....	546
Creating a log facility.....	547
Enabling access logging.....	547
Configuring Blue Coat SG for FTP uploads.....	547
Syslog log source parameters for Blue Coat SG.....	548
Log File log source parameters for Blue Coat SG.....	549
Configuring Blue Coat SG for syslog.....	552
Creating extra custom format key-value pairs.....	552
Blue Coat SG sample event messages.....	553
Blue Coat Web Security Service.....	553
Configuring Blue Coat Web Security Service to communicate with QRadar.....	555
Blue Coat Web Security Service sample event message.....	555
 Chapter 32. Box.....	557
Configuring Box to communicate with QRadar.....	558

Box sample event messages.....	560
<b>Chapter 33. Bridgewater.....</b>	<b>563</b>
Configuring Syslog for your Bridgewater Systems Device.....	563
Syslog log source parameters for Bridgewater Systems.....	563
<b>Chapter 34. Broadcom.....</b>	<b>565</b>
<b>Broadcom CA ACF2.....</b>	<b>565</b>
Create a log source for near real-time event feed.....	566
Log File log source parameter.....	566
Integrate Broadcom CA ACF2 with IBM QRadar by using audit scripts.....	570
Configuring Broadcom CA ACF2 that uses audit scripts to integrate with IBM QRadar.....	571
<b>Broadcom CA Top Secret.....</b>	<b>574</b>
Log File log source parameter.....	575
Create a log source for near real-time event feed.....	579
Integrate Broadcom CA Top Secret with IBM QRadar by using audit scripts.....	579
Configuring Broadcom CA Top Secret that uses audit scripts to integrate with IBM QRadar.....	580
<b>Broadcom Symantec SiteMinder.....</b>	<b>583</b>
Broadcom Symantec SiteMinder DSM specifications.....	583
Syslog log source parameters for Broadcom Symantec SiteMinder.....	584
Configuring syslog-ng for Broadcom Symantec SiteMinder.....	585
Broadcom Symantec SiteMinder sample event messages.....	586
<b>Chapter 35. Brocade Fabric OS.....</b>	<b>587</b>
Configuring syslog for Brocade Fabric OS appliances.....	587
Brocade Fabric OS sample event messages.....	587
<b>Chapter 36. Carbon Black.....</b>	<b>589</b>
<b>Carbon Black.....</b>	<b>589</b>
Configuring Carbon Black to communicate with QRadar.....	590
Carbon Black sample event messages.....	591
<b>Carbon Black Bit9 Parity.....</b>	<b>591</b>
Syslog log source parameters for Carbon Black Bit9 Parity.....	592
<b>Bit9 Security Platform.....</b>	<b>592</b>
Configuring Carbon Black Bit9 Security Platform to communicate with QRadar.....	593
<b>Chapter 37. Centrify Infrastructure Services.....</b>	<b>595</b>
Configuring WinCollect agent to collect event logs from Centrify Infrastructure Services.....	596
Configuring Centrify Infrastructure Services on a UNIX or Linux device to communicate with QRadar .....	598
Centrify Infrastructure Services sample event messages.....	599
<b>Chapter 38. Check Point.....</b>	<b>603</b>
<b>Integrate Check Point by using syslog.....</b>	<b>603</b>
Syslog log source parameters for Check Point.....	604
Syslog sample event messages for Check Point.....	605
<b>Integrate Check Point by using OPSEC.....</b>	<b>606</b>
Adding a Check Point Host.....	606
Creating an OPSEC Application Object.....	606
Locating the log source SIC.....	607
OPSEC/LEA log source parameters for Check Point.....	608
Edit your OPSEC communications configuration.....	608
Changing the default port for OPSEC LEA communication.....	609
Configuring OPSEC LEA for unencrypted communications.....	609
<b>Integrating Check Point by using TLS Syslog.....</b>	<b>610</b>
TLS syslog log source parameters for Check Point.....	611
Syslog Redirect log source parameters for Check Point.....	612
Configuring Check Point to forward LEEF events to QRadar.....	613

Configuring QRadar to receive LEEF events from Check Point.....	615
Integration of Check Point Firewall events.....	615
Check Point Multi-Domain Management (Provider-1).....	615
Integrating syslog for Check Point Multi-Domain Management (Provider-1).....	616
Configuring OPSEC for Check Point Multi-Domain Management (Provider-1) .....	617
Check Point Multi-Domain Management (Provider-1) sample event messages.....	618
 Chapter 39. Cilasoft QJRN/400.....	619
Configuring Cilasoft QJRN/400.....	619
Syslog log source parameters for Cilasoft QJRN/400.....	620
 Chapter 40. Cisco .....	623
Cisco ACE Firewall.....	623
Configuring Cisco ACE Firewall.....	623
Syslog log source parameters for Cisco ACE Firewall.....	623
Cisco ACS.....	624
Configuring Syslog for Cisco ACS v5.x.....	624
Creating a Remote Log Target.....	624
Configuring global logging categories.....	625
Syslog log source parameters for Cisco ACS v5.x.....	625
Configuring Syslog for Cisco ACS v4.x.....	626
Configuring syslog forwarding for Cisco ACS v4.x.....	626
Syslog log source parameters for Cisco ACS v4.x.....	627
UDP Multiline Syslog log source parameters for Cisco ACS.....	627
Cisco ACS sample event messages.....	628
Cisco Aironet.....	629
Syslog log source parameters for Cisco Aironet.....	630
Cisco ASA.....	630
Integrate Cisco ASA Using Syslog.....	630
Configuring syslog forwarding.....	631
Syslog log source parameters for Cisco ASA.....	631
Integrate Cisco ASA for NetFlow by using NSEL.....	632
Configuring NetFlow Using NSEL.....	632
Cisco NSEL log source parameters for Cisco ASA.....	633
Removing leading domain names from usernames when Cisco ASA events are processed ....	634
Collecting IP addresses for Cisco ASA Teardown TCP connection events .....	634
Cisco ASA sample event message.....	634
Cisco AMP.....	635
Cisco AMP DSM specifications.....	636
Creating a Cisco AMP Client ID and API key for event queues.....	636
Creating a Cisco AMP event stream.....	637
Cisco AMP event stream configuration.....	639
Cisco AMP sample event message.....	641
Cisco CallManager.....	641
Configuring syslog forwarding .....	641
Syslog log source parameters for Cisco CallManager.....	642
Cisco CallManager sample event message.....	642
Cisco CatOS for Catalyst Switches.....	643
Configuring syslog forwarding for Cisco CatOS devices .....	643
Syslog log source parameters for Cisco CatOS for Catalyst Switches.....	643
Cisco CatOS for Catalyst Switches sample event messages.....	644
Cisco Cloud Web Security.....	645
Configuring Cloud Web Security to communicate with QRadar .....	647
Cisco CSA.....	648
Configuring Cisco CSA to send events to IBM QRadar.....	648
Syslog log source parameters for Cisco CSA.....	648
SNMPv1 log source parameters for Cisco CSA.....	649
SNMPv2 log source parameters for Cisco CSA.....	650

Cisco Duo.....	650
Cisco Duo DSM specifications.....	651
Configuring Cisco Duo to communicate with QRadar.....	651
Cisco Duo protocol log source parameters for Cisco Duo.....	652
Cisco Duo sample event messages.....	652
Cisco Firepower Management Center.....	653
Creating Cisco Firepower Management Center 5.x, 6.x, and 7.x certificates.....	656
Importing a Cisco Firepower Management Center certificate in QRadar.....	657
Cisco Firepower Management Center log source parameters.....	658
Cisco Firepower Threat Defense.....	659
Cisco Firepower Threat Defense DSM specifications.....	659
Configuring Cisco Firepower Threat Defense to communicate with QRadar.....	660
Configuring QRadar to use previous connection event processing for Cisco Firepower Threat Defense .....	660
Cisco Firepower Threat Defense sample event message.....	661
Cisco FWSM.....	661
Configuring Cisco FWSM to forward syslog events.....	662
Syslog log source parameters for Cisco FWSM.....	662
Cisco Identity Services Engine.....	662
Configuring a remote logging target in Cisco ISE.....	665
Configuring logging categories in Cisco ISE.....	665
Cisco Identity Services Engine sample event message.....	666
Cisco IDS/IPS.....	667
SDEE log source parameters for Cisco IDS/IPS.....	667
Cisco IOS.....	669
Configuring Cisco IOS to forward events.....	669
Syslog log source parameters for Cisco IOS.....	670
Cisco IOS sample event messages.....	670
Cisco IronPort.....	671
Cisco IronPort DSM specifications.....	672
Configuring Cisco IronPort appliances to communicate with QRadar.....	672
Configuring a Cisco IronPort and Cisco ESA log source by using the log file protocol.....	673
Configuring a Cisco IronPort and Cisco WSA log source by using the Syslog protocol.....	676
Cisco IronPort sample event message.....	676
Cisco Meraki.....	677
Cisco Meraki DSM specifications.....	678
Configure Cisco Meraki to communicate with IBM QRadar .....	678
Cisco Meraki sample event messages.....	679
Cisco NAC.....	680
Configuring Cisco NAC to forward events.....	680
Syslog log source parameters for Cisco NAC.....	680
Cisco Nexus.....	681
Configuring Cisco Nexus to forward events.....	681
Syslog log source parameters for Cisco Nexus.....	681
Cisco Nexus sample event message.....	682
Cisco Pix.....	682
Configuring Cisco Pix to forward events.....	682
Syslog log source parameters for Cisco Pix.....	683
Cisco Secure Workload.....	683
Cisco Secure Workload DSM specifications.....	684
Configure Cisco Secure Workload to communicate with IBM QRadar .....	684
Cisco Secure Workload sample event message.....	685
Cisco Stealthwatch.....	685
Configuring Cisco Stealthwatch to communicate with QRadar.....	686
Cisco Stealthwatch sample event messages.....	687
Cisco Umbrella.....	688
Configure Cisco Umbrella to communicate with QRadar.....	690
Cisco Umbrella DSM specifications.....	690

Cisco Umbrella sample event messages.....	690
Cisco VPN 3000 Concentrator .....	691
Syslog log source parameters for Cisco VPN 3000 Concentrator.....	692
Cisco Wireless LAN Controllers.....	692
Configuring syslog for Cisco Wireless LAN Controller.....	692
Syslog log source parameters for Cisco Wireless LAN Controllers.....	693
Configuring SNMPv2 for Cisco Wireless LAN Controller.....	694
Configuring a trap receiver for Cisco Wireless LAN Controller.....	695
SNMPv2 log source parameters for Cisco Wireless LAN Controllers.....	695
Cisco Wireless Services Module.....	696
Configuring Cisco WiSM to forward events.....	697
Syslog log source parameters for Cisco WiSM.....	698
 Chapter 41. Citrix.....	701
Citrix Access Gateway.....	701
Syslog log source parameters for Citrix Access Gateway.....	701
Citrix NetScaler.....	702
Syslog log source parameters for Citrix NetScaler.....	703
Citrix NetScaler sample event message.....	703
 Chapter 42. Cloudera Navigator.....	705
Configuring Cloudera Navigator to communicate with QRadar.....	706
 Chapter 43. Cloudflare Logs.....	707
Cloudflare Logs DSM specifications.....	707
Configure Cloudflare to send events to IBM QRadar when you use the HTTP Receiver protocol... <td>708</td>	708
Configuring Cloudflare Logs to send events to IBM QRadar when you use the Amazon S3 REST API protocol.....	709
Create an SQS queue and configure S3 ObjectCreated notifications.....	709
Finding the S3 bucket that contains the data that you want to collect.....	710
Creating the SQS queue that is used to receive ObjectCreated notifications.....	710
Setting up SQS queue permissions.....	711
Creating ObjectCreated notifications.....	712
Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge.....	718
Configuring security credentials for your AWS user account.....	719
HTTP Receiver log source parameters for Cloudflare Logs.....	719
Amazon AWS S3 REST API log source parameters for Cloudflare Logs.....	720
Cloudflare Logs sample event messages.....	721
 Chapter 44. CloudPassage Halo .....	725
Configuring CloudPassage Halo for communication with QRadar.....	725
Syslog log source parameters for CloudPassage Halo.....	727
Log File log source parameters for CloudPassage Halo.....	727
 Chapter 45. CloudLock Cloud Security Fabric.....	729
Configuring CloudLock Cloud Security Fabric to communicate with QRadar.....	730
 Chapter 46. Correlog Agent for IBM z/OS.....	731
Configuring your CorreLog Agent system for communication with QRadar.....	732
 Chapter 47. CrowdStrike Falcon.....	733
CrowdStrike Falcon DSM specifications.....	733
Configuring CrowdStrike Falcon to communicate with QRadar.....	734
Syslog log source parameters for CrowdStrike Falcon.....	737
CrowdStrike Falcon Host sample event message.....	737
 Chapter 48. CrowdStrike Falcon Data Replicator.....	739
CrowdStrike Falcon Data Replicator DSM specifications.....	739

Configuring CrowdStrike Falcon Data Replicator to communicate with IBM QRadar.....	740
Amazon AWS S3 REST API parameters for CrowdStrike Falcon Data Replicator log source.....	740
CrowdStrike Falcon Data Replicator sample event message.....	740
 Chapter 49. CRYPTOCard CRYPTO-Shield .....	743
Configuring syslog for CRYPTOCard CRYPTO-Shield .....	743
Syslog log source parameters for CRYPTOCard CRYPTO-Shield.....	743
 Chapter 50. CyberArk.....	745
CyberArk Identity.....	745
CyberArk Identity DSM specifications.....	745
Configuring CyberArk Identity to communicate with QRadar.....	746
CyberArk Identity sample event message.....	747
CyberArk Privileged Threat Analytics.....	747
Configuring CyberArk Privileged Threat Analytics to communicate with QRadar.....	748
CyberArk Vault.....	749
Configuring syslog for CyberArk Vault.....	749
Syslog log source parameters for CyberArk Vault.....	750
 Chapter 51. CyberGuard Firewall/VPN Appliance.....	751
Configuring syslog events.....	751
Syslog log source parameters for CyberGuard.....	751
 Chapter 52. Damballa Failsafe.....	753
Configuring syslog for Damballa Failsafe .....	753
Syslog log source parameters for Damballa Failsafe.....	753
 Chapter 53. DG Technology MEAS.....	755
Configuring your DG Technology MEAS system for communication with QRadar.....	755
 Chapter 54. Digital China Networks (DCN).....	757
Configuring a DCN DCS/DCRS Series Switch.....	757
Syslog log source parameters for DCN DCS/DCRS Series switches.....	758
 Chapter 55. Enterprise-IT-Security.com SF-Sherlock.....	759
Configuring Enterprise-IT-Security.com SF-Sherlock to communicate with QRadar.....	760
 Chapter 56. Epic SIEM.....	761
Configuring Epic SIEM 2014 to communicate with QRadar.....	762
Configuring Epic SIEM 2015 to communicate with QRadar.....	762
Configuring Epic SIEM 2017 to communicate with QRadar.....	764
Configuring Epic SIEM 2022 to communicate with QRadar.....	766
 Chapter 57. ESET Remote Administrator.....	767
Configuring ESET Remote Administrator to communicate with QRadar.....	768
 Chapter 58. Exabeam.....	769
Configuring Exabeam to communicate with QRadar.....	769
Exabeam sample event message.....	770
 Chapter 59. Extreme.....	771
Extreme 800-Series Switch.....	771
Configuring your Extreme 800-Series Switch.....	771
Syslog log source parameters for Extreme 800-Series Switches.....	771
Extreme Dragon.....	772
Creating a Policy for Syslog .....	772
Syslog log source parameters for Extreme Dragon.....	774
Configure the EMS to forward syslog messages.....	774

Configuring syslog-ng Using Extreme Dragon EMS V7.4.0 and later.....	774
Configuring syslogd Using Extreme Dragon EMS V7.4.0 and earlier.....	775
Extreme HiGuard Wireless IPS.....	775
Configuring Enterasys HiGuard .....	776
Syslog log source parameters for Extreme HiGuard.....	776
Extreme HiPath Wireless Controller.....	777
Configuring your HiPath Wireless Controller.....	777
Syslog log source parameters for Extreme HiPath.....	777
Extreme Matrix Router.....	778
Extreme Matrix K/N/S Series Switch.....	779
Extreme NetSight Automatic Security Manager .....	780
Extreme NAC.....	780
Syslog log source parameters for Extreme NAC.....	781
Extreme stackable and stand-alone switches.....	781
Extreme Networks ExtremeWare.....	782
Syslog log source parameters for Extreme Networks ExtremeWare.....	783
Extreme XSR Security Router.....	783
Syslog log source parameters for Extreme XSR Security Router.....	784
 Chapter 60. F5 Networks.....	785
F5 Networks BIG-IP AFM.....	785
Configuring a logging pool.....	785
Creating a high-speed log destination.....	786
Creating a formatted log destination.....	786
Creating a log publisher.....	786
Creating a logging profile.....	787
Associating the profile to a virtual server.....	787
Syslog log source parameters for F5 Networks BIG-IP AFM.....	788
F5 Networks BIG-IP AFM sample event message.....	788
F5 Networks BIG-IP APM.....	789
Configuring Remote Syslog for F5 BIG-IP APM V11.x to V14.x .....	789
Configuring a Remote Syslog for F5 BIG-IP APM 10.x .....	789
Syslog log source parameters for F5 Networks BIG-IP APM.....	790
F5 Networks BIG-IP APM sample event message.....	790
F5 Networks BIG-IP ASM.....	791
Syslog log source parameters for F5 Networks BIG-IP ASM.....	791
F5 Networks BIG-IP ASM sample event messages.....	792
F5 Networks BIG-IP LTM.....	794
F5 Networks BIG-IP LTM DSM specifications.....	795
Syslog log source parameters for F5 Networks BIG-IP LTM.....	795
Configuring syslog forwarding in BIG-IP LTM .....	796
Configuring Remote Syslog for F5 BIG-IP LTM V11.x to V14.x .....	796
Configuring Remote Syslog for F5 BIG-IP LTM V10.x .....	796
Configuring Remote Syslog for F5 BIG-IP LTM V9.4.2 to V9.4.8.....	797
F5 Networks BIG-IP LTM sample event messages.....	797
F5 Networks FirePass.....	798
Configuring syslog forwarding for F5 FirePass.....	798
Syslog log source parameters for F5 Networks FirePass.....	799
 Chapter 61. Fair Warning.....	801
Log File log source parameters for Fair Warning.....	801
Fair Warning sample event messages.....	801
 Chapter 62. Fasoo Enterprise DRM.....	803
Configuring Fasoo Enterprise DRM to communicate with QRadar.....	808
 Chapter 63. Fidelis XPS.....	809
Configuring Fidelis XPS.....	809

Syslog log source parameters for Fidelis XPS.....	810
Fidelis XPS sample event messages.....	810
 Chapter 64. FireEye.....	813
Configuring your FireEye system for communication with QRadar.....	815
Configuring your FireEye HX system for communication with QRadar.....	815
Configuring a FireEye log source in QRadar.....	816
FireEye sample event message.....	816
 Chapter 65. Forcepoint.....	819
Forcepoint Stonesoft Management Center.....	819
Configuring FORCEPOINT Stonesoft Management Center to communicate with QRadar.....	820
Configuring a syslog traffic rule for FORCEPOINT Stonesoft Management Center.....	821
Forcepoint Sidewinder.....	822
Forcepoint Sidewinder DSM specifications.....	823
Configure Forcepoint Sidewinder to communicate with QRadar.....	823
Forcepoint Sidewinder sample event message.....	823
Forcepoint TRITON.....	824
Configuring syslog for Forcepoint TRITON.....	825
Syslog log source parameters for Forcepoint TRITON.....	825
Forcepoint V-Series Data Security Suite.....	826
Configuring syslog for Forcepoint V-Series Data Security Suite.....	826
Syslog log source parameters for Forcepoint V-Series Data Security Suite.....	826
Forcepoint V-Series Data Security Suite sample event message.....	827
Forcepoint V-Series Content Gateway.....	827
Configure syslog for Forcepoint V-Series Content Gateway.....	828
Configuring the Management Console for Forcepoint V-Series Content Gateway.....	828
Enabling Event Logging for Forcepoint V-Series Content Gateway.....	829
Syslog log source parameters for Forcepoint V-Series Content Gateway.....	829
Log file protocol for Forcepoint V-Series Content Gateway.....	829
Forcepoint V-Series Content Gateway sample event messages.....	831
 Chapter 66. ForeScout CounterACT.....	833
Syslog log source parameters for ForeScout CounterACT.....	833
Configuring the ForeScout CounterACT Plug-in.....	833
Configuring ForeScout CounterACT Policies.....	834
ForeScout CounterACT sample event messages.....	835
 Chapter 67. Fortinet FortiGate Security Gateway.....	837
Configuring a syslog destination on your Fortinet FortiGate Security Gateway device.....	838
Configuring a syslog destination on your Fortinet FortiAnalyzer device.....	839
Fortinet FortiGate Security Gateway sample event messages.....	839
Configuring QRadar to categorize App Ctrl events for Fortinet Fortigate Security Gateway.....	841
 Chapter 68. Foundry FastIron .....	843
Configuring syslog for Foundry FastIron.....	843
Syslog log source parameters for Foundry FastIron.....	843
 Chapter 69. FreeRADIUS.....	845
Configuring your FreeRADIUS device to communicate with QRadar.....	845
 Chapter 70. Generic.....	847
Generic authorization Server.....	847
Configuring event properties for authorization events .....	847
Syslog log source parameters for generic authorization server.....	849
Generic firewall.....	850
Configuring event properties for generic firewall events .....	850
Syslog log source parameters for generic firewall.....	852

Chapter 71. genua genugate.....	855
Configuring genua genugate to send events to QRadar.....	856
genua genugate sample event messages.....	856
Chapter 72. Google.....	859
Google Cloud Audit Logs.....	859
Google Cloud Audit Logs DSM specifications.....	859
Configuring Google Cloud Audit Logs to communicate with QRadar.....	860
Google Cloud Pub/Sub protocol log source parameters for Google Cloud Audit Logs.....	860
Google Cloud Audit Logs sample event messages.....	861
Google Cloud Platform - Cloud DNS.....	863
Google Cloud Platform - Cloud DNS DSM specifications.....	863
Configuring Google Cloud Platform - Cloud DNS to communicate with QRadar.....	864
Google Cloud Pub/Sub protocol log source parameters for Google Cloud Platform - Cloud DNS.....	864
Google Cloud Platform - Cloud DNS sample event message.....	865
Google Cloud Platform Firewall.....	865
Google Cloud Platform Firewall DSM specifications.....	866
Configuring Google Cloud Platform Firewall to communicate with QRadar.....	866
Google Cloud Pub/Sub log source parameters for Google Cloud Platform Firewall.....	867
Sample event message.....	867
Google G Suite Activity Reports.....	868
Google G Suite Activity Reports DSM specifications.....	868
Configuring Google G Suite Activity Reports to communicate with QRadar.....	869
Assigning a role to a user.....	869
Creating a service account with viewer access.....	871
Granting API client access to a service account.....	871
Google G Suite Activity Reports log source parameters.....	872
Google G Suite Activity Reports sample event messages.....	872
Troubleshooting Google G Suite Activity Reports.....	873
Chapter 73. Great Bay Beacon.....	879
Configuring syslog for Great Bay Beacon.....	879
Syslog log source parameters for Great Bay Beacon.....	879
Chapter 74. H3C Technologies.....	881
H3C Comware Platform.....	881
Configuring H3C Comware Platform to communicate with QRadar.....	882
Chapter 75. HBGary Active Defense.....	883
Configuring HBGary Active Defense.....	883
Syslog log source parameters for HBGary Active Defense.....	883
Chapter 76. HCL BigFix (formerly known as IBM BigFix).....	885
Chapter 77. Honeycomb Lexicon File Integrity Monitor (FIM).....	887
Supported Honeycomb FIM event types logged by QRadar.....	887
Configuring the Lexicon mesh service.....	887
Syslog log source parameters for Honeycomb Lexicon File Integrity Monitor.....	888
Chapter 78. Hewlett Packard Enterprise.....	891
HPE Network Automation.....	891
Configuring HPE Network Automation Software to communicate with QRadar.....	892
HPE ProCurve.....	893
Syslog log source parameters for HPE ProCurve.....	894
HPE Tandem.....	894
HPE Tandem sample event message.....	895

Hewlett Packard Enterprise UniX (HPE-UX).....	896
Syslog log source parameters for Hewlett Packard Enterprise UniX (HPE-UX).....	896
Chapter 79. Huawei.....	899
Huawei AR Series Router.....	899
Syslog log source parameters for Huawei AR Series Router.....	899
Configuring Your Huawei AR Series Router.....	900
Huawei S Series Switch.....	900
Syslog log source parameters for Huawei S Series Switch.....	901
Configuring Your Huawei S Series Switch.....	901
Huawei S Series Switch sample event message.....	902
Chapter 80. HyTrust CloudControl.....	903
Configuring HyTrust CloudControl to communicate with QRadar.....	904
Chapter 81. IBM .....	905
IBM AIX.....	905
IBM AIX Server DSM overview.....	905
IBM AIX Audit DSM overview.....	907
IBM BigFix Detect.....	911
IBM CICS.....	912
Create a log source for near real-time event feed.....	913
Log File log source parameter.....	913
IBM Cloud Activity Tracker.....	917
IBM Cloud Activity Tracker DSM specifications.....	918
Configuring IBM Cloud Activity Tracker to communicate with QRadar.....	918
Apache Kafka log source parameters for IBM Cloud Activity Tracker.....	919
IBM Cloud Activity Tracker sample event messages.....	920
IBM Cloud Platform (formerly known as IBM Bluemix Platform).....	923
Configuring IBM Cloud Platform to communicate with QRadar.....	924
IBM DataPower.....	926
Configuring IBM DataPower to communicate with QRadar.....	927
IBM DB2.....	928
Create a log source for near real-time event feed.....	929
Log File log source parameter.....	929
Integrating IBM DB2 Audit Events.....	933
Extracting audit data for DB2 v8.x to v9.4.....	934
Extracting audit data for DB2 v9.5.....	935
IBM DB2 sample event messages.....	935
IBM Defender Data Protect.....	936
IBM Defender Data Protect DSM specifications.....	936
Configuring IBM Defender Data Protect to communicate with QRadar.....	937
Syslog log source parameters for IBM Defender Data Protect DSM.....	937
IBM Defender Data Protect sample event messages.....	937
IBM DLC Metrics.....	939
IBM DLC Metrics DSM specifications.....	939
Configuring IBM Disconnected Log Collector to communicate with QRadar.....	940
Forwarded Log source parameters for IBM DLC Metrics.....	941
IBM DLC Metrics sample event message.....	941
IBM Federated Directory Server .....	942
Configuring IBM Federated Directory Server to monitor security events.....	943
IBM Guardium.....	943
Creating a syslog destination for events.....	944
Configuring policies to generate syslog events.....	945
Installing an IBM Guardium Policy .....	945
Syslog log source parameters for IBM Guardium.....	946
Creating an event map for IBM Guardium events.....	946
Modifying the event map.....	947

IBM Guardium sample event messages.....	948
<b>IBM i.....</b>	<b>949</b>
Configuring IBM i to integrate with IBM QRadar.....	950
Manually extracting journal entries for IBM i.....	952
Pulling Data when you use the Log File Protocol.....	953
Configuring Townsend Security Alliance LogAgent to integrate with QRadar.....	954
IBM i sample event message.....	954
<b>IBM IMS.....</b>	<b>955</b>
Configuring IBM IMS .....	955
Log File log source parameters for IBM IMS.....	958
<b>IBM Informix Audit.....</b>	<b>958</b>
<b>IBM Lotus Domino.....</b>	<b>959</b>
Setting Up SNMP Services.....	959
Setting up SNMP in AIX.....	959
Starting the Domino Server Add-in Tasks.....	960
Configuring SNMP Services.....	960
SNMPv2 log source parameters for IBM Lotus Domino.....	961
IBM Lotus Domino sample event messages.....	961
<b>IBM MaaS360 Security.....</b>	<b>962</b>
IBM Fiberlink REST API log source parameters for IBM MaaS360 Security.....	962
IBM MaaS360 Security sample event message.....	963
<b>IBM Manage Virtual Server.....</b>	<b>964</b>
IBM Manage Virtual Server DSM specifications.....	964
Syslog log source parameters for IBM Manage Virtual Server.....	964
IBM Manage Virtual Server sample event message.....	965
<b>IBM Privileged Session Recorder.....</b>	<b>966</b>
Configuring IBM Privileged Session Recorder to communicate with QRadar.....	967
JDBC log source parameters for IBM Privileged Session Recorder.....	968
<b>IBM Proventia.....</b>	<b>968</b>
IBM Proventia Management SiteProtector.....	968
JDBC log source parameters for IBM Proventia Management SiteProtector.....	969
IBM ISS Proventia .....	970
<b>IBM QRadar Packet Capture.....</b>	<b>970</b>
Configuring IBM QRadar Packet Capture to communicate with QRadar.....	972
Configuring IBM QRadar Network Packet Capture to communicate with QRadar.....	973
<b>IBM QRadar Network Security XGS.....</b>	<b>973</b>
Configuring IBM QRadar Network Security XGS Alerts.....	974
Syslog log source parameters for IBM QRadar Network Security XGS.....	975
<b>IBM RACF.....</b>	<b>975</b>
Log File log source parameter.....	976
Create a log source for near real-time event feed.....	980
Integrate IBM RACF with IBM QRadar by using audit scripts.....	981
Configuring IBM RACF that uses audit scripts to integrate with IBM QRadar.....	981
<b>IBM Red Hat OpenShift.....</b>	<b>983</b>
IBM Red Hat OpenShift DSM specifications.....	984
Configuring Red Hat OpenShift to communicate with QRadar.....	984
IBM Red Hat OpenShift Syslog log source parameters.....	984
IBM Red Hat OpenShift sample event messages.....	985
<b>IBM SAN Volume Controller.....</b>	<b>986</b>
Configuring IBM SAN Volume Controller to communicate with QRadar.....	987
<b>IBM Security Access Manager for Enterprise Single Sign-On.....</b>	<b>988</b>
Configuring a log server type.....	988
Configuring syslog forwarding.....	989
Syslog log source parameters for IBM Security Access Manager for Enterprise Single Sign-On.....	989
<b>IBM Security Access Manager for Mobile.....</b>	<b>990</b>
Configuring IBM Security Access Manager for Mobile to communicate with QRadar.....	992
Configuring IBM IDaaS Platform to communicate with QRadar.....	993

Configuring an IBM IDaaS console to communicate with QRadar.....	993
IBM Security Verify Directory.....	993
IBM Security Verify Directory DSM specifications.....	994
Configuring IBM Security Verify Directory to communicate with QRadar.....	994
Syslog log source parameters for IBM Security Verify Directory.....	996
IBM Security Guardium Insights.....	996
IBM Security Guardium Insights DSM specifications.....	997
Syslog log source parameters for IBM Security Guardium Insights.....	997
Creating an event map for IBM Guardium events.....	998
Modifying the event map.....	999
IBM Security Guardium Insights sample event messages.....	999
IBM Security Identity Governance.....	1000
JDBC log source parameters for IBM Security Identity Governance.....	1003
IBM Security Identity Manager.....	1004
IBM Security Identity Manager JDBC log source parameters for IBM Security Identity Manager.....	1004
IBM Security Network IPS (GX).....	1008
Configuring your IBM Security Network IPS (GX) appliance for communication with QRadar.....	1009
Syslog log source parameters for IBM Security Network IPS (GX).....	1010
IBM Security Privileged Identity Manager.....	1010
Configuring IBM Security Privileged Identity Manager to communicate with QRadar.....	1013
IBM Security Privileged Identity Manager sample event message.....	1014
IBM Security QRadar EDR.....	1014
QRadar EDR DSM specifications.....	1015
Configuring QRadar EDR to communicate with QRadar.....	1016
IBM Security QRadar EDR REST API data source parameters for QRadar EDR.....	1016
Configuring QRadar to collect only the first username from the alert .....	1017
QRadar EDR sample event messages.....	1017
IBM Security Randori Recon.....	1018
IBM Security Randori Recon DSM specifications.....	1019
IBM Security Randori REST API protocol log source parameters.....	1019
IBM Security Randori Recon sample event messages.....	1020
IBM Security Trusteer.....	1021
IBM Security Trusteer DSM specifications.....	1021
HTTP Receiver log source parameters for IBM Security Trusteer.....	1022
IBM Security Trusteer sample event messages.....	1022
IBM Security Trusteer Apex Advanced Malware Protection.....	1024
Configuring IBM Security Trusteer Apex Advanced Malware Protection to send syslog events to QRadar.....	1028
Configuring IBM Security Trusteer Apex Advanced Malware Protection to send TLS Syslog events to QRadar.....	1029
Configuring a Flat File Feed service.....	1031
IBM Security Trusteer Apex Local Event Aggregator.....	1032
Configuring syslog for Trusteer Apex Local Event Aggregator.....	1032
IBM Security Verify (formerly known as IBM Cloud Identity).....	1033
IBM Security Verify DSM Specifications.....	1033
Configuring QRadar to pull events from IBM Security Verify.....	1034
IBM Security Verify Event Service log source parameters for IBM Security Verify.....	1035
IBM Security Verify sample event messages.....	1035
IBM Sense.....	1039
Configuring IBM Sense to communicate with QRadar.....	1040
IBM SmartCloud Orchestrator.....	1040
Installing IBM SmartCloud Orchestrator.....	1041
IBM SmartCloud Orchestrator log source parameters.....	1041
IBM Tivoli Access Manager for e-business.....	1042
Configuring Tivoli Access Manager for e-business.....	1042
Syslog log source parameters for IBM Tivoli Access Manager for e-business.....	1043
IBM Tivoli Access Manager for e-business sample event message.....	1044

IBM Tivoli Endpoint Manager.....	1044
IBM WebSphere Application Server.....	1044
Configuring IBM WebSphere .....	1044
Customizing the Logging Option.....	1045
Log File log source parameters for IBM WebSphere.....	1045
IBM WebSphere sample event message.....	1049
IBM Storage Protect.....	1049
IBM Storage Protect DSM specifications.....	1049
Configure IBM Storage Protect.....	1050
Syslog log source parameters for IBM Storage Protect.....	1050
Sample event message for IBM Storage Protect.....	1050
IBM WebSphere DataPower.....	1051
IBM z/OS.....	1051
Create a log source for near real-time event feed.....	1052
Log File log source parameter.....	1052
IBM zOS sample event message.....	1056
IBM zSecure Alert.....	1057
Syslog log source parameters for IBM zSecure Alert.....	1057
 Chapter 82. ISC BIND.....	1059
ISC BIND DSM specifications.....	1060
Syslog log source parameters for ISC BIND.....	1061
ISC BIND sample event message.....	1061
 Chapter 83. Illumio Adaptive Security Platform.....	1063
Configuring Illumio Adaptive Security Platform to communicate with QRadar.....	1064
Configuring Exporting Events to Syslog for Illumio PCE.....	1065
Configuring Syslog Forwarding for Illumio PCE.....	1065
 Chapter 84. Imperva Incapsula.....	1067
Configuring Imperva Incapsula to communicate with QRadar.....	1068
 Chapter 85. Imperva SecureSphere.....	1071
Configuring an alert action for Imperva SecureSphere .....	1072
Configuring a system event action for Imperva SecureSphere.....	1073
Configuring Imperva SecureSphere V11.0 to V13 to send database audit records to QRadar.....	1075
 Chapter 86. Infoblox NIOS.....	1077
Infoblox NIOS DSM specifications.....	1077
Infoblox NIOS sample event message.....	1078
 Chapter 87. iT-CUBE agileSI.....	1079
Configuring agileSI to forward events .....	1079
SMB Tail log source parameters for iT-CUBE agileSI.....	1080
 Chapter 88. Itron Smart Meter.....	1081
Syslog log source parameters for Itron Smart Meter.....	1081
 Chapter 89. Juniper Networks.....	1083
Juniper Networks AVT (deprecated).....	1083
JDBC log source parameters for Juniper Networks AVT.....	1084
Juniper Networks DDoS Secure.....	1085
Juniper Networks DX Application Acceleration Platform (deprecated).....	1085
Configuring IBM QRadar to receive events from a Juniper DX Application Acceleration Platform.....	1086
Juniper Networks EX Series Ethernet Switch (deprecated).....	1086
Configuring IBM QRadar to receive events from a Juniper EX Series Ethernet Switch.....	1087
Juniper Networks IDP (deprecated).....	1087

Configure a log source.....	1088
Juniper Networks Infranet Controller (deprecated).....	1088
Juniper Networks Firewall and VPN (deprecated).....	1089
Configuring IBM QRadar to receive events .....	1089
Juniper Networks Firewall sample event message.....	1089
Juniper Networks Junos OS.....	1090
Syslog log source parameters for Juniper Junos OS.....	1092
TLS Syslog log source parameters for Juniper Junos OS.....	1092
Configure the PCAP Syslog Protocol.....	1092
PCAP Syslog Combination log source parameters for Juniper SRX Series.....	1093
Juniper Junos OS sample event message.....	1093
Juniper Networks Network and Security Manager (deprecated).....	1094
Configuring Juniper Networks NSM to export logs to syslog.....	1094
Juniper NSM log source parameters for Juniper Networks Network and Security Manager...1094	1094
Juniper Networks Secure Access (deprecated).....	1095
Juniper Networks Security Binary Log Collector (deprecated).....	1095
Configuring the Juniper Networks Binary Log Format (deprecated).....	1096
Juniper Security Binary Log Collector log source parameters for Juniper Networks Security Binary Log Collector.....	1097
Juniper Networks Steel-Belted Radius (deprecated).....	1098
Juniper Networks Steel-Belted Radius DSM specifications.....	1098
Configure Juniper Networks Steel-Belted Radius to forward Windows events to QRadar.....1099	1099
Configuring Juniper Networks Steel-Belted Radius to forward Syslog events to QRadar.....1100	1100
Configuring a Juniper Steel-Belted Radius log source by using the Syslog protocol.....1101	1101
Configuring a Juniper Networks Steel-Belted Radius log source by using the TLS syslog protocol.....	1101
Configuring a Juniper Steel-Belted Radius log source by using the Log File protocol.....1102	1102
Juniper Steel Belted Radius sample event message.....	1103
Juniper Networks vGW Virtual Gateway (deprecated).....	1103
Juniper Networks Junos WebApp Secure (deprecated).....	1105
Configuring syslog forwarding.....	1105
Configuring event logging.....	1105
Syslog log source parameters for Juniper Networks Junos WebApp Secure.....	1107
Juniper Junos WebApp Secure sample event message.....	1107
Juniper Networks WLC Series Wireless LAN Controller (deprecated).....	1108
Configuring a syslog server from the Juniper WLC user interface.....	1108
Configuring a syslog server with the command-line interface for Juniper WLC.....1109	1109
 Chapter 90. Kisco Information Systems SafeNet/i.....	1111
Configuring Kisco Information Systems SafeNet/i to communicate with QRadar.....	1112
 Chapter 91. Kubernetes Auditing.....	1115
Kubernetes Auditing DSM specifications.....	1115
Configuring Kubernetes Auditing to communicate with QRadar.....	1116
Kubernetes Auditing log source parameters.....	1117
Kubernetes Auditing sample event message.....	1117
 Chapter 92. Lastline Enterprise.....	1119
Configuring Lastline Enterprise to communicate with QRadar.....	1120
 Chapter 93. Lieberman Random Password Manager.....	1121
 Chapter 94. LightCyber Magna.....	1123
Configuring LightCyber Magna to communicate with QRadar.....	1124
 Chapter 95. Linux.....	1127
Linux DHCP Server.....	1127
Linux DHCP Server DSM specifications.....	1127

Syslog log source parameters for Linux DHCP.....	1128
Linux DHCP Server sample event message.....	1128
Linux IPtables.....	1128
Configuring IPtables.....	1129
Syslog log source parameters for Linux IPtables.....	1130
Linux OS.....	1130
Configuring syslog on Linux OS.....	1131
Configuring syslog-ng on Linux OS.....	1131
Configuring Linux OS to send audit logs.....	1132
Linux OS Sample event messages.....	1133
 Chapter 96. LOGbinder.....	1135
LOGbinder EX event collection from Microsoft Exchange Server.....	1135
Configuring your LOGbinder EX system to send Microsoft Exchange event logs to QRadar....	1136
LOGbinder SP event collection from Microsoft SharePoint.....	1136
Configuring your LOGbinder SP system to send Microsoft SharePoint event logs to QRadar..	1137
LOGbinder SQL event collection from Microsoft SQL Server.....	1138
Configuring your LOGbinder SQL system to send Microsoft SQL Server event logs to QRadar	1139
 Chapter 97. McAfee.....	1141
JDBC log source parameters for McAfee Application/Change Control.....	1141
McAfee ePolicy Orchestrator.....	1142
Configuring SNMP notifications on McAfee ePolicy Orchestrator.....	1145
Installing the Java Cryptography Extension on McAfee ePolicy Orchestrator.....	1146
Installing the Java Cryptography Extension on QRadar.....	1147
McAfee ePolicy Orchestrator sample event messages.....	1147
McAfee MVISION Cloud (formerly known as Skyhigh Networks Cloud Security Platform).....	1148
Configuring McAfee MVISION Cloud to communicate with QRadar.....	1149
McAfee MVISION Cloud sample event messages.....	1150
McAfee Network Security Platform (formerly known as McAfee Intrushield) .....	1150
McAfee Network Security Platform DSM specifications.....	1151
Configuring alert events for McAfee Network Security Platform 2.x - 5.x.....	1152
Configuring alert events for McAfee Network Security Platform 6.x - 7.x.....	1153
Configuring alert events for McAfee Network Security Platform 8.x - 10.x.....	1155
Configuring fault notification events for McAfee Network Security Platform 6.x - 7.x.....	1157
Configuring fault notification events for McAfee Network Security Platform 8.x - 10.x.....	1158
McAfee Network Security Platform sample event messages.....	1159
McAfee Web Gateway.....	1160
McAfee Web Gateway DSM integration process.....	1161
Configuring McAfee Web Gateway to communicate with QRadar (syslog).....	1161
Importing the Syslog Log Handler.....	1162
Configuring McAfee Web Gateway to communicate with IBM QRadar (log file protocol).....	1162
Pulling data by using the log file protocol.....	1163
Creation of an event map for McAfee Web Gateway events.....	1164
Discovering unknown events.....	1164
Modifying the event map.....	1164
McAfee Web Gateway sample event message.....	1165
 Chapter 98. MetaInfo MetaIP.....	1167
 Chapter 99. Microsoft.....	1169
Microsoft 365 Defender.....	1169
Microsoft 365 Defender DSM Specifications.....	1170
Microsoft Defender for Endpoint SIEM REST API log source parameters.....	1172
Microsoft Azure Event Hubs log source parameters.....	1173
Microsoft Graph Security API log source parameters.....	1173
Microsoft 365 Defender sample event messages.....	1174
Microsoft Entra ID.....	1177

Microsoft Entra ID DSM specifications.....	1178
Microsoft Entra ID log source parameters.....	1178
Microsoft Entra ID sample event messages.....	1179
Microsoft Azure Monitor Agent Linux.....	1180
Microsoft Azure Monitor Agent Linux DSM specifications.....	1180
Microsoft Azure Monitor Agent Linux sample event messages.....	1181
Microsoft Azure Platform.....	1182
Microsoft Azure Platform DSM specifications.....	1182
Microsoft Azure log source parameters for Microsoft Azure Event Hubs.....	1183
Microsoft Azure Platform sample event messages.....	1184
Microsoft Defender for Cloud.....	1186
Microsoft Defender for Cloud DSM specifications.....	1186
Microsoft Graph Security API protocol log source parameters for Microsoft Defender for Cloud.....	1187
Microsoft Azure Event Hubs protocol log source parameters for Microsoft Defender for Cloud.....	1188
Microsoft Defender for Cloud sample event message.....	1188
Microsoft DHCP Server.....	1192
Microsoft DHCP Server sample event message.....	1193
Microsoft DNS Debug.....	1193
Enabling DNS debugging on Windows Server.....	1194
Microsoft DNS Debug sample event message.....	1195
Microsoft Endpoint Protection.....	1195
Creating a database view.....	1196
JDBC log source parameters for predefined database queries.....	1196
Microsoft Exchange Server.....	1199
Configuring Microsoft Exchange Server to communicate with QRadar.....	1200
Microsoft Exchange Server log source parameters for Microsoft Exchange.....	1203
Microsoft Exchange Server sample event message.....	1205
Microsoft Hyper-V.....	1206
Microsoft Hyper-V DSM integration process.....	1207
WinCollect log source parameters for Microsoft Hyper-V.....	1207
Microsoft IAS Server.....	1208
Microsoft IIS Server.....	1208
Configuring Microsoft IIS by using the IIS Protocol.....	1209
Microsoft IIS log source parameters for Microsoft IIS Server.....	1210
Syslog log source parameters for Microsoft IIS Server.....	1210
Microsoft IIS Server sample event messages.....	1211
Microsoft ISA.....	1212
Microsoft Office 365.....	1212
Configuring a Microsoft Office 365 account in Microsoft Azure Active Directory.....	1215
Microsoft Office 365 sample event messages.....	1216
Microsoft Office 365 Message Trace.....	1217
Microsoft Office 365 Message Trace DSM specifications.....	1218
Microsoft Office Message Trace REST API log source parameters for Microsoft Office Message Trace.....	1218
Microsoft Office 365 Message Trace sample event message.....	1219
JDBC log source parameters for Microsoft Operations Manager.....	1220
Microsoft SharePoint.....	1221
Configuring Microsoft SharePoint audit events.....	1221
Creating a database view for Microsoft SharePoint.....	1222
Creating read-only permissions for Microsoft SharePoint database users.....	1222
JDBC log source parameters for Microsoft Share Point.....	1223
JDBC log source parameters for Microsoft SharePoint with predefined database queries.....	1224
Microsoft SQL Server.....	1226
Microsoft SQL Server preparation for communication with QRadar.....	1227
JDBC log source parameters for Microsoft SQL Server.....	1229
Microsoft SQL Server sample event message.....	1230

JDBC log source parameters for Microsoft System Center Operations Manager.....	1230
Microsoft Windows Security Event Log.....	1232
Installing the MSRPC protocol on the QRadar Console.....	1232
MSRPC parameters on Windows hosts.....	1233
WMI parameters on Windows hosts.....	1237
Installing Winlogbeat and Logstash on a Windows host.....	1238
Configuring which usernames QRadar considers to be system users in events that are collected.....	1239
Configuring IBM QRadar to parse XML level tag for application events.....	1240
Microsoft Windows Security Event Log sample event messages.....	1240
 Chapter 100. Motorola Symbol AP.....	1245
Syslog log source parameters for Motorola SymbolAP.....	1245
Configure syslog events for Motorola Symbol AP.....	1245
 Chapter 101. Name Value Pair.....	1247
 Chapter 102. NCC Group DDoS Secure.....	1251
Configuring NCC Group DDoS Secure to communicate with QRadar.....	1252
 Chapter 103. NetApp Data ONTAP.....	1253
 Chapter 104. Netgate pfSense.....	1255
Netgate pfSense DSM specifications.....	1255
Configuring Netgate pfSense to communicate with QRadar.....	1256
Syslog log source parameters for Netgate pfSense.....	1257
Netgate pfSense sample event messages.....	1257
 Chapter 105. Netskope Active.....	1259
Netskope Active REST API log source parameters for Netskope Active.....	1260
Netskope Active sample event messages.....	1260
 Chapter 106. NGINX HTTP Server.....	1263
NGINX HTTP Server DSM specifications.....	1263
Configuring NGINX HTTP Server to communicate with QRadar.....	1264
NGINX HTTP Server sample event messages.....	1264
 Chapter 107. Niksun.....	1267
 Chapter 108. Nokia Firewall.....	1269
Integration with a Nokia Firewall by using syslog.....	1269
Configuring IPtables .....	1269
Configuring syslog .....	1270
Configuring the logged events custom script.....	1270
Syslog log source parameters for Nokia Firewall.....	1270
Integration with a Nokia Firewall by using OPSEC.....	1271
Configuring a Nokia Firewall for OPSEC.....	1271
OPSEC/LEA log source parameters for Nokia FireWall.....	1272
 Chapter 109. Nominum Vantio.....	1273
 Chapter 110. Nortel Networks.....	1275
Nortel Multiprotocol Router.....	1275
Nortel Application Switch.....	1277
Nortel Contivity.....	1278
Nortel Ethernet Routing Switch 2500/4500/5500.....	1279
Nortel Ethernet Routing Switch 8300/8600.....	1279
Nortel Secure Router.....	1280

Nortel Secure Network Access Switch.....	1282
Nortel Switched Firewall 5100.....	1282
Integrating Nortel Switched Firewall by using syslog.....	1282
Integrate Nortel Switched Firewall by using OPSEC.....	1283
Configuring a log source.....	1283
Nortel Switched Firewall 6000.....	1284
Configuring syslog for Nortel Switched Firewalls.....	1284
Configuring OPSEC for Nortel Switched Firewalls .....	1285
Reconfiguring the Check Point SmartCenter Server.....	1285
Nortel Threat Protection System (TPS).....	1286
Nortel VPN Gateway.....	1286
 Chapter 111. Novell eDirectory.....	1289
Configuring XDASv2 to forward events.....	1289
Loading the XDASv2 Module.....	1290
Loading the XDASv2 on a Linux Operating System.....	1290
Loading the XDASv2 on a Windows Operating System.....	1291
Configuring event auditing using Novell iManager.....	1291
Configuring a log source.....	1292
Novell eDirectory sample event message.....	1292
 Chapter 112. Observe IT JDBC.....	1295
 Chapter 113. Okta.....	1301
 Chapter 114. Onapsis Security Platform.....	1305
Configuring Onapsis Security Platform to communicate with QRadar.....	1306
 Chapter 115. OpenBSD.....	1307
Syslog log source parameters for OpenBSD.....	1307
Configuring syslog for OpenBSD.....	1307
 Chapter 116. Open LDAP.....	1309
UDP Multiline Syslog log source parameters for Open LDAP.....	1309
Configuring IPtables for UDP Multiline Syslog events.....	1310
Configuring event forwarding for Open LDAP.....	1312
Configuring QRadar for users to use OP code instead of connection number.....	1312
 Chapter 117. Open Source SNORT.....	1313
Configuring Open Source SNORT.....	1313
Syslog log source parameters for Open Source SNORT.....	1314
 Chapter 118. OpenStack.....	1315
Configuring OpenStack to communicate with QRadar.....	1317
 Chapter 119. Oracle.....	1319
Oracle Acme Packet Session Border Controller.....	1319
Supported Oracle Acme Packet event types that are logged by IBM QRadar.....	1319
Syslog log source parameters for Oracle Acme Packet SBC.....	1319
Configuring SNMP to syslog conversion on Oracle Acme Packet SBC.....	1320
Enabling syslog settings on the media manager object .....	1320
Oracle Audit Vault.....	1321
Configuring Oracle Audit Vault to communicate with QRadar.....	1325
Oracle BEA WebLogic.....	1325
Enabling event logs .....	1325
Configuring domain logging.....	1326
Configuring application logging .....	1326
Configuring an audit provider.....	1326

Log file log source parameters for Oracle BEA WebLogic.....	1327
Oracle BEA WebLogic sample event messages.....	1327
Oracle Cloud Infrastructure.....	1328
Oracle Cloud Infrastructure DSM specifications.....	1329
Oracle Cloud Infrastructure sample event messages.....	1329
Oracle RDBMS Audit Record.....	1332
Enabling Unified Auditing in Oracle 12c.....	1338
Configuring an Oracle database server to send audit logs to QRadar.....	1338
Oracle DB Listener.....	1340
Oracle Database Listener log source parameters.....	1340
Collecting Oracle database events by using Perl .....	1340
Configuring the Oracle Database Listener within QRadar.....	1342
Oracle Directory Server overview.....	1343
Oracle Enterprise Manager.....	1343
Oracle Fine Grained Auditing.....	1345
JDBC log source parameters for Oracle Fine Grained Auditing.....	1345
Oracle RDBMS OS Audit Record.....	1346
Oracle RDBMS OS Audit Record DSM specifications.....	1347
Configuring Oracle RDBMS OS Audit Record to communicate with QRadar.....	1347
Syslog log source parameters for Oracle RDBMS OS Audit Record.....	1349
Log File log source parameters for Oracle RDBMS OS Audit Record.....	1350
Sample event message.....	1350
 Chapter 120. osquery.....	1353
osquery DSM specifications.....	1354
Configuring rsyslog on your Linux system.....	1354
Configuring osquery on your Linux system.....	1355
osquery log source parameters.....	1356
osquery sample event message.....	1356
 Chapter 121. OSSEC.....	1359
Configuring OSSEC.....	1359
Syslog log source parameters for OSSEC.....	1359
 Chapter 122. Palo Alto Networks.....	1361
Palo Alto Endpoint Security Manager.....	1361
Configuring Palo Alto Endpoint Security Manager to communicate with QRadar.....	1362
Palo Alto Networks PA Series.....	1363
Palo Alto PA DSM specifications.....	1363
Configuring Syslog or LEEF formatted events on your Palo Alto PA Series device.....	1365
Forwarding Palo Alto Cortex Data Lake (Next Generation Firewall) LEEF events to IBM QRadar.....	1376
Creating a forwarding policy on your Palo Alto PA Series device.....	1376
Configuring Palo Alto Networks firewall to send ArcSight CEF formatted Syslog events.....	1376
TLS Syslog log source parameters for Palo Alto PA Series.....	1378
Palo Alto PA Series Sample event message.....	1378
 Chapter 123. PingFederate.....	1383
PingFederate DSM specifications.....	1383
Configuring PingFederate to communicate with IBM QRadar.....	1383
Syslog log source parameters for PingFederate.....	1384
PingFederate sample event message.....	1384
 Chapter 124. Pirean Access: One.....	1387
JDBC log source parameters for Pirean Access: One.....	1387
 Chapter 125. PostFix Mail Transfer Agent.....	1391
Configuring syslog for PostFix Mail Transfer Agent.....	1391

UDP Multiline Syslog log source parameters for PostFix MTA.....	1391
Configuring IPtables for multiline UDP syslog events.....	1393
PostFix Mail Transfer Agent sample event messages.....	1393
Chapter 126. ProFTPD.....	1397
Configuring ProFTPD.....	1397
Syslog log source parameters for ProFTPD.....	1397
Chapter 127. Proofpoint Enterprise Protection and Enterprise Privacy.....	1399
Configuring Proofpoint Enterprise Protection and Enterprise Privacy DSM to communicate with IBM QRadar.....	1400
Syslog log source parameters for Proofpoint Enterprise Protection and Enterprise Privacy.....	1400
Proofpoint Enterprise Protection and Enterprise Privacy sample event messages.....	1401
Chapter 128. Pulse Secure.....	1403
Pulse Secure Infranet Controller.....	1403
Syslog log source parameters for Pulse Secure Infranet Controller.....	1403
Pulse Secure Pulse Connect Secure.....	1403
Configuring a Pulse Secure Pulse Connect Secure device to send WebTrends Enhanced Log File (WELF) events to IBM QRadar.....	1405
Configuring a Pulse Secure Pulse Connect Secure device to send syslog events to QRadar...1406	1406
Pulse Secure Pulse Connect Secure sample event message.....	1406
Chapter 129. Radware.....	1409
Radware AppWall.....	1409
Configuring Radware AppWall to communicate with QRadar.....	1410
Increasing the maximum TCP Syslog payload length for Radware AppWall.....	1411
Radware AppWall sample event messages.....	1411
Radware DefensePro.....	1412
Syslog log source parameters for Radware DefensePro.....	1412
Chapter 130. Raz-Lee iSecurity.....	1413
Configuring Raz-Lee iSecurity to communicate with QRadar.....	1413
Syslog log source parameters for Raz-Lee iSecurity.....	1415
Chapter 131. Redback ASE.....	1417
Configuring Redback ASE.....	1417
Syslog log source parameters for Redback ASE.....	1417
Chapter 132. Red Hat Advanced Cluster Security for Kubernetes.....	1419
Red Hat Advanced Cluster Security for Kubernetes DSM specifications.....	1419
Configuring Red Hat Advanced Cluster Security for Kubernetes to communicate with QRadar...1420	1420
HTTP Receiver log source parameters for Red Hat Advanced Cluster Security for Kubernetes...1420	1420
Red Hat Advanced Cluster Security for Kubernetes sample event messages.....	1421
Chapter 133. Resolution1 CyberSecurity.....	1423
Configuring your Resolution1 CyberSecurity device to communicate with QRadar.....	1424
Log file log source parameters for Resolution1 CyberSecurity.....	1424
Chapter 134. Riverbed.....	1425
Riverbed SteelCentral NetProfiler (Cascade Profiler) Audit.....	1425
Creating a Riverbed SteelCentral NetProfiler report template and generating an audit file...1426	1426
Riverbed SteelCentral NetProfiler (Cascade Profiler) Alert.....	1427
Configuring your Riverbed SteelCentral NetProfiler system to enable communication with QRadar.....	1429
Chapter 135. RSA Authentication Manager.....	1431
Configuration of syslog for RSA Authentication Manager 6.x, 7.x and 8.x.....	1431

Configuring Linux.....	1431
Configuring Windows.....	1432
Configuring the log file protocol for RSA Authentication Manager 6.x and 7.x.....	1432
Log File log source parameters for RSA Authentication Manager.....	1433
Configuring RSA Authentication Manager 6.x.....	1433
Configuring RSA Authentication Manager 7.x.....	1434
 Chapter 136. SafeNet DataSecure.....	1435
Configuring SafeNet DataSecure to communicate with QRadar.....	1435
 Chapter 137. Salesforce.....	1437
Salesforce Security.....	1437
Configuring the Salesforce Security Monitoring server to communicate with QRadar.....	1438
Salesforce REST API log source parameters for Salesforce Security.....	1438
Salesforce Security Auditing.....	1439
Downloading the Salesforce audit trail file.....	1440
Log File log source parameters for Salesforce Security Auditing.....	1440
 Chapter 138. Samhain Labs.....	1443
Configuring syslog to collect Samhain events.....	1443
JDBC log source parameters for Samhain.....	1444
JDBC protocol configuration options.....	1445
 Chapter 139. SAP Enterprise Threat Detection.....	1451
SAP Enterprise Threat Detection DSM specifications.....	1451
SAP Enterprise Threat Detection Alert API log source parameters for SAP Enterprise Threat Detection.....	1452
Creating a pattern filter on the SAP server.....	1453
Troubleshooting the SAP Enterprise Threat Detection Alert API.....	1454
SAP Enterprise Threat Detection V1.0 SP6 sample event messages.....	1455
SAP Enterprise Threat Detection V2.0 SP5 sample event messages.....	1464
 Chapter 140. Seculert.....	1469
 Chapter 141. SentriGo Hedgehog.....	1471
 Chapter 142. Snowflake.....	1473
Snowflake DSM specifications.....	1473
Snowflake sample event message.....	1473
 Chapter 143. SolarWinds Orion.....	1477
Configuring SolarWinds Orion to communicate with QRadar.....	1478
SNMP log source parameters for SolarWinds Orion.....	1480
Installing the Java Cryptography Extension on QRadar.....	1481
Solar Winds Orion sample event message.....	1481
 Chapter 144. SonicWALL.....	1483
Configuring SonicWALL to forward syslog events.....	1483
Syslog log source parameters for SonicWALL.....	1483
SonicWALL sample event messages.....	1484
 Chapter 145. Sophos.....	1485
Sophos Astaro Security Gateway.....	1485
Sophos Astaro Security Gateway sample event messages.....	1486
Sophos Central.....	1487
Sophos Central DSM specifications.....	1488
Sophos Central log source parameters for the Sophos Central DSM.....	1488
Sophos Central sample event message.....	1489

Sophos Enterprise Console.....	1490
Sophos Enterprise Console DSM specifications.....	1490
Configuring the database view for Sophos Enterprise Console.....	1491
Sophos Enterprise Console JDBC log source parameters for Sophos Enterprise Console.....	1491
JDBC log source parameters for Sophos Enterprise Console.....	1492
Sophos PureMessage.....	1493
Integrating QRadar with Sophos PureMessage for Microsoft Exchange.....	1493
JDBC log source parameters for Sophos PureMessage.....	1493
Integrating QRadar with Sophos PureMessage for Linux.....	1494
JDBC log source parameters for Sophos PureMessage for Microsoft Exchange.....	1495
Sophos Web Security Appliance.....	1496
 Chapter 146. Sourcefire Intrusion Sensor .....	1497
Configuring Sourcefire Intrusion Sensor.....	1497
Syslog log source parameters for Sourcefire Intrusion Sensor.....	1497
 Chapter 147. Splunk.....	1499
Collecting Windows events that are forwarded from Splunk.....	1499
TCP Multiline Syslog log source parameters for Splunk.....	1499
 Chapter 148. Squid Web Proxy.....	1501
Configuring syslog forwarding.....	1501
Syslog log source parameters for Squid Web Proxy.....	1502
Squid Web Proxy sample event messages.....	1502
 Chapter 149. SSH CryptoAuditor.....	1505
Configuring an SSH CryptoAuditor appliance to communicate with QRadar.....	1506
 Chapter 150. Starent Networks.....	1507
 Chapter 151. STEALTHbits.....	1511
STEALTHbits StealthINTERCEPT.....	1511
Syslog log source parameters for STEALTHbits StealthINTERCEPT.....	1511
Configuring your STEALTHbits StealthINTERCEPT to communicate with QRadar.....	1512
Configuring your STEALTHbits File Activity Monitor to communicate with QRadar.....	1512
Syslog log source parameters for STEALTHbits File Activity Monitor.....	1513
STEALTHbits StealthINTERCEPT Alerts.....	1513
Collecting alerts logs from STEALTHbits StealthINTERCEPT.....	1514
STEALTHbits StealthINTERCEPT Analytics.....	1514
Collecting analytics logs from STEALTHbits StealthINTERCEPT.....	1515
 Chapter 152. Sun.....	1517
Sun ONE LDAP.....	1517
Enabling the event log for Sun ONE Directory Server.....	1517
Log File log source parameters for Sun ONE LDAP.....	1518
UDP Multiline Syslog log source parameters for Sun ONE LDAP.....	1521
Configuring IPtables for UDP Multiline Syslog events.....	1521
Sun Solaris Basic Security Mode (BSM).....	1523
Enabling Basic Security Mode in Solaris 10.....	1523
Enabling Basic Security Mode in Solaris 11.....	1524
Converting Sun Solaris BSM audit logs.....	1524
Creating a cron job .....	1525
Log File log source parameters for Sun Solaris BSM.....	1525
Sun Solaris DHCP.....	1528
Syslog log source parameters for Sun Solaris DHCP.....	1529
Configuring Sun Solaris DHCP to communicate with QRadar.....	1529
Sun Solaris OS.....	1530
Sun Solaris OS DSM specifications.....	1530

Configuring Sun Solaris OS to communicate with QRadar.....	1531
Syslog log source parameters for Sun Solaris OS.....	1531
Sun Solaris OS sample event messages.....	1532
Sun Solaris Sendmail.....	1533
Syslog log source parameters for Sun Solaris Sendmail.....	1533
Chapter 153. Suricata.....	1535
Suricata DSM specifications.....	1535
Configuring Suricata to communicate with QRadar.....	1536
Syslog log source parameters for Suricata.....	1536
TLS Syslog log source parameters for Suricata.....	1537
Suricata sample event message.....	1537
Chapter 154. Sybase ASE.....	1539
JDBC log source parameters for Sybase ASE.....	1539
Chapter 155. Symantec .....	1543
Symantec Critical System Protection.....	1543
Symantec Data Loss Prevention (DLP).....	1546
Creating an SMTP response rule.....	1547
Creating a None Of SMTP response rule.....	1547
Configuring a log source .....	1548
Event map creation for Symantec DLP events.....	1549
Discovering unknown events.....	1549
Modifying the event map.....	1549
Symantec Endpoint Protection.....	1550
Configuring Symantec Endpoint Protection to Communicate with QRadar.....	1551
Symantec Endpoint Protection sample event messages.....	1552
Symantec Encryption Management Server.....	1553
Configuring Symantec Encryption Management Server to communicate with QRadar.....	1553
Syslog log source parameters for Symantec Encryption Management Servers.....	1554
Symantec SGS.....	1554
Syslog log source parameters for Symantec SGS.....	1554
Symantec System Center.....	1555
Configuring a database view for Symantec System Center.....	1555
JDBC log source parameters for Symantec System Center.....	1556
Chapter 156. SysFlow.....	1559
SysFlow DSM specifications.....	1559
Configuring SysFlow agent to communicate with QRadar.....	1560
Syslog log source parameters for SysFlow.....	1560
SysFlow sample event message.....	1561
Chapter 157. ThreatGRID Malware Threat Intelligence Platform .....	1563
Supported event collection protocols for ThreatGRID Malware Threat Intelligence.....	1563
ThreatGRID Malware Threat Intelligence configuration overview.....	1563
Syslog log source parameters for ThreatGRID Malware Threat Intelligence Platform.....	1563
Log File log source parameters for ThreatGRID Malware Threat Intelligence Platform.....	1565
Chapter 158. TippingPoint.....	1569
TippingPoint Intrusion Prevention System .....	1569
Configuring remote syslog for SMS .....	1569
Configuring notification contacts for LSM.....	1570
Configuring an Action Set for LSM.....	1570
TippingPoint X505/X506 Device.....	1571
Configuring your TippingPoint X506/X506 device to communicate with QRadar.....	1571
TippingPoint Intrusion Prevention System sample event message.....	1572

Chapter 159. Top Layer IPS.....	1573
Chapter 160. Townsend Security LogAgent.....	1575
Configuring Raz-Lee iSecurity.....	1575
Syslog log source parameters for Raz-Lee i Security.....	1575
Chapter 161. Trend Micro.....	1577
Trend Micro Apex Central.....	1577
Trend Micro Apex Central DSM specifications.....	1577
Configuring Trend Micro Apex Central to communicate with QRadar.....	1578
Syslog log source parameters for Trend Micro Apex Central.....	1579
TLS Syslog log source parameters for Trend Micro Apex Central.....	1580
Trend Micro Apex Central sample event messages.....	1580
Trend Micro Apex One.....	1581
Integrating with Trend Micro Apex One 8.x .....	1581
Integrating with Trend Micro Apex One 10.x .....	1582
Integrating with Trend Micro Apex One XG .....	1584
Changing the date format in QRadar to match the date format for your Trend Micro Apex One device.....	1585
SNMPv2 log source parameters for Trend Micro Apex One.....	1586
Trend Micro Control Manager.....	1587
SNMPv1 log source parameters for Trend Micro Control Manager.....	1587
SNMPv2 log source parameters for Trend Micro Control Manager.....	1587
SNMPv3 log source parameters for Trend Micro Control Manager.....	1588
Configuring SNMP traps .....	1589
Trend Micro Deep Discovery Analyzer.....	1589
Configuring your Trend Micro Deep Discovery Analyzer instance for communication with QRadar.....	1590
Trend Micro Deep Discovery Director.....	1591
Trend Micro Deep Discovery Director DSM specifications.....	1592
Configuring Trend Micro Deep Discovery Director to communicate with QRadar.....	1592
Trend Micro Deep Discovery Director sample event messages.....	1593
Trend Micro Deep Discovery Email Inspector.....	1594
Configuring Trend Micro Deep Discovery Email Inspector to communicate with QRadar.....	1595
Trend Micro Deep Discovery Inspector.....	1596
Configuring Trend Micro Deep Discovery Inspector V3.0 to send events to QRadar.....	1597
Configuring Trend Micro Deep Discovery Inspector V3.8, V5.0 and V5.1 to send events to QRadar.....	1598
Trend Micro Deep Security.....	1598
Configuring Trend Micro Deep Security to communicate with QRadar.....	1599
Trend Micro Deep Security sample event message.....	1600
Chapter 162. Tripwire.....	1601
Chapter 163. Tropos Control.....	1603
Chapter 164. Universal CEF.....	1605
Configuring event mapping for Universal CEF events.....	1605
Chapter 165. Universal LEEF.....	1607
Syslog protocol log source parameters for Universal LEEF.....	1607
Forwarding events to IBM QRadar.....	1607
Universal LEEF event map creation.....	1608
Discovering unknown events.....	1608

# About this DSM Configuration Guide

---

The DSM Configuration guide provides instructions about how to collect data from your third-party devices, also known as log sources.

You can configure IBM QRadar to accept event logs from log sources that are on your network. A *log source* is a data source that creates an event log.

**Note:** This guide describes the Device Support Modules (DSMs) that are produced by IBM. Third-party DSMs are available on the [IBM App Exchange](#), but are not documented here.

## Intended audience

System administrators must have QRadar access, knowledge of the corporate network security concepts and device configurations.

## Technical documentation

To find IBM Security QRadar product documentation on the web, including all translated documentation, access the [IBM Knowledge Center](#) (<http://www.ibm.com/support/knowledgecenter/SS42VS/welcome>).

For information about how to access more technical documentation in the QRadar products library, see [QRadar Support – Assistance 101](#) (<https://ibm.biz/qradarsupport>).

## Contacting customer support

For information about contacting customer support, see [QRadar Support – Assistance 101](#) (<https://ibm.biz/qradarsupport>).

## Statement of good security practices

IT system security involves protecting systems and information through prevention, detection and response to improper access from within and outside your enterprise. Improper access can result in information being altered, destroyed, misappropriated or misused or can result in damage to or misuse of your systems, including for use in attacks on others. No IT system or product should be considered completely secure and no single product, service or security measure can be completely effective in preventing improper use or access. IBM systems, products and services are designed to be part of a lawful comprehensive security approach, which will necessarily involve additional operational procedures, and may require other systems, products or services to be most effective. IBM DOES NOT WARRANT THAT ANY SYSTEMS, PRODUCTS OR SERVICES ARE IMMUNE FROM, OR WILL MAKE YOUR ENTERPRISE IMMUNE FROM, THE MALICIOUS OR ILLEGAL CONDUCT OF ANY PARTY.

### Please Note:

Use of this Program may implicate various laws or regulations, including those related to privacy, data protection, employment, and electronic communications and storage. IBM Security QRadar may be used only for lawful purposes and in a lawful manner. Customer agrees to use this Program pursuant to, and assumes all responsibility for complying with, applicable laws, regulations and policies. Licensee represents that it will obtain or has obtained any consents, permissions, or licenses required to enable its lawful use of IBM Security QRadar.

---

## **Part 1. QRadar DSM installation and log source management**

---

# Chapter 1. Event collection from third-party devices

To configure event collection from third-party devices, you need to complete configuration tasks on the third-party device, and your QRadar Console, Event Collector, or Event Processor. The key components that work together to collect events from third-party devices are log sources, DSMs, and automatic updates.

## Log sources

A *log source* is any external device, system, or cloud service that is configured to either send events to your IBM QRadar system or be collected by your QRadar system. QRadar shows events from log sources in the **Log Activity** tab.

To receive raw events from log sources, QRadar supports several protocols, including syslog from OS, applications, firewalls, IPS/IDS, SNMP, SOAP, JDBC for data from database tables and views. QRadar also supports proprietary vendor-specific protocols such as OPSEC/LEA from Checkpoint.

## DSMs

A *Device Support Module (DSM)* is a code module that parses received events from multiple log sources and converts them to a standard taxonomy format that can be displayed as output. Each type of log source has a corresponding DSM. For example, the IBM Fiberlink MaaS360 DSM parses and normalizes events from an IBM Fiberlink MaaS360 log source.

## Automatic Updates

QRadar provides daily and weekly automatic updates on a recurring schedule. The weekly automatic update includes new DSM releases, corrections to parsing issues, and protocol updates. For more information about automatic updates, see the *IBM QRadar Administration Guide*.

## Third-party device installation process

To collect events from third-party device, you must complete installation and configuration steps on both the log source device and your QRadar system. For some third-party devices, extra configuration steps are needed, such as configuring a certificate to enable communication between that device and QRadar.

The following steps represent a typical installation process:

1. Read the specific instructions for how to integrate your third-party device.
2. Download and install the RPM for your third-party device. RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>).

**Tip:** If your QRadar system is configured to accept automatic updates, this step might not be required.

3. Configure the third-party device to send events to QRadar.

After some events are received, QRadar automatically detects some third-party devices and creates a log source configuration. The log source is listed on the Log Sources list and contains default information. You can customize the information.

4. If QRadar does not automatically detect the log source, manually add a log source. The list of supported DSMs and the device-specific topics indicate which third-party devices are not automatically detected.
5. Deploy the configuration changes and restart your web services.

## Custom log source types for unsupported third-party log sources

After the events are collected and before the correlation can begin, individual events from your devices must be properly normalized. *Normalization* means to map information to common field names, such

as event name, IP addresses, protocol, and ports. If an enterprise network has one or more network or security devices that QRadar does not provide a corresponding DSM, you can use a custom log source type. QRadar can integrate with most devices and any common protocol sources by using a custom log source type.

For more information, see the *IBM QRadar Administration Guide*.

## Adding a DSM

---

If your Device Support Module (DSM) is not automatically discovered, manually install a DSM.

Each type of log source has a corresponding DSM that parses and normalizes events from the log source.

### Procedure

1. Download the DSM RPM file from the [IBM® support website](http://www.ibm.com/support) (<http://www.ibm.com/support>).
2. Copy the RPM file to QRadar.
3. Using SSH, log in to the QRadar host as the root user.
4. Go to the directory that includes the downloaded file.
5. Type the following command:

```
yum -y install <rpm_filename>
```

**Note:** The `rpm -Uvh <rpm_filename>` command line to install was replaced with the `yum -y install <rpm_filename>` command.

6. Log in to QRadar.
7. On the **Admin** tab, click **Deploy Changes**.

**Restriction:** Uninstalling a Device Support Module (DSM) is not supported in QRadar.

# Chapter 2. Introduction to log source management

You can configure IBM QRadar to accept event logs from log sources that are on your network. A *log source* is a data source that creates an event log.

For example, a firewall or intrusion protection system (IPS) logs security-based events, and switches or routers logs network-based events.

To receive raw events from log sources, QRadar supports many protocols. *Passive protocols* listen for events on specific ports. *Active protocols* use APIs or other communication methods to connect to external systems that poll and retrieve events.

Depending on your license limits, QRadar can read and interpret events from more than 300 log sources.

To configure a log source for QRadar, you must do the following tasks:

1. Download and install a device support module (DSM) that supports the log source. A *DSM* is software application that contains the event patterns that are required to identify and parse events from the original format of the event log to the format that QRadar can use.
2. If automatic discovery is supported for the DSM, wait for QRadar to automatically add the log source to your list of configured log sources.
3. If automatic discovery is not supported for the DSM, manually create the log source configuration.

## Related tasks

[“Adding bulk log sources” on page 8](#)

[“Adding a log source parsing order” on page 11](#)

You can assign a priority order for when the events are parsed by the target event collector.

[“Adding a DSM” on page 4](#)

## Adding a log source

If the log source is not automatically discovered, manually add it by using the QRadar Log Source Management app so that you can receive events from your network devices or appliances.

If you are using QRadar 7.3.1 to 7.5.0 Update Package 3, you can also add a log source by using the [Log Sources icon](#). In QRadar 7.5.0 Update Package 4 and later, when you click the **Log Sources** icon, the QRadar Log Source Management app opens.

### Before you begin

Ensure that the QRadar Log Source Management app is installed on your QRadar Console. For more information about installing the app, see [Installing the QRadar® Log Source Management app](#).

### Procedure

1. Log in to QRadar.
2. Click the **Admin** tab.
3. To open the app, click the **QRadar Log Source Management** app icon.
4. Click **New Log Source > Single Log Source**.
5. On the **Select a Log Source Type** page, select a log source type, and click **Select Protocol Type**.
6. On the **Select a Protocol Type** page, select a protocol, and click **Configure Log Source Parameters**.
7. On the **Configure the Log Source parameters** page, configure the log source parameters, and click **Configure Protocol Parameters**.

The following table describes the common log source parameters for all log source types:

Table 1. Common log source parameters

Parameter	Description
<b>Enabled</b>	When this option is not enabled, the log source does not collect events.
<b>Credibility</b>	Credibility represents the integrity or validity of events that are created by a log source. The credibility value that is assigned to a log source can increase or decrease based on incoming events and can be adjusted as a response to user-created event rules. The credibility of events from log sources contributes to the calculation of the offense magnitude and can increase or decrease the magnitude value of an offense.
<b>Target Event Collector</b>	<p>Specifies the QRadar host where the log source's protocol runs. Outbound protocols initiate connections to remote systems from this host, and inbound protocols initialize their port listeners on this host to receive event data sent by remote systems.</p> <p>This parameter is not specifically used for assigning a log source to an Event Collector appliance. Because the Event Collector component exists on the following hosts, the protocols can be assigned to any of these hosts:</p> <ul style="list-style-type: none"> <li>• Event Collectors</li> <li>• Event Processors</li> <li>• Data Gateways (QRadar on Cloud only)</li> <li>• The QRadar Console</li> </ul> <p><b>Tip:</b> All QRadar hosts that can collect events have an active syslog listener on port 514, whether they have any syslog log sources that are assigned or not. The <b>Target Event Collector</b> parameter is not used for log sources with the Syslog protocol.</p>
<b>Coalescing Events</b>	<p>When multiple events with the same <b>QID</b>, <b>Username</b>, <b>Source IP</b>, <b>Destination IP</b>, <b>Destination Port</b>, <b>Domain</b>, and <b>Log Source</b> occur within a short time interval (10 seconds), they are coalesced (bundled) together.</p> <p>Because the events are bundled together, the number of events that are stored is decreased, which reduces the storage cost of events. Coalescing events might lead to loss of information, including raw payloads or event properties. The default is enabled. For more information, see <a href="#">How does coalescing work in QRadar?</a></p>

8. On the **Configure the protocol parameters** page, configure the protocol-specific parameters.

- If your configuration can be tested, click **Test Protocol Parameters**.

- If your configuration cannot be tested, click **Finish**.
- In the **Test protocol parameters** window, click **Start Test**.
  - To fix any errors, click **Configure Protocol Parameters**. Configure the parameters and click **Test Protocol Parameters**.
  - Click **Finish**.

## Adding a log source by using the Log Sources icon

---

If the log source is not automatically discovered, manually add a log source for QRadar to receive events from your network devices or appliances.

If you are using QRadar 7.3.0 or earlier, you can add a log source in QRadar only by using the **Log Sources** icon.

If you are using QRadar 7.3.1 and later, you can add a log source by using the [QRadar Log Source Management app](#).

### Procedure

- Log on to QRadar.
- Click the **Admin** tab.
- Click the **Log Sources** icon.
- Click **Add**.
- Configure the common parameters for your log source.
- Configure the protocol-specific parameters for your log source.

The following table describes the common log source parameters for all log source types:

*Table 2. Common log source parameters*

Parameter	Description
<b>Enabled</b>	When this option is not enabled, the log source does not collect events.
<b>Credibility</b>	Credibility represents the integrity or validity of events that are created by a log source. The credibility value that is assigned to a log source can increase or decrease based on incoming events and can be adjusted as a response to user-created event rules. The credibility of events from log sources contributes to the calculation of the offense magnitude and can increase or decrease the magnitude value of an offense.

Table 2. Common log source parameters (continued)

Parameter	Description
<b>Target Event Collector</b>	<p>Specifies the QRadar host where the log source's protocol runs. Outbound protocols initiate connections to remote systems from this host, and inbound protocols initialize their port listeners on this host to receive event data sent by remote systems.</p> <p>This parameter is not specifically used for assigning a log source to an Event Collector appliance. Because the Event Collector component exists on the following hosts, the protocols can be assigned to any of these hosts:</p> <ul style="list-style-type: none"> <li>• Event Collectors</li> <li>• Event Processors</li> <li>• Data Gateways (QRadar on Cloud only)</li> <li>• The QRadar Console</li> </ul> <p><b>Tip:</b> All QRadar hosts that can collect events have an active syslog listener on port 514, whether they have any syslog log sources that are assigned or not. The <b>Target Event Collector</b> parameter is not used for log sources with the Syslog protocol.</p>
<b>Coalescing Events</b>	<p>When multiple events with the same <b>QID</b>, <b>Username</b>, <b>Source IP</b>, <b>Destination IP</b>, <b>Destination Port</b>, <b>Domain</b>, and <b>Log Source</b> occur within a short time interval (10 seconds), they are coalesced (bundled) together.</p> <p>Because the events are bundled together, the number of events that are stored is decreased, which reduces the storage cost of events. Coalescing events might lead to loss of information, including raw payloads or event properties. The default is enabled. For more information, see <a href="#">How does coalescing work in QRadar?</a></p>

7. Click **Save**.
8. On the **Admin** tab, click **Deploy Changes**.

## Adding bulk log sources

Use the QRadar Log Source Management app to add multiple log sources to IBM QRadar at the same time. You can add as many log sources as you want.

If you are using QRadar V7.3.0 or earlier, you can add a log source in QRadar only by using the [Log Sources icon](#).

In QRadar 7.5.0 Update Package 4 and later, when you click the **Log Sources** icon, the QRadar Log Source Management app opens.

## Procedure

1. In the QRadar Log Source Management app, click **+ New Log Source** and then click **Multiple Log Sources**.
2. On the **Select a Log Source type** page, select a log source type and click **Select Protocol Type**.
3. On the **Select a protocol type** page, select a protocol type and click **Configure Common Log Source Parameters**.
4. On the **Configure the common Log Source parameters** page, configure the parameters that you want to set for all of the log sources.
5. If you have log sources that have different log source parameter values, clear the relevant check boxes, and then click **Configure Common Protocol Parameters**.
6. On the **Configure the common protocol parameters** page, configure the protocol-specific parameters that you want to set for all of the log sources.
7. If you have log sources that have different protocol parameter values, clear the relevant check boxes, and then click **Configure Individual Parameters**.
8. On the **Configure the individual parameters** page, upload a CSV file that contains the individual log source parameter values, and click **Add**.

A log source is created for each line of this file, except for empty lines and comment lines that begin with a hashtag (#). Each line must contain the comma-separated list of parameter values for the **Log Source Identifier** field, and any other deferred parameters, in the order shown in the deferred parameters table.

9. Click **Bulk Template** to download the file template and add the parameters that you want to configure, in order.

For example, if you deferred the **Enabled** and **Groups** parameters, the CSV file must contain the following values:

```
Enabled, Groups, Log Source Identifier
```

If you include a comma in a parameter, enclose the value in double quotation marks.

10. If you do not upload a CSV file:
  - a) Click **Manual** to specify the values for the parameters that you deferred.
  - b) Enter a **Log Source Identifier** for each new log source and click **Add**.
11. Click **Finish**.

## What to do next

Test your log sources. For more information, see [“Testing log sources” on page 12](#)

## Adding bulk log sources by using the Log Sources icon

You can add up to 500 log sources at one time. When you add multiple log sources at one time, you add a bulk log source in QRadar. Bulk log sources must share a common configuration.

If you are using QRadar V7.3.0 or earlier, you can add a log source in QRadar only by using the **Log Sources** icon.

If you are using QRadar V7.3.1 to V7.3.3, you can also add a log source by using the [QRadar Log Source Management app](#).

## Procedure

1. On the **Admin** tab, click **Log Sources**.
2. From the **Bulk Actions** list, select **Bulk Add**.
3. In the **Bulk Log Sources** window, configure the parameters for the bulk log source.
4. Select the **Enabled** check box to enable the log source. By default, this check box is selected.

5. Select the **Coalescing Events** check box to enable the log source to coalesce (bundle) events. Automatically discovered log sources use the default value that is configured in the **Coalescing Events** list in the **System Settings** window on the **Admin** tab. However, when you create a new log source or update the configuration for an automatically discovered log source, you can override the default value by configuring this check box for each log source. For more information, see the IBM QRadar *Administration Guide*.
6. Select the **Store Event Payload** check box to enable or disable QRadar from storing the event payload. Automatically discovered log sources use the default value from the **Store Event Payload** list in the **System Settings** window on the **Admin** tab. When you create a new log source or update the configuration for an automatically discovered log source, you can override the default value by configuring this check box for each log source. For more information, see the IBM QRadar *Administration Guide*.
7. Upload the log sources by choosing one of the following methods:
  - File Upload - Upload a text file that has one host name or IP per line.  
The text file must contain one IP address or host name per line. Extra characters after an IP address or host names longer than 255 characters can result in a value being bypassed from the text file. The file upload lists a summary of all IP address or host names that were added as the bulk log source.
  - Manual - Enter the host name or IP of the host that you want to add.
8. Click **Add > Save**.
- Note:** By default, a check box is selected for each log source in the host list. Clear the check box if you want the log source to be ignored. Duplicate host names or IP addresses are ignored.
9. Click **Continue** to add the log sources.
10. On the **Admin** tab, click **Deploy Changes**.

## Editing bulk log sources

---

In the QRadar Log Source Management app, view and edit a number of log sources at the same time. You can edit the parameters of up to 1000 log sources at one time. Edit multiple log sources when the log sources have similar parameters that you want to change, instead of editing each log source individually.

If you are using QRadar V7.3.1 to V7.3.3, you can also edit bulk log sources by using the [Log Sources icon](#).

In QRadar 7.5.0 Update Package 4 and later, when you click the **Log Sources** icon, the QRadar Log Source Management app opens.

### Before you begin

Ensure that the QRadar Log Source Management app is installed on your QRadar Console. For more information about installing the app, see [Installing the QRadar Log Source Management app](#).

### Procedure

1. In the QRadar Log Source Management app, select the relevant log sources that you want to edit.
2. Click **Edit**.
3. In the **Log Source Summary** pane, select and edit the parameters and click **Save**.

**Restriction:** The **Log Source Identifier**, **Log Source Type** and **Protocol Configuration** parameters cannot be edited in bulk in the QRadar Log Source Management app. To edit the **Log Source Type** parameter in bulk by using the API, see [QRadar: How to change log source type in bulk by using the QRadar API](#).

4. In the **Name Template** and **Description Template** fields, use the available variables to create the names and descriptions of the selected log sources.
5. Click the **Protocol** tab to edit the protocol parameters for the selected log sources. The selected log sources must share a protocol.

6. Click **Save**.

## Editing bulk log sources by using the Log Sources icon

---

You can edit log sources in bulk to update the configuration parameters for log sources that were added as part of a bulk log source.

**Restriction:** The **Log Source Identifier**, **Log Source Type** and **Protocol Configuration** parameters cannot be edited in bulk by using the **Log Sources** icon. To edit the **Log Source Type** parameter in bulk by using the API, see [QRadar: How to change log source type in bulk by using the QRadar API](#).

If you are using QRadar V7.3.0 or earlier, you can edit multiple log sources in QRadar only by using the **Log Sources** icon.

If you are using QRadar V7.3.1 to V7.3.3, you can also edit multiple log sources by using the [QRadar Log Source Management app](#).

### Procedure

1. Click the **Admin** tab.
2. In the **Data Sources** section, click the **Log Sources** icon.
3. Select the log sources that you want to edit, and from the **Bulk Actions** list, select **Bulk Edit**.
4. Modify the relevant parameters.
5. The list of log sources is for display purposes only. The check boxes are only used during the workflow for adding log sources to QRadar.
6. Click **Save** to update your log source configuration.
7. Click **Continue** to add the log sources.
8. On the **Admin** tab, click **Deploy Changes** if you added an IP address or host name to your bulk log source.

### Results

The bulk log source is updated.

## Adding a log source parsing order

---

You can assign a priority order for when the events are parsed by the target event collector.

### About this task

You can order the importance of the log sources by defining the parsing order for log sources that share a common IP address or host name. Defining the parsing order for log sources ensures that certain log sources are parsed in a specific order, regardless of changes to the log source configuration. The parsing order ensures that system performance is not affected by changes to log source configuration by preventing unnecessary parsing. The parsing order ensures that low-level event sources are not parsed for events before more important log source.

### Procedure

1. Click the **Admin** tab.
2. Click the **Log Source Parsing Ordering** icon.
3. Select a log source.
4. Optional: From the **Selected Event Collector** list, select the Event Collector to define the log source parsing order.
5. Optional: From the **Log Source Host** list, select a log source.
6. Prioritize the log source parsing order.

7. Click **Save**.

## QRadar DSM installations and log source management FAQ

---

Learn about installing DSMs on QRadar.

[How do I configure automatic updates for DSMs and protocols?](#)

[How do I manually install a DSM or protocol?](#)

## Testing log sources

---

In IBM QRadar V7.3.2. Fix Pack 3 or later, test your log source configuration in the QRadar Log Source Management app to ensure that the parameters that you used are correct. The test runs from the host that you specify in the **Target Event Collector** setting, and can collect sample event data from the target system. The target system is the source of your event data.

**Restriction:** If the **Test** tab doesn't appear for your log source, you can't test the configuration. In QRadar V7.3.2. Fix Pack 3 and QRadar Log Source Management app v5.0.0, only a few protocols are updated to include test capabilities. Ensure that you install the latest version of your protocols to get the testing capability when it is available.

To download a Fix Pack, go to [Fix Central](#) (<https://www-945.ibm.com/support/fixcentral/>).

### Procedure

1. In the QRadar Log Source Management app, select a log source.

2. On the **Log Source Summary** pane, click the **Test** tab, then click **Start Test**.

If there is high network latency between the QRadar Console and the log source's **Target Event Collector**, it might take a moment for the results to appear.

When the test is successful, checkmarks are displayed next to each of the results and sample event information is generated. If the test is not successful, an **X** is displayed next to the result that failed, and no sample event information is generated. When one result fails, the test of the other results is canceled.

3. Optional: If the test is not successful, click **Edit** to configure the parameter that caused the test to fail and test your log source again.

Click the drop-down arrow next to the failed result for more information about the error.

4. Optional: Click the **Settings** icon  to edit the **Target Event Collector** settings.

5. Optional: Click the **Download** icon  to view the test results in a .txt file.

6. Click **Close**.

[“Protocols available for testing” on page 12](#)

In QRadar and QRadar Log Source Management app 5.0.0 or later, some protocols are updated to include test capabilities. Ensure that you install the latest version of your protocols to get the testing capability when it is available.

## Protocols available for testing

In QRadar and QRadar Log Source Management app 5.0.0 or later, some protocols are updated to include test capabilities. Ensure that you install the latest version of your protocols to get the testing capability when it is available.

The following table lists the protocols available to be tested in the QRadar Log Source Management app.

Protocol	Fix Central link
Amazon AWS S3 REST API	<a href="#">Download Amazon AWS S3 REST API protocol</a>

Protocol	Fix Central link
Amazon Web Services	<a href="#">Download Amazon Web Services protocol</a>
Cisco Firepower eStreamer	<a href="#">Download Cisco eStreamer protocol</a>
Google Cloud Pub Sub	<a href="#">Download Google Cloud Pub Sub protocol</a>
Google G Suite Activity Reports REST API	<a href="#">Download Google G Suite Activity Reports REST API protocol</a>
HTTP Receiver	<a href="#">Download HTTP receiver protocol</a>
IBM Cloud Identity	<a href="#">Download IBM Cloud Identity protocol</a>
JDBC	<a href="#">Download JDBC protocol</a>
Log File	<a href="#">Download Log File protocol</a>
Microsoft Azure Event Hubs	<a href="#">Download Microsoft Azure Event Hubs protocol</a>
Microsoft DHCP	<a href="#">Download Microsoft DHCP protocol</a>
Microsoft Exchange	<a href="#">Download Microsoft Exchange protocol</a>
Microsoft Graph Security API	<a href="#">Download Microsoft Graph Security API protocol</a>

## Log source groups

You can categorize your log sources into groups to efficiently view and track your log sources. For example, you might group your log sources by functional purpose, physical location, or business unit association.

You can also use log source groups in searches and rules, instead of listing the log sources to which the search or rule applies.

You must have administrative access to create, edit, or delete groups. For more information about user roles, see the *IBM QRadar Administration Guide*.

## Creating a log source group

When you create log source groups, you can drag groups in the navigation tree to change the organization of the tree items.

### Procedure

1. Click the **Admin** tab.
2. In the **Data Sources** section, click **Log Source Groups**.

3. From the navigation tree, select the group where you want to create a new group, and then click **New Group**.
4. In the **Group Properties** window, enter a name and description. The name can be up to 255 characters in length and is case-sensitive. The description can be up to 255 characters in length.
5. Click **OK**.
6. To change the location of the new group, click the group and drag the folder to your chosen location in the navigation tree.
7. To edit the group name or description, select the log source group and then click **Edit**.

## Copying and removing log sources

You can copy a log source to one or more groups to suit your organizational needs. When you no longer need a log source in a particular group, you can remove it. Removing a log source from a group does not delete the log source from IBM QRadar.

### Procedure

1. Click the **Admin** tab.
2. In the **Data Sources** section, click **Log Source Groups**.
3. From the navigation tree, select the relevant log source group.
4. To copy the log source, complete the following steps:
  - a) In the **Group Content** window, select the relevant log source and click **Copy**.
  - b) In the **Choose Group** window, select the group that you want to copy the log source to, and click **Assign Groups**.
5. To remove the log source, complete the following steps:
  - a) In the **Group Content** window, select the relevant log source and click **Remove**.
  - b) In the **Confirmation** window, click **OK**.

## Removing a log source group

You can remove a log source group that contains log sources. If any content, such as rules or saved searches, depends on the log source group it cannot be deleted.

### About this task

Removing a log source group does not delete the log sources from IBM QRadar.

### Procedure

1. Click the **Admin** tab.
2. In the **Data Sources** section, click **Log Source Groups**.
3. From the navigation tree, select the group that contains the group you want to remove.
4. In the **Group Content** window, select the group and click **Remove**.
5. If the log source group has no dependents, in the **Confirm Deletion** window, click **Delete**.
6. If the log source group has dependents, complete the following steps:
  - a) In the **Found Dependents** window, click **View**.
  - b) Delete or edit the dependents so that they do not reference the log source group. Perform these actions in the relevant areas of QRadar.
  - c) In the **Unable to delete one or more items** window, click **Cancel**.
  - d) Return to step 4.

# Chapter 3. Gateway log source

Use a gateway log source to configure a protocol to use many Device Support Modules (DSMs) instead of relying on a single DSM type. With a gateway log source, event aggregator protocols can dynamically handle various event types.

Before you configure your gateway log source, you must understand the difference between protocols, DSMs, and log sources.

## Protocol

Protocols provide the capability of collecting a set of data files by using various connection options. These connections pull the data back, or passively receive data, into the event pipeline in QRadar. Then, the corresponding DSM parses and normalizes the data.

## DSM

A DSM is a code module that parses received events from multiple log sources and converts them to a standard taxonomy format that can be displayed as output. Each type of log source has a corresponding DSM.

## Log source

A log source is a data source that creates an event log. For more information, see [Chapter 2, “Introduction to log source management,” on page 5](#).

Gateway log sources support the following protocols:

- Amazon AWS S3 REST
- Amazon AWS Web Services
- Google Cloud Pub Sub
- HTTP Receiver
- Kafka
- Microsoft Azure Event Hubs
- TCPMutilineSyslog
- TLS Syslog
- UDPMutilineSyslog

**Tip:** To provide the best fit for the generic data, use the Universal DSM when you configure your gateway log source.

A gateway log source does not use a DSM. It delegates the DSM parsing to stand-alone Syslog log sources that have an appropriate identifier and DSM. These log sources are a collector log source (the gateway) and a parser log source. Parser log sources match data that comes in from the gateway and do not actively collect the events themselves.

Before you create your gateway log source, you must know what types of data you expect to collect from the data gateway. Data gateways can collect many data types and QRadar does not support all data types by default. To parse the data correctly, a DSM must exist that can handle the events that you are collecting. Even if QRadar supports the event’s source, if the gateway returns it in an unexpected format, the DSM might not parse it. For example, if the data gateway returns an event in a JSON format, but the DSM expects a LEEF format, you might need a custom DSM to parse the data.

A gateway log source works in the same way as other log sources by using its selected protocol to reach out and collect events. The difference between a gateway log source and other log sources occurs when the collected events are ready to be posted. A normal log source attempts to force the events to be parsed by the selected DSM. A gateway log source sends the events as a Syslog payload with a default identifier set to either 0.0.0.0 or to the connected Services IP address (the packet source IP address).

When an event is posted to the event pipeline as a Syslog payload, the events are handled by log source auto detection. If an existing log source with the provided identifier exists, the event is handled by that log

source, regardless of whether the event parses with that DSM. If no existing log source exists, the event is parsed by DSMs that support auto detection. If the event correctly parses with a DSM, then it creates a log source with the naming format depending on the configuration of log source auto detection for that particular DSM, which is generally \$\$DEVICE\_TYPE\$\$ @ \$\$SOURCE\_ADDRESS\$\$.

Log sources that are automatically created usually have the **Log Source Identifier** option set to hostname/IP if it is a valid syslog header, the packet source IP, or 0.0.0.0. To match to an automatically created log source, the payload must have an identifier that matches what is in the **Log Source Identifier**, and the selected DSM must be able to parse it. Events that cannot be parsed are sent directly to sim-generic or stored.

**Tip:**

Manually created log sources that have an identifier that matches the identifier of the Syslog payload are used even if the DSM of the log source fails to parse the event.

To configure a gateway log source, enable the **Use As A Gateway Log Source** option for the selected protocol. If you enable this option, the events are sent to the event pipeline and are autodetected. To get the maximum value from this feature, use the “[Log source identifier pattern](#)” on page 16.

**Related concepts**

[“Introduction to log source management” on page 5](#)

You can configure IBM QRadar to accept event logs from log sources that are on your network. A *log source* is a data source that creates an event log.

## Log source identifier pattern

---

Use the log source identifier pattern to customize the identifier that is sent with payloads when an event is posted. You can choose identifiers for your event formats and event types.

**Important:**

To use the full capabilities of the log source identifier pattern, you must have a basic understanding of regular expressions (regex) and how to use them.

The log source identifier pattern accepts a list of key-value pairs. A key is an identifier that is represented as a regex. The value is a regex that matches to event data. When the regex matches to the data within the event, then it posts the event with the identifier that is associated with that value.

**Basic example**

Key1 = value1

Key2 = value2

Key3 = value3

In this example, if an event contains a value of “value1”, the identifier for that event is key1. If an event contains a value of “value2”, the identifier is Key2. If an event contains both “value1” and “value2”, the first identifier, Key1, is matched.

In this example, you must manually create three Syslog log sources, one for each of the identifier options.

**Regex example**

Key1 = value1

Key2 = \d\d\d (where \d\d\d is a regex that matches to three consecutive digits.)

\1= \d(\d) (where \d(\d) is a regex that matches to two consecutive digits and captures the second digit. \1 references the first captured value in the value field.)

In this example, the following statements are true:

- \d represents a “digit”.

- If an event contains a value of “value1”, the identifier for that event is Key1.
- If an event contains “111” or “652” or any three consecutive digits, the identifier would be Key2.
- If an event contains two consecutive digits such as “11”, “73”, and “24”, the identifier is \1. The regex saves the second value (“1”, “3” and “4” in the examples) for future use with the parentheses. The value that is saved by the regex is used later as the identifier. If you set the key to “\1”, the key matches to the first saved value in the regex. In this case, the identifier is not a hardcoded value, but instead it can be ten values (0 - 9.) Three identifiers are in the sample events (“1”, “3” and “4.”).

You must create a log source with the identifiers Key1 and Key2, and a log source for each possible Key1 value. In this example, for the events to go to the correct log source, you must create three Syslog log sources. For the log sources, one has the identifier set to “1”, one has the identifier set to “3” and one has the identifier set to “4”. To capture all of the possible identifiers, you need ten Syslog log sources. Each log source corresponds to a single digit.

## **Tips for using the log source identifier pattern**

It is important to know what type of data you are receiving and how granular you need your log sources to be. Each QRadar environment is unique. The following tips can help you to configure the log source identifier pattern.

### **Keep the data separated at the source**

Most gateway supported services, such as Microsoft Azure Event Hubs and Google Pub Sub, offer ways to separate the data at the source. Keep your data in separate sources to reduce the complexity on the QRadar side. For example, if you want to collect Windows Logs, Linux® Logs and Audit Logs, use three separate gateway log sources to simplify the configuration. If you collect all of those logs in one source, QRadar must identify the events and associate them with the correct log source.

### **Hardcode the regex if possible**

If you hardcode the key, all of the events that match the value’s regex are collected by a single log source. This action requires less effort to create and maintain log sources, and they are easier to monitor.

### **Use online regex testers**

Before you save and enable your log source, use online tools to test the regex.

### **Use the Event Retriever to determine the identifier**

Use the Event Retriever to display the assigned log source identifier in QRadar. You can also use it to test that your regex and identifier are matching correctly.

# Chapter 4. Log source extensions

An extension document can extend or modify how the elements of a particular log source are parsed. You can use the extension document to correct a parsing issue or override the default parsing for an event from an existing DSM.

An extension document can also provide event support when a DSM does not exist to parse events for an appliance or security device in your network.

An extension document is an Extensible Markup Language (XML) formatted document that you can create or edit one by using any common text, code or markup editor. You can create multiple extension documents but a log source can have only one applied to it.

The XML format requires that all regular expression (regex) patterns be contained in character data (CDATA) sections to prevent the special characters that are required by regular expressions from interfering with the markup format. For example, the following code shows the regex for finding protocols:

```
<pattern id="ProtocolPattern" case-insensitive="true" xmlns=""> <! [CDATA[(TCP|UDP|ICMP|GRE)]]></pattern>
```

(TCP | UDP | ICMP | GRE) is the regular expression pattern.

The log sources extension configuration consists of the following sections:

## Pattern

Regular expressions patterns that you associate with a particular field name. Patterns are referenced multiple times within the log source extension file.

## Match groups

An entity within a match group that is parsed, for example, EventName, and is paired with the appropriate pattern and group for parsing. Any number of match groups can appear in the extension document.

## Examples of log source extensions on QRadar Support Forums

You can create log source extensions (LSX) for log sources that don't have a supported DSM. To help you create your own log source extensions (also known as DSM extensions), you modify existing ones that were created.

The IBM QRadar Support Forum is an online discussion site where users and subject matter experts collaborate and share information.

You can find examples and answers to administration or troubleshooting questions that are related to the DSM Editor, log source extensions, and custom parsing issues on [IBM QRadar Support Forum](https://www.ibm.com/mysupport/s/forumsproduct?language=en_US&name=qradar-dsm-editor&id=0TO0z000000R0iKGAS) ([https://www.ibm.com/mysupport/s/forumsproduct?language=en\\_US&name=qradar-dsm-editor&id=0TO0z000000R0iKGAS](https://www.ibm.com/mysupport/s/forumsproduct?language=en_US&name=qradar-dsm-editor&id=0TO0z000000R0iKGAS)).

Optionally, for administration or troubleshooting questions that are related to the DSM Editor, log source extensions, and custom parsing issues, you can go to [IBM QRadar FORUMS 101](https://www.ibm.com/community/qradar/home/forums/) (<https://www.ibm.com/community/qradar/home/forums/>). From the **Category** list, select *Events and Log Sources*, and from the **Tag** list, select *qradar-dsm-editor*.

Figure 1. IBM QRadar Forums 101

## Related concepts

[Creating a log source extensions document to get data into QRadar](#)

You create log source extensions (LSX) when log sources don't have a supported DSM, or to repair an event that has missing or incorrect information, or to parse an event when the associated DSM fails to produce a result.

## Patterns in log source extension documents

---

Rather than associating a regular expression directly with a particular field name, patterns (*patterns*) are declared separately at the top of the extension document. These regex patterns can be then referenced multiple times within the log source extension file.

All characters between the start tag <pattern> and end tag </pattern> are considered part of the pattern. Do not use extra spaces or hard returns inside or around your pattern or <CDATA> expression. Extra characters or spaces can prevent the DSM extension from matching your intended pattern.

*Table 3. Description of pattern parameters*

Pattern	Type	Description
id (Required)	String	A regular string that is unique within the extension document.
case-insensitive (Optional)	Boolean	If true, the character case is ignored. For example, abc is the same as ABC. If not specified, this parameter defaults to false.
trim-whitespace (Optional)	Boolean	If true, whitespace and carriage returns are ignored. If the CDATA sections are split onto different lines, any extra spaces and carriage returns are not interpreted as part of the pattern. If not specified, this parameter defaults to false.
use-default-pattern (Optional)	Boolean	If true, the system uses Java Patterns for the Log Source Extension, instead of the more effective Adaptive Patterns. Set this option to true if Adaptive Patterns are providing inconsistent matching. If not specified, this parameter defaults to false.

## Match groups

---

A *match group* (*match-group*) is a set of patterns that are used for parsing or modifying one or more types of events.

A *matcher* is an entity within a match group that is parsed, for example, EventName, and is paired with the appropriate pattern and group for parsing. Any number of match groups can appear in the extension document.

*Table 4. Description of match group parameters*

Parameter	Description
order (Required)	An integer greater than zero that defines the order in which the match groups are executed. It must be unique within the extension document.
description (Optional)	A description for the match group, which can be any string. This information can appear in the logs. If not specified, this parameter defaults to empty.
device-type-id-override (Optional)	Define a different device ID to override the QID. Allows the particular match group to search in the specified device for the event type. It must be a valid log source type ID, represented as an integer. If not specified, this parameter defaults to the log source type of the log source to which the extension is attached.

Match groups can have these entities:

- [“Matcher \(matcher\)” on page 21](#)
- [“Single-event modifier \(event-match-single\)” on page 35](#)
- [“Multi-event modifier \(event-match-multiple\)” on page 35](#)

## Matcher (matcher)

A matcher entity is a field that is parsed, for example, EventName, and is paired with the appropriate pattern and group for parsing.

Matchers have an associated order. If multiple matchers are specified for the same field name, the matchers are run in the order that is presented until a successful parse is found or a failure occurs.

*Table 5. Description of matcher parameters*

Parameter	Description
field (Required)	The field to which you want the pattern to apply, for example, EventName, or SourceIp. You can use any of the field names that are listed in the <a href="#">List of valid matcher field names table</a> .
pattern-id (Required)	The pattern that you want to use when the field is parsed from the payload. This value must match (including case) the ID parameter of the pattern that is previously defined in a pattern ID parameter ( <a href="#">Table 3 on page 20</a> ).
order (Required)	The order that you want this pattern to attempt among matchers that are assigned to the same field. If two matchers are assigned to the EventName field, the one with the lowest order is attempted first.

*Table 5. Description of matcher parameters (continued)*

Parameter	Description
capture-group (Optional)	<p>Referenced in the regular expression inside parenthesis ( ). These captures are indexed starting at one and processed from left to right in the pattern. The capture-group field must be a positive integer less than or equal to the number of capture groups that are contained in the pattern. The default value is zero, which is the entire match.</p> <p>For example, you can define a single pattern for a source IP address and port; where the SourceIp matcher can use a capture group of 1, and the SourcePort matcher can use a capture group of 2, but only one pattern needs to be defined.</p> <p>This field has a dual purpose when combined with the enable-substitutions parameter.</p> <p>To see an example, review the <a href="#">extension document example</a>.</p>
enable-substitutions (Optional)	<p>Boolean</p> <p>When you set to true, a field cannot be adequately represented with a straight group capture. You can combine multiple groups with extra text to form a value.</p> <p>This parameter changes the meaning of the capture-group parameter. The capture-group parameter creates the new value, and group substitutions are specified by using \x where x is a group number, 1 - 9. You can use groups multiple times, and any free-form text can also be inserted into the value. For example, to form a value out of group 1, followed by an underscore, followed by group 2, an @, and then group 1 again, the appropriate capture-group syntax is shown in the following code:</p> <pre>capture-group="\1_\2@\1"</pre> <p>In another example, a MAC address is separated by colons, but in QRadar, MAC addresses are usually hyphen-separated. The syntax to parse and capture the individual portions is shown in the following example:</p> <pre>capture-group="\1:\2:\3:\4:\5:\6"</pre> <p>If no groups are specified in the capture-group when substitutions are enabled, a direct text replacement occurs.</p> <p>Default is false.</p>

*Table 5. Description of matcher parameters (continued)*

Parameter	Description
ext-data (Optional)	<p>An extra-data parameter that defines any extra field information or formatting that a matcher field can provide in the extension.</p> <p>The only field that currently uses this parameter is DeviceTime.</p> <p>For example, you might have a device that sends events by using a unique time stamp, but you want the event to be reformatted to a standard device time. Use the ext-data parameter included with the DeviceTime field to reformat the date and time stamp of the event. For more information, see the <a href="#">List of valid matcher field names</a>.</p>

The following table lists valid matcher field names.

*Table 6. List of valid matcher field names*

Field name	Description
EventName (Required)	<p>The event name to be retrieved from the QID to identify the event.</p> <p><b>Note:</b> This parameter doesn't appear as a field in the <b>Log Activity</b> tab.</p>
EventCategory cat (LEEF)	<p>An event category for any event with a category not handled by an event-match-single entity or an event-match-multiple entity.</p> <p>Combined with EventName, EventCategory is used to search for the event in the QID. The fields that are used for QIDmap lookups require an override flag to be set when the devices are already known to QRadar, for example,</p> <pre>&lt;event-match-single event-name="Successfully logged in" force-qidmap-lookup-on-fixup="true" device-event-category="CiscoNAC" severity="4" send-identity="OverrideAndNeverSend" /&gt;</pre> <p>The <code>force-qidmap-lookup-on-fixup="true"</code> is the flag override.</p> <p><b>Note:</b> This parameter doesn't appear as a field in the <b>Log Activity</b> tab.</p>
SourceIp src (LEEF)	The source IP address for the message.
SourcePort srcPort (LEEF)	The source port for the message.

*Table 6. List of valid matcher field names (continued)*

<b>Field name</b>	<b>Description</b>
SourceIpPreNAT srcPreNAT (LEEF)	The source IP address for the message before Network Address Translation (NAT) occurs.
SourceIpPostNAT srcPostNAT (LEEF)	The source IP address for the message after NAT occurs.
SourceMAC srcMAC (LEEF)	The source MAC address for the message.
SourcePortPreNAT srcPreNATPort (LEEF)	The source port for the message before NAT occurs.
SourcePortPostNAT srcPostNATPort (LEEF)	The source port for the message after NAT occurs.
DestinationIp dst (LEEF)	The destination IP address for the message.
DestinationPort dstPort (LEEF)	The destination port for the message.
DestinationIpPreNAT dstPreNAT (LEEF)	The destination IP address for the message before NAT occurs.
DestinationIpPostNAT dstPostNAT (LEEF)	The destination IP address for the message after NAT occurs.
DestinationPortPreNAT dstPreNATPort (LEEF)	The destination port for the message before NAT occurs.
DestinationPortPostNAT dstPostNATPort (LEEF)	The destination port for the message after NAT occurs.
DestinationMAC dstMAC (LEEF)	The destination MAC address for the message.

Table 6. List of valid matcher field names (continued)

Field name	Description
DeviceTime devTime (LEEF)	<p>The time and format that is used by the device. This date and time stamp represent the time that the event was sent, according to the device. This parameter doesn't represent the time that the event arrived. The DeviceTime field supports the ability to use a custom date and time stamp for the event by using the ext-data Matcher attribute.</p> <p>The following list contains examples of date and time stamp formats that you can use in the DeviceTime field:</p> <ul style="list-style-type: none"> <li>• ext-data="dd/MMM/YYYY:hh:mm:ss" 11/Mar/2015:05:26:00</li> <li>• ext-data="MMM dd YYYY / hh:mm:ss" Mar 11 2015 / 05:26:00</li> <li>• ext-data="hh:mm:ss:dd/MMM/YYYY" 05:26:00:11/Mar/2015</li> </ul> <p>For more information about the possible values for the data and time stamp format, see the <a href="http://www.joda.org/joda-time/key_format.html">Joda-Time web page</a> (<a href="http://www.joda.org/joda-time/key_format.html">http://www.joda.org/joda-time/key_format.html</a>).</p> <p>DeviceTime is the only event field that uses the ext-data optional parameter.</p>
Protocol proto (LEEF)	The protocol for the message; for example, TCP, UDP, or ICMP.
UserName	The user name for the message.
HostName identHostName (LEEF)	The host name for the message. Typically, this field is associated with identity events.
GroupName identGrpName (LEEF)	The group name for the message. Typically, this field is associated with identity events.
IdentityIp	The identity IP address for the message.
IdentityMac identMAC (LEEF)	The identity MAC address for the message.
IdentityIpv6	The IPv6 identity IP address for the message.
NetBIOSName identNetBios (LEEF)	The NetBIOS name for the message. Typically, this field is associated with identity events.
ExtraIdentityData	Any user-specific data for the message. Typically, this field is associated with identity events.

*Table 6. List of valid matcher field names (continued)*

Field name	Description
SourceIpv6	The IPv6 source IP address for the message.
DestinationIpv6	The IPv6 destination IP address for the message.

## JSON matcher (json-matcher)

A JSON-matcher (json-matcher) entity is a field that is parsed and is paired with the appropriate pattern and group for parsing. This entity is new in IBM QRadar V7.3.1.

If multiple matchers are specified for the same field name, the matchers are run in the order that is presented until a successful parse is found.

*Table 7. Description of JSON matcher parameters*

Parameter	Description
field (Required)	The field to which you want the pattern to apply; for example, EventName or SourceIp. You can use any of the field names that are listed in the <a href="#">List of valid matcher field names table</a> .
pattern-id (Required)	The pattern that you want to use when the field is parsed from the payload. This value must match (including case) the ID parameter of an already defined pattern. ( <a href="#">Table 3 on page 20</a> )
order (Required)	<p>The order that you want this pattern to attempt among matchers that are assigned to the same field. If two matchers are assigned to the <b>EventName</b> field, the one with the lowest order is attempted first.</p> <p>The regular regex matchers and JSON matchers are combined into one list. The different types of matchers are attempted based on their orders, and the process stops when one of the matchers is able to parse out data from the payload.</p>
enable-substitutions (Optional)	<p>Boolean</p> <p>When set to <b>true</b>, a field cannot be adequately represented with a straight group capture. You can combine multiple groups with extra text to form a value.</p> <p>Wherever the pattern is in the form of a multi-keypath, set the <b>enable-substitutions</b> value to '<b>=true</b>' so that each keypath in the pattern and expression is replaced with the value that is found by the payload. For example, if the JSON payload contains the <b>first_name</b> and <b>last_name</b> fields, but no <b>full_name</b> field, you can define an expression that contains multiple keypaths, such as <code>{/"last_name"}, {"first_name"}</code>. The captured value for this expression is smith, john.</p> <p>Default is <b>false</b>.</p>

*Table 7. Description of JSON matcher parameters (continued)*

Parameter	Description
ext-data (Optional)	<p>An extra-data parameter that defines any extra field information or formatting that a matcher field can provide in the extension.</p> <p>The only field that currently uses this parameter is DeviceTime.</p> <p>For example, you might have a device that sends events by using a unique time stamp, but you want the event to be reformatted to a standard device time. Use the ext-data parameter included with the DeviceTime field to reformat the date and time stamp of the event. For more information, see the <a href="#">List of valid JSON matcher field names</a>.</p>

The following table lists valid **JSON matcher** field names.

*Table 8. List of valid JSON matcher field names*

Field name	Description
EventName (Required)	<p>The event name to be retrieved from the QID to identify the event.</p> <p><b>Note:</b> This parameter doesn't appear as a field in the <b>Log Activity</b> tab.</p>
EventCategory	<p>An event category for any event with a category that is not handled by an event-match-single entity or an event-match-multiple entity.</p> <p>Combined with EventName, EventCategory is used to search for the event in the QID. The fields that are used for QIDmap lookups require an override flag to be set when the devices are already known to the QRadar system, for example:</p> <pre>&lt;event-match-single event-name="Successfully logged in" force-qidmap- lookup-on-fixup="true" device-event- category="CiscoNAC" severity="4" send- identity="OverrideAndNeverSend" /&gt;</pre> <p>The <b>force-qidmap-lookup-on-fixup="true"</b> is the flag override.</p> <p><b>Note:</b> This parameter doesn't appear as a field in the <b>Log Activity</b> tab.</p>
SourceIp	The source IP address for the message.
SourcePort	The source port for the message.
SourceIpPreNAT	The source IP address for the message before Network Address Translation (NAT) occurs.

Table 8. List of valid **JSON matcher** field names (continued)

Field name	Description
SourceIpPostNAT	The source IP address for the message after NAT occurs.
SourceMAC	The source MAC address for the message.
SourcePortPreNAT	The source port for the message before NAT occurs.
SourcePortPostNAT	The source port for the message after NAT occurs.
DestinationIp	The destination IP address for the message.
DestinationPort	The destination port for the message.
DestinationIpPreNAT	The destination IP address for the message before NAT occurs.
DestinationIpPostNAT	The destination IP address for the message after NAT occurs.
DestinationPortPreNAT	The destination port for the message before NAT occurs.
DestinationPortPostNAT	The destination port for the message after NAT occurs.
DestinationMAC	The destination MAC address for the message.

Table 8. List of valid **JSON matcher** field names (continued)

Field name	Description
DeviceTime	<p>The time and format that is used by the device. This date and time stamp represent the time that the event was sent, according to the device. This parameter doesn't represent the time that the event arrived. The DeviceTime field supports the ability to use a custom date and time stamp for the event by using the ext-data Matcher attribute.</p> <p>The following list contains examples of date and time stamp formats that you can use in the DeviceTime field:</p> <ul style="list-style-type: none"> <li>• ext-data="dd/MMM/YYYY:hh:mm:ss" 11/Mar/2015:05:26:00</li> <li>• ext-data="MMM dd YYYY / hh:mm:ss" Mar 11 2015 / 05:26:00</li> <li>• ext-data="hh:mm:ss:dd/MMM/YYYY" 05:26:00:11/Mar/2015</li> </ul> <p>For more information about the possible values for the data and time stamp format, see the <a href="https://docs.oracle.com/javase/8/docs/api/java/text/SimpleDateFormat.html">Java SimpleDateFormat web page</a> (<a href="https://docs.oracle.com/javase/8/docs/api/java/text/SimpleDateFormat.html">https://docs.oracle.com/javase/8/docs/api/java/text/SimpleDateFormat.html</a>).</p> <p>DeviceTime is the only event field that uses the ext-data parameter.</p>
Protocol	The protocol for the message; for example, TCP, UDP, or ICMP.
UserName	The user name for the message.
HostName	The host name for the message. Typically, this field is associated with identity events.
GroupName	The group name for the message. Typically, this field is associated with identity events.
IdentityIp	The identity IP address for the message.
IdentityMac	The identity MAC address for the message.
IdentityIpv6	The IPv6 identity IP address for the message.
NetBIOSName	The NetBIOS name for the message. Typically, this field is associated with identity events.
ExtraIdentityData	Any user-specific data for the message. Typically, this field is associated with identity events.
SourceIpv6	The IPv6 source IP address for the message.

*Table 8. List of valid **JSON matcher** field names (continued)*

Field name	Description
DestinationIpv6	The IPv6 destination IP address for the message.

## LEEF matcher (leef-matcher)

A LEEF-matcher (leef-matcher) entity is a field that is parsed and is paired with the appropriate pattern of type 'LeefKey' for parsing. This entity is new in IBM QRadar V7.3.2.

If multiple matchers are specified for the same field name, the matchers are run in the order that is presented until a successful parse is found.

*Table 9. Description of LEEF matcher parameters*

Parameter	Description
field (Required)	The field to which you want the pattern to apply; for example, EventName or SourceIp. You can use any of the field names that are listed in the <a href="#">Table 6 on page 23</a> .
pattern-id (Required)	The pattern that you want to use when the field is parsed from the payload. This value must match (including case) the ID parameter of an already defined pattern. ( <a href="#">Table 3 on page 20</a> )
order (Required)	<p>The order that you want this pattern to attempt among matchers that are assigned to the same field. If two matchers are assigned to the <b>EventName</b> field, the one with the lowest order is attempted first.</p> <p>The regular regex, JSON, LEEF, and CEF matchers are combined into one list. The different types of matchers are attempted based on their orders, and the process stops when one of the matchers is able to parse out data from the payload.</p>
enable-substitutions (Optional)	<p>Boolean</p> <p>When set to <code>true</code>, a field cannot be adequately represented with a straight group capture. You can combine multiple groups with extra text to form a value.</p> <p>Default is <code>false</code>.</p>
ext-data (Optional)	<p>An extra-data parameter that defines any extra field information or formatting that a matcher field can provide in the extension.</p> <p>The only field that currently uses this parameter is DeviceTime.</p> <p>For example, you might have a device that sends events by using a unique time stamp, but you want the event to be reformatted to a standard device time. Use the ext-data parameter included with the DeviceTime field to reformat the date and time stamp of the event. For more information, see the <a href="#">Table 6 on page 23</a>.</p>

## CEF matcher (cef-matcher)

A CEF-matcher (cef-matcher) entity is a field that is parsed and is paired with the appropriate pattern of type 'CefKey' for parsing. This entity is new in IBM QRadar V7.3.2.

If multiple matchers are specified for the same field name, the matchers are run in the order that is presented until a successful parse is found.

*Table 10. Description of CEF matcher parameters*

Parameter	Description
field (Required)	The field to which you want the pattern to apply; for example, EventName or SourceIp. You can use any of the field names that are listed in the <a href="#">Table 6 on page 23</a> table.
pattern-id (Required)	The pattern that you want to use when the field is parsed from the payload. This value must match (including case) the ID parameter of an already defined pattern. ( <a href="#">Table 3 on page 20</a> )
order (Required)	The order that you want this pattern to attempt among matchers that are assigned to the same field. If two matchers are assigned to the <b>EventName</b> field, the one with the lowest order is attempted first.  The regular regex, JSON, LEEF, and CEF matchers are combined into one list. The different types of matchers are attempted based on their orders, and the process stops when one of the matchers is able to parse out data from the payload.
enable-substitutions (Optional)	Boolean  When set to true, a field cannot be adequately represented with a straight group capture. You can combine multiple groups with extra text to form a value.  Default is false.
ext-data (Optional)	An extra-data parameter that defines any extra field information or formatting that a matcher field can provide in the extension.  The only field that currently uses this parameter is DeviceTime.  For example, you might have a device that sends events by using a unique time stamp, but you want the event to be reformatted to a standard device time. Use the ext-data parameter included with the DeviceTime field to reformat the date and time stamp of the event. For more information, see the <a href="#">Table 6 on page 23</a> .

## Name Value Pair matcher (namevaluepair-matcher)

A Name Value Pair-matcher (namevaluepair-matcher) entity is a field that is parsed and is paired with the appropriate pattern of type 'NameValuePairKey' for parsing. This entity is new in IBM QRadar V7.3.3.

If multiple matchers are specified for the same field name, the matchers are run in the order that is presented until a successful parse is found.

*Table 11. Description of Name Value Pair matcher parameters*

Parameter	Description
field (Required)	The field to which you want the pattern to apply; for example, EventName or SourceIp. You can use any of the field names that are listed in the <a href="#">Table 6 on page 23</a> .
pattern-id (Required)	The pattern that you want to use when the field is parsed from the payload. This value must match (including case) the ID parameter of an already defined pattern. ( <a href="#">Table 3 on page 20</a> )
order (Required)	<p>The order that you want this pattern to attempt among matchers that are assigned to the same field. If two matchers are assigned to the <b>EventName</b> field, the one with the lowest order is attempted first.</p> <p>The regular regex, JSON, LEEF, and CEF matchers are combined into one list. The different types of matchers are attempted based on their orders, and the process stops when one of the matchers is able to parse out data from the payload.</p>
enable-substitutions (Optional)	<p>Boolean</p> <p>When set to <code>true</code>, a field cannot be adequately represented with a straight group capture. You can combine multiple groups with extra text to form a value.</p> <p>Default is <code>false</code>.</p>
ext-data (Optional)	<p>An extra-data parameter that defines any extra field information or formatting that a matcher field can provide in the extension.</p> <p>The only field that currently uses this parameter is DeviceTime.</p> <p>For example, you might have a device that sends events by using a unique time stamp, but you want the event to be reformatted to a standard device time. Use the ext-data parameter included with the DeviceTime field to reformat the date and time stamp of the event. For more information, see the <a href="#">Table 6 on page 23</a>.</p>
delimiter-pair (Optional)	The delimiter between each value in a NameValuePair payload.
delimiter-namevalue (Optional)	The delimiter between the name and value in each pair.

### Example

In the following example, the delimiter-pair is a comma (,) and the delimiter-namevalue is an equal sign (=).

```
key1=value1,key2=value2,key3=value3
```

## Generic List matcher (genericlist-matcher)

A Generic List-matcher (genericlist-matcher) entity is a field that is parsed and is paired with the appropriate pattern of type "GenericListKey" for parsing. This entity is new in IBM QRadar V7.3.3.

If multiple matchers are specified for the same field name, the matchers are run in the order that is presented until a successful parse is found.

*Table 12. Description of Generic List matcher parameters*

Parameter	Description
field (Required)	The field to which you want the pattern to apply; for example, EventName or SourceIp. You can use any of the field names that are listed in the <a href="#">Table 6 on page 23</a> .
pattern-id (Required)	The pattern that you want to use when the field is parsed from the payload. This value must match (including case) the ID parameter of an already defined pattern. ( <a href="#">Table 3 on page 20</a> )
order (Required)	<p>The order that you want this pattern to attempt among matchers that are assigned to the same field. If two matchers are assigned to the <b>EventName</b> field, the one with the lowest order is attempted first.</p> <p>The regular regex, JSON, LEEF, and CEF matchers are combined into one list. The different types of matchers are attempted based on their orders, and the process stops when one of the matchers is able to parse out data from the payload.</p>
enable-substitutions (Optional)	<p>Boolean</p> <p>When set to <code>true</code>, a field cannot be adequately represented with a straight group capture. You can combine multiple groups with extra text to form a value.</p> <p>Default is <code>false</code>.</p>
ext-data (Optional)	<p>An extra-data parameter that defines any extra field information or formatting that a matcher field can provide in the extension.</p> <p>The only field that currently uses this parameter is DeviceTime.</p> <p>For example, you might have a device that sends events by using a unique time stamp, but you want the event to be reformatted to a standard device time. Use the ext-data parameter included with the DeviceTime field to reformat the date and time stamp of the event. For more information, see the <a href="#">Table 6 on page 23</a>.</p>
delimiter (Optional)	The delimiter between each value in a GenericList payload.

## Example

In the following example, the delimiter is a comma (,).

```
value1,value2,value3
```

## XML Matcher (xml-matcher)

A XML-matcher (xml-matcher) entity is a field that is parsed and is paired with the appropriate pattern of type 'XmlKey' for parsing.

If multiple matchers are specified for the same field name, the matchers are run in the order that is presented until a successful parse is found.

<i>Table 13. Description of XML matcher parameters</i>	
Parameter	Description
field (Required)	The field to which you want the pattern to apply; for example, EventName or SourceIp. You can use any of the field names that are listed in the <a href="#">Table 6 on page 23</a> .
pattern-id (Required)	The pattern that you want to use when the field is parsed from the payload. This value must match (including case) the ID parameter of an already defined pattern. ( <a href="#">Table 3 on page 20</a> )
order (Required)	<p>The order that you want this pattern to attempt among matchers that are assigned to the same field. If two matchers are assigned to the <b>EventName</b> field, the one with the lowest order is attempted first.</p> <p>The regular regex, JSON, LEEF, and CEF matchers are combined into one list. The different types of matchers are attempted based on their orders, and the process stops when one of the matchers is able to parse out data from the payload.</p>
enable-substitutions (Optional)	<p>Boolean</p> <p>When set to <code>true</code>, a field cannot be adequately represented with a straight group capture. You can combine multiple groups with extra text to form a value.</p> <p>Default is <code>false</code>.</p>
ext-data (Optional)	<p>An extra-data parameter that defines any extra field information or formatting that a matcher field can provide in the extension.</p> <p>The only field that currently uses this parameter is DeviceTime.</p> <p>For example, you might have a device that sends events by using a unique time stamp, but you want the event to be reformatted to a standard device time. Use the ext-data parameter included with the DeviceTime field to reformat the date and time stamp of the event. For more information, see the <a href="#">Table 6 on page 23</a>.</p>

## **Multi-event modifier (event-match-multiple)**

The multi-event modifier (event-match-multiple) matches a range of event types and then modifies them as specified by the pattern-id parameter and the capture-group-index parameter.

This match is not done against the payload, but is done against the results of the EventName matcher previously parsed out of the payload.

This entity allows mutation of successful events by changing the device event category, severity, or the method the event uses to send identity events. The capture-group-index must be an integer value (substitutions are not supported) and pattern-ID must reference an existing pattern entity. All other properties are identical to their counterparts in the single-event modifier.

## **Single-event modifier (event-match-single)**

Single-event modifier (event-match-single) matches and then modifies exactly one type of event, as specified by the required, case-sensitive EventName parameter.

This entity allows mutation of successful events by changing the device event category, severity, or the method for sending identity events.

When events that match this event name are parsed, the device category, severity, and identity properties are imposed upon the resulting event.

You must set an event-name attribute and this attribute value matches the value of the **EventName** field. In addition, an event-match-single entity consists of these optional properties:

*Table 14. Description of single-event parameters*

Parameter	Description
device-event-category	A new category for searching for a QID for the event. This parameter is an optimizing parameter because some devices have the same category for all events.
severity	The severity of the event. This parameter must be an integer value 1 - 10. If a severity of less than 1 or greater than 10 is specified, the system defaults to 5. If not specified, the default is whatever is found in the QID.

Table 14. Description of single-event parameters (continued)

Parameter	Description
send-identity	<p>Specifies the sending of identity change information from the event. Choose one of the following options:</p> <ul style="list-style-type: none"> <li>• <b>UseDSMResults</b> If the DSM returns an identity event, the event is passed on. If the DSM does not return an identity event, the extension does not create or modify the identity information.</li> <li>• <b>This option is the default value if no value is specified.</b></li> <li>• <b>SendIfAbsent</b> If the DSM creates identity information, the identity event is passed through unaffected. If no identity event is produced by the DSM, but there is enough information in the event to create an identity event, an event is generated with all the relevant fields set.</li> <li>• <b>OverrideAndAlwaysSend</b> Ignores any identity event that is returned by the DSM and creates a new identity event, if there is enough information.</li> <li>• <b>OverrideAndNeverSend</b> Suppress any identity information that is returned by the DSM. Suggested option unless you are processing events that you want to go into asset updates.</li> </ul>

## Extension document template

The example of an extension document provides information about how to parse one particular type of Cisco FWSM so that events are not sent with an incorrect event name.

For example, if you want to resolve the word session, which is embedded in the middle of the event name:

```
Nov 17 09:28:26 192.0.2.1 %FWSM-session-0-302015: Built UDP connection for faddr
<IP_address1>/80 gaddr <IP_address2>/31696 laddr <IP_address3>/2157 duration 0:00:00 bytes
57498 (TCP FINs)
```

This condition causes the DSM to not recognize any events and all the events are unparsed and associated with the generic logger.

Although only a portion of the text string (302015) is used for the QID search, the entire text string (%FWSM-session-0-302015) identifies the event as coming from a Cisco FWSM. Since the entire text string is not valid, the DSM assumes that the event is not valid.

### Extension document example for parsing one event type

An FWSM device has many event types and many with unique formats. The following extension document example indicates how to parse one event type.

**Note:** The pattern IDs do not have to match the field names that they are parsing. Although the following example duplicates the pattern, the SourceIp field and the SourceIpPreNAT field can use the exact same pattern in this case. This situation might not be true in all FWSM events.

```
<?xml version="1.0" encoding="UTF-8"?>
<device-extension xmlns="event_parsing/device_extension">
<pattern id="EventNameFWSM_Pattern" xmlns=""><! [CDATA[%FWSM[a-zA-Z\-]*\d-(\d{1,6})]]></pattern>
```

```

<pattern id="SourceIp_Pattern" xmlns=""><! [CDATA[gaddr (\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3})/(\[d]{1,5})]]></pattern>
<pattern id="SourceIpPreNAT_Pattern" xmlns=""><! [CDATA[gaddr (\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3})/(\[d]{1,5})]]></pattern>
<pattern id="SourceIpPostNAT_Pattern" xmlns=""><! [CDATA[laddr (\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3})/(\[d]{1,5})]]></pattern>

</match-group>
</device-extension>

```

## Parsing basics

The preceding extension document example demonstrates some of the basic aspects of parsing:

- IP addresses
- Ports
- Protocol
- Multiple fields that use the same pattern with different groups

This example parses all FWSM events that follow the specified pattern. The fields that are parsed might not be present in those events when the events include different content.

The information that was necessary to create this configuration that was not available from the event:

- The event name is only the last 6 digits (302015) of the %FWSM-session-0-302015 portion of the event.
- The FWSM has a hardcoded device event category of Cisco Firewall.
- The FWSM DSM uses the Cisco Pix QIDmap and therefore includes the device-type-id-override="6" parameter in the match group. The Pix firewall log source type ID is 6.

**Note:** If the QID information is not specified or is unavailable, you can modify the event mapping. For more information, see the Modifying Event Mapping section in the *IBM QRadar User Guide*.

## Event name and device event category

An event name and a device event category are required when the QIDmap is searched. This device event category is a grouping parameter within the database that helps define like events within a device. The event-match-multiple at the end of the match group includes hardcoding of the category. The event-match-multiple uses the EventNameId pattern on the parsed event name to match up to 6 digits. This pattern is not run against the full payload, just that portion parsed as the EventName field.

The EventName pattern references the %FWSM portion of the events; all Cisco FWSM events contain the %FWSM portion. The pattern in the example matches %FWSM followed by any number (zero or more) of

letters and dashes. This pattern match resolves the word session that is embedded in the middle of the event name that needs to be removed. The event severity (according to Cisco), followed by a dash and then the true event name as expected by QRadar. The `(\d{6})` string is the only string within the EventNameFWSM pattern that has a capture group.

The IP addresses and ports for the event all follow the same basic pattern: an IP address followed by a colon followed by the port number. This pattern parses two pieces of data (the IP address and the port), and specifies different capture groups in the matcher section.

```
<device-extension>
<pattern id="EventName1">(logger):</pattern>
<pattern id="DeviceTime1">time=\[(\d{2}/\w{3}/\d{4}:\d{2}:\d{2}:\d{2})\] </pattern>
<pattern id="Username">(TLSv1)</pattern>
<match-group order="1" description="Full Test">
    <matcher field="EventName" order="1" pattern-id="EventName1" capture-group="1"/>
    <matcher field="DeviceTime" order="1" pattern-id="DeviceTime1"
        capture-group="1" ext-data="dd/MMM/YYYY:hh:mm:ss"/>
    <matcher field="UserName" order="1" pattern-id="Username" capture-group="1"/>
</match-group>
</device-extension>
```

## IP address and port patterns

The IP address and port patterns are four sets of one to three digits, separated by periods followed by a colon and the port number. The IP address section is in a group, as is the port number, but not the colon. The matcher sections for these fields reference the same pattern name, but a different capture group (the IP address is group 1 and the port is group 2).

The protocol is a common pattern that searches the payload for the first instance of TCP, UDP, ICMP, or GRE. The pattern is marked with the case-insensitive parameter so that any occurrence matches.

Although a second protocol pattern does not occur in the event that is used in the example, there is a second protocol pattern that is defined with an order of two. If the lowest-ordered protocol pattern does not match, the next one is attempted, and so on. The second protocol pattern also demonstrates direct substitution; there are no match groups in the pattern, but with the enable-substitutions parameter enabled, the text TCP can be used in place of protocol=6.

# Creating a log source extensions document to get data into QRadar

You create log source extensions (LSX) when log sources don't have a supported DSM, or to repair an event that has missing or incorrect information, or to parse an event when the associated DSM fails to produce a result.

## When to create a log source extension

For log sources that don't have an official DSM, use a custom log source type to integrate log sources. A log source extension (also known as a device extension) is then applied to the custom log source type to provide the logic for parsing the logs. The LSX is based on Java™ regular expressions and can be used against any protocol type, such as syslog, JDBC, and Log File. Values can be extracted from the logs and mapped to all common fields within IBM QRadar.

When you use log source extensions to repair missing or incorrect content, any new events that are produced by the log source extensions are associated to the log source that failed to parse the original payload. Creating an extension prevents unknown or uncategorized events from being stored as unknown in QRadar.

## Using the DSM Editor to quickly create a log source extension

For IBM QRadar V7.2.8 and later, you can use the DSM Editor to create log source extensions. The DSM Editor provides real-time feedback so that you know whether the log source extension that you are creating has problems. Use the DSM Editor to extract fields, define custom properties, categorize events,

define new QID definitions, and define your own log source type. For more information about the DSM Editor, see the *IBM QRadar Administration Guide*.

## Process for manually creating a log source extension

Alternatively, to manually create a log source extension, complete the following steps:

1. Ensure that a log source is created in QRadar.

Use a custom log source type to collect events from a source when the log source type is not listed as a QRadar supported DSM.

Use the DSM Editor to create the new log source type, and then manually create the log source. You can attach an LSX to a supported log source type, such as Windows, Bluecoat, Cisco, and others that are listed as QRadar supported DSMs.

2. To determine what fields are available, use the **Log Activity** tab to export the logs for evaluation.

3. Use the extension document example template to determine the fields that you can use.

It is not necessary to use all of the fields in the template. Determine the values in the log source that can be mapped to the fields in extension document template.

4. Remove any unused fields and their corresponding Pattern IDs from the log source extension document.

5. Upload the extension document and apply the extension to the log source.

6. Map the events to their equivalents in the QIDmap.

This manual action on the **Log Activity** tab is used to map unknown log source events to known QRadar events so that they can be categorized and processed.

### Related concepts

[Examples of log source extensions on QRadar Support Forums](#)

You can create log source extensions (LSX) for log sources that don't have a supported DSM. To help you create your own log source extensions (also known as DSM extensions), you modify existing ones that were created.

[“Extension document template” on page 36](#)

The example of an extension document provides information about how to parse one particular type of Cisco FWSM so that events are not sent with an incorrect event name.

## Common regular expressions

Use regular expressions to match patterns of text in the log source file. You can scan messages for patterns of letters, numbers, or a combination of both. For example, you can create regular expressions that match source and destination IP addresses, ports, MAC addresses, and more.

The following codes show several common regular expressions:

```
\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3} \d{1,5} (?:[0-9a-fA-F]{2}\:){5}[0-9a-fA-F]{2} (TCP|UDP|ICMP|GRE) \w{3}\s\d{2}\s\d{2}:\d{2}:\d{2} \s \t .*?
```

The escape character, or "\", is used to denote a literal character. For example, "." character means "any single character" and matches A, B, 1, X, and so on. To match the ":" characters, a literal match, you must use "\:".

Table 15. Common regex expressions

Type	Expression
IP Address	\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3}

Table 15. Common regex expressions (continued)

Type	Expression
MAC Address	(?:[0-9a-fA-F]{2}\:){5}[0-9a-fA-F]{2}
Port Number	\d{1,5}
Protocol	(TCP UDP ICMP GRE)
Device Time	\w{3}\s\d{2}\s\d{2}:\d{2}:\d{2}
Whitespace	\s
Tab	\t
Match Anything	.*?

**Tip:** To ensure that you don't accidentally match another characters, escape any non-digit or non-alpha character.

## Building regular expression patterns

To create a log source extension, you use regular expressions (regex) to match strings of text from the unsupported log source.

### About this task

The following example shows a log entry that is referenced in the steps.

```
May 20 17:24:59 kernel: DROP MAC=<MAC_address>
SRC=<Source_IP_address> DST=<Destination_IP_address> LEN=351 TOS=0x00 PREC=0x00 TTL=64 ID=9582
PROTO=UDP SPT=67 DPT=68 LEN=331
May 20 17:24:59 kernel: PASS MAC=<MAC_address>
SRC=<Source_IP_address> DST=<Destination_IP_address> LEN=351 TOS=0x00 PREC=0x00 TTL=64
ID=9583 PROTO=TCP SPT=1057 DPT=80 LEN=331
May 20 17:24:59 kernel: REJECT
MAC=<MAC_address> SRC=<Source_IP_address> DST=<Destination_IP_address> LEN=351
TOS=0x00 PREC=0x00 TTL=64 ID=9584 PROTO=TCP SPT=25212 DPT=6881 LEN=331
```

### Procedure

1. Visually analyze the unsupported log source to identify unique patterns.

These patterns are later translated into regular expressions.

2. Find the text strings to match.

**Tip:** To provide basic error checking, include characters before and after the values to prevent similar values from being unintentionally matched. You can later isolate the actual value from the extra characters.

3. Develop pseudo-code for matching patterns and include the space character to denote the beginning and end of a pattern.

You can ignore the quotes. In the example log entry, the event names are DROP, PASS, and REJECT. The following list shows the usable event fields.

- EventName: " kernel: VALUE "
- SourceMAC: " MAC=VALUE "
- SourceIp: " SRC=VALUE "
- DestinationIp: " DST=VALUE "
- Protocol: " PROTO=VALUE "
- SourcePort: " SPT=VALUE "

- DestinationPort: " DPT=VALUE "

#### 4. Substitute a space with the \s regular expression.

You must use an escape character for non-digit or non-alpha characters. For example, = becomes \= and : becomes \:.

#### 5. Translate the pseudo-code to a regular expression.

*Table 16. Translating pseudo-code to regular expressions*

Field	Pseudo-code	Regular expression
EventName	" kernel: VALUE "	\skernel\:\s.*?\s
SourceMAC	" MAC=VALUE "	\sMAC\=(?:[0-9a-fA-F]{2}\:){5}[0-9a-fA-F]{2}\s
SourceIP	" SRC=VALUE "	\sSRC\=\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3}\s
DestinationIp	" DST=VALUE "	\sDST\=\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3}\s
Protocol	" PROTO=VALUE "	\sPROTO\=(TCP UDP ICMP GRE)\s
SourcePort	" SPT=VALUE "	\sSPT\=\d{1,5}\s
DestinationPort	" DPT=VALUE "	\sDPT\=\d{1,5}\s

#### 6. Specify capture groups.

A capture group isolates a certain value in the regular expression.

For example, in the SourcePort pattern in the previous example, you can't pass the entire value since it includes spaces and SRC=<code>. Instead, you specify only the port number by using a capture group. The value in the capture group is what is passed to the relevant field in IBM QRadar.

Insert parenthesis around the values you want to capture:

*Table 17. Mapping regular expressions to capture groups for event fields*

Field	Regular expression	Capture group
EventName	\skernel\:\s.*?\s	\skernel\:(\s.*?)\s
SourceMAC	\sMAC\=(?:[0-9a-fA-F]{2}\:){5}[0-9a-fA-F]{2}\s	\sMAC\=((?:[0-9a-fA-F]{2}\:){5}[0-9a-fA-F]{2})\s
SourceIP	\sSRC\=\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3}\s	\sSRC\=(\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3})\s
Destination IP	\sDST\=\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3}\s	\sDST\=(\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3})\s
Protocol	\sPROTO\=(TCP UDP ICMP GRE)\s	\sPROTO\=((TCP UDP ICMP GRE))\s
SourcePort	\sSPT\=\d{1,5}\s	\sSPT\=(\d{1,5})\s
DestinationPort	\sDPT\=\d{1,5}\s	\sDPT\=(\d{1,5})\s

#### 7. Migrate the patterns and capture groups into the log source extensions document.

The following code snippet shows part of the document that you use.

```
<device-extension xmlns="event_parsing/device_extension">
<pattern id="EventNameFWSM_Pattern" xmlns=""><![[CDATA[%FWSM[a-zA-Z-]*\d-(\d{1,6})]]></pattern>
<pattern id="SourceIp_Pattern" xmlns=""><![[CDATA[gaddr (\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3})/(\d{1,5})]]></pattern>
<pattern id="SourceIpPreNAT_Pattern" xmlns=""><![[CDATA[gaddr (\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3})/(\d{1,5})]]></pattern>
<pattern id="SourceIpPostNAT_Pattern" xmlns=""><![[CDATA[laddr (\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3})/(\d{1,5})]]></pattern>
<pattern id="DestinationIp_Pattern" xmlns=""><![[CDATA[faddr (\d{1,3}.\d{1,3}.\d{1,3}.\d{1,3})/(\d{1,5})]]></pattern>
<pattern id="Protocol_Pattern" case-insensitive="true" xmlns=""><![[CDATA[(TCP|UDP|ICMP|GRE)]]></pattern>
```

```
<pattern id="Protocol_6_Pattern" case-insensitive="true" xmlns=""><![CDATA[protocol=6]]></pattern>
<pattern id="EventNameId_Pattern" xmlns=""><![CDATA[(\d{1,6})]]></pattern>
```

## Uploading extension documents to QRadar

You can create multiple extension documents and then upload them and associate them to various log source types. The logic from the log source extension (LSX) is then used to parse the logs from the unsupported log source.

Extension documents can be stored anywhere before you upload to IBM QRadar.

### Procedure

1. On the **Admin** tab, click **Log Source Extensions**.
2. Click **Add**.
3. Assign a name.
4. If you want to apply this log source extension to more than one instance of a log source type, select the log source type from the available **Log Source Type** list and click the add arrow to set it as the default.

Setting the default log source type applies the log source extension to all events of a log source type, including those log sources that are automatically discovered.

Ensure that you test the extension for the log source type first to ensure that the events are parsed correctly.

5. Click **Browse** to locate the LSX that you saved and then click **Upload**.

QRadar validates the document against the internal XSD and verifies the validity of the document before the extension document is uploaded to the system.

6. Click **Save** and close the window.
7. Associate the log source extension to a log source.
  - a) From the **Admin** tab, click **Data Sources > Log Sources**.
  - b) Double-click the log source type that you created the extension document for.
  - c) From the **Log Source Extension** list, select the document that you created.
  - d) Click **Save** and close the window.

## Examples of parsing issues

When you create a log source extension, you might encounter some parsing issues. Use these XML examples to resolving specific parsing issues.

### Converting a protocol

The following example shows a typical protocol conversion that searches for TCP, UDP, ICMP, or GRE anywhere in the payload. The search pattern is surrounded by any word boundary, for example, tab, space, end of line. Also, the character case is ignored:

```
<pattern id="Protocol" case-insensitive="true" xmlns="">
<![CDATA[\b(TCP|UDP|ICMP|GRE)\b]]>
</pattern>
<matcher field="Protocol" order="1" pattern-id="Protocol" capture-group="1" />
```

### Making a single substitution

The following example shows a substitution that parses the source IP address, and then overrides the result and sets the IP address to 192.0.2.1, ignoring the IP address in the payload.

This example assumes that the source IP address matches something similar to SrcAddress=203.0.113.1 followed by a comma:

```
<pattern id="SourceIp_AuthenOK" xmlns="">
<! [CDATA[SrcAddress=(\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3}),]]>
</pattern>

<matcher field="SourceIp" order="1" pattern-id="SourceIp_AuthenOK"
capture-group="192.0.2.1" enable-substitutions="true"/>
```

## Generating a colon-separated MAC address

QRadar detects MAC addresses in a colon-separated form. Because all devices might not use this form, the following example shows how to correct that situation:

```
<pattern id="SourceMACWithDashes" xmlns="">
<! [CDATA[SourceMAC=([0-9a-fA-F]{2})-([0-9a-fA-F]{2})-([0-9a-fA-F]{2})-
([0-9a-fA-F]{2})-([0-9a-fA-F]{2})-([0-9a-fA-F]{2})]]>
</pattern>
<matcher field="SourceMAC" order="1" pattern-id="SourceMACWithDashes" capture-group="\1:\2:\3:\4:\5:\6" />
```

In the preceding example, SourceMAC=12-34-1a-2b-3c-4d is converted to a MAC address of 12:34:1a:2b:3c:4d.

If the dashes are removed from the pattern, the pattern converts a MAC address and has no separators. If spaces are inserted, the pattern converts a space-separated MAC address.

## Combining IP address and port

Typically an IP address and port are combined into one field, which is separated by a colon.

The following example uses multiple capture groups with one pattern:

```
pattern id="SourceIPColonPort" xmlns="">
<! [CDATA[Source=(\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3}):([\d]{1,5})]]>
</pattern>

<matcher field="SourceIp" order="1" pattern-id="SourceIPColonPort" capture-group="1" />
<matcher field="SourcePort" order="1" pattern-id="SourceIPColonPort" capture-group="2" />
```

## Modifying an Event Category

A device event category can be hardcoded, or the severity can be adjusted.

The following example adjusts the severity for a single event type:

```
<event-match-single event-name="TheEvent" device-event-category="Actual
Category" severity="6" send-identity="UseDSMResults" />
```

## Suppressing identity change events

A DSM might unnecessarily send identity change events.

The following examples show how to suppress identity change events from being sent from a single event type and a group of events.

```
// Never send identity for the event with an EventName of Authen OK
<event-match-single event-name="Authen OK" device-event-category="ACS"
severity="6" send-identity="OverrideAndNeverSend" />

// Never send any identity for an event with an event name starting with 7,
followed by one to five other digits:
<pattern id="EventNameId" xmlns=""><! [CDATA[(7\d{1,5})]]>
</pattern>

<event-match-multiple pattern-id="EventNameId" capture-group-index="1"
```

```
device-event-category="Cisco Firewall" severity="7"
send-identity="OverrideAndNeverSend"/>
```

## Formatting event dates and time stamps

A log source extension can detect several different date and time stamp formats on events.

Because device manufacturers do not conform to a standard date and time stamp format, the ext-data optional parameter is included in the log source extension to allow the DeviceTime to be reformatted. The following example shows how an event can be reformatted to correct the date and time stamp formatting:

```
<device-extension>
<pattern id="EventName1">(logger):</pattern>
<pattern id="DeviceTime1">time=\[(\d{2})\w{3}/\d{4}:\d{2}:\d{2}:\d{2})\]</pattern>
<pattern id="Username">(TLSv1)</pattern>

<match-group order="1" description="Full Test">
  <matcher field="EventName" order="1" pattern-id="EventName1_Pattern" capture-group="1"/>
  <matcher field="DeviceTime" order="1" pattern-id="DeviceTime1_Pattern"
    capture-group="1" ext-data="dd/MMM/YYYY:hh:mm:ss"/>
  <matcher field="UserName" order="1" pattern-id="Username_Pattern" capture-group="1"/>
</match-group>
</device-extension>
```

## Multiple Log Formats in a Single Log Source

Occasionally, multiple log formats are included in a single log source.

```
May 20 17:15:50 kernel: DROP IN=vlan2 OUT= MAC= SRC=<Source_IP_address>
DST=<Destination_IP_address> PROTO=UDP SPT=1900 DPT=1900
May 20 17:16:26 <server>[22331]: password auth succeeded for 'root' from <IP_address>
May 20 17:16:28 <server>[22331]: exit after auth (root): Exited normally <br>
May 20 17:16:14 <server>[22331]: bad password attempt for 'root' from <IP_address>:3364
```

For example, there are 2 log formats: one for firewall events, and one for authentication events. You must write multiple patterns for parsing the events. You can specify the order to be parsed. Typically, the more frequent events are parsed first, followed by the less frequent events. You can have as many patterns as required to parse all of the events. The order variable determines what order the patterns are matched in.

The following example shows multiple formats for the following fields EventName and UserName

Separate patterns are written to parse each unique log type. Both of the patterns are referenced when you assign the value to the normalized fields.

```
<pattern id="EventName-DDWRT-FW_Pattern" xmlns=""><! [CDATA[kernel\:\s(.*)\s]]></pattern>
<pattern id="EventName-DDWRT-Auth_Pattern" xmlns=""><! [CDATA[sdropbear\[ \d{1,5}\] :\s(.?\s.*?)\s]]>
</pattern>

<pattern id="UserName_DDWRT-Auth1__Pattern" xmlns=""><! [CDATA[\sfor\s'(.?)\s']]></pattern>
<pattern id="UserName_DDWRT-Auth2__Pattern" xmlns=""><! [CDATA[\safter\sauth\s'((.?)\):\s]]></pattern>

<match-group order="1" description="DD-WRT Device Extensions xmlns="">
  <matcher field="EventName" order="1" pattern-id="EventName-DDWRT-FW_Pattern" capture-group="1"/>
  <matcher field="EventName" order="2" pattern-id="EventName-DDWRT-Auth_Pattern" capture-group="1"/>

  <matcher field="UserName" order="1" pattern-id="UserName-DDWRT-Auth1_Pattern" capture-group="1"/>
  <matcher field="UserName" order="2" pattern-id="UserName-DDWRT-Auth2_Pattern" capture-group="1"/>
```

## Parsing a CSV log format

To parse a log file that is in CSV format, use the Generic List expression type that is available in the DSM Editor. For more information , see [Expressions in Generic List format for structured data \(https://www.ibm.com/docs/en/qrip/7.5?topic=editor-expressions-in-generic-list-format-structured-data\)](https://www.ibm.com/docs/en/qrip/7.5?topic=editor-expressions-in-generic-list-format-structured-data).

```
Event,User,Source IP,Source Port,Destination IP,Destination Port
Failed Login,<Username>,<Source_IP_address>,1024,<Destination_IP_address>,22
Successful Login,<Username>,<Source_IP_address>,1743,<Destination_IP_address>,110
Privilege Escalation,<Username>,<Source_IP_address>,1028,<Destination_IP_address>,23
```

# Chapter 5. Log source extension management

You can create log source extensions to extend or modify the parsing routines of specific devices.

A *log source extension* is an XML file that includes all of the regular expression patterns that are required to identify and categorize events from the event payload. Extension files can be used to parse events when you must correct a parsing issue or you must override the default parsing for an event from a DSM. When a DSM does not exist to parse events for an appliance or security device in your network, an extension can provide event support. The **Log Activity** tab identifies log source events in these basic types:

- Log sources that properly parse the event. Properly parsed events are assigned to the correct log source type and category. In this case, no intervention or extension is required.
- Log sources that parse events, but have a value **Unknown** in the **Log Source** parameter. Unknown events are log source events where the log source type is identified, but the payload information cannot be understood by the DSM. The system cannot determine an event identifier from the available information to properly categorize the event. In this case, the event can be mapped to a category or a log source extension can be written to repair the event parsing for unknown events.
- Log sources that cannot identify the log source type and have a value of **Stored** event in the **Log Source** parameter. Stored events require you to update your DSM files or write a log source extension to properly parse the event. After the event parses, you can then map the events.

Before you can add a log source extension, you must create the extension document. The extension document is an XML document that you can create with any common word processing or text editing application. Multiple extension documents can be created, uploaded, and associated with various log source types. The format of the extension document must conform to a standard XML schema document (XSD). To develop an extension document, knowledge of and experience with XML coding is required.

## Adding a log source extension

You can add a log source extension to extend or modify the parsing routines of specific devices.

### Procedure

1. Click the **Admin** tab.
2. Click the **Log Source Extensions** icon.
3. Click **Add**.
4. From the **Log Source Types** list, select one of the following options:

Option	Description
Available	Select this option when the device support module (DSM) correctly parses most fields for the log source. The incorrectly parsed field values are enhanced with the new XML values.
Set to default for	Select log sources to add or remove from the extension parsing. You can add or remove extensions from a log source.  When a log source extension is <b>Set to default for</b> a log source, new log sources of the same <b>Log Source Type</b> use the assigned log source extension.

5. Click **Browse** to locate your log source extension XML document.

6. Click **Upload**. The contents of the log source extension is displayed to ensure that the proper extension file is uploaded. The extension file is evaluated against the XSD for errors when the file is uploaded.
7. Click **Save**.

## Results

If the extension file does not contain any errors, the new log source extension is created and enabled. It is possible to upload a log source extension without applying the extension to a log source. Any change to the status of an extension is applied immediately and managed hosts or Consoles enforce the new event parsing parameters in the log source extension.

## What to do next

On the **Log Activity** tab, verify that the parsing patterns for events is applied correctly. If the log source categorizes events as **Stored**, the parsing pattern in the log source extension requires adjustment. You can review the extension file against log source events to locate any event parsing issues.

# Chapter 6. Threat use cases by log source type

External log sources feed raw events to the QRadar system that provide different perspectives about your network, such as audit, monitoring, and security. It's critical that you collect all types of log sources so that QRadar can provide the information that you need to protect your organization and environment from external and internal threats. For example, if your organization adopts cloud services and begins to onboard Amazon Web Services (AWS), or Azure cloud services, or Microsoft Office 365, add the log sources to QRadar so that you continue to have visibility into all malicious activity and compliance breaches.

Click a check mark in the following matrix to go to the log source that you're most interested in. For each log source, the relevant ATT&CK framework categories are listed. The Adversarial Tactics, Techniques, and Common Knowledge (ATT&CK) framework was developed by Mitre Corp. The public knowledge base of threat tactics and techniques helps your security analysts to understand hacker threats and how to prevent adversarial attacks from happening to your organization's networks. These tactics can become your weaknesses if you're not collecting that type of log source.

Table 18. Log sources in QRadar with use cases

Log sources	Advanced Persistent Threat 	Insider Threat 	Securing the Cloud 	Critical Data Protection 	Incident Response 	Compliance 	Risk and Vulnerability Management 
Firewall/Router	✓		✓	✓	✓	✓	✓
IDS/IPS (Intrusion Detection System/Intrusion Protection System)	✓			✓	✓		✓
Web Proxy	✓	✓	✓	✓		✓	
VPN	✓						
DNS	✓	✓					✓
DHCP	✓	✓			✓		
Mail Logs	✓	✓		✓			
DLP (Data Loss Prevention)	✓	✓		✓		✓	
Endpoint	✓	✓		✓		✓	✓
Identity/Authentication (LDAP/AD/Radius)	✓	✓	✓		✓		
Anti Virus	✓			✓	✓	✓	✓

Database Logs	✓	✓	✓	✓	✓	✓	
EDR	✓				✓		✓

Table 18. Log sources in QRadar with use cases (continued)

Log sources	Advanced Persistent Threat	Insider Threat	Securing the Cloud	Critical Data Protection	Incident Response	Compliance	Risk and Vulnerability Management
Cloud Infrastructure/Audit (AWS CloudTrail, Azure Event Hubs)	✓	✓	✓	✓		✓	
Office 365			✓		✓	✓	

## Firewall/Router

The following table provides examples of use cases that are affected by firewall/router log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Defense Evasion
- Discovery
- Command and Control
- Exfiltration

Table 19. Firewall/Router log source and use case examples

Use case	Examples
Advanced Persistent Threat	Firewall data helps detect command control issues. Use it for external recon and prevent malicious IP communications from entering your environment.
Securing the Cloud	Identify risky internet service provider connections, such as connections to TOR.
Critical Data Protection	Discover and protect against abnormal database connection attempts.
Incident Response	See which hosts communicated with an infected host so that you can stop the spread of data infection.
Compliance	Monitor for unauthorized or unexpected firewall configuration changes to allow access to critical business assets. For example, PCI requires all critical assets that contain “banking information” to communicate through an internal DMZ with no direct access to the outside world.
Risk and Vulnerability Management	Discover assets that are actively communicating on vulnerable ports.

Find out more about each technique and tactic: [ATT&CK Technique matrix](https://attack.mitre.org/wiki/Technique_Matrix) ([https://attack.mitre.org/wiki/Technique\\_Matrix](https://attack.mitre.org/wiki/Technique_Matrix))

[\(Back to top\)](#)

## Intrusion detection system (IDS)/Intrusion protection system (IPS)

The following table provides examples of use cases that are affected by IDS/IPS log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Defense Evasion
- Persistence Mechanism
- Discovery
- Command and Control

<i>Table 20. IDS/IPS log source and use case examples</i>	
<b>Use case</b>	<b>Examples</b>
Advanced Persistent Threat	Correlate threat events with vulnerabilities, and then escalate those threat events. Perform more acute offense detection.
Critical Data Protection	SQL, XSS Injection
Incident Response	See which hosts are infected and watch for potential epidemics so that you can stop the spread of data infection.
Risk and Vulnerability Management	Validate and assess threats to prioritize by correlating with asset and vulnerability data.

Find out more about each technique and tactic: [ATT&CK Technique matrix](https://attack.mitre.org/wiki/Technique_Matrix) ([https://attack.mitre.org/wiki/Technique\\_Matrix](https://attack.mitre.org/wiki/Technique_Matrix))

[\(Back to top\)](#)

## Web proxy

The following table provides examples of use cases that are affected by web proxy log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Defense Evasion
- Persistence Mechanism
- Data Exfiltration
- Command and Control
- Privilege Escalation
- Credential Access

<i>Table 21. Web proxy log source and use case examples</i>	
<b>Use case</b>	<b>Examples</b>
Advanced Persistent Threat	Monitor for malicious domain communication, data exfiltration, and command and control activities. Detect attempts to bypass normal user restrictions by surfing with a service account.
Insider Threat	Track malicious activity such as crypto mining that uses corporate resources.

*Table 21. Web proxy log source and use case examples (continued)*

<b>Use case</b>	<b>Examples</b>
Securing the Cloud	Detect shadow IT, unapproved cloud service usage, and potential data exfiltration from corporate environments.
Critical Data Protection	Monitor for unauthorized data exfiltration.
Compliance	Monitor for critical asset communication with the outside world.

Find out more about each technique and tactic: [ATT&CK Technique matrix](https://attack.mitre.org/wiki/Technique_Matrix) ([https://attack.mitre.org/wiki/Technique\\_Matrix](https://attack.mitre.org/wiki/Technique_Matrix))

[\(Back to top\)](#)

## VPN

The following table provides examples of use cases that are affected by VPN log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Credential Access
- Lateral Movement

*Table 22. VPN log source and use case example*

<b>Use case</b>	<b>Examples</b>
Advanced Persistent Threat	Monitor for logins from suspicious locations.
Insider Threat	Detect the use of VPN for users outside of normal usage patterns or from abnormal geographical areas.

Find out more about each technique and tactic: [ATT&CK Technique matrix](https://attack.mitre.org/wiki/Technique_Matrix) ([https://attack.mitre.org/wiki/Technique\\_Matrix](https://attack.mitre.org/wiki/Technique_Matrix))

## DNS

The following table provides examples of use cases that are affected by DNS log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Defense Evasion
- Persistence Mechanism
- Command and Control
- Exfiltration
- Credential Access (note: Technique T1171)

*Table 23. DNS log source and use case examples*

<b>Use case</b>	<b>Examples</b>
Advanced Persistent Threat	Monitor for malicious DNS usages such as domain name generation, tunneling, and squatting.
Insider Threat	Detect tunneling of traffic through DNS records.

Find out more about each technique and tactic: [ATT&CK Technique matrix](https://attack.mitre.org/wiki/Technique_Matrix) ([https://attack.mitre.org/wiki/Technique\\_Matrix](https://attack.mitre.org/wiki/Technique_Matrix))

([Back to top](#))

## DHCP

The following table provides examples of use cases that are affected by DHCP log sources. Data from this type of log source is important for detecting adversarial techniques in the Defense Evasion ATT&CK category.

<i>Table 24. DHCP log source and use case example</i>	
<b>Use case</b>	<b>Examples</b>
Advanced Persistent Threat	Detection of rogue access points or other unexpected device presence on corporate network.
Insider Threat	Detection of rogue access points or other unexpected device presence on corporate network.
Incident Response	Identification of which host had a specific IP address at the time of an incident.

Find out more about each technique and tactic: [ATT&CK Technique matrix](https://attack.mitre.org/wiki/Technique_Matrix) ([https://attack.mitre.org/wiki/Technique\\_Matrix](https://attack.mitre.org/wiki/Technique_Matrix))

([Back to top](#))

## Mail logs

The following table provides examples of use cases that are affected by mail log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Execution
- Initial Access
- Collection

<i>Table 25. Mail log source and use case examples</i>	
<b>Use case</b>	<b>Examples</b>
Advanced Persistent Threat	Monitor for phishing and spam.
Insider threat	Phishing
Critical Data Protection	Phishing, data exfiltration by email

## DLP (data loss prevention)

The following table provides examples of use cases that are affected by DLP log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Data Exfiltration
- Collection

*Table 26. DLP log source and use case examples*

Use case	Examples
Advanced Persistent Threat	Data can be exfiltrated through many methods. Identify and track suspicious files such as: <ul style="list-style-type: none"> <li>• DNS abnormalities</li> <li>• Sensitive content</li> <li>• Aberrant connections</li> <li>• Aliases</li> </ul>
Insider Threat	Data can be exfiltrated through many methods. Identify and track suspicious files such as: <ul style="list-style-type: none"> <li>• DNS abnormalities</li> <li>• Sensitive content</li> <li>• Aberrant connections</li> <li>• Aliases</li> </ul>
Critical Data Protection	Data can be exfiltrated through many methods. Identify and track suspicious files such as: <ul style="list-style-type: none"> <li>• DNS abnormalities</li> <li>• Sensitive content</li> <li>• Aberrant connections</li> <li>• Aliases</li> </ul>
Compliance	Data can be exfiltrated through many methods. Identify and track suspicious files such as: <ul style="list-style-type: none"> <li>• DNS abnormalities</li> <li>• Sensitive content</li> <li>• Aberrant connections</li> <li>• Aliases</li> </ul>

## Endpoint

The following table provides examples of use cases that are affected by Endpoint log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Privilege Escalation
- Initial Access
- Execution
- Persistence
- Credential Access
- Defense Evasion
- Discovery

- Lateral Movement
- Collection
- Exfiltration
- Command and Control

*Table 27. Endpoint log source and use case examples*

Use case	Examples
Advanced Persistent Threat	Monitor for malicious hashes, suspicious PowerShell activity, process abuse, or other suspicious endpoint activities.
Insider Threat	Detection of persistent malware by using host resources (for example, crypto mining)
Critical Data Protection	Data can be exfiltrated through many methods. Identify and track suspicious files such as: <ul style="list-style-type: none"> <li>• DNS abnormalities</li> <li>• Sensitive content</li> <li>• Aberrant connections</li> <li>• Aliases</li> </ul>
Compliance	Monitor for adherence to corporate company policy (for example, unapproved software use).
Risk and Vulnerability Management	Assess and manage risk through vulnerability.

## Identity/Authentication (LDAP/AD/Radius)

The following table provides examples of use cases that are affected by LDAP/AD/Radius log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Privilege Escalation
- Credential Access
- Initial Access

**Note:** You can also track privilege abuse (for example, surf with a super account, privileges that are given to users).

*Table 28. LDAP/AD/Radius log source and use case examples*

Use case	Examples
Advanced Persistent Threat	Monitor for activities such as brute force login by malware, lateral movement through the network, or suspicious logins.
Insider Threat	Account takeover by malware
Securing the Cloud	Provide user-to-IP association to help identify cloud users from data that has only IP source address.

*Table 28. LDAP/AD/Radius log source and use case examples (continued)*

Use case	Examples
Incident Response	Visibility into where a user logged in during the IR process.

## Anti-virus

The following table provides examples of use cases that are affected by anti-virus log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Persistence
- Initial Access
- Defense Evasion

*Table 29. Anti-virus log source and use case examples*

Use case	Examples
Advanced Persistent Threat	Monitor for activities such as: <ul style="list-style-type: none"><li>• Endpoint infection by anti-virus</li><li>• Virus that is not cleaned</li><li>• Reinforcement of other suspicious endpoint behavior</li></ul>
Critical Data Protection	Detection of virus outbreak to prevent movement to servers that contain critical business data.
Incident Response	Visibility into where a specific virus signature was seen.
Compliance	Ensuring up-to-date AV definitions on critical hosts/servers.
Risk and Vulnerability Management	Malicious WWW domain connections indication of a vulnerable host that is compromised.

## QRadar Network Insights/Netflow

The following table provides examples of use cases that are affected by QRadar Network Insights/Netflow log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Lateral Movement
- Discovery
- Persistence Mechanism
- Defense Evasion

- Data Exfiltration
- Credential Access
- Command and Control

*Table 30. QRadar Network Insights/Netflow log source and use case examples*

Use case	Examples
Advanced Persistent Threat	Monitor for activities such as: <ul style="list-style-type: none"> <li>• Recon</li> <li>• Malicious download</li> <li>• Lateral movement</li> <li>• Phishing</li> </ul>
Insider Threat	Phishing detection
Securing the Cloud	Monitor for activities such as: <ul style="list-style-type: none"> <li>• Data exfiltration</li> <li>• Expired WWW certificates</li> <li>• Self-signed WWW certificates</li> <li>• Phishing</li> <li>• Risky WWW domain connections</li> </ul>
Critical Data Protection	Data can be exfiltrated through many methods. Identify and track suspicious files such as: <ul style="list-style-type: none"> <li>• DNS abnormalities</li> <li>• Sensitive content</li> <li>• Aberrant connections</li> <li>• Aliases</li> </ul>
Incident Response	Provides a huge pool of investigative data to determine the spread of an attack from domain communication, hashes that are downloaded, IP addresses that are communicated with, file names, data volumes transferred.
Compliance	Monitor for critical asset communications (for example, crown jewel communicate to the open internet).
Risk and vulnerability management	Prioritize host vulnerability remediation based upon the level of risk that hosts are communicated with.

Find out more about each technique and tactic: [ATT&CK Technique matrix](https://attack.mitre.org/wiki/Technique_Matrix) ([https://attack.mitre.org/wiki/Technique\\_Matrix](https://attack.mitre.org/wiki/Technique_Matrix))

## Database logs

The following table provides examples of use cases that are affected by database log sources. Data from this type of log source is important for detecting adversarial techniques in the following ATT&CK categories:

- Credential Access
- Collection
- Initial Access
- Discovery
- Data Exfiltration
- Privilege Escalation

*Table 31. Database log source and use case examples*

Use case	Examples
Insider Threat	Detect unauthorized database access and data theft.
Critical Data Protection	Databases often include sensitive corporate information and require monitoring for most compliance standards. Monitor for unauthorized user permission changes.
Incident Response	Evidence of what data was accessed, and by whom, during a breach.
Compliance	Databases often include sensitive corporate information and require monitoring for most compliance standards.
Risk and Vulnerability Management	Prioritize vulnerabilities on hosts with active databases that potentially contain critical data. Detect default accounts and passwords that are enabled.

# Chapter 7. Troubleshooting DSMs

If you come across a problem with your DSM, you can troubleshoot the following issues.

## What happens when events, which are parsed, are collected with unofficial DSMs?

Not having an official DSM doesn't mean that the events aren't collected. It indicates that the event that is received by IBM QRadar might be identified as "**Unknown**" on the Log Activity tab of QRadar. "**Unknown**" means that IBM QRadar collected the event, but was unable to parse the event format to categorize the event. However, some unique events in unofficial DSMs cannot be parsed or identified if they don't follow an event format that is expected. When an event cannot be understood by the system, they are categorized as "**Unknown**".

## What is the difference between an unknown event and a stored event?

Events comprise three different categories:

### Parsed events

QRadar collects, parses, and categorizes the event to the proper log source.

### Unknown events

The event is collected and parsed, but cannot be mapped or categorized to a specific log source. The **Event Name** and the **Low-Level Category** are set as **Unknown**. Log sources that aren't automatically discovered are typically identified as **Unknown Event Log** until a log source is manually created in the system. When an event cannot be associated to a log source, the event is assigned to a generic log source. You can identify these events by searching for events that are associated with the SIM Generic log source or by using the **Event is Unparsed** filter.

### Stored events

The event cannot be understood or parsed by QRadar. When QRadar cannot parse an event, it writes the event to disk and categorize the event as **Stored**.

## How can you find these events in the Log Activity tab?

To find events specific to your device, you can search in QRadar for the source IP address of your device. You can also select a unique value from the event payload and search for **Payload Contains**. One of these searches might locate your event, and it is likely either categorized as **Unknown** or **Stored**.

The easiest way to locate unknown or stored events is to add a search filter for **Event in Unparsed**. This search filter locates all events that either cannot be parsed (stored) or events that might not be associated with a log source or auto discovered (Unknown Log Event).

For more information about officially supported DSMs, see [QRadar supported DSMs](#).

## What do you do if you have an unknown event log from a log source that is not auto discovered?

The Event Collection Service (ECS) contains a traffic analysis process that automatically discovers and creates new log sources from events. Traffic analysis tries to identify the log source by analyzing the event payloads. At minimum, 25 events are required to identify a log source. If the log source cannot be identified by traffic analysis after 1,000 events, then QRadar abandons the auto discovery process. When a log source cannot be identified by the event payload and reaches the maximum threshold for traffic analysis, then QRadar generates a notification that specifies the IP address of the log source. QRadar generates the following notification:

Unable to automatically detect the associated log source for IP address <IP>  
QRadar then categorizes the log source as SIM Generic and labels the events as **Unknown Event Log**.

QRadar can auto discover certain log sources, but some supported log sources cannot be detected. Common causes of this notification are:

- The device is a newer version than the DSM that QRadar supports to parse events.
- The device type does not support automatic log source discovery. Review the documentation for your DSM to see whether it is automatically discovered.
- The logs might not follow an expected format. A customizable event format or required field might be missing.
- The device might be creating an event format due to an incorrect configuration.
- The logs are coming from a device that is not an officially supported DSM in QRadar.

To resolve the unknown event log:

- Review the IP address to determine which device is sending unparsed events. After you identify the device, you can manually create a log source by using the IBM QRadar Log Source Management app.
- Review any log sources that forward events at a low rate. Log sources with low event rates are a common cause of this notification.
- Ensure that auto update downloads the latest DSMs to properly parse events for your QRadar system.
- Review any log sources that provide events through a central log server. Logs that are provided from central log servers or management consoles might require their log sources to be created manually.
- Review the **Log Activity** tab to determine the appliance type from the IP address in the notification message and manually create a log source in QRadar.

## What do you do if the product version or device you have is not listed in the DSM Configuration Guide?

Sometimes a version of a vendor product or a device is not listed as supported. If the product or device is not listed, follow these guidelines:

### Version not listed

If the DSM for your product is officially supported by QRadar, but your product version is not listed in the *IBM QRadar DSM Configuration Guide*, you have the following options:

- Try the DSM to see whether it works. The product versions that are listed in the guide are tested by IBM, but newer untested versions can also work.
- If you tried the DSM and it didn't work, open a support ticket for a review of the log source to troubleshoot and rule out any potential issues.

**Tip:** In most cases, no changes are necessary, or perhaps a minor update to the IBM QRadar Identifier (QID) Map might be all that is required. Software updates by vendors might on rare occasions add or change event formats that break the DSM, requiring an RFE for the development of a new integration. This is the only scenario where an RFE is required.

### Device not listed

When a device is not officially supported, you have the following options:

- Open a request for enhancement (RFE) to have your device become officially supported.
  - Go to the QRadar SIEM RFE page (<https://ibm.biz/BdRPx5>).
  - Log in to the support portal page.
  - Click the **Submit** tab and type the necessary information.

**Tip:** If you have event logs from a device, attach the event information and include the product version of the device that generated the event log.

- Write a log source extension to parse events for your device. For more information, see Chapter 4, "Log source extensions," on page 19 and the DSM Editor.

- You can use content extensions for sending events to QRadar that are provided by some third-party vendors. They can be found on the [IBM Security App Exchange](https://exchange.xforce.ibmcloud.com/hub/) (<https://exchange.xforce.ibmcloud.com/hub/>). These third-party DSM integrations are supported by the vendor, not by IBM. For a list of available third-party DSMs, see [Chapter 177, “DSMs supported by third-party vendors,” on page 1687](#).

---

## Part 2. QRadar protocol configuration

# Chapter 8. Undocumented protocols

When you configure a log source, the set of available protocol type options is limited by the selected log source type. Not all log source types support all protocol types.

The *DSM Configuration Guide* describes how to configure log sources of a particular type, with each of the protocol types that IBM fully supports for that log source type. Any protocol type that has configuration documentation for a particular log source type is considered a "documented" protocol for that log source type. By default, only these documented protocols are displayed in the **Protocol Configuration** list in the **Log Sources** window.

As an open platform, QRadar collects and processes event data through other integration methods (protocol types). Some protocol types can be configured for a particular log source type but are marked as *undocumented*. However, the *DSM Configuration Guide* doesn't contain instructions on how to set up event collection for undocumented protocols. IBM does not provide support with the configuration of log sources that use undocumented protocols because they are not internally tested and documented. Users are responsible for determining how to get the event data into QRadar.

For example, the JDBC protocol is the documented configuration for getting events from a system that stores its event data in a database. However, it is possible to collect the same event data through a third-party product and then forward it to QRadar through Syslog. Configure the log source to use the undocumented protocol type "Syslog". QRadar accepts the events and routes them to the appropriate log source.

You must configure the third-party product to retrieve the event data from the database and to send this data to QRadar through Syslog because this configuration is not the documented collection method.

**Important:** Collecting and processing event data through undocumented protocols might result in data that is formatted differently from what a documented DSM log source type expects. As a result, parsing might not work for the DSM if it's receiving events from an undocumented protocol. For example, a JDBC protocol creates event payloads that consist of a series of space-separated key and value pairs. In the target database table, the key is a column name and the value is the column for the table row that the event represents. The DSM for a supported log source type that uses the JDBC protocol expects this event format. If the event data forwarded from a third-party product through the syslog protocol is in a different format, the DSM is unable to parse it. It might be necessary to use the DSM Editor to adjust the parsing of a DSM so that it can handle these events.

## Related tasks

["Configuring an undocumented protocol" on page 65](#)

As an open platform, QRadar collects and processes event data through multiple integration methods (protocol types). Some protocol types can be configured for a particular log source type but are marked as "undocumented". The *DSM Configuration Guide* doesn't contain instructions on how to set up event collection for undocumented protocols. IBM does not offer support with the configuration of log sources that use undocumented protocols because they are not internally tested and documented.

## Configuring an undocumented protocol

As an open platform, QRadar collects and processes event data through multiple integration methods (protocol types). Some protocol types can be configured for a particular log source type but are marked as "undocumented". The *DSM Configuration Guide* doesn't contain instructions on how to set up event collection for undocumented protocols. IBM does not offer support with the configuration of log sources that use undocumented protocols because they are not internally tested and documented.

## Procedure

1. Use SSH to log in to your QRadar Console appliance as a root user.
2. Edit the following file: /store/configservices/staging/globalconfig/nva.conf

3. Set the **EXPOSE\_UNDOCUMENTED\_PROTOCOLS** property value to true.
4. Save the file.
5. To close the SSH session type exit.
6. Log in to the QRadar Console.
7. Click the **Admin** tab.
8. Click **Deploy Changes**.

Undocumented protocol options appear in the **Protocol Configuration** list in the log source **Add/Edit** window.

#### Related concepts

[“Undocumented protocols” on page 65](#)

# Chapter 9. Protocol configuration options

Protocols in IBM QRadar provide the capability of collecting a set of data files by using various connection options. These connections pull the data back or passively receive data into the event pipeline in QRadar. Then, the corresponding Device Support Module (DSM) parses and normalizes the data.

The following standard connection options pull data into the event pipeline:

- JDBC
- FTP
- SFTP
- SCP

The following standard connection options receive data into the event pipeline:

- Syslog
- HTTP Receiver
- SNMP

QRadar also supports proprietary vendor-specific protocol API calls, such as Amazon Web Services.

## Related information

[Adding a log source](#)

## Akamai Kona REST API protocol configuration options

To receive events from your Akamai Kona Platform, configure a log source to use the Akamai Kona REST API protocol.

The Akamai Kona REST API protocol is an outbound/active protocol that queries the Akamai Kona Platform and sends events to the QRadar Console.

The following table describes the parameters that require specific values for Akamai KONA DSM event collection.

Table 35. Akamai KONA DSM log source parameters	
Parameter	Value
<b>Log Source Type</b>	Akamai KONA
<b>Protocol Configuration</b>	Akamai Kona REST API
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Akamai KONA DSM log source, ensure that you give each one a unique name.
<b>Host</b>	The <b>Host</b> value is provided during the SIEM OPEN API provisioning in the Akamai Luna Control Center. The <b>Host</b> is a unique base URL that contains information about the appropriate rights to query the security events. This parameter is a password field because part of the value contains secret client information.

Table 35. Akamai KONA DSM log source parameters (continued)

Parameter	Value
<b>Client Token</b>	<b>Client Token</b> is one of the two security parameters. This token is paired with <b>Client Secret</b> to make the client credentials. This token can be found after you provision the Akamai SIEM OPEN API.
<b>Client Secret</b>	<b>Client Secret</b> is one of the two security parameters. This secret is paired with <b>Client Token</b> to make the client credentials. This token can be found after you provision the Akamai SIEM OPEN API.
<b>Access Token</b>	<b>Access Token</b> is a security parameter that is used with client credentials to authorize API client access for retrieving the security events. This token can be found after you provision the Akamai SIEM OPEN API.
<b>Security Configuration ID</b>	<b>Security Configuration ID</b> is the ID for each security configuration that you want to retrieve security events for. This ID can be found in the SIEM Integration section of your Akamai Luna portal. You can specify multiple configuration IDs in a comma-separated list. For example, configID1,configID2.
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> .  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.
<b>Automatically Acquire Server Certificate</b>	Select <b>Yes</b> for QRadar to automatically download the server certificate and begin trusting the target server.
<b>Recurrence</b>	The time interval between log source queries to the Akamai SIEM API for new events. The time interval can be in hours (H), minutes (M), or days (D). The default is 1 minute.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

## Alibaba Cloud Object Storage protocol configuration options

The Alibaba Cloud Object Storage protocol for IBM QRadar is an active outbound protocol that collects logs that are contained in objects from Alibaba Cloud Object Storage buckets.

**Important:** Before you configure the Alibaba Cloud Object Storage protocol, configure user access roles and service credentials to access the Alibaba Cloud Object Storage buckets.

- Grant permissions to another Alibaba Cloud account or to specific users, so they can access or manage resources in a bucket. For more information about user access roles and permissions, see [Bucket policy overview](https://www.alibabacloud.com/help/en/oss/user-guide/overview) (<https://www.alibabacloud.com/help/en/oss/user-guide/overview>).
- Create service credentials. For more information, see [Obtain an AccessKey pair](https://www.alibabacloud.com/help/en/beginner-guide/latest/obtain-an-accesskey-pair) (<https://www.alibabacloud.com/help/en/beginner-guide/latest/obtain-an-accesskey-pair>).

*Table 36. Alibaba Cloud Object Storage protocol common log source parameters*

Parameter	Description
<b>Protocol Configuration</b>	Alibaba Cloud Object Storage Service
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Alibaba Cloud Object Storage log source, ensure that you give each one a unique name.
<b>Access Key ID</b>	The Access Key ID generates when you configure the service credentials.
<b>Secret Access Key</b>	The Secret Access Key generates when you configure the service credentials.
<b>Endpoint</b>	The public endpoint on the bucket configuration page. For more information, see <a href="https://www.alibabacloud.com/help/en/oss/user-guide/regions-and-endpoints">Regions and endpoints</a> ( <a href="https://www.alibabacloud.com/help/en/oss/user-guide/regions-and-endpoints">https://www.alibabacloud.com/help/en/oss/user-guide/regions-and-endpoints</a> ).
<b>Bucket Name</b>	The name of the bucket that logs are stored in.
<b>Prefix</b>	The prefix filter value to limit collecting objects or file keys that begin with the prefix. To pull all files from the bucket, use a forward slash (/). <b>Important:</b> Changing the <b>Prefix</b> value clears the persisted file marker. All files that match the new prefix are downloaded in the next pull. If the <b>Prefix</b> file path is used to specify folders, you must not begin the file path with a forward slash. For example, use folder1/folder2 instead.
<b>Event Format</b>	The following event formats are supported: <b>ActionTrail</b> Raw log files that contain an array of records. You can use .gz files for compression. <b>LINEBYLINE</b> Raw log files that contain one record per line. You can use either .gz, .gzip, or .zip files for compression.

Table 36. Alibaba Cloud Object Storage protocol common log source parameters (continued)

Parameter	Description
<b>Use As A Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for the QRadar to automatically detect one or more log sources.</p> <p>When you select this option, you can optionally use the <b>Log Source Identifier Pattern</b> to define a custom <b>Log Source Identifier</b> for the events that are being processed.</p>
<b>Log Source Identifier Pattern</b>	<p>If you select <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier. Use this option for events that are being processed and for log sources that are automatically discovered.</p> <p>If you do not configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom log source identifier. The key is the identifier format string, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom log source identifier is displayed.</p> <p>The following examples show multiple key-value pair functions:</p> <pre>Patterns VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK) Events {LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0} Resulting custom log source identifier VPC-ACCEPT-OK</pre>
<b>Show Advanced Options</b>	<p>To configure the advanced options for event collection, set this option to <b>On</b>.</p>
<b>File Pattern</b>	<p>Type a regex for the file pattern that matches the files that you want to pull, such as <code>.*?\.\json\.\gz</code>.</p> <p>This option is available when you set <b>Show Advanced Options</b> to <b>On</b>.</p>

Table 36. Alibaba Cloud Object Storage protocol common log source parameters (continued)

Parameter	Description
<b>Local Directory</b>	The local directory on the Target Event Collector. The directory must exist before the protocol attempts to retrieve events.  This option is available when you set <b>Show Advanced Options</b> to <b>On</b> .
<b>Use Proxy</b>	If QRadar accesses Alibaba Cloud Object Storage by using a proxy, enable <b>Use Proxy</b> .  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> parameters. If the proxy does not require authentication, leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Recurrence</b>	Type a time interval to determine how frequently the protocol polls for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds.  The minimum value is 1M.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

## Alibaba Cloud Simple Log Service protocol configuration options

The Alibaba Cloud Simple Log Service protocol for IBM QRadar is an outbound or active protocol that collects logs from a specific Log Store available in the Alibaba Cloud Log application.

**Important:** Before you configure the Alibaba Cloud Simple Log Service protocol, configure the user access roles and the service credentials to access the Alibaba Cloud Log application.

- To access logs from the Log Store, create Log Store in the Log application. For more information, see [Manage a Logstore](#).
- Create service credentials. For more information, see [AccessKey Pair](#).

Table 37. Alibaba Cloud Simple Log Service protocol common log source parameters

Parameter	Description
<b>Protocol Configuration</b>	Alibaba Cloud Simple Log Service
<b>Log Source Identifier</b>	Type a unique name for the log source. The log source identifier does not need to reference a specific server, and it can be the same value as the <b>Log Source Name</b> .

Table 37. Alibaba Cloud Simple Log Service protocol common log source parameters (continued)

Parameter	Description
<b>Access Key ID</b>	The Access Key ID is generated when you configure the service credentials.
<b>Secret Access Key</b>	The Secret Access Key generates when you configure the service credentials.
<b>Log Store Public Endpoint</b>	The Log Store Public Endpoint on the Alibaba Cloud Log Application section. For more information, see <a href="#">Regions and endpoints</a> .
<b>Log Store Project Name</b>	The Log Store Project Name on the Alibaba Cloud Log Application.
<b>Log Store Name</b>	The Log Store Name on the Alibaba Cloud Log Application's Log Store section.
<b>Use Proxy</b>	If QRadar accesses Alibaba Cloud Simple Log Service by using a proxy, enable <b>Use Proxy</b> . If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> parameters. If the proxy does not require authentication, leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Recurrence</b>	Type a time interval to determine how frequently the protocol polls for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, <b>2H</b> = 2 hours, <b>15M</b> = 15 minutes, <b>30</b> = seconds. The minimum value is <b>60</b> (seconds) or <b>1M</b> .
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
<b>Enable Advanced Options</b>	Select this checkbox to enable the following configuration options: <ul style="list-style-type: none"><li>• <b>Allow Untrusted</b></li><li>• <b>Override Workflow</b></li></ul>

Table 37. Alibaba Cloud Simple Log Service protocol common log source parameters (continued)

Parameter	Description
<b>Allow Untrusted</b>	Enable this parameter for the protocol to accept self-signed and otherwise untrusted certificates that are located within the /opt/qradar/conf/trusted_certificates/ directory. If you disable the parameter, the scanner trusts only certificates that are signed by a trusted signer.  The certificates must be in PEM or RED-encoded binary format and saved as a .crt or .cert file.  Your workflow can override this setting. For more information about this process, see IBM Documentation.
<b>Override Workflow</b>	Enable this option to customize the workflow. When you enable this option, the <b>Workflow</b> and <b>Workflow Parameters</b> parameters appear.
<b>Workflow</b>	The XML document that defines how the protocol instance collects events from the target API. For more information on the default workflow, see “Alibaba Cloud Simple Log Service protocol workflow” on page 73.
<b>Workflow Parameters</b>	The XML document that contains the parameter values used directly by the workflow. For more information on the default workflow parameters, see “Alibaba Cloud Simple Log Service protocol workflow” on page 73.

## Alibaba Cloud Simple Log Service protocol workflow

You can customize your workflow and workflow parameters based on the default workflow.

A workflow is an XML document that describes the event retrieval process. The workflow defines one or more parameters. These parameters can either be explicitly assigned values in the workflow XML or can derive values from the 'workflow parameter values XML' document. The workflow consists of multiple actions that run sequentially.

The default workflow and workflow parameter XML files are available on GitHub. For more information, see [Alibaba Simple Log Service](#).

## Alibaba Cloud Simple Log Service default workflow

The following example shows the default Alibaba Cloud Simple Log Service workflow:

```
<?xml version="1.0" encoding="UTF-8" ?>
<!--
AliCloud Workflow
-->
<Workflow name="AliCloudLogstore" version="1.0" minimumRecurrence="360" xmlns="http://
qradar.ibm.com/UniversalCloudRESTAPI/Workflow/V2">

<Parameters>
    <Parameter name="host" label="Host" required="true" />
    <Parameter name="logstore_name" label="The name of the logstore we are pulling from"
required="true" />
    <Parameter name="access_key_id" label="Access Key" required="true" />
    <Parameter name="secret_key" label="Secret Key" required="true" secret="true" />
</Parameters>
```

```

<Actions>

    <!--
        ///////////////////////////////////////////////////////////////////
        Get data from AliCloud Logstore
        ///////////////////////////////////////////////////////////////////
    -->

    <!-- Get epoch from 10 minutes ago for "from" -->
    <Initialize path="/AliCloudLogstore/from" value="${(time() / 1000) - (60 * 15)}" />
    <!-- 15 minutes. Gets updated at end of workflow to current time to prepare for next
run, which queries to cover the time since last run. -->

    <!-- Get epoch for current time for "to" -->
    <Set path="/AliCloudLogstore/to" value="${time() / 1000}" />

    <!-- get ISO8601 time for Date fields -->
    <FormatDate pattern="E, dd MMM yyyy HH:mm:ss z" timeZone="GMT" time="${/
AliCloudLogstore/to * 1000}" savePath="/AliCloudLogstore/current_time_formatted" />

    <!-- Header Definitions -->
    <Set path="/AliCloudLogstore/headers/apiVersion" value="0.6.0" />
    <Set path="/AliCloudLogstore/headers/signatureMethod" value="hmac-sha1"/>

    <!--
        Parameters we can work with:

</Workflow>
```

## Alibaba Cloud Simple Log Service default workflow parameters

The following example shows the default Alibaba Cloud Simple Log Service workflow parameters:

```

<?xml version="1.0" encoding="UTF-8" ?>
<WorkflowParameterValues xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/
WorkflowParameterValues/V2">
    <!--
        Refer to https://static-aliyun-doc.oss-cn-hangzhou.aliyuncs.com/
download%2Fpdf%2F29006%2FAPI_Reference_intl_en-US.pdf for URLs:

        The value of the Host parameter consists of a project name and a Log Service endpoint.
        You must specify a project in the Host
        parameter when you call this API operation.

        See page 11 for different endpoints to use with your project.
    -->
    <Value name="host" value="" />
```

```
<Value name="logstore_name" value="" />
<Value name="access_key_id" value="" />
<Value name="secret_key" value="" />
</WorkflowParameterValues>
```

## Amazon AWS S3 REST API protocol configuration options

The Amazon AWS S3 REST API protocol is an active outbound protocol that collects AWS CloudTrail logs from Amazon S3 buckets.

**Note:** It's important to ensure that no data is missing when you collect logs from Amazon S3 to use with a custom DSM or other unsupported integrations. Because of the way that the S3 APIs return the data, all files must be in an alphabetically increasing order when the full path is listed. Make sure that the full path name includes a full date and time in ISO9660 format (leading zeros in all fields and a YYYY-MM-DD date format).

Consider the following file path:

```
<Name>test-bucket</Name><Prefix>MyLogs/</Prefix><Marker>MyLogs/
2018-8-9/2018-08-09T23-5925.955097.log.gz</Marker><MaxKeys>1000</
MaxKeys><IsTruncated>false</IsTruncated></ListBucketResult>
```

The full name of the file in the marker is MyLogs/2018-8-9/2018-08-09T23-59-25.955097.log.gz and the folder name is written as 2018-8-9 instead of 2018-08-09. This date format causes an issue when data for the 10 September 2018 is presented. When sorted, the date displays as 2018-8-10 and the files are not sorted chronologically:

2018-10-1  
2018-11-1  
2018-12-31  
2018-8-10  
2018-8-9  
2018-9-1

After data for 9 August 2018 comes in to IBM QRadar, you won't see data again until 1 September 2018 because leading zeros were not used in the date format. After September, you won't see data again until 2019. Leading zeros are used in the date (ISO 9660) so this issue does not occur.

By using leading zeros, files and folders are sorted chronologically:

2018-08-09  
2018-08-10  
2018-09-01  
2018-10-01  
2018-11-01  
2018-12-01  
2018-12-31

### Restriction:

A log source can retrieve data from only one region, so use a different log source for each region. Include the region folder name in the file path for the **Directory Prefix** value when you use the Directory Prefix event collection method to configure the log source.

The following table describes the common parameter values to collect audit events by using the Directory Prefix collection method or the SQS event collection method. These collection methods use the Amazon AWS S3 REST API protocol.

Table 38. Amazon AWS S3 REST API protocol common log source parameters with the Directory Prefix method or the SQS method

Parameter	Description
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one configured log source per DSM, ensure that you give each one a unique name.
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b> Standard authentication that can be used from anywhere. For more information about configuring security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p> <p><b>EC2 Instance IAM Role</b> If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata that is assigned to the instance for authentication. No keys are required. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key</b>	The Access Key ID that was generated when you configured the security credentials for your AWS user account. If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Access Key</b> parameter is displayed.
<b>Secret Key</b>	The Secret Key that was generated when you configured the security credentials for your AWS user account. If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Secret Key</b> parameter is displayed.
<b>Assume an IAM Role</b>	Enable this option by authenticating with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access.
<b>Assume Role ARN</b>	The full ARN of the role to assume. It must begin with "arn:" and can't contain any leading or trailing spaces, or spaces within the ARN. If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role ARN</b> parameter is displayed.

*Table 38. Amazon AWS S3 REST API protocol common log source parameters with the Directory Prefix method or the SQS method (continued)*

Parameter	Description
<b>Assume Role Session Name</b>	<p>The session name of the role to assume. The default is QRadarAWSsession. Leave as the default if you don't need to change it. This parameter can contain only upper and lowercase alphanumeric characters, underscores, or any of the following characters: =, . @ -</p> <p>If you enabled <b>Assume an IAM Role</b>, the <b>Assume Role Session Name</b> parameter is displayed.</p>
<b>Assume Role External ID</b>	<p>An identifier that you might need to assume a role in another account. You get this value from the administrator of the account that the role belongs to.</p> <p>This value can be any string, such as a passphrase, GUID, or account number.</p> <p>For more information, see <a href="https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create_for-user_externalid.html">How to use an external ID when granting access to your AWS resources to a third party</a> (<a href="https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create_for-user_externalid.html">https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create_for-user_externalid.html</a>).</p> <p>If you enabled <b>Assume an IAM Role</b>, the <b>Assume Role External ID</b> parameter is displayed.</p>
<b>S3 Collection Method</b>	<p><b>SQS Event Notifications</b>            Poll an SQS Queue that contains ObjectCreated notifications that are configured on the S3 folders of your choice. Then, download and process the files that are referenced in the notification from the S3 bucket. You can use either a single queue or separate queues to cover multiple buckets and accounts. This decision depends on your configuration.</p> <p>For more information, see <a href="#">Table 40 on page 83</a>.</p> <p><b>Use a Specific Prefix</b>            Logs within the specified folder are processed. For CloudTrail log sources, the prefix must be for a single account or region only. For other log sources, the prefix must point to a single directory that contains files with ISO8601 timestamps at the beginning of each file name. The timestamp in each file name ensures that the protocol collects new events with this method.</p> <p>For more information, see <a href="#">Table 39 on page 82</a>.</p>

Table 38. Amazon AWS S3 REST API protocol common log source parameters with the Directory Prefix method or the SQS method (continued)

Parameter	Description
<b>Region Name</b>	<p>The region that the SQS Queue or the AWS S3 bucket is in.</p> <p>Example: us-east-1, eu-west-1, ap-northeast-3</p>
<b>Event Format</b>	<p>Choose the format of the events that are contained in the files.</p> <p><b>AWS CloudTrail JSON</b> Files that contain JSON formatted events for Amazon Cloud Trail (.json.gz files only).</p> <p><b>LINEBYLINE</b> Raw log files that contain one record per line. Compression with gzip (.gz or .gzip), and zip (.zip) is supported.</p> <p><b>AWS VPC Flow Logs</b> Files that contain AWS native/OCSF VPC Flow logs (.txt.gz or gz.parquet files only). This option sends flows to the <b>Network Activity</b> tab in QRadar. The configured log source doesn't show a <b>Last Event Seen Time</b> because the output is flow data.</p> <p><b>AWS Network Firewall Logs</b> Files that contain AWS Network Firewall Alert or Flow logs. This option sends flow logs to the <b>Network Activity</b> tab and sends alert logs as events to the <b>Log Activity</b> tab in QRadar. The Amazon AWS Network Firewall DSM parses the logs.</p> <p><b>Tip:</b> If your system is not licensed for flows, use the <b>LINEBYLINE</b> processor so that the DSM can parse the AWS Network Firewall logs.</p> <p><b>W3C</b> For use with the Cisco Cloud Web Services DSM (.gz files only).</p> <p><b>Cisco Umbrella CSV</b> For use with the Cisco Umbrella DSM (.gz files only).</p> <p><b>Apache Parquet</b> Choose this option to convert Apache Parquet files into JSON events (.gz.parquet and .parquet files only).</p>
<b>Flow Destination Hostname</b>	<p>The flow processor hostname where the VPC Flow or AWS Network Firewall flow logs are sent.</p> <p>If you select <b>AWS VPC Flow Logs</b> or <b>AWS Network Firewall</b> in the <b>Event Format</b> parameter, you can configure this parameter.</p>

*Table 38. Amazon AWS S3 REST API protocol common log source parameters with the Directory Prefix method or the SQS method (continued)*

Parameter	Description
<b>Flow Destination Port</b>	<p>The flow processor port where the VPC Flow or AWS Network Firewall flow logs are sent.</p> <p>If you select <b>AWS VPC Flow Logs</b> or <b>AWS Network Firewall</b> in the <b>Event Format</b> parameter, you can configure this parameter.</p>
<b>Use As A Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.</p> <p>When you select this option, the <b>Log Source Identifier Pattern</b> can optionally be used to define a custom <b>Log Source Identifier</b> for events that are being processed.</p>
<b>Log Source Identifier Pattern</b>	<p>If you selected <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>

Table 38. Amazon AWS S3 REST API protocol common log source parameters with the Directory Prefix method or the SQS method (continued)

Parameter	Description
<b>Use Predictive Parsing</b>	If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.  <b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.
<b>File Pattern</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code> .
<b>Local Directory</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API protocol attempts to retrieve events.
<b>S3 Endpoint URL</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The endpoint URL that is used to query the AWS S3 REST API.  If your endpoint URL is different from the default, type your endpoint URL. The default is <code>https://s3.amazonaws.com</code> .
<b>Use S3 Path-Style Access</b>	Forces S3 requests to use path-style access.  This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> .  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.

*Table 38. Amazon AWS S3 REST API protocol common log source parameters with the Directory Prefix method or the SQS method (continued)*

Parameter	Description
<b>Recurrence</b>	<p>How often a poll is made to scan for new data.</p> <p>If you are using the SQS event collection method, <b>SQS Event Notifications</b> can have a minimum value of 10 (seconds). Because SQS Queue polling can occur more often, a lower value can be used.</p> <p>If you are using the Directory Prefix event collection method, <b>Use a Specific Prefix</b> has a minimum value of 60 (seconds) or 1M. Because every listBucket request to an AWS S3 bucket incurs a cost to the account that owns the bucket, a smaller recurrence value increases the cost.</p> <p>Type a time interval to determine how frequently the poll is made for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

The following table describes the specific parameter values to collect audit events by using the Directory Prefix event collection method:

*Table 39. Amazon AWS S3 REST API protocol log source-specific parameters with the Directory Prefix method*

Parameter	Description
<b>S3 Collection Method</b>	Select <b>Use a Specific Prefix</b> .
<b>Bucket Name</b>	The name of the AWS S3 bucket where the log files are stored.

*Table 39. Amazon AWS S3 REST API protocol log source-specific parameters with the Directory Prefix method (continued)*

Parameter	Description
<b>Directory Prefix</b>	<p>The root directory location on the AWS S3 bucket from where the CloudTrail logs are retrieved; for example, AWSLogs/&lt;AccountNumber&gt;/CloudTrail/&lt;RegionName&gt;/.</p> <p>To pull files from the root directory of a bucket, you must use a forward slash (/) in the <b>Directory Prefix</b> file path.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• Changing the <b>Directory Prefix</b> value clears the persisted file marker. All files that match the new prefix are downloaded in the next pull.</li> <li>• The <b>Directory Prefix</b> file path cannot begin with a forward slash (/) unless only the forward slash is used to collect data from the root of the bucket.</li> <li>• If the <b>Directory Prefix</b> file path is used to specify folders, you must not begin the file path with a forward slash (for example, use folder1/folder2 instead).</li> </ul>

The following table describes the parameters that require specific values to collect audit events by using the SQS event collection method:

*Table 40. Amazon AWS S3 REST API protocol log source-specific parameters with the SQS method*

Parameter	Description
<b>S3 Collection Method</b>	Select <b>SQS Event Notifications</b> .
<b>SQS Queue URL</b>	The full URL that begins with https://, for the SQS Queue that is set up to receive notifications for ObjectCreated events from S3.

#### Related concepts

[“Gateway log source” on page 15](#)

Use a gateway log source to configure a protocol to use many Device Support Modules (DSMs) instead of relying on a single DSM type. With a gateway log source, event aggregator protocols can dynamically handle various event types.

## Amazon Web Services protocol configuration options

The Amazon Web Services (AWS) protocol is an outbound/active protocol for IBM QRadar that collects AWS CloudWatch Logs, Amazon Kinesis Data Streams, and Amazon Simple Queue Service (SQS) messages.

**Important:** The Amazon Web Services protocol requires QRadar 7.3.1 or later, and the IBM QRadar Log Source Management app.

You can use the Amazon Web Services protocol with either “Amazon Kinesis Data Streams” on page 84, “AWS CloudWatch Logs” on page 88, or “Amazon Simple Queue Service (SQS)” on page 92.

## Amazon Kinesis Data Streams

The following table describes the protocol-specific parameters for collecting Amazon Kinesis Data Streams with the Amazon Web Services protocol:

Table 41. Amazon Web Services log source parameters for Amazon Kinesis Data Streams	
Parameter	Description
<b>Protocol Configuration</b>	Select <b>Amazon Web Services</b> from the Protocol Configuration list.
<b>Authentication Method</b>	<p><b>Access Key ID/Secret Key</b> Standard authentication that can be used from anywhere.</p> <p><b>EC2 Instance IAM Role</b> If your QRadar managed host is running in an AWS EC2 instance, choosing this option uses the IAM role from the metadata that is assigned to the instance for authentication. No keys are required. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key</b>	<p>The Access Key ID that was generated when you configured the security credentials for your AWS user account.</p> <p>If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b>, the <b>Access Key</b> parameter is displayed.</p>
<b>Secret Key</b>	<p>The Secret Key that was generated when you configured the security credentials for your AWS user account.</p> <p>If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b>, the <b>Secret Key</b> parameter is displayed.</p>
<b>Assume an IAM Role</b>	Enable this option to authenticate with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access.
<b>Assume Role ARN</b>	<p>The full ARN of the role to assume. It must begin with "arn:" and can't contain any leading or trailing spaces, or spaces within the ARN.</p> <p>If you enabled <b>Assume an IAM Role</b>, the <b>Assume Role ARN</b> parameter is displayed.</p>
<b>Assume Role Session Name</b>	<p>The session name of the role to assume. The default is QRadarAWSsession. Leave as the default if you don't need to change it. This parameter can contain only upper and lowercase alphanumeric characters, underscores, or any of the following characters: =, . @ -</p> <p>If you enabled <b>Assume an IAM Role</b>, the <b>Assume Role Session Name</b> parameter is displayed.</p>
<b>Assume Role External ID</b>	<p><b>Assume Role External ID</b> is an optional identifier that is required to assume a role in a different account.</p> <p>If the account administrator, to which the role belongs, provides you with an external ID, then insert that value in the <b>Assume Role External ID</b> parameter.</p> <p>This value can either be a string, a passphrase, a GUID, or an account number. For more information, see AWS documentation <a href="#">Using an external ID for third-party access</a>.</p>

Table 41. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Regions</b>	Toggle each region that is associated with the Amazon Web Service that you want to collect logs from.
<b>AWS Service</b>	From the <b>AWS Service</b> list, select <b>Kinesis Data Streams</b> .
<b>Kinesis Data Stream</b>	The Kinesis Data Stream from which to consume data.
<b>Enable Kinesis Advanced Options</b>	<p>Enable the following optional advanced configuration values. Advanced option values are only used when this option is chosen; otherwise, the default values are used.</p> <p><b>Initial Position in Stream</b>  This option controls which data to pull on a newly configured log source. Select <b>Latest</b> to pull the latest data that is available. Select <b>Trim Horizon</b> to pull the oldest data that is available.</p> <p><b>Kinesis Worker Thread Count</b>  The number of worker threads to use for Kinesis Data Stream processing. Each worker thread can process approximately 10000 - 20000 events per second depending on record size and system load. If your log source is not able to process the new data in the stream, you can increase the number of threads here to a maximum of 16. The allowed range is 1 - 16. The default value is 2.</p> <p><b>Checkpoint Interval</b>  The interval (in seconds) at which to checkpoint data sequence numbers. Each record from a shard in a Kinesis Data Stream has a sequence number. Checkpointing your position allows this shard to resume processing at the same point if processing fails or a service restarts. A more frequent interval reduces data duplication but increases Amazon Dynamo DB usage. The allowed range is 1 - 3600 seconds. The default is 10 seconds.</p> <p><b>Kinesis Application</b>  Leave this option blank to have this log source consume data from all available shards in the Kinesis Data Stream. To have multiple log sources on multiple event processors scale log consumption without loss or duplication, use a common Kinesis Application across those log sources (Example: ProdKinesisConsumers).</p> <p><b>Partition</b>  Select this option to collect data from a specific partition in the Kinesis Data Stream by specifying a partition name.</p>

Table 41. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Extract Original Event</b>	<p>Forwards only the original event that was added to the Kinesis Data Stream. Kinesis logs wrap the events that they receive with extra metadata. Select this option if you want only the original event that was sent to AWS without the additional stream metadata through Kinesis.</p> <p>The original event is the value for the message key that is extracted from the Kinesis log. The following Kinesis logs event example shows the original event that is extracted from the Kinesis log in highlighted text:</p> <pre>{"owner": "123456789012", "subscriptionFilters": ["allEvents"], "logEvents": [{"id": "35093963143971327215510178578576502306458824699048362100", "message": "{\"eventVersion\": \"1.05\", \"userIdentity\": {\"type\": \"AssumedRole\", \"principalId\": \"ARO1GH58EM3ESYDW3XHP6:test_session\", \"arn\": \"arn:aws:sts::123456789012:assumed-role/CVDevABRoleToBeAssumed/test_visibility_session\", \"accountId\": \"123456789012\", \"accessKeyId\": \"ASIAXXXXXXXXXXXXXX\", \"sessionContext\": {\"sessionIssuer\": {\"type\": \"Role\", \"principalId\": \"AROAXXXXXXXXXXXXXXXX\", \"arn\": \"arn:aws:iam::123456789012:role/CVDevABRoleToBeAssumed\", \"accountId\": \"123456789012\", \"userName\": \"CVDevABRoleToBeAssumed\", \"webIdFederationData\": {}}, \"attributes\": {\"mfaAuthenticated\": \"false\", \"creationDate\": \"2019-11-13T17:01:54Z\", \"eventTime\": \"2019-11-13T17:43:18Z\", \"eventSource\": \"cloudtrail.amazonaws.com\", \"eventName\": \"DescribeTrails\", \"awsRegion\": \"ap-northeast-1\", \"sourceIPAddress\": \"192.0.2.1\", \"requestParameters\": null, \"responseElements\": null, \"requestID\": \"41e62e80-b15d-4e3f-9b7eb309084dc092\", \"eventID\": \"904b3fda-8e48-46c0-a923-f1bb2b7a2f2a\", \"readOnly\": true, \"eventType\": \"AwsApiCall\", \"recipientAccountId\": \"123456789012\", \"timestamp\": 1573667733143}, \"messageType\": \"DATA_MESSAGE\", \"logGroup\": \"CloudTrail/DefaultLogGroup\", \"logStream\": \"123456789012_CloudTrail_us-east-2_2\"}}</pre>
<b>Use As A Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.</p> <p>When you select this option, the <b>Log Source Identifier Pattern</b> can optionally be used to define a custom <b>Log Source Identifier</b> for events that are being processed.</p>

Table 41. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>If you selected <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p><b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>
<b>Use Proxy</b>	<p>If QRadar accesses the Amazon Web Service by using a proxy, select this option.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

## AWS CloudWatch Logs

The following table describes the protocol-specific parameters for collecting AWS CloudWatch Logs with the Amazon Web Services protocol:

Table 42. Amazon Web Services log source parameters for AWS CloudWatch Logs	
Parameter	Description
<b>Protocol Configuration</b>	Select <b>Amazon Web Services</b> from the Protocol Configuration list.
<b>Authentication Method</b>	<b>Access Key ID/Secret Key</b> Standard authentication that can be used from anywhere. <b>EC2 Instance IAM Role</b> If your QRadar managed host is running in an AWS EC2 instance, choosing this option uses the IAM role from the metadata that is assigned to the instance for authentication. No keys are required. This method works only for managed hosts that are running within an AWS EC2 container.
<b>Access Key</b>	The Access Key ID that was generated when you configured the security credentials for your AWS user account. If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Access Key</b> parameter is displayed.
<b>Secret Key</b>	The Secret Key that was generated when you configured the security credentials for your AWS user account. If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Secret Key</b> parameter is displayed.
<b>Assume an IAM Role</b>	Enable this option by authenticating with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access.
<b>Assume Role ARN</b>	The full ARN of the role to assume. It must begin with "arn:" and can't contain any leading or trailing spaces, or spaces within the ARN. If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role ARN</b> parameter is displayed.
<b>Assume Role Session Name</b>	The session name of the role to assume. The default is QRadarAWSsession. Leave as the default if you don't need to change it. This parameter can contain only upper and lowercase alphanumeric characters, underscores, or any of the following characters: = , . @ - If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role Session Name</b> parameter is displayed.

Table 42. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)

Parameter	Description
<b>Assume Role External ID</b>	<p><b>Assume Role External ID</b> is an optional identifier that is required to assume a role in a different account.</p> <p>If the account administrator, to which the role belongs, provides you with an external ID, then insert that value in the <b>Assume Role External ID</b> parameter.</p> <p>This value can either be a string, a passphrase, a GUID, or an account number. For more information, see AWS documentation <a href="#">Using an external ID for third-party access</a>.</p>
<b>Regions</b>	<p>Toggle each region that is associated with the Amazon Web Service that you want to collect logs from.</p>
<b>AWS Service</b>	<p>From the <b>AWS Service</b> list, select <b>CloudWatch Logs</b>.</p>
<b>Log Group</b>	<p>The name of the log group in Amazon CloudWatch where you want to collect logs from.</p> <p><b>Tip:</b> A single log source collects CloudWatch Logs from one log group at a time. If you want to collect logs from multiple log groups, create a separate log source for each log group.</p>
<b>Enable CloudWatch Advanced Options</b>	<p>Enable the following optional advanced configuration values. Advanced option values are only used when this option is chosen; otherwise, the default values are used.</p> <p><b>Log Stream</b> The name of the log stream within a log group. If you want to collect logs from all log streams within a log group, leave this field blank.</p> <p><b>Filter Pattern</b> Type a pattern for filtering the collected events. This pattern is not a regex filter. Only the events that contain the exact value that you specified are collected from CloudWatch Logs. If you type ACCEPT as the Filter Pattern value, only the events that contain the word ACCEPT are collected, as shown in the following example.</p> <pre data-bbox="926 1664 1449 1733">{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Event Delay</b> Delay in seconds for collecting data.</p> <p><b>Other Region(s)</b> Deprecated. Use <b>Regions</b> instead.</p>

Table 42. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)

Parameter	Description
<b>Extract Original Event</b>	<p>Forwards only the original event that was added to the CloudWatch Logs.</p> <p>CloudWatch logs wrap the events that they receive with extra metadata. Select this option if you want to collect only the original event that was sent to AWS without the additional stream metadata through CloudWatch Logs.</p> <p>The original event is the value for the message key that is extracted from the CloudWatch log. The following CloudWatch Logs event example shows the original event that is extracted from CloudWatch Logs in highlighted text:</p> <pre data-bbox="878 692 1465 1347">{LogStreamName: 123456786_CloudTrail_us-east-2, Timestamp: 1505744407363, Message: {"eventVersion": "1.05", "userIdentity": {"type": "IAMUser", "principalId": "AAAABBBCCCDDDBBBCCC", "arn": "arn:aws:iam::1234567890:user/<b>username</b>", "accountId": "1234567890", "accessKeyId": "AAAABBBBCCCCDDDD", "userName": "User-Name", "sessionContext": {"attributes": {"mfaAuthenticated": "false", "creationDate": "2017-09-18T13:22:10Z"}, "invokedBy": "signin.amazonaws.com"}, "eventTime": "2017-09-18T14:10:15Z", "eventSource": "cloudtrail.amazonaws.com", "eventName": "DescribeTrails", "awsRegion": "us-east-1", "sourceIPAddress": "192.0.2.1", "userAgent": "signin.amazonaws.com", "requestParameters": {"includeShadowTrails": false, "trailNameList": []}, "responseElements": null, "requestID": "11b1a00-7a7a-11a1-1a11-44a4aaa1a", "eventID": "a4914e00-1111-491d-bbbb-a0dd3845b302", "eventType": "AwsApiCall", "recipientAccountId": "<b>1234567890</b>", "IngestionTime: 1505744407506, EventId: 3357922236111112247912667222222513333}</pre>
<b>Use As A Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.</p> <p>When you select this option, the <b>Log Source Identifier Pattern</b> can optionally be used to define a custom <b>Log Source Identifier</b> for events that are being processed.</p>

Table 42. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>If you selected <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p><b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>

*Table 42. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)*

Parameter	Description
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, select this option.  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

## Amazon Simple Queue Service (SQS)

The following table describes the protocol-specific parameters for collecting Amazon SQS log sources with the Amazon Web Services protocol:

*Table 43. Amazon Web Services log source parameters for Amazon SQS*

Parameter	Description
<b>Protocol Configuration</b>	Select <b>Amazon Web Services</b> from the Protocol Configuration list.
<b>Authentication Method</b>	<b>Access Key ID/Secret Key</b> Standard authentication that can be used from anywhere. <b>EC2 Instance IAM Role</b> If your QRadar managed host is running in an AWS EC2 instance, choosing this option uses the IAM role from the metadata that is assigned to the instance for authentication. No keys are required. This method works only for managed hosts that are running within an AWS EC2 container.
<b>Access Key</b>	The Access Key ID that was generated when you configured the security credentials for your AWS user account.  If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Access Key</b> parameter is displayed.

Table 43. Amazon Web Services log source parameters for Amazon SQS (continued)

Parameter	Description
<b>Secret Key</b>	<p>The Secret Key that was generated when you configured the security credentials for your AWS user account.</p> <p>If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b>, the <b>Secret Key</b> parameter is displayed.</p>
<b>Assume an IAM Role</b>	<p>Enable this option by authenticating with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access.</p>
<b>Assume Role ARN</b>	<p>The full ARN of the role to assume. It must begin with "arn:" and can't contain any leading or trailing spaces, or spaces within the ARN.</p> <p>If you enabled <b>Assume an IAM Role</b>, the <b>Assume Role ARN</b> parameter is displayed.</p>
<b>Assume Role Session Name</b>	<p>The session name of the role to assume. The default is QRadarAWSsession. Leave as the default if you don't need to change it. This name can contain only uppercase and lowercase alphanumeric characters, underscores, or any of the following characters: =, .@-</p> <p>If you enabled <b>Assume an IAM Role</b>, the <b>Assume Role Session Name</b> parameter is displayed.</p>
<b>Assume Role External ID</b>	<p><b>Assume Role External ID</b> is an optional identifier that is required to assume a role in a different account.</p> <p>If the account administrator, to which the role belongs, provides you with an external ID, then insert that value in the <b>Assume Role External ID</b> parameter.</p> <p>This value can either be a string, a passphrase, a GUID, or an account number. For more information, see AWS documentation <a href="#">Using an external ID for third-party access</a>.</p>
<b>Regions</b>	<p>Toggle each region that is associated with the Amazon Web Service that you want to collect logs from.</p>
<b>AWS Service</b>	<p>From the <b>AWS Service</b> list, select <b>SQS Queue</b>.</p>
<b>SQS Queue URL</b>	<p>The full URL of the SQS queue to pull data from, starting with <a href="https://">https://</a>, such as <a href="https://sqs.us-east-2.amazonaws.com/1234567890123/CloudTrail_SQS_QRadar">https://sqs.us-east-2.amazonaws.com/1234567890123/CloudTrail_SQS_QRadar</a>.</p> <p>For more information, see <a href="#">Amazon S3 Event Notifications</a> (<a href="https://docs.aws.amazon.com/AmazonS3/latest/dev/NotificationHowTo.html">https://docs.aws.amazon.com/AmazonS3/latest/dev/NotificationHowTo.html</a>).</p>

Table 43. Amazon Web Services log source parameters for Amazon SQS (continued)

Parameter	Description
<b>Extract Original Event</b>	Forwards only the original event that was added to the SQS queue to QRadar, select this option.
<b>Original Event JSON Element</b>	<p>When you use this option to extract original event with SQS, the original event might be in a specific JSON element. If so, you must specify the name of the top-level JSON element that contains the original event. This option also unescapes any data that is contained within that element.</p> <p>For example, when the Message element is used, it takes that root element and unescapes the nested JSON if necessary:</p> <pre data-bbox="878 656 1449 846">{ "Type" : "Notification", "MessageId" : "6d11936e-2361-5dc1-a689-c590f69c73da", "Subject" : "Test Notification", "Message" : "{\"eventVersion\":\"2.1\", \"eventSource\":\"aws:s3\", \"awsRegion\":\"us-east-1\", \"eventTime\":\"2020-04-01T17:47:39.107Z\"}" }</pre> <p>The unescaped data then appears as this extracted original event:</p> <pre data-bbox="878 973 1383 1058">{ "eventVersion": "2.1", "eventSource": "aws:s3", "awsRegion": "us-east-1", "eventTime": "2020-04-01T17:47:39.107Z" }</pre>
<b>Use As A Gateway Log Source</b>	<p>If you do not want to define a custom log source identifier for events, clear the checkbox.</p> <p>If you don't select <b>Use As A Gateway Log Source</b> and you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p>

Table 43. Amazon Web Services log source parameters for Amazon SQS (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>If you selected <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier. This option can be defined for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p><b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>

Table 43. Amazon Web Services log source parameters for Amazon SQS (continued)

Parameter	Description
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, select this option. If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

#### Related concepts

[“Gateway log source” on page 15](#)

Use a gateway log source to configure a protocol to use many Device Support Modules (DSMs) instead of relying on a single DSM type. With a gateway log source, event aggregator protocols can dynamically handle various event types.

#### Related information

[Adding a log source](#)

## Apache Kafka protocol configuration options

IBM QRadar uses the Apache Kafka protocol to read streams of event data from topics in a Kafka cluster that uses the Consumer API. A topic is a category or feed name in Kafka where messages are stored and published. The Apache Kafka protocol is an outbound or active protocol, and can be used as a gateway log source by using a custom log source type.

The Apache Kafka protocol supports topics of almost any scale. You can configure multiple QRadar collection hosts (EP/ECs) to collect from a single topic; for example, all firewalls. For more information, see the [Kafka Documentation](http://kafka.apache.org/documentation/) (<http://kafka.apache.org/documentation/>).

The following table describes the protocol-specific parameters for the Apache Kafka protocol:

Table 44. Apache Kafka protocol parameters

Parameter	Description
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Apache Kafka log source, ensure that you give each one a unique name.

Table 44. Apache Kafka protocol parameters (continued)

Parameter	Description
<b>Bootstrap Server List</b>	The <hostname/ip>:<port> of the bootstrap server (or servers). Multiple servers can be specified in a comma-separated list, such as in this example: <i>hostname1:9092,1.1.1.1:9092</i> .
<b>Consumer Group</b>	A unique string or label that identifies the consumer group that this log source belongs to.  Each record that is published to a Kafka topic is delivered to one consumer instance within each subscribing consumer group. Kafka uses these labels to load balance the records over all consumer instances in a group.
<b>Topic Subscription Method</b>	The method that is used for subscribing to Kafka topics. Use the <b>List Topics</b> option to specify a specific list of topics. Use the <b>Regex Pattern Matching</b> option to specify a regular expression to match against available topics.
<b>Topic List</b>	A list of topic names to subscribe to. The list must be comma-separated; for example: Topic1,Topic2,Topic3  This option is only displayed when <b>List Topics</b> is selected for the <b>Topic Subscription Method</b> option.
<b>Topic Filter Pattern</b>	A regular expression to match the topics to subscribe to.  This option is only displayed when <b>Regex Pattern Matching</b> is selected for the <b>Topic Subscription Method</b> option.
<b>Use SASL Authentication</b>	This option displays SASL authentication configuration options.  When used without client authentication, you must place a copy of the server certificate in the /opt/qradar/conf/trusted_certificates/ directory.
<b>SASL Mechanism</b>	Select the SASL mechanism that is compatible with your Kafka configuration: <ul style="list-style-type: none"><li>• PLAIN</li><li>• SCRAM-SHA-256</li><li>• SCRAM-SHA-512</li></ul>
<b>SASL Username</b>	The username that is used for SASL authentication.
<b>SASL Password</b>	The password that is used for SASL authentication.
<b>Use SSL</b>	Select this option to enable SSL (TLS) encryption if your Kafka configuration supports or requires it.

*Table 44. Apache Kafka protocol parameters (continued)*

Parameter	Description
<b>Use Client Authentication</b>	<p>Displays the client authentication configuration options.</p> <p>You can enable this option only if you enable the <b>Use SSL</b> parameter and use SSL (TLS) for authentication and data transfer.</p>
<b>Key Store/Trust Store Type</b>	<p>The archive file format for your keystore and truststore type. The following options are available for the archive file format:</p> <ul style="list-style-type: none"> <li>• JKS</li> <li>• PKCS12</li> </ul>
<b>Trust Store Filename</b>	<p>The name of the truststore file. The truststore must be placed in /opt/qradar/conf/trusted_certificates/kafka/. The file contains the username and password.</p>
<b>Key Store Filename</b>	<p>The name of the keystore file. The keystore must be placed in /opt/qradar/conf/trusted_certificates/kafka/. The file contains the username and password.</p>
<b>Use As A Gateway Log Source</b>	<p>This option enables collected events to go through the QRadar Traffic Analysis engine and to automatically detect the appropriate log sources.</p>

Table 44. Apache Kafka protocol parameters (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>Defines a custom Log Source Identifier for events that are being processed, if the <b>Use As A Gateway Log Source</b> checkbox is selected.</p> <p>Key-value pairs are used to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Multiple key-value pairs are defined by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b> VPC-ACCEPT-OK</p>
<b>Show Advanced Options</b>	<p>Show optional advanced options for the Kafka configuration. The advanced option values are in effect whether they are shown or not.</p>
<b>Use Payload Extraction</b>	<p>Enable this parameter to extract the payload and send it to the event pipeline. This parameter identifies the specified payload if it is somewhere within the Kafka log records.</p> <p>Multiple regular expressions can be defined by entering each pattern on a new line. When multiple Payload Extraction patterns are used, they are evaluated in order until a match is found and an extracted payload can be returned.</p> <p>This payload extraction occurs before any character replacements.</p>
<b>Payload Extraction Regular Expression</b>	<p>A regular expression that identifies the specified payload within the Kafka log records so it can be sent to QRadar. This expression must include a capture group and uses the first capture group as the new payload.</p>

*Table 44. Apache Kafka protocol parameters (continued)*

Parameter	Description
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns and extracts payloads from events without running the regex for every event, which increases the parsing speed.</p> <p>In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>
<b>Character Sequence Replacement</b>	<p>Replaces specific literal character sequences that are in the event payload with actual characters. One or more of the following options are available:</p> <ul style="list-style-type: none"> <li>• <b>Newline(CR LF) Character (\r\n)</b></li> <li>• <b>Line Feed Character (\n)</b></li> <li>• <b>Carriage Return Character (\r)</b></li> <li>• <b>Tab Character (\t)</b></li> <li>• <b>Space Character (\s)</b></li> <li>• <b>Unescape JSON Data</b></li> </ul> <p><b>Tip:</b> Select this option if you want the entire payload to be JSON unescaped after any payload extraction. When you unescape JSON messages, any character that prevents parsing is removed from the message.</p> <p>Enable this option when you want to extract JSON messages that are embedded in JSON objects.</p>

Table 44. Apache Kafka protocol parameters (continued)

Parameter	Description
<b>Kafka Consumer Properties Override</b>	<p>A list of key=value pairs that can be used to provide specific configuration properties to the Kafka Consumer. The list uses one pair per line.</p> <p>For example, the key=value pair <code>session.timeout.ms=10000</code> configures the session timeout in milliseconds.</p> <p>For a list of available key=value pairs, see the <a href="https://ibm.biz/kafkaconsumerconfigs">Kafka Consumer Configuration documentation</a> (<a href="https://ibm.biz/kafkaconsumerconfigs">https://ibm.biz/kafkaconsumerconfigs</a>).</p> <p>Any parameters that are entered in this field override any previous ones set during the configuration phase of the log source. These parameters include, but are not limited to, the following examples:</p> <ul style="list-style-type: none"> <li>• <code>fetch.max.bytes</code></li> <li>• <code>group.id</code></li> <li>• <code>ssl.enabled.protocols</code></li> </ul> <p>You cannot enter any password-type properties with secret values in this field. These properties include, but are not limited to, the following examples:</p> <ul style="list-style-type: none"> <li>• <code>ssl.key.password</code></li> <li>• <code>ssl.key.password</code></li> <li>• <code>ssl.keystore.password</code></li> <li>• <code>ssl.truststore.password</code></li> <li>• <code>sasl.jaas.config</code></li> <li>• <code>ssl.truststore.certificates</code></li> <li>• <code>ssl.keystore.certificate.chain</code></li> <li>• <code>ssl.keystore.key</code></li> </ul> <p>Use the <b>Private Key Password</b>, <b>Trust Store Password</b>, <b>Key Store Password</b>, <b>Private Key Password</b>, or <b>SASL Password</b> fields to enter password-type Kafka consumer properties.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p>

#### Related concepts

[“Gateway log source” on page 15](#)

Use a gateway log source to configure a protocol to use many Device Support Modules (DSMs) instead of relying on a single DSM type. With a gateway log source, event aggregator protocols can dynamically handle various event types.

## Configuring Apache Kafka to enable Client Authentication

This task discusses how to enable Client Authentication with Apache Kafka.

### Before you begin

1. Ensure that the ports that are used by the Kafka server are not blocked by a firewall.
2. To enable client authentication between the Kafka consumers (QRadar) and a Kafka brokers, a key and certificate for each broker and client in the cluster must be generated. The certificates also need to be signed by a certificate authority (CA).

### About this task

In the following steps, you generate a CA, sign the client and broker certificates with it, and add it to the client and broker truststores. You also generate the keys and certificates by using the Java keytool and OpenSSL. Alternatively, an external CA can be used along with multiple CAs, one for signing broker certificates and another for client certificates.

### Procedure

1. Generate the truststore, keystore, private key, and CA certificate.

**Note:** Replace PASSWORD, VALIDITY, SERVER\_ALIAS and CLIENT\_ALIAS in the following commands with appropriate values.

- a) Generate Server keystore.

**Note:**

The common name (CN) of the broker certificates must match the fully qualified domain name (FQDN) of the server/host. The Kafka Consumer client that is used by QRadar compares the CN with the DNS domain name to ensure that it is connecting to the correct broker instead of a malicious one. Make sure to enter the FQDN for the *CN/First and Last name* value when you generate the Server keystore.

```
keytool -keystore kafka.server.keystore.jks -alias SERVER_ALIAS  
-validity VALIDITY -genkey
```

**Example**

```
keytool -keystore kafka.server.keystore.jks -alias server.hostname  
-validity 365 -genkey
```

- b) Generate CA Certificate.

**Note:**

This CA certificate can be used to sign all broker and client certificates.

```
openssl req -new -x509 -keyout ca-key -out ca-cert -days VALIDITY
```

**Example**

```
openssl req -new -x509 -keyout ca-key -out ca-cert -days 365
```

- c) Create Server truststore and import CA Certificate.

```
keytool -keystore kafka.server.truststore.jks -alias CARoot  
-import -file ca-cert
```

- d) Create Client truststore and import CA Certificate.

```
keytool -keystore kafka.client.truststore.jks -alias CARoot  
-import -file ca-cert
```

- e) Generate a Server Certificate and sign it using the CA.

```
keytool -keystore kafka.server.keystore.jks -alias SERVER_ALIAS  
-certreq -file cert-file
```

```
openssl x509 -req -CA ca-cert -CAkey ca-key -in cert-file -out  
cert-signed -days VALIDITY -CAcreateserial
```

### Example

```
keytool -keystore kafka.server.keystore.jks -alias server.hostname  
-certreq -file cert-file
```

```
openssl x509 -req -CA ca-cert -CAkey ca-key -in cert-file -out  
cert-signed -days 365 -CAcreateserial
```

- f) Import CA Certificate into the Server keystore.

```
keytool -keystore kafka.server.keystore.jks -alias CARoot  
-import -file ca-cert
```

- g) Import Signed Server Certificate to the Server keystore.

```
keytool -keystore kafka.server.keystore.jks -alias SERVER_ALIAS -import  
-file cert-signed
```

### Example

```
keytool -keystore kafka.server.keystore.jks -alias server.hostname  
-import -file cert-signed
```

- h) Export the Server Certificate into the binary DER file.

**Note:** The keytool -exportcert command uses the DER format by default. Place the certificate in the trusted\_certificates/ directory of any EP that communicates with Kafka. You need the server certificate for every bootstrap server that you use in the configuration. Otherwise, QRadar rejects the TLS handshake with the server.

```
keytool -exportcert -keystore kafka.server.keystore.jks -alias  
SERVER_ALIAS -file SERVER_ALIAS.der
```

### Example

```
keytool -exportcert -keystore kafka.server.keystore.jks -alias  
server.hostname -file server.hostname.der
```

- i) Generate a Client keystore.

```
keytool -keystore kafka.client.keystore.jks -alias CLIENT_ALIAS  
-validity VALIDITY -genkey
```

### Example

```
keytool -keystore kafka.client.keystore.jks -alias client.hostname  
-validity 365 -genkey
```

- j) Generate a Client Certificate and sign it using the CA.

```
keytool -keystore kafka.client.keystore.jks -alias CLIENT_ALIAS  
-certreq -file client-cert-file
```

```
openssl x509 -req -CA ca-cert -CAkey ca-key -in client-cert-file -out  
client-cert-signed -days VALIDITY -CAcreateserial
```

### Example

```
keytool -keystore kafka.client.keystore.jks -alias client.hostname  
-certreq -file client-cert-file
```

```
openssl x509 -req -CA ca-cert -CAkey ca-key -in client-cert-file  
-out client-cert-signed -days 365 -CAcreateserial
```

- k) Import CA Certificate into the Client keystore.

```
keytool -keystore kafka.client.keystore.jks -alias CARoot  
-import -file ca-cert
```

- l) Import Signed Client Certificate to the Client keystore.

```
keytool -keystore kafka.client.keystore.jks -alias CLIENT_ALIAS  
-import -file client-cert-signed
```

### Example

```
keytool -keystore kafka.client.keystore.jks -alias client.hostname  
-import -file client-cert-signed
```

- m) Copy Client keystore and truststore and to QRadar.

- i) Copy the `kafka.client.keystore.jks` and `kafka.client.truststore.jks` to `/opt/qradar/conf/trusted_certificates/kafka/` on each of the Event processors that the log source is configured for.
- ii) Copy the server certificates `<filename>.der` that were generated for each broker to `/opt/qradar/conf/trusted_certificates/`.

## 2. Configure Kafka brokers for Client Authentication.

- a) Find the **Socket Server Settings** section.

- b) Complete 1 of the following options:

- If you are not using SASL Authentication, change `listeners=PLAINTEXT://:<port>` to `listeners=SSL://:<PORT>` and add `security.inter.broker.protocol=SSL`.
- If you are using SASL Authentication, change `listeners=PLAINTEXT://:<port>` to `listeners=SASL_SSL://:<PORT>` and add `security.inter.broker.protocol=SASL_SSL`.

- c) Add the following properties to force encrypted communication between brokers and between the brokers and clients. Adjust the paths, file names, and passwords as you need them. These properties are the truststore and keystore of the **server**:

```
security.inter.broker.protocol=SSL  
ssl.client.auth=required  
ssl.keystore.location=/somefolder/kafka.server.keystore.jks  
ssl.keystore.password=test1234  
ssl.key.password=test1234  
ssl.truststore.location=/somefolder/kafka.server.truststore.jks  
ssl.truststore.password=test1234
```

**Important:** Since the passwords are stored in plain text in the `server.properties`, it is advised that access to the file is restricted by way of file system permissions.

- d) Restart the Kafka brokers that had their `server.properties` modified.

## Configuring Apache Kafka to enable SASL Authentication

This task discusses how to enable SASL Authentication with Apache Kafka without SSL Client Authentication.

### Before you begin

If you are using SASL Authentication with Client Authentication enabled, see “[Configuring Apache Kafka to enable Client Authentication](#)” on page 102.

1. Ensure that the ports that are used by the Kafka server are not blocked by a firewall.
2. To enable client authentication between the Kafka consumers (QRadar) and a Kafka brokers, a key and certificate for each broker and client in the cluster must be generated. The certificates also need to be signed by a certificate authority (CA).

### About this task

In the following steps, you generate a CA, sign the client and broker certificates with it, and add it to the broker truststores. You also generate the keys and certificates by using the Java keytool and OpenSSL. Alternatively, an external CA can be used along with multiple CAs, one for signing broker certificates and another for client certificates.

### Procedure

1. Generate the truststore, keystore, private key, and CA certificate.

**Note:** Replace `PASSWORD`, `VALIDITY`, `SERVER_ALIAS` and `CLIENT_ALIAS` in the following commands with appropriate values.

- a) Generate Server keystore.

**Note:**

The common name (CN) of the broker certificates must match the fully qualified domain name (FQDN) of the server/host. The Kafka Consumer client that is used by QRadar compares the CN with the DNS domain name to ensure that it is connecting to the correct broker instead of a malicious one. Make sure to enter the FQDN for the *CN/First and Last name* value when you generate the Server keystore.

```
keytool -keystore kafka.server.keystore.jks -alias SERVER_ALIAS  
-validity VALIDITY -genkey
```

**Example**

```
keytool -keystore kafka.server.keystore.jks -alias server.hostname  
-validity 365 -genkey
```

- b) Generate CA Certificate.

**Note:**

This CA certificate can be used to sign all broker and client certificates.

```
openssl req -new -x509 -keyout ca-key -out ca-cert -days VALIDITY
```

**Example**

```
openssl req -new -x509 -keyout ca-key -out ca-cert -days 365
```

c) Create Server truststore and import CA Certificate.

```
keytool -keystore kafka.server.truststore.jks -alias CARoot  
-import -file ca-cert
```

d) Generate a Server Certificate and sign it using the CA.

```
keytool -keystore kafka.server.keystore.jks -alias SERVER_ALIAS  
-certreq -file cert-file
```

```
openssl x509 -req -CA ca-cert -CAkey ca-key -in cert-file -out  
cert-signed -days VALIDITY -CAcreateserial
```

#### Example

```
keytool -keystore kafka.server.keystore.jks -alias server.hostname  
-certreq -file cert-file
```

```
openssl x509 -req -CA ca-cert -CAkey ca-key -in cert-file -out  
cert-signed -days 365 -CAcreateserial
```

e) Import CA Certificate into the Server keystore.

```
keytool -keystore kafka.server.keystore.jks -alias CARoot  
-import -file ca-cert
```

f) Import Signed Server Certificate to the Server keystore.

```
keytool -keystore kafka.server.keystore.jks -alias SERVER_ALIAS -import  
-file cert-signed
```

#### Example

```
keytool -keystore kafka.server.keystore.jks -alias server.hostname  
-import -file cert-signed
```

g) Export the Server Certificate into the binary DER file.

**Note:** The keytool -exportcert command uses the DER format by default. Place the certificate in the trusted\_certificates/ directory of any EP that communicates with Kafka. You need the server certificate for every bootstrap server that you use in the configuration. Otherwise, QRadar rejects the TLS handshake with the server.

```
keytool -exportcert -keystore kafka.server.keystore.jks -alias  
SERVER_ALIAS -file SERVER_ALIAS.der
```

#### Example

```
keytool -exportcert -keystore kafka.server.keystore.jks -alias  
server.hostname -file server.hostname.der
```

2. Configure Kafka brokers for Client Authentication.

a) Find the **Socket Server Settings** section and then change listeners=PLAINTEXT://:<port> to listeners=SSL://:<PORT>.

b) Add the following properties to force encrypted communication between brokers and between the brokers and clients. Adjust the paths, file names, and passwords as you need them. These properties are the truststore and keystore of the **server**:

```
security.inter.broker.protocol=SASL_SSL  
ssl.client.auth=none  
ssl.keystore.location=/somefolder/kafka.server.keystore.jks  
ssl.keystore.password=test1234
```

```

ssl.key.password=test1234
ssl.truststore.location=/somefolder/kafka.server.truststore.jks
ssl.truststore.password=test1234

```

**Note:**

Since the passwords are stored in plain text in the `server.properties`, it is advised that access to the file is restricted by way of file system permissions.

- c) Restart the Kafka brokers that had their `server.properties` modified.

## Troubleshooting Apache Kafka

This reference provides troubleshooting options for configuring Apache Kafka to enable Client Authentication.

### Apache Kafka

*Table 45. Troubleshooting for Apache Kafka Client Authentication*

Issue	Solution
The <b>Use As A Gateway Log Source</b> option is selected in the log source configuration, but log sources are not being automatically detected.	Events being streamed from Kafka must contain a valid Syslog RFC3164 or RFC5424 compliant header, so QRadar can correctly determine the log source identifier of each event.
No events are being received and the following error is displayed in the log source configuration form: "Encountered an error while attempting to fetch topic metadata... Please verify the configuration information."	Verify that the bootstrap server and port details that are entered into the configuration are valid.  If Client Authentication is enabled, verify the following things: <ul style="list-style-type: none"> <li>• The passwords that are entered are correct.</li> <li>• The client truststore and keystore files are present in <code>/opt/qradar/conf/trusted_certificates/kafka/</code> folder and the file names specified match.</li> <li>• The server certificates (<code>&lt;filename&gt;.der</code>) are present in <code>/opt/qradar/conf/trusted_certificates/</code> folder.</li> </ul>
No events are being received and the following error is displayed in the log source configuration form: "The user specified list of topics did not contain any topics that exists in the Kafka cluster. Please verify the topic list."	When you use the <b>List Topics</b> options to subscribe to topics, QRadar attempts to verify the topics available in the Kafka cluster to the specified topics when the log source is initially started. If no topics match between what was entered in the configuration and what is available on the cluster, you are presented with this message.  Verify the topic names that are entered in the configuration; also, consider the use of the <b>Regex Pattern Matching</b> option for subscribing to topics.
When any parameter value in the property file on the Kafka server is changed, expected results are not received.	Disable, then re-enable the Kafka log source.

## Blue Coat Web Security Service REST API protocol configuration options

---

To receive events from Blue Coat Web Security Service, configure a log source to use the Blue Coat Web Security Service REST API protocol.

The Blue Coat Web Security Service REST API protocol is an outbound/active protocol that queries the Blue Coat Web Security Service Sync API and retrieves recently hardened log data from the cloud.

The following table describes the protocol-specific parameters for the Blue Coat Web Security Service REST API protocol:

Table 46. Blue Coat Web Security Service REST API protocol parameters	
Parameter	Description
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Blue Coat Web Security Service REST API log source, ensure that you give each one a unique name.
<b>API Username</b>	The API user name that is used for authenticating with the Blue Coat Web Security Service. The API user name is configured through the Blue Coat Threat Pulse Portal.
<b>Password</b>	The password that is used for authenticating with the Blue Coat Web Security Service.
<b>Confirm Password</b>	Confirmation of the <b>Password</b> field.
<b>Use Proxy</b>	When you configure a proxy, all traffic for the log source travels through the proxy for QRadar to access the Blue Coat Web Security Service.  Configure the <b>Proxy IP or Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Recurrence</b>	You can specify when the log collects data. The format is M/H/D for Months/Hours/Days. The default is 5 M.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

## Centrify Redrock REST API protocol configuration options

---

The Centrify Redrock REST API protocol is an outbound/active protocol for IBM Security QRadar that collects events from Centrify Identity Platform.

The Centrify Redrock REST API protocol supports Centrify Identity Platform and CyberArk Identity Security Platform.

The following parameters require specific values to collect events from Centrify Identity Platform:

Table 47. Centrify Redrock REST API protocol log source parameters

Parameter	Value
<b>Log Source type</b>	Centrify Identity Platform
<b>Protocol Configuration</b>	Centrify Redrock REST API
<b>Log Source Identifier</b>	A unique name for the log source.  The Log Source Identifier can be any valid value and does not need to reference a specific server. The Log Source Identifier can be the same value as the <b>Log Source Name</b> . If you have more than one Centrify Identity Platform log source that is configured, you might want to identify the first log source as <i>centrify1</i> , the second log source as <i>centrify2</i> , and the third log source as <i>centrify3</i> .
<b>Tenant ID</b>	The Centrify assigned unique customer or tenant ID.
<b>Tenant URL</b>	Automatically generated tenant URL for the specified tenant ID. For example, <tenant_id>.id.cyberark.cloud
<b>Username</b>	The user name that is associated with the Cloud service for Centrify Identity Platform.
<b>Password</b>	The password that is associated with the Centrify Identity Platform user name.
<b>Event Logging Filter</b>	Select the logging level of the events that you want to retrieve. <b>Info</b> , <b>Warning</b> and <b>Error</b> are selectable. At least one filter must be selected.
<b>Allow Untrusted Certificates</b>	Enable this option to allow self-signed, untrusted certificates. Do not enable this option for SaaS hosted tenants. However, if required, you can enable this option for other tenant configurations.  The certificate must be downloaded in PEM or DER encoded binary format and then placed in the /opt/qradar/conf/trusted_certificates/ directory with a .cert or .crt file extension.
<b>Use Proxy</b>	When a proxy is configured, all traffic from the Centrify Redrock REST API travels through the proxy.  Configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.

Table 47. Centrify Redrock REST API protocol log source parameters (continued)

Parameter	Value
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.
<b>Recurrence</b>	The time interval can be in hours (H), minutes (M) or days (D). The default is 5 minutes (5M).

## Cisco Duo protocol configuration options

To receive authentication events from Cisco Duo, configure a log source to use the Cisco Duo protocol.

The Cisco Duo protocol is an active outbound protocol that collects authentication logs from the Cisco Duo Admin API, and sends authentication events to IBM QRadar.

**Important:** Before you configure a log source to use the Cisco Duo protocol, you must obtain your keys from the Cisco Duo admin portal.

1. Log in to the Cisco Duo admin portal (<https://admin.duosecurity.com/>).
2. From the dashboard, go to the **Applications** tab, and then click **Protect an Application**.
3. Navigate to the **Admin API** application, and then click **Protect**.
4. In the Permissions menu, select **Grant read log** so that Cisco can collect other authentication logs from the Admin API.
5. Copy the values for **Integration key**, **Secret key**, and **API hostname**. You need these values when you configure the Cisco Duo protocol parameters.

**Important:** Because Cisco Duo has rate limits on API calls, you can create only one log source per customer account.

The following table describes the protocol-specific parameters for the Cisco Duo protocol:

Table 48. Cisco Duo protocol parameters

Parameter	Description
<b>Log Source Type</b>	<b>Cisco Duo</b>
<b>Protocol Configuration</b>	<b>Cisco Duo</b>
<b>Log Source Identifier</b>	Type a unique name for the log source as an identifier for events from Cisco Duo.  The value of the <b>Log Source Identifier</b> parameter must match the <b>Host</b> parameter when you are using the Cisco Duo default workflow. If the Cisco Duo default workflow is modified, then the <b>Log Source Identifier</b> must match the <b>Source</b> value - <code>source="\${/host}"</code> that is used under the PostEvents section. For more information, see <a href="#">Cisco Duo protocol workflow</a> .

Table 48. Cisco Duo protocol parameters (continued)

Parameter	Description
<b>Host</b>	The API hostname in the Cisco Duo portal that is used to authenticate with the Cisco Duo Admin API. Review the preceding procedure for obtaining this information from Cisco Duo.
<b>Integration Key</b>	The integration key that is used to authenticate with the Cisco Duo Admin API. Review the preceding procedure for obtaining this information from Cisco Duo.
<b>Secret Key</b>	The secret key that is used to authenticate with the Cisco Duo Admin API. Review the preceding procedure for obtaining this information from Cisco Duo.
<b>Use Proxy</b>	If the API is accessed by using a proxy, select this checkbox. Configure the <b>Proxy IP or Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Recurrence</b>	Specify how often the log collects data. The format is M/H/D for Minutes/Hours/Days. The default is 5 minutes.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
<b>Enable Advanced Options</b>	Select this checkbox to enable the following configuration options: <b>Allow Untrusted Certificates</b> , <b>Override Workflow</b> , <b>Workflow</b> , and <b>Workflow Parameters</b> . These parameters are only visible if you select this checkbox.
<b>Allow Untrusted</b>	If you enable this parameter, the protocol can accept self-signed and otherwise untrusted certificates that are located within the /opt/qradar/conf/trusted_certificates/ directory. If you disable the parameter, the scanner trusts only certificates that are signed by a trusted signer. The certificates must be in PEM or RED-encoded binary format and saved as a .crt or .cert file. If you modify the workflow to include a hardcoded value for the <b>Allow Untrusted Certificates</b> parameter, the workflow overrides your selection in the UI. If you do not include this parameter in your workflow, then your selection in the UI is used.
<b>Override Work Flow</b>	Enable this option to customize the workflow. When you enable this option, the <b>Workflow</b> and <b>Workflow Parameters</b> fields appear.
<b>Workflow</b>	The XML document that defines how the protocol instance collects events from the target API. For more information about the default workflow, see “Cisco Duo protocol workflow” on page 112.

Table 48. Cisco Duo protocol parameters (continued)

Parameter	Description
<b>Workflow Parameters</b>	The XML document that contains the parameter values used directly by the workflow.  For more information about the default workflow parameters, see “Cisco Duo protocol workflow” on page 112.
<b>Enabled</b>	By default, the checkbox is selected to enable the log source to communicate with QRadar.
<b>Credibility</b>	Select the <b>Credibility</b> of the log source. The range is 0 - 10. The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	Select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	Select this checkbox to enable the log source to coalesce (bundle) events.  By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Store Event Payload</b>	Select this checkbox to enable the log source to store event payload information.  By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

## Cisco Duo protocol workflow

You can customize your workflow and workflow parameters based on the default workflow.

A workflow is an XML document that describes the event retrieval process. The workflow defines one or more parameters, which can be explicitly assigned values in the workflow XML or can derive values from the workflow parameter values XML document. The workflow consists of multiple actions that run sequentially.

The default workflow and workflow parameter XML files are available on GitHub. For more information, see Cisco Duo (<https://github.com/IBM/IBM-QRadar-Universal-Cloud-REST-API/tree/master/IBM%20Verified/Cisco%20Duo>).

## Cisco Duo default workflow

**Important:** The value of the **Log Source Identifier** parameter must match the **Host** parameter when you are using the Cisco Duo default workflow. If the Cisco Duo default workflow is modified, then the **Log Source Identifier** must match the **Source** value - `source="$\{/host\}"` that is used under the PostEvents section.

The following example shows the default Cisco Duo workflow:

```

<?xml version="1.0" encoding="UTF-8" ?>
<!--
  Duo Admin API
  https://duo.com/docs/adminapi
  Duo Admin Panel
  https://admin.duosecurity.com/
  To obtain an 'Integration Key' and 'Secret Key':
  - Log on to the Duo Admin Panel
  - Navigate to "Applications"
  - Select the application to be monitored.
  - The "Integration Key" and "Secret Key" should be visible on the application page.
-->
<Workflow name="Duo" version="1.0" xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/Workflow/V1">
  <Parameters>
    <Parameter name="host" label="Host" required="true" />
    <Parameter name="integration_key" label="Integration Key" required="true" />
    <Parameter name="secret_key" label="Secret Key" required="true" />
  secret="true" />
  </Parameters>
  <Actions>

    <Log type="DEBUG" message="Calling workflow after recurrence" />

    <!--
    ///////////////////////////////////////////////////
    // Authentication Logs //
    ///////////////////////////////////////////////////
    -->
    <!-- Initialize the Bookmarks - mintime and maxtime -->
    <Initialize path="/auth_logs/mintime" value="${time() - 60000 * 60 * 24 * 30}" />
    <Set path="/auth_logs/maxtime" value="${time() - 60000 * 2}" />
    <!-- Log events are ranging from the last 30 days up to as recently as two minutes
before the API request -->
    <Set path="/method" value="GET" />
    <Set path="/endpoint" value="/admin/v2/logs/authentication" />
    <Set path="/limit" value="1000" />
    <Set path="/retry_counter" value="0" />
    <Set path="/retry_interval_in_seconds" value="60" />

    <While condition="${/retry_counter < 4}">
      <!--
        Generate the HTTP Password as an HMAC signature of the request https://duo.com/docs/
adminapi#authentication
          - Date enumerated as RFC 2822 format [Tue, 21 Aug 2012 17:29:18 -0000]
          - Method [GET, POST, etc.]
          - API Hostname [api-xxxxxxxx.duosecurity.com]
          - API method's path [/admin/v2/logs/]

## Cisco Duo default workflow parameters

The following example shows the default workflow parameters for Cisco Duo:

```

<?xml version="1.0" encoding="UTF-8" ?>
<WorkflowParameterValues xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/
WorkflowParameterValues/V1">
    <Value name="host"          value="" />
    <Value name="integration_key" value="" />
    <Value name="secret_key"     value="" />
</WorkflowParameterValues>

```

## Cisco Firepower eStreamer protocol configuration options

To collect events in IBM QRadar from a Cisco Firepower eStreamer (Event Streamer) service, configure a log source to use the Cisco Firepower eStreamer protocol.

The Cisco Firepower eStreamer protocol is formerly known as Sourcefire Defense Center eStreamer protocol.

The Cisco Firepower eStreamer protocol is a passive outbound protocol. For more information about how this protocol streams events, see [Understanding the eStreamer Application Protocol](https://www.cisco.com/c/en/us/td/docs/security/firepower/670/api/eStreamer/EventStreamerIntegrationGuide/Protocol.html) (<https://www.cisco.com/c/en/us/td/docs/security/firepower/670/api/eStreamer/EventStreamerIntegrationGuide/Protocol.html>).

Events are streamed to QRadar to be processed after the Cisco Firepower Management Center DSM is configured.

The following table describes the protocol-specific parameters for the Cisco Firepower eStreamer protocol:

<i>Table 49. Cisco Firepower eStreamer protocol parameters</i>	
<b>Parameter</b>	<b>Description</b>
<b>Protocol Configuration</b>	<b>Cisco Firepower eStreamer</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Cisco Firepower eStreamer log source, ensure that you give each one a unique name.
<b>Server Port</b>	The port number that the Cisco Firepower eStreamer services is configured to accept connection requests on.  The default port that QRadar uses for Cisco Firepower eStreamer is 8302.
<b>Keystore Filename</b>	The directory path and file name for the keystore private key and associated certificate. By default, the import script creates the keystore file in the following directory: /opt/qradar/conf/estreamer.keystore

*Table 49. Cisco Firepower eStreamer protocol parameters (continued)*

Parameter	Description
<b>Truststore Filename</b>	The directory path and file name for the truststore files. The truststore file contains the certificates that are trusted by the client. By default, the import script creates the truststore file in the following directory: /opt/qradar/conf/estreamer.truststore
<b>Request Extra Data</b>	Select this option to request intrusion event extra data from Cisco Firepower Management Center. For example, extra data includes the original IP address of an event.
<b>Domain</b>	<p><b>Important:</b> Domain Streaming Requests are supported for eStreamer version 6.x and later. Leave the <b>Domain</b> field blank for eStreamer version 5.x.</p> <p>The domain where the events are streamed from.</p> <p>The value in the <b>Domain</b> field must be a fully qualified domain. Therefore, all ancestors of the desired domain must be listed starting with the top-level domain and ending with the leaf domain that you want to request events from.</p> <p>Example:</p> <p>Global is the top-level domain, B is a second-level domain that is a subdomain of Global, and C is a third-level domain and a leaf domain that is a subdomain of B. To request events from C, type the following value for the <b>Domain</b> parameter:</p> <p>Global \ B \ C</p>

## Cisco NSEL protocol configuration options

To monitor NetFlow packet flows from a Cisco Adaptive Security Appliance (ASA), configure the Cisco Network Security Event Logging (NSEL) protocol source.

The Cisco NSEL protocol is an inbound/pассив protocol. To integrate Cisco NSEL with QRadar, you must manually create a log source to receive NetFlow events. QRadar does not automatically discover or create log sources for syslog events from Cisco NSEL.

The following table describes the protocol-specific parameters for the Cisco NSEL protocol:

*Table 50. Cisco NSEL protocol parameters*

Parameter	Description
<b>Protocol Configuration</b>	<b>Cisco NSEL</b>
<b>Log Source Identifier</b>	If the network contains devices that are attached to a management console, you can specify the IP address of the individual device that created the event. A unique identifier for each, such as an IP address, prevents event searches from identifying the management console as the source for all of the events.
<b>Collector Port</b>	The UDP port number that Cisco ASA uses to forward NSEL events. QRadar uses port 2055 for flow data on QRadar QFlow Collectors. You must assign a different UDP port on the Cisco Adaptive Security Appliance for NetFlow.

## Related information

[Adding a log source](#)

## EMC VMware protocol configuration options

To receive event data from the VMWare web service for virtual environments, configure a log source to use the EMC VMware protocol.

The EMC VMware protocol is an outbound/active protocol.

IBM QRadar supports the following event types for the EMC VMware protocol:

- Account Information
- Notice
- Warning
- Error
- System Informational
- System Configuration
- System Error
- User Login
- Misc Suspicious Event
- Access Denied
- Information
- Authentication
- Session Tracking

The following table describes the protocol-specific parameters for the EMC VMware protocol:

Table 51. EMC VMware protocol parameters	
Parameter	Description
Protocol Configuration	<b>EMC VMware</b>
Log Source Identifier	The value for this parameter must match the <b>VMware IP</b> parameter.
VMware IP	The IP address of the VMWare ESXi server. The VMware protocol appends the IP address of your VMware ESXi server with HTTPS before the protocol requests event data.

## Forwarded protocol configuration options

To receive events from another Console in your deployment, configure a log source to use the Forwarded protocol.

The Forwarded protocol is an inbound/pasive protocol that is typically used to forward events to another QRadar Console. For example, Console A has Console B configured as an off-site target. Data from automatically discovered log sources is forwarded to Console B. Manually created log sources on Console A must also be added as a log source to Console B with the forwarded protocol.

## Google Cloud Pub/Sub protocol configuration options

The Google Cloud Pub/Sub protocol is an outbound/active protocol for IBM QRadar that collects Google Cloud Platform (GCP) logs.

If automatic updates are not enabled, download the GoogleCloudPubSub protocol RPM from the [IBM support website](#).

**Important:** Google Cloud Pub/Sub protocol is supported on QRadar 7.3.2.6, build number 20191022133252 or later.

The following table describes the protocol-specific parameters for collecting Google Cloud Pub/Sub logs with the Google Cloud Pub/Sub protocol:

Table 52. Google Cloud Pub/Sub log source parameters for Google Cloud Pub/Sub	
Parameter	Description
<b>Service Account Credential Type</b>	<p>Specify where the required Service Account Credentials are coming from.</p> <p>Ensure that the associated service account has the <b>Pub/Sub Subscriber</b> role or the more specific <b>pubsub.subscriptions.consume</b> permission on the configured <b>Subscription Name</b> in GCP.</p> <p><b>User Managed Key</b> Provided in the <b>Service Account Key</b> field by inputting the full JSON text from a downloaded Service Account Key.</p> <p><b>GCP Managed Key</b> Ensure that the QRadar managed host is running in a GCP Compute instance and the Cloud API access scopes include Cloud Pub/Sub.</p>
<b>Service Account Key</b>	<p>The full text from the JSON file that was downloaded when you created a <b>User Managed Key</b> for a service account in the <b>IAM &amp; admin &gt; Service accounts</b> section in Google Cloud Platform (GCP).</p> <p><b>Example:</b></p> <pre>{   "type": "service_account",   "project_id": "qradar-test-123456",   "private_key_id": "453422aa6efb1c2de189f12d725c417c8346033b",   "private_key": "-----BEGIN PRIVATE KEY-----\n&lt;MULTILINE PRIVATE KEY DATA&gt;\n-----END PRIVATE KEY-----\n",   "client_email": "pubsubtest@qradar-test-123456.iam.gserviceaccount.com",   "client_id": "526344196064252652671",   "auth_uri": "https://accounts.google.com/o/oauth2/auth",   "token_uri": "https://oauth2.googleapis.com/token",   "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",   "client_x509_cert_url": "https://www.googleapis.com/robot/v1/metadata/x509/pubsubtest%40qradar-test-123456.iam.gserviceaccount.com" }</pre>
<b>Subscription Name</b>	The full name of the Cloud Pub/Sub subscription. For example, <code>projects/my-project/subscriptions/my-subscription</code> .
<b>Use As A Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.</p> <p>When you select this option, the <b>Log Source Identifier Pattern</b> can optionally be used to define a custom <b>Log Source Identifier</b> for events being processed.</p>

Table 52. Google Cloud Pub/Sub log source parameters for Google Cloud Pub/Sub (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>When the <b>Use As A Gateway Log Source</b> option is selected, use this option to define a custom log source identifier for events that are processed. If the <b>Log Source Identifier Pattern</b> is not configured, QRadar receives events as unknown generic log sources.</p> <p>The <b>Log Source Identifier Pattern</b> field accepts key-value pairs, such as <b>key</b>=value, to define the custom Log Source Identifier for events that are being processed and for log sources to be automatically discovered when applicable. <b>Key</b> is the Identifier Format String which is the resulting source or origin value. Value is the associated regex pattern that is used to evaluate the current payload. The value (regex pattern) also supports capture groups which can be used to further customize the key (Identifier Format String).</p> <p>Multiple key-value pairs can be defined by typing each pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found. When a match is found, a custom Log Source Identifier displays.</p> <p>The following examples show the multiple key-value pair functionality:</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p><b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>
<b>Use Proxy</b>	<p>Select this option for QRadar to connect to the GCP by using a proxy.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.</p>
<b>Proxy IP or Hostname</b>	The IP or host name of the proxy server.
<b>Proxy Port</b>	The port number that is used to communicate with the proxy server. The default is 8080.
<b>Proxy Username</b>	Required only when the proxy requires authentication.
<b>Proxy Password</b>	Required only when the proxy requires authentication.

Table 52. Google Cloud Pub/Sub log source parameters for Google Cloud Pub/Sub (continued)

Parameter	Description
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
<b>Convert Google VPC Flow Logs to IPFIX</b>	This option converts Google VPC Flow Logs to IPFIX that is then sent to the flow processor.
<b>Flow Destination Hostname</b>	The flow processor hostname where the Google VPC Flow logs are sent. <b>Note:</b> Enable <b>Convert Google VPC Flow Logs to IPFIX</b> to configure this parameter.
<b>Flow Destination Port</b>	The flow processor port where the Google VPC Flow logs are sent. <b>Note:</b> Enable <b>Convert Google VPC Flow Logs to IPFIX</b> to configure this parameter.

### Related concepts

[“Gateway log source” on page 15](#)

Use a gateway log source to configure a protocol to use many Device Support Modules (DSMs) instead of relying on a single DSM type. With a gateway log source, event aggregator protocols can dynamically handle various event types.

### Related tasks

[“Configuring Google Cloud Pub/Sub to integrate with QRadar” on page 120](#)

Before you can add a log source in IBM QRadar, you must create a Pub/Sub Topic and Subscription, create a service account to access the Pub/Sub Subscription, and then populate the Pub/Sub topic with data.

[“Adding a Google Cloud Pub/Sub log source in QRadar” on page 121](#)

Set up a log source in IBM QRadar to use a custom log source type or an IBM log source type that supports the Google Cloud Pub/Sub protocol.

## Configuring Google Cloud Pub/Sub to integrate with QRadar

Before you can add a log source in IBM QRadar, you must create a Pub/Sub Topic and Subscription, create a service account to access the Pub/Sub Subscription, and then populate the Pub/Sub topic with data.

### Procedure

1. Create a topic in the Pub/Sub tab on the [Google Cloud Platform](https://console.cloud.google.com) (<https://console.cloud.google.com>).

For more information about creating topics, see [Managing topics and subscriptions](https://cloud.google.com/pubsub/docs/admin) (<https://cloud.google.com/pubsub/docs/admin>).

2. Create a subscription

For more information about creating subscriptions, see [Managing topics and subscriptions](https://cloud.google.com/pubsub/docs/admin) (<https://cloud.google.com/pubsub/docs/admin>).

**Important:** The following parameters need specific configuration to work with QRadar:

- For the **Delivery Type** parameter, enable the **Pull** option.
- To ensure that messages are processed only once, set the **Acknowledgement Deadline** to 60 seconds, and deselect the **Retain acknowledged messages** option.

3. Create a service account on the **IAM & admin** menu.

For more information about service accounts, see [Creating and managing service accounts](https://cloud.google.com/iam/docs/creating-managing-service-accounts) (<https://cloud.google.com/iam/docs/creating-managing-service-accounts>).

**Tip:** You do not need to make a service account if any of the following conditions apply to you:

- You already have an account that you want to use.
- You use **GCP Managed Key** as the **Service Account Type** option on your QRadar All-in-One appliance or QRadar Event Collector that collects events from a Google Cloud Platform Compute instance.

If you use the **User Managed Key** option for the **Service Account Key** parameter when you configure a log source in QRadar, you must create a service account key. For more information, see [Creating and managing service account keys](https://cloud.google.com/iam/docs/creating-managing-service-account-keys) (<https://cloud.google.com/iam/docs/creating-managing-service-account-keys>).

4. Assign permissions to your service account.

For more information about service account permissions, see [Manage access to service accounts](https://cloud.google.com/iam/docs/manage-access-service-accounts) (<https://cloud.google.com/iam/docs/manage-access-service-accounts>).

**Tip:** You do not need to assign the permissions for the service account if any of the conditions from step 3 apply to you.

5. Populate the Pub/Sub topic with data by creating a Logging Sink.

For more information about creating a Logging Sink, see [Configure and manage sinks](https://cloud.google.com/logging/docs/export/configure_export_v2) ([https://cloud.google.com/logging/docs/export/configure\\_export\\_v2](https://cloud.google.com/logging/docs/export/configure_export_v2)).

## What to do next

Add a Google Cloud Pub/Sub log source on the QRadar Console by using the Google Cloud Pub/Sub protocol. For more information, see [“Adding a Google Cloud Pub/Sub log source in QRadar”](#) on page 121.

## Adding a Google Cloud Pub/Sub log source in QRadar

Set up a log source in IBM QRadar to use a custom log source type or an IBM log source type that supports the Google Cloud Pub/Sub protocol.

### Before you begin

You can use the Google Cloud Pub/Sub protocol to retrieve any type of event from the Google Cloud Pub/Sub service. IBM provides DSMs for some Google Cloud services. Any services that don't have a DSM can be handled by using a custom log source type.

If you want to use an existing DSM to parse data, select the **Use as a Gateway Log Source** parameter option for more log sources to be created from data that is collected by this configuration. Alternatively, if log sources are not automatically detected, you can manually create them by using Syslog for the **Protocol type** parameter option.

### Procedure

1. Log in to QRadar.
2. On the **Admin** tab, click the QRadar Log Source Management app icon.
3. Click **New Log Source > Single Log Source**.
4. On the **Select a Log Source Type** page, select a custom log source type or an IBM log source type that supports the Google Cloud Pub/Sub protocol.
5. On the **Select a Protocol Type** page, from the **Select Protocol Type** list, select **Google Pub/Sub Protocol**.
6. On the **Configure the Log Source parameters** page, configure the log source parameters, and then click **Configure Protocol Parameters**. For more information about configuring Google Cloud Pub/Sub protocol parameters, see [Adding a Google Cloud Pub/Sub log source in QRadar](#).

- Test the connection to ensure that connectivity, authentication, and authorization are working. If available, view sample events from the subscription.
  - Click **Test Protocol Parameters**, and then click **Start Test**.
  - To fix any errors, click **Configure Protocol Parameters**, then test your protocol again.

For more information about adding a log source in QRadar, see [Adding a log source](#).

## Google G Suite Activity Reports REST API protocol options

The Google G Suite Activity Reports REST API protocol is an active outbound protocol for IBM QRadar that retrieves logs from Google G Suite.

**Important:** The Google G Suite Activity Reports REST API protocol is supported on QRadar 7.3.2 Fix Pack 6, build number 20191022133252 or later.

The following table describes the protocol-specific parameters for the Google G Suite Activity Reports REST API protocol:

Table 53. Google G Suite Activity Reports REST API protocol log source parameters	
Parameter	Value
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Google G Suite log source, ensure that you give each one a unique name.
<b>Delegated User Account Email</b>	The Google user account that has report privileges.
<b>Service Account Credentials</b>	Authorizes access to Google's APIs for retrieving the events. The <b>Service Account Credentials</b> are contained in a JSON formatted file that you download when you create a new service account in the Google Cloud Platform.
<b>Use Proxy</b>	If QRadar accesses Google G Suite by using a proxy, enable this option. If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Recurrence</b>	The time interval between log source queries to the Google G Suite Activity Reports API for new events. The time interval can be in hours (H), minutes (M), or days (D). The default is 5 minutes.

Table 53. Google G Suite Activity Reports REST API protocol log source parameters (continued)

Parameter	Value
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.
<b>Event Delay</b>	The delay, in seconds, for collecting data.  Google G Suite logs work on an eventual delivery system. To ensure that no data is missed, logs are collected on a delay.  The default delay is 7200 seconds (2 hours), and can be set as low as 0 seconds.

## Google G Suite Activity Reports REST API protocol FAQ

Got a question? Check these frequently asked questions and answers to help you understand the Google G Suite Activity Reports REST API protocol.

- [“What is the event delay option used for?” on page 123](#)
- [“How does the event delay option work?” on page 124](#)
- [“What value do I use for the event delay option?” on page 124](#)

### What is the event delay option used for?

The event delay option is used to prevent events from being missed. Missed events, in this context, occur because they become available after the protocol updated its query range to a newer timeframe than the event's arrival time. If an event occurred but wasn't posted to the Google G Suite Activity Reports REST API, then when the protocol queries for that event's creation time, the protocol doesn't get that event.

**Example 1:** The following example shows how an event can be lost.

The protocol queries the Google G Suite Activity Reports REST API at 2:00 PM to collect events between 1:00 PM – 1:59 PM. The Google G Suite Activity Reports REST API response returns the events that are available in the Google G Suite Activity Reports REST API between 1:00 PM - 1:59 PM. The protocol operates as if all of the events are collected. Then, it sends the next query to the Google G Suite Activity Reports REST API at 3:00 PM to get events that occurred between 2:00 PM – 2:59 PM. The problem with this scenario is that the Google G Suite Activity Reports REST API might not include all of the events that occurred between 1:00 PM – 1:59 PM. If an event occurred at 1:58 PM, that event might not be available in the Google G Suite Activity Reports REST API until 2:03 PM. However, the protocol already queried the 1:00 PM – 1:59 PM time range, and can't requery that range without getting duplicated events. This delay can take multiple hours.

**Example 2:** The following example shows **Example 1**, except in this scenario a 15-minute delay is added.

This example uses a 15-minute delay when the protocol makes query calls. When the protocol makes a query call to the Google G Suite Activity Reports REST API at 2:00 PM, it collects the events that occurred between 1:00 - 1:45 PM. The protocol operates as if all of the events are collected. Then, it sends the next query to the Google G Suite Activity Reports REST API at 3:00 PM and collects all events that occurred between 1:45 PM – 2:45 PM. Instead of missing the event, as in **Example 1**, it gets picked up in the next query call between 1:45 PM - 2:45 PM.

**Example 3:** The following example shows **Example 2**, except in this scenario the events are available a day later.

If the event occurred at 1:58 PM, but only became available to the Google G Suite Activity Reports REST API at 1:57 PM the next day, then the event delay from **Example 2** doesn't get that event. Instead, the event delay must be set to a higher value, in this case 24 hours.

## How does the event delay option work?

Instead of querying from the **last received event time** to **current time**, the protocol queries from the **last received event time** to **current time - <event delay>**. The event delay is in seconds. For example, a delay of 15 minutes (900 seconds) means that it queries only up to 15 minutes ago. This query gives the Google G Suite Activity Reports REST API 15 minutes to make an event available before the event is lost. When the **current time - <event delay>** is less than the **last received event time**, the protocol doesn't query the Google G Suite Activity Reports REST API. Instead, it waits for the condition to pass before querying.

## What value do I use for the event delay option?

The Google G Suite Activity Reports REST API can delay an event's availability. To prevent any events from being missed, you can set the **Event Delay** parameter option value to 168 hours (one week). However, the larger the event delay, the less real time the results are. For example, with a 24-hour event delay, you see events 24 hours after they occur instead of immediately. The value depends on how much risk you're willing to take and how important real-time data is. The default delay of 2 hours (7200 seconds) provides a value that is set in real time and also prevents most events from being missed. For more information about the delay, see [Data retention and lag times](https://support.google.com/a/answer/7061566?hl=en) (<https://support.google.com/a/answer/7061566?hl=en>).

## HCL BigFix SOAP protocol configuration options (formerly known as IBM BigFix)

To receive Log Event Extended Format (LEEF) formatted events from HCL BigFix appliances, configure a log source that uses the HCL BigFix SOAP protocol.

**Important:** HCL BigFix is formerly known as IBM BigFix.

This protocol requires HCL BigFix versions 8.2.x to 9.5.2, and the Web Reports application for HCL BigFix.

The HCL BigFix SOAP protocol is an outbound/active protocol that retrieves events in 30-second intervals over HTTP or HTTPS. As events are retrieved, the HCL BigFix DSM parses and categorizes the events.

The following table describes the protocol-specific parameters for the HCL BigFix SOAP protocol:

Table 54. IBM BigFix SOAP protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	<b>HCL BigFix SOAP</b>
<b>Log Source Identifier</b>	Type the IP address or host name for your HCL BigFix appliance. The IP address or host name identifies your HCL BigFix as a unique event source in QRadar.

Table 54. IBM BigFix SOAP protocol parameters (continued)

Parameter	Description
<b>Use HTTPS</b>	If a certificate is required to connect with HTTPS, copy the required certificates to the following directory: /opt/qradar/conf/trusted_certificates. Certificates that have following file extensions: .crt, .cert, or .der are supported. Copy the certificates to the trusted certificates directory before the log source is saved and deployed.
<b>SOAP Port</b>	By default, port 80 is the port number for communicating with HCL BigFix. Most configurations use port 443 for HTTPS communications.
<b>Username</b>	The username that you use to access BigFix.
<b>Password</b>	The password that you use to access BigFix.
<b>Polling Interval (In Minutes)</b>	The number of minutes between queries to the log files to check for new data. The default is 15 minutes. The minimum value for the polling interval is 1 minute, and the maximum value is 60 minutes.

## HTTP Receiver protocol configuration options

To collect events from devices that forward HTTP or HTTPS requests, configure a log source to use the HTTP Receiver protocol.

The HTTP Receiver protocol is an inbound passive protocol. The HTTP Receiver acts as an HTTP server on the configured listening port and converts the request body of any received POST requests into events. It supports both HTTPS and HTTP requests.

**Important:** When you use the HTTP Receiver protocol, you must use a certificate that is issued by a certificate authority (CA). It can't be a self-signed certificate because it must be validated by a CA. For more information about setting up a CA certificate for HTTP Receiver, see “[Setting up certificate-based authentication for HTTP Receiver](#)” on page 131.

**Important:** If you are a QRadar on Cloud (QRoC) user, contact IBM support and open a support case to configure this certificate-based authentication if the target collector is the Console or Event Processor.

The following table describes the protocol-specific parameters for the HTTP Receiver protocol:

Table 55. HTTP Receiver protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	From the list, select <b>HTTP Receiver</b> .
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . Ensure that you give each log source a unique name.
<b>Listen Port</b>	The port that is used by IBM QRadar to accept incoming HTTP Receiver events. The default port is 12469. <b>Important:</b> Do not use port 514. Port 514 is used by the standard Syslog listener.

Table 55. HTTP Receiver protocol parameters (continued)

Parameter	Description
<b>Communication Type</b>	<p>The type of HTTP server that is created by the protocol.</p> <p><b>HTTP</b> Creates an HTTP Server without encryption and verification</p> <p><b>Important:</b> Not supported for QRadar on Cloud (QRoC).</p> <p><b>HTTPs</b> Creates an HTTP Server with encryption and verification</p> <p><b>HTTPs with Mutual TLS (mTLS)</b> Creates an HTTP Server that uses Mutual TLS Authentication (mTLS)</p>
<b>Server Certificate</b>	<p>Choose one of the following server certificate options.</p> <p><b>PKCS12 Certificate Chain and Password</b> If you select this option, you must configure a path to the PKCS12 file and provide the password. If there is more than one entry in the PKCS12 file, you must provide an alias to specify which certificate entry to use.</p> <p><b>Choose from QRadar Certificate Store</b> If you select this option, you must upload a certificate in the IBM QRadar Certificate Management app. In the app, set the certificate's <b>Purpose</b> as Server or Server Client, and its <b>Component</b> as Log Source.</p> <p><b>Self-signed Generated Certificate (Deprecated)</b> If you select this option, then a self-signed generated certificate is used. If a certificate was not already generated, then one is generated to use. This certificate is self-signed and is the same as the TLS Syslog configurations that are using generated certificates on the same host.</p>
<b>Server Certificate Friendly Name</b>	<p>The friendly name of a certificate that is available in the QRadar Certificate Store, which is uploaded in the QRadar Certificate Management app.</p> <p><b>Important:</b> The QRadar Certificate Management app is supported on QRadar 7.3.3 Fix Pack 6 or later.</p>
<b>PKCS12 Server Certificate Path</b>	<p>The absolute path to a PKCS12 file that contains a private key and certificate chain.</p> <p>If you select <b>PKCS12 Certificate Chain and Password</b> as the server certificate option, this parameter is displayed.</p>
<b>PKCS12 Password</b>	<p>The password for the PKCS12 file.</p> <p>If you select <b>PKCS12 Certificate Chain and Password</b> as the server certificate option, this parameter is displayed.</p>

Table 55. HTTP Receiver protocol parameters (continued)

Parameter	Description
<b>PKCS12 Certificate Alias</b>	<p>The alias for the certificate entry in the PKCS12 file to use.</p> <p>If there is more than one entry in the PKCS12 file, then you must provide an alias to specify which certificate entry to use.</p> <p>When there is more than one certificate entry, leave this field blank to use the single certificate entry.</p> <p>If you select <b>PKCS12 Certificate Chain and Password</b> as the server certificate option, this parameter is displayed.</p>
<b>Use HTTP Authentication Token Header</b>	This enables HTTP Header Authentication. When enabled, clients attempting to communicate with the HTTP Server must provide a valid access token via a Request Header.
<b>Authentication Token Header Name</b>	The HTTP Authentication Header is added to the HTTP request headers and contains information about the authentication header in use and the associated credentials. <b>Authentication Header:</b> This indicates the type of authentication in use. Common authentication headers include Basic, Digest, and Bearer.
<b>Authentication Token Value</b>	The Token Value included in the header depends on the authentication scheme under use. For example, in the case of Basic authentication, the Token Value consist of a username and password encoded in Base64 format.
<b>Mutual TLS Authentication Truststore</b>	<p>If you select the <b>HTTPs with Mutual TLS (mTLS)</b> communication type, select one of these truststore types.</p> <p><b>System Truststore</b> Initializes the server truststore by using the Operating System truststore on the target event collector.</p> <p><b>Custom Truststore</b> Initializes the server truststore by using a user-provided Java keystore and password.</p> <p><b>Client Certificate On Disk (Deprecated)</b> Ensures that the client certificate matches but does not validate the issuer. With this method, all clients must share one certificate.</p>
<b>Custom Truststore File Path</b>	The absolute path to a custom truststore. You must copy the custom truststore to the QRadar Console or the Event Collector for the log source.
<b>Custom Truststore Password</b>	The password for the custom truststore.
<b>Enable Issuer Verification</b>	Verify that the client certificate was issued by a specific certificate or public key. A common use case is to verify that a specific intermediate CA was used to issue the client certificate.

Table 55. HTTP Receiver protocol parameters (continued)

Parameter	Description
<b>Issuer Certificate or Public Key</b>	<p>The root or intermediate issuer's certificate or public key in PEM format.</p> <p>Enter the certificate, including this text:</p> <pre>-----BEGIN CERTIFICATE-----</pre> <pre>-----END CERTIFICATE-----</pre> <p>Or enter the public key, including this text:</p> <pre>-----BEGIN PUBLIC KEY-----</pre> <pre>-----END PUBLIC KEY-----</pre> <p>If you enabled the <b>Enable Issuer Verification</b> parameter, this parameter is displayed.</p>
<b>Use CN Allowlist</b>	<p>Specify lists or patterns of common names that client certificates must match after trust is established. Enter plain text or a regular expression. Define multiple entries by entering each entry on a new line.</p> <p>The following list shows examples of the types of common name entries to use in your <b>CN Allowlist</b>.</p> <p><b>Fixed name</b> 127.0.0.1 1.1.1.1</p> <p><b>Wildcard name</b> 1.1.1.* .*</p> <p><b>Domain name</b> www.host.*.com localhost</p> <p>By default, this parameter is disabled.</p>
<b>Check Certificate Revocation</b>	<p>Checks certificate revocation status against the client certificate revocation list.</p> <p>To configure this option, you must have network connectivity to the URL that is specified by the client certificate's <b>CRL Distribution Points</b> field in the X509v3 extension, and the URL must support only certificate revocation list (CRL) format.</p> <p>OSCP is not supported.</p>
<b>Client Certificate Path (Deprecated)</b>	<p>Set the absolute path to the client certificate. You must copy the client certificate to the QRadar Console or the Event Collector for the log source.</p> <p>If you select <b>HTTPs with Mutual TLS (mTLS)</b> as the <b>Communication Type</b>, and you select <b>Client Certificate on Disk (Deprecated)</b> as the <b>Mutual TLS Authentication Truststore</b>, this parameter is displayed.</p>

Table 55. HTTP Receiver protocol parameters (continued)

Parameter	Description
<b>Event Parsing Method</b>	<p><b>Event Per HTTP Post</b> Treat the entire HTTP post as a single event without any specific pattern.</p> <p><b>Event Per Line</b> Split the post into multiple single-line events by using a regular expression to mark the start of each event. If you select <b>Events Per Line</b>, the following two fields are visible:</p> <ul style="list-style-type: none"> <li>• <b>Match Specific Lines</b>: By default it will process one event per line. Enable it to match specific lines as per the Message Pattern.</li> <li>• <b>Message Pattern</b>: Enter a regular expression to split the post into multiple single-line events</li> </ul> <p><b>Event Per JSON Array</b> Specify a JSON Path (JPath) to identify the root of the JSON array, with each array entry as a separate event. If you select <b>Event Per JSON Array</b>, the following field is visible:</p> <ul style="list-style-type: none"> <li>• <b>JSON Path Expression</b>: Enter a JSON path to identify the root of the JSON array, with each array entry as a separate event. A JSON path must begin with a forward slash ('/') to indicate the root of the JSON object and it must be followed by one or more JSON field names within double quotes. For example:</li> </ul> <pre>JSON: {"topic": "device-events", "events": [{"device_name": "device 1"}, {"device_name": "device 2"}]} JSON Path expression: /"events"</pre>
<b>Use As A Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p>However, in rare circumstances the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p> <p>When you enable the <b>Use As A Gateway Log Source</b> parameter, you can enable predictive parsing.</p>

Table 55. HTTP Receiver protocol parameters (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>When the <b>Use As A Gateway Log Source</b> option is selected, use this option to define a custom log source identifier for events that are processed. If the <b>Log Source Identifier Pattern</b> is not configured, QRadar receives events as unknown generic log sources.</p> <p>The <b>Log Source Identifier Pattern</b> field accepts key-value pairs, such as <b>key</b>=value, to define the custom Log Source Identifier for events that are being processed and for log sources to be automatically discovered, when applicable. <b>Key</b> is the Identifier Format String, which is the resulting source or origin value. Value is the associated regex pattern that is used to evaluate the current payload. The value (regex pattern) also supports capture groups, which can be used to further customize the key (Identifier Format String).</p> <p>Multiple key-value pairs can be defined by typing each pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show the multiple key-value pair functions:</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>
<b>Enable Advanced Server Configuration Options</b>	Enable this parameter to configure more server options. If you do not enable this parameter, the default values are used.
<b>Max Payload Length (Byte)</b>	<p>The maximum payload size of a single event in bytes. The event is split when its payload size exceeds this value.</p> <p>The default value is 8192, and it must not be greater than 32767.</p> <p>When you enable the <b>Enable Advanced Server Configuration Options</b> parameter, this parameter is displayed.</p>

Table 55. HTTP Receiver protocol parameters (continued)

Parameter	Description
<b>TLS Protocols</b>	<p>The versions of TLS that can be accepted in this protocol. Send a request by using the same version that is selected for the server.</p> <p><b>TLSv1.3</b> is supported from QRadar 7.5.0 UP5 onwards.</p> <p><b>Important:</b> TLSv1.0 and TLSv1.1 are no longer supported as of QRadar 7.3.3 FP10, 7.4.3 FP3, and 7.5.0 CR. Future releases might not support TLSv1.0 and TLSv1.1.</p>
<b>Max POST method Request Length (MB)</b>	<p>The max size of a POST method request body in MB. If a POST request body size exceeds this value, an HTTP 413 status code is returned.</p> <p>The default value is 5, and it must not be greater than 10.</p> <p>When you enable the <b>Enable Advanced Server Configuration Options</b> parameter, this parameter is displayed.</p>

[QRadar Certificate Management](#)

## Setting up certificate-based authentication for HTTP Receiver

When you use the HTTP Receiver protocol, you must use a certificate that is issued by a certificate authority (CA). It can't be a self-signed certificate because it must be validated by a CA.

### About this task

**Important:** If you are a QRadar on Cloud (QRoC) user, contact IBM support and open a support case to configure this certificate-based authentication if the target collector is the Console or Event Processor.

### Before you begin

Before you import a PKCS12 file to use with the HTTP Receiver, you need a PKCS12 file that includes the certificate private key, endpoint certificate, and any intermediate certificates that are needed. Root CAs can be included in the chain but are not mandatory.

If you have a private key and certificate instead of a PKCS12 certificate, you must complete the following steps to convert them to a PKCS12 certificate:

1. Locate the endpoint certificate private key, which is in PKCS1 encoding in PEM format. The file is called `certificate.key`. The private key must begin with `BEGIN RSA PRIVATE KEY` and end with `END RSA PRIVATE KEY`.

**Tip:** If your key is in PEM format but begins with a `BEGIN PRIVATE KEY` header instead of `BEGIN RSA PRIVATE KEY`, then it is in PKCS8 encoding and must be converted to PKCS1 encoding before you continue.

2. Locate the certificate chain in PEM format, with each certificate appended in the following order in the `chain.crt` file. The endpoint certificate must be first, then followed by one or more intermediate certificates as needed.

**Important:** If your certificate is issued directly by a Root CA, you must provide only the endpoint certificate.

- Create the PKCS12 certificate with the `certificate.key` and `chain.crt` files by running the following command:

```
openssl pkcs12 -export -out myserver.mycompany.net.p12 -inkey certificate.key -in chain.crt
```

- Create an export password to protect the private key in the PKCS12 container. The password is used to import the certificate into the QRadar keystore.

- Verify the details of the certificate by running the following command:

```
keytool -list -v -keystore myserver.mycompany.net.p12 -storetype PKCS12
```

You can now import the PKCS12 certificate to use with HTTP Receiver.

## IBM Cloud Object Storage protocol configuration options

The IBM Cloud Object Storage protocol for IBM QRadar is an outbound or active protocol that collects logs that are contained in objects from IBM Cloud Object Storage buckets.

**Important:** Before you configure the IBM Cloud Object Storage protocol, configure user access roles and service credentials to access the IBM Cloud Object Storage buckets.

You must have either the Reader, Writer, or Manager role to access the buckets. For more information about user access roles and permissions, see [Bucket permissions](https://cloud.ibm.com/docs/cloud-object-storage?topic=cloud-object-storage-iam-bucket-permissions) (<https://cloud.ibm.com/docs/cloud-object-storage?topic=cloud-object-storage-iam-bucket-permissions>).

You must create service credentials that include hash-based message authentication code (HMAC) credentials. For more information about service credentials, see [Using HMAC credentials](https://cloud.ibm.com/docs/cloud-object-storage?topic=cloud-object-storage-uhc-hmac-credentials-main) (<https://cloud.ibm.com/docs/cloud-object-storage?topic=cloud-object-storage-uhc-hmac-credentials-main>).

*Table 56. IBM Cloud Object Storage protocol common log source parameters*

Parameter	Description
<b>Protocol Configuration</b>	IBM Cloud Object Storage
<b>Log Source Identifier</b>	Type a unique name for the log source. The log source identifier does not need to reference a specific server, and it can be the same value as the <b>Log Source Name</b> .
<b>HMAC Access Key ID</b>	The Access Key ID that was generated when you configured the service credentials.
<b>HMAC Secret Access Key</b>	The Secret Access Key that was generated when you configured the service credentials.
<b>Endpoint</b>	The public endpoint that is stated in the bucket configuration page.
<b>Bucket Name</b>	The name of the bucket that logs are stored in.
<b>Prefix</b>	<p>The prefix filter value to limit collecting objects or file keys that begin with the prefix.</p> <p>To pull all files from the bucket, use a forward slash (/).</p> <p><b>Important:</b> Changing the <b>Prefix</b> value clears the persisted file marker. All files that match the new prefix are downloaded in the next pull. If the <b>Prefix</b> file path is used to specify folders, you must not begin the file path with a forward slash. For example, use folder1/folder2 instead.</p>

Table 56. IBM Cloud Object Storage protocol common log source parameters (continued)

Parameter	Description
<b>Event Format</b>	<p>The following event formats are supported:</p> <p><b>LINEBYLINE</b>  Raw log files that contain one record per line. You can use either .gz, .gzip, or .zip files for compression.</p> <p><b>W3C</b>  Files that contain generic W3C formatting data to output name-value-pair events (.gz files only).</p>
<b>Use As A Gateway Log Source</b>	<p>If you do not want to define a custom log source identifier for events, clear the checkbox.</p> <p>If you don't select <b>Use As A Gateway Log Source</b> and you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p>
<b>Log Source Identifier Pattern</b>	<p>If you select <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier. Use this option for events that are being processed and for log sources that are automatically discovered.</p> <p>If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom log source identifier. The key is the identifier format string, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom log source identifier is displayed.</p> <p>The following examples show multiple key-value pair functions:</p> <pre> Patterns VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK) Events {LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0} Resulting custom log source identifier VPC-ACCEPT-OK </pre>
<b>Show Advanced Options</b>	<p>To configure the advanced options for event collection, set this option to <b>On</b>.</p>

Table 56. IBM Cloud Object Storage protocol common log source parameters (continued)

Parameter	Description
<b>File Pattern</b>	Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code> . This option is available when you set <b>Show Advanced Options</b> to <b>On</b> .
<b>Local Directory</b>	The local directory on the Target Event Collector. The directory must exist before the protocol attempts to retrieve events. This option is available when you set <b>Show Advanced Options</b> to <b>on</b> .
<b>Use Proxy</b>	If QRadar accesses the IBM Cloud Object Storage by using a proxy, enable <b>Use Proxy</b> . If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> parameters. If the proxy does not require authentication, leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Recurrence</b>	Type a time interval to determine how frequently the protocol polls for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds. The minimum value is 60 (seconds) or 1M.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

## IBM Fiberlink REST API protocol configuration options

To receive Log Event Extended Format (LEEF) formatted events from IBM MaaS360® appliances, configure a log source that uses the IBM Fiberlink® REST API protocol.

The IBM Fiberlink REST API protocol is an outbound (or active) protocol. As events are retrieved, the IBM MaaS360 DSM parses and categorizes events.

The following table describes the protocol-specific parameters for the IBM Fiberlink REST API protocol.

Table 57. IBM Fiberlink REST API protocol log source parameters

Parameter	Value
<b>Log Source Type</b>	IBM Fiberlink MaaS360
<b>Protocol Configuration</b>	IBM Fiberlink REST API

Table 57. IBM Fiberlink REST API protocol log source parameters (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type a unique identifier for the log source.  The <b>Log Source Identifier</b> can be set to any valid value and does not need to reference a specific server. You can set the <b>Log Source Identifier</b> to the same value as the Log Source Name. If you have more than one IBM Fiberlink® MaaS360® log source that is configured, you might want to give them similar but unique names. For example, you can name the first log source <code>fiberlink1</code> , the second log source <code>fiberlink2</code> , and the third log source <code>fiberlink3</code> .
<b>Login URL</b>	Copy the URL for the Fiberlink MaaS360 REST server.
<b>Username</b>	Type the username used to access the MaaS360 APIs.  Users with the following administrator roles can access the APIs: <ul style="list-style-type: none"> <li>• Service Administrator</li> <li>• Administrator</li> <li>• Administrator-Level 2</li> </ul>
<b>Password</b>	Type the password used to access your MaaS360 APIs.
<b>Secret Key</b>	The secret key provided by Fiberlink Customer Service when you enable the REST API.
<b>App ID</b>	The app ID provided by Fiberlink Customer Service when you enable the REST API.
<b>Billing ID</b>	The billing ID for your Fiberlink MaaS360 account
<b>Platform</b>	The platform version of the Fiberlink MaaS360 console.
<b>App Version</b>	The app version of the application that corresponds to your REST API account.
<b>Use Proxy</b>	If IBM QRadar accesses the Fiberlink MaaS360 API by using a proxy, enable the <b>Use Proxy</b> option.  If the proxy requires authentication, configure the <b>Proxy IP or Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> and <b>Proxy Port</b> fields.  This parameter is disabled by default.

Table 57. IBM Fiberlink REST API protocol log source parameters (continued)

Parameter	Value
<b>Proxy IP or Hostname</b>	The IP or hostname of the proxy server that you want to use. This parameter is available if the <b>Use Proxy</b> option is enabled.
<b>Proxy Port</b>	The port number used to communicate with the proxy. The default port number is 8080. This parameter is available if the <b>Use Proxy</b> option is enabled.
<b>Proxy Username</b>	The username that you use to access the proxy server. This parameter is available if the <b>Use Proxy</b> option is enabled.
<b>Proxy Password</b>	The password that you use to access the proxy server. This parameter is available if the <b>Use Proxy</b> option is enabled.
<b>Automatically Acquire Server Certificate(s)</b>	If the <b>Yes</b> option is selected, the log source automatically downloads the server certificate and begins trusting the target server.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
<b>Recurrence</b>	The time interval between log source queries to IBM Fiberlink MaaS360 for new events. The time interval can be in minutes (M), hours (H), or days (D). For example, 1 M, 3 H, 5 D. The default is 60 minutes (60 M).

## IBM Security Randori REST API protocol configuration options

To receive events from IBM Security Randori®, configure a log source to communicate with the IBM Security Randori REST API protocol.

The IBM Security Randori REST API protocol is an active outbound protocol that provides alerts about changes in an organizations attack surface. For example, new targets that are discovered.

**Important:** Before you can configure a log source for Randori, you must obtain your **API Key** from the Randori web portal.

For more information about obtaining this value, see [How to Add an API token](https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html) ([https://www.ibm.com/docs/en/SSD5I5K/intapi\\_api\\_AddAPIToken.html](https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html)).

The following table describes the protocol-specific parameters for the IBM Security Randori REST API protocol:

Table 58. IBM Security Randori REST API protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	<b>IBM Security Randori REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured IBM Security Randori log source, ensure that you give each one a unique name.
<b>Instance</b>	The <b>Instance</b> value is the URL that you use to access Randori, such as app2.randori.io. The structure for the <b>Instance</b> value is:  app[#].randori.io  where [#] is a number that might be required to access your Randori instance.
<b>API Key</b>	The API key that is used to access the IBM Security Randori REST API.  For more information about obtaining this value, see <a href="https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html">How to Add an API token</a> ( <a href="https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html">https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html</a> ).
<b>Minimum Priority Score</b>	Filters new targets by using the priority score that you select. <ul style="list-style-type: none"> <li><b>Low</b> - All new targets</li> <li><b>Medium</b> - New targets with a priority greater than 20</li> <li><b>High</b> - New targets with a priority of 30 or greater</li> </ul>
<b>Minimum Temptation</b>	Filters existing targets that have a modified temptation value. This filter is based on the temptation value that you select. <ul style="list-style-type: none"> <li><b>Low</b> - All targets with a modified temptation value</li> <li><b>Medium</b> - Targets with a temptation value greater than 14</li> <li><b>High</b> - Targets with a temptation value greater than 29</li> <li><b>Critical</b> - Targets with a temptation value greater than 39</li> </ul>
<b>Use Proxy</b>	If the API is accessed by using a proxy, select this checkbox.  Configure the <b>Proxy IP or Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Recurrence</b>	Specify how often the log collects data. The value can be in Minutes (M), Hours (H), or Days (D). The default is 1 minute.

Table 58. IBM Security Randori REST API protocol parameters (continued)

Parameter	Description
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
<b>Enable Advanced Options</b>	Select this checkbox to enable the following configuration options: <b>Allow Untrusted</b> and <b>Override Workflow</b> . These parameters are only visible if you select this checkbox.
<b>Initial Days of Historical Data</b>	Enter the number of days before the current date to collect historical data. When you configure a new log source, IBM QRadar generates New Target events for existing targets that have a first-seen date within the number of days that you enter. This value is used only before the log source runs for the first time.
<b>Allow Untrusted</b>	If you enable this parameter, the protocol can accept self-signed and otherwise untrusted certificates that are located within the /opt/qradar/conf/trusted_certificates/ directory. If you disable the parameter, the scanner trusts only certificates that are signed by a trusted signer. The certificates must be in PEM or RED-encoded binary format and saved as a .crt or .cert file. If you modify the workflow to include a hardcoded value for the <b>Allow Untrusted Certificates</b> parameter, the workflow overrides your selection in the UI. If you do not include this parameter in your workflow, then your selection in the UI is used.
<b>Override Workflow</b>	Enable this option to customize the workflow. When you enable this option, the <b>Workflow</b> and <b>Workflow Parameters</b> parameters appear.
<b>Workflow</b>	The XML document that defines how the protocol instance collects events from the target API. For more information about the default workflow, see “ <a href="#">IBM Security Randori REST API protocol workflow</a> ” on page 138.
<b>Workflow Parameters</b>	The XML document that contains the parameter values used directly by the workflow. For more information about the default workflow parameters, see “ <a href="#">IBM Security Randori REST API protocol workflow</a> ” on page 138.

## IBM Security Randori REST API protocol workflow

You can customize your workflow and workflow parameters based on the default workflow.

A workflow is an XML document that describes the event retrieval process. The workflow defines one or more parameters, which can be explicitly assigned values in the workflow XML or can derive values from the workflow parameter values XML document. The workflow consists of multiple actions that run sequentially.

The default workflow and workflow parameter XML files are available on GitHub. For more information, see [IBM Security Randori](https://github.com/IBM/IBM-QRadar-Universal-Cloud-REST-API/tree/master/IBM%20Verified/IBM%20Security%20Randori) (<https://github.com/IBM/IBM-QRadar-Universal-Cloud-REST-API/tree/master/IBM%20Verified/IBM%20Security%20Randori>).

## Randori default workflow

The following example shows the default Randori workflow:

```
<?xml version="1.0" encoding="UTF-8" ?>
<Workflow name="IBMSecurityRandoriRestAPI" version="1.0" xmlns="http://qradar.ibm.com/
UniversalCloudRESTAPI/Workflow/V2">

    <Parameters>
        <Parameter name="instance"      label="Instance"      required="true" />
        <Parameter name="apiKey"        label="API Key"        secret="true"
required="true" />
        <Parameter name="minimumPriority"    label="Minimum Priority" required="true"      />
        <Parameter name="minimumTemptation"  label="Minimum Temptation" required="true"      />
        <Parameter name="initialDaysOfHistoricalData" label="Initial Days of Historical Data"
required="true" default="1"/>
    </Parameters>

    <Actions>
        <Initialize path="/randoriDetections/detections/status_code" value="200"/> <!-- Sets
the initial status to 200. Once we get a value from the API, if the value is not 200 we will
sleep an additional 20 seconds. This prevents the protocol test event retriever from running
multiple times on failures. -->
        <If condition="${randoriDetections/detections/status_code} != 200">
            <!--
                Setting an internal sleep to slow down the protocol
test. Also applies in the main code, but only applies when the status code is in a bad
state. -->
            <Sleep duration="20000" />
        </If>
        <!--
            Clears the status and sets the workflow to running
-->
        <ClearStatus />
        <SetStatus type="INFO" message="Workflow has started." />
        <!--
            Initialization Code
-->
        <Initialize path="/randoriDetections/startTimeFirstSeenUnixTime" value="${time() -
(60000 * 60 * 24 * ${initialDaysOfHistoricalData})}" /> <!-- days previous to initialize --
        <Initialize path="/randoriDetections/startTimeTemptationLastModifiedUnixTime" value="${
time() - (60000 * 60 * 24 * ${initialDaysOfHistoricalData})}" /> <!-- days previous to
initialize --
        <Initialize path="/randoriDetections/limit"      value="2000" />           <!-- How many
we pullback at once, maximum of 2000 per request -->
        <!--
            Set the query bounds based off time values
-->

```

<?xml version="1.0" encoding="UTF-8" ?>
<WorkflowParameterValues xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/
WorkflowParameterValues/V2">
    <Value name="instance"      value="" />
    <Value name="apiKey"        value="" />
    <Value name="minimumPriority" value="" />
    <Value name="minimumTemptation" value="" />
    <Value name="initialDaysOfHistoricalData" value="" />
</WorkflowParameterValues>

```

## IBM Security QRadar EDR REST API protocol configuration options

To receive events from IBM Security QRadar EDR, configure a log source to communicate with the IBM Security QRadar EDR REST API protocol.

The IBM Security QRadar EDR REST API protocol is an active outbound protocol that provides alerts about confirmed incidents of malware that are actively communicating or exfiltrating information.

**Important:** Before you can configure a log source for IBM Security QRadar EDR, you must obtain your **App ID** and **Secret Key** from the IBM Security QRadar EDR web portal.

1. Log in to your IBM Security QRadar EDR console.
2. On the **Administration** tab, select **API Applications**, and then click **Create Application**.
3. In the **Application Name** field, type a unique name for the application. Then, click **Create**.
4. Copy and save the **App ID** and **Secret Key** values. You must have these values to add a log source for IBM Security QRadar EDR.

The following table describes the protocol-specific parameters for the IBM Security QRadar EDR REST API protocol:

Table 59. IBM Security QRadar EDR REST API protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	<b>IBM Security QRadar EDR REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured IBM Security QRadar EDR log source, ensure that you give each one a unique name.
<b>Server Address</b>	The IP address or hostname of the IBM Security QRadar EDR server.
<b>App ID</b>	The <b>App ID</b> value that you copied and saved from the IBM Security QRadar EDR application configuration.
<b>Secret Key</b>	The <b>Secret Key</b> value that you copied and saved from the IBM Security QRadar EDR application configuration.
<b>Use Proxy</b>	If the API is accessed by using a proxy, select this checkbox.  Configure the <b>Proxy IP or Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Recurrence</b>	Specify how often the log collects data. The value can be in Minutes (M), Hours (H), or Days (D). The default is 1 minute.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.
<b>Enable Advanced Options</b>	Select this checkbox to enable the following configuration options: <b>Allow Untrusted</b> , <b>Override Workflow</b> , <b>Workflow</b> , and <b>Workflow Parameters</b> .  These parameters are only visible if you select this checkbox.
<b>Allow Untrusted</b>	If you enable this parameter, the protocol can accept self-signed and otherwise untrusted certificates that are located within the /opt/qradar/conf/trusted_certificates/ directory. If you disable the parameter, the scanner trusts only certificates that are signed by a trusted signer.  The certificates must be in PEM or RED-encoded binary format and saved as a .crt or .cert file.  If you modify the workflow to include a hardcoded value for the <b>Allow Untrusted Certificates</b> parameter, the workflow overrides your selection in the UI. If you do not include this parameter in your workflow, then your selection in the UI is used.

Table 59. IBM Security QRadar EDR REST API protocol parameters (continued)

Parameter	Description
<b>Override Workflow</b>	Enable this option to customize the workflow. When you enable this option, the <b>Workflow</b> and <b>Workflow Parameters</b> parameters appear.
<b>Workflow</b>	The XML document that defines how the protocol instance collects events from the target API.  For more information about the default workflow, see “IBM Security QRadar EDR REST API protocol workflow” on page 143.
<b>Workflow Parameters</b>	The XML document that contains the parameter values used directly by the workflow.  For more information about the default workflow parameters, see “IBM Security QRadar EDR REST API protocol workflow” on page 143.

## IBM Security QRadar EDR REST API protocol workflow

You can customize your workflow and workflow parameters based on the default workflow.

A workflow is an XML document that describes the event retrieval process. The workflow defines one or more parameters, which can be explicitly assigned values in the workflow XML or can derive values from the workflow parameter values XML document. The workflow consists of multiple actions that run sequentially.

The default workflow and workflow parameter XML files are available on GitHub. For more information, see [IBM Security QRadar EDR](https://github.com/IBM/IBM-QRadar-Universal-Cloud-REST-API/tree/master/IBM%20Verified/ReaQta) (<https://github.com/IBM/IBM-QRadar-Universal-Cloud-REST-API/tree/master/IBM%20Verified/ReaQta>). *Update link?*

## IBM Security QRadar EDR default workflow

The following example shows the default IBM Security QRadar EDR workflow:

```
<?xml version="1.0" encoding="UTF-8" ?>
<Workflow name="ReaQta" version="1.0" xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/Workflow/V2">
  <Parameters>
    <Parameter name="app_id" label="ReaQta Application ID" required="true" />
    <Parameter name="secret_key" label="ReaQta secret key" required="true" />
    <Parameter name="reaqta_host" label="ReaQta Host / IP Address" required="true" />
  </Parameters>
  <Actions>
    <!-- Initialize receivedAfter timestamp -->
    <!-- 60 mins prior. Get updated at end of doWhile to current time to prepare for next run. -->
    <!-- Initialize path="/reaqtaData/receivedAfterMilli" value="${time()}" />
    <FormatDate pattern="yyyy-MM-dd'T'HH:mm:ss.SSS'Z'" timeZone="GMT" time="${reaqtaData/receivedAfterMilli}" savePath="/reaqtaData/receivedAfter_Formatted" />
    <!-- set the path to just be /alerts at first, but we will modify this as required in the DoWhile loop -->
    <Set path="/reaqtaData/url" value="https://${reaqta_host}/rqt-api/1/alerts"/>
    <!-- Get Auth Token -->
    <CallEndpoint url="https://${reaqta_host}/rqt-api/1/authenticate" method="POST" savePath="/reaqtaAuth/response">

        <PostEvents path="/reaqtaData/response/body/result" source="$/{reaqta_host}" />
        <ParseDate pattern="yyyy-MM-dd'T'HH:mm:ss.SSS'Z'" date="$/{max(/reaqtaData/response/body/
result/receivedAt)}" timeZone="UTC" savePath="/reaqtaData/receivedAfterMilli"/>
        <Set path="/reaqtaData/receivedAfterMilli" value="$/{reaqtaData/receivedAfterMilli +
1}" />
        <!-- unset this for subsequent loops -->
        <Set path="/reaqtaData/receivedAfter_Formatted" value="" />
    </If>

    <!-- Set the next page if present -->
    <If condition="not empty(/reaqtaData/response/body/nextPage)">
        <Log type="DEBUG" message="Response contained a next page link." />
        <Set path="/reaqtaData/url" value="$/{reaqtaData/response/body/nextPage}" />
    </If>
</DoWhile>
</Actions>
<Tests>
    <DNSResolutionTest host="https://$/{reaqta_host}" />
    <TCPConnectionTest host="https://$/{reaqta_host}" />
    <HTTPConnectionThroughProxyTest url="https://$/{reaqta_host}" />
</Tests>
</Workflow>

```

## IBM Security QRadar EDR default workflow parameters

The following example shows the default IBM Security QRadar EDR workflow parameters:

```

<?xml version="1.0" encoding="UTF-8" ?>
<WorkflowParameterValues xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/
WorkflowParameterValues/V2">
    <Value name="app_id"           value="App ID goes here"/>
    <Value name="secret_key"       value="Secret Key Goes here"/>
    <Value name="reaqta_host"      value="ReaQta Hostname or IP goes here"/>
</WorkflowParameterValues>

```

## IBM Security Verify Event Service protocol configuration options

IBM Security Verify Event Service protocol is formerly known as IBM Cloud® Identity Event Service protocol.

To receive events from IBM Security Verify, configure a log source in IBM QRadar to use the IBM Security Verify Event Service protocol.

The IBM Security Verify protocol is an outbound/active protocol.

When you use the IBM Security Verify Event Service protocol, there are specific parameters that you must use.

Before you can add a log source in QRadar, you must configure IBM Security Verify server to send events to QRadar. For more information, see [Configuring IBM Security Verify server to send events to QRadar](#).

The following table describes the protocol-specific parameters for the IBM Security Verify Event Service protocol:

Table 60. IBM Security Verify Event Service protocol log source parameters	
Parameter	Value
<b>Log Source Type</b>	IBM Security Verify
<b>Protocol Configuration</b>	IBM Security Verify Event Service
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured IBM Security Verify Event Service log source, ensure that you give each one a unique name.
<b>Authorization End Point</b>	<a href="https://&lt;your tenant&gt;.ice.ibmcloud.com">https://&lt;your tenant&gt;.ice.ibmcloud.com</a>
<b>Client ID</b>	The <b>Client ID</b> that you recorded when you completed the steps to generate credentials for use with the REST API in IBM Security Verify. For more information, see <a href="#">Configuring IBM Security Verify server to send events to QRadar</a> .
<b>Client Secret</b>	The <b>Client Secret</b> that you recorded when you completed the steps to generate credentials for use with the REST API in IBM Security Verify. For more information, see <a href="#">Configuring IBM Security Verify server to send events to QRadar</a> .
<b>Management Events</b>	To collect management events, enable this option. The default is enabled. If the <b>All Events</b> parameter is enabled, this option is hidden.
<b>Authentication Events</b>	To collect authentication events, enable this option. The default is enabled. If the <b>All Events</b> parameter is enabled, this option is hidden.
<b>SSO Events</b>	To collect Single Sign-On events, enable this option. The default is enabled. If the <b>All Events</b> parameter is enabled, this option is hidden.

Table 60. IBM Security Verify Event Service protocol log source parameters (continued)

Parameter	Value
<b>Enable Advanced Options</b>	If you want to configure advanced protocol parameters, enable this option. The default is disabled.
<b>Advanced Event Types</b>	If you want to collect more event types, enable this option. The default is disabled.  If the <b>All Events</b> parameter is enabled, this option is hidden.
<b>Event Types</b>	Enter the additional event types that you want to collect.  Use a comma-separated list of custom event names. For example, event_type1, event_type2, event_type3  If <b>Advanced Event Types</b> is disabled, this option is hidden.
<b>All Events</b>	To collect all event types that are stored on your tenant, enable this option. The default is disabled.  If the <b>Enable Advanced Options</b> parameter is disabled, this option is hidden.
<b>Use Proxy</b>	Select <b>True</b> or <b>False</b> . The default is <b>False</b> .
<b>Proxy IP or Hostname</b>	The IP address or host name of the proxy server.  If the <b>Use Proxy</b> parameter is <b>False</b> , this option is hidden.
<b>Proxy Port</b>	The port number that is used to communicate with the proxy. The default is 8080.  If the <b>Use Proxy</b> parameter is <b>False</b> , this option is hidden.
<b>Proxy Username</b>	The username that is used to access the proxy.  If <b>Use Proxy</b> is set to <b>False</b> , this option is hidden.
<b>Proxy Password</b>	The password that is used to access the proxy.  If the <b>Use Proxy</b> parameter is set to <b>False</b> , this option is hidden.
<b>Recurrence</b>	The time interval between log source queries to IBM Security Verify for new events. The time interval can be in minutes (M), hours (H), or days (D). For example, 1M, 3H, 5D.  The default is 1M.

Table 60. IBM Security Verify Event Service protocol log source parameters (continued)

Parameter	Value
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

[Adding a log source](#)

## JDBC protocol configuration options

QRadar uses the JDBC protocol to collect information from tables or views that contain event data from several database types.

The JDBC protocol is an outbound/active protocol. QRadar does not include a MySQL driver for JDBC. If you are using a DSM or protocol that requires a MySQL JDBC driver, you must download and install the *platform-independent MySQL Connector/J* from <http://dev.mysql.com/downloads/connector/j/>.

1. Copy the Java archive (JAR) file to /opt/qradar/jars and /opt/ibm/si/services/ecs-ec-ingress/eventgnosis/lib/q1labs/.
2. Restart Tomcat service by typing the following command:

```
systemctl restart tomcat
```

3. Restart event collection services by typing the following command:

```
systemctl restart ecs-ec-ingress
```

The following table describes the protocol-specific parameters for the JDBC protocol:

Table 61. JDBC protocol parameters

Parameter	Description
<b>Log Source Name</b>	Type a unique name for the log source.
<b>Log Source Description</b> (Optional)	Type a description for the log source.
<b>Log Source Type</b>	Select your Device Support Module (DSM) that uses the JDBC protocol from the <b>Log Source Type</b> list.
<b>Protocol Configuration</b>	<b>JDBC</b>

Table 61. JDBC protocol parameters (continued)

Parameter	Description
<b>Log Source Identifier</b>	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or hostname, use the IP address or hostname of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or hostname, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
<b>Database Type</b>	Select the type of database that contains the events.
<b>Database Name</b>	The name of the database to which you want to connect.
<b>Schema (Snowflake only)</b>	This parameter specifies either the default schema to be used for the specified database post connection, or an empty string.  The specified schema must be an existing schema for which the specified default role has privileges.
<b>IP or Hostname</b>	The IP address or hostname of the database server.
<b>Warehouse (Snowflake only)</b>	This parameter specifies the virtual warehouse to use post connection, or an empty string.  The specified warehouse must be an existing warehouse for which the specified default role has privileges.
<b>Role (Snowflake only)</b>	This parameter specifies the default access control role to be used in the Snowflake session initiated by the driver.  The specified role must be an existing role that is already assigned to the specified user for the driver.  If the specified role is not assigned to the user, then the role is not used during the session initiation by the driver.
<b>Port</b>	Enter the JDBC port. The JDBC port must match the listener port that is configured on the remote database. The database must permit incoming TCP connections. The valid range is 1 - 65535.  The defaults are: <ul style="list-style-type: none"> <li>• DB2® - 50000</li> <li>• Informix® - 9088</li> <li>• MSDE - 1433</li> <li>• MySQL - 3306</li> <li>• Oracle - 1521</li> <li>• Postgres - 5432</li> <li>• Sybase - 5000</li> <li>• Snowflake - 443</li> </ul> If you configure the <b>Database Instance</b> parameter and have an MSDE database type, leave the <b>Port</b> parameter blank.

Table 61. JDBC protocol parameters (continued)

Parameter	Description
<b>Username</b>	A user account for QRadar in the database.
<b>Password</b>	The password that is required to connect to the database.
<b>Confirm Password</b>	The password that is required to connect to the database.
<b>Authentication Domain</b> (MSDE only)	If you disable <b>Use Microsoft JDBC</b> , the <b>Authentication Domain</b> parameter is displayed. The domain for MSDE that is a Windows domain. If your network does not use a domain, leave this field blank.
<b>Database Instance</b> (MSDE or Informix only)	The database instance, if required. MSDE databases can include multiple SQL server instances on one server. When you use a different port number from the default for SQL database resolution, leave this parameter blank.
<b>Predefined Query</b> (Optional)	Select a predefined database query for the log source. If a predefined query is not available for the log source type, you can select the <b>None</b> option. If the configuration guide for a specific integration states to use a predefined query, choose it from the list. Otherwise, select <b>None</b> and populate the remaining required values.
<b>Table Name</b>	The name of the table or view that includes the event records. The table name can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period (.)
<b>Select List</b>	The list of fields to include when the table is polled for events. You can use a comma-separated list or type an asterisk (*) to select all fields from the table or view. If you defined a comma-separated list, the list must contain the field that is defined in the <b>Compare Field</b> parameter.
<b>Compare Field</b>	A numeric value or time stamp field from the table or view that identifies new events that are added to the table between queries. When you set this parameter value, the protocol identifies events that were previously pulled by the protocol to ensure that duplicate events are not created.
<b>Use Prepared Statements</b>	Prepared statements enable the JDBC protocol source to set up the SQL statement, and then run the SQL statement numerous times with different parameters. For security and performance reasons, most JDBC protocol configurations can use prepared statements.

Table 61. JDBC protocol parameters (continued)

Parameter	Description
<b>Start Date and Time</b> (Optional)	<p>Select or enter the start date and time for database polling. The format is yyyy-mm-dd HH:mm, where HH is specified by using a 24-hour clock.</p> <p>If this parameter is empty, polling begins immediately and repeats at the specified polling interval.</p> <p>This parameter is used to set the time and date at which the protocol connects to the target database to initialize event collection. It can be used along with the <b>Polling Interval</b> parameter to configure specific schedules for the database polls. For example, use these parameters to ensure that the poll happens at five minutes past the hour, every hour, or to ensure that the poll happens at exactly 1:00 AM each day.</p> <p>This parameter cannot be used to retrieve older table rows from the target database. For example, if you set the parameter to <b>Last Week</b>, the protocol does not retrieve all table rows from the previous week. The protocol retrieves rows that are newer than the maximum value of the <b>Compare Field</b> on initial connection.</p>
<b>Polling Interval</b>	<p>Enter the amount of time between queries to the event table. To define a longer polling interval, append H for hours or M for minutes to the numeric value.</p> <p>The maximum polling interval is one week.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 20,000.</p>
<b>Security Mechanism</b> (Db2 only)	<p>From the list, select the security mechanism that is supported by your Db2 server. If you don't want to select a security mechanism, select <b>None</b>.</p> <p>The default is <b>None</b>.</p> <p>For more information about security mechanisms that are supported by Db2 environments, see the <a href="https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html">IBM Support website</a> (<a href="https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html">https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html</a>)</p>
<b>Use Named Pipe Communication</b> (MSDE only)	<p>If you disable <b>Use Microsoft JDBC</b>, the <b>Use Named Pipe Communication</b> parameter is displayed.</p> <p>MSDE databases require the user name and password field to use a Windows authentication user name and password and not the database user name and password. The log source configuration must use the default that is named pipe on the MSDE database.</p>

Table 61. JDBC protocol parameters (continued)

Parameter	Description
<b>Database Cluster Name</b>	If you are running your SQL server in a cluster environment, define the cluster name to ensure named pipe communication functions properly.  This parameter is required if you enable <b>Use Named Pipe Communication</b> and select the MSDE database type option.
<b>Use NTLMv2</b> (MSDE only)	If you disable <b>Use Microsoft JDBC</b> , the <b>Use NTLMv2</b> parameter is displayed.  Select this option if you want MSDE connections to use the NTLMv2 protocol when they are communicating with SQL servers that require NTLMv2 authentication. This option does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.  Does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.
<b>Use Microsoft JDBC</b> (MSDE only)	If you want to use the Microsoft JDBC driver, you must enable <b>Use Microsoft JDBC</b> .  This parameter is enabled by default.
<b>Use SSL</b> (MSDE only)	Enable this option if your MSDE connection supports SSL.
<b>SSL Certificate Hostname</b>	This field is required when both <b>Use Microsoft JDBC</b> and <b>Use SSL</b> are enabled.  This value must be the fully qualified domain name (FQDN) for the host. The IP address is not permitted.  For more information about SSL certificates and JDBC, see the procedures at the following links: <ul style="list-style-type: none"><li>• <a href="https://www.ibm.com/support/pages/node/246077">QRadar: Configuring JDBC Over SSL with a Self-signed certificate</a> (<a href="https://www.ibm.com/support/pages/node/246077">https://www.ibm.com/support/pages/node/246077</a>)</li><li>• <a href="https://www.ibm.com/support/pages/node/246079">Configuring JDBC Over SSL with an Externally-signed Certificate</a> (<a href="https://www.ibm.com/support/pages/node/246079">https://www.ibm.com/support/pages/node/246079</a>)</li></ul>
<b>Use Oracle Encryption</b> (Oracle only)	<i>Oracle Encryption and Data Integrity settings</i> is also known as <i>Oracle Advanced Security</i> .  If selected, Oracle JDBC connections require the server to support similar Oracle Data Encryption settings as the client.
<b>Database Locale</b> (Informix only)	For multilingual installations, specify the language to use for the installation process (or software?).  After you choose a language, you can then choose the character set that is used in the installation in the <b>Code-Set</b> parameter.
<b>Code-Set</b> (Informix only)	The <b>Code-Set</b> parameter displays after you choose a language for multilingual installations.  Use this field to specify the character set to use.
<b>Enabled</b>	Select this checkbox to enable the log source. By default, the checkbox is selected.

*Table 61. JDBC protocol parameters (continued)*

Parameter	Description
<b>Credibility</b>	From the list, select the <b>Credibility</b> of the log source. The range is 0 - 10.  The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	Select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	Select the <b>Coalescing Events</b> checkbox to enable the log source to coalesce (bundle) events.  By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Store Event Payload</b>	Select the <b>Store Event Payload</b> checkbox to enable the log source to store event payload information.  By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Enable Advanced Options</b>	Select this checkbox to enable advanced options. When disabled, the default value is used.
<b>Use With (No Lock) in SQL statements</b>	Enable this option to append the tables in all SQL statements with "WITH (NOLOCK)".

## JDBC - SiteProtector protocol configuration options

You can configure log sources to use the Java Database Connectivity (JDBC) - SiteProtector protocol to remotely poll IBM Proventia® Management SiteProtector® databases for events.

The JDBC - SiteProtector protocol is an outbound/active protocol that combines information from the SensorData1 and SensorDataAVP1 tables in the creation of the log source payload. The SensorData1 and SensorDataAVP1 tables are in the IBM Proventia® Management SiteProtector® database. The maximum number of rows that the JDBC - SiteProtector protocol can poll in a single query is 30,000 rows.

The following table describes the protocol-specific parameters for the JDBC - SiteProtector protocol:

*Table 62. JDBC - SiteProtector protocol parameters*

Parameter	Description
Protocol Configuration	<b>JDBC - SiteProtector</b>

Table 62. JDBC - SiteProtector protocol parameters (continued)

Parameter	Description
Log Source Identifier	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured JDBC - SiteProtector log source, ensure that you give each one a unique name.
Database Type	From the list, select <b>MSDE</b> as the type of database to use for the event source.
Database Name	Type RealSecureDB as the name of the database to which the protocol can connect.
IP or Hostname	The IP address or host name of the database server.
Port	The port number that is used by the database server. The JDBC - SiteProtector configuration port must match the listener port of the database. The database must have incoming TCP connections enabled. If you define a <b>Database Instance</b> when with MSDE as the database type, you must leave the <b>Port</b> parameter blank in your log source configuration.
Username	If you want to track access to a database by the JDBC protocol, you can create a specific user for your QRadar system.
Authentication Domain	If you select MSDE and the database is configured for Windows, you must define a Windows domain.  If your network does not use a domain, leave this field blank.
Database Instance	If you select MSDE and you have multiple SQL server instances on one server, define the instance to which you want to connect. If you use a non-standard port in your database configuration, or access is blocked to port 1434 for SQL database resolution, you must leave the <b>Database Instance</b> parameter blank in your configuration.
Predefined Query	The predefined database query for your log source. Predefined database queries are only available for special log source connections.
Table Name	SensorData1
AVP View Name	SensorDataAVP
Response View Name	SensorDataResponse
Select List	Type * to include all fields from the table or view.
Compare Field	SensorDataRowID
Use Prepared Statements	Prepared statements allow the JDBC protocol source to set up the SQL statement, and then execute the SQL statement numerous times with different parameters. For security and performance reasons, use prepared statements. You can clear this check box to use an alternative method of querying that does not use pre-compiled statements.
Include Audit Events	Specifies to collect audit events from IBM Proventia Management SiteProtector®.

*Table 62. JDBC - SiteProtector protocol parameters (continued)*

Parameter	Description
Start Date and Time	Optional. A start date and time for when the protocol can start to poll the database.
Polling Interval	The amount of time between queries to the event table. You can define a longer polling interval by appending H for hours or M for minutes to the numeric value. Numeric values without an H or M designator poll in seconds.
EPS Throttle	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
Database Locale	For multilingual installations, use the <b>Database Locale</b> field to specify the language to use.
Database Codeset	For multilingual installations, use the <b>Codeset</b> field to specify the character set to use.
Use Named Pipe Communication	If you are using Windows authentication, enable this parameter to allow authentication to the AD server. If you are using SQL authentication, disable Named Pipe Communication.
Database Cluster Name	The cluster name to ensure that named pipe communications function properly.
Use NTLMv2	Forces MSDE connections to use the NTLMv2 protocol with SQL servers that require NTLMv2 authentication. The <b>Use NTLMv2</b> check box does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.
Use SSL	Enables SSL encryption for the JDBC protocol.
Log Source Language	Select the language of the events that are generated by the log source. The log source language helps the system parse events from external appliances or operating systems that can create events in multiple languages.

## Juniper Networks NSM protocol configuration options

To receive Juniper Networks NSM and Juniper Networks Secure Service Gateway (SSG) logs events, configure a log source to use the Juniper Networks NSM protocol.

The Juniper Networks NSM protocol is an inbound/passive protocol.

The following table describes the protocol-specific parameters for the Juniper Networks Network and Security Manager protocol:

*Table 63. Juniper Networks NSM protocol parameters*

Parameter	Description
Log Source Type	<b>Juniper Networks Network and Security Manager</b>
Protocol Configuration	<b>Juniper NSM</b>

*Table 63. Juniper Networks NSM protocol parameters (continued)*

Parameter	Description
Log Source Identifier	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Juniper Networks NSM log source, ensure that you give each one a unique name.

## Juniper Security Binary Log Collector protocol configuration options

You can configure a log source to use the Security Binary Log Collector protocol. With this protocol, Juniper appliances can send audit, system, firewall, and intrusion prevention system (IPS) events in binary format to QRadar.

The Security Binary Log Collector protocol is an inbound/pассив протокол.

The binary log format from Juniper SRX or J Series appliances are streamed by using the UDP protocol. You must specify a unique port for streaming binary formatted events. The standard syslog port 514 cannot be used for binary formatted events. The default port that is assigned to receive streaming binary events from Juniper appliances is port 40798.

The following table describes the protocol-specific parameters for the Juniper Security Binary Log Collector protocol:

*Table 64. Juniper Security Binary Log Collector protocol parameters*

Parameter	Description
Protocol Configuration	<b>Security Binary Log Collector</b>
Log Source Identifier	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Juniper Security Binary Log Collector log source, ensure that you give each one a unique name.
XML Template File Location	The path to the XML file used to decode the binary stream from your Juniper SRX or Juniper J Series appliance. By default, the device support module (DSM) includes an XML file for decoding the binary stream. The XML file is in the following directory: /opt/qradar/conf/security_log.xml.

## Log File protocol configuration options

To receive events from remote hosts, configure a log source to use the Log File protocol.

The Log File protocol is an active outbound protocol that is intended for systems that write daily event logs. It is not appropriate to use the Log File protocol for devices that append information to their event files.

Log files are retrieved one at a time by using SFTP, FTP, SCP, or FTPS. The Log File protocol can manage plain text, compressed files, or file archives. Archives must contain plain-text files that can be processed

one line at a time. When the Log File protocol downloads an event file, the information that is received in the file updates the **Log Activity** tab. If more information is written to the file after the download is complete, the appended information is not processed.

The following table describes the protocol-specific parameters for the Log File protocol:

Table 65. Log File protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	Log File
<b>Log Source Identifier</b>	<p>Type a unique name for the log source.</p> <p>The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b>. If you have more than one configured Log File log source, make sure that you give each one a unique name.</p>
<b>Service Type</b>	<p>Select the protocol to use when retrieving log files from a remote server.</p> <ul style="list-style-type: none"> <li>• SFTP - Secure File Transfer protocol (default)</li> <li>• FTP - File transfer protocol</li> <li>• FTPS - File transfer protocol secure</li> <li>• SCP - Secure copy protocol</li> </ul> <p>The server that you specify in the <b>Remote IP or Hostname</b> field must enable the SFTP subsystem to retrieve log files with SCP or SFTP.</p>
<b>Remote IP or Hostname</b>	Type the IP address or hostname of the device that contains the event log files.
<b>Remote Port</b>	If the remote host uses a nonstandard port number, you must adjust the port value to retrieve events.
<b>Remote User</b>	Type the username that you use to log in to the host that contains the event files.
<b>Remote Password</b>	Type the password that you use to log in to the host.
<b>Enable Strict Host Key Checking</b>	<p>Enable this option to define a list of permitted public keys for the target host in the <b>Host Key List</b> parameter.</p> <p><b>Note:</b> This option is only available when you select either SFTP (Secure File Transfer protocol) or SCP (Secure copy protocol) in the <b>Service Type</b> field.</p>

Table 65. Log File protocol parameters (continued)

Parameter	Description
<b>Host Key List</b>	<p>Provide a list of Base64 encoded host keys to use when connecting to the target host. Separate multiple keys by using a newline and use blank lines for formatting. Supported host key types are: ssh-dss, ssh-rsa, ecdsa-sha2-nistp256, ecdsa-sha2-nistp384, and ecdsa-sha2-nistp521.</p> <p>You can obtain these keys by running the OpenSSH command <code>ssh-keyscan</code> on Linux, or <code>ssh-keyscan.exe</code> on Windows, or getting the public key from the target system directly from a location similar to <code>/root/.ssh/id_rsa.pub</code>. Use the Base64 hash only and not the hostname or algorithm.</p> <p><b>Note:</b> This option is only available when you select either SFTP (Secure File Transfer protocol) or SCP (Secure copy protocol) in the <b>Service Type</b> field.</p>
<b>SSH Key File</b>	<p>If the system is configured to use key authentication, type the SSH key. When an SSH key file is used, the <b>Remote Password</b> field is ignored.</p> <p>The SSH key must be located in the <code>/opt/qradar/conf/keys</code> directory.</p> <p><b>Important:</b> The <b>SSH Key File</b> field no longer accepts a file path. It can't contain "/" or "~". Type the file name for the SSH key. The keys for existing configurations are copied to the <code>/opt/qradar/conf/keys</code> directory. To ensure uniqueness, the keys must have "<code>_&lt;Timestamp&gt;</code>" appended to the file name.</p>
<b>Remote Directory</b>	For FTP, if the log files are in the remote user's home directory, you can leave the remote directory blank. A blank remote directory field supports systems where a change in the working directory (CWD) command is restricted.
<b>Recursive</b>	Enable this checkbox to allow FTP or SFTP connections to recursively search subfolders of the remote directory for event data. Data that is collected from subfolders depends on matches to the regular expression in the FTP File Pattern. The <b>Recursive</b> option is not available for SCP connections.
<b>FTP File Pattern</b>	The regular expression (regex) that is needed to identify the files to download from the remote host.
<b>FTP Transfer Mode</b>	For ASCII transfers over FTP, you must select NONE in the <b>Processor</b> field and LINEBYLINE in the <b>Event Generator</b> field.

Table 65. Log File protocol parameters (continued)

Parameter	Description
<b>FTPS TLS Version</b>	The TLS versions that are compatible with FTPS connections. Select <b>TLS 1.3</b> for the highest level of TLS security. When you select an option that supports multiple versions, the FTPS connection negotiates the latest version that is supported by both the client and the server. <b>TLS 1.3</b> is compatible with QRadar 7.5.0 Update Package 5 and later.  <b>Important:</b> TLS 1.0 and TLS 1.1 are no longer supported by QRadar 7.4.3 Fix Pack 3 and 7.5.0 Candidate Release versions, and subsequent releases will cease supporting them.  <b>Restriction:</b> QRadar supports Explicit FTPS only  If the FTP server supports session reuse, ensure that you disable it in the FTP server configuration file. This configuration option is applicable when FTPS is selected in the <b>Service Type</b> parameter.
<b>SCP Remote File</b>	For SCP file transfers, type the name of the file on the remote host. You can choose only a single file. This parameter does not support adding multiple files, including methods like file globbing or regular expressions.
<b>Start Time</b>	Select the time of day for the log source to start the file import. This parameter works with the <b>Recurrence</b> parameter to establish when and how often the remote directory is scanned for files.
<b>Recurrence</b>	The time interval to determine how frequently the remote directory is scanned for new event log files. The time interval can include values in hours (H), minutes (M), or days (D). For example, a recurrence of 2H scans the remote directory every 2 hours.
<b>Run On Save</b>	Starts the log file import immediately after you save the log source configuration. When selected, this checkbox clears the list of previously downloaded and processed files. After the first file import, the Log File protocol follows the start time and recurrence schedule that the administrator defines.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.
<b>Processor</b>	If the files on the remote host are stored in an archive format, select the processor that is used to decompress the event log. If the files are not stored in an archive format, select <b>None</b> . The default value is <b>None</b> .
<b>Ignore Previously Processed File(s)</b>	Select this checkbox to track files that the log source processes. This option prevents duplicate events from files that are processed a second time. This checkbox applies to FTP and SFTP file transfers.
<b>Change Local Directory</b>	Changes the local directory on the <b>Target Event Collector</b> to store event logs before they are processed.
<b>Local Directory</b>	The local directory on the <b>Target Event Collector</b> . The directory must exist before the Log File protocol attempts to retrieve events.

Table 65. Log File protocol parameters (continued)

Parameter	Description
<b>Event Generator</b>	<p>Choose one of the following file types to use as an event generator for the protocol.</p> <p><b>LineByLine</b> Each line is processed as a single event. A 10 line file creates 10 separate events.</p> <p><b>HPTandem</b> The file is processed as a HPTandem NonStop binary audit log. Each record in the log file (whether primary or secondary) is converted into text and processed as a single event. HPTandem audit logs use the following file name pattern: [aA]\d{7}.</p> <p><b>WebSphere Application Server</b> Processes event logs for WebSphere Application Server. The remote directory must define the file path that is configured in the DSM.</p> <p><b>W3C</b> Processes log files from sources that use the W3C format. The header of the log file identifies the order and data that is contained in each line of the file.</p> <p><b>Fair Warning</b> Processes log files from Fair Warning devices that protect patient identity and medical information. The remote directory must define the file path to the event logs that the Fair Warning device generates.</p> <p><b>DPI Subscriber Data</b> The file is processed as a DPI statistic log produced by a Juniper Networks MX router. The header of the file identifies the order and data that is contained in each line of the file. Each line in the file after the header is formatted to a tab-delimited name=value pair event.</p> <p><b>SAP Audit Logs</b> Process files for SAP Audit Logs to keep a record of security-related events in SAP systems.</p> <p><b>Oracle BEA WebLogic</b> Processes files for Oracle BEA WebLogic application log files.</p> <p><b>Juniper SBR</b> Processes the event log files from Juniper Steel-belted RADIUS.</p> <p><b>ID-Linked Multiline</b> Processes multiline event logs that contain a common value at the start of each line in a multiline event message. This option uses regular expressions to identify and reassemble the multiline event in to single event payload.</p> <p><b>Line Matcher</b> Iterates through the lines until a line is found that matches the pattern, and discards any lines that do not match the pattern.</p> <p><b>Oracle OS XML Audit</b> Processes the audit log produced by Oracle Database.</p> <p><b>Oracle OS Multiline Audit</b> Processes multiline Oracle Audit logs that contains audit information like action, user, status, and so on.</p> <p><b>RegEx Based Multiline</b> Iterates through the lines based on the start pattern, end pattern, and ignore pattern of the provided regular expressions, and discards any lines in the stream that do not match the patterns.</p>

Table 65. Log File protocol parameters (continued)

Parameter	Description
<b>File Encoding</b>	The character encoding that is used by the events in your log file.
<b>Message ID Pattern</b>	Type a regular expression (regex) that identifies a common value at the start of each line in a multiline event message.
<b>Folder Separator</b>	The character that is used to separate folders for your operating system. Most configurations can use the default value in the <b>Folder Separator</b> field. This field is intended for operating systems that use a different character to define separate folders. For example, periods that separate folders on mainframe systems.
<b>Start Pattern RegEx</b>	Type a regular expression (regex) that identifies the start pattern of each line.
<b>End Pattern RegEx</b>	Type a regular expression (regex) that identifies the end pattern of each line.
<b>Ignore Pattern RegEx</b>	Type a regular expressions (regex) to exclude a specific pattern in each line.
<b>Date Time RegEx</b>	Type a regular expression (regex) that identifies the date and time format of each line.
<b>Date Time Format</b>	Type a date and time format to identify the start of an event from each line.

## Configure QRadar to use FTPS for the Log File protocol

To configure FTPS for the Log File protocol, you must place server SSL certificates on all QRadar Event Collectors that connect to your FTP server. If your SSL certificate is not RSA 2048, create a new SSL certificate.

The following command provides an example of creating a certificate on a LINUX system by using OpenSSL:

```
openssl req -newkey rsa:2048 -nodes -keyout ftpserver.key -x509 -days 365 -out ftpserver.crt
```

Files on the FTP server that have a .crt file extension must be copied to the /opt/qradar/conf/trusted\_certificates directory on each of your Event Collectors.

## Microsoft Azure Event Hubs protocol configuration options

The Microsoft Azure Event Hubs protocol is an outbound and active protocol for IBM Security QRadar that collects events from Microsoft Azure Event Hubs.

**Important:** By default, each Event Collector can collect events from up to 1000 partitions before it runs out of file handles. If you want to collect from more partitions, you can contact IBM Support for advanced tuning information and assistance. For more information, see [IBM Support](#).

The following parameters require specific values to collect events from Microsoft Azure Event Hubs appliances:

Table 66. Microsoft Azure Event Hubs log source parameters

Parameter	Value
<b>Authentication Method</b>	<p>This drop-down field is used to select the authentication method for Azure Event Hub. It supports the following two options:</p> <p><b>SAS (Shared Access Signature)</b>: Connection string-based authentication. (Default Selection)</p> <p><b>Entra ID</b>: Authentication is provided by Tenant ID, Client ID, and Client Secret.</p>
<b>Use Event Hub Connection String</b>	<p>Authenticate with an Azure Event Hub by using a connection string.</p> <p><b>Note:</b> The ability to toggle this switch to off is deprecated.</p> <p><b>Note:</b> Select <b>Authentication Method &gt; SAS (Shared Access Signature)</b> to make this parameter available.</p>
<b>Event Hub Connection String</b>	<p>Authorization string that provides access to an Event Hub. For example,</p> <pre>Endpoint=sb://&lt;Namespace Name&gt;.servicebus.windows.net/;SharedAccessKeyNam Key Name&gt;;SharedAccessKey=&lt;SAS Key&gt;;EntityPath=&lt;Event Hub Name&gt;</pre> <p><b>Note:</b> Select <b>Authentication Method &gt; SAS (Shared Access Signature)</b> to make this parameter available.</p>
<b>Tenant ID</b>	<p>Used for Azure AD authentication.</p> <p><b>Note:</b> Select <b>Authentication Method &gt; Entra ID</b> to make this parameter available.</p>
<b>Client ID</b>	<p>The Client ID is a public identifier that is used by OAuth2 for authentication.</p> <p><b>Note:</b> Select <b>Authentication Method &gt; Entra ID</b> to make this parameter available.</p>
<b>Client Secret</b>	<p>The Client Secret is used to ensure that the user is authorized to obtain an access token. The Client Secret is a password that is only available to the user when it is created. Afterward, it can be obtained only from memory or a written copy.</p> <p><b>Note:</b> Select <b>Authentication Method &gt; Entra ID</b> to make this parameter available.</p>
<b>Namespace</b>	<p>The name of the top-level directory that contains the Event Hub entities.</p> <p><b>Note:</b> Select <b>Authentication Method &gt; Entra ID</b> to make this parameter available.</p>

Table 66. Microsoft Azure Event Hubs log source parameters (continued)

Parameter	Value
<b>Event Hub Name</b>	The identifier for the Event Hub that you want to access. The Event Hub Name must match one of the Event Hub entities within the namespace.  <b>Note:</b> Select <b>Authentication Method</b> > <b>Entra ID</b> to make this parameter available.
<b>Consumer Group</b>	Specifies the view that is used during the connection. Each <b>Consumer Group</b> maintains its own session tracking. Any connection that shares consumer groups and connection information shares session tracking information.
<b>Use Storage Account Connection String</b>	Authenticates with an Azure Storage Account by using a connection string.  <b>Note:</b> The ability to toggle this switch to off is deprecated.
<b>Storage Account Connection String</b>	Authorization string that provides access to a Storage Account. <ul style="list-style-type: none"> <li>Access Key example:  <pre>DefaultEndpointsProtocol=https;AccountName=&lt;Storage Account Name&gt;;AccountKey=&lt;Storage Account Key&gt;;EndpointSuffix=core.windows.net</pre> </li> <li>Shared Access Signature example:  <pre>BlobEndpoint=&lt;Blob Endpoint&gt;;QueueEndpoint=&lt;Queue Endpoint&gt;;FileEndpoint=&lt;File Endpoint&gt;;TableEndpoint=&lt;Table Endpoint&gt;;SharedAccessSignature=&lt;Access Signature&gt;</pre> </li> </ul>
<b>Format Azure Linux Events To Syslog</b>	Formats Azure Linux logs to a single-line syslog format that resembles standard syslog logging from Linux systems.
<b>Convert VNet Flow Logs to IPFIX</b>	Microsoft Azure VNet Flow Logs.  Select this option to send flow logs to the <b>Network Activity</b> tab in QRadar.
<b>Flow HostName</b>	Enable <b>Convert VNet Flow Logs to IPFIX</b> to configure this parameter.  The flow processor hostname where the Microsoft Azure VNet Flow Logs are sent.
<b>Flow Port</b>	Enable <b>Convert VNet Flow Logs to IPFIX</b> to configure this parameter.  The flow processor port where the Microsoft Azure VNet Flow Logs are sent.

Table 66. Microsoft Azure Event Hubs log source parameters (continued)

Parameter	Value
<b>Use as a Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.</p> <p>When you select this option, the <b>Log Source Identifier Pattern</b> can optionally be used to define a custom <b>Log Source Identifier</b> for events that are being processed.</p>
<b>Log Source Identifier Pattern</b>	<p>When the <b>Use As A Gateway Log Source</b> option is selected, use this option to define a custom log source identifier for events that are processed. If the <b>Log Source Identifier Pattern</b> is not configured, QRadar receives events as unknown generic log sources.</p> <p>The <b>Log Source Identifier Pattern</b> field accepts key-value pairs, such as <b>key</b>=value, to define the custom Log Source Identifier for events that are being processed and for log sources to be automatically discovered when applicable. <b>Key</b> is the Identifier Format String, which is the resulting source or origin value. Value is the associated regex pattern that is used to evaluate the current payload. The value (regex pattern) also supports capture groups, which can be used to further customize the key (Identifier Format String).</p> <p>Multiple key-value pairs can be defined by typing each pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show the multiple key-value pair functionality:</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>

Table 66. Microsoft Azure Event Hubs log source parameters (continued)

Parameter	Value
<b>Use Predictive Parsing</b>	If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.  Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.
<b>Use Proxy</b>	When you configure a proxy, all traffic for the log source travels through the proxy to access the Azure Event Hub. After you enable this parameter, configure the <b>Proxy IP or Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not need authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.  <b>Note:</b> Digest Authentication for Proxy is not supported in the Java SDK for Azure Event Hubs. For more information, see <a href="https://docs.microsoft.com/en-us/azure/event-hubs/sdk">Azure Event Hubs - Client SDKs</a> ( <a href="https://docs.microsoft.com/en-us/azure/event-hubs/sdk">https://docs.microsoft.com/en-us/azure/event-hubs/sdk</a> ).
<b>Proxy IP or Hostname</b>	The IP address or hostname of the proxy server.  This parameter appears when <b>Use Proxy</b> is enabled.
<b>Proxy Port</b>	The port number used to communicate with the proxy. The default value is 8080.  This parameter appears when <b>Use Proxy</b> is enabled.
<b>Proxy Username</b>	The username for accessing the proxy server.  This parameter appears when <b>Use Proxy</b> is enabled.
<b>Proxy Password</b>	The password for accessing the proxy server.  This parameter appears when <b>Use Proxy</b> is enabled.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

The following table describes the Microsoft Azure Event Hubs log source parameters that are deprecated:

Table 67. Deprecated Microsoft Azure Event Hubs log source parameters

Parameter	Value
<b>Deprecated - Namespace Name</b>	This option displays if <b>Use Event Hub Connection String</b> option is set to off.  The name of the top-level directory that contains the Event Hub entities in the Microsoft Azure Event Hubs user interface.
<b>Deprecated - Event Hub Name</b>	This option displays if <b>Use Event Hub Connection String</b> option is set to off.  The identifier for the Event Hub that you want to access. The <b>Event Hub Name</b> must match one of the Event Hub entities within the namespace.
<b>Deprecated - SAS Key Name</b>	This option displays if <b>Use Event Hub Connection String</b> option is set to off.  The Shared Access Signature (SAS) name identifies the event publisher.
<b>Deprecated - SAS Key</b>	This option displays if <b>Use Event Hub Connection String</b> option is set to off.  The Shared Access Signature (SAS) key authenticates the event publisher.
<b>Deprecated - Storage Account Name</b>	This option displays if <b>Use Storage Account Connection String</b> option is set to off.  The name of the storage account that stores Event Hub data.  The <b>Storage Account Name</b> is part of the authentication process that is required to access data in the Azure Storage Account.
<b>Deprecated - Storage Account Key</b>	This option displays if <b>Use Storage Account Connection String</b> option is set to off.  An authorization key that is used for storage account authentication.  The <b>Storage Account Key</b> is part of the authentication process that is required to access data in the Azure Storage Account.

### Related concepts

[“Gateway log source” on page 15](#)

Use a gateway log source to configure a protocol to use many Device Support Modules (DSMs) instead of relying on a single DSM type. With a gateway log source, event aggregator protocols can dynamically handle various event types.

### Related information

[Adding a log source](#)

# Configuring Microsoft Azure Event Hubs to communicate with QRadar

The Microsoft Azure Event Hubs protocol collects events that are inside an Event Hub. This protocol collects events regardless of source provided they are inside the Event Hub. However, these events might not be parsable by an existing DSM.

## Before you begin

To retrieve events in QRadar, you need to create a Microsoft Azure Storage Account and an Event Hub entity under the Azure Event Hub Namespace. For every Namespace, port 5671 must be open. For every Storage Account, port 443 must be open.

The Namespace hostname is usually [Namespace Name].servicebus.windows.net and the Storage Account hostname is usually [Storage\_Account\_Name].blob.core.windows.net. The Event Hub must have at least one Shared Access Signature that is created with Listen Policy and at least one Consumer Group.

## Procedure

1. Obtain a Microsoft Azure storage account connection string by using one of the following methods.

- If you want a log source that has full access to all permissions, obtain an access key. See step [“2” on page 166](#).
- If you want a log source with specific permissions for access, create a shared access signature (SAS). See step [“3” on page 167](#).

**Important:** To connect to a Microsoft Azure Event Hub, you must be able to create a block blob on the Azure Storage Account you select. Page and append blob types are not compatible with the Microsoft Azure Event Hubs Protocol.

For more information, see [Introduction to Azure Blob storage](https://docs.microsoft.com/en-us/azure/storage/blobs/storage-blobs-introduction) (<https://docs.microsoft.com/en-us/azure/storage/blobs/storage-blobs-introduction>) and [Understanding Block Blobs, Append Blobs, and Page Blobs](https://docs.microsoft.com/en-us/rest/api/storageservices/understanding-block-blobs--append-blobs--and-page-blobs) (<https://docs.microsoft.com/en-us/rest/api/storageservices/understanding-block-blobs--append-blobs--and-page-blobs>). For further help, see [Microsoft Support](https://azure.microsoft.com/en-us/support/options) (<https://azure.microsoft.com/en-us/support/options>).

2. Obtain a Microsoft Azure Storage Account Connection String and access key.

Use this method to obtain values that give the log source full access to the storage account.

The **Storage Account Connection String** contains authentication for the **Storage Account Name** and the **Storage Account Key** that is used to access the data in the Azure Storage account.

- a) Log in to the [Azure Portal](https://portal.azure.com). (<https://portal.azure.com>)
- b) From the dashboard, in the **All resources** section, select a **Storage account**.
- c) From the **All types** list, disable **Select All**. In the filter items search box, type **Storage Accounts**, and then select **Storage Accounts** from the list.
- d) From the **Storage account** menu, select **Access keys**.
- e) Record the value for the **Storage account name**. Use this value for the **Storage Account Name** parameter value when you configure a log source in IBM QRadar.
- f) From the **key 1** or **key 2** section, record the following values.
  - **Key** - Use this value for the **Storage Account Key** parameter value when you configure a log source in QRadar.
  - **Connection string** - Use this value for the **Storage Account Connection String** parameter value when you configure a log source in QRadar.

### Example:

```
DefaultEndpointsProtocol=https;AccountName=[Storage Account Name]  
;AccountKey=[Storage Account Key];EndpointSuffix=core.windows.net
```

Most storage accounts use core.windows.net for the end-point suffix, but this value can change depending on its location. For example, a government-related storage account might have a different endpoint suffix value. You can use the **Storage Account Name** and **Storage Account Key** values, or you can use the **Storage Account Connection String** value to connect to the Storage Account. You can use key1 or key2.

QRadar creates a container that is named qradar in the provided storage blob.

**Tip:** Through the Azure Event Hubs SDK, QRadar uses a container in the configured storage account blob to track event consumption from the Event Hub. A container that is named qradar is automatically created to store the tracking data, or you can manually create the container.

### 3. Generate a shared access signature (SAS).

Use this method to obtain values to give the log source specific permissions for accessing the storage account.

- a) Log in to the [Azure Portal](https://portal.azure.com). (<https://portal.azure.com>)
- b) From the dashboard, in the **All resources** section, select a **Storage account**.
- c) From the **All types** list, disable **Select All**. In the filter items search box, type **Storage Accounts**, and then select **Storage Accounts** from the list.
- d) From the **Storage account** menu, select **Shared access signature**.
- e) Configure a SAS with the following permissions:

**Important:** These permissions are the minimum amount that you must give to your SAS, so QRadar can access Microsoft Azure. You can give the SAS more permissions.

Permission	Value
Allowed services	Blob
Allowed resource types	Container Object
Allowed permissions	Read Write Delete List

f) Click **Generate SAS and connection string**.

g) Record the following value:

**Shared access signature** - Use this value for the **Storage Account Connection String** parameter value when you configure a log source in QRadar.

**Example:**

```
BlobEndpoint=[BlobEndpoint];QueueEndpoint=[QueueEndpoint];FileEndpoint=[FileEndpoint];TableEndpoint=[TableEndpoint];SharedAccessSignature=[Access Signature]
```

### 4. Obtain a Microsoft Azure Event Hub Connection String.

The Event Hub Connection String contains the **Namespace Name**, the path to the Event Hub within the namespace and the Shared Access Signature (SAS) authentication information.

- a) Log in to the [Azure Portal](https://portal.azure.com) (<https://portal.azure.com>).
- b) From the dashboard, in the **All resources** section, select an Event Hub. Record this value to use as the **Namespace Name** parameter value when you configure a log source in QRadar.
- c) In the **Entities** section, select **Event Hubs**. Record this value to use for the **Event Hub Name** parameter value when you configure a log source in QRadar.

- d) From the **All types** list, disable **Select All**. In the **filter items** search box, type event hub, and then select **Event Hubs Namespace** from the list.
- e) In the Event Hub section, select the event hub that you want to use from the list. Record this value to use for the Event Hub Name parameter value when you configure a log source in QRadar.
- f) In the **Settings** section, select **Shared access policies**.

**Important:** In the Entities section, ensure that the Consumer Groups option is listed. If Event Hubs is listed, return to Step c.

- i) Select a **POLICY** that contains a **Listen CLAIMS**. Record this value to use for the **SAS Key Name** parameter value when you configure a log source in QRadar.
- ii) Record the values for the following parameters:

#### Primary key or Secondary key

Use the value for the **SAS Key** parameter value when you configure a log source in QRadar. The Primary key and Secondary key are functionally the same.

#### Connection string-primary key or Connection string-secondary key

Use this value for the **Event Hub Connection String** parameter value when you configure a log source in QRadar. The Connection string-primary key and Connection string-secondary key are functionally the same.

#### Example:

```
Endpoint=sb://[Namespace Name].servicebus.windows.net
;/SharedAccessKeyName=[SAS Key Name];SharedAccessKey=[SAS Key];
EntityPath=[Event Hub Name]
```

You can use the **Namespace Name**, **Event Hub Name**, **SAS Key Name** and **SAS Key** values, or you can use the **Event Hub Connection String** value to connect to the Event Hub.

5. In the **Entities** section, select **Consumer groups**. Record the value to use for the **Consumer Group** parameter value when you configure a log source in QRadar.

**Important:** Do not use the **\$Default** consumer group that is automatically created. Use an existing consumer group that is not in use or create a new consumer group. Each consumer group must be used by only one device, such as QRadar.

## Configuring VNet Flow Logs on the Microsoft Azure portal

The **Virtual Network (VNet) Flow Logs** event is a feature of Microsoft Azure Network Watcher. You can use the flow logs to log information about the IP traffic that is flowing through a virtual network.

### Before you begin

To configure the **VNet flow logs** in the [Microsoft Azure](#), complete the below prerequisites.

1. Configure **Event Hub**, **Consumer Group** and **Storage Account**.

**Attention:** If these tools are already created in your azure portal, you can skip the create process and gather the name of the tool.

2. Create a **Resource Group** for the same **Region** as that of the **VNet flow logs**. For more information, see [Create resource groups](#).
3. Create a new **Event Hubs namespace** and enter the **Resource Group** and **Region**. For more information, see [Create an Event Hubs namespace](#).
  - a. Create an **Event Hub** under the **Event Hub namespace**. For more information, see [Create an event hub](#).

4. Create a shared access policy under the **Event Hub**. Assign **Send** and **Listen** access and configure the **Event Hub Connection String**.
5. Create a consumer group under the **Event Hub**.
6. From the Storage Account's Access Key, fetch the **Storage Account Connection String**.

## Procedure

1. Create a **Virtual Network** with data traffic before you enable the **VNet flow logs**. For more information, see [Create a virtual network and an Azure Bastion host](#).
2. Create a **Log Analytics Workspace** by entering the **Resource Group** and **Region**. For more information, see [Create a Log Analytics workspace](#).
3. Enable **Network Watcher** and add the **Region** for which you are configuring the **VNet flow logs**. For more information, see [Enable Network Watcher for your region](#).
4. Enable **VNet flow log**.
  - a) Gather the **Region**, the **Virtual Network**, the **Storage Account**, and the **Log Analytics Workspace**.
  - b) Enter the information in the below command. For more information, see [Create, change, enable, disable, or delete VNet flow logs using the Azure CLI](#).

```
az network watcher flow-log create --location <region> --name <myVNetFlowLog> --resource-group <myResourceGroup> --vnet <myVNet> --storage-account <myStorageAccount> --workspace <myWorkspace> --interval 10 --traffic-analytics true
```

5. Create **Traffic Analytics**.
  - a) Navigate to the **Log Analytics Workspace**.
  - b) Select **Data Export** and click **Create Export Rule**.
  - c) Enter the rule **Name** and select the table name **NTANetAnalytics**.
  - d) Select **Event Hub** as the **Destination** name.
  - e) Enter a **Subscription**.
  - f) Enter the **Event Hub Workspace** name and **Event Hub** name.
  - g) Click **Create**.
6. After completing the above steps, add the **Event Hub Connection String**, **Consumer Group** name and **Storage Account String** to the **Log Source**. The events are now recorded as per the configurations.

## Troubleshooting Microsoft Azure Event Hubs protocol

To resolve issues with the Microsoft Azure Event Hubs protocol use the troubleshooting and support information. Find the errors by using the protocol testing tools in the QRadar Log Source Management app.

### General troubleshooting

The following steps apply to all user input errors. The general troubleshooting procedure contains the first steps to follow any errors with the Microsoft Azure Event Hubs protocol.

1. If the **Use Event Hub Connection String** or **Use Storage Account Connection String** option is set to off, switch it to **On**. For more information about getting the connection strings, see [Configuring Microsoft Azure Event Hubs to communicate with QRadar](#).

2. Confirm that the Microsoft Azure event hub connection string follows the format in the following example. Ensure that the **entityPath** parameter value is the name of your event hub.

```
Endpoint=sb://<Namespace  
Name>.servicebus.windows.net/;SharedAccessKeyName=<SAS Key  
Name>;SharedAccessKey=<SAS Key>;EntityPath=<Event Hub Name>
```

After the log source is saved and closed, for security reasons, you can no longer see the entered values. If you don't see the values, enter them and then confirm their validity.

3. Confirm that the Microsoft Azure storage account connection string follows the format of the following example.

```
DefaultEndpointsProtocol=https;AccountName=<Storage Account  
Name>;AccountKey=<Storage Account Key>;EndpointSuffix=core.windows.net
```

After the log source is saved and closed, for security reasons, you can no longer see the entered values. If you don't see the values, reenter them and then confirm their validity.

4. Optional: For troubleshooting, set **Use As a Gateway Log Source** to **Off** and set **Format Azure Linux Events to Syslog** to **On**. This forces all events to go through the selected log source type. This can quickly determine whether minimum events are arriving and that there is no network or access issue.

If you leave **Use As a Gateway Log Source** set to **On**, ensure that the events are not arriving in QRadar as **unknown, stored, or sim-generic**. If they are, it might explain why the protocol appears to be not working.

5. Ensure that the provided consumer group exists for the selected event hub. For more information, see [Configuring Microsoft Azure Event Hubs to communicate with QRadar](#).
6. Enable the **Automatically Acquire Server Certificate** option or confirm that the certificate is manually added in QRadar.
7. Ensure that the QRadar system time is accurate; if the system time is not in real time, you might have network issues.
8. Ensure that the port 443 is open to the storage account host. The storage account host is usually `<Storage_Account_Name>.<something>`, where `<something>` usually refers to the endpoint suffix.
9. Ensure that port 5671 is open on the event hub host. The event hub host is usually the `<Endpoint>` from the event hub connection string.

For more information, see:

- [“Illegal connection string format exception” on page 170](#)
- [“Storage exception” on page 171](#)
- [“Illegal Entity exception” on page 172](#)
- [“URI Syntax exception” on page 172](#)
- [“Invalid key exception” on page 173](#)
- [“Timeout exception” on page 173](#)
- [“Other exceptions” on page 174](#)
- [“Microsoft Azure Event Hubs protocol FAQ” on page 174](#)

## Illegal connection string format exception

### Symptoms

Error: “Ensure that the Event Hub Connection String or Event Hub parameters are valid.”

“This exception is thrown when the Event Hub Connection String or Event Hub information that is provided does not meet the requirements to be a valid connection string. An attempt will be made to query for content at the next retry interval.”

## Causes

The **Event Hub Connection String** doesn't match the specifications set by Microsoft. This error can also occur if unexpected characters, such as white space, are copied into the event hub connection string.

## Resolving the problem

Follow these steps to resolve your illegal connection string error.

1. Ensure that the storage account connection string is valid and appears in a similar format to the following example:

```
Endpoint=sb://<Namespace  
Name>.servicebus.windows.net/;SharedAccessKeyName=<SAS Key  
Name>;SharedAccessKey=<SAS Key>;EntityPath=<Event Hub Name>
```

2. When you move the event hub connection string from the Azure portal to IBM QRadar, ensure that no additional white space or invisible characters are added. Alternatively, before you copy the string, ensure that you don't copy any additional characters or white space.

## Storage exception

### Symptoms

Error: "Unable to connect to the Storage Account **[Storage Account Name]**. Ensure that the Storage Account Connection String is valid and that QRadar can connect to **[Storage Account Host Name]**."

"An error occurred that represents an exception for the Microsoft Azure Storage Service. An attempt will be made to query for content at the next retry interval."

### Causes

Storage exception errors represent issues that occur when you authenticate with a storage account or when you communicate with a storage account. An attempt is made to query for content at the next retry interval. There are two common issues that might occur due to a storage exception.

1. The storage account connection string is invalid.
2. Network issues are preventing QRadar from communicating with the storage account.

## Resolving the problem

Follow these steps to resolve your storage exception error.

1. Ensure that the storage account connection string is valid and displays in a similar format to the following example.

```
DefaultEndpointsProtocol=https;AccountName=<Storage Account  
Name>;AccountKey=<Storage Account Key>;EndpointSuffix=core.windows.net
```

2. Ensure that QRadar can communicate with the storage account host on port 443.
3. Ensure that QRadar can communicate with the event hub on port 5671.
4. Verify that the system time in QRadar matches the current time. Security settings on the storage account prevent mismatched times between the server (storage account) and the client (QRadar).
5. Ensure that a certificate is downloaded manually or by using the **Automatically Acquire Server Certificate(s)** option. The certificates are downloaded from <Storage Account Name>.blob.core.windows.net.

## Illegal Entity exception

### Symptoms

Error: "An entity, such as the Event Hub, cannot be found. Verify that the Event Hub information provided is valid. This exception is thrown when the Event Hub Connection String or Event Hub information that is provided does not meet the requirements to be a valid connection string. An attempt will be made to query for content at the next retry interval."

Error: "The messaging entity 'sb://qahub4.servicebus.windows.net/notreal' could not be found. To know more visit <https://aka.ms/sbResourceMgrExceptions>."

Error: "com.microsoft.azure.eventhubs.IllegalEntityException: The messaging entity 'sb://qahub4.servicebus.windows.net/notreal' could not be found. To know more visit <https://aka.ms/sbResourceMgrExceptions>."

### Causes

The event hub (entity) doesn't exist or the event hub connection string doesn't contain a reference to an event hub (entity).

### Resolving the problem

Follow these steps to resolve your illegal entity error.

1. Make sure that the event hub connection string contains the **entitypath** section and that it refers to the event hubs name. For example,

```
Endpoint=sb://<Namespace  
Name>.servicebus.windows.net/;SharedAccessKeyName=<SAS Key  
Name>;SharedAccessKey=[SAS Key];EntityPath=<Event Hub Name>
```

2. Verify that the event hub exists on the Azure portal, and that the event hub path references the **entitypath** that you want to connect to.
3. Verify that the consumer group is created and entered correctly in the **Consumer Group** field.

## URI Syntax exception

### Symptoms

Error: "The Storage Account URI is malformed. Ensure that the Storage Account information is valid and properly formatted. Unable to connect to the host."

Error: "Could not parse text as a URI reference. For more information see the "Raw Error Message". An attempt will be made to query for content at the next retry interval."

### Causes

The URI that is formed from the storage account connection string is invalid. The URI is formed from the **DefaultEndpointsProtocol**, **AccountName**, and **EndpointSuffix** fields. If one of these fields is altered, this exception can occur.

### Resolving the problem

Recopy the Storage Account Connection String from the Azure Portal. It displays similar to the following example:

```
DefaultEndpointsProtocol=https;AccountName=<Storage Accounts  
Name>;AccountKey=<Storage Account Key>;EndpointSuffix=core.windows.net
```

## Invalid key exception

### Symptoms

Error: "The Storage Account Key was invalid. Unable to connect to the host."

Error: "An invalid key was encountered. This error is commonly associated with passwords or authorization keys. For more information see the "Raw Error Message". An attempt will be made to query for content at the next retry interval"

### Causes

The key that is formed from the storage account connection string is invalid. The storage account key is in the connection string. If the key is altered, it might become invalid.

### Resolving the problem

From the Azure portal, recopy the storage account connection string. It displays similar to the following example:

```
DefaultEndpointsProtocol=https;AccountName=<Storage Account Name>;AccountKey=<Storage Account Key>;EndpointSuffix=core.windows.net
```

## Timeout exception

### Symptoms

Error: "Ensure that there are no network related issues preventing the connection. Additionally ensure that the Event Hub and Storage Account Connection Strings are valid."

Error: "The server did not respond to the requested operation within the specified time, which is controlled by OperationTimeout. The server might have completed the requested operation. This exception can be caused by network or other infrastructure delays. An attempt will be made to query for content at the next retry interval."

### Causes

The most common cause is that the connection string information is invalid. The network might be blocking communication, resulting in a timeout. While rare, it is possible that the default timeout period (60 seconds) is not long enough due to network congestion.

### Resolving the problem

Follow these steps to resolve your timeout exception error.

1. When you copy the event hub connection string from the Azure portal to IBM QRadar, ensure that no additional white space or invisible characters are added. Alternatively, before you copy the string, ensure that you don't copy any additional characters or white space.
2. Verify that the storage account connection string is valid and appears in a similar format to the following example:

```
DefaultEndpointsProtocol=https;AccountName=<Storage Account Name>;AccountKey=<Storage Account Key>;EndpointSuffix=core.windows.net
```

3. Ensure that QRadar can communicate with the storage account host on port 443, and with the event hub on ports 5671 and 5672.
4. Ensure that a certificate is downloaded manually or by using the **Automatically Acquire Server Certificate(s)** option. The certificates are downloaded from <Storage Account Name>.blob.core.windows.net.

5. Advanced- There is a hidden parameter that can increase the default timeout from 60 seconds. Contact support for assistance in getting the timeout increased.

## Other exceptions

### Symptoms

Error: "Ensure that there are no network related issues preventing the connection. Additionally ensure that the Event Hub and Storage Account Connection Strings are valid."

Error: "An error occurred. For more information, see the \"Raw Error Message\". An attempt will be made to query for content at the next retry interval"

### Causes

Exceptions in this category are unknown to the protocol and are unexpected. These exceptions can be difficult to troubleshoot and usually require research to resolve.

### Resolving the problem

Follow these steps to resolve your error. They might resolve some of the more common issues.

1. Ensure that the event hub connection string uses the same or a similar format as displayed in the following example:

```
Endpoint=sb://<Namespace  
Name>.servicebus.windows.net/;SharedAccessKeyName=<SAS Key  
Name>;SharedAccessKey=[SAS Key];EntityPath=<Event Hub Name>
```

2. When you move the event hub connection string from the Azure portal to IBM QRadar, ensure that no additional white space or invisible characters are added. Alternatively, before you copy the string, ensure that you don't copy any additional characters or white space.

3. Ensure that the storage account connection string is valid and displays in a similar format to the following example:

```
DefaultEndpointsProtocol=https;AccountName=<Storage Account  
Name>;AccountKey=<Storage Account Key>;EndpointSuffix=core.windows.net
```

4. Ensure that QRadar can communicate with the storage account host on port 443, and with the event hub on port 5671 and 5672.

5. Verify that a certificate is downloaded manually or by using the **Automatically Acquire Server Certificate(s)** option. The certificates are downloaded from <Storage Account Name>.blob.core.windows.net.

6. Verify that the system time in QRadar matches the current time. Security settings on the storage account prevent mismatched times between the server (storage account) and the client (QRadar).

## Microsoft Azure Event Hubs protocol FAQ

Use these frequently asked questions and answers to help you understand the Microsoft Azure Event Hubs protocol.

- “Can I collect <Service/Product> events by using the Microsoft Event Hubs protocol?” on page 176
- “What does the Format Azure Linux Events To Syslog option do?” on page 176

## **Why do I need a storage account to connect to an event hub?**

You must have a storage account for the Microsoft Azure Event Hubs protocol to manage the lease and partitions of an event hub. For more information, see the [Event processor host documentation](https://docs.microsoft.com/en-us/azure/event-hubs/event-hubs-event-processor-host) (<https://docs.microsoft.com/en-us/azure/event-hubs/event-hubs-event-processor-host>).

## **Why does the Microsoft Azure Event Hubs protocol use the storage account?**

The Microsoft Azure Event Hubs protocol uses the storage account to track partition ownership. This protocol creates blob files in the Azure storage account in the <Event Hub Name> → <Consumer group Name> directory. Each blob file relates to a numbered partition that is managed by the event hub. For more information, see the [Event processor host documentation](https://docs.microsoft.com/en-us/azure/event-hubs/event-hubs-event-processor-host) (<https://docs.microsoft.com/en-us/azure/event-hubs/event-hubs-event-processor-host>).

## **How much data does the storage account need to store?**

The amount of data that needs to be stored in a storage account is the number of partitions that are multiplied by ~150 bytes.

## **Does my storage account need to contain events?**

No. Storing the logs in storage is an option that is provided by Microsoft. However, this option is not used by the protocol.

## **What does a blob file that is created by the Microsoft Azure Event Hubs protocol look like?**

The following example shows what is stored in a blob file that is created by the protocol:

```
{"offset": "@latest", "sequenceNumber": 0, "partitionId": "3", "epoch": 8, "owner": "", "token": ""}
```

## **Can I use the same storage account with other event hubs?**

There are no restrictions on how many event hubs can store data in a storage account. You can use the same storage account for all log sources in the same QRadar environment. This creates a single location for all event hub partition management folders and files.

## **What do I do if the protocol isn't collecting events?**

If the protocol appears to be working and the protocol testing tools pass all of the tests, and you don't see events, follow these steps to confirm whether events are posted.

1. Confirm that there are events for the event hub to collect. If the Azure side configuration is not correct, the event hub might not collect the events.
2. If the **Use as a Gateway Log Source** is enabled, do a payload search for events that the Event Hub log source collects. If you are not sure what the events should look like, then go to step 4.
3. If the **Use as a Gateway Log Source** option is enabled, and the protocol is not collecting events, test the same log source with the gateway disabled. By setting the **Use as a Gateway Log Source** to disabled, all collected events are forced to use the log source that is connected to the protocol. If events are arriving when the **Use as a Gateway Log Source** is disabled, but events are not arriving

when **Use as a Gateway Log Source** is enabled, there might be an issue with the log source identifier options or the Traffic Analysis can't automatically match the events to a DSM.

4. If you identified in Step 2 or Step 3 that the events are not coming in under the expected log source, there might be an issue with the event hub log sources *logsourceidentifierpattern*. For issues related to the event hub log source identifier pattern, you might need to contact Support.

## Why do I need to open the ports for two different IPs that have different ports?

You need two different IPs to have different ports open because the Microsoft Azure Event Hub protocol communicates between the event hub host and the storage account host.

The event hub connection uses the Advanced Message Queuing Protocol (AMQP) with ports 5671 and 5672. The storage account uses HTTPS with ports 443. Because the storage account and the event hub have different IPs, you must open two different ports.

## Can I collect <Service/Product> events by using the Microsoft Event Hubs protocol?

The Microsoft Event Hubs protocol collects all events that are sent to the event hub, but not all events are parsed by a supported DSM. For a list of supported DSMs, see [QRadar supported DSMs](#).

## What does the *Format Azure Linux Events To Syslog* option do?

This option takes the Azure Linux event, which is wrapped in a JSON format with metadata, and converts it to a standard syslog format. Unless there is a specific reason that the metadata on the payload is required, enable this option. When this option is disabled, the payloads do not parse with Linux DSMs.

## Microsoft Defender for Endpoint SIEM REST API protocol configuration options

Configure a Microsoft Defender for Endpoint SIEM REST API protocol to receive events from supported Device Support Modules (DSMs).

The Microsoft Defender for Endpoint SIEM REST API protocol is an outbound/active protocol.

**Important:** Due to a change in the Microsoft Defender API suite as of 25 November 2021, Microsoft no longer allows the onboarding of new integrations with their SIEM API. For more information, see [Deprecating the legacy SIEM API](#) (<https://techcommunity.microsoft.com/t5/microsoft-defender-for-endpoint/deprecating-the-legacy-siem-api/ba-p/3139643>).

The Streaming API can be used with the Microsoft Azure Event Hubs protocol to provide event and alert forwarding to QRadar. For more information about the service and its configuration, see [Configure Microsoft 365 Defender to stream Advanced Hunting events to your Azure Event Hub](#) (<https://docs.microsoft.com/en-us/microsoft-365/security/defender/streaming-api-event-hub?view=o365-worldwide>)

The following table describes the protocol-specific parameters for the Microsoft Defender for Endpoint SIEM REST API protocol:

Table 68. Microsoft Defender for Endpoint SIEM REST API protocol	
Parameter	Value
Log Source type	Microsoft 365 Defender
Protocol Configuration	Microsoft Defender for Endpoint SIEM REST API

Table 68. Microsoft Defender for Endpoint SIEM REST API protocol (continued)

Parameter	Value
<b>Log Source Identifier</b>	<p>Type a unique name for the log source.</p> <p>The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b>. If you have more than one configured Microsoft Defender for Endpoint SIEM REST API log source, ensure that you give each one a unique name.</p>
<b>Authorization Server URL</b>	<p>The URL for the server that provides the authorization to obtain an access token. The access token is used as the authorization to collect events from Microsoft 365 Defender.</p> <p>The Authorization Server URL uses the following format:</p> <pre data-bbox="866 783 1432 846">"https://login.microsoftonline.com/&lt;Tenant_ID&gt;/oauth2/token"</pre> <p>where &lt;Tenant_ID&gt; is a UUID.</p>
<b>Resource</b>	The resource that is used to access Microsoft 365 Defender SIEM API events.
<b>Client ID</b>	Ensures that the user is authorized to obtain an access token.
<b>Client Secret</b>	The <b>Client Secret</b> value is displayed only one time, and then is no longer visible. If you don't have access to the <b>Client Secret</b> value, contact your Microsoft Azure administrator to request a new client secret.
<b>Region</b>	Select the regions that are associated with Microsoft 365 Defender SIEM API that you want to collect logs from.
<b>Other Region</b>	<p>Type the names of any additional regions that are associated with the Microsoft 365 Defender SIEM API that you want to collect logs from.</p> <p>Use a comma-separated list; for example, region1,region2.</p>

Table 68. Microsoft Defender for Endpoint SIEM REST API protocol (continued)

Parameter	Value
<b>Use GCC Endpoints</b>	Enable or disable the use of <b>GCC</b> and <b>GCC High &amp; DOD</b> endpoints. <b>GCC</b> and <b>GCC High &amp; DOD</b> endpoints are endpoints for US Government customers.  <b>Tip:</b> When this parameter is enabled, you cannot configure the <b>Regions</b> parameter.  For more information, see Microsoft Defender for Endpoint for US Government customers ( <a href="https://docs.microsoft.com/en-us/microsoft-365/security/defender-endpoint/gov?view=o365-worldwide">https://docs.microsoft.com/en-us/microsoft-365/security/defender-endpoint/gov?view=o365-worldwide</a> ).
<b>GCC Type</b>	Select <b>GCC</b> or <b>GCC High &amp; DOD</b> . <ul style="list-style-type: none"><li>• <b>GCC</b>: Microsoft's Government Community Cloud</li><li>• <b>GCC High &amp; DoD</b>: Compliant with the regulations from Department of Defense.</li></ul>
<b>Use Proxy</b>	If a proxy for QRadar is configured, all traffic for the log source travels through the proxy so that QRadar can access the Microsoft 365 Defender SIEM API.  Configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Recurrence</b>	You can specify how often the log collects data. The format is M/H/D for Minutes/Hours/Days.  The default is 5 M.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

If you need to create virtual machines (VMs) and test the connection between Microsoft Defender for Endpoint and QRadar, see [Microsoft Defender for Endpoint evaluation lab](https://docs.microsoft.com/en-us/microsoft-365/security/defender-endpoint/evaluation-lab?view=o365-worldwide) (<https://docs.microsoft.com/en-us/microsoft-365/security/defender-endpoint/evaluation-lab?view=o365-worldwide>).

## Microsoft DHCP protocol configuration options

To receive events from Microsoft DHCP servers, configure a log source to use the Microsoft DHCP protocol.

The Microsoft DHCP protocol is an active outbound protocol.

To read the log files, folder paths that contain an administrative share (C\$), require NetBIOS privileges on the administrative share (C\$). Local or domain administrators have sufficient privileges to access log files on administrative shares.

Fields for the Microsoft DHCP protocol that support file paths allow administrators to define a drive letter with the path information. For example, the field can contain the c\$/LogFiles/ directory for an administrative share, or the LogFiles/ directory for a public share folder path, but cannot contain the c:/LogFiles directory.

**Restriction:** The Microsoft authentication protocol NTLMv2 is not supported by the Microsoft DHCP protocol.

The following table describes the protocol-specific parameters for the Microsoft DHCP protocol:

Table 69. Microsoft DHCP protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	<b>Microsoft DHCP</b>
<b>Log Source Identifier</b>	Type a unique hostname or other identifier unique to the log source.
<b>Server Address</b>	The IP address or host name of your Microsoft DHCP server.
<b>Domain</b>	Type the domain for your Microsoft DHCP server. This parameter is optional if your server is not in a domain.
<b>Username</b>	Type the user name that is required to access the DHCP server.
<b>Password</b>	Type the password that is required to access the DHCP server.
<b>Confirm Password</b>	Type the password that is required to access the server.
<b>Folder Path</b>	The directory path to the DHCP log files. The default is /WINDOWS/system32/dhcp/
<b>File Pattern</b>	The regular expression (regex) that identifies event logs. The log files must contain a three-character abbreviation for a day of the week. Use one of the following file patterns:  English: <ul style="list-style-type: none"><li>• IPv4 file pattern: DhcpSrvLog- (? :Sun   Mon   Tue   Wed   Thu   Fri   Sat) \.log.</li><li>• IPv6 file pattern: DhcpV6SrvLog- (? :Sun   Mon   Tue   Wed   Thu   Fri   Sat) \.log.</li><li>• Mixed IPv4 and IPv6 file pattern: Dhcp.*SrvLog- (? :Sun   Mon   Tue   Wed   Thu   Fri   Sat) \.log.</li></ul> Polish: <ul style="list-style-type: none"><li>• IPv4 file pattern: DhcpSrvLog- (? :Pią   Pon   Sob   Wto   Śro   Czw   Nie) \.log</li><li>• IPv6 file pattern: DhcpV6SrvLog- (? :Pt   Pon   So   Wt   Śr   Czw   Nie) \.log</li></ul>

Table 69. Microsoft DHCP protocol parameters (continued)

Parameter	Description
<b>Recursive</b>	Select this option if you want the file pattern to search the sub folders.
<b>SMB Version</b>	<p>Select the version of SMB that you want to use.</p> <p><b>AUTO</b> Auto-detects to the highest version that the client and server agree to use.</p> <p><b>SMB1</b> Forces the use of SMB1. SMB1 uses the <code>jCIFS.jar</code> (Java ARchive) file.</p> <p><b>Important:</b> SMB1 is no longer supported. All administrators must update existing configurations to use SMB2 or SMB3.</p> <p><b>SMB2</b> Forces the use of SMB2. SMB2 uses the <code>jNQ.jar</code> file.</p> <p><b>SMB3</b> Forces the use of SMB3. SMB3 uses the <code>jNQ.jar</code> file.</p> <p><b>Note:</b> Before you create a log source with a specific SMB version (for example: SMBv1, SMBv2, and SMBv3), ensure that the specified SMB version is supported by the Windows OS that is running on your server. You also need to verify that SMB versions is enabled on the specified Windows Server.</p> <p>For more information about which Windows version supports which SMB versions, go to the Microsoft TechNet website (<a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/</a>).</p> <p>For more information about how to detect, enable and disable SMBv1, SMBv2, and SMBv3 in Windows and Windows Server, go to the Microsoft support website (<a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server</a>).</p>
<b>Polling Interval (in seconds)</b>	The number of seconds between queries to the log files to check for new data. The minimum polling interval is 10 seconds. The maximum polling interval is 3,600 seconds.
<b>Throttle events/sec</b>	The maximum number of events the DHCP protocol can forward per second. The minimum value is 100 EPS. The maximum value is 20,000 EPS.
<b>File Encoding</b>	The character encoding that is used by the events in your log file.

Table 69. Microsoft DHCP protocol parameters (continued)

Parameter	Description
<b>File Exclusion List</b>	<p>A list of regular expressions that prevent certain file directories from opening. The list includes one regular expression per line.</p> <p>When a file or directory matches one of the regular expressions, that file or directory does not open. When a file is in use, other applications might not be able to use it. Use this parameter to prevent locking those files or to prevent the protocol from accessing specific files.</p> <p>The pattern does not apply to the full Folder Path. It applies only to the final directory that is listed in the path. The pattern applies against all files or directories that are found within the Folder Path's directory.</p> <p>The following list is the default value for this parameter:</p> <pre>/j50.*\log dhcp\.mdb dhcp\.tmp j50\.chk.</pre>
<b>Enabled</b>	When this option is not enabled, the log source does not collect events and the log source is not counted in the license limit.
<b>Credibility</b>	Credibility is a representation of the integrity or validity of events that are created by a log source. The credibility value that is assigned to a log source can increase or decrease based on incoming events or adjusted as a response to user-created event rules. The credibility of events from log sources contributes to the calculation of the offense magnitude and can increase or decrease the magnitude value of an offense.
<b>Target Event Collector</b>	<p>Specifies the QRadar Event Collector that polls the remote log source.</p> <p>Use this parameter in a distributed deployment to improve Console system performance by moving the polling task to an Event Collector.</p>
<b>Coalescing Events</b>	<p>Increases the event count when the same event occurs multiple times within a short time interval. Coalesced events provide a way to view and determine the frequency with which a single event type occurs on the <b>Log Activity</b> tab.</p> <p>When this check box is clear, events are viewed individually and events are not bundled.</p> <p>New and automatically discovered log sources inherit the value of this check box from the <b>System Settings</b> configuration on the <b>Admin</b> tab. You can use this check box to override the default behavior of the system settings for an individual log source.</p>

## Microsoft Exchange protocol configuration options

To receive events from SMTP, OWA, and message tracking events from Microsoft Windows Exchange 2007, 2010, 2013 and 2017 servers, configure a log source to use the Microsoft Exchange protocol.

The Microsoft Exchange protocol is an outbound/active protocol.

To read the log files, folder paths that contain an administrative share (C\$), require NetBIOS privileges on the administrative share (C\$). Local or domain administrators have sufficient privileges to access log files on administrative shares.

Fields for the Microsoft Exchange protocol that support file paths allow administrators to define a drive letter with the path information. For example, the field can contain the c\$/LogFiles/ directory for an administrative share, or the LogFiles/directory for a public share folder path, but cannot contain the c:/LogFiles directory.

**Important:** The Microsoft Exchange protocol does not support Microsoft Exchange 2003 or Microsoft authentication protocol NTLMv2 Session.

The following table describes the protocol-specific parameters for the Microsoft Exchange protocol:

<i>Table 70. Microsoft Exchange protocol parameters</i>	
<b>Parameter</b>	<b>Description</b>
<b>Protocol Configuration</b>	<b>Microsoft Exchange</b>
<b>Log Source Identifier</b>	Type the IP address, host name, or name to identify your log source.
<b>Server Address</b>	The IP address or host name of your Microsoft Exchange server.
<b>Domain</b>	Type the domain for your Microsoft Exchange server. This parameter is optional if your server is not in a domain.
<b>Username</b>	Type the user name that is required to access your Microsoft Exchange server.
<b>Password</b>	Type the password that is required to access your Microsoft Exchange server.
<b>Confirm Password</b>	Type the password that is required to access your Microsoft Exchange server.
<b>SMTP Log Folder Path</b>	The directory path to access the SMTP log files. The default file path is Program Files/Microsoft/Exchange Server/ TransportRoles/Logs/ProtocolLog When the folder path is clear, SMTP event collection is disabled.
<b>OWA Log Folder Path</b>	The directory path to access OWA log files. The default file path is Windows/system32/LogFiles/W3SVC1 When the folder path is clear, OWA event collection is disabled.
<b>MSGTRK Log Folder Path</b>	The directory path to access message tracking logs. The default file path is Program Files/Microsoft/Exchange Server/ TransportRoles/Logs/MessageTracking Message tracking is available on Microsoft Exchange 2017 or 2010 servers that are assigned the Hub Transport, Mailbox, or Edge Transport server role.
<b>Use Custom File Patterns</b>	Select this check box to configure custom file patterns. Leave the check box clear to use the default file patterns.

Table 70. Microsoft Exchange protocol parameters (continued)

Parameter	Description
<b>MSGTRK File Pattern</b>	The regular expression (regex) that is used to identify and download the MSTRK logs. All files that match the file pattern are processed. The default file pattern is MSGTRK\d+-\d+\.(?:log LOG)\$ All files that match the file pattern are processed.
<b>MSGTRKMD File Pattern</b>	The regular expression (regex) that is used to identify and download the MSGTRKMD logs. All files that match the file pattern are processed. The default file pattern is MSGTRKMD\d+-\d+\.(?:log LOG)\$ All files that match the file pattern are processed.
<b>MSGTRKMS File Pattern</b>	The regular expression (regex) that is used to identify and download the MSGTRKMS logs. All files that match the file pattern are processed. The default file pattern is MSGTRKMS\d+-\d+\.(?:log LOG)\$ All files that match the file pattern are processed.
<b>MSGTRKMA File Pattern</b>	The regular expression (regex) that is used to identify and download the MSGTRKMA logs. All files that match the file pattern are processed. The default file pattern is MSGTRKMA\d+-\d+\.(?:log LOG)\$ All files that match the file pattern are processed.
<b>SMTP File Pattern</b>	The regular expression (regex) that is used to identify and download the SMTP logs. All files that match the file pattern are processed. The default file pattern is *\.(?:log LOG)\$ All files that match the file pattern are processed.
<b>OWA File Pattern</b>	The regular expression (regex) that is used to identify and download the OWA logs. All files that match the file pattern are processed. The default file pattern is *\.(?:log LOG)\$ All files that match the file pattern are processed.
<b>Force File Read</b>	If the check box is cleared, the log file is read only when QRadar detects a change in the modified time or file size.
<b>Recursive</b>	If you want the file pattern to search sub folders, use this option. By default, the check box is selected.

Table 70. Microsoft Exchange protocol parameters (continued)

Parameter	Description
<b>SMB Version</b>	<p>Select the version of SMB that you want to use.</p> <p><b>AUTO</b> Auto-detects to the highest version that the client and server agree to use.</p> <p><b>SMB1</b> Forces the use of SMB1. SMB1 uses the <code>jCIFS.jar</code> (Java ARchive) file.</p> <p><b>Important:</b> SMB1 is no longer supported. All administrators must update existing configurations to use SMB2 or SMB3.</p> <p><b>SMB2</b> Forces the use of SMB2. SMB2 uses the <code>jNQ.jar</code> file.</p> <p><b>SMB3</b> Forces the use of SMB3. SMB3 uses the <code>jNQ.jar</code> file.</p> <p><b>Note:</b> Before you create a log source with a specific SMB version (for example: SMBv1, SMBv2, and SMBv3), ensure that the specified SMB version is supported by the Windows OS that is running on your server. You also need to verify that SMB versions is enabled on the specified Windows Server.</p> <p>For more information about which Windows version supports which SMB versions, go to the <a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">Microsoft TechNet website</a> (<a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/</a>).</p> <p>For more information about how to detect, enable and disable SMBv1, SMBv2, and SMBv3 in Windows and Windows Server, go to the <a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">Microsoft support website</a> (<a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server</a>).</p>
<b>Polling Interval (in seconds)</b>	Type the polling interval, which is the number of seconds between queries to the log files to check for new data. The default is 10 seconds.
<b>Throttle Events/Sec</b>	The maximum number of events the Microsoft Exchange protocol can forward per second.
<b>File Encoding</b>	The character encoding that is used by the events in your log file.

## Microsoft Graph Security API protocol configuration options

To receive events from the Microsoft Graph Security API, configure a log source in IBM QRadar to use the Microsoft Graph Security API protocol.

The Microsoft Graph Security API protocol is an outbound/active protocol. Your DSM might also use this protocol. For a list of supported DSMs, see [QRadar supported DSMs](#).

The following parameters require specific values to collect events from Microsoft Graph Security servers:

Table 71. Microsoft Graph Security log source parameters

Parameter	Value
<b>Log Source type</b>	A custom log source type or a specific DSM that uses this protocol.
<b>Protocol Configuration</b>	Microsoft Graph Security API
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Microsoft Graph Security log source, ensure that you give each one a unique name.
<b>Tenant ID</b>	The <b>Tenant ID</b> value that is used for Microsoft Azure Active Directory authentication.
<b>Client ID</b>	The <b>Client ID</b> parameter value from your application configuration of Microsoft Azure Active Directory.
<b>Client Secret</b>	You receive the <b>Client Secret</b> password when you configure Microsoft Azure Event Directory. This password confirms that your user account is authorized to obtain an access token. You can obtain this value only when it is created, and it cannot be recovered later. If you lose your client secret password, you must create a new API key to continue to receive events from the Microsoft Graph Security API.
<b>API</b>	The API dictates the types and formats of events that the protocol can collect. Select an API that is compatible with the selected DSM. If you use the Microsoft Azure Security Center DSM, select <b>Alerts V1</b> . If you use the Microsoft 365 Defender DSM, select <b>Alerts V2</b> .
<b>Service</b>	Limits the events to a specific service or product. Select a product that is compatible with the selected DSM. You can use the <b>Other</b> option to remove the filter or to add more filter settings. If you use the Microsoft 365 Defender DSM, select <b>Microsoft Defender for Endpoint</b> .
<b>Event Filter</b>	Retrieve events by using the Microsoft Security Graph API query filter. For example, <code>severity eq 'high'</code> . Do not type "filter=" before the filter parameter. For more information about query parameters, see <a href="https://learn.microsoft.com/en-us/graph/filter-query-parameter?tabs=http">filter query parameter</a> ( <a href="https://learn.microsoft.com/en-us/graph/filter-query-parameter?tabs=http">https://learn.microsoft.com/en-us/graph/filter-query-parameter?tabs=http</a> ).

Table 71. Microsoft Graph Security log source parameters (continued)

Parameter	Value
<b>Use Proxy</b>	If QRadar accesses the Microsoft Graph Security API by proxy, enable this checkbox.  If the proxy requires authentication, configure the <b>Proxy Hostname or IP</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy</b> fields.  If the proxy does not require authentication, configure the <b>Proxy Hostname or IP</b> and <b>Proxy Port</b> fields.
<b>Proxy IP or Hostname</b>	The IP address or hostname of the proxy server.  If the <b>Use Proxy</b> parameter is set to <b>False</b> , this option is hidden.
<b>Proxy Port</b>	The port number that is used to communicate with the proxy. The default is 8080.  If the <b>Use Proxy</b> parameter is set to False, this option is hidden.
<b>Proxy Username</b>	The username that is used to communicate with the proxy.  If <b>Use Proxy</b> is set to <b>False</b> , this option is hidden.
<b>Proxy Password</b>	The password that is used to access the proxy.  If <b>Use Proxy</b> is set to <b>False</b> , this option is hidden.
<b>Recurrence</b>	Type a time interval beginning at the <b>Start Time</b> to determine how frequently the poll scans for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H - 2 hours, 15M - 15 minutes. The default is 1M.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.
<b>Show Advanced Options</b>	To configure the advanced options for event collection, enable this option.
<b>Login Endpoint</b>	Specify the Azure AD Login Endpoint. The default value is <code>login.microsoftonline.com</code> .  If you disable <b>Show Advanced Options</b> , this option is hidden.

Table 71. Microsoft Graph Security log source parameters (continued)

Parameter	Value
<b>Graph API Endpoint</b>	Specify the Microsoft Graph Security API URL. The default value is <code>https://graph.microsoft.com</code> . If you disable <b>Show Advanced Options</b> , this option is hidden.

## Configuring Microsoft Graph Security API to communicate with QRadar

Integrate the Microsoft Graph Security API with IBM QRadar before you use the protocol.

### Before you begin

To integrate the Microsoft Graph Security API with QRadar, you need Microsoft Azure Active Directory.

### Procedure

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console.
  - Protocol Common RPM
  - Microsoft Graph Security API Protocol RPM
2. Configure your Microsoft Graph Security API server to forward events to QRadar by following these instructions:
  - a) Create an Azure AD application. For more information, see [Use the portal to create an Azure AD application and service principal that can access resources](https://docs.microsoft.com/en-us/azure/active-directory/develop/how-to-create-service-principal-portal) (<https://docs.microsoft.com/en-us/azure/active-directory/develop/how-to-create-service-principal-portal>).
  - b) Set up an authorization in security API client applications. For more information, see [Authorization and the Microsoft Graph Security API](https://docs.microsoft.com/en-us/graph/security-authorization) (<https://docs.microsoft.com/en-us/graph/security-authorization>).

When you use the Alerts V1 API, you must include the following app roles in the Access Token:

- `SecurityEvents.Read.All`
- `User.Read.All`
- `SecurityActions.Read.All`
- `IdentityRiskyUser.Read.All`
- `IdentityRiskEvent.Read.All`

#### Important:

When you use the Alerts V2 API, you must include the `SecurityEvents.Read.All` app role. Other types of events can require different roles.

You must designate the app roles with **Application** permissions. If your environment does not accept **Application** permissions, you can use **Delegated** permissions.

3. Add a Microsoft Security Graph API protocol log source on the QRadar Console by using a custom log source type or a specific DSM that uses this protocol.

For more information about supported DSMs, see [QRadar supported DSMs](#). For more information about adding a log source in QRadar, see [Adding a log source](#).

# Migrating Microsoft Defender for Endpoint REST API log sources to Microsoft Graph Security API log sources

Microsoft deprecated the legacy SIEM API. To continue to receive data from Microsoft Defender for Endpoint in IBM QRadar, you must register a new application and create a Microsoft Graph Security API log source to collect the data.

For more information about the SIEM API deprecation, see [Deprecating the legacy SIEM API](https://techcommunity.microsoft.com/t5/microsoft-defender-for-endpoint/deprecating-the-legacy-siem-api/ba-p/3139643) (<https://techcommunity.microsoft.com/t5/microsoft-defender-for-endpoint/deprecating-the-legacy-siem-api/ba-p/3139643>).

## Procedure

1. Register a new application.

When you migrate to the Microsoft Graph Security API, the application permissions change; you must register a new application to ensure that the permissions are correct.

- a) Create an application that can be used to authenticate with the Microsoft Graph Security API.

For more information, see [Use the portal to create an Azure AD application and service principal that can access resources](https://docs.microsoft.com/en-us/azure/active-directory/develop/howto-create-service-principal-portal) (<https://docs.microsoft.com/en-us/azure/active-directory/develop/howto-create-service-principal-portal>).

- b) Set the `SecurityAlert.Read.All` application permission.

- c) On the **Overview** page, you can find the **Client ID** and **Tenant ID**. Copy this information for when you create a log source.

- d) On the **Certificates and Secrets** page, click **New Secret** to create the client secret for the log source. Copy this information for when you create a log source.

2. Create a Microsoft 365 Defender log source that uses the Microsoft Graph Security API protocol.

When you migrate to the Microsoft Graph Security API, you create a new log source to pull events from the new configuration. For more information, see [Adding a log source](#).

The following table describes the parameters that require specific values to collect Microsoft Graph Security API events from Microsoft 365 Defender.

Table 72. Microsoft Graph Security API log source parameters for the Microsoft 365 Defender DSM

Parameter	Value
<b>Log Source type</b>	Microsoft 365 Defender DSM
<b>Protocol Configuration</b>	Microsoft Graph Security API
<b>Tenant ID</b>	Enter the value that you obtained in step 3.
<b>Client ID</b>	Enter the value that you obtained in step 3.
<b>Client Secret</b>	Enter the value that you obtained in step 4.
<b>API</b>	<b>Alerts V2</b>
<b>Service</b>	<b>Microsoft Defender for Endpoint</b>
<b>Show Advanced Options</b>	Enable this parameter to configure the <b>Login Endpoint</b> and <b>Graph API Endpoint</b> parameters.  <b>Important:</b> If your deployment is in a Government Community Cloud (GCC) environment, the <b>Login Endpoint</b> and <b>Graph API Endpoint</b> have specific values. For more information about these values, see <a href="https://docs.microsoft.com/en-us/graph/deployments">National cloud deployments</a> ( <a href="https://docs.microsoft.com/en-us/graph/deployments">https://docs.microsoft.com/en-us/graph/deployments</a> ).

*Table 72. Microsoft Graph Security API log source parameters for the Microsoft 365 Defender DSM (continued)*

Parameter	Value
<b>Login Endpoint</b>	login.microsoftonline.com
<b>Graph API Endpoint</b>	<a href="https://graph.microsoft.com">https://graph.microsoft.com</a>

For more information about the Microsoft Graph Security API protocol parameters, see “[Microsoft Graph Security API protocol configuration options](#)” on page 184.

## Microsoft IIS protocol configuration options

You can configure a log source to use the Microsoft IIS protocol. This protocol supports a single point of collection for W3C format log files that are located on a Microsoft IIS web server.

The Microsoft IIS protocol is an outbound/active protocol.

To read the log files, folder paths that contain an administrative share (C\$), require NetBIOS privileges on the administrative share (C\$). Local or domain administrators have sufficient privileges to access log files on administrative shares.

Fields for the Microsoft IIS protocol that support file paths allow administrators to define a drive letter with the path information. For example, the field can contain the c\$/LogFiles/ directory for an administrative share, or the LogFiles/directory for a public share folder path, but cannot contain the c:/LogFiles directory.

**Restriction:** The Microsoft authentication protocol NTLMv2 is not supported by the Microsoft IIS protocol.

The following table describes the protocol-specific parameters for the Microsoft IIS protocol:

<i>Table 73. Microsoft IIS protocol parameters</i>	
Parameter	Description
<b>Protocol Configuration</b>	<b>Microsoft IIS</b>
<b>Log Source Identifier</b>	Type the IP address, host name, or a unique name to identify your log source.
<b>Server Address</b>	The IP address or host name of your Microsoft IIS server.
<b>Domain</b>	Type the domain for your Microsoft IIS server. This parameter is optional if your server is not in a domain.
<b>Username</b>	Type the user name that is required to access your server.
<b>Password</b>	Type the password that is required to access your server.
<b>Confirm Password</b>	Type the password that is required to access the server.
<b>Log Folder Path</b>	The directory path to access the log files. For example, administrators can use the c\$/LogFiles/ directory for an administrative share, or the LogFiles/ directory for a public share folder path. However, the c:/LogFiles directory is not a supported log folder path.  If a log folder path contains an administrative share (C\$), users with NetBIOS access on the administrative share (C\$) have the privileges that are required to read the log files.  Local system or domain administrator privileges are also sufficient to access a log files that are on an administrative share.

Table 73. Microsoft IIS protocol parameters (continued)

Parameter	Description
<b>File Pattern</b>	The regular expression (regex) that identifies the event logs.
<b>Recursive</b>	If you want the file pattern to search sub folders, use this option. By default, the check box is selected.
<b>SMB Version</b>	<p>Select the version of SMB that you want to use.</p> <p><b>AUTO</b> Auto-detects to the highest version that the client and server agree to use.</p> <p><b>SMB1</b> Forces the use of SMB1. SMB1 uses the <code>jCIFS.jar</code> (Java ARchive) file.</p> <p><b>Important:</b> SMB1 is no longer supported. All administrators must update existing configurations to use SMB2 or SMB3.</p> <p><b>SMB2</b> Forces the use of SMB2. SMB2 uses the <code>jNQ.jar</code> file.</p> <p><b>SMB3</b> Forces the use of SMB3. SMB3 uses the <code>jNQ.jar</code> file.</p> <p><b>Note:</b> Before you create a log source with a specific SMB version (for example: SMBv1, SMBv2, and SMBv3), ensure that the specified SMB version is supported by the Windows OS that is running on your server. You also need to verify that SMB versions is enabled on the specified Windows Server.</p> <p>For more information about which Windows version supports which SMB versions, go to the <a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">Microsoft TechNet website</a> (<a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/</a>).</p> <p>For more information about how to detect, enable and disable SMBv1, SMBv2, and SMBv3 in Windows and Windows Server, go to the <a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">Microsoft support website</a> (<a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server</a>).</p>
<b>Polling Interval (in seconds)</b>	Type the polling interval, which is the number of seconds between queries to the log files to check for new data. The default is 10 seconds.
<b>Throttle Events/Sec</b>	The maximum number of events the IIS protocol can forward per second.
<b>File Encoding</b>	The character encoding that is used by the events in your log file.

**Note:** If you use Advanced IIS Logging, you need to create a new log definition. In the **Log Definition** window, ensure that the following fields are selected in the **Selected Fields** section:

- Date-UTC
- Time-UTC
- URI-Stem
- URI-QueryString

- ContentPath
- Status
- Server Name
- Referer
- Win325Status
- Bytes Sent

## Microsoft Security Event Log protocol configuration options

---

Support for the Windows Event Log protocols ended on 31 October 2022.

**Important:** Support for the Windows Event Log protocols ended on 31 October 2022. To continue collecting Windows Event Log events, you must select a new protocol type from the [Microsoft Windows Security Event Log page](#). For more information, see [QRadar: End of life announcement for WMI-based Microsoft Windows Security Event Log protocols \(31 Oct 2022\)](#) (<https://www.ibm.com/support/pages/node/6616223>).

## Microsoft Security Event Log over MSRPC protocol

The Microsoft Security Event Log over Microsoft Remote Procedure Call (MSRPC) protocol is an active outbound protocol that collects Windows events without an agent that is installed on the Windows host.

The MSRPC protocol uses the Microsoft Distributed Computing Environment (DCE) or Remote Procedure Call (RPC) specification to provide agentless, encrypted event collection.

The following table lists the supported features of the MSRPC protocol.

<i>Table 74. Supported features of the MSRPC protocol</i>	
<b>Features</b>	<b>Microsoft Security Event Log over MSRPC protocol</b>
Maximum EPS rate	100 EPS / Windows host
Maximum overall EPS rate of MSRPC	8500 EPS / IBM QRadar 16xx or 18xx appliance
Maximum number of supported log sources	500 log sources / QRadar 16xx or 18xx appliance
Bulk log source support	Yes
Encryption	Yes
Supported Windows operating systems	Windows Server 2022 (including Core) <a href="#">WinCollect v10.1.2 and later</a> Windows Server 2019 (including Core) Windows Server 2016 (including Core) Windows Server 2012 (including Core) Windows 10 Windows 11 <a href="#">WinCollect v10.1.2 and later</a>

Table 74. Supported features of the MSRPC protocol (continued)

Features	Microsoft Security Event Log over MSRPC protocol
Required permissions	<p>The log source user must be a member of the Event Log Readers group. If this group is not configured, then domain admin privileges are required to poll a Windows event log across a domain. Occasionally, the backup operators group can be used depending on how Microsoft Group Policy Objects are configured.</p> <ul style="list-style-type: none"> <li>• HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\eventlog</li> <li>• HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Nls\Language</li> <li>• HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion</li> </ul>
Required Rational Portfolio Manager (RPM) files	<p>PROTOCOL-WindowsEventRPC-QRadar_release-Build_number.noarch.rpm</p> <p>DSM-MicrosoftWindows-QRadar_release-Build_number.noarch.rpm</p> <p>DSM-DSMCommon-QRadar_release-Build_number.noarch.rpm</p>
Windows service requirements	<ul style="list-style-type: none"> <li>• Remote Procedure Call (RPC)</li> <li>• RPC Endpoint Mapper</li> </ul>
Windows port requirements	<ul style="list-style-type: none"> <li>• TCP port 135</li> <li>• TCP port 445</li> <li>• TCP port that is dynamically allocated for RPC, from port 49152 up to 65535</li> </ul>
Special features	Supports encrypted events by default.
Automatically discovered?	No
Includes identity?	Yes
Includes custom properties?	A security content pack with Windows custom event properties is available on IBM Fix Central.
Intended application	Agentless event collection for Windows operating systems that can support 100 EPS per log source.
Tuning support	MSRPC is limited to 100 EPS per Windows host. For higher event rate systems, see the <i>IBM QRadar WinCollect User Guide</i> .
More information	<a href="http://support.microsoft.com/">Microsoft support (http://support.microsoft.com/)</a>

## MQ protocol configuration options

To receive messages from a message queue (MQ) service, configure a log source to use the MQ protocol. The protocol name displays in IBM QRadar as **MQ JMS**.

IBM MQ is supported.

The MQ protocol is an outbound/active protocol that can monitor multiple message queues, up to a maximum of 50 per log source.

The following table describes the protocol-specific parameters for the MQ protocol:

Table 75. MQ protocol parameters	
Parameter	Description
<b>Protocol Name</b>	<b>MQ JMS</b>
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured MQ log source, ensure that you give each one a unique name.
<b>IP or Hostname</b>	The IP address or host name of the primary queue manager.
<b>Port</b>	The default port that is used for communicating with the primary queue manager is 1414.
<b>Standby IP or Hostname</b>	The IP address or host name of the standby queue manager.
<b>Standby Port</b>	The port that is used to communicate with the standby queue manager.
<b>Queue Manager</b>	The name of the queue manager.
<b>Channel</b>	The channel through which the queue manager sends messages. The default channel is SYSTEM.DEF.SVRCONN.
<b>Queue</b>	The queue or list of queues to monitor. A list of queues is specified with a comma-separated list.
<b>Username</b>	The user name that is used for authenticating with the MQ service.
<b>Password</b>	Optional: The password that is used to authenticate with the MQ service.
<b>Incoming Message Encoding</b>	The character encoding that is used by incoming messages.
<b>Process Computational Fields</b>	Optional: Select this option only if the retrieved messages contain computational data that is defined in a COBOL copybook. The binary data in the messages is processed according to the field definition found in the specified copybook file.
<b>CopyBook File Name</b>	This parameter displays when <b>Process Computational Fields</b> is selected. The name of the copybook file to use for processing data. The CopyBook file must be placed in /store/ec/mqjms/*.
<b>Event Formatter</b>	Select the event formatting to be applied for any events that are generated from processing data containing computational fields. By default, <b>No Formatting</b> is used.
<b>Include JMS Message Header</b>	Select this option to include a header in each generated event containing JMS message fields such as the JMSMessageID and JMSTimestamp.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.

## Related concepts

[Creating a log source extensions document to get data into QRadar](#)

# Office 365 Message Trace REST API protocol configuration options

The Office 365 Message Trace REST API protocol for IBM Security QRadar collects message trace logs from the Message Trace REST API. This active outbound protocol is used to collect Office 365 email logs.

**Important:** As of 1 January 2023, Microsoft will no longer support basic authentication. To continue receiving Message Trace events, you must use modern authentication. Modern authentication uses OAuth 2.0 to authenticate and authorize access to the events. For more information about the deprecation of basic authentication, see [Basic Authentication Deprecation in Exchange Online – September 2022 Update](#).

To use modern authentication, you must register a new application in the Microsoft Azure portal (<https://portal.azure.com/>). In the portal, you can obtain important values that you must use when you create a Microsoft Office 365 Message Trace log source.

1. Create an application that can be used to authenticate with the Office 365 Message Trace REST API. For more information, see [Use the portal to create an Azure AD application and service principal that can access resources](#).
  - a. Assign **Azure AD** roles to the application. For more information, see [Assign Azure AD roles to the application](#).
  - b. Set the **ReportingWebService.Read.All** application permission. For more information, see [Specify the permissions your app requires to access the Reporting Web Service](#).
2. Obtain the **Client ID**, **Tenant ID**, and **Client Secret** values.
  - a. On the **Overview** page of the application, locate and copy the **Client ID** and **Tenant ID** values. You use these values when you create a Microsoft Office 365 Message Trace log source. For more information, see [Get tenant and app ID values for signing in](#).
  - b. On the **Certificates and Secrets** page of the application, click **New Secret** to create the client secret, and then copy the client secret to a text editor. You use this value for the **Client Secret** parameter when you create a Microsoft Office 365 Message Trace log source. For more information, see [Create a new application secret](#).

The following parameters require specific values to collect events from the Office 365 Message Trace REST API:

**Important:** If the **start date** and **end date** in an audit log run are overlapping, then there is duplication of events in the reports with different indexes. In such cases, you must manually handle the events in the reports.

*Table 76. Office 365 Message Trace REST API protocol log source parameters*

Parameter	Value
<b>Log Source Identifier</b>	A unique name for the log source. The name can't include spaces and must be unique among all log sources of this type that are configured with the Office 365 Message Trace REST API protocol.

Table 76. Office 365 Message Trace REST API protocol log source parameters (continued)

Parameter	Value
<b>Authentication Method</b>	<p>Modern authentication uses OAuth 2.0 to authenticate and authorize access to the resource. Basic authentication uses the username and password.</p> <p>If you select the <b>Basic</b> authentication method, the <b>Office 365 User Account email</b> and <b>Office 365 User Account Password</b> parameters appear. Provide an Office 365 email account with proper permissions.</p> <p><b>Important:</b> As of 1 January 2023, Microsoft will no longer support basic authentication. To continue receiving Message Trace events, you must use <b>Modern</b> authentication.</p>
<b>Client ID</b>	The <b>Client ID</b> value from your application configuration of Microsoft Azure Active Directory. For more information, see <a href="#">Get tenant and app ID values for signing in</a> .
<b>Client Secret</b>	The client secret that you created for your application on the Microsoft Azure portal. For more information, see <a href="#">Create a new application secret</a> .
<b>Tenant ID</b>	The <b>Tenant ID</b> value that is used for Microsoft Azure Active Directory authentication. For more information, see <a href="#">Get tenant and app ID values for signing in</a> .
<b>Event Delay</b>	<p>The delay, in seconds, for collecting data.</p> <p>Office 365 Message Trace logs work on an eventual delivery system. To ensure that no data is missed, logs are collected on a delay. The default delay is 900 seconds (15 minutes), and can be set as low as 0 seconds.</p>
<b>Use Proxy</b>	<p>If the API is accessed by using a proxy, select this checkbox.</p> <p>Configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.</p>
<b>Enable Advanced Options</b>	Select this option to modify the default values for the <b>Microsoft API Login Endpoint</b> and <b>Office 365 Message Trace API Management URL</b> parameters. If you do not enable this parameter, the default values are used.
<b>Microsoft API Login Endpoint</b>	<p>Specify the Microsoft API login endpoint. The default value is <code>https://login.windows.net</code>.</p> <p>If you do not enable the <b>Enable Advanced Options</b> parameter, the default value is used.</p>

Table 76. Office 365 Message Trace REST API protocol log source parameters (continued)

Parameter	Value
<b>Office 365 Message Trace API Management URL</b>	The Office 365 Message Trace API management URL grants your token access to the specified resource. The default value is <code>https://outlook.office365.com</code> . If you do not enable the <b>Enable Advanced Options</b> parameter, the default value is used.
<b>Recurrence</b>	The time interval between log source queries to the Office 365 Message Trace REST API for new events. The time interval can be in hours (H), minutes (M), or days (D). The default is 5 minutes.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

## Conditional access for reading reports

If you receive the error message "Status Code: 401 | Status Reason: Unauthorized," review the following Conditional Access policies documentation to confirm that the user account has access to the legacy application Office 365 Message Trace API:

- For more information about blocking and unblocking legacy content in Conditional Access policies, see [Conditional Access: Block legacy authentication](#).
- For more information about creating Conditional Access policies for users and groups, see [Conditional Access: Users and groups](#).
- For more information about creating Conditional Access policies for Cloud apps or actions, see [Conditional Access: Cloud apps or actions](#).
- For more information about granting or blocking access to resources with a Conditional Access policy, see [Conditional Access: Grant](#).

## Troubleshooting the Office 365 Message Trace REST API protocol

To resolve issues with the Office 365 Message Trace REST API protocol, use the troubleshooting and support information. Find the errors by using the protocol testing tools in the QRadar Log Source Management app.

### General troubleshooting

The following steps apply to all user input errors. The general troubleshooting procedure contains the first steps to follow any errors with the Office 365 Message Trace REST API protocol.

1. If you use QRadar 7.3.2, software update 3 or later, run the testing tool before you enable the log source. If the testing tool doesn't pass all tests, the log source fails when enabled. If a test fails, an error message with more information displays.
2. Verify that the selected Event Collector can access the `reports.office365.com` host. This protocol connects by using HTTPS (port 443).
3. Verify that the Office 365 email account username and password are valid.
4. Ensure that the Office 365 email account has the correct permissions. For more information, see [Office 365 Message Trace protocol FAQ](#).
5. Ensure that your access is not blocked to the Reporting Web Services legacy authentication protocol. For more information, see [HTTP Status code 401](#).
6. Reenter all fields.
7. If available, rerun the testing tool.

For more information, see:

- [HTTP Status code 401](#)
- [HTTP Status code 404](#)
- [Office 365 Message Trace protocol FAQ](#)

## HTTP Status code 401

### Symptoms

Error: "Status Code: 401 | Status Reason: Unauthorized"

Error: "Invalid Office 365 User Account E-mail or Password"

Error: <A response received from the Office 365 Message Trace REST API displays>

### Causes

QRadar connected to the Office 365 Message Trace protocol, but because of invalid user credentials, it could not authenticate.

### Resolving the problem

To resolve your HTTP Status code 401 error, verify that the following conditions are met.

1. Verify that your Office 365 email account username and the account password are valid.
2. Check if your Microsoft security settings are blocking access to the Office 365 Message Trace REST API.

To use the Office 365 Message Trace REST API, you need access to the Reporting Web Services legacy authentication protocol.

For more information about blocking and unblocking legacy authentications, see [How to: Block legacy authentication to Azure AD with Conditional Access](#) (<https://docs.microsoft.com/en-us/azure/active-directory/conditional-access/block-legacy-authentication#indirectly-blocking-legacy-authentication>). If you need assistance with configuring Azure AD with Conditional Access, contact Microsoft Support.

For more information about creating Conditional Access policies for users and groups, see [Conditional Access: Users and groups](#) (<https://docs.microsoft.com/en-us/azure/active-directory/conditional-access/concept-conditional-access-users-groups>).

For more information about creating Conditional Access policies for Cloud apps or actions, see [Conditional Access: Cloud apps or actions](#) (<https://docs.microsoft.com/en-us/azure/active-directory/conditional-access/concept-conditional-access-cloud-apps>).

For more information about granting or blocking access to resources with a Conditional Access policy, see [Conditional Access: Grant](https://docs.microsoft.com/en-us/azure/active-directory/conditional-access/concept-conditional-access-grant) (<https://docs.microsoft.com/en-us/azure/active-directory/conditional-access/concept-conditional-access-grant>).

## HTTP Status code 404

### Symptoms

Error: "Status Code : 404 | Status Reason: Not Found"

Error: "Occasionally 404 responses are related to the user account permissions not granting access to the Message Trace API"

Error: <A response received from the Office 365 Message Trace REST API displays>

### Causes

404 responses are usually due to the server not being found. However, the Office 365 Message Trace REST API can return this response when the **User Account** that was provided does not have proper permissions. Most instances of this exception occur because the **User Account** does not have the necessary permissions.

### Resolving the problem

To resolve your HTTP Status code 404 error, ensure that the user accounts have the necessary permissions. For more information, see [Office 365 Message Trace REST API protocol FAQ](#).

## Office 365 Message Trace REST API protocol FAQ

Got a question? Check these frequently asked questions and answers to help you understand the Office 365 Message Trace REST API protocol.

- ["What permissions are required to collect logs from the Office 365 Message Trace REST API?" on page 198](#)
- ["What information is contained in the events that are collected by a Microsoft Office 365 Message Trace REST API protocol?" on page 198](#)
- ["What is the event delay option used for?" on page 199](#)
- ["How does the event delay option work?" on page 199](#)
- ["What value do I use for the event delay option?" on page 199](#)

### What permissions are required to collect logs from the Office 365 Message Trace REST API?

Use the same administrative permissions that you use to access the reports in the Office 365 organization. For more information, see [Permissions](#). ([https://docs.microsoft.com/en-us/previous-versions/office/developer/office-365-enterprise-developers/jj984335\(v=office.15\)#permissions](https://docs.microsoft.com/en-us/previous-versions/office/developer/office-365-enterprise-developers/jj984335(v=office.15)#permissions)).

### What information is contained in the events that are collected by a Microsoft Office 365 Message Trace REST API protocol?

This protocol returns the same information that is provided in the message trace in the Security and Compliance Center. For more information, see the [Message trace in the Security & Compliance Center](#) (<https://docs.microsoft.com/en-us/microsoft-365/security/office-365-security/message-trace-scc?view=o365-worldwide>).

**Note:** Extended and enhanced reports are not available when you use the Office 365 Message Trace REST API.

For a specific reference to the API that contains a list of MessageTrace report fields, see [Fields](https://docs.microsoft.com/en-us/previous-versions/office/developer/o365-enterprise-developers/jj984335(v=office.15)#fields) ([https://docs.microsoft.com/en-us/previous-versions/office/developer/o365-enterprise-developers/jj984335\(v=office.15\)#fields](https://docs.microsoft.com/en-us/previous-versions/office/developer/o365-enterprise-developers/jj984335(v=office.15)#fields)).

## What is the event delay option used for?

The event delay option is used to prevent events from being missed. Missed events, in this context, occur because they become available after the protocol updated its query range to a newer time frame than the event's arrival time. If an event occurred but wasn't posted to the Office 365 Message Trace REST API, then when the protocol queries for that event's creation time, the protocol doesn't get that event.

**Example 1:** The following example shows how an event can be lost.

The protocol queries the Office 365 Message Trace API at 2:00 PM to collect events between 1:00 PM – 1:59 PM. The Office 365 Message Trace API response returns the events that are available in the Office 365 Message Trace API between 1:00 PM - 1:59 PM. The protocol operates as if all of the events are collected and then sends the next query to the Office 365 Message Trace API at 3:00 PM to get events that occurred between 1:45 PM – 2:59 PM. The problem with this scenario is that the Office 365 Message Trace API might not include all of the events that occurred between 1:00 PM – 1:59 PM. If an event occurred at 1:58 PM, that event might not be available in the Office 365 Message Trace API until 2:03 PM. However, the protocol has already queried the 1:00 PM – 1:59 PM time range, and can't re-query that range without getting duplicated events. This delay can vary between 1 minute to 24 hours.

**Example 2:** The following example shows **Example 1**, except in this scenario a 15-minute delay is added.

This example uses a 15-minute delay when the protocol makes query calls. When the protocol makes a query call to the Office 365 Message Trace API at 2:00 PM, it collects the events that occurred between 1:00 - 1:45 PM. The protocol operates as if all of the events are collected, sends the next query to the Office 365 Message Trace API at 3:00 PM and collects all events that occurred between 1:45 PM – 2:45 PM. Instead of the event being missed, as in **Example 1**, it gets picked up in the next query call between 1:45 PM - 2:45 PM.

**Example 3:** The following example shows **Example 2**, except in this scenario the events are available a day later.

If the event occurred at 1:58 PM, but only became available to the Office 365 Message Trace API at 1:57 PM the next day, then the event delay that is described in **Example 2** no longer gets that event. Instead, the event delay must be set to a higher value, in this case 24 hours.

## How does the event delay option work?

Instead of querying from the **last received event time** to **current time**, the protocol queries from the **last received event time** to **current time** - <event delay>. The event delay is in seconds. For example, a delay of 15 minutes (900 seconds) means that it queries only up to 15 minutes ago. This query gives the Office 365 Message Trace API 15 minutes to make an event available before the event is lost. When the **current time** - <event delay> is less than the **last received event time**, the protocol doesn't query the Office 365 Message Trace API; it waits for the condition to pass before querying.

## What value do I use for the event delay option?

The Office 365 Message Trace API can delay the event's availability for up to 24 hours. To prevent any events from being missed, the **Event Delay** parameter option value can be set to 24 hours. However, the larger the event delay, the less real time the results are. With a 24-hour event delay, you see events only 24 hours after they occur. The value depends on how much risk you're willing to take and how important real-time data is. This default delay of 15 minutes provides a value that is set in real time and also prevents most events from being missed. For more information about the delay, see [Data granularity, persistence, and availability](https://docs.microsoft.com/en-us/previous-versions/office/developer/o365-enterprise-developers/jj984335(v=office.15)#data-granularity-persistence-and-availability) ([https://docs.microsoft.com/en-us/previous-versions/office/developer/o365-enterprise-developers/jj984335\(v=office.15\)#data-granularity-persistence-and-availability](https://docs.microsoft.com/en-us/previous-versions/office/developer/o365-enterprise-developers/jj984335(v=office.15)#data-granularity-persistence-and-availability)).

## Office 365 REST API protocol configuration options

The Office 365 REST API protocol for IBM Security QRadar is an active outbound protocol.

The following table describes the protocol-specific parameters for the Office 365 REST API protocol:

Table 77. Office 365 REST API protocol log source parameters	
Parameter	Value
<b>Protocol Configuration</b>	<b>Office 365 REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Office 365 REST API log source, ensure that you give each one a unique name.
<b>Client ID</b>	In your application configuration of Azure Active Directory, this parameter is under <b>Client ID</b> .
<b>Authentication Method</b>	<ul style="list-style-type: none"><li>Client Secret: Standard Client Secret based authentication.</li><li>Client Certificate: Self signed Certificate based authentication.</li></ul>
<b>Client Secret</b>	In your application configuration of Azure Active Directory, this parameter is under <b>Value</b> . <b>Note:</b> Select <b>Authentication Method &gt; Client Secret</b> to make the <b>Client Secret</b> parameter available.
<b>Client Certificate</b>	Specify the self signed .pfx certificate path. <b>Note:</b> Select <b>Authentication Method &gt; Client Certificate</b> to make the <b>Client Certificate</b> parameter available. For more information, see " <a href="#">Creating self-signed certificates and keys for Office 365 REST API protocol</a> " on page 201.
<b>Client Certificate Password</b>	Specify the .pfx certificate password. <b>Note:</b> Select <b>Authentication Method &gt; Client Certificate</b> to make the <b>Client Certificate Password</b> parameter available.
<b>Tenant ID</b>	Used for Azure AD authentication.

Table 77. Office 365 REST API protocol log source parameters (continued)

Parameter	Value
<b>Event Filter</b>	The type of audit events to retrieve from Microsoft Office. <ul style="list-style-type: none"> <li>• Azure Active Directory</li> <li>• Exchange</li> <li>• SharePoint</li> <li>• General</li> <li>• DLP</li> </ul>
<b>Use Proxy</b>	For QRadar to access the Office 365 Management APIs, all traffic for the log source travels through configured proxies. Configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, keep the <b>Proxy Username</b> and <b>Proxy Password</b> fields empty.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
<b>Show Advanced Options</b>	Show optional advanced options for event collection. The <b>Advanced Options</b> values are in effect whether they are shown or not.
<b>Management Activity API URL</b>	Specify the Office 365 Management Activity API URL. Default is <a href="https://manage.office.com">https://manage.office.com</a> .
<b>Azure AD Sign-in URL</b>	Specify the Azure AD sign-in URL. Default is <a href="https://login.microsoftonline.com">https://login.microsoftonline.com</a> .

## Creating self-signed certificates and keys for Office 365 REST API protocol

To establish a communication between QRadar and Office 365 REST API, you can use OpenSSH to create a self-signed X509 certificate with PKCS #8 private key pairs.

### Procedure

1. Create the private keys:

a) Create a private key in the PEM format for the certificate. For example,

```
openssl genrsa -out private_key.pem 2048
```

b) Create a private key in the PKCS #8 format for the application. For example,

```
openssl pkcs8 -topk8 -inform PEM -outform DER -in private_key.pem -nocrypt > pkcs8_key
```

2. Create a certificate signing request (CSR). The request is associated with your private key and is later transformed into a certificate. For example,

```
openssl req -new -key private_key.pem -out cert.csr
```

After you run the command, you are asked to provide information that helps your users to identify your certificate and ensure that it can be trusted. The following excerpt from the command line is filled in with example information:

```
Country Name (2 letter code) [XX]: US
State or Province Name (full name) []: New York
Locality Name (eg, city) [Default City]: New York
Organization Name (eg, company) [Default Company Ltd]: IBM
Organizational Unit Name (eg, section) []: Software
Common Name (eg, your name or your server's hostname) []: example.ibm.com
Email Address []: example@ibm.com
```

3. Use the CA certificate to sign the certificate signing request.

```
openssl x509 -req -days 365 -in cert.csr -signkey private_key.pem -out cert.crt
```

4. Go to **Microsoft Entra admin center**:

- Select the application, and then click **Certificates & secrets**.
- In the **Certificates** section, click **Upload certificate**.
- Select the certificate you created and click **Add**.
- Your certificate is now listed in the **Certificates** section.

5. Convert the .crt file to the .pfx format.

```
openssl pkcs12 -export -out domain.name.pfx -inkey private_key_example.pem -in cert.crt
```

## What to do next

[“Uploading a self-signed certificate to Azure portal” on page 202](#)

## Uploading a self-signed certificate to Azure portal

Learn how to upload a self-signed certificate to Microsoft Azure Portal.

### Procedure

1. Log in to Azure Portal (<https://portal.azure.com>).
2. Go to **App Registration**, and search for your application. For example, *Office365\_Certificate Generate*.
3. In the **Essentials** section, click **Client credentials**.
4. From the **Manage** menu, go to **Certificates & secrets > Certificates**.
5. Click **Upload certificate**.
6. From the **Upload certificate** window pane, click the folder icon.
7. Select your certificate and click **Add**.

## Okta REST API protocol configuration options

To receive events from Okta, configure a log source in IBM QRadar by using the Okta REST API protocol.

The Okta REST API protocol is an outbound/active protocol that queries Okta events and users API endpoints to retrieve information about actions that are completed by users in an organization.

The following table describes the protocol-specific parameters for the Okta REST API protocol:

*Table 78. Okta REST API protocol parameters*

Parameter	Description
<b>Log Source Identifier</b>	A unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the log source <b>Name</b> . If you have more than one Okta log source that is configured, you might want to identify the first log source as okta1, the second log source as okta2, and the third log source as okta3.
<b>IP or Hostname</b>	oktprise.okta.com
<b>Authentication Token</b>	A single authentication token that is generated by the Okta console and must be used for all API transactions.
<b>Use Proxy</b>	If QRadar accesses Okta by using a proxy, enable this option.  When a proxy is configured, all traffic for the log source travels through the proxy for QRadar to access Okta.  If the proxy requires authentication, configure the <b>Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Hostname</b>	If you select <b>Use Proxy</b> , this parameter is displayed.
<b>Proxy Port</b>	If you select <b>Use Proxy</b> , this parameter is displayed.
<b>Proxy Username</b>	If you select <b>Use Proxy</b> , this parameter is displayed.
<b>Proxy Password</b>	If you select <b>Use Proxy</b> , this parameter is displayed.
<b>Recurrence</b>	A time interval to determine how frequently the poll is made for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds. The default is 1M.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

## OPSEC/LEA protocol configuration options

To receive events on port 18184, configure a log source to use the OPSEC/LEA protocol.

The OPSEC/LEA protocol is an outbound/active protocol.

The following table describes the protocol-specific parameters for the OPSEC/LEA protocol:

*Table 79. OPSEC/LEA protocol parameters*

Parameter	Description
<b>Protocol Configuration</b>	<b>OPSEC/LEA</b>

Table 79. OPSEC/LEA protocol parameters (continued)

Parameter	Description
<b>Log Source Identifier</b>	The IP address, host name, or any name to identify the device. Must be unique for the log source type.
<b>Server IP</b>	Type the IP address of the server.
<b>Server Port</b>	The port number that is used for OPSEC communication. The valid range is 0 - 65,536 and the default is 18184.
<b>Use Server IP for Log Source</b>	Select the <b>Use Server IP for Log Source</b> check box if you want to use the LEA server IP address instead of the managed device IP address for a log source. By default, the check box is selected.
<b>Statistics Report Interval</b>	The interval, in seconds, during which the number of syslog events are recorded in the <code>qradar.log</code> file. The valid range is 4 - 2,147,483,648 and the default interval is 600.
<b>Authentication Type</b>	From the list, select the <b>Authentication Type</b> that you want to use for this LEA configuration. The options are <code>sslca</code> (default), <code>sslca_clear</code> , or <code>clear</code> . This value must match the authentication method that is used by the server.
<b>OPSEC Application Object SIC Attribute (SIC Name)</b>	The Secure Internal Communications (SIC) name is the distinguished name (DN) of the application; for example: <code>CN=LEA, o=fwconsole..7psasx</code> .
<b>Log Source SIC Attribute (Entity SIC Name)</b>	The SIC name of the server, for example: <code>cn=cp_mgmt, o=fwconsole..7psasx</code> .
<b>Specify Certificate</b>	Select this check box if you want to define a certificate for this LEA configuration. QRadar attempts to retrieve the certificate by using these parameters when the certificate is needed.
<b>Certificate Filename</b>	This option appears only if <b>Specify Certificate</b> is selected. Type the file name of the certificate that you want to use for this configuration. The certificate file must be located in the <code>/opt/qradar/conf/trusted_certificates/lea</code> directory.
<b>Certificate Authority IP</b>	Type the Check Point Manager Server IP address.
<b>Pull Certificate Password</b>	Type the activation key password.
<b>OPSEC Application</b>	The name of the application that makes the certificate request.
<b>Enabled</b>	Select this check box to enable the log source. By default, the check box is selected.
<b>Credibility</b>	From the list, select the <b>Credibility</b> of the log source. The range is 0 - 10.  The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	From the list, select the <b>Target Event Collector</b> to use as the target for the log source.

*Table 79. OPSEC/LEA protocol parameters (continued)*

Parameter	Description
<b>Coalescing Events</b>	Select the <b>Coalescing Events</b> check box to enable the log source to coalesce (bundle) events. By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Store Event Payload</b>	Select the <b>Store Event Payload</b> check box to enable the log source to store event payload information. By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

**Important:** If you receive the error message **Unable to pull SSL certificate** after an upgrade, follow these steps:

1. Clear the **Specify Certificate** check box.
2. Reenter the password for **Pull Certificate Password**.

## Oracle Database Listener protocol configuration options

To remotely collect log files that are generated from an Oracle database server, configure a log source to use the Oracle Database Listener protocol source.

The Oracle Database Listener protocol is an outbound/active protocol.

Before you configure the Oracle Database Listener protocol to monitor log files for processing, you must obtain the directory path to the Oracle database log files.

The following table describes the protocol-specific parameters for the Oracle Database Listener protocol:

*Table 80. Oracle Database Listener protocol parameters*

Parameter	Description
<b>Protocol Configuration</b>	<b>Oracle Database Listener</b>
<b>Log Source Identifier</b>	Type the IP address, host name, or a unique name to identify your log source.
<b>Server Address</b>	The IP address or host name of your Oracle Database Listener server.
<b>Domain</b>	Type the domain for your Oracle Database Learner server. This parameter is optional if your server is not in a domain.
<b>Username</b>	Type the user name that is required to access your server.
<b>Password</b>	Type the password that is required to access your server.
<b>Confirm Password</b>	Type the password that is required to access the server.
<b>Log Folder Path</b>	Type the directory path to access the Oracle Database Listener log files.

Table 80. Oracle Database Listener protocol parameters (continued)

Parameter	Description
<b>File Pattern</b>	The regular expression (regex) that identifies the event logs.
<b>Force File Read</b>	Select this check box to force the protocol to read the log file when the timing of the polling interval specifies.  When the check box is selected, the log file source is always examined when the polling interval specifies, regardless of the last modified time or file size attribute.  When the check box is not selected, the log file source is examined at the polling interval if the last modified time or file size attributes changed.
<b>Recursive</b>	If you want the file pattern to search sub folders, use this option. By default, the check box is selected.
<b>SMB Version</b>	Select the version of SMB that you want to use.  <b>AUTO</b> Auto-detects to the highest version that the client and server agree to use.  <b>SMB1</b> Forces the use of SMB1. SMB1 uses the <code>jCIFS.jar</code> (Java ARchive) file.  <b>Important:</b> SMB1 is no longer supported. All administrators must update existing configurations to use SMB2 or SMB3.  <b>SMB2</b> Forces the use of SMB2. SMB2 uses the <code>jNQ.jar</code> file.  <b>SMB3</b> Forces the use of SMB3. SMB3 uses the <code>jNQ.jar</code> file.  <b>Note:</b> Before you create a log source with a specific SMB version (for example: SMBv1, SMBv2, and SMBv3), ensure that the specified SMB version is supported by the Windows OS that is running on your server. You also need to verify that SMB versions is enabled on the specified Windows Server.  For more information about which Windows version supports which SMB versions, go to the <a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">Microsoft TechNet website</a> ( <a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/</a> ).  For more information about how to detect, enable and disable SMBv1, SMBv2, and SMBv3 in Windows and Windows Server, go to the <a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">Microsoft support website</a> ( <a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server</a> ).
<b>Polling Interval (in seconds)</b>	Type the polling interval, which is the number of seconds between queries to the log files to check for new data. The default is 10 seconds.
<b>Throttle events/sec</b>	The maximum number of events the Oracle Database Listener protocol forwards per second.

*Table 80. Oracle Database Listener protocol parameters (continued)*

Parameter	Description
<b>File Encoding</b>	The character encoding that is used by the events in your log file.

## PCAP Syslog Combination protocol configuration options

To collect events from Juniper SRX Series Services Gateway or Juniper Junos OS Platform that forward packet capture (PCAP) data, configure a log source to use the PCAP Syslog Combination protocol.

The PCAP Syslog Combination protocol is an inbound/passive protocol.

Before you configure a log source that uses the PCAP Syslog Combination protocol, determine the outgoing PCAP port that is configured on the Juniper SRX Series Services Gateway or Juniper Junos OS Platform. PCAP data cannot be forwarded to port 514.

**Note:**

QRadar supports receiving PCAP data only from Juniper SRX Series Services Gateway or Juniper Junos OS Platform for each event collector.

The following table describes the protocol-specific parameters for the PCAP Syslog Combination protocol:

*Table 81. PCAP Syslog Combination protocol parameters*

Parameter	Description
Log Source Name	Type a unique name of the log source.
Log Source Description	Optional. Type a description for the log source.
Log Source Type	From the list, you can select either <b>Juniper SRX Series Services Gateway</b> or <b>Juniper Junos OS Platform</b> .
Protocol Configuration	From the list, select <b>PCAP Syslog Combination</b> .
Log Source Identifier	Type an IP address, host name, or name to identify the <b>Juniper SRX Series Services Gateway</b> or <b>Juniper Junos OS Platform</b> appliance. The log source identifier must be unique for the log source type.
Incoming PCAP Port	If the outgoing PCAP port is edited on the <b>Juniper SRX Series Services Gateway</b> or <b>Juniper Junos OS Platform</b> appliance, you must edit the log source to update the incoming PCAP Port.  To edit the Incoming PCAP Port number, complete the following steps: <ol style="list-style-type: none"><li>1. Type the new port number for receiving PCAP data</li><li>2. Click <b>Save</b>.</li></ol> The port update is complete and event collection starts on the new port number.
Enabled	Select this check box to enable the log source.  When this check box is clear, the log source does not collect events and the log source is not counted in the license limit.

Table 81. PCAP Syslog Combination protocol parameters (continued)

Parameter	Description
Credibility	<p>Select the credibility of the log source. The range is 0 (lowest) - 10 (highest). The default credibility is 5.</p> <p>Credibility is a representation of the integrity or validity of events that are created by a log source. The credibility value that is assigned to a log source can increase or decrease based on incoming events or adjusted as a response to user created event rules. The credibility of events from log sources contributes to the calculation of the offense magnitude and can increase or decrease the magnitude value of an offense.</p>
Target Event Collector	<p>Select the target for the log source. When a log source actively collects events from a remote source, this field defines which appliance polls for the events.</p> <p>This option enables administrators to poll and process events on the target event collector, instead of the Console appliance. This can improve performance in distributed deployments.</p>
Coalescing Events	<p>Select this check box to enable the log source to coalesce (bundle) events.</p> <p>Coalescing events increase the event count when the same event occurs multiple times within a short time interval. Coalesced events provide administrators a way to view and determine the frequency with which a single event type occurs on the <b>Log Activity</b> tab.</p> <p>When this check box is clear, the events are displayed individually and the information is not bundled.</p> <p>New and automatically discovered log sources inherit the value of this check box from the <b>System Settings</b> configuration on the <b>Admin</b> tab. Administrators can use this check box to override the default behavior of the system settings for an individual log source.</p>
Store Event Payload	<p>Select this check box to enable the log source to store the payload information from an event.</p> <p>New and automatically discovered log sources inherit the value of this check box from the <b>System Settings</b> configuration on the <b>Admin</b> tab. Administrators can use this check box to override the default behavior of the system settings for an individual log source.</p>
Log Source Extension	<p>Optional. Select the name of the extension to apply to the log source.</p> <p>This parameter is available after a log source extension is uploaded. Log source extensions are XML files that contain regular expressions, which can override or repair the event parsing patterns that are defined by a device support module (DSM).</p>
Extension Use Condition	<p>From the list box, select the use condition for the log source extension. The options include:</p> <ul style="list-style-type: none"> <li>• <b>Parsing enhancement</b> - Select this option when most fields parse correctly for your log source.</li> <li>• <b>Parsing override</b> - Select this option when the log source is unable to correctly parse events.</li> </ul>

*Table 81. PCAP Syslog Combination protocol parameters (continued)*

Parameter	Description
Groups	Select one or more groups for the log source.

## RabbitMQ protocol configuration options

To receive messages from a Cisco AMP DSM, configure a log source to use the RabbitMQ protocol.

The RabbitMQ protocol is an active outbound protocol.

**Important:** The Cisco AMP integration does not support private cloud if the Server Name Indication (SNI) is required. Contact Cisco for more details.

The following table describes the protocol-specific parameters for the RabbitMQ protocol:

*Table 82. RabbitMQ protocol parameters*

Parameter	Description
<b>Protocol Name</b>	<b>RabbitMQ</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured RabbitMQ log source, ensure that you give each one a unique name.
<b>Event Format</b>	The Event Format tells the protocol what type of events to expect. Officially supported products have specific options available for them. For unsupported products, you can use <b>No Formatting</b> or <b>JSON</b> .
<b>IP or Hostname</b>	The IP address or hostname of the primary queue manager.
<b>Port</b>	The port that is provided by the AMQP service when a queue is created or viewed.
<b>Queue</b>	The queue or list of queues to monitor. A list of queues is specified with a comma-separated list.
<b>Username</b>	The username that is used for authenticating with the RabbitMQ service.
<b>Password</b>	The password that is used to authenticate with the RabbitMQ service.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

*Table 82. RabbitMQ protocol parameters (continued)*

Parameter	Description
<b>Allow Untrusted Certificates</b>	Enable this option when the endpoint is using a certificate that cannot be verified via the Certificate Chain. This would include a self-signed certificate, or one from a private CA that you do not want to import into your CA trust.  This option should not be used for endpoints with a certificate issued by a Public CA (SaaS Products, Public Cloud Infrastructure, and so on.)  The certificate must be downloaded in PEM or DER encoded binary format and then placed in the /opt/qradar/conf/trusted_certificates/ directory with a .cert or .crt file extension.

### Related concepts

[“Copy the server certificate” on page 210](#)

You need a server certificate to support HTTPS connections. QRadar supports certificates with the .crt, .cert, or .der file extensions.

### Related information

[Adding a log source](#)

## Copy the server certificate

You need a server certificate to support HTTPS connections. QRadar supports certificates with the .crt, .cert, or .der file extensions.

To copy a certificate to the /opt/qradar/conf/trusted\_certificates directory, choose one of the following options:

- Manually copy the certificate to the /opt/qradar/conf/trusted\_certificates directory by using SCP or SFTP.
- Use SSH to log in to the QRadar Console or managed host and retrieve the certificate by typing the following command:

```
/opt/qradar/bin/getcert.sh <IP or Hostname for RabbitMQ> <Port for RabbitMQ>
```

A certificate is downloaded from the specified host name or IP address and placed into the /opt/qradar/conf/trusted\_certificates directory in the appropriate format.

## SDEE protocol configuration options

You can configure a log source to use the Security Device Event Exchange (SDEE) protocol. QRadar uses the protocol to collect events from appliances that use SDEE servers.

The SDEE protocol is an outbound/active protocol.

The following table describes the protocol-specific parameters for the SDEE protocol:

*Table 83. SDEE protocol parameters*

Parameter	Description
Protocol Configuration	<b>SDEE</b>

Table 83. SDEE protocol parameters (continued)

Parameter	Description
Log Source Identifier	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured SDEE log source, ensure that you give each one a unique name.
URL	The HTTP or HTTPS URL that is required to access the log source, for example, <code>https://www.example.com/cgi-bin/sdee-server</code> . For SDEE/CIDEE (Cisco IDS v5.x and later), the URL must end with <code>/cgi-bin/sdee-server</code> . Administrators with RDEP (Cisco IDS v4.x), the URL must end with <code>/cgi-bin/event-server</code> .
Force Subscription	When the check box is selected, the protocol forces the server to drop the least active connection and accept a new SDEE subscription connection for the log source.
Maximum Wait To Block For Events	When a collection request is made and no new events are available, the protocol enables an event block. The block prevents another event request from being made to a remote device that did not have any new events. This timeout is intended to conserve system resources.

## Seculert Protection REST API protocol configuration options

To receive events from Seculert, configure a log source to use the Seculert Protection REST API protocol.

The Seculert Protection REST API protocol is an active outbound protocol that provides alerts about confirmed incidents of malware that are actively communicating or exfiltrating information.

**Important:** Before you can configure a log source for Seculert, you must use the following steps to obtain your API key from the Seculert web portal.

1. Log in to the Seculert web portal.
2. On the dashboard, click the **API** tab.
3. Copy the value for **Your API Key**.

The following table describes the protocol-specific parameters for the Seculert Protection REST API protocol:

Table 84. Seculert Protection REST API protocol parameters

Parameter	Description
<b>Log Source Type</b>	<b>Seculert</b>
<b>Protocol Configuration</b>	<b>Seculert Protection REST API</b>
<b>Log Source Identifier</b>	Type the IP address or hostname for the log source as an identifier for events from Seculert.  Each additional log source that you create when you have multiple installations ideally includes a unique identifier, such as an IP address or hostname.

Table 84. Seculert Protection REST API protocol parameters (continued)

Parameter	Description
<b>API Key</b>	The API key that is used for authenticating with the Seculert Protection REST API. The API key is obtained from the Seculert web portal.
<b>Use Proxy</b>	If the API is accessed by using a proxy, select this checkbox. Configure the <b>Proxy IP or Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Recurrence</b>	Specify how often the log collects data. The value can be in Minutes (M), Hours (H), or Days (D). The default is 10 minutes.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
<b>Enable Advanced Options</b>	Select this checkbox to enable the following configuration options: <b>Server</b> , <b>API Version</b> , <b>Query Time Interval</b> , <b>Allow Untrusted Certificates</b> , <b>Override Workflow</b> , <b>Workflow</b> , and <b>Workflow Parameters</b> . These parameters are only visible if you select this checkbox.
<b>Server</b>	The server that is used for forming the API query. For example, [Server]/1.1/incidents/records. The default value is <a href="https://api.seculert.com">https://api.seculert.com</a> .../.
<b>API Version</b>	The API version that is used for forming the API query. For example, <a href="https://api.seculert.com/[API Version]/incidents/records">https://api.seculert.com/[API Version]/incidents/records</a> . The default value is 1.1.
<b>Query Time Interval</b>	The maximum time interval for each query to collect events. For example, if you set the interval as 15 minutes, the query collects events from the last query time to 15 minutes later. If the current time is less than 15 minutes since the last query, the query collects events from the last query time until the current time. The value must be in milliseconds (ms); 1000 ms is 1 second. The default value is 900000 ms (15 minutes).

Table 84. Seculert Protection REST API protocol parameters (continued)

Parameter	Description
<b>Allow Untrusted</b>	<p>If you enable this parameter, the protocol can accept self-signed and otherwise untrusted certificates that are located within the /opt/qradar/conf/trusted_certificates/ directory. If you disable the parameter, the scanner trusts only certificates that are signed by a trusted signer.</p> <p>The certificates must be in PEM or RED-encoded binary format and saved as a .crt or .cert file.</p> <p>If you modify the workflow to include a hardcoded value for the <b>Allow Untrusted Certificates</b> parameter, the workflow overrides your selection in the UI. If you do not include this parameter in your workflow, then your selection in the UI is used.</p>
<b>Override Work Flow</b>	<p>Enable this option to customize the workflow. When you enable this option, the <b>Workflow</b> and <b>Workflow Parameters</b> parameters appear.</p>
<b>Work Flow</b>	<p>The XML document that defines how the protocol instance collects events from the target API.</p> <p>For more information about the default workflow, see “<a href="#">Seculert Protection REST API protocol workflow</a>” on page 214.</p>
<b>Workflow Parameters</b>	<p>The XML document that contains the parameter values used directly by the workflow.</p> <p>For more information about the default workflow parameters, see “<a href="#">Seculert Protection REST API protocol workflow</a>” on page 214.</p>
<b>Enabled</b>	<p>By default, the checkbox is selected to enable the log source to communicate with QRadar.</p>
<b>Credibility</b>	<p>Select the <b>Credibility</b> of the log source. The range is 0 - 10.</p> <p>The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.</p>
<b>Target Event Collector</b>	<p>Select the <b>Target Event Collector</b> to use as the target for the log source.</p>
<b>Coalescing Events</b>	<p>Select this checkbox to enable the log source to coalesce (bundle) events.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>

Table 84. Seculert Protection REST API protocol parameters (continued)

Parameter	Description
<b>Store Event Payload</b>	Select this checkbox to enable the log source to store event payload information.  By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

## Seculert Protection REST API protocol workflow

You can customize your workflow and workflow parameters based on the default workflow.

A workflow is an XML document that describes the event retrieval process. The workflow defines one or more parameters, which can be explicitly assigned values in the workflow XML or can derive values from the workflow parameter values XML document. The workflow consists of multiple actions that run sequentially.

The default workflow and workflow parameter XML files are available on GitHub. For more information, see Seculert Protection (<https://github.com/IBM/IBM-QRadar-Universal-Cloud-REST-API/tree/master/IBM%20Verified/Seculert%20Protection>).

### Seculert default workflow

The following example shows the default Seculert workflow:

```
<?xml version="1.0" encoding="UTF-8" ?>
<Workflow name="Seculert" version="1.1" xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/Workflow/V2">
    <Parameters>
        <Parameter name="apiKey" label="API Key" required="true" />
        <Parameter name="queryTimeInterval" label="Query Time Interval" required="true" default="900000" />
        <Parameter name="server" label="Server" required="true" default="https://api.secert.com" />
        <Parameter name="apiVersion" label="API Version" required="true" default="1.1" />
    </Parameters>
    <Actions>
        <Log type="DEBUG" message="Initializing bookmark values" />
        <!-- Initialize the Bookmark -->
        <Initialize path="/bookmarkRecords" value="${time() - /queryTimeInterval}" />
        <Initialize path="/bookmarkAlerts" value="${time() - /queryTimeInterval}" />
        <Initialize path="/firstRun" value="1" />
        <Initialize path="/sevenDays" value="604800000" />
        <!-- Event retriever thread is a bit slow to kill error'd out provider threads, this prevents duplicate errors. -->
        <If condition="/firstRun = 1" >
            <Sleep duration="2000" />
        </If>
        <Log type="DEBUG" message="Checking if the current bookmarks are older than 7 days." />
        <If condition="time() > /bookmarkRecords + /sevenDays" >
            <Set path="/bookmarkRecords" value="${time() - /sevenDays}" />
        </If>
        <If condition="time() > /bookmarkAlerts + /sevenDays" >
            <Set path="/bookmarkAlerts" value="${time() - /sevenDays}" />
        </If>
        <Set path="/doOnceMore" value="1" />
        <Log type="DEBUG" message="The current bookmark for bookmarkRecords is /bookmarkRecords" />
        <Log type="DEBUG" message="The current bookmark for bookmarkAlerts is /bookmarkAlerts" />
        <Log type="DEBUG" message="Iterating through events in till we are caught up." />
    </Actions>
</Workflow>
```

```

<While condition="time() > /bookmarkRecords + /queryTimeInterval or /doOnceMore = 1">
    <!-- Get the start/end date. start_time=bookmark. End_time is the bookmark time + X
seconds (userconfigurable) -->
    <FormatDate pattern="MM/dd/yyyy HH:mm:ss" timeZone="UTC" time="${/bookmarkRecords}" savePath="/start_time" />

    <If condition="time() > /bookmarkRecords + /queryTimeInterval" >

```

## Seculert default workflow parameters

The following example shows the default workflow parameters for Seculert:

```

<?xml version="1.0" encoding="UTF-8" ?>
<WorkflowParameterValues xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/
WorkflowParameterValues/V2">
    <Value name="apiKey" value="" />
    <Value name="queryTimeInterval" value="900000" />
    <Value name="server" value="https://api.seculeit.com" />
    <Value name="apiVersion" value="1.1" />
</WorkflowParameterValues>

```

## SMB Tail protocol configuration options

You can configure a log source to use the SMB Tail protocol. Use this protocol to watch events on a remote Samba share and receive events from the Samba share when new lines are added to the event log.

The SMB Tail protocol is an active outbound protocol.

The following table describes the protocol-specific parameters for the SMB Tail protocol:

*Table 85. SMB Tail protocol parameters*

Parameter	Description
<b>Protocol Configuration</b>	<b>SMB Tail</b>
<b>Log Source Identifier</b>	Type the IP address, hostname, or a unique name to identify your log source.
<b>Server Address</b>	The IP address or hostname of your SMB Tail server.
<b>Domain</b>	Type the domain for your SMB Tail server. This parameter is optional if your server is not in a domain.
<b>Username</b>	Type the username that is required to access your server.
<b>Password</b>	Type the password that is required to access your server.
<b>Confirm Password</b>	Confirm the password that is required to access the server.
<b>Log Folder Path</b>	The directory path to access the log files. For example, administrators can use the c\$/LogFiles/ directory for an administrative share, or the LogFiles/ directory for a public share folder path. However, the c:/LogFiles directory is not a supported log folder path.  If a log folder path contains an administrative share (C\$), users with NetBIOS access on the administrative share (C\$) have the privileges that are required to read the log files.  Local system or domain administrator privileges are also sufficient to access all log files that are on an administrative share.
<b>File Pattern</b>	The regular expression (regex) that identifies the event logs.

Table 85. SMB Tail protocol parameters (continued)

Parameter	Description
<b>SMB Version</b>	<p>Select the version of Server Message Block (SMB) that you want to use.</p> <p><b>AUTO</b> Auto-detects to the highest version that the client and server agree to use.</p> <p><b>SMB1</b> Forces the use of SMB1. SMB1 uses the <code>jCIFS.jar</code> (Java ARchive) file.</p> <p><b>Important:</b> SMB1 is no longer supported. All administrators must update existing configurations to use SMB2 or SMB3.</p> <p><b>SMB2</b> Forces the use of SMB2. SMB2 uses the <code>jNQ.jar</code> file.</p> <p><b>SMB3</b> Forces the use of SMB3. SMB3 uses the <code>jNQ.jar</code> file.</p> <p><b>Note:</b> Before you create a log source with a specific SMB version (for example: SMBv1, SMBv2, and SMBv3), ensure that the specified SMB version is supported by the Windows OS that is running on your server. You also need to verify that SMB versions are enabled on the specified Windows Server.</p> <p>For more information about which Windows version supports which SMB versions, go to the <a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">Microsoft TechNet website</a> (<a href="https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/">https://blogs.technet.microsoft.com/josebda/2012/06/06/windows-server-2012-which-version-of-the-smb-protocol-smb-1-0-smb-2-0-smb-2-1-or-smb-3-0-are-you-using-on-your-file-server/</a>).</p> <p>For more information about how to detect, enable and disable SMBv1, SMBv2, and SMBv3 in Windows and Windows Server, go to the <a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">Microsoft support website</a> (<a href="https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server">https://support.microsoft.com/en-us/help/2696547/detect-enable-disable-smbv1-smbv2-smbv3-in-windows-and-windows-server</a>).</p>
<b>Force File Read</b>	If the checkbox is cleared, the log file is read only when QRadar detects a change in the modified time or file size.
<b>Recursive</b>	If you want the file pattern to search sub folders, use this option. By default, the checkbox is selected.
<b>Polling Interval (in seconds)</b>	Type the polling interval, which is the number of seconds between queries to the log files to check for new data. The default is 10 seconds.
<b>Throttle Events/Sec</b>	The maximum number of events the SMB Tail protocol forwards per second.
<b>File Encoding</b>	The character encoding that is used by the events in your log file.

Table 85. SMB Tail protocol parameters (continued)

Parameter	Description
<b>File Exclusion List</b>	A list of regular expressions that prevent certain file directories from opening. The list includes one regular expression per line.  When a file or directory matches one of the regular expressions, that file or directory does not open. When a file is in use, other applications might not be able to use it. Use this parameter to prevent locking those files or to prevent the protocol from accessing specific files.  The pattern does not apply to the full Log Folder Path. It applies only to the final directory that is listed in the path. The pattern applies against all files or directories that are found within the Log Folder Path's directory.  The following list is an example of what you can enter in this field.  <code>/j50.*\log</code> <code>dhcp\.mdb</code> <code>dhcp\.tmp</code>

## SNMPv2 protocol configuration options

You can configure a log source to use the SNMPv2 protocol to receive SNMPv2 events.

The SNMPv2 protocol is an inbound/pассив протокол.

The following table describes the protocol-specific parameters for the SNMPv2 protocol:

Table 86. SNMPv2 protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	SNMPv2
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured SNMPv2 log source, ensure that you give each one a unique name.
<b>Community</b>	The SNMP community name that is required to access the system that contains SNMP events. For example, Public.
<b>Include OIDs in Event Payload</b>	Specifies that the SNMP event payload is constructed by using name-value pairs instead of the event payload format.  When you select specific log sources from the <b>Log Source Types</b> list, OIDs in the event payload are required for processing SNMPv2 or SNMPv3 events.

*Table 86. SNMPv2 protocol parameters (continued)*

Parameter	Description
<b>Coalescing Events</b>	Select this check box to enable the log source to coalesce (bundle) events.  Coalescing events increase the event count when the same event occurs multiple times within a short time interval. Coalesced events provide administrators a way to view and determine the frequency with which a single event type occurs on the <b>Log Activity</b> tab.  When this check box is clear, the events are displayed individually and the information is not bundled.  New and automatically discovered log sources inherit the value of this check box from the <b>System Settings</b> configuration on the <b>Admin</b> tab. Administrators can use this check box to override the default behavior of the system settings for an individual log source.
<b>Store Event Payload</b>	Select this check box to enable the log source to store the payload information from an event.  New and automatically discovered log sources inherit the value of this check box from the <b>System Settings</b> configuration on the <b>Admin</b> tab. Administrators can use this check box to override the default behavior of the system settings for an individual log source.

## SNMPv3 protocol configuration options

You can configure a log source to use the SNMPv3 protocol to receive SNMPv3 events.

The SNMPv3 protocol is an inbound/pассив protocol.

The following table describes the protocol-specific parameters for the SNMPv3 protocol:

*Table 87. SNMPv3 protocol parameters*

Parameter	Description
<b>Protocol Configuration</b>	<b>SNMPv3</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.
<b>Authentication Protocol</b>	The algorithm that you want to use to authenticate SNMPv3 traps: <ul style="list-style-type: none"><li>• <b>SHA</b> uses Secure Hash Algorithm (SHA) as your authentication protocol.</li><li>• <b>MD5</b> uses Message Digest 5 (MD5) as your authentication protocol.</li></ul>
<b>Authentication Password</b>	The password to authenticate SNMPv3. Your authentication password must include a minimum of 8 characters.

*Table 87. SNMPv3 protocol parameters (continued)*

Parameter	Description
<b>Decryption Protocol</b>	Select the algorithm that you want to use to decrypt the SNMPv3 traps. <ul style="list-style-type: none"><li>• DES</li><li>• AES128</li><li>• AES192</li><li>• AES256</li></ul> <b>Note:</b> If you select AES192 or AES256 as your decryption algorithm, you must install the Java Cryptography Extension. For more information about installing the Java Cryptography Extension on McAfee ePolicy Orchestrator, see <a href="#">Installing the Java Cryptography Extension</a> .
<b>Decryption Password</b>	The password to decrypt SNMPv3 traps. Your decryption password must include a minimum of 8 characters.
<b>User</b>	The user name that was used to configure SNMPv3 on your appliance
<b>Include OIDs in Event Payload</b>	Specifies that the SNMP event payload is constructed by using name-value pairs instead of the standard event payload format. When you select specific log sources from the <b>Log Source Types</b> list, OIDs in the event payload are required for processing SNMPv2 or SNMPv3 events. <b>Important:</b> You must include OIDs in the event payload for processing SNMPv3 events for McAfee ePolicy Orchestrator.

## Sophos Enterprise Console JDBC protocol configuration options

To receive events from Sophos Enterprise Consoles, configure a log source to use the Sophos Enterprise Console JDBC protocol.

The Sophos Enterprise Console JDBC protocol is an outbound/active protocol that combines payload information from application control logs, device control logs, data control logs, tamper protection logs, and firewall logs in the vEventsCommonData table. If the Sophos Enterprise Console does not have the Sophos Reporting Interface, you can use the standard JDBC protocol to collect antivirus events.

The following table describes the parameters for the Sophos Enterprise Console JDBC protocol:

*Table 88. Sophos Enterprise Console JDBC protocol parameters*

Parameter	Description
Protocol Configuration	<b>Sophos Enterprise Console JDBC</b>

Table 88. Sophos Enterprise Console JDBC protocol parameters (continued)

Parameter	Description
Log Source Identifier	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
Database Type	<b>MSDE</b>
Database Name	The database name must match the database name that is specified in the <b>Log Source Identifier</b> field.
Port	The default port for MSDE in Sophos Enterprise Console is 1168. The JDBC configuration port must match the listener port of the Sophos database to communicate with QRadar. The Sophos database must have incoming TCP connections enabled.  If a <b>Database Instance</b> is used with the MSDE database type, you must leave the <b>Port</b> parameter blank.
Authentication Domain	If your network does not use a domain, leave this field blank.
Database Instance	The database instance, if required. MSDE databases can include multiple SQL server instances on one server.  When a non-standard port is used for the database or administrators block access to port 1434 for SQL database resolution, the <b>Database Instance</b> parameter must be blank.
Table Name	vEventsCommonData
Select List	*
Compare Field	InsertedAt
Use Prepared Statements	Prepared statements enable the protocol source to set up the SQL statement, and then run the SQL statement numerous times with different parameters. For security and performance reasons, most configurations can use prepared statements. Clear this check box to use an alternative method of querying that do not use pre-compiled statements.
Start Date and Time	Optional. A start date and time for when the protocol can start to poll the database. If a start time is not defined, the protocol attempts to poll for events after the log source configuration is saved and deployed.
Polling Interval	The polling interval, which is the amount of time between queries to the database. You can define a longer polling interval by appending H for hours or M for minutes to the numeric value. The maximum polling interval is 1 week in any time format. Numeric values without an H or M designator poll in seconds.

*Table 88. Sophos Enterprise Console JDBC protocol parameters (continued)*

Parameter	Description
EPS Throttle	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.
Use Named Pipe Communication	If MSDE is configured as the database type, administrators can select this check box to use an alternative method to a TCP/IP port connection.  Named pipe connections for MSDE databases require the user name and password field to use a Windows authentication username and password and not the database user name and password. The log source configuration must use the default named pipe on the MSDE database.
Database Cluster Name	If you use your SQL server in a cluster environment, define the cluster name to ensure that named pipe communications function properly.
Use NTLMv2	Forces MSDE connections to use the NTLMv2 protocol with SQL servers that require NTLMv2 authentication. The default value of the check box is selected.  The <b>Use NTLMv2</b> check box does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.

## Sophos Central protocol configuration options

To receive events from Sophos Central, configure a log source to use the Sophos Central protocol.

The Sophos Central protocol is a cloud-based protocol that combines payload information from application control logs, device control logs, data control logs, tamper protection logs, and firewall logs.

The following table describes the parameters for the Sophos Central protocol:

*Table 89. Sophos Central protocol parameters*

Parameter	Description
Protocol Configuration	<b>Sophos Central</b>
Log Source Identifier	Type a unique name for the log source. The Log Source Identifier can be any valid value and does not need to reference a specific server. The Log Source Identifier can have the same value as the Log Source Name. If you have more than one configured log source per DSM, ensure to give unique name to each log source.
Authentication URL	The Authentication URL configured on your Sophos Central appliance to get the access token.
Tenant URL	The Tenant URL configured on your Sophos Central appliance to get the Tenant ID.
Client ID	The Client ID is a public identifier that is used by auth API for authentication.
Client Secret	The Client Secret is used to ensure that the user is authorized to obtain an access token.

*Table 89. Sophos Central protocol parameters (continued)*

Parameter	Description
Hostname	The Hostname configured on your Sophos Central appliance to access the API.
Events	Switch on the Events toggles if you want to capture events. Events are records of activities or occurrences that are related to the security operations within your network and devices that are managed by Sophos Central.
Alerts	Switch on the Alerts toggle if you want to capture alerts. Alerts are notifications that are generated by Sophos Central when certain predefined conditions or thresholds are met. Alerts indicate potential security issues that require attention.
Limits	The Limit is the maximum number of records to be returned. The default value is 200, and maximum value is 1000.
Recurrence	Specify how often the log source collects data. The value can be in Minutes (M), Hours (H), or Days (D). The default value is 5 minutes.
EPS Throttle	The limit for the maximum number of events per second (EPS) for events that are received from the API. The default is 5000.

## Sourcefire Defense Center eStreamer protocol options

Sourcefire Defense Center eStreamer protocol is now known as Cisco Firepower eStreamer protocol.

## Syslog Redirect protocol overview

The Syslog Redirect protocol is a passive inbound protocol that is used as an alternative to the Syslog protocol. Use this protocol when you want QRadar to identify the specific device name that sent the events. QRadar can passively listen for Syslog events by using TCP or UDP on any unused port that you specify.

The following table describes the protocol-specific parameters for the Syslog Redirect protocol:

*Table 90. Syslog Redirect protocol parameters*

Parameter	Description
<b>Protocol Configuration</b>	<b>Syslog Redirect</b>
<b>Log Source Identifier</b>	Enter a <b>Log Source Identifier</b> to use as a default. If the <b>Log Source Identifier Regex</b> cannot parse the <b>Log Source Identifier</b> from a particular payload by using the regex that is provided, the default is used.
<b>Log Source Identifier Regex</b>	Enter a regex to parse the <b>Log Source Identifier</b> from the payload.

Table 90. Syslog Redirect protocol parameters (continued)

Parameter	Description
<b>Log Source Identifier Regex Format String</b>	<p>Format string to combine capture groups from the Log Source Identifier Regex.</p> <p>For example:</p> <ul style="list-style-type: none"> <li>"\$1" would use the first capture group.</li> <li>"\$1\$2" would concatenate capture groups 1 and 2.</li> <li>"\$1 TEXT \$2" would concatenate capture group 1, the literal "TEXT" and capture group 2.</li> </ul> <p>The resulting string is used as the new log source identifier.</p>
<b>Listen Port</b>	Enter any unused port and set your log source to send events to QRadar on that port.
<b>Protocol</b>	<p>From the list, select either <b>TCP</b> or <b>UDP</b>.</p> <p>The Syslog Redirect protocol supports any number of UDP syslog connections, but restricts TCP connections to 2500. If the syslog stream has more than 2500 log sources, you must enter a second log source and listen port number.</p>
<b>Perform DNS Lookup On Regex Match</b>	Select the <b>Perform DNS Lookup On Regex Match</b> checkbox to enable DNS functionality, which is based on the <b>Log Source Identifier</b> parameter value.  By default, the checkbox is not selected.
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p><b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>
<b>Payload Size</b>	<p>The payload size is the length of data that is sent by the communicating endpoint. The default is 2048.</p> <p>The payload size must be an integer between 2048 and 32000.</p>
<b>Enabled</b>	Select this checkbox to enable the log source. By default, the checkbox is selected.
<b>Credibility</b>	<p>From the list, select the <b>Credibility</b> of the log source. The range is 0 - 10.</p> <p>The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.</p>

## TCP Multiline Syslog protocol configuration options

The TCP Multiline Syslog protocol is a passive inbound protocol that uses regular expressions to identify the start and end pattern of multiline events.

The following example is a multiline event:

```
06/13/2012 08:15:15 PM
LogName=Security
SourceName=Microsoft Windows security auditing.
EventCode=5156
EventType=0
TaskCategory=Filtering Platform Connection
Keywords=Audit Success
Message=The Windows Filtering Platform permitted a connection.
Process ID: 4
Application Name: System
Direction: Inbound
Source Address: <IP_address>
Source Port: 80
Destination Address: <IP_address>
Destination Port:444
```

The following table describes the protocol-specific parameters for the TCP Multiline Syslog protocol:

Table 91. TCP Multiline Syslog protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	<b>TCP Multiline Syslog</b>
<b>Log Source Identifier</b>	Type an IP address or hostname to identify the log source. To use a source name instead of a log source identifier, select <b>Use Custom Source Name</b> and enter values for the <b>Source Name Regex</b> and <b>Source Name Formatting String</b> parameters.  <b>Note:</b> These parameters are only available if <b>Show Advanced Options</b> is set to <b>Yes</b> .
<b>Listen Port</b>	The number of the port that accepts incoming TCP Multiline Syslog events. The default listen port is 12468.  To edit the port number, complete the following steps: <ol style="list-style-type: none"><li>Enter the new port number for the protocol.</li><li>Click <b>Save</b>.</li><li>On the <b>Admin</b> tab, click <b>Advanced &gt; Deploy Full Configuration</b>.</li></ol> <p> <b>Attention:</b> When administrators click <b>Deploy Full Configuration</b>, the system restarts all services, which can create a gap in data collection until the deployment completes.</p>
<b>Aggregation Method</b>	The method that you use to aggregate your TCP Multiline Syslog data. You can choose one of the following methods:  <b>ID-Linked Multiline</b> Processes multiline event logs that contain a common value at the start of each line.  <b>Start/End Matching</b> Processes multiline events by specifying start and end patterns for the events.

Table 91. TCP Multiline Syslog protocol parameters (continued)

Parameter	Description
<b>Event Start Pattern</b>	<p>This parameter is available when you set the <b>Aggregation Method</b> parameter to <b>Start/End Matching</b>.</p> <p>The regular expression (regex) that is required to identify the start of a TCP multiline event payload. Syslog headers typically begin with a date or timestamp. The protocol can create a single-line event that is based on solely on an event start pattern, such as a timestamp. When only a start pattern is available, the protocol captures all the information between each start value to create a valid event.</p>
<b>Event End Pattern</b>	<p>This parameter is available when you set the <b>Aggregation Method</b> parameter to <b>Start/End Matching</b>.</p> <p>This regular expression (regex) that is required to identify the end of a TCP multiline event payload. If the syslog event ends with the same value, use a regular expression to determine the end of an event.</p> <p>When only an <b>Event Start Pattern</b> is used and the sending device sends a few events (low EPS) in an interval, then the last sent event is not processed until the pipeline detects a new <b>Event Start Pattern</b>. For example, when a single "Test event" is sent, it might be invisible in the QRadar Log Activity without adding an <b>Event End Pattern</b>. To circumvent this scenario, send 2 to 3 test events at a time. Without an <b>Event End Pattern</b>, the last event is not captured until a new <b>Event Start Pattern</b> is detected.</p>
<b>Message ID Pattern</b>	<p>This parameter is available when you set the <b>Aggregation Method</b> parameter to <b>ID-Linked</b>.</p> <p>This regular expression (regex) is required to filter the event payload messages. The TCP multiline event messages must contain a common identifying value that repeats on each line of the event message.</p>
<b>Event Formatter</b>	Use the <b>Windows Multiline</b> option for multiline events that are formatted specifically for Windows.
<b>Show Advanced Options</b>	The default is <b>No</b> . Select <b>Yes</b> if you want to customize the event data.
<b>Use Custom Source Name</b>	<p>This parameter is available when you set <b>Show Advanced Options</b> to <b>Yes</b>.</p> <p>Select the checkbox if you want to customize the source name with regex.</p>
<b>Source Name Regex</b>	<p>This parameter is available when you check <b>Use Custom Source Name</b>.</p> <p>The regular expression (regex) that captures one or more values from event payloads that are handled by this protocol. These values are used with the <b>Source Name Formatting String</b> parameter to set a source or origin value for each event. This source value is used to route the event to a log source with a matching <b>Log Source Identifier</b> value.</p>

Table 91. TCP Multiline Syslog protocol parameters (continued)

Parameter	Description
<b>Source Name Formatting String</b>	<p>This parameter is available when you enable <b>Use Custom Source Name</b>.</p> <p>You can use a combination of one or more of the following inputs to form a source value for event payloads that are processed by this protocol:</p> <ul style="list-style-type: none"> <li>One or more capture groups from the <b>Source Name Regex</b>. To refer to a capture group, use  x notation where x is the index of a capture group from the <b>Source Name Regex</b>.</li> <li>The IP address where the event data originated from. To refer to the packet IP, use the token \$PIP\$.</li> <li>Literal text characters. The entire <b>Source Name Formatting String</b> can be user-provided text. For example, if the <b>Source Name Regex</b> is 'hostname=( .*)' and you want to append hostname.com to the capture group 1 value, set the <b>Source Name Formatting String</b> to \1.hostname.com. If an event is processed that contains hostname=ibm, then the event payload's source value is set to ibm.hostname.com, and QRadar routes the event to a log source with that <b>Log Source Identifier</b>.</li> </ul>
<b>Use as a Gateway Log Source</b>	<p>This parameter is available when you set <b>Show Advanced Options</b> to <b>Yes</b>.</p> <p>When selected, events that flow through the log source are routed to other log sources, based on the source name tagged on the events.</p> <p>When this option is not selected and <b>Use Custom Source Name</b> is not enabled, incoming events are tagged with a source name that corresponds to the Log Source Identifier parameter.</p>
<b>Flatten Multiline Events into Single Line</b>	<p>This parameter is available when you set <b>Show Advanced Options</b> to <b>Yes</b>.</p> <p>Shows an event in one single line or multiple lines.</p>
<b>Retain Entire Lines during Event Aggregation</b>	<p>This parameter is available when you set <b>Show Advanced Options</b> to <b>Yes</b>.</p> <p>If you set the <b>ID-Linked Multiline</b> method for the <b>Aggregation Method</b> parameter, then this parameter can modify aggregated event data outputs.</p> <p>If you enable <b>Retain Entire Lines during Event Aggregation</b>, then all parts of events are kept when aggregating events with the same ID pattern. If you don't enable this parameter, the part of the events before the <b>Message ID Pattern</b> are discarded when the events are aggregated.</p>
<b>Time Limit</b>	The number of seconds to wait for additional matching payloads before the event is pushed into the event pipeline. The default is 10 seconds.
<b>Initial Number of Threads</b>	The initial number of threads to use for formatting and posting events.

Table 91. TCP Multiline Syslog protocol parameters (continued)

Parameter	Description
<b>Maximum Number of Threads</b>	The maximum number of threads to use for formatting and posting events. When the task queue is full, more threads are created up to the value set by the <b>Maximum Number of Threads</b> parameter.
<b>Enabled</b>	Select this checkbox to enable the log source.
<b>Credibility</b>	Select the credibility of the log source. The range is 0 - 10. The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	Select the Event Collector in your deployment to host the TCP Multiline Syslog listener.
<b>Coalescing Events</b>	Select this checkbox to enable the log source to coalesce (bundle) events. By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Store Event Payload</b>	Select this checkbox to enable the log source to store event payload information. By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

## TCP Multiline Syslog protocol configuration use cases

To set the TCP Multiline Syslog listener log source to collect all events that are sent from the same system, follow these steps:

1. Leave **Use As A Gateway Log Source** and **Use Custom Source Name** cleared.
2. Enter the IP address of the system that is sending events in the **Log Source Identifier** parameter.

Figure 2. A QRadar log source collects events sent from a single system to a TCP Multiline Syslog Listener

If multiple systems are sending events to the TCP Multiline Syslog listener, or if one intermediary system is forwarding events from multiple systems and you want the events to be routed to separate log sources based on their syslog header or IP address, select the **Use As A Gateway Log Source** checkbox.

**Note:** QRadar checks each event for an RFC3164 or RFC5424-compliant syslog header, and if present, uses the IP or hostname from that header as the source value for the event. The event is routed to a log source with that same IP or hostname as its Log Source Identifier. If no such header is present, QRadar uses the source IP value from the network packet that the event arrived on as the source value for the event.

Figure 3. Separate QRadar log sources collect events sent from multiple systems to a TCP Multiline Listener, by using the syslog header.

Figure 4. Separate QRadar log sources collect events sent from multiple systems and forwarded through an intermediate system to a TCP Multiline Listener, by using the syslog header.

To route events to separate log sources based on a value other than the IP or hostname in their syslog header, follow these steps:

1. Select the **Use Custom Source Name** checkbox.
2. Configure a **Source Name Regex** and **Source Name Formatting String** to customize how QRadar sets a source name value for routing the received events to log sources.

Figure 5. Separate QRadar log sources collect events sent from multiple systems and forwarded through an intermediate system to a TCP Multiline Listener, by using the Source Name Regex and Source Name Formatting String.

## Related concepts

[“Gateway log source” on page 15](#)

Use a gateway log source to configure a protocol to use many Device Support Modules (DSMs) instead of relying on a single DSM type. With a gateway log source, event aggregator protocols can dynamically handle various event types.

## TLS Syslog protocol configuration options

---

Configure a TLS Syslog protocol log source to receive encrypted syslog events from network devices that support TLS Syslog event forwarding for each listener port.

The TLS Syslog protocol is a passive inbound protocol. The log source creates a listen port for incoming TLS Syslog events. By default, TLS Syslog log sources use the certificate and key that is generated by IBM QRadar. The TLS Log Source protocol supports the following functions.

- An **Event Collector** supports up to 1000 TLS connections.
- Each TLS Log Source (except **AutoDiscovered**) must use a unique port on that **Event Collector**.
- You can also create up to 1000 TLS Log Sources on an **Event Collector**.
- For **Pem** and **Key**, the **Key** must be in PKCS8/DER format.
- If you are using the **Cert Management** app, the **Key** must be in PKCS8 format.

The following table describes the protocol-specific parameters for the TLS Syslog protocol:

Table 92. TLS Syslog protocol parameters	
Parameter	Description
<b>Protocol Configuration</b>	<b>TLS Syslog</b>
<b>Log Source Identifier</b>	An IP address or hostname to identify the log source.
<b>TLS Listen Port</b>	The default TLS listen port is 6514. <b>Important:</b> You can assign only one TLS Syslog log source to each TLS listen port.
<b>Authentication Mode</b>	The mode your TLS connection uses to authenticate. If you select the <b>TLS and Client Authentication</b> option, you must configure the certificate parameters.
<b>Client Certificate Authentication</b>	Select one of the following options from the list: <ul style="list-style-type: none"><li>• <b>CN Allowlist and Issuer Verification</b></li><li>• <b>Client Certificate on Disk</b></li></ul>
<b>Use CN Allowlist</b>	Enable this parameter to use a CN allowlist.
<b>CN Allowlist</b>	The allowlist of trusted client certificate common names. You can enter plain text or a regular expression (regex). To define multiple entries, enter each one on a separate line.
<b>Use Issuer Verification</b>	Enable this parameter to use issuer verification.

Table 92. TLS Syslog protocol parameters (continued)

Parameter	Description
<b>Root/Intermediate Issuer's Certificate or Public key</b>	<p>Enter the Root/Intermediate issuer's certificate or public key in PEM format.</p> <ul style="list-style-type: none"> <li>Enter the certificate, beginning with: -----BEGIN CERTIFICATE----- and ending with: -----END CERTIFICATE-----</li> <li>Enter the public key beginning with: -----BEGIN PUBLIC KEY----- and ending with: -----END PUBLIC KEY-----</li> </ul>
<b>Check Certificate Revocation</b>	<p>Checks the certificate revocation status against the client certificate. This option requires network connectivity to the URL that is specified by the <b>CRL Distribution Points</b> field for the client certificate in the X509v3 extension.</p>
<b>Check Certificate Usage</b>	<p>Checks the contents of the certificate X509v3 extensions in the <b>Key Usage</b> and <b>Extended Key Usage</b> extension fields. For incoming client certificate, the allow values of X509v3 Key Usage are digitalSignature and keyAgreement. The allow value for X509v3 Extended Key Usage is TLS Web Client Authentication.</p> <p>This property is disabled by default.</p>
<b>Client Certificate Path</b>	<p>The absolute path to the client-certificate on disk. The certificate must be stored on the QRadar Console or Event Collector for this log source.</p> <p><b>Important:</b> Ensure that the certificate file that you enter begins with: -----BEGIN CERTIFICATE----- and ends with: -----END CERTIFICATE-----</p>
<b>Server Certificate Type</b>	<p>The type of certificate to use for authentication for the server certificate and server key.</p> <p>Select one of the following options from the <b>Server Certificate Type</b> list:</p> <ul style="list-style-type: none"> <li>Generated Certificate</li> <li>PEM Certificate and Private Key</li> <li>PKCS12 Certificate Chain and Password</li> <li>Choose from QRadar Certificate Store</li> </ul>

Table 92. TLS Syslog protocol parameters (continued)

Parameter	Description
<b>Generated Certificate</b>	<p>This option is available when you configure the <b>Certificate Type</b>. If you want to use the default certificate and key that is generated by QRadar for the server certificate and server key, select this option. The generated certificate is named <code>syslog-tls.cert</code> in the <code>/opt/qradar/conf/trusted_certificates/</code> directory on the target Event Collector that the log source is assigned to.</p>
<b>Single Certificate and Private Key</b>	<p>This option is available when you configure the <b>Certificate Type</b>. If you want to use a single PEM certificate for the server certificate, select this option and then configure the following parameters:</p> <ul style="list-style-type: none"> <li>• <b>Provided Server Certificate Path</b> - The absolute path to the server certificate.</li> <li>• <b>Provided Private Key Path</b> - The absolute path to the private key.</li> </ul> <p><b>Important:</b> The corresponding private key must be a DER-encoded PKCS8 key. The configuration fails with any other key format.</p>
<b>PKCS12 Certificate and Password</b>	<p>This option is available when you configure the <b>Certificate Type</b>. If you want to use a PKCS12 file that contains the server certificate and server key, select this option and then configure the following parameters:</p> <ul style="list-style-type: none"> <li>• <b>PKCS12 Certificate Path</b> - Type the file path for the PKCS12 file that contains the server certificate and server key.</li> <li>• <b>PKCS12 Password</b> - Type the password to access the PKCS12 file.</li> <li>• <b>Certificate Alias</b> - If there is more than one entry in the PKCS12 file, an alias must be provided to specify which entry to use. If only one alias is in the PKCS12 file, leave this field blank.</li> </ul>
<b>Choose from QRadar Certificate Store</b>	<p>This option is available when you configure the <b>Certificate Type</b>. You can use the Certificate Management app to upload a certificate from the QRadar Certificate Store.</p>
<b>Max Payload Length</b>	<p>The maximum payload length (characters) that is displayed for TLS Syslog message.</p>
<b>Maximum Connections</b>	<p>The <b>Maximum Connections</b> parameter controls how many simultaneous connections the TLS Syslog protocol can accept for each Event Collector.</p> <p>For each Event Collector, there is a limit of 1000 connections, including enabled and disabled log sources, in the TLS Syslog log source configuration for each Event Collector.</p> <p>The default for each device connection is 50 but not the limit for each port.</p> <p><b>Tip:</b> Automatically discovered log sources share a listener with another log source. For example, if you use the same port on the same event collector, it counts only one time toward the limit.</p>

Table 92. TLS Syslog protocol parameters (continued)

Parameter	Description
<b>TLS Protocols</b>	The TLS Protocol to be used by the log source. Select the "TLS 1.2 or later" option.
<b>Use As A Gateway Log Source</b>	Sends collected events through the QRadar Traffic Analysis Engine to automatically detect the appropriate log source.  If you do not want to define a custom log source identifier for events, clear the checkbox.  When this option is not selected and <b>Log Source Identifier Pattern</b> is not configured, QRadar receives events as unknown generic log sources.
<b>Use Predictive Parsing</b>	If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.  <b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.
<b>Log Source Identifier Pattern</b>	Use the <b>Use As A Gateway Log Source</b> option to define a custom log source identifier for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b> , QRadar receives events as unknown generic log sources.  Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.  Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.  The following examples show multiple key-value pair functions.  <b>Patterns</b> VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)  <b>Events</b> {LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}  <b>Resulting custom log source identifier</b> VPC-ACCEPT-OK
<b>Enable Multiline</b>	Aggregate multiple messages into single events based on a Start/End Matching or an ID-Linked regular expression.

Table 92. TLS Syslog protocol parameters (continued)

Parameter	Description
<b>Aggregation Method</b>	<p>This parameter is available when <b>Enable Multiline</b> is turned on.</p> <ul style="list-style-type: none"> <li>• <b>ID-Linked</b> - Processes event logs that contain a common value at the beginning of each line.</li> <li>• <b>Start/End Matching</b> - Aggregates events based on a start or end regular expression (regex).</li> </ul>
<b>Event Start Pattern</b>	<p>This parameter is available when <b>Enable Multiline</b> is turned on and the <b>Aggregation Method</b> is set to <b>Start/End Matching</b>.</p> <p>The regular expression (regex) is required to identify the start of a TCP multiline event payload. Syslog headers typically begin with a date or timestamp. The protocol can create a single-line event that is based on solely on an event start pattern, such as a timestamp. When only a start pattern is available, the protocol captures all the information between each start value to create a valid event.</p>
<b>Event End Pattern</b>	<p>This parameter is available when <b>Enable Multiline</b> is turned on and the <b>Aggregation Method</b> is set to <b>Start/End Matching</b>.</p> <p>This regular expression (regex) is required to identify the end of a TCP multiline event payload. If the syslog event ends with the same value, you can use a regular expression to determine the end of an event. The protocol can capture events that are based on solely on an event end pattern. When only an end pattern is available, the protocol captures all the information between each end value to create a valid event.</p>
<b>Message ID Pattern</b>	<p>This parameter is available when <b>Enable Multiline</b> is turned on and the <b>Aggregation Method</b> is set to <b>ID-Linked</b>.</p> <p>This regular expression (regex) required to filter the event payload messages. The TCP multiline event messages must contain a common identifying value that repeats on each line of the event message.</p>
<b>Time Limit</b>	<p>This parameter is available when <b>Enable Multiline</b> is turned on and the <b>Aggregation Method</b> is set to <b>ID-Linked</b>.</p> <p>The number of seconds to wait for more matching payloads before the event is pushed into the event pipeline. The default is 10 seconds.</p>
<b>Retain Entire Lines during Event Aggregation</b>	<p>This parameter is available when <b>Enable Multiline</b> is turned on and the <b>Aggregation Method</b> is set to <b>ID-Linked</b>.</p> <p>If you set the <b>Aggregation Method</b> parameter to <b>ID-Linked</b>, you can enable <b>Retain Entire Lines during Event Aggregation</b> to discard or keep the part of the events that precedes <b>Message ID Pattern</b>. You can enable this function only when concatenating events with the same ID pattern together.</p>
<b>Flatten Multiline Events Into Single Line</b>	<p>This parameter is available when <b>Enable Multiline</b> is turned on.</p> <p>Shows an event in one single line or multiple lines.</p>

Table 92. TLS Syslog protocol parameters (continued)

Parameter	Description
<b>Event Formatter</b>	This parameter is available when <b>Enable Multiline</b> is turned on. Use the <b>Windows Multiline</b> option for multiline events that are formatted specifically for Windows.

After the log source is saved, a syslog-tls certificate is created for the log source. The certificate must be copied to any device on your network that is configured to forward encrypted syslog. Other network devices that have a syslog-tls certificate file and the TLS listen port number can be automatically discovered as a TLS Syslog log source.

## TLS Syslog use cases

The following use cases represent possible configurations that you can create:

### Client Certificate on Disk

You can supply a client-certificate that enables the protocol to engage in client-authentication. If you select this option and provide the certificate, incoming connections are validated against the client-certificate.

### CN Allowlist and Issuer Verification

If you selected this option, you must copy the issuer certificate (with the .crt, .cert, or .der file extensions) to the following directory:

/opt/qradar/conf/trusted\_certificates

This directory is on the Target Event Collector that the log source is assigned to.

Any incoming client certificate is verified by the following methods to check whether the certificate was signed by the trusted issuer and other checks. You can choose one or both methods for client certificate authentication:

#### CN Allowlist

Provide an allowlist of trusted client certificate common names. You can enter plain text or a regular expression. Define multiple entries by entering each on a new line.

#### Issuer Verification

Provide a trusted client certificate's root or intermediate issuer certificate, or a public key in PEM format.

#### Check Certificate Revocation

Checks certificate revocation status against the client certificate. This option needs network connectivity to the URL that is specified by the **CRL Distribution Points** field in the client certificate for the X509v3 extension.

#### Check Certificate Usage

Checks the contents of the certificate X509v3 extensions in the **Key Usage** and **Extended Key Usage** extension fields. For incoming client certificate, the allow values of X509v3 Key Usage are digitalSignature and keyAgreement. The allow value for X509v3 Extended Key Usage is TLS Web Client Authentication.

#### User-provided Server Certificates

You can configure your own server certificate and corresponding private key. The configured TLS Syslog provider uses the certificate and key. Incoming connections are presented with the user-supplied certificate, rather than the automatically generated TLS Syslog certificate.

## Default authentication

To use the default authentication method, use the default values for the **Authentication Mode** and **Certificate Type** parameters. After the log source is saved, a `syslog-tls` certificate is created for log source device. The certificate must be copied to any device on your network that forwards encrypted syslog data.

## Related concepts

[“Gateway log source” on page 15](#)

Use a gateway log source to configure a protocol to use many Device Support Modules (DSMs) instead of relying on a single DSM type. With a gateway log source, event aggregator protocols can dynamically handle various event types.

## Multiple log sources over TLS Syslog

You can configure multiple devices in your network to send encrypted Syslog events to a single TLS Syslog listen port. The TLS Syslog listener acts as a gateway, decrypts the event data, and feeds it within QRadar to extra log sources configured with the Syslog protocol.

When using the TLS Syslog protocol, there are specific parameters that you must use.

Multiple devices within your network that support TLS-encrypted Syslog can send encrypted events via a TCP connection to the TLS Syslog listen port. These encrypted events are decrypted by the TLS Syslog (gateway) and are injected into the event pipeline. The decrypted events get routed to the appropriate receiver log sources or to the traffic analysis engine for autodiscovery.

Events are routed within QRadar to log sources with a **Log Source Identifier** value that matches the source value of an event. For Syslog events with an RFC3164-, or RFC5425-, or RFC5424-compliant Syslog header, the source value is the IP address or the host name from the header. For events that do not have a compliant header, the source value is the IP address of the device that sent the Syslog event.

On QRadar, you can configure multiple log sources with the Syslog protocol to receive encrypted events that are sent to a single TLS Syslog listen port from multiple devices.

**Note:** Most TLS-enabled clients require the target server or listener's public certificate to authenticate the server's connection. By default, a TLS Syslog log source generates a certificate that is named `syslog-tls.cert` in `/opt/qradar/conf/trusted_certificates/` on the target Event Collector that the log source is assigned to. This certificate file must be copied to all clients that are making a TLS connection.

To add a log source over TLS Syslog, go to [Adding a log source](#).

**Note:** You need to repeat the procedure for adding a log source for each device in your network. You can also add multiple receiver log sources in bulk from the **Log Sources** window. See [Adding bulk log sources](#).

## UDP multiline syslog protocol configuration options

To create a single-line syslog event from a multiline event, configure a log source to use the UDP multiline protocol. The UDP multiline syslog protocol uses a regular expression to identify and reassemble the multiline syslog messages into single event payload.

The UDP multiline syslog protocol is an inbound/pasive protocol. The original multiline event must contain a value that repeats on each line in order for a regular expression to capture that value and identify and reassemble the individual syslog messages that make up the multiline event. For example, this multiline event contains a repeated value, 2467222, in the conn field. This field value is captured so that all syslog messages that contain conn=2467222 are combined into a single event.

```
15:08:56 <IP_address> slapd[517]: conn=2467222 op=2 SEARCH RESULT tag=101
15:08:56 <IP_address> slapd[517]: conn=2467222 op=2 SRCH base="dc=xxx"
15:08:56 <IP_address> slapd[517]: conn=2467222 op=2 SRCH attr=gidNumber
15:08:56 <IP_address> slapd[517]: conn=2467222 op=1 SRCH base="dc=xxx"
```

The following table describes the protocol-specific parameters for the UDP multiline syslog protocol:

Table 93. UDP multiline syslog protocol parameters

Parameter	Description
<b>Protocol Configuration</b>	<b>UDP Multiline Syslog</b>
<b>Log Source Identifier</b>	<p>Type a unique name for the log source.</p> <p>The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b>. If you have more than one configured UDP multiline syslog log source, ensure that you give each one a unique name.</p>
<b>Listen Port</b>	<p>The default port number that is used by QRadar to accept incoming UDP Multiline Syslog events is 517. You can use a different port in the range 1 - 65535.</p> <p>To edit a saved configuration to use a new port number, complete the following steps:</p> <ol style="list-style-type: none"> <li>1. In the <b>Listen Port</b> field, type the new port number for receiving UDP Multiline Syslog events.</li> <li>2. Click <b>Save</b>.</li> <li>3. Click <b>Deploy Changes</b> to make this change effective.</li> </ol> <p>The port update is complete and event collection starts on the new port number.</p>
<b>Message ID Pattern</b>	The regular expression (regex) required to filter the event payload messages. The UDP multiline event messages must contain a common identifying value that repeats on each line of the event message.
<b>Event Formatter</b>	<p>The event formatter that formats incoming payloads that are detected by the listener. Select <b>No Formatting</b> to leave the payload untouched. Select <b>Cisco ACS Multiline</b> to format the payload into a single-line event.</p> <p>In ACS syslog header, there are <code>total_seg</code> and <code>seg_num</code> fields. These two fields are used to rearrange ACS multiline events into a single-line event with correct order when you select the Cisco ACS Multiline option.</p>
<b>Show Advanced Options</b>	The default is <b>No</b> . Select <b>Yes</b> if you want to configure advanced options.
<b>Use Custom Source Name</b>	Select the check box if you want to customize the source name with regex.

Table 93. UDP multiline syslog protocol parameters (continued)

Parameter	Description
<b>Source Name Regex</b>	<p>Use the <b>Source Name Regex</b> and <b>Source Name Formatting String</b> parameters if you want to customize how QRadar determines the source of the events that are processed by this UDP Multiline Syslog configuration.</p> <p>For <b>Source Name Regex</b>, enter a regex to capture one or more identifying values from event payloads that are handled by this protocol. These values are used with the <b>Source Name Formatting String</b> to set a source or origin value for each event. This source value is used to route the event to a log source with a matching <b>Log Source Identifier</b> value when the <b>Use As A Gateway Log Source</b> option is enabled.</p>
<b>Source Name Formatting String</b>	<p>You can use a combination of one or more of the following inputs to form a source value for event payloads that are processed by this protocol:</p> <ul style="list-style-type: none"> <li>One or more capture groups from the <b>Source Name Regex</b>. To refer to a capture group, use \x notation where x is the index of a capture group from the <b>Source Name Regex</b>.</li> <li>The IP address from which the event data originated. To refer to the packet IP, use the token \$PIP\$.</li> <li>Literal text characters. The entire <b>Source Name Formatting String</b> can be user-provided text.</li> </ul> <p>For example, CiscoACS\1\2\$PIP\$, where \1\2 means first and second capture groups from the <b>Source Name Regex</b> value, and \$PIP\$ is the packet IP.</p>
<b>Use As A Gateway Log Source</b>	<p>If this check box is clear, incoming events are sent to the log source with the <b>Log Source Identifier</b> matching the IP that they originated from.</p> <p>When checked, this log source serves as a single entry point or gateway for multiline events from many sources to enter QRadar and be processed in the same way, without the need to configure a UDP Multiline Syslog log source for each source. Events with an RFC3164- or RFC5424-compliant syslog header are identified as originating from the IP or host name in their header, unless the <b>Source Name Formatting String</b> parameter is in use, in which case that format string is evaluated for each event. Any such events are routed through QRadar based on this captured value.</p> <p>If one or more log sources exist with a corresponding <b>Log Source Identifier</b>, they are given the event based on configured Parsing Order. If they do not accept the event, or if no log sources exist with a matching <b>Log Source Identifier</b>, the events are analyzed for autodetection.</p>
<b>Flatten Multiline Events Into Single Line</b>	<p>Shows an event in one single line or multiple lines. If this check box is selected, all newline and carriage return characters are removed from the event.</p>

Table 93. UDP multiline syslog protocol parameters (continued)

Parameter	Description
<b>Retain Entire Lines During Event Aggregation</b>	Choose this option to either discard or keep the part of the events that comes before <b>Message ID Pattern</b> when the protocol concatenates events with same ID pattern together.
<b>Time Limit</b>	The number of seconds to wait for additional matching payloads before the event is pushed into the event pipeline. The default is 10 seconds.
<b>Enabled</b>	Select this check box to enable the log source.
<b>Credibility</b>	Select the credibility of the log source. The range is 0 - 10. The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	Select the Event Collector in your deployment that should host the UDP Multiline Syslog listener.
<b>Coalescing Events</b>	Select this check box to enable the log source to coalesce (bundle) events. By default, automatically discovered log sources inherit the value of the Coalescing Events list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Store Event Payload</b>	Select this check box to enable the log source to store event payload information. By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

## VMware vCloud Director protocol configuration options

To collect events from VMware vCloud Director virtual environments, create a log source that uses the VMware vCloud Director protocol, which is an active outbound protocol.

The following table describes the protocol-specific parameters for the VMware vCloud Director protocol:

Table 94. VMware vCloud Director protocol parameters

Parameter	Description
<b>Log Source Identifier</b>	The log source name can't include spaces and must be unique among all log sources of this type that are configured with the VMware vCloud Director protocol.
<b>Protocol Configuration</b>	<b>VMware vCloud Director</b>
<b>vCloud URL</b>	The URL that is configured on your VMware vCloud appliance to access the REST API. The URL must match the address that is configured as the <b>VCD public REST API base URL</b> field on the vCloud server. For example, <code>https://&lt;my.vcloud.server&gt;/api</code>
<b>User Name</b>	<p>The username that is required to remotely access the vCloud server. For example, <code>console/user@organization</code></p> <p>If you want to configure a read-only account to use with IBM QRadar, create a vCloud user in your organization that has the <b>Console Access Only</b> permission.</p>
<b>Password</b>	The password that is required to remotely access the vCloud Server.
<b>Polling Interval (in seconds)</b>	The amount of time between queries to the vCloud server for new events. The default polling interval is 10 seconds.
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>
<b>Enable Advanced Options</b>	Enable this option to configure more parameters.
<b>API PageSize</b>	<p>The number of records to return per API call. The maximum is 128. If you select <b>Enable Advanced Options</b>, this parameter is displayed.</p>
<b>vCloud API Version</b>	<p>The vCloud version that is used in your API request. This version must match a version that is compatible with your vCloud installation.</p> <p>Use the following examples to help you determine which version is compatible with your vCloud installation:</p> <ul style="list-style-type: none"> <li>• vCloud API 33.0 (vCloud Director 10.0)</li> <li>• vCloud API 32.0 (vCloud Director 9.7)</li> <li>• vCloud API 31.0 (vCloud Director 9.5)</li> <li>• vCloud API 30.0 (vCloud Director 9.1)</li> <li>• vCloud API 29.0 (vCloud Director 9.0)</li> </ul> <p>If you select <b>Enable Advanced Options</b>, this parameter is displayed.</p>

Table 94. VMware vCloud Director protocol parameters (continued)

Parameter	Description
<b>Allow Untrusted Certificates</b>	<p>When you connect to vCloud 5.1 or later, you must enable this option to allow self-signed, untrusted certificates.</p> <p>The certificate must be downloaded in PEM or DER encoded binary format and then placed in the /opt/qradar/conf/trusted_certificates/ directory with a .cert or .crt file extension.</p> <p>If you select <b>Enable Advanced Options</b>, this parameter is displayed.</p>
<b>Use Proxy</b>	<p>If the server is accessed by using a proxy, select the <b>Use Proxy</b> checkbox. If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.</p> <p>If you select <b>Enable Advanced Options</b>, this parameter is displayed.</p>
<b>Proxy IP or Hostname</b>	If you select <b>Use Proxy</b> , this parameter is displayed.
<b>Proxy Port</b>	<p>If you select <b>Use Proxy</b>, this parameter is displayed.</p> <p>The port number that is used to communicate with the proxy. The default is 8080.</p>
<b>Proxy Username</b>	If you select <b>Use Proxy</b> , this parameter is displayed.
<b>Proxy Password</b>	If you select <b>Use Proxy</b> , this parameter is displayed.

# Chapter 10. Universal Cloud REST API protocol

The Universal Cloud REST API protocol is an outbound, active protocol for IBM QRadar. You can customize the Universal Cloud REST API protocol to collect events from various REST APIs, including data sources that do not have a specific DSM or protocol.

The Universal Cloud REST API protocol behavior is defined by a workflow XML document. You can create your own XML document, or you can get it from [IBM Fix Central](#), or from third parties on [GitHub](#).

**Important:** The Universal Cloud REST API protocol is supported on QRadar 7.3.2 or later, and the QRadar Log Source Management app must be installed. For more information about how to install the app, see [Installing the QRadar Log Source Management app](#).

For Universal Cloud REST API protocol examples, see [GitHub samples](#) (<https://github.com/ibm-security-intelligence/IBM-QRadar-Universal-Cloud-REST-API>).

**Tip:** IBM supports only the workflows that are directly referenced in the *DSM Configuration Guide*. The workflows on GitHub can be used as educational resources but are not supported by IBM.

The following table describes the protocol-specific parameters for the Universal Cloud REST API protocol.

Table 95. Universal Cloud REST API protocol parameters	
Parameter	Description
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the <b>Log Source Name</b> . If you have more than one configured Universal Cloud REST API log source, ensure that you give each one a unique name.
<b>Workflow</b>	The XML document that defines how the protocol instance collects events from the target API. For more information, see <a href="#">“Workflow” on page 245</a> .
<b>Workflow Parameter Values</b>	The XML document that contains the parameter values used directly by the workflow. For more information, see <a href="#">“Workflow Parameter Values” on page 246</a> .

Table 95. Universal Cloud REST API protocol parameters (continued)

Parameter	Description
<b>Allow Untrusted Certificates</b>	<p>If you enable this parameter, the protocol can accept self-signed and otherwise untrusted certificates that are located within the /opt/qradar/conf/trusted_certificates/ directory. If you disable the parameter, the scanner trusts only certificates that are signed by a trusted signer.</p> <p>The certificates must be in PEM or RED-encoded binary format and saved as a .crt or .cert file.</p> <p>If you modify the workflow to include a hardcoded value for the <b>Allow Untrusted Certificates</b> parameter, the workflow overrides your selection in the UI. If you do not include this parameter in your workflow, then your selection in the UI is used.</p>
<b>Use Proxy</b>	<p>If the API is accessed by using a proxy, select this checkbox.</p> <p>Configure the <b>Proxy IP or Hostname</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.</p>
<b>Recurrence</b>	<p>Specify how often the log collects data. The value can be in Minutes (M), Hours (H), or Days (D). The default is 10 minutes.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

## Related concepts

[“Workflow” on page 245](#)

The Workflow is an XML document that describes the event retrieval process. The Workflow defines one or more parameters, which can be explicitly assigned values in the Workflow XML or can derive values from the Workflow parameter values XML document. The Workflow consists of multiple actions that run sequentially. When you run the Workflow, the parameter values are added to the [State](#), and the State can then be accessed and changed by actions as the Workflow runs.

[“Workflow Parameter Values” on page 246](#)

The Workflow Parameter Values is an XML document that contains the input parameters of a workflow instance. It is a set of name/value pairs where the name must match one of the parameters defined in the associated workflow. The following table shows the Workflow Parameter Values parameters.

[“State” on page 246](#)

The State is a JSON object that represents the data of a running Workflow. Because the State is not strictly defined, data is dynamically stored in the State.

## Workflow

The Workflow is an XML document that describes the event retrieval process. The Workflow defines one or more parameters, which can be explicitly assigned values in the Workflow XML or can derive values from the Workflow parameter values XML document. The Workflow consists of multiple actions that run sequentially. When you run the Workflow, the parameter values are added to the State, and the State can then be accessed and changed by actions as the Workflow runs.

The following table shows the Workflow attributes.

Table 96. Workflow attributes		
Name	Description	Required
name	The name of the Workflow.	Yes
description	The description of the Workflow.	No
version	The version of the Workflow.	Yes
minimumRecurrence	The minimum recurrence allowed for a Workflow in seconds. You can set this attribute for APIs that have a minimum amount of time between requests.	No

## Parameters

Use the Workflow actions to access the parameter values. Parameters mostly consist of authentication credentials, but can be used for anything that you want the user to configure. The following table shows the Workflow parameters.

Table 97. Workflow parameters		
Name	Data type	Description
name	String	The name of the parameter. The name must match the corresponding name value in the parameter values XML.
label	String	The display name of the parameter.
description	String	The description of the parameter.
required	Boolean	Indicates whether the parameter is required.
secret	Boolean	Indicates whether the parameter is confidential, for example, a password.
default	String	The default value of the parameter. If you don't enter a value for this parameter in the parameter values XML, the default value is used.

## XML Example

This example shows a workflow example which requires a host with a username and password, where <x> is the version of the workflow schema that you are using.

```
<Workflow name="Test" version="1.0" xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/Workflow/
V<x>">
    <Parameters>
        <Parameter name="host" label="Host" required="true" />
        <Parameter name="username" label="Username" required="true" />
        <Parameter name="password" label="Password" required="true" />
    </Parameters>
```

```

<Actions>
  ...
</Actions>
</Workflow>

```

## Workflow Parameter Values

The Workflow Parameter Values is an XML document that contains the input parameters of a workflow instance. It is a set of name/value pairs where the name must match one of the parameters defined in the associated workflow. The following table shows the Workflow Parameter Values parameters.

Table 98. Workflow Parameter Values parameters			
Name	Data type	Description	Required
name	String	The name of the parameter, as defined in the workflow	Yes
value	String	The value of the parameter, as defined in the workflow	No

### XML Example

In this example, the host parameter is given the value "mycloud.com". The username parameter is given the value "admin". And the password parameter is given the value "password123."

```

<?xml version="1.0" encoding="UTF-8" ?>
<WorkflowParameterValues xmlns="http://qradar.ibm.com/UniversalCloudRESTAPI/
WorkflowParameterValues/V1">
  <Value name="host"    value="" />
  <Value name="username" value="" />
  <Value name="password" value="" />
</WorkflowParameterValues>

```

## State

The State is a JSON object that represents the data of a running Workflow. Because the State is not strictly defined, data is dynamically stored in the State.

JSON can store almost any kind of data and allows data to be classified in subobjects. API responses are stored in JSON format and events are assembled to be sent to the pipeline in JSON.

### Persistence

The State is persisted and is not lost during upgrades, restarts, and deployments of IBM QRadar.

### Encryption

The State supports encryption to prevent sensitive data from being displayed.

### Querying

The State can be queried with JPath, which is a JSON query language that is similar to XPath for XML. For more information, see ["JPath" on page 268](#).

### Template Strings

A template string is a string that can contain JPath expressions. JPath expressions are referenced by using the \${...} syntax. For more information, see ["JPath" on page 268](#).

### Example

You can use JPath expressions to determine a result from the following State.

```

{
  "some": [
    {
      "value": 123
    }
  ]
}

```

The following table shows JPath expressions and their results.

Table 99. Template string examples		
Description	Template string	Result
Simple value reference	"The value is \${/some/value}"	"The value is 123"
Arithmetic	"The value is \${/some/value * 2}"	"The value is 246"
Logical operations	"The expression is \${/some/value > 12}"	"The expression is true"
Built-in function	"The current time is \${time()}ms since epoch"	"The current time is 1586968388123ms since epoch"

## Actions

Actions are the building blocks of the workflow. Each action has a specific purpose, such as calling HTTP endpoints, or posting events to the QRadar pipeline.

### Abort

The Abort action aborts the workflow.

The workflow is aborted immediately, in error. If the terminate flag is false, the workflow resumes on the next recurrence, otherwise it stops until either the event collection service is restarted, or the log source is edited.

The following table shows the parameters for the Abort action.

Table 100. Abort action parameters			
Name	Data type	Required	Notes
reason	String	Yes	The reason why the workflow was aborted. This string displays in the log source status as an error message.
terminate	Boolean	No	Indicates whether the event retrieval loop is terminated. The default is False.  Use this parameter only in extreme situations. The parameter puts the log source in error and stops it completely. The log source restarts only when the event collection service is restarted, or if the log source is edited.  You can use the terminate parameter to stop the workflow on authentication failure to prevent account lockouts.

#### XML Example:

This action stops the current execution of the workflow, but it runs again on the next recurrence. Until the log source status is cleared or updated, it includes the following error message:

The password for <user value> has expired.

```
<Abort reason="The password for '${/user}' has expired." />
```

## Add

The Add action adds a value to an array in the State.

The following table shows the parameters for the Add action.

<i>Table 101. Add action parameters</i>			
Name	Data type	Required	Notes
path	JPath	Yes	The location of the array. The path must reference an array value.
value	String/Number	Yes	

### XML Example:

This action adds the string "V2hhCBhIHdvbmRlcmb1bCB3b3JsZC4uLg==" to the State at location /tokens.

```
<Add path="/tokens" value="V2hhCBhIHdvbmRlcmb1bCB3b3JsZC4uLg==" />
```

## CallEndpoint

The CallEndpoint action calls an HTTP endpoint.

The following table shows the parameters for the CallEndpoint action.

<i>Table 102. CallEndpoint action parameters</i>				
Name	Data type	Relationship	Required	Notes
method	Enumeration	Attribute	Yes	Possible values: <ul style="list-style-type: none"><li>• GET</li><li>• POST</li><li>• PUT</li><li>• DELETE</li><li>• PATCH</li></ul>
url	String	Attribute	Yes	The base URL of the endpoint (excluding the query parameters).

Table 102. CallEndpoint action parameters (continued)

Name	Data type	Relationship	Required	Notes
savePath	String	Attribute	No	<p>The response is stored as a JSON object with the following format:</p> <pre>/response {   status_code: 200,   status_message: "OK",   headers: {     "Date": "Tue, 16 Jun 2020 17:31:29 GMT",     "Content-Type": "application/json",   },   body: ... }</pre> <p>If you do not provide a savePath value, the endpoint response is not saved in a default location. A savePath value must be provided if you want to store the response.</p>
sslConfiguration	SSLConfiguration	Subelement	No	For more information, see <a href="#">SSLConfiguration</a> .
authentication	Authentication	Subelement	No	<p>An Authentication object must be one of the following types:</p> <ul style="list-style-type: none"> <li>• <a href="#">BasicAuthentication</a></li> <li>• <a href="#">BearerAuthentication</a></li> <li>• <a href="#">DigestAuthentication</a></li> <li>• <a href="#">New in V2 Akamai EdgeGrid Authentication</a></li> <li>• <a href="#">New in V2 Hawk Authentication</a></li> </ul>
queryParameters	QueryParameter	Subelement	No	You can have more than one query parameter. For more information, see <a href="#">QueryParameter</a> .
requestHeaders	RequestHeaders	Subelement	No	You can have more than one request header. For more information, see <a href="#">RequestHeader</a> .
requestCookie	RequestCookie	Subelement	No	<a href="#">New in V2_1</a> You can have more than one request cookies. For more information, see <a href="#">RequestCookie</a>

*Table 102. CallEndpoint action parameters (continued)*

Name	Data type	Relationship	Required	Notes
body	RequestBody UrlEncodedFormRequestBody XmlRequestBody	Subelement	No	The body must be one of the following types: <ul style="list-style-type: none"><li>• RequestBody</li><li>• UrlEncodedFormRequestBody</li><li>• XmlRequestBody</li></ul>

The following table shows the parameters for SSLConfiguration.

*Table 103. SSLConfiguration structure*

Name	Data type	Required	Notes
protocol	String	No	The SSL protocol to use. The default is TLSv1.2.
allowUntrustedServerCertificate	Boolean	No	Indicates whether untrusted server certificates are allowed. The default is False.

**XML Example:**

This example allows an untrusted server certificate.

```
<SSLConfiguration allowUntrustedServerCertificate="true" />
```

The following table shows the parameters for BasicAuthentication.

*Table 104. BasicAuthentication structure*

Name	Data type	Required
username	String	Yes
password	String	No

**XML Example:**

This example sets an authentication username and password.

```
<BasicAuthentication username="${username}" password="${password}" />
```

The following table shows the parameters for BearerAuthentication.

*Table 105. BearerAuthentication structure*

Name	Data type	Required	Notes
token	String	Yes	The access token.

**XML Example:**

This example sets an access token for authentication.

```
<BearerAuthentication token="${access_token}" />
```

The following table shows the parameters for DigestAuthentication.

*Table 106. DigestAuthentication structure*

Name	Data type	Required
username	String	Yes
password	String	Yes
realm	String	No
nonce	String	No
algorithm	String	No
qop	String	No
cnonce	String	No
nonceCount	String	No

**XML Example:**

This example sets a username and password for authentication.

```
<DigestAuthentication username="${public_key}" password="${private_key}" />
```

New in V2

The following table shows the parameters for Akamai EdgeGrid authentication.

*Table 107. Akamai EdgeGrid authentication structure*

Name	Data type	Required
accessToken	String	Yes
clientToken	String	Yes
clientSecret	String	Yes

New in V2

The following table shows the parameters for Hawk authentication.

*Table 108. Hawk authentication structure*

Name	Data type	Required
keyID	String	Yes
key	String	Yes
algorithm	String	Yes
hash	String	No
ext	String	No
app	String	No
dlg	String	No

The following table shows the parameters for QueryParameter.

*Table 109. QueryParameter structure*

Name	Data type	Required	Notes
name	String	Yes	

*Table 109. QueryParameter structure (continued)*

Name	Data type	Required	Notes
value	String	Yes	
omitIfEmpty	Boolean	No	Omits the parameter if the value is empty.

**XML Example:**

This example sets a name and value for a query, and omits the parameter if the value is empty.

```
<QueryParameter name="stream_position" value="${/bookmark}" omitIfEmpty="true" />
```

The following table shows the parameters for RequestHeader.

*Table 110. RequestHeader structure*

Name	Data type	Required	Notes
name	String	Yes	
value	String	No	
omitIfEmpty	Boolean	No	Omits the header if the value is empty.

**XML Example:**

This example sets a name and value for a request header.

```
<RequestHeader name="authorization" value="client_id:${/client_id}, client_secret:${/client_secret}" />
```

New in V2\_1

The following table shows the parameters for Request Cookie.

*Table 111. RequestCookie structure*

Name	Data type	Required	Notes
name	String	Yes	
value	String	Yes	
domain	String	No	Sets the domain for the cookie. The default value of the domain will be the hostname captured from the callendpoint url attribute. The default value is the domain of the url attribute. If the domain returned by the cookie is not the same as the domain of the URL, you must specify the domain.

*Table 111. RequestCookie structure (continued)*

Name	Data type	Required	Notes
path	String	No	Sets the path for the cookie. The default value is the path of the url attribute. If the path returned by the cookie does not match the path of the URL, you must specify the path.
secret	Boolean	No	Encrypts the value field. The default value is set to false.

**XML Example:**

This example sets the required field (name and value) for a request cookie.

```
<RequestCookie name="${<savePath>/cookies/<cookie_name>/name}" value="${< savePath>/cookies/<cookie_name> /value}">
```

This Example sets all the required and optional fields of the cookie.

```
<RequestCookie name="${<savePath>/cookies/<cookie_name>/name}" value="${< savePath>/cookies/<cookie_name> /value}" domain="${<savePath>/cookies/<cookie_name>/domain}" path = "${<savePath>/cookies/<cookie_name>/path}" secret = "true">
```

The following table shows the parameters for RequestBody.

*Table 112. RequestBody structure*

Name	Data type	Required	Notes
type	String	Yes	Must be a valid HTTP request content-type. For example, application/json.
encoding	String	Yes	Must be a valid HTTP body encoding type. For example, UTF-8.
content	String	Yes	Include the body content between the opening and closing tags of the <RequestBody> element.

**XML Example:**

This example sets a content-type, body encoding, and content for a request body.

```
<RequestBody type="application/json" encoding="UTF-8">{ "grant_type": "client_credentials" }</RequestBody>
```

The following table shows the parameters for UrlEncodedFormRequestBody.

*Table 113. UrlEncodedFormRequestBody structure*

Name	Data type	Required	Notes
parameters	Map <String, String>	Yes	A collection of name/value pairs.

**XML Example:**

This example sets the name/value pairs for a URL encoded form request body.

```
<UrlEncodedFormRequestBody>
    <Parameter name="grant_type" value="urn:ietf:params:oauth:grant-type:jwt-
bearer" />
    <Parameter name="client_id" value="${client_id}" />
    <Parameter name="client_secret" value="${client_secret}" />
    <Parameter name="assertion" value="${jwt_assertion}" />
</UrlEncodedFormRequestBody>
```

The following table shows the parameters for XmlRequestBody.

Table 114. XmlRequestBody structure			
Name	Data type	Required	Notes
type	String	No	Must be a valid HTTP request content-type. For example, application/json.
encoding	String	No	Must be a valid HTTP body encoding type. For example, UTF-8.
content	XML	Yes	The actual XML content of the body must be nested within the <b>&lt;XmlRequestBody&gt;</b> element as subelements.

### XML Example:

This example sets the content for an XML request body.

```
<XmlRequestBody>
    <authRequest>
        <maaS360AdminAuth>
            <billingID>${/billing_id}</billingID>
            <platformID>${/platform_id}</platformID>
            <appID>${/app_id}</appID>
            <appVersion>${/app_version}</appVersion>
            <appAccessKey>${/app_access_key}</appAccessKey>
            <userName>${/username}</userName>
            <password>${/password}</password>
        </maaS360AdminAuth>
    </authRequest>
</XmlRequestBody>
```

### XML Example:

This action calls makes a POST request to https://\${host}/auth/oauth2/token with a request header and a request body, and saves the response in the State at /get\_access\_token.

```
<CallEndpoint url="https://${host}/auth/oauth2/token" method="POST" savePath="/
get_access_token">
    <RequestHeader name="authorization" value="client_id:${client_id}, client_secret:${/
client_secret}" />
    <RequestBody type="application/json" encoding="UTF-8">{ "grant_type": "client_credentials" }</RequestBody>
</CallEndpoint>
```

## ClearStatus

The ClearStatus action clears the runtime status of the protocol instance. This clears the status of the log source.

### XML Example

This action clears any info, warning or error messages that are displayed for the log source.

```
<ClearStatus />
```

## Copy

The Copy action copies one part of the State to another.

The following table shows the parameters for the Copy action.

Table 115. Copy action parameters				
Name	Data type	Required	Notes	
sourcePath	JPath	Yes	The path to copy. This path can be either a static path or a query.	
targetPath	JPath	Yes	The location to which the path is copied. This path overwrites anything that is stored at this location.	

### XML Example

This action copies the objects from the array at /events with a **type\_id** of 4 to an array at location /interestingEvents, and erasing anything that was stored there previously.

```
<Copy sourcePath="/events[@type_id = 4]" targetPath="/interestingEvents" />
```

## Create JWTAccessToken

The JWTAccessToken action creates a JSON Web Token (JWT).

For more information, see [JWT documentation](#).

The following table shows the parameters for the Create JWTAccessToken action.

Table 116. Create JWTAccessToken action parameters				
Name	Data type	Relationship	Required	Notes
Header	KeyValuePairs	Subelement	Yes	The set of name/value pairs that form the JWT header. For more information, see <a href="#">Table 117 on page 256</a>
Payload	KeyValuePairs	Subelement	Yes	The set of name/value pairs that form the JWT payload. For more information, see <a href="#">Table 118 on page 256</a>

*Table 116. Create JWTAccessToken action parameters (continued)*

Name	Data type	Relationship	Required	Notes
Secret	String	Subelement	Yes	In V1, the Secret must be a Base64 PKCS8 PEM file. In V2 or later, it can be either a PVKS1 or PVKS8 PEM file, and can be entered as plain text or Base64 encoded. For more information, see <a href="#">Table 119 on page 256</a>
savePath	JPath	Attribute	Yes	The location in the state to store this value.

*Table 117. Header structure*

Name	Data type	Description	Required	Notes
name	String	The name of the header.	Yes	
value	String	The value of the header.	No	

*Table 118. Payload structure*

Name	Data type	Description	Required	Notes
name	String	The name of the payload.	Yes	
value	String	The value of the payload.	No	

*Table 119. Secret structure*

Name	Data type	Description	Required	Notes
value	String	The value of the secret.	No	

### XML Example

This action creates a JWT with the provided header, payload and secret values, and saves it in the State at location /access\_token.

```
<CreateJWTAccessToken savePath="/access_token">
    <Header>
        <Value name="alg" value="HS256" />
        <Value name="typ" value="JWT" />
    </Header>
    <Payload>
        <Value name="iss" value="${/api_key}" />
    </Payload>
    <Secret value="${/api_secret}" />
</CreateJWTAccessToken>
```

## Delete

The Delete action deletes an element from the State.

The following table shows the parameters for the Delete action.

*Table 120. Delete action parameters*

Name	Data type	Required	Notes
path	JPath	Yes	The location of the element to delete.

### XML Example

This action deletes the value that exists in the State at location /token

```
<Delete path="/token" />
```

## DoWhile

The DoWhile action loops a series of actions while a condition is true.

The condition is evaluated at the end of the loop. Even if the condition is never true, the contents are executed once. This action is different from the While action, where the condition is evaluated at the beginning of the loop.

The following table shows the parameters for the DoWhile action.

*Table 121. DoWhile action parameters*

Name	Data type	Required	Notes
condition	JPath	Yes	The condition that determines whether to continue looping.
actions	JPath Condition	Yes	Must be a JPath expression that resolves to a value of true or false. References to the State should not be within the \${} notation for JPath conditions. See “ <a href="#">JPath</a> ” on page 268

### XML Example

This action executes the nested CallEndpoint action and PostEvent action. If there is a value in the State at location /next\_page the condition is true and the nested actions are executed, and the condition check is performed until the condition is false.

```
<DoWhile condition="/next_page != null">
  <CallEndpoint ... />
  <PostEvent path="/current/event" />
</DoWhile>
```

## ForEach

The ForEach action executes a series of actions for each value in an array or object. In V1, the action works only for each value in an array.

The following table shows the parameters for the ForEach action.

*Table 122. ForEach action parameters*

Name	Data type	Description	Required	Notes
item	JPath	The path to store the current item of the iteration.	Yes	The path to store the current item of the iteration.

*Table 122. ForEach action parameters (continued)*

Name	Data type	Description	Required	Notes
items	JPath	The array in the State to iterate.	Yes	The array in the State to iterate.
actions	Actions[]	The sequence of actions to execute for each iteration.	Yes	The sequence of actions to execute for each iteration. Cannot be empty.

### XML Example

An array of objects exists in the State at /events. This action iterates through the array and executes the nested PostEvent action for each object in the array.

```
<ForEach item="/current_event" items="/events">
  <PostEvent path="/current_event" source="${host}" />
</ForEach>
```

## FormatDate

The FormatDate action formats a UNIX timestamp to a date.

The following table shows the parameters for the FormatDate action.

*Table 123. FormatDate action parameters*

Name	Data type	Required	Notes
pattern	String	Yes	See Java <a href="#">DateTimeFormatter</a> for possible values.
timeZone	String	No	See Java <a href="#">DateTimeFormatter</a> for possible values.
time	Number	No	The time to format, in milliseconds since epoch. The default is the current time.
savePath	JPath	Yes	The location to store the result.

### XML Example

This action extracts the UNIX timestamp currently stored in the State at /bookmark and converts it to a meaningful timestamp in the following format in the UTC time zone.

```
yyyy-MM-dd'T'HH:mm:ss.SSS'Z'
```

```
<FormatDate pattern="yyyy-MM-dd'T'HH:mm:ss" timeZone="UTC" time="${bookmark}" savePath="/formatted_bookmark" />
```

The reformatted value is saved in the State at /formatted\_bookmark.

## GenerateHMAC

The GenerateHMAC action applies an HMAC hash to a given input.

The following table shows the parameters for the GenerateHMAC action.

*Table 124. GenerateHMAC action parameters*

Name	Data type	Required	Notes
algorithm	Enumeration	Yes	Possible values: <ul style="list-style-type: none"><li>• MD5</li><li>• SHA1</li><li>• SHA256</li><li>• SHA512</li></ul>
secretKey	String	Yes	The secret to use.
message	String	Yes	The input message to process.
saveFormat	String	Yes	Possible values: <ul style="list-style-type: none"><li>• BASE64</li><li>• HEX</li></ul>
savePath	JPath	Yes	The location to store the result.

### XML Example

This action generates an HMAC hash of the value stored in the State at `/value`. The hash is generated in hex format by using the SHA1 algorithm and the provided **secretKey**, and is saved in the State at location `/signature`.

```
<GenerateHMAC algorithm="SHA1" secretKey="${/secret_key}" message="${/value}" saveFormat="HEX"
savePath="/signature" />
```

## If/ElseIf/Else

The If/ElseIf/Else actions execute actions if a condition is satisfied.

The If/ElseIf/Else actions execute nested actions based on one or more mutually-exclusive conditions:

- "If" conditions are always checked.
- "ElseIf" conditions are only checked if all preceding "If" and "ElseIf" conditions were not satisfied.
- "Else" actions have no condition; if none of the preceding "If" or "ElseIf" conditions were satisfied, the "Else" actions are automatically executed.

The following table shows the parameters for the If action.

*Table 125. If action parameters*

Name	Data type	Required	Notes
condition	JPath	Yes	The condition to evaluate. Cannot be empty.
actions	Actions[]	Yes	The sequence of actions to execute if the condition is true. Cannot be empty.

The following table shows the parameters for the ElseIf action.

*Table 126. ElseIf action parameters*

Name	Data type	Required	Notes
condition	JPath	Yes	The condition to evaluate. Cannot be empty.
actions	Actions[]	Yes	The sequence of actions to execute if the condition is true. Cannot be empty.

The following table shows the parameters for the Else action.

*Table 127. Else action parameters*

Name	Data type	Required	Notes
actions	Actions[]	Yes	The sequence of actions to execute if none of the preceding "If" or "ElseIf" conditions are true. Cannot be empty.

### XML Example

In this example, the following actions are taken:

- If the State value at location /status is 200, only the SetStatus action that sets the status to an INFO "Success" message is executed.
- If the /status value is 401, only the SetStatus action that sets the status to an ERROR "Authentication Failure" message is executed.
- If the /status value is 404, only the SetStatus action that sets the status to an ERROR "No Route Exists" message is executed.
- If the /status value is anything else, only the final SetStatus action is executed.

```
<If condition="/status = 200">
    <SetStatus type="INFO" message="Success." />
</If>
<ElseIf condition="/status = 401">
    <SetStatus type="ERROR" message="Authentication Failure." />
</ElseIf>
<ElseIf condition="/status = 404">
    <SetStatus type="ERROR" message="No Route Exists." />
</ElseIf>
<Else>
    <SetStatus type="ERROR" message="An unknown error (${/status}) has occurred." />
</Else>
```

## Initialize

The Initialize action initializes a value in the State.

If a value exists in the location, the new value does not override the existing value.

*Table 128. Initialize action parameters*

Name	Data type	Required	Notes
path	JPath	Yes	The location to initialize.
value	String/Number	Yes	The value to set.

## XML Example

This action adds the value "1" to the State at location /bookmark, if no value exists at that location. If a value does exist at that location, the action does nothing.

```
<Initialize path="/bookmark" value="1" />
```

## Log

The Log action logs troubleshooting messages.

Troubleshooting messages are typically stored in the QRadar log files at /var/log/qradar.error, /var/log/qradar.log, and /var/log/qradar.java.debug

The following table shows the parameters for the Log action.

Table 129. Log action parameters			
Name	Data type	Required	Notes
type	Enumeration	Yes	The log type. Possible values: <ul style="list-style-type: none"><li>• INFO</li><li>• WARN</li><li>• ERROR</li><li>• DEBUG</li></ul>
message	String	Yes	The message to log.

## XML Example

This action writes a DEBUG level log to the QRadar logs that contain the specified message.

```
<Log type="DEBUG" message="The value was ${some_value}." />
```

## Merge

The Merge action merges an array into an array, or an object into an object.

The following table shows the parameters for the Merge action.

Table 130. Merge action parameters			
Name	Data type	Required	Notes
sourcePath	JPath	Yes	The object or array to copy from.
targetPath	JPath	Yes	The object or array to merge into.

## XML Example:

This action copies all objects that have a type\_id value of 4 in the array at location /events in the State to the array at /cumulativeEvents. Any objects already in /cumulativeEvents are preserved.

```
<Merge sourcePath="/events[@type_id = 4]" targetPath="/cumulativeEvents" />
```

## ParseDate

The ParseDate action parses a date into a UNIX timestamp.

The ParseDate action is supported by the Java `DateTimeFormatter`. Some of the ParseDate action parameters are passed directly to Java.

The following table shows the parameters for the ParseDate action.

<i>Table 131. ParseDate action parameters</i>			
Name	Data type	Required	Notes
pattern	String	Yes	The formatting pattern to use. See <a href="#">Java <code>DateTimeFormatter</code></a> for possible values.
timeZone	String	No	The time zone to use. See <a href="#">Java <code>DateTimeFormatter</code></a> for possible values.
date	String	Yes	The formatted date to parse.
savePath	JPath	Yes	The location to store the result.

### XML Example:

This action converts the timestamp that is stored in the State at location `/formatted_time` to a UNIX timestamp and stores it in the State at location `/timestamp`. The current timestamp must be in the `yyyy-MM-dd'T'HH:mm:ss'Z'` format and represent a time in the Coordinated Universal Time (UTC) zone.

```
<ParseDate pattern="yyyy-MM-dd'T'HH:mm:ss" timeZone="UTC" time="${/formatted_time}"  
savePath="/timestamp" />
```

## PostEvent

The PostEvent action posts an event to the QRadar event pipeline, which allows the event to be parsed, correlated, and stored.

The following table shows the parameters for the PostEvent action.

<i>Table 132. PostEvent action parameters</i>			
Name	Data type	Required	Notes
path	JPath	Yes	The path of the element to the post.
encoding	String	No	The encoding of the event.  Possible values: <ul style="list-style-type: none"><li>• UTF-8</li><li>• BASE64</li><li>• HEX</li></ul> The default is UTF-8.

*Table 132. PostEvent action parameters (continued)*

Name	Data type	Required	Notes
source	String	Yes  (Optional field for V2_1)	The source (host) of the event.  The source value is used to route the event within the event pipeline to the correct log source. The event is matched to the log source identifier of an existing log source.  For V1 and V2, if no log source exists with a matching log source identifier, the event is stored without parsing and a copy of the event is sent to the log source autodetection engine.  For V2_1, if no source attribute is defined in the workflow, the value of the log source identifier is used as the event generation source.  If a log source is autodetected from the event, it is created with its log source identifier set to the source value.

#### XML Example:

##### For V1 and V2

This action posts the array of strings that are stored in the State at /events into the QRadar event pipeline as a series of events. If a log source has a log source identifier that matches the value that is stored in /host, the events are routed to that log source.

```
<PostEvents path="/events" host="${/host}" >
```

##### For V2\_1

This action posts the array of strings that are stored in the State at /events into the QRadar event pipeline as a series of events.

```
<PostEvents path="/event">
```

## PostEvents

The PostEvents action posts an array of events to the QRadar event pipeline, which allows the events to be parsed, correlated, and stored.

The following table shows the parameters for the PostEvents action.

*Table 133. PostEvents action parameters*

Name	Data type	Required	Notes
path	JPath	Yes	The path of the array element to post.

Table 133. PostEvents action parameters (continued)

Name	Data type	Required	Notes
encoding	String	No	<p>The encoding of the event.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>• UTF-8</li> <li>• BASE64</li> <li>• HEX</li> </ul> <p>The default is UTF-8.</p>
source	String	Yes (Optional field for V2_1)	<p>The source (host) of the event.</p> <p>The source value is used to route the event within the event pipeline to the correct log source. The event is matched to the log source identifier of an existing log source.</p> <p>For V1 and V2, if no log source exists with a matching log source identifier, the event is stored without parsing and a copy of the event is sent to the log source autodetection engine.</p> <p>For V2_1, if no source attribute is defined in the workflow, the value of the log source identifier is used as the event generation source.</p> <p>If a log source is autodetected from the event, it is created with its log source identifier set to the source value.</p>

#### XML Example:

##### For V1 and V2

This action posts the array of strings that are stored in the State at /events into the QRadar event pipeline as a series of events. If a log source has a log source identifier that matches the value that is stored in /host, the events are routed to that log source.

```
<PostEvents path="/events" host="${/host}" >
```

##### For V2\_1

This action posts the array of strings that are stored in the State at /events into the QRadar event pipeline as a series of events.

```
<PostEvents path="/events">
```

## RegexCapture

The RegexCapture action captures part of a string with a regular expression (regex).

The following table shows the parameters for the RegexCapture action.

*Table 134. RegexCapture action parameters*

Name	Data type	Required	Notes
pattern	RegEx	Yes	The regular expression pattern. The pattern must contain only one capture group. The regex pattern must be a Java-type regex. For more information, see <a href="https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html">Class Pattern</a> ( <a href="https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html">https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html</a> ).
value	String	Yes	The value to capture from.
savePath	JPath	Yes	The location to store the result.

#### **XML Example:**

This action runs the regex that is defined in the pattern to the string stored in the State as /data. The capture group value is stored in the State at location /id. The provided regex captures one or more digits that follow "id=".

```
<RegexCapture pattern="id=([0-9]+)" value="${/data}" savePath="/id" />
```

## **Set**

The Set action sets a value in the State.

If a value exists at the location, the new value overrides the existing value.

The following table shows the parameters for the Set action.

*Table 135. Set action parameters*

Name	Data type	Required	Notes
path	JPath	Yes	The location to store the value.
value	String/Number	Yes	The value to set.
dataType	String	No	The data type of the value provided must be either integer or float.

#### **XML Example:**

This action adds the value that is returned by the time() function to the State at location /current\_time. If a value exists at that location, it is overwritten.

```
<Set path="/current_time" value="${time()}" />
```

This action adds the value as an integer in the State at the location /count.

```
<Set path="/count" value="20" datatype="integer" />
```

This action adds the value as an float in the State at the location /point.

```
<Set path="/point" value="12" datatype="float" />
```

## SetStatus

The SetStatus action sets the runtime status of the protocol instance. This information appears in the status of the log source.

The following table shows the parameters for the SetStatus action.

<i>Table 136. SetStatus action parameters</i>			
Name	Data type	Required	Notes
type	Enumeration	Yes	The status type. Possible values include: <ul style="list-style-type: none"><li>• INFO</li><li>• WARN</li><li>• ERROR</li></ul>
message	String	Yes	The status message.

### XML Example:

This action sets the runtime status of the protocol instance to ERROR with a message that states:

The password has expired

This information is displayed as the log source status in the IBM QRadar Log Source Management app and API.

```
<SetStatus type="ERROR" message="The password has expired" />
```

## Sleep

The Sleep action suspends the Workflow for a specified amount of time.

The following table shows the parameters for the Sleep action.

<i>Table 137. Sleep action parameters</i>			
Name	Data type	Required	Notes
duration	Number	Yes	The amount of time to wait, in milliseconds.

### XML Example:

This action causes the Workflow to pause execution for 5 seconds.

```
<Sleep duration="5000" />
```

## Split

The Split action splits a string.

For example, if an API returns a set of events as a long string, where each event is separated by a comma or other delimiter, you can split the string to use the PostEvent or PostEvents action.

The following table shows the parameters for the Split action.

*Table 138. Split action parameters*

Name	Data type	Required	Notes
value	String	Yes	The value to split.
delimiter	String	No	The delimiter is a regex expression. Defaults to "newline". If a delimiter is supplied with regex elements, it must be a Java-type regex.
savePath	JPath	Yes	The location to store the result.

**XML Example:**

This action splits the string "value 1,value 2,value 3" into an array of three strings "value1", "value2", and "value3". The strings are stored in the State at location /values.

```
<Split value="value 1,value 2,value 3" delimiter="," savePath="/values" />
```

## While

The While action loops a series of nested actions while a condition is true.

The condition is evaluated at the beginning of the loop so if the condition is never true, it never executes its nested actions. This action is different from the DoWhile action, where the condition is evaluated at the end of the loop.

The following table shows the parameters for the While action.

*Table 139. While action parameters*

Name	Data type	Required	Notes
condition	JPath	Yes	The condition that determines whether to continue looping. A loop is an execution of all nested actions.
actions	JPath Condition	Yes	The sequence of actions to execute. Must be a JPath expression that resolves to a value of true or false. References to the State should not be within the \${ } notation for JPath conditions. See " <a href="#">JPath</a> on page 268.

**XML Example:**

This action executes the nested CallEndpoint action if a value exists in the State at location /next\_page. The While action executes the nested CallEndpoint action until the /next\_page value is null. If /next\_page is always null, the nested action is not executed.

```
<While condition="/next_page != null">
    <CallEndpoint ... />
</While>
```

## Related concepts

["CallEndpoint" on page 248](#)

The CallEndpoint action calls an HTTP endpoint.

["DoWhile" on page 257](#)

The DoWhile action loops a series of actions while a condition is true.

## XPathQuery

The XPathQuery action executes an XPath query on an XML document value.

If an API returns a response in XML format, you can extract a certain value or set of values from the response. You can use XPath to extract values.

The following table shows the parameters for the XPathQuery action.

Table 140. XPathQuery action parameters			
Name	Data type	Required	Notes
xmlPath	JPath	Yes	The location of the XML document in the State.
xPathQuery	XPath	Yes	
singleton	Boolean	No	Interprets the results as a single value instead of an array. The default is False.
savePath	JPath	Yes	The location to store the result.

### XML Example:

This action executes the XPath query "`//event/id/text()`" against the XML document that is stored in the State at `/xml_events`, and stores it in the State at location `/event/id` as a single value.

```
<XPathQuery xmlPath="/xml_events" xPathQuery="//event/id/text()" singleton="true" savePath="/event/id" />
```

## JPath

JPath is a language for querying and manipulating JSON elements. You can use JPath to compute values, such as strings, numbers, and boolean values, from JSON elements.

## Basic selection

Select elements by using a forward slash (/). Select array items by using square brackets ([ ]).

The following table shows examples of basic selection of JSON elements.

Table 141. Basic selection examples				
Example	Description	State	Expression	Result
Primitive	Selects a JSON primitive.	{ "object": { "attr1": "value1", "attr2": "value2" }}	/object/attr1	"value1"

Table 141. Basic selection examples (continued)

Example	Description	State	Expression	Result
Object	Selects a JSON object.	{ "object": { "attr1": "value1", "attr2": "value2" } }	/object	{ "attr1": "value1", "attr2": "value2" }
Array	Selects a JSON array.	{ "array": [ "value1", "value2" ] }	/array	[ "value1", "value2" ]
Array Index	Selects an item of a JSON array by index. The index starts at 0.	{ "array": [ 1.1, 2.2 ] }	/array[1]	2.2
Nested	Selects an attribute of an object that is nested in an array.	{ "array": [ { "id": 123 }, { "id": 456 } ] }	/array[1]/id	456
Multiple Nested	Selects all attributes of an object that is nested in an array.	{ "array": [ { "id": 123 }, { "id": 456 } ] }	/array/id	[ 123, 456 ]
Single Quoted Keys	Selects key names by using single quotation marks.	{ "name with spaces": { "some attribute": true, "another attribute": false } }	/'name with spaces'/'some attribute'	true
Double Quoted Keys	Selects key names by using double quotation marks.	{ "name with spaces": { "some attribute": true, "another attribute": false } }	/"name with spaces"/"some attribute"	true
Unicode Support	Selects by using Unicode keys and values.	{ "a_t_t_r": "v_a_l_u_e" }	/"a_t_t_r"/"v_a_l_u_e"	"v_a_l_u_e"

## Query

Array elements can be queried by using square brackets ([ ]). The query is evaluated against all of the array elements. The query can select any fields of the element for comparison and reference anything in the JSON document.

The following table shows query operators. *a* and *b* can be either a constant or a JPath construct. Basic selection, query, arithmetic, and functions are JPath constructs.

Table 142. Query operators

Operator	Description
$a = b$	Equal
$a != b$	Not equal
$a > b$	Greater than
$a < b$	Less than
$a >= b$	Greater than or equal
$a <= b$	Less than or equal
not $a$	Negates the result of $a$
exists $a$	Checks if $a$ exists as an attribute

The following table shows examples of the query operators that you can apply to the array elements.

Table 143. Query examples

Example	Description	State	Expression	Result
Equality (or Inequality)	Queries an array for objects with an attribute equal to a value.	{ "array": [ { "id": 1, "name": "Object 1" }, { "id": 2, "name": "Object 2" }, { "id": 3, "name": "Object 3" } ] }	/array[@id = 2]	[ { "id": 2, "name": "Object 2" } ]
Greater than	Queries an array of objects with attributes greater than a value.	{ "array": [ { "id": 1, "name": "Object 1" }, { "id": 2, "name": "Object 2" }, { "id": 3, "name": "Object 3" } ] }	/array[@id > 1]	[ { "id": 2, "name": "Object 2" }, { "id": 3, "name": "Object 3" } ]
Primitives	Selects primitives from an array that passes a specific query.	{ "array": [ "value 1", "value 2", "value 3" ] }	/array[@ != "value 2"]	[ "value 1", "value 3" ]
And	Selects with the 'and' operator.	{ "array": [ "value 1", "value 2", "value 3" ] }	/array[@ != "value 2" and @ != 'value 3']	[ "value 1" ]
Or	Selects with the 'or' operator.	{ "array": [ "value 1", "value 2", "value 3" ] }	/array[@ = "value 2" or @ = "value 3"]	[ "value 2", "value 3" ]

*Table 143. Query examples (continued)*

Example	Description	State	Expression	Result
Parentheses	Selects with parentheses.	{ "array": [ "value 1", "value 2", "value 3" ] }	/array[not (@ = "value 2" or @ = "value 3"))]	[ "value 1" ]
Exists	Selects objects of an array that have a specific attribute.	{ "array": [ { "id": 1, "name": "Object 1" }, { "id": 2, "name": "Object 2" }, { "id": 3, "name": "Object 3" } ] }	/array[exists @name]	[ { "id": 1, "name": "Object 1" }, { "id": 2, "name": "Object 2" } ]

## Arithmetic operations in JSON elements

Some basic arithmetic operations can be applied to the JSON elements.

The following table shows arithmetic operators.  $a$  and  $b$  can be either a constant or a JPath construct. Basic selection, query, arithmetic, and functions are JPath constructs.

*Table 144. Arithmetic operators*

Operator	Description
$a + b$	Add
$a - b$	Subtract
$a * b$	Multiply
$a / b$	Divide

The following table shows examples of the arithmetic operations that you can apply to JSON elements.

*Table 145. Arithmetic examples*

Example	Description	State	Expression	Result
Addition	Basic addition	{ "attr1": 1, "attr2": 4 }	/attr1 + /attr2	5
Subtraction	Basic subtraction	{ "attr1": 1, "attr2": 4 }	/attr1 - /attr2	-3
Multiplication	Basic multiplication	{ "attr1": 2, "attr2": 4 }	/attr1 * /attr2	8
Division	Basic division	{ "attr1": 12, "attr2": 4 }	/attr1 / /attr2	3
Parentheses	Arithmetic that uses parentheses.	{ "attr1": 4, "attr2": 2 }	(/attr1 - /attr2) * (/attr1 + /attr2)	12
Arithmetic as Array Index	Uses arithmetic to compute an array index.	{ "attr1": 4, "attr2": 2, "array": [ "value 1", "value 2", "value 3", ] }	/array[/attr1 - /attr2]	"value 3"

*Table 145. Arithmetic examples (continued)*

Example	Description	State	Expression	Result
Arithmetic in Query	Uses arithmetic as part of a query.	{ "attr1": 4, "attr2": 2, "array": [ { "id": 1, "name": "Object 1" }, { "id": 2, "name": "Object 2" }, { "id": 3, "name": "Object 3" } ] }	/array[@id != (/attr1 - /attr2)]	[ { "id": 1, "name": "Object 1" }, { "id": 3, "name": "Object 3" } ]

## Functions in JPath expressions

Some basic functions can be used in JPath expressions, such as using a function as part of a query.

The following table shows the basic functions that can be used in JPath expressions.

*Table 146. Functions*

Function	Description
<i>count(path)</i>	Returns the number of items at a specific path expression. <ul style="list-style-type: none"><li>• For an object, returns the number of members.</li><li>• For an array, returns the number of array elements.</li><li>• For a string, returns the string length.</li></ul>
<i>base64_encode(expr)</i>	Returns the base64 encoded value of a specific expression.
<i>base64_decode(expr)</i>	Returns the base64 decoded value of a specific expression.
<i>url_encode(expr)</i>	Returns the url encoded value of a specific expression.
<i>url_decode(expr)</i>	Returns the url decoded value of a specific expression.
<i>min(path)</i>	Returns the minimum value from an array at a specific path expression.
<i>max(path)</i>	Returns the maximum value from an array at a specific path expression.
<i>time()</i>	Returns time in milliseconds since epoch.

The following table shows examples of basic functions that can be used in JPath expressions.

*Table 147. Function examples*

Example	Description	State	Expression	Result
Function in query	Uses a function as part of a query.	{ "array": [ { "id": 1, "timestamp": 1186978597 }, { "id": 2, "timestamp": 1286978597 }, { "id": 3, "timestamp": 17586978597 } ] }	/array[@timestamp > time()]	[ { "id": 3, "timestamp": 17586978597 } ]
Find an event with the biggest timestamp	Uses the max() function in combination with a generated array of numbers.	{ "array": [ { "id": 1, "timestamp": 1186978597 }, { "id": 2, "timestamp": 1286978597 }, { "id": 3, "timestamp": 17586978597 } ] }	max(/array/timestamp)	17586978597

## Command line testing tool

Use the command line tool to execute a workflow. The command line tool provides quick feedback while you develop or troubleshoot the contents of a workflow.

The command line tool does not interact with the live IBM QRadar event pipeline. Any events that are retrieved from the Universal Cloud REST API protocol are written to the QRadar Console.

New in V2

To run the tool in V2 or later, type the following command.

```
/opt/qradar/bin/test-workflow.sh
```

To run the tool in V1, add one or more commands to the end of the following command line to run the tool. If you don't specify any arguments, the entire usage is written.

```
java -cp "/opt/ibm/si/services/ecs-ec-ingress/current/bin/*:/opt/ibm/si/services/ecs-ec-ingress/eventgnosis/lib/q1labs/*" com.q1labs.semsources.universalcloudrestapi.UniversalCloudRESTAPITest
```

The following table shows the commands for the command line testing tool.

*Table 148. Command line testing tool usage*

Command	Description
-?, --help	Displays the usage and exits.
-p <[user@]server:port>	Specifies the proxy to use.
-r <seconds>	Specifies the poll frequency. In V2 or later, by default the tool runs only once. If you enter a frequency, the tool runs at that interval.
-s <file>	Specifies the file for state persistence.
-v	Displays more logging.
-w <file>	Specifies the workflow to load.
-wp <file>	Specifies the workflow parameter values to load. In V2 or later, this parameter is optional.

### **XML Example**

In the following example, the command line is used to specify the workflow and workflow parameter values to load. The -w command is used to specify the myworkflow.XML workflow and the -wp command is used to specify the myworkflow.parameter.values.xml workflow parameter values.

```
/opt/qradar/bin/test-workflow.sh -w myworkflow.xml -wp myworkflow.parameter.values.xml
```

---

# Chapter 11. Protocols that support Certificate Management

You can use Certificate Management to upload and manage certificates that can be used by log sources with supported protocols.

The following table lists the protocols that support Certificate Management.

Protocol	Fix Central link
TLS Syslog	<a href="#">Download TLS Syslog protocol</a>
HTTP Receiver	<a href="#">Download HTTP Receiver protocol</a>

**Related information**

[QRadar Certificate Management](#)

---

## Part 3. DSMs

# Chapter 12. 3Com Switch 8800

The IBM QRadar DSM for 3Com Switch 8800 receives events by using syslog.

The following table identifies the specifications for the 3Com Switch 8800 DSM:

Specification	Value
Manufacturer	3Com
DSM name	Switch 8800 Series
RPM file name	DSM-3ComSwitch_QRadar-version_build-number.noarch.rpm
Supported versions	3.01.30
Protocol	Syslog
QRadar recorded events	Status and network condition events
Automatically discovered?	Yes
Includes identity?	No
Includes custom event properties?	No
More information	For more information, see the 3Com link to public site website ( <a href="https://www.3com.com">https://www.3com.com</a> )

To send 3COM Switch 8800 events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](https://www.ibm.com/support/fixcentral) (<https://www.ibm.com/support/fixcentral>) onto your QRadar Console:
  - Protocol Common RPM
  - DSM Common RPM
  - 3COM Switch 8800 DSM RPM
2. Configure each 3COM Switch 8800 instance to communicate with QRadar.
3. If QRadar does not automatically discover the DSM, create a log source on the QRadar Console for each 3COM Switch 8800 instance. Configure all the required parameters, and use the following table for specific values:

Parameter	Description
Log Source Type	3COM Switch 8800
Protocol Configuration	Syslog

## Related tasks

[Configuring your 3COM Switch 8800](#)

Configure your 3COM Switch 8800 to forward syslog events to IBM QRadar.

## Configuring your 3COM Switch 8800

---

Configure your 3COM Switch 8800 to forward syslog events to IBM QRadar.

### Procedure

1. Log in to 3COM Switch 8800.
2. To enable the information center, type the following command:

```
info-center enable
```

3. To configure the log host, type the following command:

```
info-center loghost QRadar_ip_address facility informational language english
```

4. To configure the ARP and IP information modules, type the following commands.

```
info-center source arp channel loghost log level informational  
info-center source ip channel loghost log level informational
```

# Chapter 13. AhnLab Policy Center

The IBM QRadar DSM for AhnLab Policy Center retrieves events from the DB2 database that AhnLab Policy Center uses to store their log.

The following table identifies the specifications for the AhnLab Policy Center DSM:

Table 149. AhnLab Policy Center DSM specifications	
Specification	Value
Manufacturer	AhnLab
DSM	AhnLab Policy Center
RPM file names	DSM-AhnLabPolicyCenter-QRadar-Release_Build-Number.noarch.rpm
Supported versions	4.0
Protocol	AhnLabPolicyCenterJdbc
QRadar recorded events	Spyware detection, Virus detection, Audit
Automatically discovered?	No
Includes identity	Yes
More information	Ahnlab website ( <a href="https://global.ahnlab.com/">https://global.ahnlab.com/</a> )

To integrate AhnLab Policy Center DSM with QRadar, complete the following steps:

1. Download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - JDBC protocol RPM
  - AhnLabPolicyCenterJdbc protocol RPM
  - AhnLab Policy Center RPM
2. Ensure that your AhnLab Policy Center system meets the following criteria:
  - The DB2 Database allows connections from QRadar.
  - The port for AhnLabPolicyCenterJdbc Protocol matches the listener port of the DB2 Database.
  - Incoming TCP connections on the DB2 Database are enabled to communicate with QRadar.
3. For each AhnLab Policy Center server you want to integrate, create a log source on the QRadar Console. The following table identifies Ahnlab-specific protocol values:

Parameter	Value
Log Source Type	AhnLab Policy Center APC
Protocol Configuration	AhnLabPolicyCenterJdbc
Access credentials	Use the access credentials of the DB2 server.
Log Source Language	If you use QRadar v7.2 or later, you must select a log source language.

# Chapter 14. Akamai Kona

The IBM QRadar DSM for Akamai Kona collects event logs from your Akamai Kona platforms.

The following table identifies the specifications for the Akamai KONA DSM:

Table 150. Akamai KONA DSM specifications	
Specification	Value
Manufacturer	Akamai
Product	Kona
DSM RPM name	DSM-AkamaiKona-QRadar_Version-Build_Number.noarch.rpm
Protocol	<a href="#">HTTP Receiver</a> , <a href="#">Akamai Kona REST API</a>
Event Format	JSON
Recorded event types	All security events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="#">Akamai Kona SIEM API Documentation</a>

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configure an Akamai Kona log source by using the HTTP Receiver protocol

Collect events from Akamai Kona in QRadar by using the HTTP Receiver protocol.

Collect events by using the HTTP Receiver Protocol:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol Common RPM
  - DSMCommon RPM
  - HTTPReceiver Protocol RPM
  - Akamai KONA DSM RPM
2. Configure your Akamai KONA system to communicate with QRadar. For more information, contact Akamai.
3. If you plan to configure the log source to use the **HTTPs** and **Client Authentication** options, copy the Akamai KONA certificate to the target QRadar Event Collector.
4. For each Akamai KONA server that you want to integrate, create a log source on the QRadar Console. Configure all the required parameters. Use this table to configure Akamai Kona specific parameters:

Table 151. Akamai KONA log source parameters

Parameter	Description
Log source type	Akamai KONA
Protocol Configuration	HTTP Receiver
Client Certificate Path	<p>The absolute file path to the client certificate on the target QRadar Event Collector.</p> <p>Ensure that the Akamai KONA certificate is already copied to the Event Collector.</p> <p>If you select the <b>HTTPs and Client Authentication</b> option from the <b>Communication Type</b> list, the <b>Client Certificate Path</b> parameter is required.</p>
Listen Port	<p>The destination port that is configured on the Akamai KONA system.</p> <p><b>Important:</b> Do not use port 514. Port 514 is used by the standard Syslog listener.</p>
Message Pattern	The <b>Message Pattern</b> '\{"type'

For more information about this protocol, see “[HTTP Receiver protocol configuration options](#)” on page [125](#).

**Restriction:** This integration requires you to open a non-standard port in your firewall for incoming Akamai connections. Use an internal proxy to route the incoming Akamai connections. Do not point the Akamai data stream directly to the QRadar Console. For more information about opening a non-standard port in your firewall, consult your Network security professionals.

[“Adding a log source” on page 5](#)

## Configure an Akamai Kona log source by using the Akamai Kona REST API protocol

Collect events from Akamai Kona in QRadar by using the Akamai Kona REST API protocol.

Collect events from Akamai Kona REST API:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol Common RPM
  - Akamai Kona REST API RPM
  - DSMCommon RPM
  - Akamai KONA DSM RPM
2. Configure Akamai Kona to send Security events to QRadar by using the Akamai Kona REST API protocol.
3. Configure Akamai Kona to communicate with QRadar.

**Note:** The Akamai KONA DSM supports only JSON formatted events. Akamai's sample CEF and Syslog connector does not work with the Akamai KONA DSM.

4. Add a log source in QRadar.

The following table describes the log source parameters that require specific values for Akamai KONA DSM event collection:

*Table 152. Akamai KONA DSM log source parameters*

Parameter	Value
Log Source Type	Akamai KONA
Protocol Configuration	Akamai Kona REST API
Host	Provided during the SIEM OPEN API provisioning in the Akamai Luna Control Center. The <b>Host</b> is a unique base URL that contains information about the appropriate rights to query the security events. This parameter is a password field because part of the value contains secret information.
Client Token	One of the two security parameters. This token is paired with <b>Client Secret</b> to make the client credentials. This token can be found after you provision the Akamai SIEM OPEN API.
Client Secret	One of the two security parameters. This secret is paired with <b>Client Token</b> to make the client credentials. This token can be found after you provision the Akamai SIEM OPEN API.
Access Token	Security parameter that is used with client credentials to authorize API client access for retrieving the security events. This token can be found after you provision the Akamai SIEM OPEN API.
Security Configuration ID	ID for each security configuration that you want to retrieve security events for. This ID can be found in the SIEM Integration section of your Akamai Luna portal. You can specify multiple configuration IDs in a comma-separated list. For example: configID1, configID2.
Use Proxy	If QRadar accesses Akamai Kona by using a proxy, enable <b>Use Proxy</b> . If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
Automatically Acquire Server Certificate	Select Yes for QRadar to automatically download the server certificate and begin trusting the target server.

Table 152. Akamai KONA DSM log source parameters (continued)

Parameter	Value
Recurrence	The time interval between log source queries to the Akamai SIEM API for new events. The time interval can be in hours (H), minutes (M), or days (D). The default is 1 minute.
EPS Throttle	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.

For more information about this protocol, see [“Akamai Kona REST API protocol configuration options” on page 67](#).

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring Akamai Kona to communicate with QRadar

You must configure your Akamai Kona platform to make the security events available for IBM QRadar.

#### Procedure

1. Ensure that you have access to your [Akamai Luna Control center](#) (<https://control.akamai.com>) to configure and provision the SIEM integration.
2. Go to the [Akamai online documentation](#) (<https://developer.akamai.com/tools/siem-integration/docs/siem.htm>).
3. Follow steps 1 - 3 in the Akamai documentation to successfully provision the integration.
4. Record the values for the Host, Client Token, Client Secret, Access Token, and Security Configuration Key.

You need these values when you configure a log source in QRadar.

## Creating an event map for Akamai Kona events

Event mapping is required for a number of Akamai Kona events. Because of the customizable nature of policy rules, some events might not contain a predefined IBM QRadar Identifier (QID) map to categorize security events.

#### About this task

You can individually map each event for your device to an event category in QRadar. Mapping events allows QRadar to identify, coalesce, and track recurring events from your network devices. Until you map an event, all events that are displayed in the **Log Activity** tab for Akamai Kona are categorized as unknown. Unknown events are easily identified as the **Event Name** column and **Low Level Category** columns display Unknown.

As your device forwards events to QRadar, it can take time to categorize all of the events for a device, as some events might not be generated immediately by the event source appliance or software. It is helpful

to know how to quickly search for unknown events. When you know how to search for unknown events, you might want to repeat this search until you are satisfied that most of your events are identified.

## Procedure

1. Log in to QRadar.
2. Click the **Log Activity** tab.
3. Click **Add Filter**.
4. From the first list, select **Log Source**.
5. From the **Log Source Group** list, select the log source group or **Other**.

Log sources that are not assigned to a group are categorized as Other.

6. From the **Log Source** list, select your Akamai Kona log source.
7. Click **Add Filter**.

The **Log Activity** tab is displayed with a filter for your log source.

8. From the **View** list, select **Last Hour**.

Any events that are generated by the Akamai Kona DSM in the last hour are displayed. Events that are displayed as unknown in the **Event Name** column or **Low Level Category** column require event mapping in QRadar.

**Tip:** You can save your existing search filter by clicking **Save Criteria**.

## What to do next

Modify the event map. For more information about modifying the event map for Akamai Kona, see “[Modifying the event map for Akamai Kona](#)” on page 287

## Modifying the event map for Akamai Kona

---

You can manually map events to an external device in the IBM QRadar Identifier (QID) map tool. Any event that is categorized to a log source can be remapped to a new QRadar Identifier (QID).

## About this task

Akamai Kona events that do not have a defined log source can't be mapped to a QRadar Identifier (QID) map by a mapped event. Events without a log source display as **SIM Generic Log** in the **Log Source** column.

## Procedure

1. In the **Event Name** column, double-click an unknown event for Akamai Kona.  
The detailed event information is displayed.
2. Click **Map Event**.
3. From the **Browse for QID** pane, select any of the following search options to narrow the event categories for a QRadar Identifier (QID):
  - From the **High-Level Category** list, select a high-level event categorization.
  - For a full list of high-level and low-level event categories or category definitions, see the Event Categories section of the *IBM QRadar Administration Guide*.
  - From the **Low-Level Category** list, select a low-level event categorization.
  - From the **Log Source Type** list, select a log source type.

The **Log Source Type** list gives the option to search for QIDs from other log sources. Searching for QIDs by log source is useful when events are similar to another existing network device. For example, Akamai Kona provides all events. You might select another product that likely captures similar events.

4. To search for a QID by name, type a name in the **QID/Name** field.

The **QID/Name** field gives the option to filter the full list of QIDs for a specific word, for example, policy.

5. Click **Search**.

A list of QIDs are displayed.

6. Select the QID that you want to associate to your unknown event.

7. Click **OK**.

QRadar maps any additional events that are forwarded from your device with the same QID that matches the event payload. The event count increases each time that the event is identified by QRadar.

If you update an event with a new QRadar Identifier (QID) map, past events that are stored in QRadar are not updated. Only new events are categorized with the new QID.

## Akamai Kona sample event messages

---

Use these sample event messages as a way of verifying a successful integration with QRadar.

The following table provides a sample event message when you use the *Akamai Kona REST API* protocol for the *Akamai KONA DSM*:

**Note:** Each event might contain multiple Event IDs and Names.

Table 153. Akamai KONA sample message supported by Akamai Kona REST API.

Event name	Low-level category	Sample log message
The application is not available - Deny Rule	Warning	<pre> {   "type": "akamai_siem",   "format": "json",   "version": "1.0",   "attackData": {     "configId": "&lt;Config Id&gt;",     "policyId": "&lt;Policy Id&gt;",     "clientIP": "192.0.2.0",     "rules": "970901",     "ruleVersions": "1",     "ruleMessages": "Application is not Available (HTTP 5XX)",     "ruleTags": "AKAMAI/BOT/UNKNOWN_BOT",     "ruleData": "Vector Score: 4, DENY threshold: 2, Alert Rules: 3990001:970901, Deny Rule: , Last Matched Message: Application is not Available (HTTP 5XX)",     "ruleSelectors": "",     "ruleActions": "monitor",     "httpMessage": {       "requestId": "&lt;Request Id&gt;",       "start": "1517337032",       "protocol": "HTTP/1.1",       "method": "GET",       "host": "siem-sample.csi.edgesuite.net",       "port": "80",       "path": "path",       "requestHeaders": "User-Agent: curl/7.35.0 Host: siem-sample.csi.edgesuite.netAccept: */*edge_maprule:ksd",       "status": "403",       "bytes": "298",       "responseHeaders": "Server: AkamaiGHostMime-Version: 1.0Content-Type: text/htmlContent-Length: 298Expires: Tue, 30 Jan 2018 18:30:32 GMTDate: Tue, 30 Jan 2018 18:30:32 GMTConnection: close",       "geo": {         "continent": "&lt;Continent&gt;",         "country": "&lt;Country&gt;",         "city": "&lt;City&gt;",         "regionCode": "&lt;Region Code&gt;",         "asn": "&lt;asn&gt;"       }     }   } } </pre>

Anomaly Score Exceeded for Outbound	Suspicious Activity	<pre>{   "type": "akamai_siem",   "format": "json",   "version": "1.0",   "attackData": {     "configId": "&lt;Config Id&gt;",     "policyId": "&lt;Policy Id&gt;",     "clientIP": "192.0.2.0",     "rules": "OUTBOUND-ANOMALY",     "ruleVersions": "4",     "ruleMessages": "Anomaly Score Exceeded for Outbound",     "ruleTags": "AKAMAI/POLICY/OUTBOUND_ANOMALY",     "ruleData": "curl_85D6E381D300243323148F63983BD735",     "ruleSelectors": "",     "ruleActions": "alert"   },   "httpMessage": {     "requestId": "&lt;Request Id&gt;",     "start": "1517337032",     "protocol": "HTTP/1.1",     "method": "GET",     "host": "siem-sample.csi.edgesuite.net",     "port": "80",     "path": "path",     "requestHeaders": "User-Agent: curl/7.35.0 Host: siem-sample.csi.edgesuite.netAccept: */*edge_maprule: ksd",     "status": "403",     "bytes": "298",     "responseHeaders": "Server: AkamaiGHostMime-Version: 1.0Content-Type: text/htmlContent-Length: 298Expires: Tue, 30 Jan 2018 18:30:32 GMTDate: Tue, 30 Jan 2018 18:30:32 GMTConnection: close",     "geo": {       "continent": "&lt;Continent&gt;",       "country": "&lt;Country&gt;",       "city": "&lt;City&gt;",       "regionCode": "&lt;Region Code&gt;",       "asn": "&lt;asn&gt;"     }   } }  {   "type": "akamai_siem",   "format": "json",   "version": "1.0",   "attackData": {     "configId": "&lt;Config Id&gt;",     "policyId": "&lt;Policy Id&gt;",     "clientIP": "192.0.2.0",     "rules": "OUTBOUND-ANOMALY",     "ruleVersions": "4",     "ruleMessages": "Anomaly Score Exceeded for Outbound",     "ruleTags": "AKAMAI/POLICY/OUTBOUND_ANOMALY",     "ruleData": "curl_85D6E381D300243323148F63983BD735",     "ruleSelectors": "",     "ruleActions": "alert"   },   "httpMessage": {     "requestId": "&lt;Request Id&gt;",     "start": "1517337032",     "protocol": "HTTP/1.1",     "method": "GET",     "host": "siem-sample.csi.edgesuite.net",     "port": "80",     "path": "path",     "requestHeaders": "User-Agent: curl/7.35.0 Host: siem-sample.csi.edgesuite.netAccept: */*edge_maprule: ksd",     "status": "403",     "bytes": "298",     "responseHeaders": "Server: AkamaiGHostMime-Version: 1.0Content-Type: text/htmlContent-Length: 298Expires: Tue, 30 Jan 2018 18:30:32 GMTDate: Tue, 30 Jan 2018 18:30:32 GMTConnection: close",     "geo": {       "continent": "&lt;Continent&gt;",       "country": "&lt;Country&gt;",       "city": "&lt;City&gt;",       "regionCode": "&lt;Region Code&gt;",       "asn": "&lt;asn&gt;"     }   } }</pre>

# Chapter 15. Alibaba ActionTrail

The IBM QRadar DSM for Alibaba ActionTrail supports events that are collected from Alibaba Cloud Object Storage buckets with the help of Alibaba Cloud Object Storage protocol. It also supports Alibaba Cloud Simple Log Service Protocol.

The following table lists the specifications for the Alibaba ActionTrail DSM:

Table 154. Alibaba ActionTrail DSM specifications	
Specification	Value
Manufacturer	Alibaba Cloud
DSM	Alibaba ActionTrail
RPM name	DSM-AlibabaActionTrail-<QRadar_version-Build_number>.noarch.rpm
Supported protocols	Alibaba Cloud Object Storage Alibaba Cloud Simple Log Service Syslog
Event format	JSON
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="#">ActionTrail</a>

## Related concepts

[“Alibaba Cloud Object Storage protocol configuration options” on page 69](#)

The Alibaba Cloud Object Storage protocol for IBM QRadar is an active outbound protocol that collects logs that are contained in objects from Alibaba Cloud Object Storage buckets.

[“Alibaba Cloud Simple Log Service protocol configuration options” on page 71](#)

The Alibaba Cloud Simple Log Service protocol for IBM QRadar is an outbound or active protocol that collects logs from a specific Log Store available in the Alibaba Cloud Log application.

## Alibaba ActionTrail sample event message

Use this sample event message as a way of verifying a successful integration with IBM QRadar.

The following sample event message shows Logon to the Alibaba Cloud Management console.

```
{"eventId": "2542222-2222-2222-2222-500d4449 ****", "eventVersion": 1, "eventSource": "http://account.test.com/test/login_aliyun.htm", "sourceIpAddress": "10.0.0.1", "userAgent": "Mozilla/5.0 (iPhone; CPU iPhone OS 15_0 like Mac OS X) AppleWebKit/605.1.15 (KHTML, like Gecko) Mobile/11111 Ariver/1.1.0 AliApp(AP/10.2.28.6000) AlipayClient/10.2.11.6000 Language/zh-Hans Region/CN", "eventType": "ConsoleSignin", "userIdentity": {"accountId": "11122223333***", "principalId": "11122223333***", "type": "root-account", "userName": "test"}, "serviceName": "Customer", "additionalEventData": {"loginAccount": "user1", "isMFAChecked": "false"}, "extend": "2", "requestId": "111111-6b56-2222-5555-500d8d25***", "eventTime": "2021-01-01T00:00:00Z", "isGlobal": true, "acsRegion": "cn-abcd", "eventName": "ConsoleSignin"}
```

Table 155. Highlighted values in the Alibaba ActionTrail sample event

QRadar field name	Highlighted payload field name
Event ID	eventName
Username	userIdentity.userName
Source IP	sourceIpAddress
Device Time	eventTime

The following sample event message is for Alibaba Cloud Simple Log Service Protocol.

```
{"owner_id": "1111111111111111", "event": {"additionalEventData": {"CallerId": "11111"}, "apiVersion": "2020-06-16", "datasource": "pop-test-east-1", "eventSource": "alb.test-east-1.test.com", "product": "Alb", "requestParameters": {"stsTokenPrincipalName": "test@example", "AcProduct": "Alb", "X-Acs-Public-Access": true, "MaxResults": 50, "ClientPort": 13230, "SignatureType": "", "RegionId": "test-east-1"}, "sourceIpAddress": "audit.log.test.com", "tlsDetails": {"tlsVersion": "TLSv1.2", "cipherSuite": "AAAAA-AAAAA-AAAAAA-AAA-SHA384", "clientProvidedHostHeader": "alb.test-east-1.test.com"}, "userAgent": "audit.log.test.com", "userIdentity": {"accessKeyId": "STS.N11111111111111111111", "accountId": "1111111111111111", "principalId": "1111111111111111:example", "sessionContext": {"attributes": {"mfaAuthenticated": "false"}}, "type": "assumed-role", "userName": "test@example"}, "eventId": "11151579-1111-1111-1111-CCA7EC29C6C1", "eventName": "ListLoadBalancers", "eventType": "AliyunServiceEvent", "acsRegion": "test-east-1", "serviceName": "ALB", "eventTime": "2024-02-27T09:45:08Z"}, "__topic__": "actiontrail_event", "__source__": "log_service", "__time__": "1709027108"}
```

Table 156. Highlighted values in the Alibaba Cloud Simple Log Service Protocol sample event

# Chapter 16. Amazon

IBM QRadar supports a range of Amazon products.

## Amazon AWS Application Load Balancer Access Logs

The IBM QRadar DSM for Amazon Application Load Balancer Access Logs collects access logs from Amazon AWS Application Load Balancers. The logs are collected in an Amazon S3 bucket by a Simple Queue Service (SQS) queue.

To integrate Amazon Application Load Balancer Access Logs with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](#).
  - Protocol Common RPM
  - Amazon AWS S3 REST API protocol RPM
  - DSM Common RPM
  - Amazon Application Load Balancer Access Logs DSM RPM
2. Configure your Amazon Application Load Balancer Access Logs application to communicate with QRadar. For more information, see [Amazon AWS Enable access logging](#).
3. Publish flow logs to an SQS bucket. For more information, see [Publishing flow logs to an S3 bucket](#).
4. Create the SQS queue that is used to receive ObjectCreated notifications, then configure S3 ObjectCreated notifications. For more information, see [Create an SQS queue and configure S3 ObjectCreated notifications](#).
5. Configure the security credentials for your AWS user account. For more information, see [Configuring security credentials for your AWS user account](#).
6. If QRadar does not automatically detect the log source, add an Amazon Application Load Balancer Access Logs log source on the QRadar Console.

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Amazon AWS Application Load Balancer Access Logs DSM specifications

When you configure the Amazon AWS Application Load Balancer Access Logs, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported protocol is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Amazon AWS Application Load Balancer Access Logs DSM.

Table 157. Amazon AWS Application Load Balancer Access Logs DSM specifications	
Specification	Value
Manufacturer	Amazon
DSM name	Amazon AWS Application Load Balancer Access Logs
RPM file name	DSM-AmazonAWSALBAccessLogs-QRadar_version-build_number.noarch.rpm
Protocol	Amazon AWS S3 REST API
Event format	Space delimited pre-defined fields

Table 157. Amazon AWS Application Load Balancer Access Logs DSM specifications (continued)

Specification	Value
Recorded event types	Access logs
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="#">Access logs for your Application Load Balancer</a>

## Publishing flow logs to an S3 bucket

Complete these steps to publish flow logs to an S3 bucket.

### Procedure

1. Log in to your AWS Management console, and then from the **Services** menu, navigate to the **VPC Dashboard**.
2. Enable the check box for the VPC ID that you want to create flow logs for.
3. Click the **Flow Logs** tab.
4. Click **Create Flow Log**, and then configure the following parameters:

Table 158. Create Flow Log parameters

Parameter	Description
<b>Filter</b>	Select <b>Accept, Reject, or All</b> .
<b>Destination</b>	Select <b>Send to an S3 Bucket</b> .
<b>S3 Bucket ARN</b>	Type the ARN for the S3 Bucket. Examples: <ul style="list-style-type: none"><li>• arn:aws:s3:::myTestBucket</li><li>• arn:aws:s3:::myTestBucket/testFlows</li></ul>

5. Click **Create**.

For more information about publishing flow logs to Amazon S3, see the [Publishing Flow Logs to Amazon S3](#) documentation on the AWS website.

### What to do next

Create the SQS queue that is used to receive ObjectCreated notifications.

## Create an SQS queue and configure S3 ObjectCreated notifications

Before you can add a log source in IBM QRadar, you must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

Complete the following procedures:

1. [Finding the S3 Bucket that contains the data that you want to collect](#).
2. [Creating the SQS queue that is used to receive the ObjectCreated notifications from the S3 Bucket that you used in Step 1](#).
3. [Setting up SQS queue permissions](#).

4. [Creating ObjectCreated notifications.](#)
5. [Configuring security credentials for your AWS user account.](#)
6. [Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge.](#)

## Finding the S3 bucket that contains the data that you want to collect

You must find and note the region for S3 bucket that contains the data that you want to collect.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to **S3**.
3. From the **AWS Region** column in the **Buckets** list, note the region where the bucket that you want to collect data from is located. You need the region for the **Region Name** parameter value when you add a log source in IBM QRadar.
4. Enable the checkbox beside the bucket name, and then from the panel that opens to the right, click **Copy Bucket ARN** to copy the value to the clipboard. Save this value or leave it on the clipboard. You need this value when you set up **SQS queue permissions**.

## Creating the SQS queue that is used to receive ObjectCreated notifications

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

### Before you begin

You must complete **Finding the S3 Bucket that contains the data that you want to collect**. The SQS Queue must be in the same region as the AWS S3 bucket that the queue is collecting from.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to the Simple Queue Service Management Console.
3. In the upper right of the window, change the region to where the bucket is located. You noted this value when you completed the **Finding the S3 Bucket that contains the data that you want to collect** procedure.
4. Select **Create New Queue**, and then type a value for the **Queue Name**.
5. Click **Standard Queue**, select **Configure Queue**, and then change the default values for the following **Queue Attributes**.
  - **Default Visibility Timeout** - 60 seconds (You can use a lower value. In the case of load balanced collection, duplicate events might occur with values of less than 30 seconds. This value can't be 0.)
  - **Message Retention Period** - 14 days (You can use a lower value. In the event of an extended collection, data might be lost.)

Use the default value for the remaining **Queue Attributes**.

More options such as **Redrive Policy** or **SSE** can be used depending on the requirements for your AWS environment. These values should not affect the data collection.

Queue Attributes

<b>Default Visibility Timeout</b>	<input type="text" value="60"/>	<b>seconds</b>	Value must be between 0 seconds and 12 hours.
<b>Message Retention Period</b>	<input type="text" value="14"/>	<b>days</b>	Value must be between 1 minute and 14 days.
<b>Maximum Message Size</b>	<input type="text" value="256"/>	<b>KB</b>	Value must be between 1 and 256 KB.
<b>Delivery Delay</b>	<input type="text" value="0"/>	<b>seconds</b>	Value must be between 0 seconds and 15 minutes.
<b>Receive Message Wait Time</b>	<input type="text" value="0"/>	<b>seconds</b>	Value must be between 0 and 20 seconds.

---

Picture © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

## 6. Select **Create Queue**.

## Setting up SQS queue permissions

You must set up SQS queue permissions for users to access the queue.

### Before you begin

You must complete **Creating the SQS queue that is used to receive ObjectCreated notifications**.

You can set the SQS queue permissions by using either the Permissions Editor or a JSON policy document.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Go to the SQS Management Console, and then select the queue that you created from the list.
3. From the **Details** panel, record the **ARN** field value.

For example: **arn:aws:sqs:us-east-1:123456789012:MySQSQueueName**

4. To set the SQS queue **Access policy (Permissions)** by using the **AWS Policy generator**, complete the following steps:
  - a) Select **Policy Type > SQS Queue Policy**.
  - b) Add an Access Policy statement.
  - c) From the **Access policy** tab, click **Policy generator**, and then configure the following parameters:

Table 159. Permission parameters

Parameter	Value
<b>Effect</b>	Click <b>Allow</b> .
<b>Principal</b>	Type <b>*</b> (Everybody).
<b>Actions</b>	From the list, select <b>SendMessage</b>
<b>Amazon Resource Name (ARN)</b>	Type your queue ARN: <b>arn:aws:sqs:us-east-1:123456789012:MySQSQueueName</b>

- d) Click **Add Conditionals (Optional)**, and then configure the following parameters:

Table 160. Add Conditionals (Optional) parameters

Parameter	Value
<b>Qualifier</b>	None
<b>Condition</b>	<b>ARNLike</b>
<b>Key</b>	Type aws:SourceArn.
<b>Value</b>	<p>The ARN of the S3 bucket from when you completed the “<a href="#">Finding the S3 bucket that contains the data that you want to collect</a>” on page 308 procedure.</p> <p>For example: aws:s3:::my-example-s3bucket</p>

5. To set the SQS queue permissions by using a JSON policy document, complete the following steps:

a) Click **Add Condition** > **Add Statement**. > **Generate Policy**.

b) Copy and paste the following JSON policy into the **Access policy** window:

Copy and paste might not preserve the white space in the JSON policy. The white space is required. If the white space is not preserved when you paste the JSON policy, paste it into a text editor and restore the white space. Then, copy and paste the JSON policy from your text editor into the **Edit Policy Document** window.

```
{
  "Version": "2008-10-17",
  "Id": "example-ID",
  "Statement": [
    {
      "Sid": "example-statement-ID",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::my-example-s3bucket"
        }
      }
    }
  ]
}
```

6. Click **Review Policy**. Ensure that the data is correct, and then click **Save Changes**.

## Creating ObjectCreated notifications

Configure ObjectCreated notifications for the folders that you want to monitor in the bucket.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, go to **S3**, and then select a bucket.
3. Click the **Properties** tab, and in the **Events** pane, click **Add notification**. Configure the parameters for the new event.

The following table shows an example of an ObjectCreated notification parameter configuration:

Table 161. Example: New ObjectCreated notification parameter configuration

Parameter	Value
<b>Name</b>	Type a name of your choosing.
<b>Events</b>	Select <b>All object create events</b> .
<b>Prefix</b>	AWSLogs/  <b>Tip:</b> You can choose a prefix that contains the data that you want to find, depending on where the data is located and what data that you want to go to the queue. For example, AWSLogs/, CustomPrefix/AWSLogs/, AWSLogs/123456789012/.
<b>Suffix</b>	json.gz
<b>Send to</b>	SQS queue  <b>Tip:</b> You can send the data from different folders to the same or different queues to suit your collection or QRadar tenant needs. Choose one or more of the following methods: <ul style="list-style-type: none"> <li>• Different folders that go to different queues</li> <li>• Different folders from different buckets that go to the same queue</li> <li>• Everything from a single bucket that goes to a single queue</li> <li>• Everything from multiple buckets that go to a single queue</li> </ul>
<b>SQS</b>	The <b>Queue Name</b> from step 4 of <b>Creating the SQS queue that is used to receive the ObjectCreated notifications</b> .

## Create event notification

The notification configuration identifies the events you want Amazon S3 to publish and the destinations where you want Amazon S3 to send the notifications. [Learn more](#)

### General configuration

Event name  
NewS3ObjectToSQS

Event name can contain up to 255 characters.

Prefix - optional  
Limit the notifications to objects with key starting with specified characters.  
 AWSLogs/

Example. This value must match the location of the data that you want to collect.

Suffix - optional  
Limit the notifications to objects with key ending with specified characters.  
 .json.gz

Example. Enter a value so that you can filter out unwanted files that match the prefix.

### Event types

Specify at least one type of event for which you want to receive notifications. [Learn more](#)

All object create events  
s3:ObjectCreated:  
 Put  
s3:ObjectCreated:Put  
 Post  
s3:ObjectCreated:Post  
 Copy  
s3:ObjectCreated:Copy  
 Multipart upload completed  
s3:ObjectCreated:CompleteMultipartUpload

Figure 6. Example: Events

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

In the example in figure 1 of a parameter configuration, notifications are created for AWSLogs/ from the root of the bucket. When you use this configuration, All ObjectCreated events trigger a notification. If there are multiple accounts and regions in the bucket, everything gets processed. In this example, json.gz is used. This file type can change depending on the data that you are collecting. Depending on the content in your bucket, you can omit the extension or choose an extension that matches the data you are looking for in the folders where you have events set up.

After approximately 5 minutes, the queue that contains data displays. In the **Messages Available** column, you can view the number of messages.

Figure 7. Number of available messages

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

4. Click **Services**, then go to **Simple Queue Services**.
5. Right-click the **Queue Name** from step 4 of **Creating the SQS queue that is used to receive the ObjectCreated notifications**, then select **View/Delete Messages** to view the messages.

                "s3SchemaVersion": "1.0",  
                "configurationId": "test_SQS_Notification_1",  
                "bucket": {  
                    "name": "myBucketName",  
                    "ownerIdentity": {  
                        "principalId": "A2SGQBYRFBZET"  
                    },  
                    "arn": "arn:aws:s3:::myBucketName"  
                },  
                "object": {  
                    "key": "AWSLogs/123456789012/CloudTrail/eu-west-1/2018/12/19/10/51/03/251Z/123456789012.log"  
                }  
            }  
        }  
    ]  
}
```

```

3/2018/12/19/123456789012_CloudTrail_eu-west-3_TestAccountTrail
_us-east-2_20181219T014838Z.json.gz",
    "size":713,
    "eTag":"1ff1209e4140b4ff7a9d2b922f57f486",
    "sequencer":"005C19A40717D99642"
}
]
}
}

```

**Tip:** In the **key** value, your DSM name displays.

6. Click **Services**, then navigate to **IAM**.
7. Set a **User or Role** permission to access the SQS queue and for permission to download from the target bucket. The user or user role must have permission to read and delete from the SQS queue. For information about adding, managing and changing permissions for IAM users, see the [IAM Users documentation](#). After QRadar reads the notification, and then downloads and processes the target file, the message must be deleted from the queue.

Sample Policy:

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sqs:DeleteMessage",
                "sqs:ReceiveMessage",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket_name>/AWSLogs/*",
                "arn:aws:sqs:us-east-2:<AWS_account_number>:<queue_name>"
            ]
        }
    ]
}

```

You can add multiple buckets to the S3 queue. To ensure that all objects are accessed, you must have a trailing `/*` at the end of the folder path that you added.

You can add this policy directly to a user, a user role, or you can create a minimal access user with **sts:AssumeRole** permissions only. When you configure a log source in QRadar, configure the **assume Role ARN** parameter for QRadar to assume the role. To ensure that all files waiting to be processed in a single run (emptying the queue) can finish without retries, use the default value of 1 hour for the **API Session Duration** parameter.

When you use assumed roles, ensure that the ARN of the user that is assuming the role is in the **Trusted Entities** for that role. You can view the trusted entities that can assume the rule from the **Trust Relationship** tab in **IAM Role**. In addition, the user must have permission to assume roles in that (or any) account. The following examples show a sample trust policy:

#### Allow all IAM users within a specific AWS account to assume a role

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:root"
            },
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"
        }
    ]
}

```

## Allow a specific user to assume a role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:user/USERNAME"  
            },  
            "Action": "sts:AssumeRole",  
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"  
        }  
    ]  
}
```

The following image example shows a sample Amazon AWS CloudTrail log source configuration in QRadar.

**Tip:** Use the Amazon AWS S3 REST API log source parameter values for your DSM when you configure your log source.

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### Related information

[Adding a log source](#)

## Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge

Create an Amazon EventBridge rule to forward ObjectCreated notifications to a target SQS queue.

### Before you begin

Before you can create a rule in Amazon EventBridge, you must enable Amazon EventBridge on your AWS Management console. For more information, see [Enabling Amazon EventBridge](#).

### Procedure

1. Open the [Amazon EventBridge console](#).
2. From the **Navigation** menu, click **Rules > Create rule**.
3. On the **Create rule** window, complete the following steps:
  - a) Enter a name and description for the rule.  
**Important:** A rule can't have the same name as another rule that is both in the same region and on the same event bus.
  - b) For **Event bus**, select the event bus that you want to associate with this rule. If you select **AWS default event bus**, the rule matches the events that come from your account.
  - c) For **Rule type**, select **Rule with an event pattern**.
4. Click **Next**.
5. For **Event source**, select **AWS events or EventBridge partner events**.
6. For **Creation method**, select **Use pattern form**.
7. In the **Event pattern** window, configure the event pattern by completing the following steps:
  - a) Select the values listed in the table for the following parameters:

Parameter	Value
<b>Event source</b>	<b>AWS services</b>
<b>AWS service</b>	<b>Simple Storage Service (S3)</b>
<b>Event type</b>	<b>Amazon S3 Event Notification</b>

- b) Click the **Specific event(s)** option and select **Object Created**.

c) Click **Specific bucket(s) by name** and enter the name of the specific bucket that you want to collect events from.

d) Optional: To enable notifications for a specific folder prefix or file extension, choose **Custom pattern (JSON editor)** instead of **Use pattern form** for the creation method, and create your custom event pattern.

For example, this event pattern filters for Object Created events in your bucket. In this example, example/directory is the directory prefix and .png is the suffix.

```
{  
    "source": ["aws.s3"],  
    "detail-type": ["Object Created"],  
    "detail": {  
        "bucket": {  
            "name": ["<example-bucket>"]  
        },  
        "object": {  
            "key": [{  
                "prefix": "example/directory/"  
            }],  
            "key": [{  
                "suffix": ".png"  
            }]  
        }  
    }  
}
```

e) Click **Add**, then click **Next**.

8. Choose the SQS queue that you want to use as the target. Enter the name of the queue, then click **Next**.

9. On the **Review and create** page, click **Create rule**.

## Amazon AWS S3 REST API log source parameters for Amazon AWS Application Load Balancer Access Logs

If IBM QRadar does not automatically detect the log source, add an Amazon AWS Application Load Balancer Access Logs log source on the QRadar Console by using the Amazon AWS S3 REST API protocol.

When you use the Amazon AWS S3 REST API protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Amazon AWS S3 REST API events from Amazon AWS Application Load Balancer Access Logs:

*Table 162. Amazon AWS S3 REST API protocol log source parameters for the Amazon AWS Application Load Balancer Access Logs DSM*

Parameter	Value
<b>Log Source type</b>	Amazon AWS Application Load Balancer Access Logs
<b>Protocol Configuration</b>	Amazon AWS S3 REST API
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one Amazon AWS Application Load Balancer Access Logs log source that is configured, you might want to identify the first log source as <i>awsalb1</i> , the second log source as <i>awsalb2</i> , and the third log source as <i>awsalb3</i> .
<b>Event Format</b>	LINEBYLINE

For a complete list of Amazon AWS S3 REST API protocol parameters and their values, see [Amazon S3 REST API protocol configuration options](#).

## Configuring an Amazon AWS CloudTrail log source that uses an S3 bucket with an SQS queue

If you want to collect AWS CloudTrail logs from multiple accounts or regions in an Amazon S3 bucket, configure a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

### About this task

Using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue instead of a directory prefix has the following advantages:

- You can use one log source for an S3 bucket, rather than one log source for each region and account.
- There is a reduced chance of missing files because this method uses ObjectCreate notifications to determine when new files are ready.
- It's easy to balance the load across multiple Event Collectors because the SQS queue supports connections from multiple clients
- Unlike the directory prefix method, the SQS queue method does not require that the file names in the folders be in a string sorted in ascending order based on the full path. File names from custom applications don't always conform to this.
- You can monitor the SQS queue and set up alerts if it gets over a certain number of records. These alerts provide information about whether QRadar is either falling behind or not collecting events.
- You can use IAM Role authentication with SQS, which is Amazon's best practice for security.

- Certificate handling is improved with the SQS method and does not require the downloading of certificates to the Event Collector.

## Procedure

1. [Create the SQS queue that is used to receive ObjectCreated notifications.](#)
2. [Create an Amazon AWS Identity and Access Management \(IAM\) user and then apply the \*\*AmazonS3ReadOnlyAccess\*\* policy.](#)
3. [Configure the security credentials for your AWS user account.](#)
4. [Add an Amazon AWS CloudTrail log source on the QRadar Console using an SQS queue](#)

### **Create an SQS queue and configure S3 ObjectCreated notifications**

Before you can add a log source in IBM QRadar, you must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

Complete the following procedures:

1. [Finding the S3 Bucket that contains the data that you want to collect.](#)
2. [Creating the SQS queue that is used to receive the ObjectCreated notifications from the S3 Bucket that you used in Step 1.](#)
3. [Setting up SQS queue permissions.](#)
4. [Creating ObjectCreated notifications.](#)
5. [Configuring security credentials for your AWS user account.](#)
6. [Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge.](#)
7. [Adding an Amazon AWS CloudTrail log source on the QRadar Console using an SQS queue.](#)

#### *Finding the S3 bucket that contains the data that you want to collect*

You must find and note the region for S3 bucket that contains the data that you want to collect.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to **S3**.
3. From the **AWS Region** column in the **Buckets** list, note the region where the bucket that you want to collect data from is located. You need the region for the **Region Name** parameter value when you add a log source in IBM QRadar.
4. Enable the checkbox beside the bucket name, and then from the panel that opens to the right, click **Copy Bucket ARN** to copy the value to the clipboard. Save this value or leave it on the clipboard. You need this value when you set up **SQS queue permissions**.

#### *Creating the SQS queue that is used to receive ObjectCreated notifications*

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

## Before you begin

You must complete **Finding the S3 Bucket that contains the data that you want to collect**. The SQS Queue must be in the same region as the AWS S3 bucket that the queue is collecting from.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to the Simple Queue Service Management Console.

3. In the upper right of the window, change the region to where the bucket is located. You noted this value when you completed the **Finding the S3 Bucket that contains the data that you want to collect** procedure.
4. Select **Create New Queue**, and then type a value for the **Queue Name**.
5. Click **Standard Queue**, select **Configure Queue**, and then change the default values for the following **Queue Attributes**.
  - **Default Visibility Timeout** - 60 seconds (You can use a lower value. In the case of load balanced collection, duplicate events might occur with values of less than 30 seconds. This value can't be 0.)
  - **Message Retention Period** - 14 days (You can use a lower value. In the event of an extended collection, data might be lost.)

Use the default value for the remaining **Queue Attributes**.

More options such as **Redrive Policy** or **SSE** can be used depending on the requirements for your AWS environment. These values should not affect the data collection.

Queue Attributes

<b>Default Visibility Timeout</b>	<input type="text" value="60"/>	seconds	Value must be between 0 seconds and 12 hours.
<b>Message Retention Period</b>	<input type="text" value="14"/>	days	Value must be between 1 minute and 14 days.
<b>Maximum Message Size</b>	<input type="text" value="256"/>	KB	Value must be between 1 and 256 KB.
<b>Delivery Delay</b>	<input type="text" value="0"/>	seconds	Value must be between 0 seconds and 15 minutes.
<b>Receive Message Wait Time</b>	<input type="text" value="0"/>	seconds	Value must be between 0 and 20 seconds.

---

Picture © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

## 6. Select **Create Queue**.

### *Setting up SQS queue permissions*

You must set up SQS queue permissions for users to access the queue.

### **Before you begin**

You must complete **Creating the SQS queue that is used to receive ObjectCreated notifications**.

You can set the SQS queue permissions by using either the Permissions Editor or a JSON policy document.

### **Procedure**

1. Log in to the AWS Management Console as an administrator.
2. Go to the SQS Management Console, and then select the queue that you created from the list.
3. From the **Details** panel, record the **ARN** field value.

For example: **arn:aws:sqs:us-east-1:123456789012:MySQSQueueName**

4. To set the SQS queue **Access policy (Permissions)** by using the **AWS Policy generator**, complete the following steps:
  - a) Select **Policy Type > SQS Queue Policy**.
  - b) Add an Access Policy statement.
  - c) From the **Access policy** tab, click **Policy generator**, and then configure the following parameters:

Table 165. Permission parameters

Parameter	Value
<b>Effect</b>	Click <b>Allow</b> .
<b>Principal</b>	Type <b>*</b> (Everybody).
<b>Actions</b>	From the list, select <b>SendMessage</b>
<b>Amazon Resource Name (ARN)</b>	Type your queue ARN: <i>arn:aws:sqs:us-east-1:123456789012:MySQSQueueName</i>

d) Click **Add Conditionals (Optional)**, and then configure the following parameters:

Table 166. Add Conditionals (Optional) parameters

Parameter	Value
<b>Qualifier</b>	None
<b>Condition</b>	<b>ARNLike</b>
<b>Key</b>	Type <b>aws:SourceArn</b> .
<b>Value</b>	The ARN of the S3 bucket from when you completed the “ <a href="#">Finding the S3 bucket that contains the data that you want to collect</a> ” on page 308 procedure.  For example: <b>aws:s3:::my-example-s3bucket</b>

5. To set the SQS queue permissions by using a JSON policy document, complete the following steps:

a) Click **Add Condition** > **Add Statement**. > **Generate Policy**.

b) Copy and paste the following JSON policy into the **Access policy** window:

Copy and paste might not preserve the white space in the JSON policy. The white space is required. If the white space is not preserved when you paste the JSON policy, paste it into a text editor and restore the white space. Then, copy and paste the JSON policy from your text editor into the **Edit Policy Document** window.

```
{
  "Version": "2008-10-17",
  "Id": "example-ID",
  "Statement": [
    {
      "Sid": "example-statement-ID",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::my-example-s3bucket"
        }
      }
    }
  ]
}
```

6. Click **Review Policy**. Ensure that the data is correct, and then click **Save Changes**.

### *Creating ObjectCreated notifications*

Configure ObjectCreated notifications for the folders that you want to monitor in the bucket.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, go to **S3**, and then select a bucket.
3. Click the **Properties** tab, and in the **Events** pane, click **Add notification**. Configure the parameters for the new event.

The following table shows an example of an ObjectCreated notification parameter configuration:

*Table 167. Example: New ObjectCreated notification parameter configuration*

Parameter	Value
<b>Name</b>	Type a name of your choosing.
<b>Events</b>	Select <b>All object create events</b> .
<b>Prefix</b>	AWSLogs/ <b>Tip:</b> You can choose a prefix that contains the data that you want to find, depending on where the data is located and what data that you want to go to the queue. For example, AWSLogs/, CustomPrefix/AWSLogs/, AWSLogs/123456789012/.
<b>Suffix</b>	json.gz
<b>Send to</b>	SQS queue <b>Tip:</b> You can send the data from different folders to the same or different queues to suit your collection or QRadar tenant needs. Choose one or more of the following methods: <ul style="list-style-type: none"><li>• Different folders that go to different queues</li><li>• Different folders from different buckets that go to the same queue</li><li>• Everything from a single bucket that goes to a single queue</li><li>• Everything from multiple buckets that go to a single queue</li></ul>
<b>SQS</b>	The <b>Queue Name</b> from step 4 of <b>Creating the SQS queue that is used to receive the ObjectCreated notifications</b> .

## Create event notification

The notification configuration identifies the events you want Amazon S3 to publish and the destinations where you want Amazon S3 to send the notifications. [Learn more](#)

### General configuration

Event name  
NewS3ObjectToSQS

Event name can contain up to 255 characters.

Prefix - optional  
Limit the notifications to objects with key starting with specified characters.  
 Example. This value must match the location of the data that you want to collect.

Suffix - optional  
Limit the notifications to objects with key ending with specified characters.  
 Example. Enter a value so that you can filter out unwanted files that match the prefix.

### Event types

Specify at least one type of event for which you want to receive notifications. [Learn more](#)

All object create events  
s3:ObjectCreated:  
 Put  
s3:ObjectCreated:Put  
 Post  
s3:ObjectCreated:Post  
 Copy  
s3:ObjectCreated:Copy  
 Multipart upload completed  
s3:ObjectCreated:CompleteMultipartUpload

Figure 10. Example: Events

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

In the example in figure 1 of a parameter configuration, notifications are created for AWSLogs / from the root of the bucket. When you use this configuration, All ObjectCreated events trigger a notification. If there are multiple accounts and regions in the bucket, everything gets processed. In this example, json.gz is used. This file type can change depending on the data that you are collecting. Depending on the content in your bucket, you can omit the extension or choose an extension that matches the data you are looking for in the folders where you have events set up.

After approximately 5 minutes, the queue that contains data displays. In the **Messages Available** column, you can view the number of messages.

Figure 11. Number of available messages

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

4. Click **Services**, then go to **Simple Queue Services**.
5. Right-click the **Queue Name** from step 4 of **Creating the SQS queue that is used to receive the ObjectCreated notifications**, then select **View/Delete Messages** to view the messages.

    "eTag":"1ff1209e4140b4ff7a9d2b922f57f486",
    "sequencer":"005C19A40717D99642"
}
]
}
}

```

**Tip:** In the **key** value, your DSM name displays.

6. Click **Services**, then navigate to **IAM**.
7. Set a **User or Role** permission to access the SQS queue and for permission to download from the target bucket. The user or user role must have permission to read and delete from the SQS queue. For information about adding, managing and changing permissions for IAM users, see the [IAM Users documentation](#). After QRadar reads the notification, and then downloads and processes the target file, the message must be deleted from the queue.

Sample Policy:

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sqs:DeleteMessage",
                "sqs:ReceiveMessage",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket_name>/AWSLogs/*",
                "arn:aws:sqs:us-east-2:<AWS_account_number>:<queue_name>"
            ]
        }
    ]
}

```

You can add multiple buckets to the S3 queue. To ensure that all objects are accessed, you must have a trailing `/*` at the end of the folder path that you added.

You can add this policy directly to a user, a user role, or you can create a minimal access user with **sts:AssumeRole** permissions only. When you configure a log source in QRadar, configure the **assume Role ARN** parameter for QRadar to assume the role. To ensure that all files waiting to be processed in a single run (emptying the queue) can finish without retries, use the default value of 1 hour for the **API Session Duration** parameter.

When you use assumed roles, ensure that the ARN of the user that is assuming the role is in the **Trusted Entities** for that role. You can view the trusted entities that can assume the rule from the **Trust Relationship** tab in **IAM Role**. In addition, the user must have permission to assume roles in that (or any) account. The following examples show a sample trust policy:

#### Allow all IAM users within a specific AWS account to assume a role

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:root"
            },
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"
        }
    ]
}

```

## Allow a specific user to assume a role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:user/USERNAME"  
            },  
            "Action": "sts:AssumeRole",  
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"  
        }  
    ]  
}
```

The following image example shows a sample Amazon AWS CloudTrail log source configuration in QRadar.

**Tip:** Use the Amazon AWS S3 REST API log source parameter values for your DSM when you configure your log source.

Figure 13. Example: Amazon AWS CloudTrail log source configuration in QRadar

## *Configuring security credentials for your AWS user account*

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### **Procedure**

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### **Related information**

#### [Adding a log source](#)

#### *Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge*

Create an Amazon EventBridge rule to forward ObjectCreated notifications to a target SQS queue.

### **Before you begin**

Before you can create a rule in Amazon EventBridge, you must enable Amazon EventBridge on your AWS Management console. For more information, see [Enabling Amazon EventBridge](#).

### **Procedure**

1. Open the [Amazon EventBridge console](#).
2. From the **Navigation** menu, click **Rules > Create rule**.
3. On the **Create rule** window, complete the following steps:

- a) Enter a name and description for the rule.

**Important:** A rule can't have the same name as another rule that is both in the same region and on the same event bus.

- b) For **Event bus**, select the event bus that you want to associate with this rule. If you select **AWS default event bus**, the rule matches the events that come from your account.
- c) For **Rule type**, select **Rule with an event pattern**.

4. Click **Next**.
5. For **Event source**, select **AWS events or EventBridge partner events**.
6. For **Creation method**, select **Use pattern form**.
7. In the **Event pattern** window, configure the event pattern by completing the following steps:

- a) Select the values listed in the table for the following parameters:

Parameter	Value
<b>Event source</b>	<b>AWS services</b>
<b>AWS service</b>	<b>Simple Storage Service (S3)</b>
<b>Event type</b>	<b>Amazon S3 Event Notification</b>

- b) Click the **Specific event(s)** option and select **Object Created**.
- c) Click **Specific bucket(s) by name** and enter the name of the specific bucket that you want to collect events from.

- d) Optional: To enable notifications for a specific folder prefix or file extension, choose **Custom pattern (JSON editor)** instead of **Use pattern form** for the creation method, and create your custom event pattern.
- For example, this event pattern filters for Object Created events in your bucket. In this example, example/directory is the directory prefix and .png is the suffix.

```
{
  "source": ["aws_s3"],
  "detail-type": ["Object Created"],
  "detail": {
    "bucket": {
      "name": ["<example-bucket>"]
    },
    "object": {
      "key": [
        {
          "prefix": "example/directory/"
        },
        {
          "key": [
            {
              "suffix": ".png"
            }
          ]
        }
      ]
    }
  }
}
```

e) Click **Add**, then click **Next**.

8. Choose the SQS queue that you want to use as the target. Enter the name of the queue, then click **Next**.

9. On the **Review and create** page, click **Create rule**.

*Adding an Amazon AWS CloudTrail log source on the QRadar Console using an SQS queue*

If you want to collect AWS CloudTrail logs from multiple accounts or regions in an Amazon S3 bucket, add a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

## Procedure

1. Use the following table to set the parameters for an Amazon AWS CloudTrail log source that uses the Amazon AWS S3 REST API protocol and an SQS queue.

*Table 168. Amazon AWS S3 REST API protocol log source parameters*

Parameter	Description
<b>Log Source Type</b>	<b>Amazon AWS CloudTrail</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one Amazon AWS CloudTrail log source that is configured, you might want to identify the first log source as <i>awscloudtrail1</i> , the second log source as <i>awscloudtrail2</i> , and the third log source as <i>awscloudtrail3</i> .

Table 168. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>  Standard authentication that can be used from anywhere.</p> <p><b>Assume IAM Role</b>  Authenticate with keys and then temporarily assume a role for access. This option is available only when you select <b>SQS Event Notifications</b> for the <b>S3 Collection Method</b>. The supported <b>S3 Collection Method</b> is <b>Use a Specific Prefix</b>.</p> <p><b>EC2 Instance IAM Role</b>  If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata that is assigned to the instance for authentication; no keys are required. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Access Key ID</b> parameter is displayed.  The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.
<b>Secret Key</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Secret Key ID</b> parameter is displayed.  The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Secret Key ID</b> that is used to access the AWS S3 bucket.
<b>Event Format</b>	Select <b>AWS Cloud Trail JSON</b> . The log source retrieves JSON formatted events.
<b>S3 Collection Method</b>	Select <b>SQS Event Notifications</b> .
<b>SQS Queue URL</b>	Enter the full URL, starting with <code>https://</code> , of the SQS queue that is set up to receive notifications for ObjectCreate events from S3.
<b>Region Name</b>	The region that the SQS Queue or the S3 Bucket is in.  Example: us-east-1, eu-west-1, ap-northeast-3
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.
<b>Log Source Identifier Pattern</b>	This option is available when you set <b>Use as a Gateway Log Source</b> is set to yes.  Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.

Table 168. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.
<b>File Pattern</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code>
<b>Local Directory</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.
<b>S3 Endpoint URL</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The endpoint URL that is used to query the AWS REST API.  If your endpoint URL is different from the default, type your endpoint URL. The default is <code>http://s3.amazonaws.com</code>
<b>Use S3 Path-Style Access</b>	Forces S3 requests to use path-style access.  This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> .  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Recurrence</b>	How often a poll is made to scan for new data.  If you are using the SQS event collection method, <b>SQS Event Notifications</b> can have a minimum value of 10 (seconds). Because SQS Queue polling can occur more often, a lower value can be used.  If you are using the Directory Prefix event collection method, <b>Use a Specific Prefix</b> has a minimum value of 60 (seconds) or 1M. Because every listBucket request to an AWS S3 bucket incurs a cost to the account that owns the bucket, a smaller recurrence value increases the cost.  Type a time interval to determine how frequently the poll is made for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds.

Table 168. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

2. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

Table 169. Amazon AWS CloudTrail sample message supported by Amazon AWS CloudTrail.

Event name	Low-level category	Sample log message
Console Login	General Audit Event	<pre>{"eventVersion": "1.02", "userIdentity": {"type": "IAMUser", "principalId": "XXXXXXXXXXXXXXXXXXXXXX", "arn": "arn:aws:iam::&lt;Account_number&gt;:user/ xx.xxxxcountId": "&lt;Account_number&gt;", "userName": "&lt;Username&gt;"}, "eventTime": "2016-05-04T14:10:58Z", "eventSource": "f.amazonaws.com", "eventName": "ConsoleLogin", "awsRegion": "us-east-1", "sourceIPAddress": "&lt;Source_IP_address&gt; Agent": "Mozilla/5.0 (Windows NT 6.1; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/50.0.1.1 Safari/537.36", "requestParameters": null, "responseElements": {"ConsoleLogin": "Success"}, "additionalEventData": {"LoginTo": "www.webpage.com", "MobileVersion": "No", "MFAUsed": "No"}, "eventID": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx", "eventType": "AwsConsoleSignIn", "recipientAccountId": "&lt;Account_ID&gt;"}</pre>

## Configuring an Amazon AWS CloudTrail log source that uses an S3 bucket with a directory prefix

If you want to collect AWS CloudTrail logs from a single account and region in an Amazon S3 bucket, configure a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon AWS S3 REST API protocol with a directory prefix.

### About this task

If you have log sources in an S3 bucket from multiple regions or using multiple accounts, use the [Amazon AWS S3 REST API protocol with an SQS queue](#) instead of with a directory prefix.

**Restriction:** A log source using directory prefix can retrieve data from only one region and one account, so use a different log source for each region and account. Include the region folder name in the file path for the **Directory Prefix** value when you configure the log source.

### Procedure

- [Finding an S3 bucket name and directory prefix.](#)

2. Create an Amazon AWS Identity and Access Management (IAM) user and then apply the [AmazonS3ReadOnlyAccess](#) policy.
3. Configure the security credentials for your AWS user account.
4. Add an Amazon AWS CloudTrail log source on the QRadar Console using a directory prefix.

### **Finding an S3 bucket name and directory prefix**

An Amazon administrator must create a user and then apply the **AmazonS3ReadOnlyAccess** policy in the AWS Management Console. The QRadar user can then create a log source in QRadar.

**Note:** Alternatively, you can assign more granular permissions to the bucket. The minimum required permissions are **s3:listBucket** and **s3:getObject**.

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

### **Procedure**

1. Click **Services**.
2. From the list, select **Config**.
3. From the **Config** page, click the name of the Config.
4. Note the name of the S3 bucket that is displayed in the **S3 bucket** field.
5. Click the **Edit** icon.
6. Note the location path for the S3 bucket that is displayed underneath the **Log file prefix** field.

### **Creating an Identity and Access Management (IAM) user in the AWS Management Console**

An Amazon administrator must create a user and then apply the **s3:listBucket** and **s3:getObject** permissions to that user in the AWS Management Console. The QRadar user can then create a log source in QRadar.

### **About this task**

The minimum required permissions are **s3:listBucket** and **s3:getObject**. You can assign other permissions to the user as needed.

Sample policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3>ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::<bucket_name>",
        "arn:aws:s3:::<bucket_name>/AWSLogs/<AWS_account_number>/<DSM_name>/us-east-1/*"
      ]
    }
  ]
}
```

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

### **Procedure**

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**.

3. From the list, select **IAM**.
4. Click **Users > Add user**.
5. Create an Amazon AWS IAM user and then apply the **AmazonS3ReadOnlyAccess** policy.

### **Configuring security credentials for your AWS user account**

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### **Procedure**

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### **Related information**

[Adding a log source](#)

### **Adding an Amazon AWS CloudTrail log source on the QRadar Console using a directory prefix**

If you want to collect AWS CloudTrail logs from a single account and region in an Amazon S3 bucket, add a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon AWS S3 REST API protocol with a directory prefix.

### **Procedure**

1. Use the following table to set the parameters for an Amazon AWS CloudTrail log source that uses the Amazon AWS S3 REST API protocol and a directory prefix.

*Table 170. Amazon AWS S3 REST API protocol log source parameters*

Parameter	Description
<b>Log Source Type</b>	<b>Amazon AWS CloudTrail</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	<p>Type a unique name for the log source.</p> <p>The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b>. If you have more than one Amazon AWS CloudTrail log source that is configured, you might want to identify the first log source as <i>awscloudtrail1</i>, the second log source as <i>awscloudtrail2</i>, and the third log source as <i>awscloudtrail3</i>.</p>

Table 170. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>  Standard authentication that can be used from anywhere.  For more information about configuring security credentials, see “<a href="#">Configuring security credentials for your AWS user account</a>” on page 316.</p> <p><b>Assume IAM Role</b>  Authenticate with keys and then temporarily assume a role for access. This option is available only when you select <b>SQS Event Notifications</b> for the <b>S3 Collection Method</b>. The supported <b>S3 Collection Method</b> is <b>Use a Specific Prefix</b>.  For more information about creating IAM users and assigning roles, see <a href="#">Creating an IAM user in the AWS Management Console</a>.</p> <p><b>EC2 Instance IAM Role</b>  If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata assigned to the instance for authentication; no keys are required. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Access Key ID</b> parameter is displayed.  The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.
<b>Secret Key</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Secret Key ID</b> parameter is displayed.  The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Secret Key ID</b> that is used to access the AWS S3 bucket.
<b>Event Format</b>	Select <b>AWS Cloud Trail JSON</b> . The log source retrieves JSON formatted events.
<b>S3 Collection Method</b>	Select <b>Use a Specific Prefix</b> .
<b>Bucket Name</b>	The name of the AWS S3 bucket where the log files are stored.

Table 170. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Directory Prefix</b>	<p>The root directory location on the AWS S3 bucket from where the CloudTrail logs are retrieved; for example, AWSLogs/&lt;AccountNumber&gt;/CloudTrail/&lt;RegionName&gt;/</p> <p>To pull files from the root directory of a bucket, you must use a forward slash (/) in the <b>Directory Prefix</b> file path.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• Changing the <b>Directory Prefix</b> value clears the persisted file marker. All files that match the new prefix are downloaded in the next pull.</li> <li>• The <b>Directory Prefix</b> file path cannot begin with a forward slash (/) unless only the forward slash is used to collect data from the root of the bucket.</li> <li>• If the <b>Directory Prefix</b> file path is used to specify folders, you must not begin the file path with a forward slash (for example, use folder1/folder2 instead).</li> </ul>
<b>Region Name</b>	<p>The region that the SQS Queue or the S3 Bucket is in.</p> <p>Example: us-east-1, eu-west-1, ap-northeast-3</p>
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.
<b>Log Source Identifier Pattern</b>	<p>This option is available when you set <b>Use as a Gateway Log Source</b> is set to yes.</p> <p>Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.</p>
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.
<b>File Pattern</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>Type a regex for the file pattern that matches the files that you want to pull; for example, .*?\.\json\.\gz</p>
<b>Local Directory</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.</p>

Table 170. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>S3 Endpoint URL</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The endpoint URL that is used to query the AWS REST API. If your endpoint URL is different from the default, type your endpoint URL. The default is <a href="http://s3.amazonaws.com">http://s3.amazonaws.com</a>
<b>Use S3 Path-Style Access</b>	Forces S3 requests to use path-style access.  This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> .  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Recurrence</b>	How often the Amazon AWS S3 REST API Protocol connects to the Amazon cloud API, checks for new files, and if they exist, retrieves them. Every access to an AWS S3 bucket incurs a cost to the account that owns the bucket. Therefore, a smaller recurrence value increases the cost.  Type a time interval to determine how frequently the remote directory is scanned for new event log files. The minimum value is 1 minute. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15 M = 15 minutes.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

2. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

Table 171. Amazon AWS CloudTrail sample message supported by Amazon AWS CloudTrail.

Event name	Low-level category	Sample log message
Console Login	General Audit Event	<pre>{   "eventVersion": "1.02",   "userIdentity": {     "type": "IAMUser",     "principalId": "XXXXXXXXXXXXXXXXXXXXXX",     "arn": "arn:aws:iam::&lt;Account_number&gt;:user/ xx.xxxxxxcountId": "&lt;Account_number&gt;", "userName": "&lt;Username&gt;" },   "eventTime": "2016-05-04T14:10:58Z",   "eventSource": "f.amazonaws.com",   "eventName": "ConsoleLogin",   "awsRegion": "us-east-1",   "sourceIPAddress": "&lt;Source_IP address&gt; Agent": "Mozilla/5.0 (Windows NT 6.1; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/50.0.11 Safari/537.36",   "requestParameters": null,   "responseElements": {     "ConsoleLogin": "Success"   },   "additionalEventData": {     "LoginTo": "www.webpage.com",     "MobileVersion": "No",     "MFAUsed": "No"   },   "eventID": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",   "eventType": "AwsConsoleSignIn",   "recipientAccountId": "&lt;Account_ID&gt;" }</pre>

## Configuring an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol

If you want to collect AWS CloudTrail logs from Amazon CloudWatch logs, configure a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon Web Services protocol.

### Procedure

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol Common
  - Amazon AWS REST API Protocol RPM
  - Amazon Web Services Protocol RPM
  - DSMCommon RPM
  - Amazon AWS CloudTrail DSM RPM
2. Choose which method you will use to configure an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol.
  - [“Configuring an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and Kinesis Data Streams” on page 327](#)
  - [“Configuring an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and CloudWatch Logs” on page 332](#)

### Related tasks

[“Configuring an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and CloudWatch Logs” on page 332](#)

If you want to collect AWS CloudTrail logs from Amazon CloudWatch logs, configure a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon Web Services protocol.

[“Configuring an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and Kinesis Data Streams” on page 327](#)

If you want to collect AWS CloudTrail logs from Amazon Kinesis Data Streams, configure a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon Web Services protocol.

## **Configuring an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and Kinesis Data Streams**

If you want to collect AWS CloudTrail logs from Amazon Kinesis Data Streams, configure a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon Web Services protocol.

### **Procedure**

1. Follow the procedures in the AWS online documentation [Sending Events to CloudWatch Logs](https://docs.aws.amazon.com/awscloudtrail/latest/userguide/send-cloudtrail-events-to-cloudwatch-logs.html) (<https://docs.aws.amazon.com/awscloudtrail/latest/userguide/send-cloudtrail-events-to-cloudwatch-logs.html>) to configure CloudTrail to deliver the logs in a log group of the AWS CloudWatch Logs.
2. Create CloudWatch Logs destinations and a CloudWatch Logs subscription filter.  
For more information about CloudWatch Logs Destinations and Subscriptions, see [Cross-Account Log Data Sharing with Subscriptions](#).
  - a) Create a CloudWatch Logs destination that points to a destination Kinesis Data Stream.  
Only one CloudWatch Logs destination is required per region and the destination Kinesis Data Stream can be in any region.
  - b) Create a CloudWatch Logs subscription filter with a blank filter pattern to subscribe the destination to the CloudWatch Logs log group and match all events.  
The subscription filter is now associated with a Cloud Watch Logs log group that contains AWS CloudTrail logs, and delivers those logs to a Kineses Data Stream.
3. Add an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and Kinesis Data Streams.

### **Related information**

## ***Adding an Amazon CloudFront log source by using the Amazon Web Services protocol and Kinesis Data Streams***

If you want to collect AWS CloudTrail logs from Amazon Kinesis Data Streams, add a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon Web Services protocol.

### **Procedure**

1. Use the following table describes the parameters that require specific values to collect audit events from Amazon AWS CloudTrail by using the Amazon Web Services protocol:

Table 172. Amazon Web Services log source parameters for Amazon Kinesis Data Streams

Parameter	Description
<b>Protocol Configuration</b>	Select <b>Amazon Web Services</b> from the Protocol Configuration list.
<b>Authentication Method</b>	<p><b>Access Key ID/Secret Key</b>  Standard authentication that can be used from anywhere.</p> <p><b>EC2 Instance IAM Role</b>  If your QRadar managed host is running in an AWS EC2 instance, choosing this option uses the IAM role from the metadata that is assigned to the instance for authentication. No keys are required. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key</b>	<p>The Access Key ID that was generated when you configured the security credentials for your AWS user account.</p> <p>If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b>, the <b>Access Key</b> parameter is displayed.</p>
<b>Secret Key</b>	<p>The Secret Key that was generated when you configured the security credentials for your AWS user account.</p> <p>If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b>, the <b>Secret Key</b> parameter is displayed.</p>
<b>Assume an IAM Role</b>	Enable this option to authenticate with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access.
<b>Assume Role ARN</b>	<p>The full ARN of the role to assume. It must begin with "arn:" and can't contain any leading or trailing spaces, or spaces within the ARN.</p> <p>If you enabled <b>Assume an IAM Role</b>, the <b>Assume Role ARN</b> parameter is displayed.</p>
<b>Assume Role Session Name</b>	<p>The session name of the role to assume. The default is QRadarAWSsession. Leave as the default if you don't need to change it. This parameter can contain only upper and lowercase alphanumeric characters, underscores, or any of the following characters: =, . @ -</p> <p>If you enabled <b>Assume an IAM Role</b>, the <b>Assume Role Session Name</b> parameter is displayed.</p>
<b>Assume Role External ID</b>	<p><b>Assume Role External ID</b> is an optional identifier that is required to assume a role in a different account.</p> <p>If the account administrator, to which the role belongs, provides you with an external ID, then insert that value in the <b>Assume Role External ID</b> parameter.</p> <p>This value can either be a string, a passphrase, a GUID, or an account number. For more information, see AWS documentation <a href="#">Using an external ID for third-party access</a>.</p>
<b>Regions</b>	Toggle each region that is associated with the Amazon Web Service that you want to collect logs from.
<b>AWS Service</b>	From the <b>AWS Service</b> list, select <b>Kinesis Data Streams</b> .
<b>Kinesis Data Stream</b>	The Kinesis Data Stream from which to consume data.

Table 172. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Enable Kinesis Advanced Options</b>	<p>Enable the following optional advanced configuration values. Advanced option values are only used when this option is chosen; otherwise, the default values are used.</p> <p><b>Initial Position in Stream</b>  This option controls which data to pull on a newly configured log source. Select <b>Latest</b> to pull the latest data that is available. Select <b>Trim Horizon</b> to pull the oldest data that is available.</p> <p><b>Kinesis Worker Thread Count</b>  The number of worker threads to use for Kinesis Data Stream processing. Each worker thread can process approximately 10000 - 20000 events per second depending on record size and system load. If your log source is not able to process the new data in the stream, you can increase the number of threads here to a maximum of 16. The allowed range is 1 - 16. The default value is 2.</p> <p><b>Checkpoint Interval</b>  The interval (in seconds) at which to checkpoint data sequence numbers. Each record from a shard in a Kinesis Data Stream has a sequence number. Checkpointing your position allows this shard to resume processing at the same point if processing fails or a service restarts. A more frequent interval reduces data duplication but increases Amazon Dynamo DB usage. The allowed range is 1 - 3600 seconds. The default is 10 seconds.</p> <p><b>Kinesis Application</b>  Leave this option blank to have this log source consume data from all available shards in the Kinesis Data Stream. To have multiple log sources on multiple event processors scale log consumption without loss or duplication, use a common Kinesis Application across those log sources (Example: ProdKinesisConsumers).</p> <p><b>Partition</b>  Select this option to collect data from a specific partition in the Kinesis Data Stream by specifying a partition name.</p>

Table 172. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Extract Original Event</b>	<p>Fowards only the original event that was added to the Kinesis Data Stream. Kinesis logs wrap the events that they receive with extra metadata. Select this option if you want only the original event that was sent to AWS without the additional stream metadata through Kinesis.</p> <p>The original event is the value for the message key that is extracted from the Kinesis log. The following Kinesis logs event example shows the original event that is extracted from the Kinesis log in highlighted text:</p> <pre>{"owner": "123456789012", "subscriptionFilters": ["allEvents"], "logEvents": [{"id": "35093963143971327215510178578576502306458824699048362100", "message": "{\"eventVersion\": \"1.05\", \"userIdentity\": {\"type\": \"AssumedRole\", \"principalId\": \"ARO1GH58EM3ESYDW3XHP6:test_session\", \"arn\": \"arn:aws:sts::123456789012:assumed-role/CVDevABRoleToBeAssumed/test_visibility_session\", \"accountId\": \"123456789012\", \"accessKeyId\": \"ASIAXXXXXXXXXXXXXX\", \"sessionContext\": {\"sessionIssuer\": {\"type\": \"Role\", \"principalId\": \"AROAXXXXXXXXXXXXXXXX\", \"arn\": \"arn:aws:iam::123456789012:role/CVDevABRoleToBeAssumed\", \"accountId\": \"123456789012\", \"userName\": \"CVDevABRoleToBeAssumed\", \"webIdFederationData\": {}}, \"attributes\": {\"mfaAuthenticated\": \"false\", \"creationDate\": \"2019-11-13T17:01:54Z\", \"eventTime\": \"2019-11-13T17:43:18Z\", \"eventSource\": \"cloudtrail.amazonaws.com\", \"eventName\": \"DescribeTrails\", \"awsRegion\": \"ap-northeast-1\", \"sourceIPAddress\": \"192.0.2.1\", \"requestParameters\": {\"null\", \"responseElements\": null, \"requestID\": \"41e62e80-b15d-4e3f-9b7e-b309084dc092\", \"eventID\": \"904b3fda-8e48-46c0-a923-f1bb2b7a2f2a\", \"readOnly\": true, \"eventType\": \"AwsApiCall\", \"recipientAccountId\": \"123456789012\"}, \"timestamp\": 1573667733143}, \"messageType\": \"DATA_MESSAGE\", \"logGroup\": \"CloudTrail\\DefaultLogGroup\", \"logStream\": \"123456789012_CloudTrail_us-east-2_2\"}}</pre>
<b>Use As A Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.</p> <p>When you select this option, the <b>Log Source Identifier Pattern</b> can optionally be used to define a custom <b>Log Source Identifier</b> for events that are being processed.</p>

Table 172. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>If you selected <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p><b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>
<b>Use Proxy</b>	<p>If QRadar accesses the Amazon Web Service by using a proxy, select this option.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

2. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

The actual CloudTrail logs are wrapped in a Kinesis Data Streams JSON payload:

Table 173. Kinesis Data Streams sample message supported by the Amazon AWS CloudTrail DSM

Event name	Low-level category	Sample log message
Describe Trails	Read Activity Attempted	<pre>{"owner": "123456789012", "subscriptionFilters": ["allEvents"], "logEvents": [{"id": "35101382794889527301913782399021634305485606205478862909", "message": "{\"eventVersion\": \"1.05\", \"userIdentity\": {\"type\": \"AssumedRole\", \"principalId\": \"AROA3GFMEP3ESYDW3XHP6:cloud_visibility_session\", \"arn\": \"arn:aws:sts::123456789012:assumed-role/CVDevABRoleToBeAssumed/cloud_visibility_session\", \"accountId\": \"123456789012\", \"accessKeyId\": \"ASIA3ABCDE3E6ZUV7IF5\", \"sessionContext\": {\"sessionIssuer\": {\"type\": \"Role\", \"principalId\": \"AROA3GABCD3ESYDW3XHP6\", \"arn\": \"arn:aws:iam::123456789012:role/CVDevABRoleToBeAssumed\", \"accountId\": \"123456789012\", \"userName\": \"CVDevABRoleToBeAssumed\", \"webIdFederationData\": {}}, \"attributes\": {\"mfaAuthenticated\": \"false\", \"creationDate\": \"2019-11-17T13:34:07Z\"}}, \"eventTime\": \"2019-11-17T14:10:48Z\", \"eventSource\": \"cloudtrail.amazonaws.com\", \"eventName\": \"DescribeTrails\", \"awsRegion\": \"ap-northeast-3\", \"sourceIPAddress\": \"192.0.2.1\", \"requestParameters\": null, \"responseElements\": null, \"requestID\": \"31afb5b7-6857-467a-bce4-835ee7d02ad2\", \"eventID\": \"26caf544-010c-423a-88a1-ca71cbd243ca\", \"readOnly\": true, \"eventType\": \"AwsApiCall\", \"recipientAccountId\": \"123456789012\", \"timestamp\": 1574000441797}], \"messageType\": \"DATA_MESSAGE\", \"logGroup\": \"CloudTrail/DefaultLogGroup\", \"logStream\": \"123456789012_CloudTrail_us-east-2\"}"}</pre>

## Configuring an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and CloudWatch Logs

If you want to collect AWS CloudTrail logs from Amazon CloudWatch logs, configure a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon Web Services protocol.

### Procedure

1. [“Creating an Identity and Access \(IAM\) user in the AWS Management Console” on page 332](#)
2. [“Creating a log group in Amazon CloudWatch Logs to retrieve logs in QRadar” on page 333](#)
3. [“Configure Amazon AWS CloudTrail to send log files to CloudWatch Logs” on page 333](#)
4. [“Configuring security credentials for your AWS user account” on page 333](#)
5. [“Adding an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and CloudWatch Logs” on page 333](#)

### Related tasks

- [“Adding a DSM” on page 4](#)  
[“Adding a log source” on page 5](#)

### ***Creating an Identity and Access (IAM) user in the AWS Management Console***

An Amazon administrator must create a user and then apply the **CloudWatchLogsReadOnlyAccess** policy in the AWS Management Console. The QRadar user can then create a log source in QRadar.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Create an Amazon AWS IAM user and then apply the **CloudWatchLogsReadOnlyAccess** policy.

### What to do next

[Amazon Web Services log source parameters for Amazon AWS Security Hub](#)

## ***Creating a log group in Amazon CloudWatch Logs to retrieve logs in QRadar***

You must create a log group in Amazon CloudWatch Logs to make the log available for QRadar polling.

### **Procedure**

1. Log in to your [CloudWatch console](https://console.aws.amazon.com/cloudwatch) (<https://console.aws.amazon.com/cloudwatch>).
2. Select **Logs** from left navigation pane.
3. Click **Actions > Create Log Group**.
4. Type the name of your log group. For example, CloudTrailAuditLogs.
5. Click **Create log group**.

For more information about working with log groups and log streams, see <https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/Working-with-log-groups-and-streams.html>

## ***Configure Amazon AWS CloudTrail to send log files to CloudWatch Logs***

You must configure CloudTrail to deliver the logs in a log group of the AWS CloudWatch Logs.

Follow the procedures in the AWS online documentation [Sending Events to CloudWatch Logs](#).

## ***Configuring security credentials for your AWS user account***

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### **Procedure**

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### **Related information**

[Adding a log source](#)

## ***Adding an Amazon AWS CloudTrail log source by using the Amazon Web Services protocol and CloudWatch Logs***

If you want to collect AWS CloudTrail logs from Amazon CloudWatch logs, add a log source on the QRadar Console so that Amazon AWS CloudTrail can communicate with QRadar by using the Amazon Web Services protocol.

### **Procedure**

1. Use the following table describes the parameters that require specific values to collect audit events from Amazon AWS CloudTrail by using the Amazon Web Services protocol:

*Table 174. Amazon Web Services log source parameters for AWS CloudWatch Logs*

Parameter	Description
<b>Protocol Configuration</b>	Select <b>Amazon Web Services</b> from the Protocol Configuration list.

Table 174. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)

Parameter	Description
<b>Authentication Method</b>	<b>Access Key ID/Secret Key</b> Standard authentication that can be used from anywhere. <b>EC2 Instance IAM Role</b> If your QRadar managed host is running in an AWS EC2 instance, choosing this option uses the IAM role from the metadata that is assigned to the instance for authentication. No keys are required. This method works only for managed hosts that are running within an AWS EC2 container.
<b>Access Key</b>	The Access Key ID that was generated when you configured the security credentials for your AWS user account. If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Access Key</b> parameter is displayed.
<b>Secret Key</b>	The Secret Key that was generated when you configured the security credentials for your AWS user account. If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Secret Key</b> parameter is displayed.
<b>Assume an IAM Role</b>	Enable this option by authenticating with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access.
<b>Assume Role ARN</b>	The full ARN of the role to assume. It must begin with "arn:" and can't contain any leading or trailing spaces, or spaces within the ARN. If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role ARN</b> parameter is displayed.
<b>Assume Role Session Name</b>	The session name of the role to assume. The default is QRadarAWSsession. Leave as the default if you don't need to change it. This parameter can contain only upper and lowercase alphanumeric characters, underscores, or any of the following characters: = , . @- If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role Session Name</b> parameter is displayed.

Table 174. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)

Parameter	Description
<b>Assume Role External ID</b>	<p><b>Assume Role External ID</b> is an optional identifier that is required to assume a role in a different account.</p> <p>If the account administrator, to which the role belongs, provides you with an external ID, then insert that value in the <b>Assume Role External ID</b> parameter.</p> <p>This value can either be a string, a passphrase, a GUID, or an account number. For more information, see AWS documentation <a href="#">Using an external ID for third-party access</a>.</p>
<b>Regions</b>	<p>Toggle each region that is associated with the Amazon Web Service that you want to collect logs from.</p>
<b>AWS Service</b>	<p>From the <b>AWS Service</b> list, select <b>CloudWatch Logs</b>.</p>
<b>Log Group</b>	<p>The name of the log group in Amazon CloudWatch where you want to collect logs from.</p> <p><b>Tip:</b> A single log source collects CloudWatch Logs from one log group at a time. If you want to collect logs from multiple log groups, create a separate log source for each log group.</p>
<b>Enable CloudWatch Advanced Options</b>	<p>Enable the following optional advanced configuration values. Advanced option values are only used when this option is chosen; otherwise, the default values are used.</p> <p><b>Log Stream</b> The name of the log stream within a log group. If you want to collect logs from all log streams within a log group, leave this field blank.</p> <p><b>Filter Pattern</b> Type a pattern for filtering the collected events. This pattern is not a regex filter. Only the events that contain the exact value that you specified are collected from CloudWatch Logs. If you type ACCEPT as the Filter Pattern value, only the events that contain the word ACCEPT are collected, as shown in the following example.</p> <pre data-bbox="943 1712 1432 1790">{LogStreamName: LogStreamTest,Timestamp: 0,Message: ACCEPT OK,IngestionTime: 0,EventId: 0}</pre> <p><b>Event Delay</b> Delay in seconds for collecting data.</p> <p><b>Other Region(s)</b> Deprecated. Use <b>Regions</b> instead.</p>

Table 174. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)

Parameter	Description
<b>Extract Original Event</b>	<p>Forwards only the original event that was added to the CloudWatch Logs.</p> <p>CloudWatch logs wrap the events that they receive with extra metadata. Select this option if you want to collect only the original event that was sent to AWS without the additional stream metadata through CloudWatch Logs.</p> <p>The original event is the value for the message key that is extracted from the CloudWatch log. The following CloudWatch Logs event example shows the original event that is extracted from CloudWatch Logs in highlighted text:</p> <pre data-bbox="894 692 1465 1404">{LogStreamName: 123456786_CloudTrail_us-east-2, Timestamp: 1505744407363, Message: {"eventVersion": "1.05", "userIdentity": {"type": "IAMUser", "principalId": "AAAABBBCCDDDBBBCC", "arn": "arn:aws:iam::1234567890:user/&lt;username&gt;", "accountId": "1234567890", "accessKeyId": "AAAABBBBCCCCDDDD", "userName": "User-Name", "sessionContext": {"attributes": {"mfaAuthenticated": "false", "creationDate": "2017-09-18T13:22:10Z"}, "invokedBy": "signin.amazonaws.com"}, "eventTime": "2017-09-18T14:10:15Z", "eventSource": "cloudtrail.amazonaws.com", "eventName": "DescribeTrails", "awsRegion": "us-east-1", "sourceIPAddress": "192.0.2.1", "userAgent": "signin.amazonaws.com", "requestParameters": {"includeShadowTrails": false}, "trailNameList": [], "responseElements": null, "requestID": "11b1a00-7a7a-11a1-1a11-44a4aaa1a", "eventID": "a4914e00-1111-491d-bbbb-a0dd3845b302", "eventType": "AwsApiCall", "recipientAccountId": "1234567890"}, IngestionTime: 1505744407506, EventId: 3357922236111112247912667222222513333}</pre>
<b>Use As A Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.</p> <p>When you select this option, the <b>Log Source Identifier Pattern</b> can optionally be used to define a custom <b>Log Source Identifier</b> for events that are being processed.</p>

Table 174. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>If you selected <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p><b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>

*Table 174. Amazon Web Services log source parameters for AWS CloudWatch Logs (continued)*

Parameter	Description
<b>Use Proxy</b>	<p>If QRadar accesses the Amazon Web Service by using a proxy, select this option.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

2. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

The actual CloudTrail logs are wrapped in a CloudWatch logs JSON payload:

*Table 175. Amazon CloudTrail Logs sample message supported by the Amazon AWS CloudTrail DSM*

Event name	Low-level category	Sample log message
Describe Trails	Read Activity Attempted	{LogStreamName: 1234567890_CloudTrail_us-east-2, Timestamp: 1505744407363, Message: {"eventVersion": "1.05", "userIdentity": {"type": "IAMUser", "principalId": "AIDAIEGANDWTHAAUMATYA", "arn": "arn:aws:iam::1234567890:user/QRadar-ITeam", "accountId": "1234567890", "accessKeyId": "AAAABBBBCCCCDDDD", "userName": "QRadar-ITeam", "sessionContext": {"attributes": {"mfaAuthenticated": "false"}, "creationDate": "2017-09-18T13:22:10Z"}}, "invokedBy": "signin.amazonaws.com", "eventTime": "2017-09-18T14:10:15Z", "eventSource": "cloudtrail.amazonaws.com", "eventName": "DescribeTrails", "awsRegion": "us-east-1", "sourceIPAddress": "127.0.0.1", "userAgent": "signin.amazonaws.com", "requestParameters": {"includeShadowTrails": false, "trailNameList": []}, "responseElements": null, "requestID": "17b7a04c-99cc-a1a1-9d83-43d5bce2d2fc", "eventID": "a4444e00-55e5-4444-bbbb-a0dd3845b302", "eventType": "AwsApiCall", "recipientAccountId": "1234567890"}, IngestionTime: 1505744407506, EventId: 3357922236271111111111112222222222222222}

# Configuring an Amazon AWS CloudTrail log source that uses Amazon Security Lake

You can collect AWS CloudTrail logs from multiple accounts or regions in an Amazon S3 bucket. IBM QRadar uses the Amazon AWS S3 REST API protocol to communicate with Amazon Security Lake, where QRadar obtains the CloudTrail logs.

## Procedure

1. Configure Amazon Security Lake to log Open Cybersecurity Schema Framework (OCSF) data in Parquet format to an S3 bucket. For more information, see [Collecting data from custom sources](#).

**Note:** The supported OCSF version of the DSM is OCSF 1.0RC2. The version OCSF 1.1 is not currently supported.

2. Configure access to the OCSF data in Amazon Security Lake by using one of two methods.
  - To create a subscriber to provision the SQS queue and IAM role, see step 3.  
For more information about creating a subscriber, see [Managing data access for Security Lake subscribers](#).
  - To manually configure the SQS queue and ObjectCreated notifications, see step 4.
3. Create a subscriber to provision the SQS queue and IAM role.
  - a) When you create the subscription, take note of the following values: **SQS Queue URL**, **IAM Role ARN**, and **External ID**.
  - b) If you plan to access this subscription from a different account than where Amazon Security Lake is set up, you must provide that account ID to configure the trust relationship properly.
4. Manually configure the SQS queue and ObjectCreated notifications.
  - a) Configure an SQS queue to receive ObjectCreated notifications with either [Amazon S3 Event Notifications](#) or [AWS EventBridge](#) when new OCSF Parquet data is available in the Amazon Security Lake bucket in the folder you choose.
  - b) Provision access keys with permission (either directly or with an **IAM Assume Role**) to access both the SQS queue and the bucket that contain the Amazon Security Lake data.  
For more information, see [Create SQS and S3 object REST API](#).
5. Configure a log source in QRadar to collect and parse the data.

**Tip:** When new OCSF parquet data is available, a message that contains the bucket name and object key of the file with the data to be processed is sent to the SQS queue. QRadar then downloads and processes this file.

## What to do next

Add a CloudTrail log source in QRadar. For more information, see [“Adding an Amazon AWS CloudTrail log source on the QRadar Console using an SQS queue” on page 317](#).

[What Is Amazon EventBridge?](#)

[Amazon S3 Event Notifications](#)

## Amazon AWS CloudTrail sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## Amazon AWS CloudTrail sample message when you use the Amazon REST API protocol

The following sample event message shows the specified managed policy that is attached to a specified user.

```
{"eventVersion": "1.05", "userIdentity": {"type": "Root", "principalId": "555555555555", "arn": "arn:aws:iam::555555555555:root", "accountId": "555555555555", "accessKeyId": "AAAAAA1AAAAA1A1AAA11", "sessionContext": {"attributes": {"mfaAuthenticated": "false", "creationDate": "2019-06-11T16:43:07Z"}}, "invokedBy": "signin.qradar.example.test", "eventTime": "2019-06-11T16:54:03Z", "eventSource": "iam.qradar.example.test", "eventName": "AttachUserPolicy", "awsRegion": "us-east-1", "sourceIPAddress": "172.16.89.242", "userAgent": "signin.qradar.example.test", "requestParameters": {"userName": "sampleuser", "policyArn": "arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryFullAccess"}, "responseElements": null, "requestID": "849df62f-8c69-11e9-bb3c-abc750f0b415", "eventID": "bdcc7610-7f82-4cde-9f6e-1c3cb1927353", "eventType": "AwsApiCall", "recipientAccountId": "555555555555"}}
```

## Amazon AWS CloudTrail sample message when you use the Amazon Web Services protocol

The following sample event message describes trails.

```
{LogStreamName: 111111111111_CloudTrail_us-east-2, Timestamp: 1505744407363, Message: {"eventVersion": "1.05", "userIdentity": {"type": "IAMUser", "principalId": "AAAAAAAAAAAAAAAAAAAA", "arn": "arn:aws:iam::111111111111:user/Test-User", "accountId": "111111111111", "accessKeyId": "AAAAA1A1AA1AA1111AA", "userName": "Test-User", "sessionContext": {"attributes": {"mfaAuthenticated": "false", "creationDate": "2017-09-18T13:22:10Z"}}, "invokedBy": "sub.domain.test", "eventTime": "2017-09-18T14:10:15Z", "eventSource": "sub2.domain.test", "eventName": "DescribeTrails", "awsRegion": "us-east-1", "sourceIPAddress": "192.168.10.187", "userAgent": "sub.domain.test", "requestParameters": {"includeShadowTrails": false, "trailNameList": []}, "responseElements": null, "requestID": "17b7a04c-9c7b-11e7-9d83-43d5bce2d2fc", "eventID": "a4914e00-65e5-491d-b1c6-a0dd3845b302", "eventType": "AwsApiCall", "recipientAccountId": "111111111111"}, IngestionTime: 1505744407506, EventId: 33579222362714760922479126672120053866513932467844153344}
```

## AWS Config

The IBM QRadar DSM for AWS Config supports events that are collected from Amazon S3 buckets, and from a Log group in the AWS Config Logs.

The following table lists the specifications for the AWS Config DSM:

Table 176. AWS Config DSM specifications	
Specification	Value
Manufacturer	Amazon
DSM	AWSConfig
RPM name	DSM-AWSConfig-QRadar_version-Build_number.noarch.rpm
Supported protocols	<ul style="list-style-type: none"><li>AmazonAWS S3 REST API</li><li>Syslog</li></ul>
Event format	JSON
Automatically discovered?	Yes
Includes identity?	No

Table 176. AWS Config DSM specifications (continued)

Specification	Value
Includes custom properties?	Yes
More information	<a href="#">AWS Config</a>

If you want to collect AWS Config logs from Amazon S3 buckets, configure a log source on the QRadar Console so that AWS Config can communicate with QRadar by using the Amazon AWS S3 REST API protocol.

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar. For more information, see [Configuring security credentials for your AWS user account](#).

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Configuring an Amazon AWS Config log source by using the Amazon AWS S3 REST API protocol” on page 342](#)

If you want to collect AWS Config logs from Amazon S3 buckets, configure a log source on the QRadar Console so that AWS Config can communicate with QRadar by using the Amazon AWS S3 REST API protocol.

## Enabling AWS Config logs

When you enable AWS Config logs, you must specify a destination for the log data.

#### About this task

Users must have the following permissions to enable AWS Config logs for delivery to Amazon S3.

- `ec2:ModifyVerifiedAccessInstanceLoggingConfiguration` on the Config instance
- `logs>CreateLogDelivery`, `logs>DeleteLogDelivery`, `logs:GetLogDelivery`, `logs>ListLogDeliveries`, and `logs:UpdateLogDelivery` on all resources
- `s3:GetBucketPolicy` and `s3:PutBucketPolicy` on the destination bucket

#### Procedure

1. Open the Amazon VPC console at [Amazon VPC](#).
2. In the navigation pane, select **AWS Config**.
3. Select AWS Config.
4. On the **AWS Config logging configuration** tab, select **Modify AWS Config logging configuration**.
5. Enable **Deliver to Amazon S3**.
6. Enter the name, owner, and prefix of the destination bucket.
7. Click **Modify AWS Config logging configuration**.

# Configuring an Amazon AWS Config log source by using the Amazon AWS S3 REST API protocol

If you want to collect AWS Config logs from Amazon S3 buckets, configure a log source on the QRadar Console so that AWS Config can communicate with QRadar by using the Amazon AWS S3 REST API protocol.

## Procedure

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console.
  - Protocol Common RPM
  - Amazon AWS S3 REST API Protocol RPM
  - DSM Common RPM
  - Amazon Web Service RPM
  - AWS Config DSM RPM
2. Select one of the following methods to configure an AWS Config log source by using the Amazon AWS S3 REST API protocol.
  - [“Configuring an AWS Config log source that uses an S3 bucket with an SQS queue” on page 342](#).
  - [“Configuring an AWS Config log source that uses an S3 bucket with a directory prefix” on page 354](#).

## Configuring an AWS Config log source that uses an S3 bucket with an SQS queue

If you want to collect AWS Config logs from multiple accounts or regions in an Amazon S3 bucket, configure a log source on the QRadar Console so that AWS Config can communicate with QRadar by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

### About this task

Using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue instead of with a directory prefix has the following advantages:

- You can use one log source for an S3 bucket, rather than one log source for each region and account.
- There is a reduced chance of missing files because this method uses ObjectCreated notifications to determine when new files are ready.
- It's easy to balance the load across multiple Event Collectors because the SQS queue supports connections from multiple clients.
- Unlike the directory prefix method, the SQS queue method does not require that the file names in the folders be in a string that is sorted in ascending order based on the full path. File names from custom applications don't always conform to this.
- You can monitor the SQS queue and set up alerts if it gets over a certain number of records. These alerts provide information about whether QRadar is either falling behind or not collecting events.
- You can use IAM Role authentication with SQS, which is Amazon's best practice for security.
- Certificate handling is improved with the SQS method and does not require the downloading of certificates to the Event Collector.

## Procedure

1. [Create the SQS queue that is used to receive ObjectCreated notifications.](#)
2. [Create an Amazon AWS Identity and Access Management \(IAM\) user and then apply the \*\*AmazonS3ReadOnlyAccess\*\* policy.](#)
3. [Configure the security credentials for your AWS user account.](#)
4. [Add an AWS Config log source on the QRadar Console that uses an SQS queue.](#)

### **Create an SQS queue and configure S3 ObjectCreated notifications**

Before you can add a log source in IBM QRadar, you must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

Complete the following procedures:

1. [Finding the S3 Bucket that contains the data that you want to collect.](#)
2. [Creating the SQS queue that is used to receive the ObjectCreated notifications from the S3 Bucket that you used in Step 1.](#)
3. [Setting up SQS queue permissions.](#)
4. [Creating ObjectCreated notifications.](#)
5. [Configuring security credentials for your AWS user account.](#)
6. [Adding an AWS Config log source on the QRadar Console using an SQS queue.](#)

#### *Finding the S3 bucket that contains the data that you want to collect*

You must find and note the region for S3 bucket that contains the data that you want to collect.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to **S3**.
3. From the **AWS Region** column in the **Buckets** list, note the region where the bucket that you want to collect data from is located. You need the region for the **Region Name** parameter value when you add a log source in IBM QRadar.
4. Enable the checkbox beside the bucket name, and then from the panel that opens to the right, click **Copy Bucket ARN** to copy the value to the clipboard. Save this value or leave it on the clipboard. You need this value when you set up **SQS queue permissions**.

#### *Creating the SQS queue that is used to receive ObjectCreated notifications*

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

## Before you begin

You must complete **Finding the S3 Bucket that contains the data that you want to collect**. The SQS Queue must be in the same region as the AWS S3 bucket that the queue is collecting from.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to the Simple Queue Service Management Console.
3. In the upper right of the window, change the region to where the bucket is located. You noted this value when you completed the **Finding the S3 Bucket that contains the data that you want to collect** procedure.
4. Select **Create New Queue**, and then type a value for the **Queue Name**.
5. Click **Standard Queue**, select **Configure Queue**, and then change the default values for the following **Queue Attributes**.

- **Default Visibility Timeout** - 60 seconds (You can use a lower value. In the case of load balanced collection, duplicate events might occur with values of less than 30 seconds. This value can't be 0.)
- **Message Retention Period** - 14 days (You can use a lower value. In the event of an extended collection, data might be lost.)

Use the default value for the remaining **Queue Attributes**.

More options such as **Redrive Policy** or **SSE** can be used depending on the requirements for your AWS environment. These values should not affect the data collection.

Queue Attributes

<b>Default Visibility Timeout</b>	<input type="text" value="60"/>	<b>seconds</b>	Value must be between 0 seconds and 12 hours.
<b>Message Retention Period</b>	<input type="text" value="14"/>	<b>days</b>	Value must be between 1 minute and 14 days.
<b>Maximum Message Size</b>	<input type="text" value="256"/>	<b>KB</b>	Value must be between 1 and 256 KB.
<b>Delivery Delay</b>	<input type="text" value="0"/>	<b>seconds</b>	Value must be between 0 seconds and 15 minutes.
<b>Receive Message Wait Time</b>	<input type="text" value="0"/>	<b>seconds</b>	Value must be between 0 and 20 seconds.

---

Picture © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

## 6. Select **Create Queue**.

### *Setting up SQS queue permissions*

You must set up SQS queue permissions for users to access the queue.

### Before you begin

You must complete **Creating the SQS queue that is used to receive ObjectCreated notifications**.

You can set the SQS queue permissions by using either the Permissions Editor or a JSON policy document.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Go to the SQS Management Console, and then select the queue that you created from the list.
3. From the **Details** panel, record the **ARN** field value.

For example: **arn:aws:sqs:us-east-1:123456789012:MySQSQueueName**

4. To set the SQS queue **Access policy (Permissions)** by using the **AWS Policy generator**, complete the following steps:
  - a) Select **Policy Type > SQS Queue Policy**.
  - b) Add an Access Policy statement.
  - c) From the **Access policy** tab, click **Policy generator**, and then configure the following parameters:

Table 177. Permission parameters

Parameter	Value
<b>Effect</b>	Click <b>Allow</b> .
<b>Principal</b>	Type <b>*</b> (Everybody).

Table 177. Permission parameters (continued)

Parameter	Value
<b>Actions</b>	From the list, select <b>SendMessage</b>
<b>Amazon Resource Name (ARN)</b>	Type your queue ARN: <i>arn:aws:sqs:us-east-1:123456789012:MySQSQueueName</i>

d) Click **Add Conditionals (Optional)**, and then configure the following parameters:

Table 178. Add Conditionals (Optional) parameters

Parameter	Value
<b>Qualifier</b>	None
<b>Condition</b>	<b>ARNLike</b>
<b>Key</b>	Type <code>aws:SourceArn</code> .
<b>Value</b>	<p>The ARN of the S3 bucket from when you completed the “<a href="#">Finding the S3 bucket that contains the data that you want to collect</a>” on page 308 procedure.</p> <p>For example: <code>aws:s3:::my-example-s3bucket</code></p>

5. To set the SQS queue permissions by using a JSON policy document, complete the following steps:

a) Click **Add Condition > Add Statement. > Generate Policy**.

b) Copy and paste the following JSON policy into the **Access policy** window:

Copy and paste might not preserve the white space in the JSON policy. The white space is required. If the white space is not preserved when you paste the JSON policy, paste it into a text editor and restore the white space. Then, copy and paste the JSON policy from your text editor into the **Edit Policy Document** window.

```
{
  "Version": "2008-10-17",
  "Id": "example-ID",
  "Statement": [
    {
      "Sid": "example-statement-ID",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::my-example-s3bucket"
        }
      }
    }
  ]
}
```

6. Click **Review Policy**. Ensure that the data is correct, and then click **Save Changes**.

#### *Creating ObjectCreated notifications*

Configure ObjectCreated notifications for the folders that you want to monitor in the bucket.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, go to **S3**, and then select a bucket.

3. Click the **Properties** tab, and in the **Events** pane, click **Add notification**. Configure the parameters for the new event.

The following table shows an example of an ObjectCreated notification parameter configuration:

*Table 179. Example: New ObjectCreated notification parameter configuration*

Parameter	Value
<b>Name</b>	Type a name of your choosing.
<b>Events</b>	Select <b>All object create events</b> .
<b>Prefix</b>	AWSLogs/ <b>Tip:</b> You can choose a prefix that contains the data that you want to find, depending on where the data is located and what data that you want to go to the queue. For example, AWSLogs/, CustomPrefix/AWSLogs/, AWSLogs/123456789012/.
<b>Suffix</b>	json.gz
<b>Send to</b>	SQS queue <b>Tip:</b> You can send the data from different folders to the same or different queues to suit your collection or QRadar tenant needs. Choose one or more of the following methods: <ul style="list-style-type: none"> <li>• Different folders that go to different queues</li> <li>• Different folders from different buckets that go to the same queue</li> <li>• Everything from a single bucket that goes to a single queue</li> <li>• Everything from multiple buckets that go to a single queue</li> </ul>
<b>SQS</b>	The <b>Queue Name</b> from step 4 of <b>Creating the SQS queue that is used to receive the ObjectCreated notifications</b> .

## Create event notification

The notification configuration identifies the events you want Amazon S3 to publish and the destinations where you want Amazon S3 to send the notifications. [Learn more](#)

### General configuration

Event name  
NewS3ObjectToSQS

Event name can contain up to 255 characters.

Prefix - optional  
Limit the notifications to objects with key starting with specified characters.  
 AWSLogs/

Example. This value must match the location of the data that you want to collect.

Suffix - optional  
Limit the notifications to objects with key ending with specified characters.  
 .json.gz

Example. Enter a value so that you can filter out unwanted files that match the prefix.

### Event types

Specify at least one type of event for which you want to receive notifications. [Learn more](#)

All object create events  
s3:ObjectCreated:  
 Put  
s3:ObjectCreated:Put  
 Post  
s3:ObjectCreated:Post  
 Copy  
s3:ObjectCreated:Copy  
 Multipart upload completed  
s3:ObjectCreated:CompleteMultipartUpload

Figure 14. Example: Events

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

In the example in figure 1 of a parameter configuration, notifications are created for AWSLogs / from the root of the bucket. When you use this configuration, All ObjectCreated events trigger a notification. If there are multiple accounts and regions in the bucket, everything gets processed. In this example, json .gz is used. This file type can change depending on the data that you are collecting. Depending on the content in your bucket, you can omit the extension or choose an extension that matches the data you are looking for in the folders where you have events set up.

After approximately 5 minutes, the queue that contains data displays. In the **Messages Available** column, you can view the number of messages.

Figure 15. Number of available messages

_us-east-2_20181219T014838Z.json.gz",
    "size":713,
    "eTag":"1ff1209e4140b4ff7a9d2b922f57f486",
    "sequencer":"005C19A40717D99642"
}
]
}
}

```

**Tip:** In the **key** value, your DSM name displays.

6. Click **Services**, then navigate to **IAM**.
7. Set a **User or Role** permission to access the SQS queue and for permission to download from the target bucket. The user or user role must have permission to read and delete from the SQS queue. For information about adding, managing and changing permissions for IAM users, see the [IAM Users documentation](#). After QRadar reads the notification, and then downloads and processes the target file, the message must be deleted from the queue.

Sample Policy:

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sqs:DeleteMessage",
                "sqs:ReceiveMessage",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket_name>/AWSLogs/*",
                "arn:aws:sqs:us-east-2:<AWS_account_number>:<queue_name>"
            ]
        }
    ]
}

```

You can add multiple buckets to the S3 queue. To ensure that all objects are accessed, you must have a trailing `/*` at the end of the folder path that you added.

You can add this policy directly to a user, a user role, or you can create a minimal access user with **sts:AssumeRole** permissions only. When you configure a log source in QRadar, configure the **assume Role ARN** parameter for QRadar to assume the role. To ensure that all files waiting to be processed in a single run (emptying the queue) can finish without retries, use the default value of 1 hour for the **API Session Duration** parameter.

When you use assumed roles, ensure that the ARN of the user that is assuming the role is in the **Trusted Entities** for that role. You can view the trusted entities that can assume the rule from the **Trust Relationship** tab in **IAM Role**. In addition, the user must have permission to assume roles in that (or any) account. The following examples show a sample trust policy:

#### Allow all IAM users within a specific AWS account to assume a role

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:root"
            },
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"
        }
    ]
}

```

## Allow a specific user to assume a role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:user/USERNAME"  
            },  
            "Action": "sts:AssumeRole",  
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"  
        }  
    ]  
}
```

The following image example shows a sample Amazon AWS CloudTrail log source configuration in QRadar.

**Tip:** Use the Amazon AWS S3 REST API log source parameter values for your DSM when you configure your log source.

Figure 17. Example: Amazon AWS CloudTrail log source configuration in QRadar

## *Configuring security credentials for your AWS user account*

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### **Procedure**

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### **Related information**

#### [Adding a log source](#)

#### *Adding an AWS Config log source on the QRadar Console using an SQS queue*

If you want to collect AWS Config logs from multiple accounts or regions in an Amazon S3 bucket, add a log source on the QRadar Console so that AWS Config can communicate with QRadar by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

### **Procedure**

1. Use the following table to set the parameters for an Amazon AWS Config log source that uses the Amazon AWS S3 REST API protocol and an SQS queue.

*Table 180. Amazon AWS S3 REST API protocol log source parameters*

Parameter	Description
<b>Log Source Type</b>	<b>AWS Config</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one AWS Config log source that is configured, you might want to identify the first log source as <i>awsconfig1</i> , the second log source as <i>awsconfig2</i> , and the third log source as <i>awsconfig3</i> .

Table 180. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>  Standard authentication that can be used from anywhere.</p> <p><b>Assume IAM Role</b>  Authenticate with keys and then temporarily assume a role for access. This option is available only when you select <b>SQS Event Notifications</b> for the <b>S3 Collection Method</b>. The supported <b>S3 Collection Method</b> is <b>Use a Specific Prefix</b>.</p> <p><b>EC2 Instance IAM Role</b>  If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata that is assigned to the instance for authentication; no keys are required. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Access Key ID</b> parameter is displayed.  The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.
<b>Secret Key</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Secret Key ID</b> parameter is displayed.  The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Secret Key ID</b> that is used to access the AWS S3 bucket.
<b>Event Format</b>	Select <b>LINEBYLINE</b> . The log source retrieves JSON formatted events.
<b>S3 Collection Method</b>	Select <b>SQS Event Notifications</b> .
<b>SQS Queue URL</b>	Enter the full URL, starting with <code>https://</code> , of the SQS queue that is set up to receive notifications for ObjectCreate events from S3.
<b>Region Name</b>	The region that the SQS Queue or the S3 Bucket is in.  Example: us-east-1, eu-west-1, ap-northeast-3
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.
<b>Log Source Identifier Pattern</b>	This option is available when you set <b>Use as a Gateway Log Source</b> is set to yes.  Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.

Table 180. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.
<b>File Pattern</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code>
<b>Local Directory</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.
<b>S3 Endpoint URL</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The endpoint URL that is used to query the AWS REST API.  If your endpoint URL is different from the default, type your endpoint URL. The default is <code>http://s3.amazonaws.com</code>
<b>Use S3 Path-Style Access</b>	Forces S3 requests to use path-style access.  This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> .  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Recurrence</b>	How often a poll is made to scan for new data.  If you are using the SQS event collection method, <b>SQS Event Notifications</b> can have a minimum value of 10 (seconds). Because SQS Queue polling can occur more often, a lower value can be used.  If you are using the Directory Prefix event collection method, <b>Use a Specific Prefix</b> has a minimum value of 60 (seconds) or 1M. Because every listBucket request to an AWS S3 bucket incurs a cost to the account that owns the bucket, a smaller recurrence value increases the cost.  Type a time interval to determine how frequently the poll is made for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds.

Table 180. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

2. To verify that QRadar is configured correctly, review the [AWS Config sample event messages](#).

## Configuring an AWS Config log source that uses an S3 bucket with a directory prefix

If you want to collect AWS Config from a single account and region in an Amazon S3 bucket, configure a log source on the QRadar Console so AWS Config can communicate with QRadar by using the Amazon AWS S3 REST API protocol with a directory prefix.

### About this task

If you have log sources in an S3 bucket from multiple regions or that use multiple accounts, use the [Amazon AWS REST API protocol with an SQS queue](#) instead of with a directory prefix.

**Restriction:** A log source that uses directory prefix can retrieve data from only one region and one account, so use a different log source for each region and account. Include the region folder name in the file path for the **Directory Prefix** value when you configure the log source.

### Procedure

1. [Find an S3 bucket name and directory prefix](#).
2. [Create an Amazon AWS Identity and Access Management \(IAM\) user and then apply the \*\*AmazonS3ReadOnlyAccess\*\* policy](#).
3. [Configure the security credentials for your AWS user account](#).
4. [Add an AWS Config log source on the QRadar Console using a directory prefix](#).

### Finding an S3 bucket name and directory prefix

An Amazon administrator must create a user and then apply the **AmazonS3ReadOnlyAccess** policy in the AWS Management Console. The QRadar user can then create a log source in QRadar.

**Note:** Alternatively, you can assign more granular permissions to the bucket. The minimum required permissions are **s3:listBucket** and **s3:getObject**.

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

### Procedure

1. Click **Services**.
2. From the list, select **Config**.
3. From the **Config** page, click the name of the Config.
4. Note the name of the S3 bucket that is displayed in the **S3 bucket** field.
5. Click the **Edit** icon.
6. Note the location path for the S3 bucket that is displayed underneath the **Log file prefix** field.

## **Creating an Identity and Access Management (IAM) user in the AWS Management Console**

An Amazon administrator must create a user and then apply the **s3:listBucket** and **s3:getObject** permissions to that user in the AWS Management Console. The QRadar user can then create a log source in QRadar.

### **About this task**

The minimum required permissions are **s3:listBucket** and **s3:getObject**. You can assign other permissions to the user as needed.

Sample policy:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::<bucket_name>",  
                "arn:aws:s3:::<bucket_name>/AWSLogs/<AWS_account_number>/<DSM_name>/us-east-1/*"  
            ]  
        }  
    ]  
}
```

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

### **Procedure**

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**.
3. From the list, select **IAM**.
4. Click **Users > Add user**.
5. Create an Amazon AWS IAM user and then apply the **AmazonS3ReadOnlyAccess** policy.

### **Configuring security credentials for your AWS user account**

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### **Procedure**

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### **Related information**

[Adding a log source](#)

## **Adding an AWS Config log source on the QRadar Console using a directory prefix**

If you want to collect AWS Config logs from a single account and region in an Amazon S3 bucket, add a log source on the QRadar Console so that Amazon AWS Config can communicate with QRadar by using the Amazon AWS S3 REST API protocol with a directory prefix.

### **Procedure**

1. Use the following table to set the parameters for an Amazon AWS Config log source that uses the Amazon AWS S3 REST API protocol and a directory prefix.

*Table 181. Amazon AWS S3 REST API protocol log source parameters*

Parameter	Description
<b>Log Source Type</b>	<b>AWS Config</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one AWS Config log source that is configured, you might want to identify the first log source as <i>awsconfig1</i> , the second log source as <i>awsconfig2</i> , and the third log source as <i>awsconfig3</i> .
<b>Authentication Method</b>	<b>Access Key ID / Secret Key</b> Standard authentication that can be used from anywhere. For more information about configuring security credentials, see <a href="#">Configuring security credentials for your AWS user account</a> .  <b>Assume IAM Role</b> Authenticate with keys and then temporarily assume a role for access. This option is available only when you select <b>SQS Event Notifications</b> for the <b>S3 Collection Method</b> . The supported <b>S3 Collection Method</b> is <b>Use a Specific Prefix</b> . For more information about creating IAM users and assigning roles, see <a href="#">Creating an Identity and Access Management (IAM) user in the AWS Management Console</a> .  <b>EC2 Instance IAM Role</b> If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata assigned to the instance for authentication; no keys are required. This method works only for managed hosts that are running within an AWS EC2 container.
<b>Access Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Access Key ID</b> parameter is displayed.  The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.

Table 181. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Secret Key</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Secret Key ID</b> parameter is displayed.  The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Secret Key ID</b> that is used to access the AWS S3 bucket.
<b>Event Format</b>	Select <b>AWS Config JSON</b> . The log source retrieves JSON formatted events.
<b>S3 Collection Method</b>	Select <b>Use a Specific Prefix</b> .
<b>Bucket Name</b>	The name of the AWS S3 bucket where the log files are stored.
<b>Directory Prefix</b>	The root directory location on the AWS S3 bucket from where the AWS Config logs are retrieved; for example, AWSLogs/ <AccountNumber>/Config/<RegionName>/  To pull files from the root directory of a bucket, you must use a forward slash (/) in the <b>Directory Prefix</b> file path.  <b>Note:</b> <ul style="list-style-type: none"> <li>• Changing the <b>Directory Prefix</b> value clears the persisted file marker. All files that match the new prefix are downloaded in the next pull.</li> <li>• The <b>Directory Prefix</b> file path cannot begin with a forward slash (/) unless only the forward slash is used to collect data from the root of the bucket.</li> <li>• If the <b>Directory Prefix</b> file path is used to specify folders, you must not begin the file path with a forward slash (for example, use folder1/folder2 instead).</li> </ul>
<b>Region Name</b>	The region that the SQS Queue or the S3 Bucket is in.  Example: us-east-1, eu-west-1, ap-northeast-3
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.
<b>Log Source Identifier Pattern</b>	This option is available when you set <b>Use as a Gateway Log Source</b> is set to yes.  Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.

Table 181. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>File Pattern</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code></p>
<b>Local Directory</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.</p>
<b>S3 Endpoint URL</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The endpoint URL that is used to query the AWS REST API.</p> <p>If your endpoint URL is different from the default, type your endpoint URL. The default is <a href="http://s3.amazonaws.com">http://s3.amazonaws.com</a></p>
<b>Use S3 Path-Style Access</b>	<p>Forces S3 requests to use path-style access.</p> <p>This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.</p>
<b>Use Proxy</b>	<p>If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b>.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.</p>
<b>Recurrence</b>	<p>How often the Amazon AWS S3 REST API Protocol connects to the Amazon cloud API, checks for new files, and if they exist, retrieves them. Every access to an AWS S3 bucket incurs a cost to the account that owns the bucket. Therefore, a smaller recurrence value increases the cost.</p> <p>Type a time interval to determine how frequently the remote directory is scanned for new event log files. The minimum value is 1 minute. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15 M = 15 minutes.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

- To verify that QRadar is configured correctly, review the “AWS Config sample event messages” on page 359.

## AWS Config sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### AWS Config sample messages when you use the Amazon REST API protocol

**Sample 1:** The following sample event message shows that a resource is deleted.

```
"relatedEvents":[], "relationships":[], "supplementaryConfiguration":{}, "tags": {}, "configurationItemVersion": "1.3", "configurationItemCaptureTime": "2023-01-14T04:04:35.970Z", "configurationStateId": 123456789000, "awsAccountId": "987654321000", "configurationItemStatus": "ResourceDeleted", "resourceType": "AWS::SSM::AssociationCompliance", "resourceId": "AWS::SSM::ManagedInstanceInventory/i-0001bbbbbbbbbbbbb", "awsRegion": "us-east-1", "availabilityZone": "Regional", "configurationStateMd5Hash": ""}
```

*Table 182. Highlighted values in the AWS Config sample event*

QRadar field name	Highlighted values in the event payload
Event ID	<b>ResourceDeleted</b>
Event Category	<b>AWSConfig</b>
Timestamp	<b>2023-01-14T04:04:35.970Z</b>

**Sample 2:** The following sample event message shows the status of the configuration.

```
{"relatedEvents":[], "relationships":[], "configuration": {"ReceiveMessageWaitTimeSeconds": "0", "SqsManagedSseEnabled": "false", "CreatedTimestamp": "1585762081", "DelaySeconds": "0", "MessageRetentionPeriod": "345600", "MaximumMessageSize": "262144", "VisibilityTimeout": "30", "LastModifiedTimestamp": "1585762081", "QueueArn": "arn:aws:sqs:us-east-1:987654321000:demo_queue", "supplementaryConfiguration": {"Tags": {}, "tags": {}}, "configurationItemVersion": "1.3", "configurationItemCaptureTime": "2021-11-18T09:29:16.982Z", "configurationStateId": 123456789000, "awsAccountId": "987654321000", "configurationItemStatus": "OK", "resourceType": "AWS::SQS::Queue", "resourceId": "https://sqs.us-east-1.example.com/987654321000/demo_queue", "resourceName": "demo_queue", "ARN": "arn:aws:sqs:us-east-1:987654321000:demo_queue", "awsRegion": "us-east-1", "availabilityZone": "Not Applicable", "configurationStateMd5Hash": "", "resourceCreationTime": "2020-04-01T17:28:01.000Z"}}

## Amazon AWS Elastic Kubernetes Service

The IBM QRadar DSM for Amazon AWS Elastic Kubernetes Service collects JSON formatted events from the log group of the Amazon CloudWatch logs service.

To integrate Amazon Elastic Kubernetes Service (Amazon EKS) with QRadar, complete the following steps:

- If automatic updates are not enabled, download the most recent versions of the RPMs from the IBM support website (<http://www.ibm.com/support>).
- Kubernetes Auditing DSM

- Amazon Web Services Protocol RPM
  - DSM Common RPM
  - Amazon AWS Kubernetes DSM RPM
2. Configure Amazon Elastic Kubernetes Service (Amazon EKS) to send events to QRadar. For more information, see [Configuring Amazon Elastic Kubernetes Service to communicate with QRadar](#)
  3. If QRadar does not automatically detect the log source, add an Amazon AWS Elastic Kubernetes Service log source on the QRadar Console.

#### **Related tasks**

[“Adding a log source” on page 5](#)

## **Amazon AWS Elastic Kubernetes Service DSM specifications**

When you configure Amazon AWS Elastic Kubernetes Service, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported version of Amazon AWS Elastic Kubernetes Service is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Amazon AWS Elastic Kubernetes Service DSM.

<i>Table 184. Amazon AWS Elastic Kubernetes Service DSM specifications</i>	
<b>Specification</b>	<b>Value</b>
Manufacturer	Amazon
DSM name	Amazon AWS Elastic Kubernetes Service
RPM file name	DSM-AmazonAWSKubernetes-QRadar_version-build_number.noarch.rpm
Supported version	Kubernetes API 1.19
Protocol	Amazon Web Services
Event format	JSON
Recorded event types	Amazon AWS Kubernetes
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	Amazon Elastic Kubernetes Service (Amazon EKS) documentation ( <a href="https://docs.aws.amazon.com/eks/latest/userguide/what-is-eks.html">https://docs.aws.amazon.com/eks/latest/userguide/what-is-eks.html</a> )

## **Configuring Amazon Elastic Kubernetes Service to communicate with QRadar**

Before you can add a logsource in IBM QRadar, you must enable logging on your Amazon AWS console.

#### **Before you begin**

You must have a cluster that is created in the Amazon Container Services application. For more information about creating clusters, see your Amazon Elastic Kubernetes Service (Amazon EKS) documentation (<https://docs.aws.amazon.com/eks/latest/userguide/create-cluster.html>).

## Procedure

1. Log in to your IAM console (<https://console.aws.amazon.com/iam/>).
2. Click **Services > Amazon Kubernetes Service > Clusters**.
3. From the **Clusters** list, select the cluster that you want to use, then click the **Configuration** tab.
4. Click the **Logging** tab and then enable the options that you want the logging service to monitor.
5. To create the log group, click **Manage logging**.
6. To view the log group, click **Services > CloudWatch > Log groups**. The log group displays in the **Log groups** list as /aws/eks/<cluster name>/cluster.
7. Click **Services > Amazon Kubernetes Service > Clusters**.
8. Click the **Details** tab, then record the **Cluster ARN** value. You need this value for the **Log Group** parameter value when you add a log source in QRadar.

## What to do next

["Adding a log source" on page 5](#)

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

## Procedure

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

## Amazon Web Services log source parameters for Amazon AWS Elastic Kubernetes Service

If IBM QRadar does not automatically detect the log source, add an Amazon AWS Elastic Kubernetes Service log source on the QRadar Console by using the Amazon Web Services protocol.

When you use the Amazon Web Service protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Amazon Web Services events from Amazon Elastic Kubernetes Service:

Table 185. Amazon Web Services log source parameters for the Amazon AWS Elastic Kubernetes Service DSM	
Parameter	Value
<b>Log Source type</b>	Amazon AWS Elastic Kubernetes Service
<b>Protocol Configuration</b>	Amazon Web Services

Table 185. Amazon Web Services log source parameters for the Amazon AWS Elastic Kubernetes Service DSM (continued)

Parameter	Value
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>  Standard authentication that can be used from any location.</p> <p><b>EC2 Instance IAM Role</b>  If your QRadar managed host is running on an AWS EC2 instance, choose this option to use the <b>IAM Role</b> from the metadata that is assigned to the instance for authentication. No keys are required.</p> <p><b>Tip:</b> This method works only for managed hosts that run within an AWS EC2 container.</p>
<b>Access Key ID</b>	<p>If you selected , <b>Access Key ID/ Secret Key</b> as the <b>Authentication Method</b>, configure this parameter.</p> <p>The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account.</p> <p>For more information about configuring the security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p>
<b>Secret Access Key</b>	<p>If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b>, configure this parameter.</p> <p>The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account.</p> <p>For more information about configuring the security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p>
<b>Regions</b>	Select the checkbox for each region that is associated with the Amazon Web Service that you want to collect logs from.
<b>Other Regions</b>	<p>Enter the names of any additional regions that are associated with the Amazon Web Service that you want to collect logs from.</p> <p>To collect from multiple regions, use a comma-separated list, which is shown in the following example:</p> <p>region1,region2</p>
<b>AWS Service</b>	<p>The name of the Amazon Web Service.</p> <p>From the <b>AWS Service</b> list, select <b>CloudWatch Logs</b>.</p>

Table 185. Amazon Web Services log source parameters for the Amazon AWS Elastic Kubernetes Service DSM (continued)

Parameter	Value
<b>Log Group</b>	<p>The name of the log group in Amazon CloudWatch that you want to collect logs from.</p> <p><b>Tip:</b> A single log source can collect CloudWatch logs from only one log group at a time. If you want to collect logs from multiple log groups, create a separate log source for each log group.</p>
<b>Log Stream (Optional)</b>	<p>The name of the log stream within a log group that you want to collect logs from.</p>
<b>Filter Pattern (Optional)</b>	<p>Type a pattern for filtering the collected events. This pattern is not a regex filter. Only the events that contain the exact value that you specify are collected from CloudWatch Logs.</p> <p>If you enter <b>ACCEPT</b> as the Filter Pattern value, only events that contain the word <b>ACCEPT</b> are collected. The following example shows the effect of the <b>ACCEPT</b> value:</p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre>
<b>Extract Original Event</b>	<p>CloudWatch Logs wrap events that they receive with extra metadata. If you want only the original event that was added to the CloudWatch logs to be forwarded to QRadar, select this option. The original event is the value for the message key that is extracted from the CloudWatch Logs.</p> <p>The following CloudWatch logs event example shows the original event that is extracted from the CloudWatch log in bold text:</p> <pre>{LogStreamName: guardDutyLogStream, Timestamp: 1519849569827, Message: {"version": "0", "id": "00-00", "detail-type": "GuardDuty Finding", "account": "1234567890", "region": "us-west-2", "resources": [], "detail": {"schemaVersion": "2.0", "accountId": "1234567890", "region": "us-west-2", "partition": "aws", "type": "Behavior:IAMUser/InstanceLaunchUnusual", "severity": 5.0, "createdAt": "2018-02-28T20:22:26.344Z", "updatedAt": "2018-02-28T20:22:26.344Z"}, "IngestionTime: 1519849569862, EventId: 0000}</pre>

*Table 185. Amazon Web Services log source parameters for the Amazon AWS Elastic Kubernetes Service DSM (continued)*

Parameter	Value
<b>Use As A Gateway Log Source</b>	When you select this option, the collected events flow through the QRadar Traffic Analysis engine and QRadar automatically detects one or more log sources.  If the Amazon AWS S3 bucket is dedicated only to AWS Kubernetes events, do not select this checkbox.  If the Amazon AWS S3 bucket contains data from multiple AWS sources, you must select this checkbox.
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable this option.  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Automatically Acquire Server Certificates</b>	If you select <b>Yes</b> from the list, QRadar downloads the certificate and begins trusting the target server.  This function can be used to initialize a newly created log source and obtain certificates initially, or to replace expired certificates.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

For a complete list of Amazon Web Services protocol parameters and their values, see [Amazon Web Services protocol configuration options](#).

## Amazon AWS Network Firewall

The IBM QRadar DSM for Amazon AWS Network Firewall collects events from an Amazon AWS Network Firewall device by using the Amazon AWS REST API protocol.

Amazon AWS Network Firewall is a stateful network firewall that allows users to filter traffic at the perimeter of their Amazon Virtual Private Cloud (VPC) service.

To integrate Amazon AWS Network Firewall with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol Common RPM
  - AWS S3 REST API PROTOCOL RPM
  - Amazon AWS Network Firewall DSM RPM
2. Configure your Amazon AWS Network Firewall device to publish alert or flow logs to an S3 bucket. For more information, see your Amazon AWS documentation.
3. Create the SQS queue that is used to receive notifications ObjectCreated from the S3 bucket that you used in Step 2. For more information, see [Create an SQS queue and configure S3 ObjectCreated notifications](#).
4. Configure security credentials for your AWS user account. For more information, see [Configuring security credentials for your AWS user account](#).
5. Add an Amazon AWS Network Firewall log source on the QRadar Console by using the Amazon AWS REST API protocol. For more information, see [Amazon AWS REST API log source parameters for Amazon AWS Network Firewall](#).

**Important:** To receive flow logs in QRadar, a QRadar Flow Processor must be available and licensed. Unlike other log sources, AWS Network flow logs are not sent to the **Log Activity** tab. They are sent to the **Network Activity** tab.

## Amazon AWS Network Firewall DSM specifications

When you configure the Amazon AWS Network Firewall DSM, understanding the specifications for the Amazon AWS Network Firewall DSM can help ensure a successful integration. For example, knowing what the supported version of Amazon AWS Network Firewall is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Amazon AWS Network Firewall DSM.

Table 188. Amazon AWS Network Firewall DSM specifications

Specification	Value
Manufacturer	Amazon
DSM name	Amazon AWS Network Firewall
RPM file name	DSM-AmazonAWSNetworkFirewall-QRadar_version-build_number.noarch.rpm
Protocol	AWS S3 REST API
Automatically discovered?	No
Event format	JSON
Recorded event types	Firewall Alert logs, Firewall Flow logs
Includes identity?	No
Includes custom properties?	No

## Create an SQS queue and configure S3 ObjectCreated notifications

Before you can add a log source in IBM QRadar, you must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

Complete the following procedures:

1. [Finding the S3 Bucket that contains the data that you want to collect.](#)
2. [Creating the SQS queue that is used to receive the ObjectCreated notifications from the S3 Bucket that you used in Step 1.](#)
3. [Setting up SQS queue permissions.](#)
4. [Creating ObjectCreated notifications.](#)
5. [Configuring security credentials for your AWS user account.](#)

### Finding the S3 bucket that contains the data that you want to collect

You must find and note the region for S3 bucket that contains the data that you want to collect.

#### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to **S3**.
3. From the **AWS Region** column in the **Buckets** list, note the region where the bucket that you want to collect data from is located. You need the region for the **Region Name** parameter value when you add a log source in IBM QRadar.
4. Enable the checkbox beside the bucket name, and then from the panel that opens to the right, click **Copy Bucket ARN** to copy the value to the clipboard. Save this value or leave it on the clipboard. You need this value when you set up **SQS queue permissions**.

### Creating the SQS queue that is used to receive ObjectCreated notifications

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

## Before you begin

You must complete **Finding the S3 Bucket that contains the data that you want to collect**. The SQS Queue must be in the same region as the AWS S3 bucket that the queue is collecting from.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to the Simple Queue Service Management Console.
3. In the upper right of the window, change the region to where the bucket is located. You noted this value when you completed the **Finding the S3 Bucket that contains the data that you want to collect** procedure.
4. Select **Create New Queue**, and then type a value for the **Queue Name**.
5. Click **Standard Queue**, select **Configure Queue**, and then change the default values for the following **Queue Attributes**.
  - **Default Visibility Timeout** - 60 seconds (You can use a lower value. In the case of load balanced collection, duplicate events might occur with values of less than 30 seconds. This value can't be 0.)
  - **Message Retention Period** - 14 days (You can use a lower value. In the event of an extended collection, data might be lost.)

Use the default value for the remaining **Queue Attributes**.

More options such as **Redrive Policy** or **SSE** can be used depending on the requirements for your AWS environment. These values should not affect the data collection.

Queue Attributes

<b>Default Visibility Timeout</b>  60	seconds 	Value must be between 0 seconds and 12 hours.
<b>Message Retention Period</b>  14	days 	Value must be between 1 minute and 14 days.
<b>Maximum Message Size</b>  256	KB	Value must be between 1 and 256 KB.
<b>Delivery Delay</b>  0	seconds 	Value must be between 0 seconds and 15 minutes.
<b>Receive Message Wait Time</b>  0	seconds	Value must be between 0 and 20 seconds.

Picture © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

6. Select **Create Queue**.

## Setting up SQS queue permissions

You must set up SQS queue permissions for users to access the queue.

## Before you begin

You must complete **Creating the SQS queue that is used to receive ObjectCreated notifications**.

You can set the SQS queue permissions by using either the Permissions Editor or a JSON policy document.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Go to the SQS Management Console, and then select the queue that you created from the list.

3. From the **Details** panel, record the **ARN** field value.

For example: **arn:aws:sqs:us-east-1:123456789012:MySQSQueueName**

4. To set the SQS queue **Access policy (Permissions)** by using the **AWS Policy generator**, complete the following steps:

a) Select **Policy Type > SQS Queue Policy**.

b) Add an Access Policy statement.

c) From the **Access policy** tab, click **Policy generator**, and then configure the following parameters:

*Table 189. Permission parameters*

Parameter	Value
<b>Effect</b>	Click <b>Allow</b> .
<b>Principal</b>	Type <b>*</b> (Everybody).
<b>Actions</b>	From the list, select <b>SendMessage</b>
<b>Amazon Resource Name (ARN)</b>	Type your queue ARN: <i>arn:aws:sqs:us-east-1:123456789012:MySQSQueueName</i>

- d) Click **Add Conditionals (Optional)**, and then configure the following parameters:

*Table 190. Add Conditionals (Optional) parameters*

Parameter	Value
<b>Qualifier</b>	None
<b>Condition</b>	<b>ARNLike</b>
<b>Key</b>	Type <b>aws:SourceArn</b> .
<b>Value</b>	The ARN of the S3 bucket from when you completed the “ <a href="#">Finding the S3 bucket that contains the data that you want to collect</a> ” on page 308 procedure.  For example: <b>aws:s3:::my-example-s3bucket</b>

5. To set the SQS queue permissions by using a JSON policy document, complete the following steps:

a) Click **Add Condition > Add Statement. > Generate Policy**.

b) Copy and paste the following JSON policy into the **Access policy** window:

Copy and paste might not preserve the white space in the JSON policy. The white space is required. If the white space is not preserved when you paste the JSON policy, paste it into a text editor and restore the white space. Then, copy and paste the JSON policy from your text editor into the **Edit Policy Document** window.

```
{
  "Version": "2008-10-17",
  "Id": "example-ID",
  "Statement": [
    {
      "Sid": "example-statement-ID",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::my-example-s3bucket"
        }
      }
    }
  ]
}
```

```
    }  
}  
}
```

6. Click **Review Policy**. Ensure that the data is correct, and then click **Save Changes**.

## Creating ObjectCreated notifications

Configure ObjectCreated notifications for the folders that you want to monitor in the bucket.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, go to **S3**, and then select a bucket.
3. Click the **Properties** tab, and in the **Events** pane, click **Add notification**. Configure the parameters for the new event.

The following table shows an example of an ObjectCreated notification parameter configuration:

*Table 191. Example: New ObjectCreated notification parameter configuration*

Parameter	Value
<b>Name</b>	Type a name of your choosing.
<b>Events</b>	Select <b>All object create events</b> .
<b>Prefix</b>	AWSLogs/ <b>Tip:</b> You can choose a prefix that contains the data that you want to find, depending on where the data is located and what data that you want to go to the queue. For example, AWSLogs/, CustomPrefix/AWSLogs/, AWSLogs/123456789012/.
<b>Suffix</b>	json.gz
<b>Send to</b>	SQS queue <b>Tip:</b> You can send the data from different folders to the same or different queues to suit your collection or QRadar tenant needs. Choose one or more of the following methods: <ul style="list-style-type: none"><li>• Different folders that go to different queues</li><li>• Different folders from different buckets that go to the same queue</li><li>• Everything from a single bucket that goes to a single queue</li><li>• Everything from multiple buckets that go to a single queue</li></ul>
<b>SQS</b>	The <b>Queue Name</b> from step 4 of <b>Creating the SQS queue that is used to receive the ObjectCreated notifications</b> .

## Create event notification

The notification configuration identifies the events you want Amazon S3 to publish and the destinations where you want Amazon S3 to send the notifications. [Learn more](#)

### General configuration

Event name  
NewS3ObjectToSQS

Event name can contain up to 255 characters.

Prefix - optional  
Limit the notifications to objects with key starting with specified characters.  
 AWSLogs/

Example. This value must match the location of the data that you want to collect.

Suffix - optional  
Limit the notifications to objects with key ending with specified characters.  
 .json.gz

Example. Enter a value so that you can filter out unwanted files that match the prefix.

### Event types

Specify at least one type of event for which you want to receive notifications. [Learn more](#)

All object create events  
s3:ObjectCreated:  
 Put  
s3:ObjectCreated:Put  
 Post  
s3:ObjectCreated:Post  
 Copy  
s3:ObjectCreated:Copy  
 Multipart upload completed  
s3:ObjectCreated:CompleteMultipartUpload

Figure 18. Example: Events

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

In the example in figure 1 of a parameter configuration, notifications are created for AWSLogs/ from the root of the bucket. When you use this configuration, All ObjectCreated events trigger a notification. If there are multiple accounts and regions in the bucket, everything gets processed. In this example, json.gz is used. This file type can change depending on the data that you are collecting. Depending on the content in your bucket, you can omit the extension or choose an extension that matches the data you are looking for in the folders where you have events set up.

After approximately 5 minutes, the queue that contains data displays. In the **Messages Available** column, you can view the number of messages.

Figure 19. Number of available messages

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

4. Click **Services**, then go to **Simple Queue Services**.
5. Right-click the **Queue Name** from step 4 of **Creating the SQS queue that is used to receive the ObjectCreated notifications**, then select **View/Delete Messages** to view the messages.

    "size":713,
    "eTag":"1ff1209e4140b4ff7a9d2b922f57f486",
    "sequencer":"005C19A40717D99642"
}
]
}
}

```

**Tip:** In the **key** value, your DSM name displays.

6. Click **Services**, then navigate to **IAM**.
7. Set a **User or Role** permission to access the SQS queue and for permission to download from the target bucket. The user or user role must have permission to read and delete from the SQS queue. For information about adding, managing and changing permissions for IAM users, see the [IAM Users documentation](#). After QRadar reads the notification, and then downloads and processes the target file, the message must be deleted from the queue.

Sample Policy:

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sqs:DeleteMessage",
                "sqs:ReceiveMessage",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket_name>/AWSLogs/*",
                "arn:aws:sqs:us-east-2:<AWS_account_number>:<queue_name>"
            ]
        }
    ]
}

```

You can add multiple buckets to the S3 queue. To ensure that all objects are accessed, you must have a trailing `/*` at the end of the folder path that you added.

You can add this policy directly to a user, a user role, or you can create a minimal access user with **sts:AssumeRole** permissions only. When you configure a log source in QRadar, configure the **assume Role ARN** parameter for QRadar to assume the role. To ensure that all files waiting to be processed in a single run (emptying the queue) can finish without retries, use the default value of 1 hour for the **API Session Duration** parameter.

When you use assumed roles, ensure that the ARN of the user that is assuming the role is in the **Trusted Entities** for that role. You can view the trusted entities that can assume the rule from the **Trust Relationship** tab in **IAM Role**. In addition, the user must have permission to assume roles in that (or any) account. The following examples show a sample trust policy:

#### Allow all IAM users within a specific AWS account to assume a role

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:root"
            },
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"
        }
    ]
}

```

## Allow a specific user to assume a role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:user/USERNAME"  
            },  
            "Action": "sts:AssumeRole",  
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"  
        }  
    ]  
}
```

The following image example shows a sample Amazon AWS CloudTrail log source configuration in QRadar.

**Tip:** Use the Amazon AWS S3 REST API log source parameter values for your DSM when you configure your log source.

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### Related information

[Adding a log source](#)

## Amazon AWS S3 REST API log source parameters for Amazon AWS Network Firewall

If QRadar does not automatically detect the log source, add an Amazon AWS Network Firewall log source on the QRadar Console by using the Amazon AWS REST API protocol.

When using the Amazon AWS S3 REST API protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Amazon AWS S3 REST API events from Amazon AWS Network Firewall:

Table 192. Amazon AWS S3 REST API log source parameters for the Amazon AWS Network Firewall DSM	
Parameter	Value
<b>Log Source type</b>	Amazon AWS Network Firewall
<b>Protocol Configuration</b>	Amazon AWS S3 REST API
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one Amazon AWS Network Firewall log source that is configured, you might want to identify the first log source as awsnetworkfirewall1, the second log source as awsnetworkfirewall2, and the third log source as awsnetworkfirewall3.
<b>Event Format</b>	If you have a QRadar Flow Processor available and licensed to receive flow logs, select <b>AWS Network Firewall</b> . If you do not have a QRadar Flow Processor available and licensed to receive flow logs, select <b>LINEBYLINE</b> .

For a complete list of Amazon AWS S3 REST API protocol parameters and their values, see [Amazon AWS S3 REST API protocol configuration options](#).

## Amazon AWS Route 53

The IBM QRadar DSM for Amazon AWS Route 53 collects events from an Amazon AWS Route 53 device by using the Amazon AWS S3 REST API and Amazon Web Services protocols.

To integrate Amazon AWS Route 53 with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
  - Protocol Common RPM
  - Amazon Web Services Protocol RPM (If you want to add a log source by using the Amazon Web Services protocol, download this RPM.)
  - Amazon AWS S3 REST API Protocol RPM (If you want to add a log source by using the Amazon AWS S3 REST API protocol, download this RPM.)
  - DSM Common RPM
  - Amazon AWS Route 53 DSM RPM
2. Optional: If you want QRadar to collect Amazon AWS Route 53 logs by using the Amazon Web Services protocol, see [Configuring an Amazon AWS Route 53 log source by using the Amazon Web Services protocol](#).
3. Optional: If you want QRadar to collect Amazon AWS Route 53 logs by using the Amazon AWS S3 REST API protocol, select one of the following configuration methods.:

**Important:** You can collect only AWS Resolver query logs when using these methods.

  - [Configuring an Amazon AWS Route 53 log source that uses an S3 bucket with an SQS queue](#)
  - [Configuring an Amazon AWS Route 53 log source that uses an S3 bucket with a directory prefix](#)

### Related tasks

## Amazon AWS Route 53 DSM specifications

The IBM QRadar DSM for Amazon AWS Route 53 supports Public DNS log events that are collected from a log group in AWS CloudWatch Logs. Resolver query events that are collected from Amazon S3 buckets and from a log group in the AWS CloudWatch logs are also supported.

When you configure Amazon AWS Route 53, understanding the specifications for the Amazon AWS Route 53 DSM can help ensure a successful integration. For example, knowing what the supported protocols are before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Amazon AWS Route 53 DSM.

*Table 195. Amazon AWS Route 53 DSM specifications*

Specification	Value
Manufacturer	Amazon
DSM name	Amazon AWS Route 53

Table 195. Amazon AWS Route 53 DSM specifications (continued)

Specification	Value
RPM file name	DSM-AmazonAWSRoute53-QRadar_version-build_number.noarch.rpm
Protocol	<ul style="list-style-type: none"> <li>Amazon Web Services (Resolver and Public DNS query logs)</li> <li>Amazon AWS S3 REST API (Resolver query logs only)</li> <li>Syslog (The Syslog protocol uses common log source parameters)</li> </ul>
Event format	<ul style="list-style-type: none"> <li>JSON (Resolver query logs)</li> <li>Space delimited pre-defined fields (Public DNS query logs)</li> </ul>
Recorded event types	Event versions 1.0
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<p>For more information about Public DNS query logs, see the Amazon website (<a href="https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/query-logs.html">https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/query-logs.html</a>)</p> <p>For more information about Resolver query logging, see the Amazon website (<a href="https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/resolver-query-logs.html">https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/resolver-query-logs.html</a>)</p>

## Configuring an Amazon AWS Route 53 log source by using the Amazon Web Services protocol and CloudWatch logs

To collect AWS Route 53 public DNS query logs or Resolver query logs, or both, from Amazon CloudWatch logs, add a log source on the QRadar Console by using the Amazon Web Services protocol.

### Procedure

1. Create a log group in Amazon CloudWatch Logs to retrieve logs in QRadar.

**Important:** For public DNS query logs, the log group must be in the US East (N.Virginia) region.
2. Configure AWS Route 53 to send logs to a log group in the AWS CloudWatch Logs.
  - For public DNS logs, configure public DNS query logging.
  - For Resolver query logs, configure Resolver query logging.
3. Create an Identity and Access (IAM) user in the AWS Management Console.
4. Configure security credentials for your AWS user account.
5. Amazon Web services log source parameters for Amazon AWS Route 53.

## Configuring public DNS query logging

Before you can add a log source in IBM QRadar, you must configure logging for DNS queries.

### Procedure

1. Log in to the [AWS Management console](#) to open the Route 53 console (<https://console.aws.amazon.com/route53>).
2. From the **Amazon Route 53** navigation pane, select **Hosted zones**.
3. Select the relevant hosted zone.
4. From the **Hosted zone details** section, click **Configure query logging**.
5. Select an existing log group or create a new log group.

**Important:** The log group must be in the US East (N. Virginia) region.

6. If you see an alert about permissions, choose one of the following troubleshooting options:
  - If you have 10 resource policies, you reached the limit. Select one of your resource policies and click **Edit** to allow Route 53 to write logs to your log groups, then click **Save** and continue to step 7.
  - If this configuration is the first time that you have configured query logging, or if you have less than 10 resource policies, grant permission to Route 53 to write logs to your CloudWatch log groups by selecting **Grant permissions**, then continue to the next step.
7. To verify that the resource policy matches the CloudWatch Log log group and if Route 53 has permission to publish logs to CloudWatch, click **Permissions - optional**.
8. Click **Create**.

### What to do next

[Create an Identity and Access \(IAM\) user in the AWS Management Console](#)

## Configuring Resolver query logging

Before you can add a log source in IBM QRadar, you must configure Resolver query logging on the AWS Management console.

### Procedure

1. Log in to your [AWS Management console](#) to open the Route 53 console.
2. From the **Route 53** navigation menu, select **Resolver > Query logging**.
3. From the region list, select the region where you want to create the query logging configuration.

**Tip:** The region that you select must be the same region where you created the Amazon Virtual Private Clouds (VPCs) that you want to log queries for. If your VPCs are in multiple regions, create at least one query logging configuration for each region.

4. Click **Configure query logging**, then type a name for your query logging configuration. Your configuration name displays in the console in the list of query logging configurations.
5. In the **Query logs destination** section, select a destination where you want Resolver to publish query logs. QRadar supports CloudWatch Logs log group and S3 bucket as destinations for query logs.
  - If you are using the Amazon AWS S3 REST API, select **S3 bucket**.
  - If you are using the Amazon Web Services protocol, select **CloudWatch Logs log group**.
6. To log VPCs, in the **VPCs to log queries for** section, click **Add VPC**. DNS queries that originate in the VPCs that you select are logged. If you don't select any VPCs, no queries are logged by Resolver.
7. Click **Configure query logging**.

### What to do next

[Create an Identity and Access \(IAM\) user in the AWS Management Console](#)

## Creating an Identity and Access Management (IAM) user in the AWS Management Console

An Amazon administrator must create a user and then apply the **s3:listBucket** and **s3:getObject** permissions to that user in the AWS Management Console. The QRadar user can then create a log source in QRadar.

### About this task

The minimum required permissions are **s3:listBucket** and **s3:getObject**. You can assign other permissions to the user as needed.

Sample policy:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::<bucket_name>",  
                "arn:aws:s3:::<bucket_name>/AWSLogs/<AWS_account_number>/<DSM_name>/us-east-1/*"  
            ]  
        }  
    ]  
}
```

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**.
3. From the list, select **IAM**.
4. Click **Users > Add user**.
5. Create an Amazon AWS IAM user and then apply the **AmazonS3ReadOnlyAccess** policy.

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### Related information

[Adding a log source](#)

## Creating a log group in Amazon CloudWatch Logs to retrieve logs in QRadar

You must create a log group in Amazon CloudWatch Logs to make the log available for QRadar polling.

### Procedure

1. Log in to your [CloudWatch console](https://console.aws.amazon.com/cloudwatch) (<https://console.aws.amazon.com/cloudwatch>).
2. Select **Logs** from left navigation pane.
3. Click **Actions > Create Log Group**.
4. Type the name of your log group. For example, `CloudTrailAuditLogs`.
5. Click **Create log group**.

For more information about working with log groups and log streams, see <https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/Working-with-log-groups-and-streams.html>

## Amazon Web Services log source parameters for Amazon AWS Route 53

If you want to collect AWS Route 53 logs from Amazon CloudWatch logs, add a log source on the QRadar Console by using the Amazon Web Services protocol.

When you use the Amazon Web Services protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Amazon Web Services events from Amazon AWS Route 53:

Table 196. Amazon Web Services log source parameters for the Amazon AWS Route 53 DSM	
Parameter	Value
<b>Log Source type</b>	<b>Amazon AWS Route 53</b>
<b>Protocol Configuration</b>	<b>Amazon Web Services</b>
<b>Authentication Method</b>	<b>Access Key ID/Secret Key</b> Standard authentication that can be used from anywhere. <b>EC2 Instance IAM Role</b> If your QRadar managed host is running in an AWS EC2 instance, choosing this option uses the IAM role from the metadata that is assigned to the instance for authentication. No keys are required. This method works only for managed hosts that are running within an AWS EC2 container.
<b>Access Key</b>	The Access Key ID that was generated when you configured the security credentials for your AWS user account. If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Access Key</b> parameter is displayed.
<b>Secret Key</b>	The Secret Key that was generated when you configured the security credentials for your AWS user account. If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Secret Key</b> parameter is displayed.

Table 196. Amazon Web Services log source parameters for the Amazon AWS Route 53 DSM (continued)

Parameter	Value
<b>Assume an IAM Role</b>	Enable this option by authenticating with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access.
<b>Assume Role ARN</b>	The full ARN of the role to assume. It must begin with "arn:" and can't contain any leading or trailing spaces, or spaces within the ARN.  If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role ARN</b> parameter is displayed.
<b>Assume Role Session Name</b>	The session name of the role to assume. The default is QRadarAWSsession. Leave as the default if you don't need to change it. This parameter can contain only upper and lowercase alphanumeric characters, underscores, or any of the following characters: =, . @ -  If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role Session Name</b> parameter is displayed.
<b>Regions</b>	Toggle each region that is associated with the Amazon Web Service that you want to collect logs from.
<b>AWS Service</b>	From the <b>AWS Service</b> list, select <b>CloudWatch Logs</b> .
<b>Log Group</b>	The name of the log group in Amazon CloudWatch that you want to collect logs from.  <b>Note:</b> A single log source collects CloudWatch Logs from one log group at a time. If you want to collect logs from multiple log groups, create a separate log source for each log group.

Table 196. Amazon Web Services log source parameters for the Amazon AWS Route 53 DSM (continued)

Parameter	Value
<b>Enable CloudWatch Advanced Options</b>	<p>Enable the following optional advanced configuration values; otherwise the default values are used.</p> <p><b>Log Stream</b>          (Optional) The name of the log stream within a log group. If you want to collect logs from all log streams within a log group, leave this field blank.</p> <p><b>Filter Pattern</b>          (Optional) Type a pattern for filtering the collected events. This pattern is not a regex filter. Only the events that contain the exact value that you specified are collected from CloudWatch Logs. If you type ACCEPT as the Filter Pattern value, only the events that contain the word ACCEPT are collected, as shown in the following example.</p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Event Delay</b>          Delay in seconds for collecting data.</p> <p><b>Other Region(s)</b>          Deprecated. Use <b>Regions</b> instead.</p>

Table 196. Amazon Web Services log source parameters for the Amazon AWS Route 53 DSM (continued)

Parameter	Value
<b>Extract Original Event</b>	<p>Forwards only the original event that was added to the CloudWatch Logs.</p> <p>CloudWatch logs wrap the events that they receive with extra metadata. Select this option if you want to collect only the original event that was sent to AWS without the additional stream metadata through CloudWatch Logs.</p> <p>The original event is the value for the message key that is extracted from the CloudWatch log. The following CloudWatch Logs event example shows the original event that is extracted from CloudWatch Logs in highlighted text:</p> <pre data-bbox="878 692 1470 1241">{LogStreamName: 123456786_CloudTrail_us-east-2, Timestamp: 1505744407363, Message: {"eventVersion": "1.05", "userIdentity": {"type": "IAMUser", "principalId": "AAAAABBBCCCCDDBBBCCC", "arn": "arn:aws:iam::1234567890:user/&lt;username&gt;", "accountId": "1234567890", "accessKeyId": "AAAAABBBCCCCDDDD", "userName": "UserName", "sessionContext": {"attributes": {"mfaAuthenticated": "false", "creationDate": "2017-09-18T13:22:10Z"}}, "invokedBy": "signin.amazonaws.com"}, "eventTime": "2017-09-18T14:10:15Z", "eventSource": "cloudtrail.amazonaws.com", "eventName": "DescribeTrails", "awsRegion": "us-east-1", "sourceIPAddress": "192.0.2.1", "userAgent": "signin.amazonaws.com", "requestParameters": {"includeShadowTrails": false, "trailNameList": []}, "responseElements": null, "requestID": "11ba00-7a7a-11a1-1a11-44a4aaa1a", "eventID": "a4914e00-1111-491d-bbbb-a0dd3845b302", "eventType": "AwsApiCall", "recipientAccountId": "1234567890"}, IngestionTime: 1505744407506, EventId: 3357922236111112247912667222222513333}</pre>
<b>Use As A Gateway Log Source</b>	<p>If you do not want to define a custom log source identifier for events, clear the checkbox.</p> <p>If you don't select <b>Use As A Gateway Log Source</b> and you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p>

Table 196. Amazon Web Services log source parameters for the Amazon AWS Route 53 DSM (continued)

Parameter	Value
<b>Log Source Identifier Pattern</b>	<p>If you selected <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier. This option can be defined for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>Use Proxy</b>	<p>If QRadar accesses the Amazon Web Service by using a proxy, select this option.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.</p>

Table 196. Amazon Web Services log source parameters for the Amazon AWS Route 53 DSM (continued)

Parameter	Value
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

For more information about the Amazon Web Services protocol, see [Amazon Web Services protocol configuration options](#).

[Adding a log source](#)

## Configuring an Amazon AWS Route 53 log source by using an S3 bucket with an SQS queue

You can collect AWS Route 53 Resolver query logs from multiple accounts or regions in an Amazon S3 bucket. Configure a log source on the QRadar Console so that Amazon AWS Route 53 can communicate with QRadar by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

#### About this task

Using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue instead of with a directory prefix has the following advantages:

- You can use one log source for an S3 bucket, rather than one log source for each region and account.
- There is a reduced chance of missing files because this method uses ObjectCreate notifications to determine when new files are ready.
- It's easy to balance the load across multiple Event Collectors because the SQS queue supports connections from multiple clients.
- Unlike the directory prefix method, the SQS queue method does not require that the file names in the folders be in a string that is sorted in ascending order based on the full path. File names from custom applications don't always conform to this method.
- You can monitor the SQS queue and set up alerts if it gets over a certain number of records. These alerts provide information about whether QRadar is either falling behind or not collecting events.
- You can use IAM Role authentication with SQS, which is Amazon's best practice for security.
- Certificate handling is improved with the SQS method and does not require the downloading of certificates to the Event Collector.

#### Procedure

1. [Configure Resolver query logging](#). In Step 5 of that procedure , select **S3 bucket** as the destination for query logs.
2. Create the SQS queue that is used to receive ObjectCreated notifications.
3. Create an Amazon AWS Identity and Access Management (IAM) user and then apply the **AmazonS3ReadOnlyAccess** policy.
4. Configure the security credentials for your AWS user account.
5. [Amazon AWS S3 REST API log source parameters for Amazon AWS Route 53 when using a SWS queue](#).

## Configuring Resolver query logging

Before you can add a log source in IBM QRadar, you must configure Resolver query logging on the AWS Management console.

### Procedure

1. Log in to your [AWS Management console](#) to open the [Route 53 console](#).
2. From the **Route 53** navigation menu, select **Resolver > Query logging**.
3. From the region list, select the region where you want to create the query logging configuration.

**Tip:** The region that you select must be the same region where you created the Amazon Virtual Private Clouds (VPCs) that you want to log queries for. If your VPCs are in multiple regions, create at least one query logging configuration for each region.
4. Click **Configure query logging**, then type a name for your query logging configuration. Your configuration name displays in the console in the list of query logging configurations.
5. In the **Query logs destination** section, select a destination where you want Resolver to publish query logs. QRadar supports CloudWatch Logs log group and S3 bucket as destinations for query logs.
  - If you are using the Amazon AWS S3 REST API, select **S3 bucket**.
  - If you are using the Amazon Web Services protocol, select **CloudWatch Logs log group**.
6. To log VPCs, in the **VPCs to log queries for** section, click **Add VPC**. DNS queries that originate in the VPCs that you select are logged. If you don't select any VPCs, no queries are logged by Resolver.
7. Click **Configure query logging**.

### What to do next

[Create an Identity and Access \(IAM\) user in the AWS Management Console](#)

## Create an SQS queue and configure S3 ObjectCreated notifications

Before you can add a log source in IBM QRadar, you must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

Complete the following procedures:

1. [Finding the S3 Bucket that contains the data that you want to collect](#).
2. [Creating the SQS queue that is used to receive the ObjectCreated notifications from the S3 Bucket that you used in Step 1](#).
3. [Setting up SQS queue permissions](#).
4. [Creating ObjectCreated notifications](#).
5. [Configuring security credentials for your AWS user account](#).

### **Finding the S3 bucket that contains the data that you want to collect**

You must find and note the region for S3 bucket that contains the data that you want to collect.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to **S3**.
3. From the **AWS Region** column in the **Buckets** list, note the region where the bucket that you want to collect data from is located. You need the region for the **Region Name** parameter value when you add a log source in IBM QRadar.
4. Enable the checkbox beside the bucket name, and then from the panel that opens to the right, click **Copy Bucket ARN** to copy the value to the clipboard. Save this value or leave it on the clipboard. You need this value when you set up **SQS queue permissions**.

## ***Creating the SQS queue that is used to receive ObjectCreated notifications***

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

### **Before you begin**

You must complete **Finding the S3 Bucket that contains the data that you want to collect**. The SQS Queue must be in the same region as the AWS S3 bucket that the queue is collecting from.

### **Procedure**

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to the Simple Queue Service Management Console.
3. In the upper right of the window, change the region to where the bucket is located. You noted this value when you completed the **Finding the S3 Bucket that contains the data that you want to collect** procedure.
4. Select **Create New Queue**, and then type a value for the **Queue Name**.
5. Click **Standard Queue**, select **Configure Queue**, and then change the default values for the following **Queue Attributes**.
  - **Default Visibility Timeout** - 60 seconds (You can use a lower value. In the case of load balanced collection, duplicate events might occur with values of less than 30 seconds. This value can't be 0.)
  - **Message Retention Period** - 14 days (You can use a lower value. In the event of an extended collection, data might be lost.)

Use the default value for the remaining **Queue Attributes**.

More options such as **Redrive Policy** or **SSE** can be used depending on the requirements for your AWS environment. These values should not affect the data collection.

Queue Attributes

<b>Default Visibility Timeout</b>  60	seconds 	Value must be between 0 seconds and 12 hours.
<b>Message Retention Period</b>  14	days 	Value must be between 1 minute and 14 days.
<b>Maximum Message Size</b>  256	KB	Value must be between 1 and 256 KB.
<b>Delivery Delay</b>  0	seconds 	Value must be between 0 seconds and 15 minutes.
<b>Receive Message Wait Time</b>  0	seconds	Value must be between 0 and 20 seconds.

Picture © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

6. Select **Create Queue**.

### ***Setting up SQS queue permissions***

You must set up SQS queue permissions for users to access the queue.

### **Before you begin**

You must complete **Creating the SQS queue that is used to receive ObjectCreated notifications**.

You can set the SQS queue permissions by using either the Permissions Editor or a JSON policy document.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Go to the SQS Management Console, and then select the queue that you created from the list.
3. From the **Details** panel, record the **ARN** field value.  
For example: **arn:aws:sqs:us-east-1:123456789012:MySQSQueueName**
4. To set the SQS queue **Access policy (Permissions)** by using the **AWS Policy generator**, complete the following steps:
  - a) Select **Policy Type > SQS Queue Policy**.
  - b) Add an Access Policy statement.
  - c) From the **Access policy** tab, click **Policy generator**, and then configure the following parameters:

*Table 197. Permission parameters*

Parameter	Value
<b>Effect</b>	Click <b>Allow</b> .
<b>Principal</b>	Type <b>*</b> (Everybody).
<b>Actions</b>	From the list, select <b>SendMessage</b>
<b>Amazon Resource Name (ARN)</b>	Type your queue ARN: <i>arn:aws:sqs:us-east-1:123456789012:MySQSQueueName</i>

- d) Click **Add Conditionals (Optional)**, and then configure the following parameters:

*Table 198. Add Conditionals (Optional) parameters*

Parameter	Value
<b>Qualifier</b>	None
<b>Condition</b>	<b>ARNLike</b>
<b>Key</b>	Type <b>aws:SourceArn</b> .
<b>Value</b>	The ARN of the S3 bucket from when you completed the “ <a href="#">Finding the S3 bucket that contains the data that you want to collect</a> ” on page 308 procedure. For example: <b>aws:s3:::my-example-s3bucket</b>

5. To set the SQS queue permissions by using a JSON policy document, complete the following steps:
  - a) Click **Add Condition > Add Statement. > Generate Policy**.
  - b) Copy and paste the following JSON policy into the **Access policy** window:

Copy and paste might not preserve the white space in the JSON policy. The white space is required. If the white space is not preserved when you paste the JSON policy, paste it into a text editor and restore the white space. Then, copy and paste the JSON policy from your text editor into the **Edit Policy Document** window.

```
{  
    "Version": "2008-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "example-statement-ID",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "*"  
            },  
            "Action": "SendMessage",  
            "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName"  
        }  
    ]  
}
```

```

    "Action": "SQS:SendMessage",
    "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName",
    "Condition": {
        "ArnLike": {
            "aws:SourceArn": "arn:aws:s3:::my-example-s3bucket"
        }
    }
}
]
}

```

6. Click **Review Policy**. Ensure that the data is correct, and then click **Save Changes**.

### **Creating ObjectCreated notifications**

Configure ObjectCreated notifications for the folders that you want to monitor in the bucket.

### **Procedure**

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, go to **S3**, and then select a bucket.
3. Click the **Properties** tab, and in the **Events** pane, click **Add notification**. Configure the parameters for the new event.

The following table shows an example of an ObjectCreated notification parameter configuration:

*Table 199. Example: New ObjectCreated notification parameter configuration*

Parameter	Value
<b>Name</b>	Type a name of your choosing.
<b>Events</b>	Select <b>All object create events</b> .
<b>Prefix</b>	AWSLogs/ <b>Tip:</b> You can choose a prefix that contains the data that you want to find, depending on where the data is located and what data that you want to go to the queue. For example, AWSLogs/, CustomPrefix/AWSLogs/, AWSLogs/123456789012/.
<b>Suffix</b>	json.gz
<b>Send to</b>	SQS queue <b>Tip:</b> You can send the data from different folders to the same or different queues to suit your collection or QRadar tenant needs. Choose one or more of the following methods: <ul style="list-style-type: none"> <li>• Different folders that go to different queues</li> <li>• Different folders from different buckets that go to the same queue</li> <li>• Everything from a single bucket that goes to a single queue</li> <li>• Everything from multiple buckets that go to a single queue</li> </ul>
<b>SQS</b>	The <b>Queue Name</b> from step 4 of <b>Creating the SQS queue that is used to receive the ObjectCreated notifications</b> .

## Create event notification

The notification configuration identifies the events you want Amazon S3 to publish and the destinations where you want Amazon S3 to send the notifications. [Learn more](#)

### General configuration

Event name  
NewS3ObjectToSQS

Event name can contain up to 255 characters.

Prefix - optional  
Limit the notifications to objects with key starting with specified characters.  
 AWSLogs/

Example. This value must match the location of the data that you want to collect.

Suffix - optional  
Limit the notifications to objects with key ending with specified characters.  
 .json.gz

Example. Enter a value so that you can filter out unwanted files that match the prefix.

### Event types

Specify at least one type of event for which you want to receive notifications. [Learn more](#)

All object create events  
s3:ObjectCreated:  
 Put  
s3:ObjectCreated:Put  
 Post  
s3:ObjectCreated:Post  
 Copy  
s3:ObjectCreated:Copy  
 Multipart upload completed  
s3:ObjectCreated:CompleteMultipartUpload

Figure 22. Example: Events

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

In the example in figure 1 of a parameter configuration, notifications are created for AWSLogs/ from the root of the bucket. When you use this configuration, All ObjectCreated events trigger a notification. If there are multiple accounts and regions in the bucket, everything gets processed. In this example, json.gz is used. This file type can change depending on the data that you are collecting. Depending on the content in your bucket, you can omit the extension or choose an extension that matches the data you are looking for in the folders where you have events set up.

After approximately 5 minutes, the queue that contains data displays. In the **Messages Available** column, you can view the number of messages.

Figure 23. Number of available messages

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

4. Click **Services**, then go to **Simple Queue Services**.
5. Right-click the **Queue Name** from step 4 of **Creating the SQS queue that is used to receive the ObjectCreated notifications**, then select **View/Delete Messages** to view the messages.

                }  
            }  
        }  
    ]  
}
```

```

3/2018/12/19/123456789012_CloudTrail_eu-west-3_TestAccountTrail
_us-east-2_20181219T014838Z.json.gz",
    "size":713,
    "eTag":"1ff1209e4140b4ff7a9d2b922f57f486",
    "sequencer":"005C19A40717D99642"
}
]
}
}

```

**Tip:** In the **key** value, your DSM name displays.

6. Click **Services**, then navigate to **IAM**.
7. Set a **User or Role** permission to access the SQS queue and for permission to download from the target bucket. The user or user role must have permission to read and delete from the SQS queue. For information about adding, managing and changing permissions for IAM users, see the [IAM Users documentation](#). After QRadar reads the notification, and then downloads and processes the target file, the message must be deleted from the queue.

Sample Policy:

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sqs:DeleteMessage",
                "sqs:ReceiveMessage",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket_name>/AWSLogs/*",
                "arn:aws:sqs:us-east-2:<AWS_account_number>:<queue_name>"
            ]
        }
    ]
}

```

You can add multiple buckets to the S3 queue. To ensure that all objects are accessed, you must have a trailing `/*` at the end of the folder path that you added.

You can add this policy directly to a user, a user role, or you can create a minimal access user with **sts:AssumeRole** permissions only. When you configure a log source in QRadar, configure the **assume Role ARN** parameter for QRadar to assume the role. To ensure that all files waiting to be processed in a single run (emptying the queue) can finish without retries, use the default value of 1 hour for the **API Session Duration** parameter.

When you use assumed roles, ensure that the ARN of the user that is assuming the role is in the **Trusted Entities** for that role. You can view the trusted entities that can assume the rule from the **Trust Relationship** tab in **IAM Role**. In addition, the user must have permission to assume roles in that (or any) account. The following examples show a sample trust policy:

#### Allow all IAM users within a specific AWS account to assume a role

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:root"
            },
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"
        }
    ]
}

```

## Allow a specific user to assume a role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:user/USERNAME"  
            },  
            "Action": "sts:AssumeRole",  
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"  
        }  
    ]  
}
```

The following image example shows a sample Amazon AWS CloudTrail log source configuration in QRadar.

**Tip:** Use the Amazon AWS S3 REST API log source parameter values for your DSM when you configure your log source.

## **Configuring security credentials for your AWS user account**

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### **Procedure**

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### **Related information**

[Adding a log source](#)

## **Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge**

Create an Amazon EventBridge rule to forward ObjectCreated notifications to a target SQS queue.

### **Before you begin**

Before you can create a rule in Amazon EventBridge, you must enable Amazon EventBridge on your AWS Management console. For more information, see [Enabling Amazon EventBridge](#).

### **Procedure**

1. Open the [Amazon EventBridge console](#).
2. From the **Navigation** menu, click **Rules > Create rule**.
3. On the **Create rule** window, complete the following steps:
  - a) Enter a name and description for the rule.  
**Important:** A rule can't have the same name as another rule that is both in the same region and on the same event bus.
  - b) For **Event bus**, select the event bus that you want to associate with this rule. If you select **AWS default event bus**, the rule matches the events that come from your account.
  - c) For **Rule type**, select **Rule with an event pattern**.
4. Click **Next**.
5. For **Event source**, select **AWS events or EventBridge partner events**.
6. For **Creation method**, select **Use pattern form**.
7. In the **Event pattern** window, configure the event pattern by completing the following steps:
  - a) Select the values listed in the table for the following parameters:

Parameter	Value
<b>Event source</b>	<b>AWS services</b>
<b>AWS service</b>	<b>Simple Storage Service (S3)</b>
<b>Event type</b>	<b>Amazon S3 Event Notification</b>

- b) Click the **Specific event(s)** option and select **Object Created**.

- c) Click **Specific bucket(s) by name** and enter the name of the specific bucket that you want to collect events from.
- d) Optional: To enable notifications for a specific folder prefix or file extension, choose **Custom pattern (JSON editor)** instead of **Use pattern form** for the creation method, and create your custom event pattern.  
For example, this event pattern filters for Object Created events in your bucket. In this example, example/directory is the directory prefix and .png is the suffix.

```
{
  "source": ["aws.s3"],
  "detail-type": ["Object Created"],
  "detail": {
    "bucket": {
      "name": ["<example-bucket>"]
    },
    "object": {
      "key": [
        {
          "prefix": "example/directory/"
        },
        {
          "key": [
            {
              "suffix": ".png"
            }
          ]
        }
      ]
    }
  }
}
```

- e) Click **Add**, then click **Next**.
- 8. Choose the SQS queue that you want to use as the target. Enter the name of the queue, then click **Next**.
- 9. On the **Review and create** page, click **Create rule**.

## **Amazon AWS S3 REST API log source parameters for Amazon AWS Route 53 when using an SQS queue**

If you want to collect AWS Route 53 Resolver query logs from multiple accounts or regions in an Amazon S3 bucket, add an Amazon AWS Route 53 log source on the QRadar Console by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

The following table describes the parameters for an Amazon AWS Route 53 log source that uses the Amazon AWS S3 REST API protocol:

<i>Table 200. Amazon AWS S3 REST API log source parameters for the Amazon AWS Route 53 DSM</i>	
<b>Parameter</b>	<b>Value</b>
<b>Log Source type</b>	Amazon AWS Route 53
<b>Protocol Configuration</b>	Amazon AWS S3 REST API
<b>Log Source Identifier</b>	<p>Type a unique name for the log source.</p> <p>The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b>. If you have more than one Amazon AWS Route 53 log source that is configured, you might want to identify the first log source as <i>awsroute53-1</i>, the second log source as <i>awsroute53-2</i>, and the third log source as <i>awsroute53-3</i>.</p>

*Table 200. Amazon AWS S3 REST API log source parameters for the Amazon AWS Route 53 DSM (continued)*

Parameter	Value
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>  Standard authentication that can be used from anywhere.  For more information about configuring security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p> <p><b>Assume IAM Role</b>  Authenticate with keys and then temporarily assume a role for access. This option is available only when you use the SQS Event Notifications collection method.  For more information about creating IAM users and assigning roles, see <a href="#">Creating an Identity and Access Management (IAM) user in the AWS Management Console</a>.</p>
<b>Access Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Access Key ID</b> parameter is displayed.  The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.
<b>Secret Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Secret Key ID</b> parameter is displayed.  The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Decret Key ID</b> that is used to access the AWS S3 bucket.
<b>Event Format</b>	Select <b>LINEBYLINE</b> . The log source collects JSON formatted events.
<b>S3 Collection Method</b>	Select <b>SQS Event Notifications</b> .
<b>SQS Queue URL</b>	Enter the full URL, starting with <code>https://</code> , of the SQS queue that is set up to receive notifications for ObjectCreate events from S3.
<b>Region Name</b>	The region that the SQS Queue or the S3 Bucket is in.  Example: us-east-1, eu-west-1, ap-northeast-3
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar traffic analysis engine and for QRadar to automatically detect one or more log sources.

Table 200. Amazon AWS S3 REST API log source parameters for the Amazon AWS Route 53 DSM  
(continued)

Parameter	Value
<b>Log Source Identifier Pattern</b>	<p>This option is available when <b>Use as a Gateway Log Source</b> is set to yes.</p> <p>Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.</p>
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.
<b>File Pattern</b>	<p>This option is available when you set <b>Show Advanced Options</b> to <b>Yes</b>.</p> <p>Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code></p>
<b>Local Directory</b>	<p>This option is available when you set <b>Show Advanced Options</b> to <b>Yes</b>.</p> <p>The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.</p>
<b>S3 Endpoint URL</b>	<p>This option is available when you set <b>Show Advanced Options</b> to <b>Yes</b>.</p> <p>The endpoint URL that is used to query the AWS REST API.</p> <p>If your endpoint URL is different from the default, type your endpoint URL. The default is <code>http://s3.amazonaws.com</code></p>
<b>Use S3 Path-Style Access</b>	<p>Forces S3 requests to use path-style access.</p> <p>This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.</p>

*Table 200. Amazon AWS S3 REST API log source parameters for the Amazon AWS Route 53 DSM (continued)*

Parameter	Value
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> . If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.
<b>Recurrence</b>	How often a poll is made to scan for new data. When using the SQS event collection method, <b>SQS Event Notifications</b> can have a minimum value of 10 (seconds). Because SQS Queue polling can occur more often, a lower value can be used. Type a time interval to determine how frequently the poll is made for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

For more information about the Amazon AWS S3 REST API protocol, see [Amazon AWS S3 REST API protocol configuration options](#).

#### Related tasks

[Adding a log source](#)

## Configuring an Amazon AWS Route 53 log source by using an S3 bucket with a directory prefix

You can collect AWS Route 53 Resolver query logs from a single account and region in an Amazon S3 bucket. Add a log source on the QRadar Console so that Amazon AWS Route 53 can communicate with QRadar by using the Amazon AWS S3 REST API protocol with a directory prefix.

### Before you begin

If you have log sources in an S3 bucket from multiple regions or you are using multiple accounts, use the [Configuring an Amazon AWS Route 53 log source that uses an S3 bucket with an SQS queue procedure](#).

### About this task

A log source that uses directory prefix can retrieve data from only one region and one account. Use a different log source for each region and account. Include the region folder name in the file path for the **Directory Prefix** parameter value when you configure the log source.

## Procedure

1. Configure Resolver query logging. When you configure the **Query logs destination** parameter, select **S3 bucket** for the value.
2. Find an S3 bucket name and directory prefix for Amazon AWS Route 53.
3. Create an Amazon AWS Identity and Access Management (IAM) user and then apply the [AmazonS3ReadOnlyAccess policy](#).
4. Configure the security credentials for your AWS user account.
5. Amazon AWS S3 REST API log source parameters for Amazon AWS Route 53 when using a directory prefix.

## Configuring Resolver query logging

Before you can add a log source in IBM QRadar, you must configure Resolver query logging on the AWS Management console.

## Procedure

1. Log in to your [AWS Management console](#) to open the [Route 53 console](#).
2. From the **Route 53** navigation menu, select **Resolver > Query logging**.
3. From the region list, select the region where you want to create the query logging configuration.  
**Tip:** The region that you select must be the same region where you created the Amazon Virtual Private Clouds (VPCs) that you want to log queries for. If your VPCs are in multiple regions, create at least one query logging configuration for each region.
4. Click **Configure query logging**, then type a name for your query logging configuration. Your configuration name displays in the console in the list of query logging configurations.
5. In the **Query logs destination** section, select a destination where you want Resolver to publish query logs. QRadar supports CloudWatch Logs log group and S3 bucket as destinations for query logs.
  - If you are using the Amazon AWS S3 REST API, select **S3 bucket**.
  - If you are using the Amazon Web Services protocol, select **CloudWatch Logs log group**.
6. To log VPCs, in the **VPCs to log queries for** section, click **Add VPC**. DNS queries that originate in the VPCs that you select are logged. If you don't select any VPCs, no queries are logged by Resolver.
7. Click **Configure query logging**.

## What to do next

[Create an Identity and Access \(IAM\) user in the AWS Management Console](#)

## Finding an S3 bucket name and directory prefix

An Amazon administrator must create a user and then apply the **AmazonS3ReadOnlyAccess** policy in the AWS Management Console. The QRadar user can then create a log source in QRadar.

**Note:** Alternatively, you can assign more granular permissions to the bucket. The minimum required permissions are **s3:listBucket** and **s3:getObject**.

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

## Procedure

1. Click **Services**.
2. From the list, select **Config**.
3. From the **Config** page, click the name of the Config.
4. Note the name of the S3 bucket that is displayed in the **S3 bucket** field.

5. Click the **Edit** icon.
6. Note the location path for the S3 bucket that is displayed underneath the **Log file prefix** field.

## Creating an Identity and Access Management (IAM) user in the AWS Management Console

An Amazon administrator must create a user and then apply the **s3:listBucket** and **s3:getObject** permissions to that user in the AWS Management Console. The QRadar user can then create a log source in QRadar.

### About this task

The minimum required permissions are **s3:listBucket** and **s3:getObject**. You can assign other permissions to the user as needed.

Sample policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3>ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::<bucket_name>",
        "arn:aws:s3:::<bucket_name>/AWSLogs/<AWS_account_number>/<DSM_name>/us-east-1/*"
      ]
    }
  ]
}
```

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**.
3. From the list, select **IAM**.
4. Click **Users > Add user**.
5. Create an Amazon AWS IAM user and then apply the **AmazonS3ReadOnlyAccess** policy.

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your IAM console.
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

## Related information

[Adding a log source](#)

## Amazon AWS S3 REST API log source parameters for Amazon AWS Route 53 when using a directory prefix

If you want to collect AWS Route 53 Resolver query logs from a single account and region in an Amazon S3 bucket, add a log source on the IBM QRadar Console that uses the Amazon AWS S3 REST API protocol with a directory prefix.

When you use the Amazon AWS S3 REST API protocol with a directory prefix, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Amazon AWS S3 REST API events from Amazon AWS Route 53:

Table 201. Amazon AWS S3 REST API log source parameters for the Amazon AWS Route 53 DSM	
Parameter	Value
<b>Log Source type</b>	Amazon AWS Route 53
<b>Protocol Configuration</b>	Amazon AWS S3 REST API
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one Amazon AWS Route 53 log source that is configured, you might want to identify the first log source as <code>awsroute53-1</code> , the second log source as <code>awsroute53-2</code> , and the third log source as <code>awsroute53-3</code> .
<b>Authentication Method</b>	<b>Access Key ID / Secret Key</b> Standard authentication that can be used from anywhere.  For more information about configuring security credentials, see <a href="#">Configuring security credentials for your AWS user account</a> .  <b>Assume IAM Role</b> Authenticate with keys and then temporarily assume a role for access. This option is available only when you use the SQS Event Notifications collection method.  For more information about creating IAM users and assigning roles, see <a href="#">Creating an Identity and Access Management (IAM) user in the AWS Management Console</a> .  <b>EC2 Instance IAM Role</b> If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata that is assigned to the instance for authentication; no keys are required. This method works only for managed hosts that are running within an AWS EC2 container.

Table 201. Amazon AWS S3 REST API log source parameters for the Amazon AWS Route 53 DSM  
(continued)

Parameter	Value
<b>Access Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Access Key ID</b> parameter is displayed.  The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.
<b>Secret Key</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Secret Key ID</b> parameter is displayed.  The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Decret Key ID</b> that is used to access the AWS S3 bucket.
<b>Event Format</b>	Select <b>AWS Cloud Trail JSON</b> . The log source retrieves JSON formatted events.
<b>S3 Collection Method</b>	Select <b>Use a Specific Prefix</b> .
<b>Bucket Name</b>	The name of the AWS S3 bucket where the log files are stored.
<b>Directory Prefix</b>	The root directory location on the AWS S3 bucket from where the Resolver logs are retrieved; for example, AWSLogs/<AccountNumber>/Resolver/<RegionName>/  To pull files from the root directory of a bucket, you must use a forward slash (/) in the <b>Directory Prefix</b> file path.  <b>Note:</b> <ul style="list-style-type: none"> <li>• Changing the <b>Directory Prefix</b> value clears the persisted file marker. All files that match the new prefix are downloaded in the next pull.</li> <li>• The <b>Directory Prefix</b> file path cannot begin with a forward slash (/) unless only the forward slash is used to collect data from the root of the bucket.</li> <li>• If the <b>Directory Prefix</b> file path is used to specify folders, you must not begin the file path with a forward slash (for example, use folder1/folder2 instead).</li> </ul>
<b>Region Name</b>	The region that the SQS Queue or the AWS S3 bucket is in.  Example: us-east-1, eu-west-1, ap-northeast-3

*Table 201. Amazon AWS S3 REST API log source parameters for the Amazon AWS Route 53 DSM (continued)*

Parameter	Value
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.
<b>Log Source Identifier Pattern</b>	This option is available when <b>Use as a Gateway Log Source</b> is set to yes.  Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.
<b>File Pattern</b>	This option is available when you set <b>Show Advanced Options</b> to <b>Yes</b> .  Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code>
<b>Local Directory</b>	This option is available when you set <b>Show Advanced Options</b> to <b>Yes</b> .  The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.
<b>S3 Endpoint URL</b>	This option is available when you set <b>Show Advanced Options</b> to <b>Yes</b> .  The endpoint URL that is used to query the AWS S3 REST API.  If your endpoint URL is different from the default, type your endpoint URL. The default is <code>https://s3.amazonaws.com</code> .
<b>Use S3 Path-Style Access</b>	Forces S3 requests to use path-style access.  This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.

*Table 201. Amazon AWS S3 REST API log source parameters for the Amazon AWS Route 53 DSM (continued)*

Parameter	Value
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> . If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.
<b>Recurrence</b>	How often a poll is made to scan for new data. If you are using the SQS event collection method, <b>SQS Event Notifications</b> can have a minimum value of 10 (seconds). Because SQS Queue polling can occur more often, a lower value can be used. If you are using the Directory Prefix event collection method, <b>Use a Specific Prefix</b> has a minimum value of 60 (seconds) or 1M. Because every listBucket request to an AWS S3 bucket incurs a cost to the account that owns the bucket, a smaller recurrence value increases the cost. Type a time interval to determine how frequently the poll is made for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

For more information about the Amazon AWS S3 REST API protocol, see [Amazon AWS S3 REST API protocol configuration options](#).

#### Related tasks

[Adding a log source](#)

## Configuring an Amazon Route 53 log source that uses Amazon Security Lake

You can collect Amazon Route 53 logs from multiple accounts or regions in an Amazon S3 bucket. IBM QRadar uses the Amazon AWS S3 REST API protocol to communicate with Amazon Security Lake, where QRadar obtains the Amazon Route 53 logs.

#### Procedure

1. Configure Amazon Security Lake to log Open Cybersecurity Schema Framework (OCSF) data in Parquet format to an S3 bucket. For more information, see [Collecting data from custom sources](#).

**Note:** The supported OCSF version of the DSM is OCSF 1.0RC2. The version OCSF 1.1 is not currently supported.

2. Configure access to the OCSF data in Amazon Security Lake by using one of two methods.

- To create a subscriber to provision the SQS queue and IAM role, see step 3.

For more information about creating a subscriber, see [Managing data access for Security Lake subscribers](#).

- To manually configure the SQS queue and ObjectCreated notifications, see step 4.

3. Create a subscriber to provision the SQS queue and IAM role.

- When you create the subscription, take note of the following values: **SQS Queue URL, IAM Role ARN, and External ID**.

- If you plan to access this subscription from a different account than where Amazon Security Lake is set up, you must provide that account ID to configure the trust relationship properly.

4. Manually configure the SQS queue and ObjectCreated notifications.

- Configure an SQS queue to receive ObjectCreated notifications with either [Amazon S3 Event Notifications](#) or [AWS EventBridge](#) when new OCSF Parquet data is available in the Amazon Security Lake bucket in the folder you choose.

- Provision access keys with permission (either directly or with an **IAM Assume Role**) to access both the SQS queue and the bucket that contain the Amazon Security Lake data.

For more information, see [Create SQS and S3 object REST API](#).

5. Configure a log source in QRadar to collect and parse the data.

**Tip:** When new OCSF parquet data is available, a message that contains the bucket name and object key of the file with the data to be processed is sent to the SQS queue. QRadar then downloads and processes this file.

## What to do next

Add a Amazon Route 53 log source in QRadar. For more information, see [“Configuring an Amazon AWS Route 53 log source by using an S3 bucket with an SQS queue” on page 386](#).

## Amazon AWS Security Hub

The IBM QRadar DSM for Amazon AWS Security Hub collects events from the AWS CloudWatch log group of Amazon CloudWatch service.

To integrate Amazon AWS Security Hub with QRadar, complete the following steps:

- If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
- DSM Common RPM
- Protocol Common RPM
- Amazon Web Services Protocol RPM
- Amazon AWS Security Hub DSM RPM
- Create and configure an Amazon EventBridge rule to send events from AWS Security Hub to AWS CloudWatch log group. For more information, see [Creating an EventBridge rule for sending events](#).
- Create an Identity and Access (IAM) user in the Amazon AWS user interface when using the Amazon Web Services protocol. For more information, see [Creating an Identity and Access \(IAM\) user in the AWS Management Console](#).
- Add an Amazon AWS Security Hub log source on the QRadar Console. For more information, see [Amazon Web Services log source parameters for Amazon AWS Security Hub](#).

## Amazon AWS Security Hub DSM specifications

The following table describes the specifications for the Amazon AWS Security Hub DSM.

Table 204. Amazon AWS Security Hub DSM specifications	
Specification	Value
Manufacturer	Amazon
DSM name	AWS Security Hub
RPM file name	DSM-AmazonAWSSecurityHub-QRadar_version-build_number.noarch.rpm
Protocol	Amazon Web Services
Event format	JSON
Recorded event types	AWS Security Finding Format (ASFF)
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://docs.aws.amazon.com/securityhub/index.html">AWS Security Hub documentation (https://docs.aws.amazon.com/securityhub/index.html)</a>

## Creating an EventBridge rule for sending events

You need to create and configure an Amazon EventBridge rule to send events from AWS Security Hub to AWS CloudWatch log group.

#### Procedure

1. Go to [Amazon EventBridge](https://console.aws.amazon.com/events/home?region=us-east-1#/) (<https://console.aws.amazon.com/events/home?region=us-east-1#/>).
2. In the **Create a new rule** pane, click **Create rule**.
3. In the **Name and description** pane, type a name for your rule in the **Name** field and if you want, type a description for your rule in the **Description** field.
4. In the **Define pattern** pane, select **Event pattern**, and then select **Pre-defined pattern by service** to build an event pattern.
5. From the **Service provider** list, select **AWS**.
6. From the **Service name** list, select **SecurityHub**.
7. From the **Event type** list, select **All Events**.
8. In the **Select event bus** pane, select **AWS default event bus**.
9. In the **Select targets** pane, from the **Target** list, select **CloudWatch log group**.
10. In the **Log Group:** section, specify a new log group or select an existing log group from the list.

**Important:** You need the name of the log group when you configure a log source in QRadar.

11. Click **Create**.

### What to do next

[Creating an Identity and Access \(IAM\) user in the AWS Management Console](#)

## Creating an Identity and Access (IAM) user in the AWS Management Console

An Amazon administrator must create a user and then apply the **CloudWatchLogsReadOnlyAccess** policy in the AWS Management Console. The QRadar user can then create a log source in QRadar.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Create an Amazon AWS IAM user and then apply the **CloudWatchLogsReadOnlyAccess** policy.

### What to do next

[Amazon Web Services log source parameters for Amazon AWS Security Hub](#)

## Amazon Web Services log source parameters for Amazon AWS Security Hub

Add an Amazon AWS Security Hub log source on the QRadar Console to collect AWS CloudWatch logs by using the Amazon Web Services protocol.

When using the Amazon Web Services protocol to collect AWS CloudWatch logs, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect AWS CloudWatch logs with the Amazon Web Services protocol:

Table 205. Amazon Web Services log source parameters for the Amazon AWS Security Hub DSM	
Parameter	Value
<b>Log Source type</b>	Amazon AWS Security Hub
<b>Protocol Configuration</b>	Amazon Web Services
<b>Log Source Identifier</b>	The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one Amazon AWS Security Hub log source that is configured, you might want to identify the first log source as awssecurityhub1, the second log source as awssecurityhub2, and the third log source as awssecurityhub3.

For a complete list of Amazon Web Services protocol parameters and their values for collecting AWS CloudWatch logs, see [Amazon Web Services protocol configuration options](#).

## Amazon AWS WAF

The IBM QRadar DSM for Amazon AWS WAF collects Amazon AWS REST API events from an Amazon AWS WAF service.

To integrate Amazon AWS WAF with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol Common RPM
  - Protocol Amazon Web Services RPM
  - Protocol Amazon AWS REST API RPM
  - Amazon AWS WAF DSM RPM
2. Configure your Amazon AWS WAF service to send events to QRadar. For more information about configuring Amazon AWS WAF, see [Configuring Amazon AWS WAF to communicate with QRadar](#).
3. Add an Amazon AWS WAF log source on the QRadar Console. For more information about configuring the log source parameters, see [Amazon AWS S3 REST API log source parameters for Amazon AWS WAF](#).

## Amazon AWS WAF DSM specifications

When you configure the Amazon AWS WAF DSM, understanding the specifications for the Amazon AWS WAF DSM can help ensure a successful integration. For example, knowing what event types are supported by Amazon AWS WAF before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Amazon AWS WAF DSM.

Table 206. Amazon AWS WAF DSM specifications	
Specification	Value
Manufacturer	Amazon AWS
DSM name	Amazon AWS WAF

Table 206. Amazon AWS WAF DSM specifications (continued)

Specification	Value
RPM file name	DSM-AmazonAWSWAF-QRadar_version-build_number.noarch.rpm
Protocol	Amazon AWS S3 REST API
Event format	JSON
Recorded event types	Traffic allow, Traffic block
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://docs.aws.amazon.com/waf/latest/developerguide/waf-auth-and-access-control.html">AWS WAF documentation</a> ( <a href="https://docs.aws.amazon.com/waf/latest/developerguide/waf-auth-and-access-control.html">https://docs.aws.amazon.com/waf/latest/developerguide/waf-auth-and-access-control.html</a> )

## Configuring Amazon AWS WAF to communicate with QRadar

Before you can add a log source in IBM QRadar, you must configure Amazon AWS WAF to send logs to an Amazon Kinesis Data Firehouse Delivery Stream that uses an Amazon AWS S3 bucket.

### Before you begin

You must have an Amazon Kinesis Data Firehose Delivery Stream configured. For more information, see the Amazon documentation about [Creating an Amazon Kinesis Data Firehose Delivery Stream](https://docs.aws.amazon.com/firehose/latest/dev/basic-create.html) (<https://docs.aws.amazon.com/firehose/latest/dev/basic-create.html>). The delivery stream must be linked to the Amazon AWS S3 Bucket.

### About this task

Logging must be enabled to forward events to QRadar. If you don't have logging enabled for Amazon AWS WAF, complete the following steps.

### Procedure

1. Log in to your [IAM console](https://console.aws.amazon.com/iam/) (<https://console.aws.amazon.com/iam/>).
2. Click **Services > WAF & Shield**.
3. From the **WAF & Shield** navigation menu, select **Web ACLs**.
4. Click the **Logging and metrics** tab.
5. To enable logging, click **Enable logging**.
6. From the region list, select your region.
7. From the **Web ACLs** list, select the Amazon Kinesis Data Firehose Delivery Stream that is linked to your Amazon AWS S3 bucket.
8. Click **Enable Logging**.

### What to do next

[Add a log source in QRadar](#).

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

[Adding a log source](#)

## Amazon AWS S3 REST API log source parameters for Amazon AWS WAF

If QRadar does not automatically detect the log source, add an Amazon AWS WAF log source on the QRadar Console by using the Amazon AWS S3 REST API protocol.

When you use the Amazon AWS S3 REST API protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Amazon AWS S3 REST API events from Amazon AWS WAF:

Table 207. Amazon AWS S3 REST API log source parameters for the Amazon AWS WAF DSM	
Parameter	Value
<b>Log Source type</b>	<b>Amazon AWS WAF</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source. The Log Source Identifier can be any valid value and does not need to reference a specific server. The Log Source Identifier can be the same value as the Log Source Name. If you have more than one Amazon AWS WAF log source that is configured, you might want to identify the first log source as awswaf1, the second log source as awswaf2, and the third log source as awswaf3.
<b>Authentication Method</b>	<b>Access Key ID / Secret Key</b>
<b>Access Key</b>	The Access key ID that you created when you configured your AWS security credentials. For more information, see <a href="#">Configuring security credentials for your AWS user account</a> .
<b>Secret Key</b>	The Secret access key that you created when you configured your AWS security credentials. For more information, see <a href="#">Configuring security credentials for your AWS user account</a> .

Table 207. Amazon AWS S3 REST API log source parameters for the Amazon AWS WAF DSM (continued)

Parameter	Value
<b>S3 Collection Method</b>	<b>SQS Event Notifications</b>
<b>SQS Queue URL</b>	The full URL that begins with https://, for the SQS Queue that is set up to receive notifications for ObjectCreated events from S3.
<b>Region Name</b>	The region that is assigned to your Amazon AWS WAF. Example: us-east-2
<b>Event Format</b>	<b>LINEBYLINE</b>

For a complete list of Amazon AWS S3 REST API protocol parameters and their values, see [Amazon AWS S3 REST API protocol configuration options](#).

## Amazon AWS WAF sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Amazon AWS WAF sample messages when you use the Amazon AWS S3 REST API protocol

**Sample 1:** The following sample event message shows that Amazon AWS WAF allowed access the underlying resource.

```
{"timestamp":1613576332142,"formatVersion":1,"webaclId":"webaclId","terminatingRuleId":"First_Rule","terminatingRuleType":"REGULAR","action":"ALLOW","terminatingRuleMatchDetails":[],"httpSourceName":"APIGW","httpSourceId":"111111111111:1111111111:First_API_Gateway","ruleGroupList":[],"rateBasedRuleList":[],"nonTerminatingMatchingRules":[],"requestHeadersInserted":null,"responseCodeSent":null,"httpRequest":{"clientIp":"10.2.173.13","country":"country","headers":[{"name":"accept","value":"text/html,application/xhtml+xml,application/xml;q=0.9,image/avif,image/webp,image/apng,*/*;q=0.8,application/signed-exchange;v=b3;q=0.9"}, {"name":"accept-encoding","value":"gzip, deflate, br"}, {"name":"accept-language","value":"en-US,en;q=0.9"}, {"name":"cache-control","value":"max-age=0"}, {"name":"Host","value":"1111111111.execute-api.region.amazonaws.com"}, {"name":"sec-fetch-dest","value":"document"}, {"name":"sec-fetch-mode","value":"navigate"}, {"name":"sec-fetch-site","value":"none"}, {"name":"sec-fetch-user","value":"?1"}, {"name":"upgrade-insecure-requests","value":1}, {"name":"user-agent","value":"Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/88.0.4324.150 Safari/537.36"}, {"name":"X-Amzn-Trace-Id","value": "Root=1-11111aaaaa111111"}, {"name":"X-Forwarded-For","value": "10.2.173.13"}, {"name":"X-Forwarded-Port","value": "443"}, {"name":"X-Forwarded-Proto","value": "https"}, {"name":"Content-Length","value": "0"}, {"name":"Connection","value": "Keep-Alive"}], "uri":"/First_API_Gateway/pets","args": "", "httpVersion": "HTTP/1.1", "httpMethod": "GET", "requestId": "111111aaaa1aaa1"}}
```

Table 208. Highlighted fields in the Amazon AWS WAF sample event

QRadar field name	Highlighted values in the event payload
<b>Event ID</b>	<b>ALLOW</b>
<b>Event Category</b>	For this DSM, the value in QRadar is always <b>AmazonAWSWAF</b> .
<b>Timestamp</b>	<b>1613576332142</b>
<b>Src IP</b>	<b>10.2.173.13</b>

**Sample 2:** The following sample event message shows that Amazon AWS WAF blocked traffic to the underlying resource.

```
{"timestamp":16135764421213,"formatVersion":1,"webaclId":"webaclId","terminatingRuleId":"First_Rule","terminatingRuleType":"REGULAR","action":"BLOCK","terminatingRuleMatchDetails":[],"httpSourceName":"APIGW","httpSourceId":1111111111111111:First_API_Gateway","ruleGroupList":[],"rateBasedRuleList":[],"nonTerminatingMatchingRules":[],"requestHeadersInserted":null,"responseCodeSent":null,"httpRequest":{"clientIp":"10.2.173.14","country":"country","headers":[{"name":"accept","value":"text/html,application/xhtml+xml,application/xml;q=0.9,image/avif,image/webp,image/apng,*/*;q=0.8,application/signed-exchange;v=b3;q=0.9"}, {"name":"accept-encoding","value":"gzip, deflate, br"}, {"name":"accept-language","value":"en-US,en;q=0.9"}, {"name":"cache-control","value":"max-age=0"}, {"name":"Host","value":1111111111.execute-api.region.amazonaws.com}], "name":"sec-fetch-dest","value":"document"}, {"name":"sec-fetch-mode","value":"navigate"}, {"name":"sec-fetch-site","value":"none"}, {"name":"sec-fetch-user","value":"?1"}, {"name":"upgrade-insecure-requests","value":1}, {"name":"user-agent","value":"Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/88.0.4324.150 Safari/537.36"}, {"name":"X-Amzn-Trace-Id","value":Root=1-11111aaaa11111111}, {"name":"X-Forwarded-For","value":10.2.173.13}, {"name":"X-Forwarded-Port","value":443}, {"name":"X-Forwarded-Proto","value":https}, {"name":"Content-Length","value":0}, {"name":"Connection","value":Keep-Alive}], "uri":"/First_API_Gateway/pets", "args": "", "httpVersion":HTTP/1.1, "httpMethod":GET, "requestId":111111aaaa1aaa1}], "value":16135764421213}, "srcIP":10.2.173.14}
```

Table 209. Highlighted values in the Amazon AWS WAF sample event

QRadar field name	Highlighted values in the event payload
Event ID	BLOCK
Event Category	For this DSM, the value in QRadar is always <b>AmazonAWSWAF</b> .
Timestamp	16135764421213
Src IP	10.2.173.14

## Amazon CloudFront

The IBM QRadar DSM for Amazon CloudFront collects events from Amazon S3 Buckets and Amazon Kinesis Data Streams.

The following table lists the specifications for the Amazon CloudFront DSM:

Table 210. Amazon CloudFront DSM specifications

Specification	Value
Manufacturer	Amazon
DSM	Amazon CloudFront
RPM name	DSM-AmazonCloudFront-QRadar_version-Build_number.noarch.rpm
Supported protocols	Amazon Web Services
Event format	Tab Separated Value (TSV)
Recorded event types	RealTime Log - TSV
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://docs.aws.amazon.com/AmazonCloudFront/latest/DeveloperGuide/real-time-logs.html">Amazon CloudFront documentation</a> ( <a href="https://docs.aws.amazon.com/AmazonCloudFront/latest/DeveloperGuide/real-time-logs.html">https://docs.aws.amazon.com/AmazonCloudFront/latest/DeveloperGuide/real-time-logs.html</a> )

## Related concepts

# Configuring an Amazon CloudFront log source by using the Amazon Web Services protocol and Kinesis Data Streams

Before you can add a log source that uses the Amazon Web Services protocol in IBM QRadar, you must create a data stream and then create a real-time log configuration on the AWS Management Console.

## Procedure

1. On the AWS Management console, create a data stream. For more information, see [Creating a stream via the AWS Management Console](#).
2. On the AWS Management console, create real-time logs. For more information, see [Real-time logs](#).

3. [Create a real-time log configuration on the AWS Management Console.](#)

**Important:** Real-time log configuration requires all 40 fields to be configured. For more information, see [Understanding real-time log configurations](#).

The position/index number for the following fields must be as documented in the [Amazon AWS Fields documentation](#):

- timestamp
- c-ip
- sc-status
- x-edge
- x-edge-result-type
- c-port
- x-edge-detailed-result-type

For example, the c-ip position, is in the 2 position and the x-edge-detailed-result-type is in the 33rd position.

4. Add an Amazon CloudFront log source in QRadar. [Adding an Amazon CloudFront log source by using the Amazon Web Services protocol an Kinesis Data Streams.](#)

[“Adding a log source” on page 5](#)

#### ***Adding an Amazon CloudFront log source by using the Amazon Web Services protocol and Kinesis Data Streams***

If you want to collect Amazon CloudFront logs from Amazon Kinesis Data Streams, add a log source on the QRadar Console so that Amazon CloudFront can communicate with QRadar by using the Amazon Web Services protocol.

#### Procedure

1. The following table describes the parameters that require specific values to collect audit events from Amazon CloudFront by using the Amazon Web Services protocol:

*Table 211. Amazon Web Services log source parameters for Amazon Kinesis Data Streams*

Parameter	Description
Protocol Configuration	Select <b>Amazon Web Services</b> from the Protocol Configuration list.
Authentication Method	<b>Access Key ID/Secret Key</b> Standard authentication that can be used from anywhere. <b>EC2 Instance IAM Role</b> If your QRadar managed host is running in an AWS EC2 instance, choosing this option uses the IAM role from the metadata that is assigned to the instance for authentication. No keys are required. This method works only for managed hosts that are running within an AWS EC2 container.

Table 211. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Access Key</b>	The Access Key ID that was generated when you configured the security credentials for your AWS user account.  If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Access Key</b> parameter is displayed.
<b>Secret Key</b>	The Secret Key that was generated when you configured the security credentials for your AWS user account.  If you selected <b>Access Key ID / Secret Key</b> or <b>Assume IAM Role</b> , the <b>Secret Key</b> parameter is displayed.
<b>Assume an IAM Role</b>	Enable this option to authenticate with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access.
<b>Assume Role ARN</b>	The full ARN of the role to assume. It must begin with "arn:" and can't contain any leading or trailing spaces, or spaces within the ARN.  If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role ARN</b> parameter is displayed.
<b>Assume Role Session Name</b>	The session name of the role to assume. The default is QRadarAWSsession. Leave as the default if you don't need to change it. This parameter can contain only upper and lowercase alphanumeric characters, underscores, or any of the following characters: =, . @-  If you enabled <b>Assume an IAM Role</b> , the <b>Assume Role Session Name</b> parameter is displayed.
<b>Assume Role External ID</b>	<b>Assume Role External ID</b> is an optional identifier that is required to assume a role in a different account.  If the account administrator, to which the role belongs, provides you with an external ID, then insert that value in the <b>Assume Role External ID</b> parameter.  This value can either be a string, a passphrase, a GUID, or an account number. For more information, see AWS documentation <a href="#">Using an external ID for third-party access</a> .
<b>Regions</b>	Toggle each region that is associated with the Amazon Web Service that you want to collect logs from.
<b>AWS Service</b>	From the <b>AWS Service</b> list, select <b>Kinesis Data Streams</b> .
<b>Kinesis Data Stream</b>	The Kinesis Data Stream from which to consume data.

Table 211. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Enable Kinesis Advanced Options</b>	<p>Enable the following optional advanced configuration values. Advanced option values are only used when this option is chosen; otherwise, the default values are used.</p> <p><b>Initial Position in Stream</b>  This option controls which data to pull on a newly configured log source. Select <b>Latest</b> to pull the latest data that is available. Select <b>Trim Horizon</b> to pull the oldest data that is available.</p> <p><b>Kinesis Worker Thread Count</b>  The number of worker threads to use for Kinesis Data Stream processing. Each worker thread can process approximately 10000 - 20000 events per second depending on record size and system load. If your log source is not able to process the new data in the stream, you can increase the number of threads here to a maximum of 16. The allowed range is 1 - 16. The default value is 2.</p> <p><b>Checkpoint Interval</b>  The interval (in seconds) at which to checkpoint data sequence numbers. Each record from a shard in a Kinesis Data Stream has a sequence number. Checkpointing your position allows this shard to resume processing at the same point if processing fails or a service restarts. A more frequent interval reduces data duplication but increases Amazon Dynamo DB usage. The allowed range is 1 - 3600 seconds. The default is 10 seconds.</p> <p><b>Kinesis Application</b>  Leave this option blank to have this log source consume data from all available shards in the Kinesis Data Stream. To have multiple log sources on multiple event processors scale log consumption without loss or duplication, use a common Kinesis Application across those log sources (Example: ProdKinesisConsumers).</p> <p><b>Partition</b>  Select this option to collect data from a specific partition in the Kinesis Data Stream by specifying a partition name.</p>

Table 211. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Extract Original Event</b>	<p>Fowards only the original event that was added to the Kinesis Data Stream. Kinesis logs wrap the events that they receive with extra metadata. Select this option if you want only the original event that was sent to AWS without the additional stream metadata through Kinesis.</p> <p>The original event is the value for the message key that is extracted from the Kinesis log. The following Kinesis logs event example shows the original event that is extracted from the Kinesis log in highlighted text:</p> <pre>{"owner": "123456789012", "subscriptionFilters": ["allEvents"], "logEvents": [{"id": "35093963143971327215510178578576502306458824699048362100", "message": "{\"eventVersion\": \"1.05\", \"userIdentity\": {\"type\": \"AssumedRole\", \"principalId\": \"ARO1GH58EM3ESYDW3XHP6:test_session\", \"arn\": \"arn:aws:sts::123456789012:assumed-role/CVDevABRoleToBeAssumed/test_visibility_session\", \"accountId\": \"123456789012\", \"accessKeyId\": \"ASIAXXXXXXXXXXXXXX\", \"sessionContext\": {\"sessionIssuer\": {\"type\": \"Role\", \"principalId\": \"AROAXXXXXXXXXXXXXXXX\", \"arn\": \"arn:aws:iam::123456789012:role/CVDevABRoleToBeAssumed\", \"accountId\": \"123456789012\", \"userName\": \"CVDevABRoleToBeAssumed\", \"webIdFederationData\": {}}, \"attributes\": {\"mfaAuthenticated\": \"false\", \"creationDate\": \"2019-11-13T17:01:54Z\", \"eventTime\": \"2019-11-13T17:43:18Z\", \"eventSource\": \"cloudtrail.amazonaws.com\", \"eventName\": \"DescribeTrails\", \"awsRegion\": \"ap-northeast-1\", \"sourceIPAddress\": \"192.0.2.1\", \"requestParameters\": {\"null\", \"responseElements\": null, \"requestID\": \"41e62e80-b15d-4e3f-9b7e-b309084dc092\", \"eventID\": \"904b3fda-8e48-46c0-a923-f1bb2b7a2f2a\", \"readOnly\": true, \"eventType\": \"AwsApiCall\", \"recipientAccountId\": \"123456789012\"}, \"timestamp\": 1573667733143}, \"messageType\": \"DATA_MESSAGE\", \"logGroup\": \"CloudTrail\\DefaultLogGroup\", \"logStream\": \"123456789012_CloudTrail_us-east-2_2\"}}</pre>
<b>Use As A Gateway Log Source</b>	<p>Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.</p> <p>When you select this option, the <b>Log Source Identifier Pattern</b> can optionally be used to define a custom <b>Log Source Identifier</b> for events that are being processed.</p>

Table 211. Amazon Web Services log source parameters for Amazon Kinesis Data Streams (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>If you selected <b>Use As A Gateway Log Source</b>, you can define a custom log source identifier for events that are being processed and for log sources to be automatically discovered when applicable. If you don't configure the <b>Log Source Identifier Pattern</b>, QRadar receives events as unknown generic log sources.</p> <p>Use key-value pairs to define the custom Log Source Identifier. The key is the Identifier Format String, which is the resulting source or origin value. The value is the associated regex pattern that is used to evaluate the current payload. This value also supports capture groups that can be used to further customize the key.</p> <p>Define multiple key-value pairs by typing each pattern on a new line. Multiple patterns are evaluated in the order that they are listed. When a match is found, a custom Log Source Identifier is displayed.</p> <p>The following examples show multiple key-value pair functions.</p> <p><b>Patterns</b></p> <pre>VPC=\sREJECT\sFAILURE \$1=\s(REJECT)\sOK VPC-\$1-\$2=\s(ACCEPT)\s(OK)</pre> <p><b>Events</b></p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre> <p><b>Resulting custom log source identifier</b></p> <p>VPC-ACCEPT-OK</p>
<b>Use Predictive Parsing</b>	<p>If you enable this parameter, an algorithm extracts log source identifier patterns from events without running the regex for every event, which increases the parsing speed.</p> <p><b>Tip:</b> In rare circumstances, the algorithm can make incorrect predictions. Enable predictive parsing only for log source types that you expect to receive high event rates and require faster parsing.</p>
<b>Use Proxy</b>	<p>If QRadar accesses the Amazon Web Service by using a proxy, select this option.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy IP or Hostname</b> field.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

2. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

The actual CloudFront logs are wrapped in a Kinesis Data Streams tab-separated value (TSV) payload:

Table 212. Kinesis Data Streams sample message supported by the Amazon CloudFront DSM

Event name	Low-level category	Sample log message
hit_ok	Request Successful	<pre>1663583003.838 2001:DB8:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF timeToFirstByte status scbytes GET https host /uri csbytes xEdgeLocation xedgeRequestId xHostHeader timeTaken csProtocolVersion cIpversion userAgent csReferer cs-cookie csUriQuery xEdgeResultResponseType xForwardedFor sslProtocol sslCipher xEdgeResultType fileEncryptedFields fileStatus scContentType scContentLen scRangeStart scRangeEnd 80 xEdgeDetailedResultType country csAcceptEncoding csAccept cacheBehaviour csHeader csHeaderName csHeaderCount</pre>

## Amazon CloudFront sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## Amazon CloudFront sample message when you use the Amazon Web Services protocol

The following sample event message describes trails.

```
1663583003.838 2001:DB8:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF timeToFirstByte status
scbytes GET https host /uri csbytes xEdgeLocation xedgeRequestId
xHostHeader timeTaken csProtocolVersion cIpversion userAgent csReferer cs-cookie csUriQuery
xEdgeResultResponseType xForwardedFor sslProtocol sslCipher
xEdgeResultType fileEncryptedFields fileStatus scContentType scContentLen scRangeStart
scRangeEnd 80 xEdgeDetailedResultType country csAcceptEncoding csAccept cacheBehaviour csHeader
csHeaderName csHeaderCount
```

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

## Amazon GuardDuty

The IBM QRadar DSM for Amazon GuardDuty collects Amazon GuardDuty events from the log group of the Amazon CloudWatch logs services.

The following table identifies the specifications for the Amazon GuardDuty DSM:

Table 213. Amazon GuardDuty DSM specifications	
Specification	Value
Manufacturer	Amazon
DSM name	Amazon GuardDuty
RPM file name	DSM-AmazonGuardDuty-QRadar_version-buildbuild_number.noarch.rpm
Supported versions	GuardDuty Schema Version 2.0
Protocol	Amazon Web Services Amazon AWS REST API
Event format	JSON
Recorded event types	Amazon GuardDuty Findings
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	For more information, see the <a href="https://aws.amazon.com/documentation/guardduty">Amazon GuardDuty Documentation</a> ( <a href="https://aws.amazon.com/documentation/guardduty">https://aws.amazon.com/documentation/guardduty</a> ).

## Configuring an Amazon GuardDuty log source by using the Amazon Web Services protocol

If you want to collect Amazon GuardDuty logs from the Amazon Cloud Watch group, configure a log source on the IBM QRadar Console so that Amazon Guard Duty can communicate with QRadar by using the Amazon Web Services protocol.

### Procedure

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](https://www.ibm.com/support/fixcentral) (<https://www.ibm.com/support/fixcentral>) onto your QRadar Console:
  - Protocol Common RPM
  - Amazon Web Services Protocol RPM
  - DSMCommon RPM
  - Amazon GuardDuty DSM RPM
2. Create and configure an Amazon EventBridge rule to send events from AWS Security Hub to AWS CloudWatch log group.
3. Create an Identity and Access (IAM) user in the Amazon AWS user interface when using the Amazon Web Services protocol.
4. Add a Log source for Amazon GuardDuty on the QRadar Console. The following table describes the Amazon Web Services protocol parameters that require specific values for Amazon GuardDuty Logs collection:

Table 214. Amazon GuardDuty Web Services protocol parameters

Parameter	Value
<b>Log source type</b>	<b>Amazon GuardDuty</b>
<b>Protocol configuration</b>	<b>Amazon Web Services</b>
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>  Standard authentication that can be used anywhere.</p> <p><b>EC2 Instance IAM Role</b>  If your QRadar managed host is running in an AWS EC2 instance, choose this option to use the <b>IAM Role</b> from the metadata assigned to the instance for authentication. No keys are required.</p> <p><b>Note:</b> This method works only for managed hosts that run within an AWS EC2 container.</p>
<b>Access Key ID</b>	<p>If you selected <b>Access Key ID / Secret Key</b>, the <b>Access Key ID</b> parameter displays.</p> <p>The <b>Access Key ID</b> was generated when you configured the security credentials for your AWS user account.</p> <p>For more information about configuring the security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p>
<b>Secret Access Key</b>	<p>If you selected <b>Access Key ID / Secret Key</b>, the <b>Secret Access Key</b> parameter displays.</p> <p>The <b>Secret Key</b> was generated when you configured the security credentials for your AWS user account.</p> <p>For more information about configuring the security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p>
<b>Regions</b>	Select the check box for each region that is associated with the Amazon Web Service that you want to collect logs from.
<b>Other Regions</b>	<p>Type the names of any additional regions that are associated with the Amazon Web Service that you want to collect logs from.</p> <p>To collect from multiple regions, use a comma-separated list, such as the following example:  region1,region2</p>
<b>AWS Service</b>	<p>The name of the Amazon Web Service.</p> <p>From the <b>AWS Service</b> list, select <b>CloudWatch Logs</b>.</p>

Table 214. Amazon GuardDuty Web Services protocol parameters (continued)

Parameter	Value
<b>Log Group</b>	<p>The name of the log group in Amazon CloudWatch where you want to collect logs from.</p> <p><b>Tip:</b> A single log source can collect CloudWatch logs from only one log group at a time. If you want to collect logs from multiple log groups, create a separate log source for each log group.</p>
<b>Log Stream (Optional)</b>	<p>The name of the log stream within a log group that you want to collect logs from.</p>
<b>Filter Pattern (Optional)</b>	<p>Type a pattern for filtering the collected events. This pattern is not a regex filter. Only the events that contain the exact value that you specify are collected from CloudWatch Logs.</p> <p>If you enter <b>ACCEPT</b> as the Filter Pattern value, only events that contain the word <b>ACCEPT</b> are collected. The following example shows the effect of the <b>ACCEPT</b> value:</p> <pre>{LogStreamName: LogStreamTest, Timestamp: 0, Message: ACCEPT OK, IngestionTime: 0, EventId: 0}</pre>
<b>Extract Original Event</b>	<p>CloudWatch Logs wrap events that it receives with extra metadata. If you want only the original event that was added to the CloudWatch logs to be forwarded to QRadar, select this option. The original event is the value for the message key that is extracted from the CloudWatch Logs.</p> <p>The following CloudWatch logs event example shows the original event that is extracted from the CloudWatch log in bold text:</p> <pre>{LogStreamName: guardDutyLogStream, Timestamp: 1519849569827, Message: {"version": "0", "id": "00-00", "detail-type": "GuardDuty Finding", "account": "1234567890", "region": "us-west-2", "resources": [], "detail": {"schemaVersion": "2.0", "accountId": "1234567890", "region": "us-west-2", "partition": "aws", "type": "Behavior:IAMUser/InstanceLaunchUnusual", "severity": 5.0, "createdAt": "2018-02-28T20:22:26.344Z", "updatedAt": "2018-02-28T20:22:26.344Z"}, "IngestionTime: 1519849569862, EventId: 0000}</pre>
<b>Use As A Gateway Log Source</b>	<p>Do not select this check box.</p>

Table 214. Amazon GuardDuty Web Services protocol parameters (continued)

Parameter	Value
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> . If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Automatically Acquire Server Certificates</b>	If you select <b>Yes</b> from the list, QRadar downloads the certificate and begins trusting the target server. This function can be used to initialize a newly created log source and obtain certificates initially, or to replace expired certificates.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

#### Related tasks

[“Creating an EventBridge rule for sending events” on page 425](#)

You need to create and configure an Amazon EventBridge rule to send events from AWS Security Hub to AWS CloudWatch log group.

[“Creating an Identity and Access \(IAM\) user in the AWS Management Console” on page 332](#)

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Creating an EventBridge rule for sending events

You need to create and configure an Amazon EventBridge rule to send events from AWS Security Hub to AWS CloudWatch log group.

#### Procedure

1. Go to [Amazon EventBridge](#).
2. In the **Create a new rule** pane, click **Create rule**.
3. In the **Name and description** pane, type a name for your rule in the **Name** field and if you want, type a description for your rule in the **Description** field.
4. In the **Define pattern** pane, select **Event pattern**, and then select **Pre-defined pattern by service** to build an event pattern.
5. From the **Service provider** list, select **AWS**.
6. From the **Service name** list, select **GuardDuty**.
7. From the **Event type** list, select **All Events**.
8. In the **Select event bus** pane, select **AWS default event bus**.
9. In the **Select targets** pane, from the **Target** list, select **CloudWatch log group**.

10. In the **Log Group**: section, specify a new log group or select an existing log group from the list.

**Important:** You need the name of the log group when you configure a log source in QRadar.

11. Click **Create**.

### What to do next

[Creating an Identity and Access \(IAM\) user in the AWS Management Console](#)

## Creating an Identity and Access (IAM) user in the AWS Management Console

An Amazon administrator must create a user and then apply the **CloudWatchLogsReadOnlyAccess** policy in the AWS Management Console. The QRadar user can then create a log source in QRadar.

### Procedure

1. Log in to the AWS Management Console as an administrator.

2. Create an Amazon AWS IAM user and then apply the **CloudWatchLogsReadOnlyAccess** policy.

### What to do next

[Amazon Web Services log source parameters for Amazon AWS Security Hub](#)

## Configuring an Amazon GuardDuty log source by using the Amazon AWS S3 REST API protocol

If you want to collect Amazon GuardDuty findings when you use an AWS S3 Bucket, add a log source in IBM QRadar by using the Amazon AWS S3 REST API protocol.

### Procedure

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:

- Protocol Common RPM
- Amazon AWS REST API Protocol RPM
- DSMCommon RPM
- Amazon GuardDuty DSM RPM

2. Configure Amazon GuardDuty to forward events to an AWS S3 Bucket.

3. Use the following table to set the parameters for an Amazon AWS CloudTrail log source that uses the Amazon AWS S3 REST API protocol.

*Table 215. Amazon AWS S3 REST API protocol log source parameters*

Parameter	Description
<b>Log Source Type</b>	<b>Amazon GuardDuty</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>

Table 215. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>  Standard authentication that can be used from anywhere.  For more information about configuring security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p> <p><b>EC2 Instance IAM Role</b>  If your QRadar managed host is running in an AWS EC2 instance, choose this option to use the <b>IAM Role</b> from the metadata that is assigned to the instance for authentication. No keys are required.</p> <p><b>Important:</b> This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key ID</b>	<p>If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b>, configure this parameter.</p> <p>The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account.</p> <p>For more information about configuring the security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p>
<b>Secret Key</b>	<p>If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b>, configure this parameter.</p> <p>The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Secret Key ID</b> that is used to access the AWS S3 bucket.</p> <p>For more information about configuring the security credentials, see <a href="#">Configuring security credentials for your AWS user account</a>.</p>
<b>S3 Collection Method</b>	<p>Select one of the following collection methods.</p> <ul style="list-style-type: none"> <li>• <b>SQS Event Notifications</b></li> <li>• <b>Use a Specific Prefix - Single Account/Region Only</b></li> </ul>
<b>SQS Queue URL</b>	<p>If you selected <b>SQS Event Notifications</b> for the <b>S3 Collection Method</b>, configure this parameter.</p> <p>This field uses the full url of the SWS setup, beginning with <code>https://</code>, to receive notifications for ObjectCreate events from S3. For example, <code>https://sqs.us-east-2.amazonaws.com/1234567890123/CloudTrail_SQS_QRadar</code></p> <p>For more information, see the <a href="#">Configuring Amazon S3 event notifications</a> link to public site website (<a href="https://docs.aws.amazon.com/AmazonS3/latest/dev/NotificationHowTo.html">https://docs.aws.amazon.com/AmazonS3/latest/dev/NotificationHowTo.html</a>)</p> <p>To ensure that all data is processed and messages are deleted from the queue after the files are successfully processed, this configuration must be the only consumer of this queue.</p>

Table 215. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Bucket Name</b>	If you selected <b>Use a Specific Prefix - Single Account/Region Only</b> for the <b>S3 Collection Method</b> , configure this parameter.  The name of the AWS S3 bucket where the log files are stored.
<b>Directory Prefix</b>	If you selected <b>Use a Specific Prefix - Single Account/Region Only</b> for the <b>S3 Collection Method</b> , configure this parameter.  The root directory location on the AWS S3 bucket from where the CloudTrail logs are retrieved; for example, AWSLogs/<AccountNumber>/CloudTrail/<RegionName>/  To pull files from the root directory of a bucket, you must use a forward slash (/) in the <b>Directory Prefix</b> file path.  <b>Tip:</b> <ul style="list-style-type: none"> <li>• Changing the <b>Directory Prefix</b> value clears the persisted file marker. All files that match the new prefix are downloaded in the next pull.</li> <li>• The <b>Directory Prefix</b> file path cannot begin with a forward slash (/) unless only the forward slash is used to collect data from the root of the bucket.</li> <li>• If the <b>Directory Prefix</b> file path is used to specify folders, you must not begin the file path with a forward slash (for example, use folder1/folder2 instead).</li> </ul>
<b>Region Name</b>	The region that the SQS Queue or the S3 Bucket is in.  Example: us-east-1, eu-west-1, ap-northeast-3
<b>Event Format</b>	Select <b>LINEBYLINE</b> . The log files that are collected contain one record per line.  Compression with gzip (.gz or .gzip) and zip (.zip) is supported.
<b>Use as a Gateway Log Source</b>	Do not enable this option.
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> .  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Automatically Acquire Server Certificate</b>	If you select Yes from the list, QRadar downloads the certificate and begins trusting the target server.  This function can be used to initialize a newly created log source and obtain certificates initially, or to replace expired certificates.

Table 215. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your [IAM](#) console.
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### Related information

[Adding a log source](#)

## Configuring an Amazon GuardDuty log source that uses Amazon Security Lake

You can collect Amazon GuardDuty logs from multiple accounts or regions in an Amazon S3 bucket. IBM QRadar uses the Amazon AWS S3 REST API protocol to communicate with Amazon Security Lake, where QRadar obtains the Amazon GuardDuty logs.

### Procedure

1. Configure Amazon Security Lake to log Open Cybersecurity Schema Framework (OCSF) data in Parquet format to an S3 bucket. For more information, see [Collecting data from custom sources](#).  
**Note:** The supported OCSF version of the DSM is OCSF 1.0RC2. The version OCSF 1.1 is not currently supported.
2. Configure access to the OCSF data in Amazon Security Lake by using one of two methods.
  - To create a subscriber to provision the SQS queue and IAM role, see step 3.  
For more information about creating a subscriber, see [Managing data access for Security Lake subscribers](#).
  - To manually configure the SQS queue and ObjectCreated notifications, see step 4.
3. Create a subscriber to provision the SQS queue and IAM role.
  - a) When you create the subscription, take note of the following values: **SQS Queue URL**, **IAM Role ARN**, and **External ID**.
  - b) If you plan to access this subscription from a different account than where Amazon Security Lake is set up, you must provide that account ID to configure the trust relationship properly.

4. Manually configure the SQS queue and ObjectCreated notifications.
  - a) Configure an SQS queue to receive ObjectCreated notifications with either [Amazon S3 Event Notifications](#) or [AWS EventBridge](#) when new OCSF Parquet data is available in the Amazon Security Lake bucket in the folder you choose.
  - b) Provision access keys with permission (either directly or with an **IAM Assume Role**) to access both the SQS queue and the bucket that contain the Amazon Security Lake data.
- For more information, see “[Create an SQS queue and configure S3 ObjectCreated notifications](#)” on [page 308](#).

5. Configure a log source in QRadar to collect and parse the data.

**Tip:** When new OCSF parquet data is available, a message that contains the bucket name and object key of the file with the data to be processed is sent to the SQS queue. QRadar then downloads and processes this file.

## What to do next

Add a CloudTrail log source in QRadar. For more information, see [“Adding an Amazon GuardDuty log source on the QRadar Console using an SQS queue” on page 439](#).

### Related information

[What Is Amazon EventBridge?](#)

[Amazon S3 Event Notifications](#)

## Create an SQS queue and configure S3 ObjectCreated notifications

Before you can add a log source in IBM QRadar, you must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

Complete the following procedures:

1. [Finding the S3 Bucket that contains the data that you want to collect](#).
2. [Creating the SQS queue that is used to receive the ObjectCreated notifications from the S3 Bucket that you used in Step 1](#).
3. [Setting up SQS queue permissions](#).
4. [Creating ObjectCreated notifications](#).

### Finding the S3 bucket that contains the data that you want to collect

You must find and note the region for S3 bucket that contains the data that you want to collect.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to **S3**.
3. From the **AWS Region** column in the **Buckets** list, note the region where the bucket that you want to collect data from is located. You need the region for the **Region Name** parameter value when you add a log source in IBM QRadar.
4. Enable the checkbox beside the bucket name, and then from the panel that opens to the right, click **Copy Bucket ARN** to copy the value to the clipboard. Save this value or leave it on the clipboard. You need this value when you set up **SQS queue permissions**.

### Creating the SQS queue that is used to receive ObjectCreated notifications

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

## Before you begin

You must complete **Finding the S3 Bucket that contains the data that you want to collect**. The SQS Queue must be in the same region as the AWS S3 bucket that the queue is collecting from.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to the Simple Queue Service Management Console.
3. In the upper right of the window, change the region to where the bucket is located. You noted this value when you completed the **Finding the S3 Bucket that contains the data that you want to collect** procedure.
4. Select **Create New Queue**, and then type a value for the **Queue Name**.
5. Click **Standard Queue**, select **Configure Queue**, and then change the default values for the following **Queue Attributes**.
  - **Default Visibility Timeout** - 60 seconds (You can use a lower value. In the case of load balanced collection, duplicate events might occur with values of less than 30 seconds. This value can't be 0.)
  - **Message Retention Period** - 14 days (You can use a lower value. In the event of an extended collection, data might be lost.)

Use the default value for the remaining **Queue Attributes**.

More options such as **Redrive Policy** or **SSE** can be used depending on the requirements for your AWS environment. These values should not affect the data collection.

Queue Attributes

<b>Default Visibility Timeout</b>  60	seconds 	Value must be between 0 seconds and 12 hours.
<b>Message Retention Period</b>  14	days 	Value must be between 1 minute and 14 days.
<b>Maximum Message Size</b>  256	KB	Value must be between 1 and 256 KB.
<b>Delivery Delay</b>  0	seconds 	Value must be between 0 seconds and 15 minutes.
<b>Receive Message Wait Time</b>  0	seconds	Value must be between 0 and 20 seconds.

Picture © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

6. Select **Create Queue**.

## Setting up SQS queue permissions

You must set up SQS queue permissions for users to access the queue.

## Before you begin

You must complete **Creating the SQS queue that is used to receive ObjectCreated notifications**.

You can set the SQS queue permissions by using either the Permissions Editor or a JSON policy document.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Go to the SQS Management Console, and then select the queue that you created from the list.

3. From the **Details** panel, record the **ARN** field value.

For example: **arn:aws:sqs:us-east-1:123456789012:MySQSQueueName**

4. To set the SQS queue **Access policy (Permissions)** by using the **AWS Policy generator**, complete the following steps:

a) Select **Policy Type > SQS Queue Policy**.

b) Add an Access Policy statement.

c) From the **Access policy** tab, click **Policy generator**, and then configure the following parameters:

*Table 216. Permission parameters*

Parameter	Value
<b>Effect</b>	Click <b>Allow</b> .
<b>Principal</b>	Type <b>*</b> (Everybody).
<b>Actions</b>	From the list, select <b>SendMessage</b>
<b>Amazon Resource Name (ARN)</b>	Type your queue ARN: <i>arn:aws:sqs:us-east-1:123456789012:MySQSQueueName</i>

d) Click **Add Conditionals (Optional)**, and then configure the following parameters:

*Table 217. Add Conditionals (Optional) parameters*

Parameter	Value
<b>Qualifier</b>	None
<b>Condition</b>	<b>ARNLike</b>
<b>Key</b>	Type <b>aws:SourceArn</b> .
<b>Value</b>	The ARN of the S3 bucket from when you completed the “ <a href="#">Finding the S3 bucket that contains the data that you want to collect</a> ” on page 308 procedure.  For example: <b>aws:s3:::my-example-s3bucket</b>

5. To set the SQS queue permissions by using a JSON policy document, complete the following steps:

a) Click **Add Condition > Add Statement. > Generate Policy**.

b) Copy and paste the following JSON policy into the **Access policy** window:

Copy and paste might not preserve the white space in the JSON policy. The white space is required. If the white space is not preserved when you paste the JSON policy, paste it into a text editor and restore the white space. Then, copy and paste the JSON policy from your text editor into the **Edit Policy Document** window.

```
{
  "Version": "2008-10-17",
  "Id": "example-ID",
  "Statement": [
    {
      "Sid": "example-statement-ID",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::my-example-s3bucket"
        }
      }
    }
  ]
}
```

```
    }  
}  
]
```

6. Click **Review Policy**. Ensure that the data is correct, and then click **Save Changes**.

## Creating ObjectCreated notifications

Configure ObjectCreated notifications for the folders that you want to monitor in the bucket.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, go to **S3**, and then select a bucket.
3. Click the **Properties** tab, and in the **Events** pane, click **Add notification**. Configure the parameters for the new event.

The following table shows an example of an ObjectCreated notification parameter configuration:

*Table 218. Example: New ObjectCreated notification parameter configuration*

Parameter	Value
<b>Name</b>	Type a name of your choosing.
<b>Events</b>	Select <b>All object create events</b> .
<b>Prefix</b>	AWSLogs/ <b>Tip:</b> You can choose a prefix that contains the data that you want to find, depending on where the data is located and what data that you want to go to the queue. For example, AWSLogs/, CustomPrefix/AWSLogs/, AWSLogs/123456789012/.
<b>Suffix</b>	json.gz
<b>Send to</b>	SQS queue <b>Tip:</b> You can send the data from different folders to the same or different queues to suit your collection or QRadar tenant needs. Choose one or more of the following methods: <ul style="list-style-type: none"><li>• Different folders that go to different queues</li><li>• Different folders from different buckets that go to the same queue</li><li>• Everything from a single bucket that goes to a single queue</li><li>• Everything from multiple buckets that go to a single queue</li></ul>
<b>SQS</b>	The <b>Queue Name</b> from step 4 of <b>Creating the SQS queue that is used to receive the ObjectCreated notifications</b> .

## Create event notification

The notification configuration identifies the events you want Amazon S3 to publish and the destinations where you want Amazon S3 to send the notifications. [Learn more](#)

### General configuration

Event name  
NewS3ObjectToSQS

Event name can contain up to 255 characters.

Prefix - optional  
Limit the notifications to objects with key starting with specified characters.  
 Example. This value must match the location of the data that you want to collect.

Suffix - optional  
Limit the notifications to objects with key ending with specified characters.  
 Example. Enter a value so that you can filter out unwanted files that match the prefix.

### Event types

Specify at least one type of event for which you want to receive notifications. [Learn more](#)

All object create events  
s3:ObjectCreated:  
 Put  
s3:ObjectCreated:Put  
 Post  
s3:ObjectCreated:Post  
 Copy  
s3:ObjectCreated:Copy  
 Multipart upload completed  
s3:ObjectCreated:CompleteMultipartUpload

Figure 26. Example: Events

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

In the example in figure 1 of a parameter configuration, notifications are created for AWSLogs / from the root of the bucket. When you use this configuration, All ObjectCreated events trigger a notification. If there are multiple accounts and regions in the bucket, everything gets processed. In this example, json.gz is used. This file type can change depending on the data that you are collecting. Depending on the content in your bucket, you can omit the extension or choose an extension that matches the data you are looking for in the folders where you have events set up.

After approximately 5 minutes, the queue that contains data displays. In the **Messages Available** column, you can view the number of messages.

Figure 27. Number of available messages

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

4. Click **Services**, then go to **Simple Queue Services**.
5. Right-click the **Queue Name** from step 4 of **Creating the SQS queue that is used to receive the ObjectCreated notifications**, then select **View/Delete Messages** to view the messages.

                    "ownerIdentity": {  
                        "principalId": "A2SGQBYRFBZET"  
                    },  
                    "arn": "arn:aws:s3:::myBucketName"  
                },  
                "object": {  
                    "key": "AWSLogs/123456789012/CloudTrail/eu-west-"  
                }  
            }  
        }  
    ]  
}
```

```

3/2018/12/19/123456789012_CloudTrail_eu-west-3_TestAccountTrail
_us-east-2_20181219T014838Z.json.gz",
    "size":713,
    "eTag":"1ff1209e4140b4ff7a9d2b922f57f486",
    "sequencer":"005C19A40717D99642"
}
]
}
}

```

**Tip:** In the **key** value, your DSM name displays.

6. Click **Services**, then navigate to **IAM**.
7. Set a **User or Role** permission to access the SQS queue and for permission to download from the target bucket. The user or user role must have permission to read and delete from the SQS queue. For information about adding, managing and changing permissions for IAM users, see the [IAM Users documentation](#). After QRadar reads the notification, and then downloads and processes the target file, the message must be deleted from the queue.

Sample Policy:

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sqs:DeleteMessage",
                "sqs:ReceiveMessage",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket_name>/AWSLogs/*",
                "arn:aws:sqs:us-east-2:<AWS_account_number>:<queue_name>"
            ]
        }
    ]
}

```

You can add multiple buckets to the S3 queue. To ensure that all objects are accessed, you must have a trailing `/*` at the end of the folder path that you added.

You can add this policy directly to a user, a user role, or you can create a minimal access user with **sts:AssumeRole** permissions only. When you configure a log source in QRadar, configure the **assume Role ARN** parameter for QRadar to assume the role. To ensure that all files waiting to be processed in a single run (emptying the queue) can finish without retries, use the default value of 1 hour for the **API Session Duration** parameter.

When you use assumed roles, ensure that the ARN of the user that is assuming the role is in the **Trusted Entities** for that role. You can view the trusted entities that can assume the rule from the **Trust Relationship** tab in **IAM Role**. In addition, the user must have permission to assume roles in that (or any) account. The following examples show a sample trust policy:

#### Allow all IAM users within a specific AWS account to assume a role

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:root"
            },
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"
        }
    ]
}

```

## Allow a specific user to assume a role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:user/USERNAME"  
            },  
            "Action": "sts:AssumeRole",  
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"  
        }  
    ]  
}
```

The following image example shows a sample Amazon AWS CloudTrail log source configuration in QRadar.

**Tip:** Use the Amazon AWS S3 REST API log source parameter values for your DSM when you configure your log source.

### ▼ [ AWS Authentication Configuration ]

## Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge

Create an Amazon EventBridge rule to forward ObjectCreated notifications to a target SQS queue.

### Before you begin

Before you can create a rule in Amazon EventBridge, you must enable Amazon EventBridge on your AWS Management console. For more information, see [Enabling Amazon EventBridge](#).

### Procedure

1. Open the [Amazon EventBridge console](#).
2. From the **Navigation** menu, click **Rules > Create rule**.
3. On the **Create rule** window, complete the following steps:
  - a) Enter a name and description for the rule.  
**Important:** A rule can't have the same name as another rule that is both in the same region and on the same event bus.
  - b) For **Event bus**, select the event bus that you want to associate with this rule. If you select **AWS default event bus**, the rule matches the events that come from your account.
  - c) For **Rule type**, select **Rule with an event pattern**.
4. Click **Next**.
5. For **Event source**, select **AWS events or EventBridge partner events**.
6. For **Creation method**, select **Use pattern form**.
7. In the **Event pattern** window, configure the event pattern by completing the following steps:
  - a) Select the values listed in the table for the following parameters:

Parameter	Value
<b>Event source</b>	<b>AWS services</b>
<b>AWS service</b>	<b>Simple Storage Service (S3)</b>
<b>Event type</b>	<b>Amazon S3 Event Notification</b>

- b) Click the **Specific event(s)** option and select **Object Created**.
- c) Click **Specific bucket(s) by name** and enter the name of the specific bucket that you want to collect events from.
- d) Optional: To enable notifications for a specific folder prefix or file extension, choose **Custom pattern (JSON editor)** instead of **Use pattern form** for the creation method, and create your custom event pattern.

For example, this event pattern filters for Object Created events in your bucket. In this example, example/directory is the directory prefix and .png is the suffix.

```
{  
  "source": ["aws.s3"],  
  "detail-type": ["Object Created"],  
  "detail": {  
    "bucket": {  
      "name": ["<example-bucket>"]  
    },  
    "object": {  
      "key": [{  
        "prefix": "example/directory/"  
      }],  
      "key": [{  
        "suffix": ".png"  
      }]  
    }  
  }  
}
```

- e) Click **Add**, then click **Next**.
8. Choose the SQS queue that you want to use as the target. Enter the name of the queue, then click **Next**.
9. On the **Review and create** page, click **Create rule**.

## Configuring Amazon GuardDuty to forward events to an AWS S3 Bucket

To collect events in QRadar, you must configure Amazon GuardDuty to forward events to an AWS S3 Bucket.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. On the menu bar, type GuardDuty in the search field.
3. From the Navigation menu, select **Findings**.
4. From the **Frequency for updated findings** list, select **Update CWE and S3 every 15 minutes**.
5. In the S3 bucket section, click **Configure now**.
6. Click one of the following S3 bucket options:
  - **Existing bucket - In your account**
  - **Existing bucket - In another account**
  - **New bucket - Create a new bucket**
7. From the **Choose a bucket** list, select your S3 bucket.
8. Optional: Enter a path prefix in the **Log file prefix** field. A new folder is created in the bucket with the path prefix name that you specified. The path that follows the field is updated to reflect the path to exported findings in the bucket.
9. Select one of the following **KMS encryption** options:
  - Select **Choose key from your account**, and then from the **Key alias** list, select the key that you changed the policy for.
  - Select **Choose key from another account**, and then type the full ARN to the key that you changed the policy for.
- The key that you select must be in the same region as the S3 bucket. For more information about how to find the key ARN, go to *Finding the key ID and ARN* on the Amazon AWS website (<https://docs.aws.amazon.com/kms/latest/developerguide/find-cmk-id-arn.html>).
- For more information about key policies, go to *Using key policies in AWS KMS* on the Amazon AWS website (<https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html>).
10. Click **Save**.

When you generate findings in GuardDuty, they are sent to your S3 Bucket.

## Adding an Amazon GuardDuty log source on the QRadar Console using an SQS queue

If you want to collect Amazon GuardDuty logs from multiple accounts or regions in an Amazon S3 bucket, add a log source on the QRadar Console so that Amazon GuardDuty can communicate with QRadar by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

### Procedure

1. Use the following table to set the parameters for an Amazon GuardDuty log source that uses the Amazon AWS S3 REST API protocol and an SQS queue.

Table 219. Amazon AWS S3 REST API protocol log source parameters

Parameter	Description
<b>Log Source Type</b>	<b>Amazon GuardDuty</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	<p>Type a unique name for the log source.</p> <p>The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b>. If you have more than one Amazon AWS CloudTrail log source that is configured, you might want to identify the first log source as <i>Guardduty1</i>, the second log source as <i>guardduty2</i>, and the third log source as <i>guardduty3</i>.</p>
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>            Standard authentication that can be used from anywhere.</p> <p><b>Assume IAM Role</b>            Authenticate with keys and then temporarily assume a role for access. This option is available only when you select <b>SQS Event Notifications</b> for the <b>S3 Collection Method</b>. The supported <b>S3 Collection Method</b> is <b>Use a Specific Prefix</b>.</p> <p><b>EC2 Instance IAM Role</b>            If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata that is assigned to the instance for authentication; no keys are required. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key ID</b>	<p>If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b>, the <b>Access Key ID</b> parameter is displayed.</p> <p>The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.</p>
<b>Secret Key</b>	<p>If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b>, the <b>Secret Key ID</b> parameter is displayed.</p> <p>The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Secret Key ID</b> that is used to access the AWS S3 bucket.</p>
<b>Event Format</b>	Select <b>AWS Cloud Trail JSON</b> . The log source retrieves JSON formatted events.
<b>S3 Collection Method</b>	Select <b>SQS Event Notifications</b> .
<b>SQS Queue URL</b>	Enter the full URL, starting with <code>https://</code> , of the SQS queue that is set up to receive notifications for ObjectCreate events from S3.
<b>Region Name</b>	<p>The region that the SQS Queue or the S3 Bucket is in.</p> <p>Example: us-east-1, eu-west-1, ap-northeast-3</p>
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.

Table 219. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Log Source Identifier Pattern</b>	<p>This option is available when you set <b>Use as a Gateway Log Source</b> is set to yes.</p> <p>Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.</p>
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.
<b>File Pattern</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.json\.gz</code></p>
<b>Local Directory</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.</p>
<b>S3 Endpoint URL</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The endpoint URL that is used to query the AWS REST API. If your endpoint URL is different from the default, type your endpoint URL. The default is <code>http://s3.amazonaws.com</code></p>
<b>Use S3 Path-Style Access</b>	<p>Forces S3 requests to use path-style access.</p> <p>This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.</p>
<b>Use Proxy</b>	<p>If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b>.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.</p>

Table 219. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Recurrence</b>	<p>How often a poll is made to scan for new data.</p> <p>If you are using the SQS event collection method, <b>SQS Event Notifications</b> can have a minimum value of 10 (seconds). Because SQS Queue polling can occur more often, a lower value can be used.</p> <p>If you are using the Directory Prefix event collection method, <b>Use a Specific Prefix</b> has a minimum value of 60 (seconds) or 1M. Because every listBucket request to an AWS S3 bucket incurs a cost to the account that owns the bucket, a smaller recurrence value increases the cost.</p> <p>Type a time interval to determine how frequently the poll is made for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

2. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

Table 220. Amazon sample message supported by Amazon GuardDuty.

Event name	Low-level category	Sample log message
Console Login	General Audit Event	<pre>{"eventVersion": "1.02", "userIdentity": {"type": "IAMUser", "principalId": "XXXXXXXXXXXXXXXXXXXXXX", "arn": "arn:aws:iam::&lt;Account_number&gt;:user/ xx.xxxxcountId": "&lt;Account_number&gt;", "userName": "&lt;Username&gt;"}, "eventTime": "2016-05-04T14:10:58Z", "eventSource": "f.amazonaws.com", "eventName": "ConsoleLogin", "awsRegion": "us-east-1", "sourceIPAddress": "&lt;Source_IP_address&gt; Agent": "Mozilla/5.0 (Windows NT 6.1; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/50.0.1.1 Safari/537.36", "requestParameters": null, "responseElements": {"ConsoleLogin": "Success"}, "additionalEventData": {"LoginTo": "www.webpage.com", "MobileVersion": "No", "MFAUsed": "No"}, "eventID": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx", "eventType": "AwsConsoleSignIn", "recipientAccountId": "&lt;Account_ID&gt;"}</pre>

## Amazon GuardDuty sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Amazon GuardDuty sample message when you use the Amazon AWS S3 REST API protocol

**Sample 1:** The following sample event message shows that an IAM entity requested an API to disable S3 and block public access on a bucket.

```
{"schemaVersion": "2.0", "accountId": "111111111111", "region": "region", "partition": "aws", "id": "6ab971cccd774293fcb8a9eaff944711", "arn": "arn:aws:guardduty:region:111111111111:detector/42b0d9e4fcad1600d444fc52278999c2/finding/6ab971cccd774293fcb8a9eaff944711", "type": "Policy:S3/BucketBlockPublicAccessDisabled", "resource": {"resourceType": "AccessKey", "accessKeyDetails": {"accessKeyId": "GeneratedFindingAccessKeyId", "principalId": "GeneratedFindingPrincipalId", "userType": "IAMUser", "userName": "GeneratedFindingUserName"}, "s3BucketDetails": [{"arn": "arn:aws:s3:::bucketName", "name": "bucketName", "type": "Destination", "createdAt": "1513612692", "owner": {"id": "CanonicalId of Owner"}, "tags": [{"key": "foo", "value": "bar"}], "defaultServerSideEncryption": {"encryptionType": "SSEAlgorithm", "kmsMasterKeyArn": "arn:aws:kms:region:123456789012:key/key-id"}, "publicAccess": {"permissionConfiguration": {"bucketLevelPermissions": {"accessControlList": {"allowsPublicReadAccess": false, "allowsPublicWriteAccess": false}, "bucketPolicy": {"allowsPublicReadAccess": false, "allowsPublicWriteAccess": false}, "blockPublicAccess": {"ignorePublicAcls": false, "restrictPublicBuckets": false}, "blockPublicPolicy": {"ignorePublicAcls": false, "restrictPublicBuckets": false}, "blockPublicAcls": false, "blockPublicPolicy": false}}, "accountLevelPermissions": {"blockPublicAccess": {"ignorePublicAcls": false, "restrictPublicBuckets": false}, "blockPublicAcls": false, "blockPublicPolicy": false}}, "effectivePermission": "NOT_PUBLIC"}]}, "instanceDetails": {"instanceId": "i-99999999", "instanceType": "m3.xlarge", "outpostArn": "arn:aws:outposts:region-name:123456789000:outpost/op-0fb006e9abb73c3", "launchTime": "2016-08-02T02:05:06Z", "platform": null, "productCodes": [{"productCodeId": "GeneratedFindingProductCodeId", "productCodeType": "GeneratedFindingProductCodeType"}], "iamInstanceProfile": {"arn": "GeneratedFindingInstanceProfileArn", "id": "GeneratedFindingInstanceProfileId"}, "networkInterfaces": [{"ipv6Addresses": []}, {"networkInterfaceId": "test", "privateDnsName": "GeneratedFindingPrivateDnsName", "privateIpAddress": "10.0.0.1"}, {"privateIpAddresses": [{"privateDnsName": "GeneratedFindingPrivateName", "privateIpAddress": "10.0.0.1"}]}, {"subnetId": "GeneratedFindingSubnetId", "vpcId": "GeneratedFindingVPCId"}, {"securityGroups": [{"groupName": "GeneratedFindingSecurityGroupName", "groupId": "GeneratedFindingSecurityId"}]}, {"publicDnsName": "GeneratedFindingPublicDNSName", "publicIp": "10.51.100.0"}], "tags": [{"key": "GeneratedFindingInstaceTag1", "value": "GeneratedFindingInstaceValue1"}, {"key": "GeneratedFindingInstaceTag2", "value": "GeneratedFindingInstaceTagValue2"}, {"key": "GeneratedFindingInstaceTag3", "value": "GeneratedFindingInstaceTagValue3"}, {"key": "GeneratedFindingInstaceTag4", "value": "GeneratedFindingInstaceTagValue4"}, {"key": "GeneratedFindingInstaceTag5", "value": "GeneratedFindingInstaceTagValue5"}, {"key": "GeneratedFindingInstaceTag6", "value": "GeneratedFindingInstaceTagValue6"}, {"key": "GeneratedFindingInstaceTag7", "value": "GeneratedFindingInstaceTagValue7"}, {"key": "GeneratedFindingInstaceTag8", "value": "GeneratedFindingInstaceTagValue8"}, {"key": "GeneratedFindingInstaceTag9", "value": "GeneratedFindingInstaceTagValue9"}]}, {"instanceState": "running", "availabilityZone": "GeneratedFindingInstaceAvailabilityZone", "imageId": "ami-99999999", "imageDescription": "GeneratedFindingInstaceImageDescription"}, {"service": {"serviceName": "guardduty", "detectorId": "11a1a1a1aaa1111a111aa11111111a1", "action": {"actionType": "AWS_API_CALL", "awsApiCallAction": {"api": "GeneratedFindingAPIName", "serviceName": "GeneratedFindingAPIServiceName", "callerType": "Remote IP", "remoteIpDetails": {"ipAddressV4": "10.51.100.0"}, "organization": {"asn": "-1", "asnOrg": "GeneratedFindingASN0Org", "isp": "GeneratedFindingISP", "org": "GeneratedFindin gORG"}, "country": {"countryName": "GeneratedFindingCountryName"}, "city": {"cityName": "GeneratedFindingCityName"}, "geoLocation": {"lat": 44.972686, "lon": -65.860879}}, "affectedResources": {"AWS::S3::Bucket": "GeneratedFindingS3Bucket"}}, "resourceRole": "TARGET", "additionalInfo": {"unusual": {"hoursOfDay": [1513609200000]}, "userNames": [{"GeneratedFindingUserName"}], "sample": true}, "eventFirstSeen": "2020-06-23T23:53:14.222Z", "eventLastSeen": "2020-06-24T00:26:33.501Z", "archived": false, "count": 2, "severity": 2, "createdAt": "2020-06-23T23:53:14.222Z", "updatedAt": "2020-06-24T00:26:33.501Z", "title": "Amazon S3 Block Public Access was disabled for S3 bucket GeneratedFindingS3Bucket.", "description": "Amazon S3 Block Public Access was disabled for S3 bucket GeneratedFindingS3Bucket by GeneratedFindingUserName calling GeneratedFindingAPIName. ## Amazon VPC Flow Logs

The IBM QRadar integration for Amazon VPC (Virtual Private Cloud) Flow Logs collects VPC flow logs from an Amazon S3 bucket by using an SQS queue.

**Important:** This integration supports the default format for Amazon VPC Flow Logs and any custom formats that contain version 3, 4, or 5 fields. However, all version 2 fields must be included in your custom format. The default format includes the following fields.

```
 ${version} ${account-id} ${interface-id} ${srcaddr} ${dstadir} ${srcport} ${dstport} $  
 ${protocol} ${packets} ${bytes} ${start} ${end} ${action} ${log-status}
```

For more information, see the [Amazon VPC Flow Logs documentation](#).

To integrate Amazon VPC Flow Logs with QRadar, complete the following steps:

- If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the following RPMs on your QRadar Console.
  - Protocol Common RPM
  - AWS S3 REST API PROTOCOL RPM

**Important:** If you are installing the RPM to enable more AWS-related VPC flow fields in the QRadar Network Activity Flow Details window, then the following services must be restarted before they are visible. You don't need to restart the services for the protocol to function.

### Hostcontext

To restart **host context**, see [QRadar: Hostcontext service and the impact of a service restart](https://www.ibm.com/support/pages/qradar-hostcontext-service-and-impact-service-restart) (<https://www.ibm.com/support/pages/qradar-hostcontext-service-and-impact-service-restart>).

### Tomcat

On the Console, click the **Admin** tab, and then click **Advanced > restart Web Server**.

- Configure your Amazon VPC Flow Logs to publish the flow logs to an S3 bucket.
- Create the SQS queue that is used to receive ObjectCreated notifications from the S3 bucket that you used in step 2.
- Create security credentials for your AWS user account.
- Add an Amazon VPC Flow Logs log source on the QRadar Console.

**Important:** A Flow Processor must be available and have a FPM license to receive the flow logs. VPC Flow Log does not use an EPS license. Unlike other log sources, AWS VPC Flow Log events are not sent to the **Log Activity** tab. They are sent to the **Network Activity** tab.

**Important:** When the VPC Flow Logs log source is configured by using Universal DSM, it does not generate any event. In this case, the **Last Event** time status remains blank.

The following table describes the parameters that require specific values to collect events from Amazon VPC Flow Logs:

Table 223. Amazon VPC Flow Logs log source parameters

Parameter	Value
<b>Log Source type</b>	A custom log source type.
<b>Protocol Configuration</b>	Amazon AWS S3 REST API
<b>Target Event Collector</b>	<p>The Event Collector or Event Processor that receives and parses the events from this log source.</p> <p><b>Tip:</b> This integration collects raw event logs of Amazon VPC Flow Logs from the target AWS S3 bucket. Then, it generates IPFIX flow records and forwards the records to the <b>VPC Flow Destination Hostname</b>. You can use a Flow Collector or a Flow Processor as the target event collector only when it is a combined Flow Collector and Flow Processor or an all-in-one console.</p>
<b>Log Source Identifier</b>	<p>Type a unique name for the log source.</p> <p>The Log Source Identifier can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b>. If you configured more than one Amazon VPC flow Logs log source, you might want to name them in an identifiable way. For example, you can identify the first log source as <i>vpcflowlogs1</i> and the second log source as <i>vpcflowlogs2</i>.</p>
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>            Standard authentication that can be used from anywhere.            For more information about configuring security credentials, see <a href="#">“Configuring security credentials for your AWS user account” on page 316</a>.</p> <p><b>EC2 Instance IAM Role</b>            If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata that is assigned to the instance for authentication. No keys are needed. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Assume IAM Role</b>	<p>Enable this option by authenticating with an Access Key or EC2 instance IAM Role. Then, you can temporarily assume an IAM Role for access. This option is available only when you use the SQS Event Notifications collection method.</p> <p>For more information about creating IAM users and assigning roles, see <a href="#">Creating an Identity and Access Management (IAM) user in the AWS Management Console</a>.</p>
<b>Event Format</b>	AWS VPC Flow Logs
<b>S3 Collection Method</b>	SQS Event Notifications

Table 223. Amazon VPC Flow Logs log source parameters (continued)

Parameter	Value
<b>VPC Flow Destination Hostname</b>	<p>The hostname or IP address of the Flow Processor where you want to send the VPC logs.</p> <p><b>Tip:</b> For QRadar to accept IPFIX flow traffic, you must configure a NetFlow/IPFIX flow source that uses UDP. Most deployments can use a <b>default_Netflow</b> flow source and set the <b>VPC Flow Destination Hostname</b> to the hostname of that managed host.</p> <p>If the managed host that is configured with the NetFlow/IPFIX flow source is the same as the <b>Target Event Collector</b> that was chosen earlier in the configuration, you can set the <b>VPC Flow Destination Hostname</b> to <i>localhost</i>.</p> <p>For more information about creating flow sources, see the <i>IBM QRadar Administration Guide</i>.</p>
<b>VPC Flow Destination Port</b>	<p>The port for the Flow Processor where you want to send the VPC logs.</p> <p><b>Important:</b> This port must be the same as the monitoring port that is specified in the NetFlow flow source. The port for the <b>default_Netflow</b> flow source is 2055.</p>
<b>SQS Queue URL</b>	The full URL that begins with <code>https://</code> , for the SQS Queue that is set up to receive notifications for ObjectCreated events from S3.
<b>Region Name</b>	<p>The region that is associated with the SQS queue and S3 bucket.</p> <p>Example: us-east-1, eu-west-1, ap-northeast-3</p>
<b>Show Advanced Options</b>	<p>The default is <b>No</b>. Select <b>Yes</b> if you want to customize the event data.</p>
<b>File Pattern</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*\?\.\json\.\gz</code></p>
<b>Local Directory</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.</p>
<b>S3 Endpoint URL</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The endpoint URL that is used to query the AWS REST API.</p> <p>If your endpoint URL is different from the default, type your endpoint URL. The default is <code>http://s3.amazonaws.com</code>.</p>

Table 223. Amazon VPC Flow Logs log source parameters (continued)

Parameter	Value
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> . If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Recurrence</b>	How often the Amazon AWS S3 REST API Protocol connects to the Amazon cloud API, checks for new files, and if they exist, retrieves them. Every access to an AWS S3 bucket incurs a cost to the account that owns the bucket. Therefore, a smaller recurrence value increases the cost. Type a time interval to determine how frequently the remote directory is scanned for new event log files. The minimum value is 1 minute. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15 M = 15 minutes.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.

6. To send VPC flow logs to the IBM QRadar Cloud Visibility app for visualization, complete the following steps:
  - a. On the Console, click the **Admin** tab, and then click **System Configuration > System Settings**.
  - b. Click the **QFlow Settings** menu, and in the **IPFix additional field encoding** field, choose either the **TLV** or **TLV and Payload** format.
  - c. Click **Save**.
  - d. From the menu bar on the **Admin** tab, click **Deploy Full Configuration** and confirm your changes.

**Warning:** When you deploy the full configuration, QRadar services are restarted. During this time, events and flows are not collected, and offenses are not generated.

- e. Refresh your browser.

For more information about configuring the Amazon AWS S3 REST API protocol, see [Amazon AWS S3 REST API protocol configuration options](#).

#### Related concepts

[“Create the SQS queue that is used to receive ObjectCreated notifications” on page 450](#)  
You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when using the Amazon AWS REST API protocol.

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Publishing flow logs to an S3 bucket” on page 294](#)

Complete these steps to publish flow logs to an S3 bucket.

[“Configuring security credentials for your AWS user account” on page 316](#)

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

## Amazon VPC Flow Logs specifications

The following table describes the specifications for collecting Amazon VPC Flow Logs.

Table 224. Amazon VPC Flow Logs specifications	
Specification	Value
Manufacturer	Amazon
DSM name	A custom log source type
RPM file name	AWS S3 REST API PROTOCOL
Supported versions	Flow logs v5
Protocol	AWS S3 REST API PROTOCOL
Event format	IPFIX by using QRadar Flow Sources
Recorded event types	Network Flows
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://docs.aws.amazon.com/vpc/latest/userguide/flow-logs.html">Amazon's VPC Flow Logs documentation (https://docs.aws.amazon.com/vpc/latest/userguide/flow-logs.html)</a>

## Publishing flow logs to an S3 bucket

Complete these steps to publish flow logs to an S3 bucket.

### Procedure

1. Log in to your AWS Management console, and then from the **Services** menu, navigate to the **VPC Dashboard**.
2. Enable the check box for the VPC ID that you want to create flow logs for.
3. Click the **Flow Logs** tab.
4. Click **Create Flow Log**, and then configure the following parameters:

Table 225. Create Flow Log parameters

Parameter	Description
<b>Filter</b>	Select <b>Accept, Reject, or All</b> .
<b>Destination</b>	Select <b>Send to an S3 Bucket</b> .
<b>S3 Bucket ARN</b>	Type the ARN for the S3 Bucket. Examples: <ul style="list-style-type: none"><li>• arn:aws:s3:::myTestBucket</li><li>• arn:aws:s3:::myTestBucket/testFlows</li></ul>

## 5. Click **Create**.

For more information about publishing flow logs to Amazon S3, see the [Publishing Flow Logs to Amazon S3 documentation](#) on the AWS website.

### What to do next

Create the SQS queue that is used to receive ObjectCreated notifications.

## Create the SQS queue that is used to receive ObjectCreated notifications

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when using the Amazon AWS REST API protocol.

To create the SQS queue and configure S3 ObjectCreated notifications, see the AWS S3 REST API documentation about “[Creating ObjectCreated notifications](#)” on page 311.

## Configuring security credentials for your AWS user account

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### Related information

[Adding a log source](#)

## AWS Verified Access

The IBM QRadar DSM for AWS Verified Access supports events that are collected from Amazon S3 buckets, and from a Log group in the AWS Verified Access Logs.

Before you can integrate AWS Verified Access Logs with QRadar, you need to enable Verified Access logs on the Amazon VPC console. To enable Verified Access logs, you must have permissions for delivery to Amazon S3.

For more information about permissions for delivery to Amazon S3 and enabling AWS Verified Access logs, go to the [Enable Access Logs documentation](#) on the Amazon website (<https://docs.aws.amazon.com/verified-access/latest/ug/access-logs-enable.html>).

**Tip:** When you enable Verified Access Logs, select the option to enable delivery to Amazon S3.

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

[“Configuring an AWS Verified Access log source by using the Amazon AWS S3 REST API protocol” on page 451](#)

If you want to collect AWS Verified Access logs from Amazon S3 buckets, configure a log source on the QRadar Console so that AWS Verified Access can communicate with QRadar by using the Amazon AWS S3 REST API protocol.

## AWS Verified Access DSM specifications

When you configure the AWS Verified Access DSM, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported protocols are before you begin can help reduce frustration during the configuration process.

The following table lists the specifications for the AWS Verified Access DSM:

Table 226. AWS Verified Access DSM specifications	
Specification	Value
Manufacturer	Amazon
DSM	AWS Verified Access
RPM name	DSM-AWSVerifiedAccess-QRadar_version-Build_number.noarch.rpm
Supported protocols	<ul style="list-style-type: none"><li>Amazon AWS S3 REST API</li><li>Syslog</li></ul>
Event format	JSON
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	Yes
More information	For more information about AWS Verified Access logs, go to the <a href="#">AWS website</a> .

## Configuring an AWS Verified Access log source by using the Amazon AWS S3 REST API protocol

If you want to collect AWS Verified Access logs from Amazon S3 buckets, configure a log source on the QRadar Console so that AWS Verified Access can communicate with QRadar by using the Amazon AWS S3 REST API protocol.

### Procedure

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console.
  - Protocol Common RPM
  - Amazon AWS S3 REST API Protocol RPM
  - DSMCommon RPM
  - Amazon Web Service RPM
  - AWS Verified Access DSM RPM
2. Choose which method that you want to use to configure an AWS Verified Access log source by using the Amazon AWS S3 REST API protocol.
  - [“Configuring an AWS Verified Access log source that uses an S3 bucket with an SQS queue” on page 452](#)

- “Configuring an AWS Verified Access log source that uses an S3 bucket with a directory prefix” on page 464

#### Related tasks

## Configuring an AWS Verified Access log source that uses an S3 bucket with an SQS queue

If you want to collect AWS Verified Access logs from multiple accounts or regions in an Amazon S3 bucket, configure a log source on the QRadar Console so that AWS Verified Access can communicate with QRadar by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

#### About this task

Using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue instead of with a directory prefix has the following advantages:

- You can use one log source for an S3 bucket, rather than one log source for each region and account.
- There is a reduced chance of missing files because this method uses ObjectCreated notifications to determine when new files are ready.
- It's easy to balance the load across multiple Event Collectors because the SQS queue supports connections from multiple clients
- Unlike the directory prefix method, the SQS queue method does not require that the file names in the folders be in a string that is sorted in ascending order based on the full path. File names from custom applications don't always conform to this.
- You can monitor the SQS queue and set up alerts if it gets over a certain number of records. These alerts provide information about whether QRadar is either falling behind or not collecting events.
- You can use IAM Role authentication with SQS, which is Amazon's best practice for security.
- Certificate handling is improved with the SQS method and does not require the downloading of certificates to the Event Collector.

#### Procedure

1. [Create the SQS queue that is used to receive ObjectCreated notifications.](#)
2. [Create an Amazon AWS Identity and Access Management \(IAM\) user and then apply the \*\*AmazonS3ReadOnlyAccess\*\* policy.](#)
3. [Configure the security credentials for your AWS user account.](#)
4. [Add an AWS Verified Access log source on the QRadar Console that uses an SQS queue.](#)

#### Create an SQS queue and configure S3 ObjectCreated notifications

Before you can add a log source in IBM QRadar, you must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

Complete the following procedures:

1. [Finding the S3 Bucket that contains the data that you want to collect.](#)
2. [Creating the SQS queue that is used to receive the ObjectCreated notifications from the S3 Bucket that you used in Step 1.](#)
3. [Setting up SQS queue permissions.](#)
4. [Creating ObjectCreated notifications.](#)

#### Related tasks

[“Adding a log source” on page 5](#)

### *Finding the S3 bucket that contains the data that you want to collect*

You must find and note the region for S3 bucket that contains the data that you want to collect.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to **S3**.
3. From the **AWS Region** column in the **Buckets** list, note the region where the bucket that you want to collect data from is located. You need the region for the **Region Name** parameter value when you add a log source in IBM QRadar.
4. Enable the checkbox beside the bucket name, and then from the panel that opens to the right, click **Copy Bucket ARN** to copy the value to the clipboard. Save this value or leave it on the clipboard. You need this value when you set up **SQS queue permissions**.

### *Creating the SQS queue that is used to receive ObjectCreated notifications*

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

## Before you begin

You must complete **Finding the S3 Bucket that contains the data that you want to collect**. The SQS Queue must be in the same region as the AWS S3 bucket that the queue is collecting from.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to the Simple Queue Service Management Console.
3. In the upper right of the window, change the region to where the bucket is located. You noted this value when you completed the **Finding the S3 Bucket that contains the data that you want to collect** procedure.
4. Select **Create New Queue**, and then type a value for the **Queue Name**.
5. Click **Standard Queue**, select **Configure Queue**, and then change the default values for the following **Queue Attributes**.
  - **Default Visibility Timeout** - 60 seconds (You can use a lower value. In the case of load balanced collection, duplicate events might occur with values of less than 30 seconds. This value can't be 0.)
  - **Message Retention Period** - 14 days (You can use a lower value. In the event of an extended collection, data might be lost.)

Use the default value for the remaining **Queue Attributes**.

More options such as **Redrive Policy** or **SSE** can be used depending on the requirements for your AWS environment. These values should not affect the data collection.

Queue Attributes

<b>Default Visibility Timeout</b>	<input type="text" value="60"/>	<b>seconds</b>	Value must be between 0 seconds and 12 hours.
<b>Message Retention Period</b>	<input type="text" value="14"/>	<b>days</b>	Value must be between 1 minute and 14 days.
<b>Maximum Message Size</b>	<input type="text" value="256"/>	<b>KB</b>	Value must be between 1 and 256 KB.
<b>Delivery Delay</b>	<input type="text" value="0"/>	<b>seconds</b>	Value must be between 0 seconds and 15 minutes.
<b>Receive Message Wait Time</b>	<input type="text" value="0"/>	<b>seconds</b>	Value must be between 0 and 20 seconds.

---

## 6. Select **Create Queue**.

### *Setting up SQS queue permissions*

You must set up SQS queue permissions for users to access the queue.

### Before you begin

You must complete **Creating the SQS queue that is used to receive ObjectCreated notifications**.

You can set the SQS queue permissions by using either the Permissions Editor or a JSON policy document.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Go to the SQS Management Console, and then select the queue that you created from the list.
3. From the **Details** panel, record the **ARN** field value.

For example: **arn:aws:sqs:us-east-1:123456789012:MySQSQueueName**

4. To set the SQS queue **Access policy (Permissions)** by using the **AWS Policy generator**, complete the following steps:
  - a) Select **Policy Type > SQS Queue Policy**.
  - b) Add an Access Policy statement.
  - c) From the **Access policy** tab, click **Policy generator**, and then configure the following parameters:

Table 227. Permission parameters

Parameter	Value
<b>Effect</b>	Click <b>Allow</b> .
<b>Principal</b>	Type <b>*</b> (Everybody).
<b>Actions</b>	From the list, select <b>SendMessage</b>
<b>Amazon Resource Name (ARN)</b>	Type your queue ARN: <b>arn:aws:sqs:us-east-1:123456789012:MySQSQueueName</b>

- d) Click **Add Conditionals (Optional)**, and then configure the following parameters:

Table 228. Add Conditionals (Optional) parameters

Parameter	Value
<b>Qualifier</b>	None
<b>Condition</b>	<b>ARNLike</b>
<b>Key</b>	Type aws:SourceArn.
<b>Value</b>	The ARN of the S3 bucket from when you completed the “ <a href="#">Finding the S3 bucket that contains the data that you want to collect</a> ” on page 308 procedure.  For example: aws:s3:::my-example-s3bucket

5. To set the SQS queue permissions by using a JSON policy document, complete the following steps:

a) Click **Add Condition** > **Add Statement**. > **Generate Policy**.

b) Copy and paste the following JSON policy into the **Access policy** window:

Copy and paste might not preserve the white space in the JSON policy. The white space is required. If the white space is not preserved when you paste the JSON policy, paste it into a text editor and restore the white space. Then, copy and paste the JSON policy from your text editor into the **Edit Policy Document** window.

```
{
  "Version": "2008-10-17",
  "Id": "example-ID",
  "Statement": [
    {
      "Sid": "example-statement-ID",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::my-example-s3bucket"
        }
      }
    }
  ]
}
```

6. Click **Review Policy**. Ensure that the data is correct, and then click **Save Changes**.

#### *Creating ObjectCreated notifications*

Configure ObjectCreated notifications for the folders that you want to monitor in the bucket.

## Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, go to **S3**, and then select a bucket.
3. Click the **Properties** tab, and in the **Events** pane, click **Add notification**. Configure the parameters for the new event.

The following table shows an example of an ObjectCreated notification parameter configuration:

Table 229. Example: New ObjectCreated notification parameter configuration

Parameter	Value
<b>Name</b>	Type a name of your choosing.

Table 229. Example: New ObjectCreated notification parameter configuration (continued)

Parameter	Value
<b>Events</b>	Select <b>All object create events</b> .
<b>Prefix</b>	AWSLogs/ <b>Tip:</b> You can choose a prefix that contains the data that you want to find, depending on where the data is located and what data that you want to go to the queue. For example, AWSLogs/, CustomPrefix/AWSLogs/, AWSLogs/123456789012/.
<b>Suffix</b>	json.gz
<b>Send to</b>	SQS queue <b>Tip:</b> You can send the data from different folders to the same or different queues to suit your collection or QRadar tenant needs. Choose one or more of the following methods: <ul style="list-style-type: none"> <li>• Different folders that go to different queues</li> <li>• Different folders from different buckets that go to the same queue</li> <li>• Everything from a single bucket that goes to a single queue</li> <li>• Everything from multiple buckets that go to a single queue</li> </ul>
<b>SQS</b>	The <b>Queue Name</b> from step 4 of <b>Creating the SQS queue that is used to receive the ObjectCreated notifications</b> .

## Create event notification

The notification configuration identifies the events you want Amazon S3 to publish and the destinations where you want Amazon S3 to send the notifications. [Learn more](#)

### General configuration

Event name  
NewS3ObjectToSQS

Event name can contain up to 255 characters.

Prefix - optional  
Limit the notifications to objects with key starting with specified characters.  
 AWSLogs/

Example. This value must match the location of the data that you want to collect.

Suffix - optional  
Limit the notifications to objects with key ending with specified characters.  
 .json.gz

Example. Enter a value so that you can filter out unwanted files that match the prefix.

### Event types

Specify at least one type of event for which you want to receive notifications. [Learn more](#)

All object create events  
s3:ObjectCreated:  
 Put  
s3:ObjectCreated:Put  
 Post  
s3:ObjectCreated:Post  
 Copy  
s3:ObjectCreated:Copy  
 Multipart upload completed  
s3:ObjectCreated:CompleteMultipartUpload

Figure 30. Example: Events

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

In the example in figure 1 of a parameter configuration, notifications are created for AWSLogs/ from the root of the bucket. When you use this configuration, All ObjectCreated events trigger a notification. If there are multiple accounts and regions in the bucket, everything gets processed. In this example, json.gz is used. This file type can change depending on the data that you are collecting. Depending on the content in your bucket, you can omit the extension or choose an extension that matches the data you are looking for in the folders where you have events set up.

After approximately 5 minutes, the queue that contains data displays. In the **Messages Available** column, you can view the number of messages.

Figure 31. Number of available messages

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

4. Click **Services**, then go to **Simple Queue Services**.
5. Right-click the **Queue Name** from step 4 of **Creating the SQS queue that is used to receive the ObjectCreated notifications**, then select **View/Delete Messages** to view the messages.

Figure 32. SecureQueue TEST list

                "configurationId": "test_SQS_Notification_1",  
                "bucket": {  
                    "name": "myBucketName",  
                    "ownerIdentity": {  
                        "principalId": "A2SGQBYRFBZET"  
                    },  
                    "arn": "arn:aws:s3:::myBucketName"  
                },  
                "object": {  
                    "key": "AWSLogs/123456789012/CloudTrail/eu-west-1/2018/12/19/10/51/03/251Z/test_SQS_Notification_1.log"  
                }  
            }  
        }  
    ]  
}
```

```

3/2018/12/19/123456789012_CloudTrail_eu-west-3_TestAccountTrail
_us-east-2_20181219T014838Z.json.gz",
    "size":713,
    "eTag":"1ff1209e4140b4ff7a9d2b922f57f486",
    "sequencer":"005C19A40717D99642"
}
]
}
}

```

**Tip:** In the **key** value, your DSM name displays.

6. Click **Services**, then navigate to **IAM**.
7. Set a **User or Role** permission to access the SQS queue and for permission to download from the target bucket. The user or user role must have permission to read and delete from the SQS queue. For information about adding, managing and changing permissions for IAM users, see the [IAM Users documentation](#). After QRadar reads the notification, and then downloads and processes the target file, the message must be deleted from the queue.

Sample Policy:

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sqs:DeleteMessage",
                "sqs:ReceiveMessage",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket_name>/AWSLogs/*",
                "arn:aws:sqs:us-east-2:<AWS_account_number>:<queue_name>"
            ]
        }
    ]
}

```

You can add multiple buckets to the S3 queue. To ensure that all objects are accessed, you must have a trailing `/*` at the end of the folder path that you added.

You can add this policy directly to a user, a user role, or you can create a minimal access user with **sts:AssumeRole** permissions only. When you configure a log source in QRadar, configure the **assume Role ARN** parameter for QRadar to assume the role. To ensure that all files waiting to be processed in a single run (emptying the queue) can finish without retries, use the default value of 1 hour for the **API Session Duration** parameter.

When you use assumed roles, ensure that the ARN of the user that is assuming the role is in the **Trusted Entities** for that role. You can view the trusted entities that can assume the rule from the **Trust Relationship** tab in **IAM Role**. In addition, the user must have permission to assume roles in that (or any) account. The following examples show a sample trust policy:

#### Allow all IAM users within a specific AWS account to assume a role

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:root"
            },
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"
        }
    ]
}

```

## Allow a specific user to assume a role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:user/USERNAME"  
            },  
            "Action": "sts:AssumeRole",  
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"  
        }  
    ]  
}
```

The following image example shows a sample Amazon AWS CloudTrail log source configuration in QRadar.

**Tip:** Use the Amazon AWS S3 REST API log source parameter values for your DSM when you configure your log source.

Figure 33. Example: Amazon AWS CloudTrail log source configuration in QRadar

## *Configuring security credentials for your AWS user account*

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### **Procedure**

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### **Related information**

#### [Adding a log source](#)

#### *Adding an AWS Verified Access log source on the QRadar Console using an SQS queue*

If you want to collect AWS Verified Access logs from multiple accounts or regions in an Amazon S3 bucket, add a log source on the QRadar Console so that AWS Verified Access can communicate with QRadar by using the Amazon AWS S3 REST API protocol and a Simple Queue Service (SQS) queue.

### **Procedure**

1. Use the following table to set the parameters for an Amazon AWS Verified Access log source that uses the Amazon AWS S3 REST API protocol and an SQS queue.

*Table 230. Amazon AWS S3 REST API protocol log source parameters*

Parameter	Description
<b>Log Source Type</b>	<b>AWS Verified Access</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one AWS Verified Access log source that is configured, you might want to identify the first log source as <i>awsverifiedaccess1</i> , the second log source as <i>awsverifiedaccess2</i> , and the third log source as <i>awsverifiedaccess3</i> .

Table 230. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Authentication Method</b>	<p><b>Access Key ID / Secret Key</b>  Standard authentication that can be used from anywhere.</p> <p><b>Assume IAM Role</b>  Authenticate with keys and then temporarily assume a role for access. This option is available only when you select <b>SQS Event Notifications</b> for the <b>S3 Collection Method</b>. The supported <b>S3 Collection Method</b> is <b>Use a Specific Prefix</b>.</p> <p><b>EC2 Instance IAM Role</b>  If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata that is assigned to the instance for authentication; no keys are required. This method works only for managed hosts that are running within an AWS EC2 container.</p>
<b>Access Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Access Key ID</b> parameter is displayed.  The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.
<b>Secret Key</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Secret Key ID</b> parameter is displayed.  The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Secret Key ID</b> that is used to access the AWS S3 bucket.
<b>Event Format</b>	Select <b>LINEBYLINE</b> . The log source retrieves JSON formatted events.
<b>S3 Collection Method</b>	Select <b>SQS Event Notifications</b> .
<b>SQS Queue URL</b>	Enter the full URL, starting with <code>https://</code> , of the SQS queue that is set up to receive notifications for ObjectCreate events from S3.
<b>Region Name</b>	The region that the SQS Queue or the S3 Bucket is in.  Example: us-east-1, eu-west-1, ap-northeast-3
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.
<b>Log Source Identifier Pattern</b>	This option is available when you set <b>Use as a Gateway Log Source</b> is set to yes.  Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.

Table 230. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.
<b>File Pattern</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code>
<b>Local Directory</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.
<b>S3 Endpoint URL</b>	This option is available when you set <b>Show Advanced Options</b> to Yes.  The endpoint URL that is used to query the AWS REST API.  If your endpoint URL is different from the default, type your endpoint URL. The default is <code>http://s3.amazonaws.com</code>
<b>Use S3 Path-Style Access</b>	Forces S3 requests to use path-style access.  This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.
<b>Use Proxy</b>	If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b> .  If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.  If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
<b>Recurrence</b>	How often a poll is made to scan for new data.  If you are using the SQS event collection method, <b>SQS Event Notifications</b> can have a minimum value of 10 (seconds). Because SQS Queue polling can occur more often, a lower value can be used.  If you are using the Directory Prefix event collection method, <b>Use a Specific Prefix</b> has a minimum value of 60 (seconds) or 1M. Because every listBucket request to an AWS S3 bucket incurs a cost to the account that owns the bucket, a smaller recurrence value increases the cost.  Type a time interval to determine how frequently the poll is made for new data. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15M = 15 minutes, 30 = seconds.

Table 230. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.

2. To verify that QRadar is configured correctly, review the [AWS Config sample event messages](#).

## Configuring an AWS Verified Access log source that uses an S3 bucket with a directory prefix

If you want to collect AWS Verified Access from a single account and region in an Amazon S3 bucket, configure a log source on the QRadar Console so AWS Verified Access can communicate with QRadar by using the Amazon AWS S3 REST API protocol with a directory prefix.

### About this task

If you have log sources in an S3 bucket from multiple regions or that use multiple accounts, use the [Amazon AWS REST API protocol with an SQS queue](#) instead of with a directory prefix.

**Restriction:** A log source that uses directory prefix can retrieve data from only one region and one account, so use a different log source for each region and account. Include the region folder name in the file path for the **Directory Prefix** value when you configure the log source.

### Procedure

1. [Finding an S3 bucket name and directory prefix](#).
2. [Create an Amazon AWS Identity and Access Management \(IAM\) user and then apply the \*\*AmazonS3ReadOnlyAccess\*\* policy](#).
3. [Configure the security credentials for your AWS user account](#).
4. [Add an AWS Verified Access log source on the QRadar Console using a directory prefix](#).

### Finding an S3 bucket name and directory prefix

An Amazon administrator must create a user and then apply the **AmazonS3ReadOnlyAccess** policy in the AWS Management Console. The QRadar user can then create a log source in QRadar.

**Note:** Alternatively, you can assign more granular permissions to the bucket. The minimum required permissions are **s3:listBucket** and **s3:getObject**.

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

### Procedure

1. Click **Services**.
2. From the list, select **Config**.
3. From the **Config** page, click the name of the Config.
4. Note the name of the S3 bucket that is displayed in the **S3 bucket** field.
5. Click the **Edit** icon.
6. Note the location path for the S3 bucket that is displayed underneath the **Log file prefix** field.

## **Creating an Identity and Access Management (IAM) user in the AWS Management Console**

An Amazon administrator must create a user and then apply the **s3:listBucket** and **s3:getObject** permissions to that user in the AWS Management Console. The QRadar user can then create a log source in QRadar.

### **About this task**

The minimum required permissions are **s3:listBucket** and **s3:getObject**. You can assign other permissions to the user as needed.

Sample policy:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::<bucket_name>",  
                "arn:aws:s3:::<bucket_name>/AWSLogs/<AWS_account_number>/<DSM_name>/us-east-1/*"  
            ]  
        }  
    ]  
}
```

For more information about permissions that are related to bucket operations, go to the [AWS documentation website](#).

### **Procedure**

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**.
3. From the list, select **IAM**.
4. Click **Users > Add user**.
5. Create an Amazon AWS IAM user and then apply the **AmazonS3ReadOnlyAccess** policy.

### **Configuring security credentials for your AWS user account**

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### **Procedure**

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

### **Related information**

[Adding a log source](#)

## **Adding an AWS Verified Access log source on the QRadar Console using a directory prefix**

If you want to collect AWS Verified Access logs from a single account and region in an Amazon S3 bucket, add a log source on the QRadar Console so that Amazon AWS Verified Access can communicate with QRadar by using the Amazon AWS S3 REST API protocol with a directory prefix.

### **Procedure**

1. Use the following table to set the parameters for an Amazon AWS Verified Access log source that uses the Amazon AWS S3 REST API protocol and a directory prefix.

*Table 231. Amazon AWS S3 REST API protocol log source parameters*

Parameter	Description
<b>Log Source Type</b>	<b>AWS Verified Access</b>
<b>Protocol Configuration</b>	<b>Amazon AWS S3 REST API</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.  The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one AWS Verified Access log source that is configured, you might want to identify the first log source as <i>awsverifiedaccess1</i> , the second log source as <i>awsverifiedaccess2</i> , and the third log source as <i>awsverifiedaccess3</i> .
<b>Authentication Method</b>	<b>Access Key ID / Secret Key</b> Standard authentication that can be used from anywhere.  For more information about configuring security credentials, see " <a href="#">Configuring security credentials for your AWS user account</a> " on page 316.  <b>Assume IAM Role</b> Authenticate with keys and then temporarily assume a role for access. This option is available only when you select <b>SQS Event Notifications</b> for the <b>S3 Collection Method</b> . The supported <b>S3 Collection Method</b> is <b>Use a Specific Prefix</b> .  For more information about creating IAM users and assigning roles, see <a href="#">Creating an IAM user in the AWS Management Console</a> .  <b>EC2 Instance IAM Role</b> If your managed host is running on an AWS EC2 instance, choosing this option uses the IAM Role from the instance metadata assigned to the instance for authentication; no keys are required. This method works only for managed hosts that are running within an AWS EC2 container.
<b>Access Key ID</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Access Key ID</b> parameter is displayed.  The <b>Access Key ID</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Access Key ID</b> that is used to access the AWS S3 bucket.

Table 231. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>Secret Key</b>	If you selected <b>Access Key ID / Secret Key</b> for the <b>Authentication Method</b> , the <b>Secret Key ID</b> parameter is displayed.  The <b>Secret Key</b> that was generated when you configured the security credentials for your AWS user account. This value is also the <b>Secret Key ID</b> that is used to access the AWS S3 bucket.
<b>Event Format</b>	Select <b>LINEBYLINE</b> . The log source retrieves JSON formatted events.
<b>S3 Collection Method</b>	Select <b>Use a Specific Prefix</b> .
<b>Bucket Name</b>	The name of the AWS S3 bucket where the log files are stored.
<b>Directory Prefix</b>	The root directory location on the AWS S3 bucket from where the AWS Verified Access logs are retrieved; for example, AWSLogs/ <AccountNumber>/VerifiedAccess/<RegionName>/  To pull files from the root directory of a bucket, you must use a forward slash (/) in the <b>Directory Prefix</b> file path.  <b>Note:</b> <ul style="list-style-type: none"> <li>• Changing the <b>Directory Prefix</b> value clears the persisted file marker. All files that match the new prefix are downloaded in the next pull.</li> <li>• The <b>Directory Prefix</b> file path cannot begin with a forward slash (/) unless only the forward slash is used to collect data from the root of the bucket.</li> <li>• If the <b>Directory Prefix</b> file path is used to specify folders, you must not begin the file path with a forward slash (for example, use folder1/folder2 instead).</li> </ul>
<b>Region Name</b>	The region that the SQS Queue or the S3 Bucket is in.  Example: us-east-1, eu-west-1, ap-northeast-3
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.
<b>Log Source Identifier Pattern</b>	This option is available when you set <b>Use as a Gateway Log Source</b> is set to yes.  Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.
<b>Show Advanced Options</b>	Select this option if you want to customize the event data.

Table 231. Amazon AWS S3 REST API protocol log source parameters (continued)

Parameter	Description
<b>File Pattern</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\json\.\gz</code></p>
<b>Local Directory</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The local directory on the Target Event Collector. The directory must exist before the AWS S3 REST API PROTOCOL attempts to retrieve events.</p>
<b>S3 Endpoint URL</b>	<p>This option is available when you set <b>Show Advanced Options</b> to Yes.</p> <p>The endpoint URL that is used to query the AWS REST API.</p> <p>If your endpoint URL is different from the default, type your endpoint URL. The default is <code>http://s3.amazonaws.com</code></p>
<b>Use S3 Path-Style Access</b>	<p>Forces S3 requests to use path-style access.</p> <p>This method is deprecated by AWS. However, it might be required when you use other S3 compatible APIs. For example, the <code>https://s3.region.amazonaws.com/bucket-name/key-name</code> path-style is automatically used when a bucket name contains a period (.). Therefore, this option is not required, but can be used.</p>
<b>Use Proxy</b>	<p>If QRadar accesses the Amazon Web Service by using a proxy, enable <b>Use Proxy</b>.</p> <p>If the proxy requires authentication, configure the <b>Proxy Server</b>, <b>Proxy Port</b>, <b>Proxy Username</b>, and <b>Proxy Password</b> fields.</p> <p>If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.</p>
<b>Recurrence</b>	<p>How often the Amazon AWS S3 REST API Protocol connects to the Amazon cloud API, checks for new files, and if they exist, retrieves them. Every access to an AWS S3 bucket incurs a cost to the account that owns the bucket. Therefore, a smaller recurrence value increases the cost.</p> <p>Type a time interval to determine how frequently the remote directory is scanned for new event log files. The minimum value is 1 minute. The time interval can include values in hours (H), minutes (M), or days (D). For example, 2H = 2 hours, 15 M = 15 minutes.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p>

2. To verify that QRadar is configured correctly, review the [AWS Verified Access sample event messages](#).

## AWS Verified Access sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### AWS Verified Access sample messages when you use the Amazon REST API protocol

**Sample 1:** The following sample event message shows that access to an application is granted.

```
2023-02-16T20: 43: 03.713Z{"activity": "Access Granted", "activity_id": "1", "category_name": "Application Activity", "category_uid": "8", "class_name": "Access Logs", "class_uid": "208001", "device": {"ip": "10.0.0.1", "os": {"name": "Windows 11", "type": "Windows", "type_id": 100}, "type": "Unknown", "type_id": 0, "uid": "99c11111111740d3a2222222f4ba65a", "hw_info": {"serial_number": "ec211111b-2222-3333-438b-52fd84444f05"}, "duration": "0.185", "end_time": "1676046036224", "time": "1676046036224", "http_request": {"http_method": "GET", "url": {"hostname": "test.example.com", "path": "/", "port": 443, "scheme": "h2", "text": "https://test.example.com:443/"}, "user_agent": "Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/109.0.0.0 Safari/537.36", "version": "HTTP/2.0"}, "http_response": {"code": 200}, "identity": {"authorizations": [{"decision": "Allow", "policy": {"name": "inline"}}, {"name": "idc", "uid": "vatp-0387011111e9779af"}, {"user": {"email_addr": "test@example.com", "name": "testuser", "uid": "281111e0-2222-3333-a99e-e5944037876"}], "idp": {"uid": "Root=1-6311111d4-57b0b8e7722222226c26acae"}, "logged_time": 1676046491347, "version": "", "product": {"name": "Verified Access", "version": "0.1", "vendor_name": "AWS"}}, "ref_time": "2023-02-10T16:20:36.224567Z", "proxy": {"ip": "10.0.0.2", "port": 443, "svc_name": "Verified Access", "uid": "vatp-01a31111151959c75"}, "severity": "Informational", "severity_id": "1", "src_endpoint": {"ip": "10.0.0.1", "port": 49339}, "start_time": "1676046036039", "status_code": "100", "status_details": "Access Granted", "status_id": "1", "status": "Success", "type_uid": "20800101", "type_name": "AccessLogs: Access Granted", "unmapped": null}

# Chapter 17. Ambiron TrustWave ipAngel

The IBM QRadar DSM for Ambiron TrustWave ipAngel receives Snort-based events from the ipAngel console.

The following table identifies the specifications for the Ambiron TrustWave ipAngel DSM:

Table 234. Ambiron TrustWave ipAngel DSM specifications	
Specification	Value
Manufacturer	Ambiron
DSM name	Ambiron TrustWave ipAngel
RPM file name	DSM-AmbironTrustwaveIpAngel-QRadar_version-build_number.noarch.rpm
Supported versions	V4.0
Protocol	Syslog
Recorded event types	Snort-based events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.apache.org">Ambiron website</a> ( <a href="http://www.apache.org">http://www.apache.org</a> )

To send Ambiron TrustWave ipAngel events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Ambiron TrustWave ipAngel DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
2. Configure your Ambiron TrustWave ipAngel device to forward your cache and access logs to QRadar. For information on forwarding device logs to QRadar, see your vendor documentation.
3. Add an Ambiron TrustWave ipAngel log source on the QRadar Console. The following table describes the parameters that require specific values that are required for Ambiron TrustWave ipAngel event collection:

Table 235. Ambiron TrustWave ipAngel log source parameters

Parameter	Value
Log Source type	Ambiron TrustWave ipAngel Intrusion Prevention System (IPS)
Protocol Configuration	Syslog

# Chapter 18. APC UPS

The IBM QRadar DSM for APC UPS accepts syslog events from the APC Smart-Uninterruptible Power Supply (UPS) family of products.

**Restriction:** Events from RC-Series Smart-UPS are not supported.

The following table identifies the specifications for the APC UPS DSM:

Table 236. APC UPS DSM specifications	
Specification	Value
Manufacturer	APC
DSM name	APC UPS
RPM file name	DSM-APCUPS-Qradar_version-build_number.noarch.rpm
Protocol	Syslog
Recorded event types	UPS events Battery events Bypass events Communication events Input power events Low battery condition events SmartBoost events SmartTrim events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.apc.com">APC website (http://www.apc.com)</a>

To send APC UPS events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the APC UPS DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
2. Create an APC UPS log source on the QRadar Console and use the following table to configure the specific values that are required to collect APC UPS events:

Table 237. APC UPS log source parameters

Parameter	Value
Log Source type	APC UPS
Protocol Configuration	Syslog

3. Configure your APC UPS device to forward syslog events to QRadar.

## Related tasks

[Adding a DSM](#)

[Adding a log source](#)

## [Configuring your APC UPS to forward syslog events](#)

To collect events from your APC UPS, you must configure the device to forward syslog events to IBM QRadar.

# Configuring your APC UPS to forward syslog events

To collect events from your APC UPS, you must configure the device to forward syslog events to IBM QRadar.

## Procedure

1. Log in to the APC Smart-UPS web interface.
2. In the navigation menu, click **Network > Syslog**.
3. From the **Syslog** list, select **Enable**.
4. From the **Facility** list, select a facility level for your syslog messages.
5. In the **Syslog Server** field, type the IP address of your QRadar Console or Event Collector.
6. From the **Severity** list, select **Informational**.
7. Click **Apply**.

# APC UPS sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## APC UPS sample message when you use the **Syslog** protocol

**Sample 1:** The following sample event message shows that a site wiring fault exists.

```
<10>Jan 10 15:25:44 apc.ups.test UPS: A site wiring fault exists. 0x0235
```

```
<10>Jan 10 15:25:44 apc.ups.test UPS: A site wiring fault exists. 0x0235
```

*Table 238. Highlighted values in the event payload*

QRadar field name	Highlighted values in the event payload
Event ID	A site wiring fault exists

**Sample 2:** The following sample event message shows that the local network management interface to UPS communication is restored.

```
<14>Jan 11 12:45:12 apc.ups.test UPS: Restored the local network management interface-to-UPS communication. 0x0101
```

```
<14>Jan 11 12:45:12 apc.ups.test UPS: Restored the local network management interface-to-UPS communication. 0x0101
```

# Chapter 19. Apache HTTP Server

The IBM QRadar DSM for Apache HTTP Server accepts Apache events by using syslog or syslog-ng.

QRadar records all relevant HTTP status events. The following procedure applies to Apache DSMs operating on UNIX/Linux operating systems only.

Do not run both syslog and syslog-ng at the same time.

Select one of the following configuration methods:

- [“Configuring Apache HTTP Server with syslog” on page 475](#)
- [“Configuring Apache HTTP Server with syslog-\*ng\*” on page 476](#)

## Configuring Apache HTTP Server with syslog

---

You can configure your Apache HTTP Server to forward events with the syslog protocol.

### About this task

The following procedure applies to Apache DSMs operating on most UNIX or Linux operating systems. Check your vendor's documentation for more information about configuring the server.

### Procedure

1. Log in to the server that hosts Apache, as the root user.
2. Edit the Apache configuration file `httpd.conf`.
3. Add the following information in the Apache configuration file to specify the custom log format:

```
LogFormat "%h %A %l %u %t \"%r\" %>s %p %b" <log format name>
```

Where `<log format name>` is a variable name you provide to define the log format.

4. Add the following information in the Apache configuration file to specify a custom path for the syslog events:

```
CustomLog "|/usr/bin/logger -t httpd -p <facility>.<priority>" <log format name>
```

Where:

- `<facility>` is a syslog facility, for example, local0.
- `<priority>` is a syslog priority, for example, info or notice.
- `<log format name>` is a variable name that you provide to define the custom log format. The log format name must match the log format name that is defined in Step 3.

For example,

```
CustomLog "|/usr/bin/logger -t httpd -p local1.info" MyApacheLogs
```

5. Type the following command to disable `hostname` lookup:

```
HostnameLookups off
```

6. Save the Apache configuration file.

7. Edit the syslog configuration file.

```
/etc/syslog.conf
```

8. Add the following information to your syslog configuration file:

```
<facility>.<priority> <TAB><TAB>@<host>
```

Where:

- <facility> is the syslog facility, for example, local0. This value must match the value that you typed in Step 4.
- <priority> is the syslog priority, for example, info or notice. This value must match the value that you typed in Step 4.
- <TAB> indicates you must press the **Tab** key.
- <host> is the IP address of the QRadar Console or Event Collector.

9. Save the syslog configuration file.

10. Type the following command to restart the syslog service:

```
/etc/init.d/syslog restart
```

11. Restart Apache to complete the syslog configuration.

The configuration is complete. The log source is added to QRadar as syslog events from Apache HTTP Servers are automatically discovered. Events that are forwarded to QRadar by Apache HTTP Servers are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Apache HTTP Server

If QRadar does not automatically detect the log source, add an Apache HTTP Server log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Apache HTTP Server:

Table 240. Syslog log source parameters for the Apache HTTP Server DSM	
Parameter	Value
<b>Log Source name</b>	Type the name of your log source.
<b>Log Source description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Apache HTTP Server</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Apache installations.

### Related tasks

[“Adding a log source” on page 5](#)

## Configuring Apache HTTP Server with syslog-ng

You can configure your Apache HTTP Server to forward events with the syslog-*ng* protocol.

### Procedure

1. Log in to the server that hosts Apache, as the root user.
2. Edit the Apache configuration file.

```
/etc/httpd/conf/httpd.conf
```

3. Add the following information to the Apache configuration file to specify the **LogLevel**:

```
LogLevel info
```

The **LogLevel** might already be configured to the info level; it depends on your Apache installation.

4. Add the following to the Apache configuration file to specify the custom log format:

```
LogFormat "%h %A %l %u %t \"%r\" %>s %p %b" <log format name>
```

Where <log format name> is a variable name you provide to define the custom log format.

5. Add the following information to the Apache configuration file to specify a custom path for the syslog events:

```
CustomLog "|/usr/bin/logger -t 'httpd' -u /var/log/httpd/apache_log.socket" <log format name>
```

The log format name must match the log format name that is defined in Step 4.

6. Save the Apache configuration file.

7. Edit the syslog-ng configuration file.

```
/etc/syslog-nginx/syslog-nginx.conf
```

8. Add the following information to specify the destination in the syslog-nginx configuration file:

```
source s_apache {  
    unix-stream("/var/log/httpd/apache_log.socket"  
    max-connections(512)  
    keep-alive(yes));  
};  
destination auth_destination { <udp|tcp> ("<IP address>" port(514)); };  
log{  
    source(s_apache);  
    destination(auth_destination);  
};
```

Where:

<IP address> is the IP address of the QRadar Console or Event Collector.

<udp | tcp> is the protocol that you select to forward the syslog event.

9. Save the syslog-nginx configuration file.

10. Type the following command to restart syslog-nginx:

```
service syslog-nginx restart
```

11. You can now configure the log source in QRadar.

The configuration is complete. The log source is added to QRadar as syslog events from Apache HTTP Servers are automatically discovered. Events that are forwarded to QRadar by Apache HTTP Servers are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Apache HTTP Server

If QRadar does not automatically detect the log source, add an Apache HTTP Server log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Apache HTTP Server:

Table 241. Syslog log source parameters for the Apache HTTP Server DSM

Parameter	Value
<b>Log Source name</b>	Type the name of your log source.
<b>Log Source description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Apache HTTP Server</b>
<b>Protocol Configuration</b>	<b>Syslog</b>

Table 241. Syslog log source parameters for the Apache HTTP Server DSM (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Apache installations.

#### Related tasks

[“Adding a log source” on page 5](#)

## Apache HTTP Server sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Apache HTTP Server sample messages when you use the Syslog protocol

**Sample 1:** The following sample event is generated when a user is authenticated.

```
<86>Jun 28 06:00:19 apache.httpserver.test sshd[11148]: pam_vas: Authentication <succeeded>
for <Active Directory> user: <svc_unix> account: <DOMAINNAME\svc_unix_secscan> service: <sshd>
reason: <>
```

```
<86>Jun 28 06:00:19 apache.httpserver.test sshd[11148]: pam_vas: Authentication <succeeded>
for <Active Directory> user: <svc_unix> account: <DOMAINNAME\svc_unix_secscan> service: <sshd>
reason: <>
```

Table 242. Highlighted values in the Apache HTTP Server event

QRadar field name	Highlighted values in the event payload
<b>Event ID</b>	<b>Authentication user</b> (extracted from the event content)
<b>Event Category</b>	<b>sshd</b>
<b>Username</b>	<b>svc_unix</b>

**Sample 2:** The following sample event message shows that an HTTP 403 system status occurred.

```
Oct 21 10:05:35 apache.httpserver.test httpd: 10.100.100.101 172.16.210.237 - - [26/Jan/
2006:12:24:54 +0000] "HEAD / HTTP/1.0" 403 123 "-" "-"
```

```
Oct 21 10:05:35 apache.httpserver.test httpd: 10.100.100.101 172.16.210.237 - - [26/Jan/
2006:12:24:54 +0000] "HEAD / HTTP/1.0" 403 123 "-" "-"
```

Table 243. Highlighted values in the Apache HTTP Server event

QRadar field name	Highlighted values in Apache event
<b>Event ID</b>	<b>403</b>
<b>Event Category</b>	apache (extracted from the event content)
<b>Source IP</b>	<b>10.100.100.101</b>
<b>Destination IP</b>	<b>172.16.210.237</b>

# Chapter 20. Apple Mac OS X

The IBM QRadar DSM for Apple Mac OS X accepts events by using syslog.

QRadar records all relevant firewall, web server access, web server error, privilege escalation, and informational events.

To integrate Apple Mac OS X events with QRadar, you must manually create a log source to receive syslog events.

To complete this integration, you must configure a log source, then configure your Apple Mac OS X to forward syslog events. Syslog events that are forwarded from Apple Mac OS X devices are not automatically discovered. Syslog events from Apple Mac OS X can be forwarded to QRadar on TCP port 514 or UDP port 514.

## Apple Mac OS X DSM specifications

Understanding the specifications for the Apple Mac OS X DSM helps to ensure a successful integration. For example, knowing what the supported version of Apple Mac OS X is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Apple Mac OS X DSM.

Table 244. Apple Mac OS X DSM specifications	
Specification	Value
Manufacturer	Apple
DSM name	Apple Mac OS X
RPM file name	DSM-AppleOSX-QRadar_version-build_number.noarch.rpm
Supported version	10.12
Protocol	Syslog
Recorded event types	Firewall, web server access, web server error, privilege, and informational events
Automatically discovered?	No
Includes identity?	Yes
Includes custom properties?	No

## Syslog log source parameters for Apple Mac OS X

If QRadar does not automatically detect the log source, add an Apple Mac OS X log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Apple Mac OS X:

Table 245. Syslog log source parameters for the Apple Mac OS X DSM	
Parameter	Value
Log Source name	A name of your log source.

Table 245. Syslog log source parameters for the Apple Mac OS X DSM (continued)

Parameter	Value
<b>Log Source description</b>	A description for your log source.
<b>Log Source type</b>	<b>Mac OS X</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Apple Mac OS X device.

#### Related tasks

[“Adding a log source” on page 5](#)

## Configuring syslog on your Apple Mac OS X

Configure syslog on systems that run Apple Mac OS X operating systems by using a log stream script to send the MAC system logs to QRadar.

### Procedure

1. To implement the 7.3-QRADAR-QRSCRIPT-logStream-1.0 fix, download the following files from [IBM Fix Central](https://www-945.ibm.com/support/fixcentral/swg/downloadFixes?parent=IBM%20Security&product=ibm/Other+software/IBM+Security+QRadar+SIEM&release=7.3.0&platform=Linux&function=fixId&fixids=7.3-QRADAR-QRSCRIPT-logStream-1.0&includeRequisites=1&includeSupersedes=0&downloadMethod=http). (<https://www-945.ibm.com/support/fixcentral/swg/downloadFixes?parent=IBM%20Security&product=ibm/Other+software/IBM+Security+QRadar+SIEM&release=7.3.0&platform=Linux&function=fixId&fixids=7.3-QRADAR-QRSCRIPT-logStream-1.0&includeRequisites=1&includeSupersedes=0&downloadMethod=http>)
  - logStream.pl.tar.gz (2.88 KB)
  - 7.3-QRADAR-QRSCRIPT-logStream.sha256 (41 bytes)
2. From the terminal, go to the folder that you chose to contain the `logStream.pl` file that you extracted.
3. To make the `logStream.pl` file an executable file, type the following command:

```
chmod +x logStream.pl
```

4. Create an executable shell script with an `.sh` extension with the following naming convention:

```
<FILE_NAME>.sh
```

5. Add the following command to the file that you created:

```
#!/bin/sh /Users/<PathToPerlScript>/logStream.pl -<Parameters1> <Value1> -<Parameters2>
<Value2>
```

The path is an absolute path that usually starts from `/Users/....`

You can use the following parameters for `logStream.pl`:

Table 246. `logStream.pl` parameters

Parameter	Description
<b>-H</b>	The <b>-H</b> parameter defines the host name or IP to send the logs to.
<b>-p</b>	The <b>-p</b> parameter defines the port on the remote host, where a syslog receiver is listening. If this parameter is not specified, by default the <code>logStream.pl</code> script uses the TCP port 514 for sending events to QRadar.

Table 246. *logStream.pl* parameters (continued)

Parameter	Description
<b>-0</b>	The <b>-0</b> parameter overrides the automatic host name from the OS's /bin/hostname command.
<b>-s</b>	The syslog header format default is 5424 (RFC5424 time stamp), but 3339 can be specified instead to output the time stamp in RFC3339 format.
<b>-u</b>	The <b>-u</b> parameter forces logStream to send events by using UDP.
<b>-v</b>	The <b>-v</b> parameter displays the version information for the logStream.
<b>-x</b>	The <b>-x</b> parameter is an exclusion filter in grep extended Regex format. For example: parentalcontrolsd com.apple.Webkit.WebContent

**Example:**

```
#!/bin/sh /Users/...../logStream.pl -H 172.16.70.135
```

6. Save your changes.
7. From the terminal, go to the folder that contains the shell file that you created.
8. To make the perl file an executable file, type the following command:

```
chmod +x <FILE_NAME>.sh
```

9. In the terminal, create a file with a .plist file extension as in the following example:

<fileName>.plist.

10. Add the following XML command to the file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
  <dict>
    <key>Label</key>
    <string>com.logSource.app</string>
    <key>Program</key>
    <string>/Users/...[Path_to_Shell_Script_Created_In_Step2]/[FILE_NAME].sh</string>
    <key>RunAtLoad</key>
    <true />
  </dict>
</plist>
```

The XML command holds data in key-value pair. The following table provides the key-value pairs:

Table 247. Key-value pairs

Key	Value
<b>Label</b>	com.logSource.app
<b>Program</b>	/Users/...[Path_To_Shell_Script_Created_In Step2].../[FILE_NAME].sh
<b>RunAtLoad</b>	True

**Note:**

The value of the **Label** key must be unique for each .plist file. For example, if you use the **Label** value com.logSource.app for one .plist file, you can't use the same value for another .plist file.

The Program key holds the path of the shell script that you want to run. The path is an absolute path that usually starts from /Users/....

The **RunAtLoad** key shows events when you want to run your shell program automatically.

11. Save your changes.

12. To make the .plist file an executable file, type the following command:

```
chmod +x <FILE_NAME>.plist
```

13. Copy the file to /Library/LaunchDaemons/ by using the following command:

```
sudo cp <Path_To_Your_plist_file> /Library/LaunchDaemons/
```

14. Restart your Mac system.

15. Log in to QRadar, and then from the **Log Activity** tab, verify that events are arriving from the Apple Mac system. If events are arriving as Sim Generic, you must manually configure a log source for the Apple Mac system.

**Example:** Consider the following event:

```
<13>1 2020-06-25T16:06:55.198987-0300 AAAA-MacBook-Pro.local trustd[130]:  
[com.apple.securityd.policy] cert[2]: AnchorTrusted =(leaf)[force]> 0
```

The log source parameter values for that event are:

*Table 248. Log source parameters*

Parameter	Value
<b>Log Source Type</b>	Apple Mac OS X
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	AAAA-MacBook-Pro.local

## Apple Mac OS X sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Apple Mac OS X sample message when you use the Syslog protocol

The following sample event message shows an invalid user.

```
May  1 10:33:35 apple.macosx.test sshd[8565]: Invalid user testUser from 192.168.0.1
```

```
May  1 10:33:35 apple.macosx.test sshd[8565]: Invalid user testUser from 192.168.0.1
```

*Table 249. Highlighted values in the Apple Mac OS X sample event*

QRadar field name	Highlighted payload field name
<b>Event ID</b>	<b>Invalid user</b> is extracted from the event.
<b>Username</b>	<b>testUser</b> is extracted from the event.
<b>Source IP</b>	<b>192.168.0.1</b> is extracted from the event.
<b>Device Time</b>	<b>May 1 10:33:35</b> is extracted from the event header.

# Chapter 21. Application Security DbProtect

The IBM QRadar DSM for Application Security DbProtect collects event from DbProtect devices that are installed with the Log Event Extended Format (LEEF) Service.

The following table identifies the specifications for the Application Security DbProtect DSM:

Table 250. Application Security DbProtect DSM specifications	
Specification	Value
Manufacturer	Application Security, Inc
DSM name	DbProtect
RPM file name	DSM-AppSecDbProtect-QRadar_version-build_number.noarch.rpm
Supported versions	v6.2 v6.3 v6.3sp1 v6.3.1 v6.4
Protocol	LEEF
Recorded event types	All events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.appsecinc.com/">Application Security website (http://www.appsecinc.com/)</a>

To send Application Security DbProtect events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Application Security DbProtect DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
2. Configure your Application Security DbProtect device to communicate with QRadar. Complete the following steps:
  - a. Install the DbProtect LEEF Relay Module.
  - b. Configure the DbProtect LEEF Relay
  - c. Configure DbProtect alerts.
3. If QRadar does not automatically detect the log source, add an Application Security DbProtect log source on the QRadar Console. Configure all required parameters, and use the following table for DbProtect-specific values:

Table 251. Application Security DbProtect log source parameters

Parameter	Value
Log Source type	Application Security DbProtect
Protocol Configuration	Syslog

# Installing the DbProtect LEEF Relay Module

---

To enable DbProtect to communicate with IBM QRadar, install the DbProtect LEEF Relay module on the same server as the DbProtect console.

## Before you begin

Before you install the DbProtect LEEF Relay module on a Windows 2003 host, you must install Windows Imaging Components. The `wic_x86.exe` file contains the Windows Imaging Components and is on the Windows Server Installation CD. For more information, see your Windows 2003 Operating System documentation.

## About this task

The LEEF Relay module for DbProtect translates the default events messages to Log Event Extended Format (LEEF) messages for QRadar. Before you can receive events in QRadar, you must install and configure the LEEF Service for your DbProtect device to forward syslog events. The DbProtect LEEF Relay requires that you install the .NET 4.0 Framework, which is bundled with the LEEF Relay installation.

## Procedure

1. Download the DbProtect LEEF Relay module for DbProtect from the [Application Security, Inc. customer portal](http://www.appsecinc.com) (`http://www.appsecinc.com`).
2. Save the setup file to the same host as your DbProtect console.
3. Click **Accept** to agree with the Microsoft .NET Framework 4 End-User License Agreement.
4. In the **DbProtect LEEF Relay module installation Wizard**, click **Next**.
5. To select the default installation path, click **Next**.  
If you change the default installation directory, make note of the file location.
6. On the **Confirm Installation** window, click **Next**.
7. Click **Close**.

## What to do next

[“Configuring the DbProtect LEEF Relay” on page 484](#)

# Configuring the DbProtect LEEF Relay

---

After you install the DbProtect LEEF Relay module, configure the service to forward events to IBM QRadar.

## Before you begin

Stop the DbProtect LEEF Relay service before you edit any configuration values.

## Procedure

1. Log in to the DbProtect LEEF Relay server.
2. Access the `C:\Program Files (x86)\AppSecInc\AppSecLEEFConverter` directory.
3. Edit the `AppSecLEEFConverter.exe.config` file. Configure the following values:

Parameter	Description
<code>SyslogListenerPort</code>	The port number that the DbProtect LEEF Relay uses to listen for syslog messages from the DbProtect console.
<code>SyslogDestinationHost</code>	The IP address of your QRadar Console or Event Collector.
<code>SyslogDestinationPort</code>	514

Parameter	Description
<b>LogFileName</b>	A file name for the DbProtect LEEF Relay to write debug and log messages. The LocalSystem user account that runs the DbProtect LEEF Relay service must have write privileges to the file path that you specify.

4. Save the configuration changes to the file.
5. On the desktop of the DbProtect console, select **Start > Run**.
6. Type the following command:  
`services.msc`
7. Click **OK**.
8. In the details pane of the **Services** window, verify the **DbProtect LEEF Relay** is started and set to **automatic startup**.
9. To change a service property, right-click the service name, and then click **Properties**.
10. Using the **Startup type** list, select **Automatic**.
11. If the **DbProtect LEEF Relay** is not started, click **Start**.

## What to do next

[“Configuring DbProtect alerts” on page 485](#)

## Configuring DbProtect alerts

---

Configure sensors on your DbProtect console to generate alerts.

### Procedure

1. Log in to the DbProtect console.
  2. Click the **Activity Monitoring** tab.
  3. Click the **Sensors** tab.
  4. Select a sensor and click **Reconfigure**.
  5. Select a database instance and click **Reconfigure**.
  6. Click **Next** until the **Sensor Manager Policy** window is displayed.
  7. Select the **Syslog** check box and click **Next**.
  8. In the **Send Alerts to the following Syslog console** field, type the IP address of your DbProtect console.
  9. In the **Port** field, type the port number that you configured in the **SyslogListenerPort** field of the DbProtect LEEF Relay.
- Tip:** By default, 514 is the default Syslog listen port for the DbProtect LEEF Relay.
10. Click **Add**.
  11. Click **Next** until you reach the **Deploy to Sensor** window.
  12. Click **Deploy to Sensor**.

# Chapter 22. Arbor Networks

Several Arbor Networks devices can be integrated with IBM QRadar.

This section provides information on the following DSMs:

- [“Arbor Networks Peakflow SP” on page 487](#)
- [“Arbor Networks Pravail” on page 490](#)

## Arbor Networks Peakflow SP

IBM QRadar can collect and categorize syslog and TLS syslog events from Arbor Networks Peakflow SP appliances that are in your network.

Arbor Networks Peakflow SP appliances store the syslog events locally.

To collect local syslog events, you must configure your Peakflow SP appliance to forward the syslog events to a remote host. QRadar automatically discovers and creates log sources for syslog events that are forwarded from Arbor Networks Peakflow SP appliances. QRadar supports syslog events that are forwarded from Peakflow V5.8 to V8.1.2.

To configure Arbor Networks Peakflow SP, complete the following steps:

1. On your Peakflow SP appliance, create a notification group for QRadar.
2. On your Peakflow SP appliance, configure the global notification settings.
3. On your Peakflow SP appliance, configure your alert notification rules.
4. If automatic updates are not enabled for QRadar, RPMs are available for download from the [IBM support website](#). Download and install the most recent version of the following RPMs on your QRadar Console.
  - DSMCommon RPM
  - Arbor Networks Peakflow SP DSM RPM
5. Configure your Arbor Networks Peakflow SP appliance to send syslog or TLS syslog events to QRadar.
6. If QRadar does not automatically detect the log source, add an Arbor Networks Peakflow SP log source on the QRadar Console. The following tables describe the parameters that require specific values to collect events from Arbor Networks Peakflow SP:

*Table 252. Arbor Networks Peakflow SP log source parameters*

Parameter	Value
Log Source type	Arbor Networks Peakflow SP
Protocol Configuration	Select <b>Syslog</b> or <b>TLS Syslog</b>
Log Source Identifier	Type a unique name for the log source.

### Related concepts

[“TLS Syslog protocol configuration options” on page 231](#)

Configure a TLS Syslog protocol log source to receive encrypted syslog events from network devices that support TLS Syslog event forwarding for each listener port.

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Supported event types for Arbor Networks Peakflow SP

The Arbor Networks Peakflow DSM for IBM QRadar collects events from several categories.

Each event category contains low-level events that describe the action that is taken within the event category. For example, authentication events can have low-level categories of login successful or login failure.

The following list defines the event categories that are collected by QRadar from Peakflow SP appliances:

- Denial of Service (DoS) events
- Authentication events
- Exploit events
- Suspicious activity events
- System events

## Configuring a remote syslog in Arbor Networks Peakflow SP

To collect events, you must configure a new notification group or edit existing groups to add IBM QRadar as a remote syslog destination.

### Procedure

1. Log in to your Peakflow SP configuration interface as an administrator.
2. In the navigation menu, select **Administration > Notification > Groups**.
3. Click **Add Notification Group**.
4. In the **Destinations** field, type the IP address of your QRadar system.
5. In the **Port** field, type 514 as the port for your syslog destination.
6. From the **Facility** list, select a syslog facility.
7. From the **Severity** list, select **info**.

The informational severity collects all event messages at the informational event level and higher severity.

8. Click **Save**.
9. Click **Configuration Commit**.

## Configuring global notifications settings for alerts in Arbor Networks Peakflow SP

Global notifications in Arbor Networks Peakflow SP provide system notifications that are not associated with rules.

### About this task

This procedure defines how to add IBM QRadar as the default notification group and enable system notifications.

### Procedure

1. Log in to the configuration interface for your Arbor Networks Peakflow SP appliance as an administrator.
2. In the navigation menu, select **Administration > Notification > Global Settings**.
3. In the **Default Notification Group** field, select the notification group that you created for QRadar syslog events.
4. Click **Save**.

5. Click **Configuration Commit** to apply the configuration changes.
6. Log in to the Arbor Networks Peakflow SP command-line interface as an administrator.
7. Type the following command to list the current alert configuration:  

```
services sp alerts system_errors show
```
8. Optional: Type the following command to list the fields names that can be configured:  

```
services sp alerts system_errors ?
```
9. Type the following command to enable a notification for a system alert:  

```
services sp alerts system_errors <name> notifications enable
```

Where <name> is the field name of the notification.
10. Type the following command to commit the configuration changes:  

```
config write
```

## Configuring alert notification rules in Arbor Networks Peakflow SP

To generate events, you must edit or add rules to use the notification group that IBM QRadar uses as a remote syslog destination.

### Procedure

1. Log in to your Arbor Networks Peakflow SP configuration interface as an administrator.
2. In the navigation menu, select **Administration > Notification > Rules**.
3. Select one of the following options:
  - Click a current rule to edit the rule.
  - Click **Add Rule** to create a new notification rule.
4. Configure the following values:

*Table 253. Arbor Networks Peakflow SP notification rule parameters*

Parameter	Description
<b>Name</b>	Type the IP address or host name as an identifier for events from your Peakflow SP installation. The log source identifier must be a unique value.
<b>Resource</b>	Type a CIDR address or select a managed object from the list of Peakflow resources.
<b>Importance</b>	Select the <b>Importance</b> of the rule.
<b>Notification Group</b>	Select the <b>Notification Group</b> that you assigned to forward syslog events to QRadar.

5. Repeat these steps to configure any other rules that you want to create.
6. Click **Save**.
7. Click **Configuration Commit** to apply the configuration changes.

QRadar automatically discovers and creates a log source for Arbor Networks Peakflow SP appliances. Events that are forwarded to QRadar are displayed on the **Log Activity** tab.

## Syslog log source parameters for Arbor Networks Peakflow SP

If QRadar does not automatically detect the log source, add an Arbor Networks Peakflow SP log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Arbor Networks Peakflow SP:

*Table 254. Syslog log source parameters for the Arbor Networks Peakflow SP DSM*

Parameter	Value
<b>Log Source name</b>	The name of your log source.
<b>Log Source description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Arbor Networks Peakflow</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	The IP address or host name is used as an identifier for events from your Peakflow SP installation. The log source identifier must be a unique value.
<b>Credibility</b>	The credibility of the log source. The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event.
<b>Target Event Collector</b>	The event collector to use as the target for the log source.
<b>Coalescing Events</b>	Enables the log source to coalesce (bundle) events. By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Incoming Event Payload</b>	The incoming payload encoder for parsing and storing the logs.
<b>Store Event Payload</b>	Enables the log source to store event payload information. By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

#### Related tasks

[“Adding a log source” on page 5](#)

## Arbor Networks Pravail

The IBM QRadar DSM for Arbor Networks Pravail receives event logs from your Arbor Networks Pravail servers.

The following table identifies the specifications for the Arbor Networks Pravail DSM:

*Table 255. Arbor Networks Pravail DSM specifications*

Specification	Value
Manufacturer	Arbor Networks
DSM	Arbor Networks Pravail
RPM file name	DSM-ArborNetworksPravail-build_number.noarch.rpm
Protocol	Syslog
Recorded events	All relevant events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.arbornetworks.com">Arbor Networks website (www.arbornetworks.com)</a>

To send Arbor Networks Pravail events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Arbor Networks Pravail RPM from the [IBM Support Website](#) onto your QRadar Console.
2. Configure each Arbor Networks Pravail system to send events to QRadar.
3. If QRadar does not automatically discover the Arbor Pravail system, create a log source on the QRadar Console. Configure the required parameters, and use the following table for the Arbor Pravail specific parameters:

*Table 256. Arbor Pravail parameters*

Parameter	Value
<b>Log Source Type</b>	Arbor Networks Pravail
<b>Protocol Configuration</b>	Syslog

#### Related tasks

[Adding a DSM](#)

[Configuring your Arbor Networks Pravail system to send events to IBM QRadar](#)

To collect all audit logs and system events from Arbor Networks Pravail, you must add a destination that specifies QRadar as the syslog server.

[Adding a log source](#)

## Configuring your Arbor Networks Pravail system to send events to IBM QRadar

To collect all audit logs and system events from Arbor Networks Pravail, you must add a destination that specifies QRadar as the syslog server.

#### Procedure

1. Log in to your Arbor Networks Pravail server.
2. Click **Settings & Reports**.
3. Click **Administration > Notifications**.
4. On the **Configure Notifications** page, click **Add Destinations**.
5. Select **Syslog**.
6. Configure the following parameters:

Table 257. Syslog parameters

Parameter	Description
<b>Host</b>	The IP address of the QRadar Console
<b>Port</b>	514
<b>Severity</b>	Info
<b>Alert Types</b>	The alert types that you want to send to the QRadar Console

7. Click **Save**.

## Arbor Networks Pravail sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Arbor Networks Pravail sample message when you use the Syslog protocol

The following sample event message shows that a malformed SIP traffic is blocked.

```
<25>May 15 17:17:31 arbornetworks.pravail.test arbor-networks-aps: Blocked Host: Blocked host  
192.168.124.175 at 05:16 by Block Malformed SIP Traffic using UDP/5060 (SIP) destination  
192.168.161.35 source port 5060, URL: https://arbornetworks.pravail.test/summary/
```

```
<25>May 15 17:17:31 arbornetworks.pravail.test arbor-networks-aps: Blocked Host: Blocked host

# Chapter 23. Arpeggio SIFT-IT

The IBM QRadar DSM for SIFT-IT accepts syslog events from Arpeggio SIFT-IT running on IBM i that are formatted as Log Event Extended Format (LEEF).

QRadar supports events from Arpeggio SIFT-IT 3.1 and later installed on IBM i version 5 revision 3 (V5R3) and later.

Arpeggio SIFT-IT supports syslog events from the journal QAUDJRN in LEEF format.

Example:

```
Jan 29 01:33:34 <Server> LEEF:1.0|Arpeggio|SIFT-IT|3.1|PW_U|sev=3
usrName=<Username> src=<Source_IP_address> srcPort=543 jJobNam=QBASE
jJobUsr=<Username> jJobNum=1664 jrmtpIP=<SourceIP_address> jrmtpPort=543
jSeqNo=4755 jPgm=QWTMCMNL jPgmLib=QSYS jMsgId=PWU0000 jType=U jUser=ROOT
jDev=QPADEV000F jMsgTxt=Invalid user id <Username>. Device <Device_ID>.
```

Events that SIFT-IT sends to QRadar are determined with a configuration rule set file. SIFT-IT includes a default configuration rule set file that you can edit to meet your security or auditing requirements. For more information about configuring rule set files, see your *SIFT-IT User Guide*.

## Configuring a SIFT-IT agent

Arpeggio SIFT-IT can forward syslog events in LEEF format with SIFT-IT agents.

### About this task

A SIFT-IT agent configuration defines the location of your IBM QRadar installation, the protocol and formatting of the event message, and the configuration rule set.

### Procedure

1. Log in to your IBM i.
2. Type the following command and press Enter to add SIFT-IT to your library list:  
`ADDLIBLE SIFTITLIB0`
3. Type the following command and press Enter to access the SIFT-IT main menu:  
`GO SIFTIT`
4. From the main menu, select **1. Work with SIFT-IT Agent Definitions**.
5. Type 1 to add an agent definition for QRadar and press Enter.
6. In the **SIFT-IT Agent Name** field, type a name.  
For example, QRadar.
7. In the **Description** field, type a description for the agent.  
For example, Arpeggio agent for QRadar.
8. In the **Server host name or IP address** field, type the location of your QRadar Console or Event Collector.
9. In the **Connection type** field, type either \*TCP, \*UDP, or \*SECURE.  
The \*SECURE option requires the TLS protocol.
10. In the **Remote port number** field, type 514.  
By default, QRadar supports both TCP and UDP syslog messages on port 514.
11. In the **Message format options** field, type \*QRadar.
12. Optional: Configure any additional parameters for attributes that are not QRadar specific.

The additional operational parameters are described in the *SIFT-IT User Guide*.

13. Press F3 to exit to the **Work with SIFT-IT Agents Description** menu.
14. Type 9 and press Enter to load a configuration rule set for QRadar.
15. In the **Configuration file** field, type the path to your QRadar configuration rule set file.

Example:

```
/sifitit/Qradarconfig.txt
```

16. Press F3 to exit to the **Work with SIFT-IT Agents Description** menu.
17. Type 11 to start the QRadar agent.

## What to do next

Syslog events that are forwarded by Arpeggio SIFT-IT in LEEF format are automatically discovered by QRadar. In most cases, the log source is automatically created in QRadar after a few events are detected. If the event rate is low, you might be required to manually create a log source for Arpeggio SIFT-IT in QRadar.

Until the log source is automatically discovered and identified, the event type displays as Unknown on the **Log Activity** tab of QRadar.

### Related concepts

[“TLS Syslog protocol configuration options” on page 231](#)

Configure a TLS Syslog protocol log source to receive encrypted syslog events from network devices that support TLS Syslog event forwarding for each listener port.

## Syslog log source parameters for Arpeggio SIFT-IT

If QRadar does not automatically detect the log source, add a Arpeggio SIFT-IT log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Arpeggio SIFT-IT:

Table 259. Syslog log source parameters for the Arpeggio SIFT-IT DSM	
Parameter	Value
<b>Log Source name</b>	Type the name of your log source.
<b>Log Source description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Arpeggio SIFT-IT</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Arpeggio SIFT-IT installation.

### Related tasks

[“Adding a log source” on page 5](#)

## Additional information

After you create your IBM QRadar agent definition, you can use your Arpeggio SIFT-IT software and QRadar integration to customize your security and auditing requirements.

You can customize the following security and auditing requirements:

- Create custom configurations in Arpeggio SIFT-IT with granular filtering on event attributes.

For example, filtering on job name, user, file or object name, system objects, or ports. All events that are forwarded from SIFT-IT and the contents of the event payload in QRadar are easily searched.

- Configure rules in QRadar to generate alerts or offenses for your security team to identify potential security threats, data loss, or breaches in real time.
- Configuring processes in Arpeggio SIFT-IT to trigger real-time remediation of issues on your IBM i.
- Creating offenses for your security team from Arpeggio SIFT-IT events in QRadar with the **Offenses** tab or configuring email job logs in SIFT-IT for your IBM i administrators.
- Creating multiple configuration rule sets for multiple agents that run simultaneously to handle specific security or audit events.

For example, you can configure one QRadar agent with a specific rule set for forwarding all IBM i events, then develop multiple configuration rule sets for specific compliance purposes. You can easily manage configuration rule sets for compliance regulations, such as FISMA, PCI, HIPPA, SOX, or ISO 27001. All of the events that are forwarded by SIFT-IT QRadar agents are contained in a single log source and categorized to be easily searched.

---

# Chapter 24. Array Networks SSL VPN

The IBM QRadar DSM for Array Networks SSL VPN collects events from an ArrayVPN appliance by using syslog.

QRadar records all relevant SSL VPN events that are forwarded by using syslog on TCP port 514 or UDP port 514.

## Syslog log source parameters for Array Networks SSL VPN

If QRadar does not automatically detect the log source, add a Array Networks SSL VPN log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Array Networks SSL VPN:

Table 260. Syslog log source parameters for the Array Networks SSL VPN DSM	
Parameter	Value
<b>Log Source Name</b>	Type the name of your log source.
<b>Log Source Description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Array Networks SSL VPN Access Gateways</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.

# Chapter 25. Aruba Networks

Several Aruba devices can be integrated with IBM QRadar.

## Aruba ClearPass Policy Manager

The IBM QRadar DSM for Aruba ClearPass Policy Manager can collect event logs from your Aruba ClearPass Policy Manager servers.

The following table identifies the specifications for the Aruba ClearPass Policy Manager DSM:

Table 261. Aruba ClearPass Policy Manager DSM specifications	
Specification	Value
Manufacturer	Aruba Networks
DSM name	ClearPass
RPM file name	DSM-ArubaClearPass-QRadar_version-build_number.noarch.rpm
Supported versions	6.5.0.71095 to 6.11.1
Event format	LEEF
Recorded event types	Session Audit System Insight
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="#">Aruba Networks website</a>

To integrate Aruba ClearPass Policy Manager with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Aruba ClearPass DSM RPM
  - DSMCommon RPM
2. Configure your Aruba ClearPass Policy Manager device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an Aruba ClearPass log source on the QRadar Console. The following table describes the parameters that require specific values for Aruba ClearPass Policy Manager event collection:

Table 262. Aruba ClearPass Policy Manager log source parameters

Parameter	Value
Log Source type	Aruba ClearPass Policy Manager
Protocol Configuration	Syslog

## Procedure

1. Log in to your Aruba ClearPass Policy Manager server.
2. Start the Administration Console.

3. Click **External Servers > Syslog Targets**.
4. Click **Add**, and then configure the details for the QRadar host.
5. On the Administration Console, click **External Servers > Syslog Export Filters**
6. Click **Add**.
7. Select **LEEF** for the **Export Event Format Type**, and then select the **Syslog Server** that you added.
8. Click **Save**.

## TCP Multiline Syslog log source parameters for Aruba ClearPass Policy Manager

The Aruba ClearPass Policy Manager DSM for IBM QRadar accepts Syslog events with log sources that are configured with the TCP Multiline Syslog protocol when the events are fragmented.

If QRadar does not automatically detect a log source, add the Aruba ClearPass Policy Manager log source on the QRadar Console by using the TCP Multiline Syslog protocol.

The following table describes the parameters that require specific values to collect TCP Multiline Syslog events from Aruba ClearPass Policy Manager:

Table 264. TCP Multiline Syslog log source parameters for the Aruba ClearPass Policy Manager DSM	
Parameter	Value
<b>Log Source type</b>	Aruba ClearPass Policy Manager
<b>Protocol Configuration</b>	TCP Multiline Syslog
<b>Log Source Identifier</b>	<p>Type the IP address or host name to identify the log source.</p> <p>To use a source name instead of a log source identifier, select <b>Use Custom Source Name</b> and enter the values for <b>Source Name Regex</b> and <b>Source Name Formatting String</b>.</p> <p><b>Important:</b> These parameters are available only if <b>Show Advanced Options</b> is set to <b>Yes</b>.</p> <p>The log source identifier must be a unique value.</p>
<b>Listen Port</b>	<p>The port number that accepts incoming TCP Multiline Syslog events.</p> <p>The default <b>Listen Port</b> is <b>12468</b>.</p> <p>To edit the port number, complete the following steps:</p> <ol style="list-style-type: none"> <li>1. Enter the new port number for the protocol.</li> <li>2. Click <b>Save</b>.</li> <li>3. Under the <b>Admin</b> tab, click <b>Advanced &gt; Deploy Full Configuration</b>.</li> </ol> <p><b>Important:</b> When the admin clicks <b>Deploy Full Configuration</b>, the system restarts all services, which can create a gap in the data collection until the deployment is completed.</p>
<b>Aggregation Method</b>	ID-Linked

Table 264. TCP Multiline Syslog log source parameters for the Aruba ClearPass Policy Manager DSM  
(continued)

Parameter	Value
<b>Message ID Pattern</b>	<p>This parameter is available when you set <b>Aggregation Method</b> to <b>ID-Linked</b>.</p> <p>This regular expression (regex) is used to filter the event payload messages. The TCP multiline event messages must contain a common identifying value that repeats on each line of the event message.</p> <p><b>Important:</b> In the case of message ID, enter this pattern:</p> <pre>messageId=(\d+)\d\d</pre>
<b>Event Formatter</b>	No formatting
<b>Show Advanced Options</b>	Yes
<b>Use Custom Source Name</b>	Off
<b>Use as a Gateway Log Source</b>	Off, unless you have multiple Aruba devices sending to the same port.
<b>Flatten Multiline Events Into Single Line</b>	On
<b>Retain Entire Lines During Event Aggregation</b>	Off
<b>Time Limit</b>	3

The following is a sample event message for Aruba ClearPass Policy Manager for TCP Multiline Syslog protocol:

```

## Aruba Introspect

The IBM QRadar DSM for Aruba Introspect collects events from an Aruba Introspect device.

The following table describes the specifications for the Aruba Introspect DSM:

*Table 266. Aruba Introspect DSM specifications*

Specification	Value
Manufacturer	Aruba
DSM name	Aruba Introspect
RPM file name	DSM-ArubaIntrospect-QRadar_version-build_number.noarch.rpm
Supported versions	1.6
Protocol	Syslog
Event format	Name-value pair (NVP)
Recorded event types	Security System Internal Activity Exfiltration Infection Command & Control
Automatically discovered?	Yes
Includes identity?	No

*Table 266. Aruba Introspect DSM specifications (continued)*

<b>Specification</b>	<b>Value</b>
Includes custom properties?	No
More information	<a href="https://www.arubanetworks.com">Aruba website</a> ( <a href="https://www.arubanetworks.com">https://www.arubanetworks.com</a> )

To integrate Aruba Introspect with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the IBM support website (<http://www.ibm.com/support>).
  - DSMCommon RPM
  - ArubaIntrospect DSM RPM
2. Configure your Aruba Introspect device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an Aruba Introspect log source on the QRadar Console. The following table describes the parameters that require specific values for Aruba Introspect event collection:

*Table 267. Aruba Introspect log source parameters*

<b>Parameter</b>	<b>Value</b>
Log Source type	Aruba Introspect
Protocol Configuration	Syslog
Log Source Identifier	A unique identifier for the log source.

4. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

The following table shows a sample event message for Aruba Introspect

Table 268. Aruba Introspect sample event message

Event name	Low level category	Sample log message

## Configuring Aruba Introspect to communicate with QRadar

Before IBM QRadar can collect events from Aruba Introspect, you must configure Aruba Introspect to send events to QRadar.

### Procedure

1. Log in to the Aruba Introspect Analyzer.
2. Configure forwarding.
  - a) Click **System Configuration > Syslog Destinations**.
  - b) Configure the following forwarding parameters:

*Table 269. Aruba Introspect Analyzer forwarding parameters*

Parameter	Value
Syslog Destination	IP or host name of the QRadar Event Collector.
Protocol	TCP or UDP
Port	514

3. Configure notification.

a) Click **System Configuration > Security Alerts / Emails > Add New**.

b) Configure the following notification parameters:

*Table 270. Aruba Introspect Analyzer notification parameters*

Parameter	Value
<b>Enable Alert Syslog Forwarding</b>	Enable the <b>Enable Alert Syslog Forwarding</b> check box.
<b>Sending Notification</b>	As Alerts are produced. You can customize this setting to send in batches instead of a live stream.
<b>TimeZone</b>	Your local time zone.

**Note:** Leave **Query**, **Severity**, and **Confidence** values as default to send all Alerts. These values can be customized to filter out and send only a subset of Alerts to QRadar.

## What to do next

To help you troubleshoot, you can look at the forwarding logs in the `/var/log/notifier.log` file.

When a new notification is created, as described in Step 3, alerts for the last week that match the **Query**, **Severity**, and **Confidence** fields are sent.

## Aruba Mobility Controllers

The Aruba Mobility Controllers DSM for IBM QRadar accepts events by using syslog.

QRadar records all relevant events that are forwarded by using syslog on TCP port 514 or UDP port 514.

## Configuring your Aruba Mobility Controller

You can configure the Aruba Wireless Networks (Mobility Controller) device to forward syslog events to IBM QRadar.

### Procedure

1. Log in to Aruba Mobility Controller.
2. From the top menu, select **Configuration**.
3. From the **Switch** menu, select **Management**.
4. Click the **Logging** tab.
5. From the **Logging Servers** menu, select **Add**.
6. Type the IP address of the QRadar server that you want to collect logs.
7. Click **Add**.
8. Optional: Change the logging level for a module:
  - a) Select the check box next to the name of the logging module.

- b) Choose the logging level that you want to change from the list that is displayed at the bottom of the window.
9. Click **Done**.
10. Click **Apply**.

## Syslog log source parameters for Aruba Mobility Controllers

If QRadar does not automatically detect the log source, add a Aruba Mobility Controllers log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Aruba Mobility Controllers:

Table 271. Syslog log source parameters for the Aruba Mobility Controllers DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Aruba Mobility Controller</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.

# Chapter 26. Avaya VPN Gateway

The IBM QRadar DSM for Avaya VPN Gateway can collect event logs from your Avaya VPN Gateway servers.

The following table identifies the specifications for the Avaya VPN Gateway DSM.

Table 273. Avaya VPN Gateway DSM specifications	
Specification	Value
Manufacturer	Avaya Inc.
DSM	Avaya VPN Gateway
RPM file name	DSM-AvayaVPNGateway-7.1-799033.noarch.rpm DSM-AvayaVPNGateway-7.2-799036.noarch.rpm
Supported versions	9.0.7.2
Protocol	syslog
QRadar recorded events	OS, System Control Process, Traffic Processing, Startup, Configuration Reload, AAA Subsystem, IPsec Subsystem
Automatically discovered	Yes
Includes identity	Yes
More information	<a href="http://www.avaya.com">http://www.avaya.com</a>

## Avaya VPN Gateway DSM integration process

You can integrate Avaya VPN Gateway DSM with IBM QRadar.

### About this task

To integrate Avaya VPN Gateway DSM with QRadar, use the following procedure:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Syslog protocol RPM
  - DSMCommon RPM
  - Avaya VPN Gateway RPM
2. For each instance of Avaya VPN Gateway, configure your Avaya VPN Gateway system to enable communication with QRadar.
3. If QRadar automatically discovers the log source, for each Avaya VPN Gateway server you want to integrate, create a log source on the QRadar Console.

### Related tasks

# Configuring your Avaya VPN Gateway system for communication with IBM QRadar

---

To collect all audit logs and system events from Avaya VPN Gateway, you must specify QRadar as the syslog server and configure the message format.

## Procedure

1. Log in to your Avaya VPN Gateway command-line interface (CLI).

2. Type the following command:

```
/cfg/sys/syslog/add
```

3. At the prompt, type the IP address of your QRadar system.

4. To apply the configuration, type the following command:

```
apply
```

5. To verify that the IP address of your QRadar system is listed, type the following command:

```
/cfg/sys/syslog/list
```

## Syslog log source parameters for Avaya VPN Gateway

---

If QRadar does not automatically detect the log source, add a Avaya VPN Gateway log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Avaya VPN Gateway:

Table 274. Syslog log source parameters for the Avaya VPN Gateway DSM	
Parameter	Value
Log Source type	Avaya VPN Gateway
Protocol Configuration	Syslog

# Chapter 27. BalaBit IT Security

The BalaBit Syslog-*ng* Agent application can collect and forward syslog events for the Microsoft Security Event Log DSM and the Microsoft ISA DSM in IBM QRadar.

## BalaBit IT Security for Microsoft Windows Events

The Microsoft Windows Security Event Log DSM in IBM QRadar can accept Log Event Extended Format (LEEF) events from BalaBit's Syslog-*ng* Agent.

The BalaBit Syslog-*ng* Agent forwards the following Windows events to QRadar by using syslog:

- Windows security
- Application
- System
- DNS
- DHCP
- Custom container event logs

Before you can receive events from BalaBit IT Security Syslog-*ng* Agents, you must install and configure the agent to forward events.

### Before you begin

Review the following configuration steps before you configure the BalaBit Syslog-*ng* Agent:

1. Install the BalaBit Syslog-*ng* Agent on your Windows host. For more information, see your BalaBit Syslog-*ng* Agent documentation.
2. Configure Syslog-*ng* Agent Events.
3. Configure QRadar as a destination for the Syslog-*ng* Agent.
4. Restart the Syslog-*ng* Agent service.
5. Optional. Configure the log source in QRadar.

## Configuring the Syslog-*ng* Agent event source

Before you can forward events to IBM QRadar, you must specify what Windows-based events the Syslog-*ng* Agent collects.

### Procedure

1. From the **Start** menu, select **All Programs > syslog-*ng* Agent for Windows > Configure syslog-*ng* Agent for Windows**.

The **Syslog-*ng* Agent** window is displayed.

2. Expand the **Syslog-*ng* Agent Settings** pane, and select **Eventlog Sources**.

3. Double-click **Event Containers**.

The **Event Containers Properties** window is displayed.

4. From the **Event Containers** pane, select the **Enable** radio button.

5. Select a check box for each event type you want to collect:

- **Application** - Select this check box if you want the device to monitor the Windows application event log.
- **Security** - Select this check box if you want the device to monitor the Windows security event log.

- **System** - Select this check box if you want the device to monitor the Windows system event log.

**Note:** BalaBit's Syslog-*ng* Agent supports other event types, such as DNS or DHCP events by using custom containers. For more information, see your *BalaBit Syslog-*ng* Agent documentation*.

6. Click **Apply**, and then click **OK**.

The event configuration for your BalaBit Syslog-*ng* Agent is complete. You are now ready to configure QRadar as a destination for Syslog-*ng* Agent events.

## Configuring a syslog destination

The Syslog-*ng* Agent enables you to configure multiple destinations for your Windows based events.

### About this task

To configure IBM QRadar as a destination, you must specify the IP address for QRadar, and then configure a message template for the LEEF format.

### Procedure

1. From the **Start** menu, select **All Programs > Syslog-*ng* Agent for Windows > Configure syslog-*ng* Agent for Windows**.

The **Syslog-*ng* Agent** window is displayed.

2. Expand the **Syslog-*ng* Agent Settings** pane, and click **Destinations**.
3. Double-click **Add new server**.

The **Server Property** window is displayed.

4. Click the **Server** tab, and then click **Set Primary Server**.
5. Configure the following parameters:

- **Server Name** - Type the IP address of your QRadar Console or Event Collector.
- **Server Port** - Type 514 as the TCP port number for events to be forwarded to QRadar.

6. Click the **Messages** tab.

7. From the **Protocol** list, select **Legacy BSD Syslog Protocol**.

8. In the **Template** field, define a custom template message for the protocol by typing:

```
<${PRI}>${BSDDATE} ${HOST} LEEF:${MSG}
```

The information that is typed in this field is space delimited.

9. In the **Event Message Format** pane, in the **Message Template** field, type or copy and paste the following text to define the format for the LEEF events:

**Note:** It is suggested that you do not change the text.

```
1.0|Microsoft|Windows|2k8r2|${EVENT_ID}|devTime=${R_YEAR}-${R_MONTH}-$R_DAYT${R_HOUR}: ${R_MIN}: ${R_SEC}GMT${TZOFFSET} devTimeFormat=yyyy-MM-dd'T'HH:mm:ssz cat=${EVENT_TYPE} sev=${EVENT_LEVEL} resource=${HOST} usrName=${EVENT_USERNAME} application=${EVENT_SOURCE} message=${EVENT_MSG}
```

**Note:** The LEEF format uses tab as a delimiter to separate event attributes from each other. However, the delimiter does not start until after the last pipe character for `{Event_ID}`. The following fields must include a tab before the event name: `devTime`, `devTimeFormat`, `cat`, `sev`, `resource`, `usrName`, `application`, and `message`.

You might need to use a text editor to copy and paste the LEEF message format into the **Message Template** field.

10. Click **OK**.

The destination configuration is complete. You are now ready to restart the Syslog-*ng* Agent service.

## Restarting the Syslog-*ng* Agent service

Before the Syslog-*ng* Agent can forward LEEF formatted events, you must restart the Syslog-*ng* Agent service on the Windows host.

### Procedure

1. From the **Start** menu, select **Run**.

The **Run** window is displayed.

2. Type the following text:

```
services.msc
```

3. Click **OK**.

The **Services** window is displayed.

4. In the **Name** column, right-click on **Syslog-*ng* Agent for Windows**, and select **Restart**.

After the Syslog-*ng* Agent for Windows service restarts, the configuration is complete. Syslog events from the BalaBit Syslog-*ng* Agent are automatically discovered by IBM QRadar. The Windows events that are automatically discovered are displayed as Microsoft Windows Security Event Logs on the **Log Activity** tab.

## Syslog log source parameters for BalaBit IT Security for Microsoft Windows Events

If QRadar does not automatically detect the log source, add a BalaBit IT Security for Microsoft Windows Events log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from BalaBit Syslog-*ng* Agent:

Table 277. Syslog log source parameters for the BalaBit IT Security for Microsoft Windows Events DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your BalaBit Syslog- <i>ng</i> Agent log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source type</b>	Microsoft Windows <b>Security Event Log</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from the BalaBit Syslog- <i>ng</i> Agent.

### Related tasks

[“Adding a log source” on page 5](#)

## BalaBit IT Security for Microsoft ISA or TMG Events

You can integrate the BalaBit Syslog-*ng* Agent application to forward syslog events to IBM QRadar.

The BalaBit Syslog-*ng* Agent reads Microsoft ISA or Microsoft TMG event logs, and forwards syslog events by using the Log Event Extended Format (LEEF).

The events that are forwarded by BalaBit IT Security are parsed and categorized by the Microsoft Internet and Acceleration (ISA) DSM for QRadar. The DSM accepts both Microsoft ISA and Microsoft Threat Management Gateway (TMG) events.

## Before you begin

Before you can receive events from BalaBit IT Security Syslog-*ng* Agents you must install and configure the agent to forward events.

**Note:** This integration uses BalaBit's Syslog-*ng* Agent for Windows and BalaBit's Syslog-*ng* PE to parse and forward events to QRadar for the DSM to interpret.

Review the following configuration steps before you attempt to configure the BalaBit Syslog-*ng* Agent:

To configure the BalaBit Syslog-*ng* Agent, you must take the following steps:

1. Install the BalaBit Syslog-*ng* Agent on your Windows host. For more information, see your *BalaBit Syslog-*ng* Agent vendor documentation*.
2. Configure the BalaBit Syslog-*ng* Agent.
3. Install a BalaBit Syslog-*ng* PE for Linux or Unix in relay mode to parse and forward events to QRadar. For more information, see your *BalaBit Syslog-*ng* PE vendor documentation*.
4. Configure syslog for BalaBit Syslog-*ng* PE.
5. Optional. Configure the log source in QRadar.

## Configure the BalaBit Syslog-*ng* Agent

Before you can forward events to IBM QRadar, you must specify the file source for Microsoft ISA or Microsoft TMG events in the Syslog-*ng* Agent collects.

If your Microsoft ISA or Microsoft TMG appliance is generating event files for the Web Proxy Server and the Firewall Service, both files can be added.

## Configuring the BalaBit Syslog-*ng* Agent file source

Use the BalaBit Syslog-*ng* Agent file source to define the base log directory and files that are to be monitored by the Syslog-*ng* Agent.

### Procedure

1. From the **Start** menu, select **All Programs > syslog-*ng* Agent for Windows > Configure syslog-*ng* Agent for Windows**.  
The **Syslog-*ng* Agent** window is displayed.
2. Expand the **Syslog-*ng* Agent Settings** pane, and select **File Sources**.
3. Select the **Enable** radio button.
4. Click **Add** to add your Microsoft ISA and TMG event files.
5. From the **Base Directory** field, click **Browse** and select the folder for your Microsoft ISA or Microsoft TMG log files.
6. From the **File Name Filter** field, click **Browse** and select a log file that contains your Microsoft ISA or Microsoft TMG events.

**Note:** The **File Name Filter** field supports the wild card (\*) and question mark (?) characters, which help you to find log files that are replaced, when they reach a specific file size or date.

7. In the **Application Name** field, type a name to identify the application.
8. From the **Log Facility** list, select **Use Global Settings**.
9. Click **OK**.

To add additional file sources, repeat steps 4 to 9.

10. Click **Apply**, and then click **OK**.

The event configuration is complete. You are now ready to configure a syslog destinations and formatting for your Microsoft TMG and ISA events.

Web Proxy Service events and Firewall Service events are stored in individual files by Microsoft ISA and TMG.

## Configuring a BalaBit Syslog-*ng* Agent syslog destination

The event logs captured by Microsoft ISA or TMG cannot be parsed by the BalaBit Syslog-*ng* Agent for Windows, so you must forward your logs to a BalaBit Syslog-*ng* Premium Edition (PE) for Linux or UNIX.

### About this task

To forward your TMG and ISA event logs, you must specify the IP address for your PE relay and configure a message template for the LEEF format. The BalaBit Syslog-*ng* PE acts as an intermediate syslog server to parse the events and to forward the information to IBM QRadar.

### Procedure

1. From the **Start** menu, select **All Programs > syslog-*ng* Agent for Windows > Configure syslog-*ng* Agent for Windows**.

The **Syslog-*ng* Agent** window is displayed.

2. Expand the **Syslog-*ng* Agent Settings** pane, and click **Destinations**.

3. Double-click **Add new Server**.

4. On the **Server** tab, click **Set Primary Server**.

5. Configure the following parameters:

- For the **Server Name** type the IP address of your BalaBit Syslog-*ng* PE relay.
- For the **Server Port** type 514 as the TCP port number for events that are forwarded to your BalaBit Syslog-*ng* PE relay.

6. Click the **Messages** tab.

7. From the **Protocol** list, select **Legacy BSD Syslog Protocol**.

8. From the **File Message Format** pane, in the **Message Template** field, type the following code:

`${FILE_MESSAGE} ${TZOFFSET}`

9. Click **Apply**, and then click **OK**.

The destination configuration is complete. You are now ready to filter comment lines from the event log.

## Filtering the log file for comment lines

The event log file for Microsoft ISA or Microsoft TMG might contain comment markers. Comments must be filtered from the event message.

### Procedure

1. From the **Start** menu, select **All Programs > Syslog-*ng* Agent for Windows > Configure syslog-*ng* Agent for Windows**.

The **Syslog-*ng* Agent** window is displayed.

2. Expand the **Syslog-*ng* Agent Settings** pane, and select **Destinations**.

3. Right-click on your IBM QRadar **Syslog destination** and select **Event Filters > Properties**.

The **Global event filters Properties** window is displayed.

4. Configure the following values:

- From the **Global file filters** pane, select **Enable**.
  - From the **Filter Type** pane, select **Black List Filtering**.
5. Click **OK**.
6. From the **Filter List** menu, double-click **Message Contents**.  
The **Message Contents Properties** window is displayed.
7. From the **Message Contents** pane, select **Enable**.
8. In the **Regular Expression** field, type the following regular expression:  
`^#`
9. Click **Add**.
10. Click **Apply**, and then click **OK**.  
The event messages with comments are no longer forwarded.
- Note:** You might need to restart Syslog-*ng* Agent for Windows service to begin syslog forwarding. For more information, see your *BalaBit Syslog-*ng* Agent documentation*.

## Configuring a BalaBit Syslog-*ng* PE Relay

The BalaBit Syslog-*ng* Agent for Windows sends Microsoft TMG and ISA event logs to a Balabit Syslog-*ng* PE installation, which is configured in relay mode.

### About this task

The relay mode installation is responsible for receiving the event log from the BalaBit Syslog-*ng* Agent for Windows, parsing the event logs in to the LEEF format, then forwarding the events to IBM QRadar by using syslog.

To configure your BalaBit Syslog-*ng* PE Relay, you must:

- Install BalaBit Syslog-*ng* PE for Linux or Unix in relay mode. For more information, see your BalaBit Syslog-*ng* PE vendor documentation.
- Configure syslog on your Syslog-*ng* PE relay.

The BalaBit Syslog-*ng* PE formats the TMG and ISA events in the LEEF format based on the configuration of your *syslog.conf* file. The *syslog.conf* file is responsible for parsing the event logs and forwarding the events to QRadar.

### Procedure

- Using SSH, log in to your BalaBit Syslog-*ng* PE relay command-line interface (CLI).
- Edit the following file:  
`/etc/syslog-ng/etc/syslog.conf`
- From the destinations section, add an IP address and port number for each relay destination.

For example,

```
# ##### # destinations
destination d_messages { file("/var/log/messages"); };
destination d_remote_tmgfw { tcp("QRadar_IP" port(QRadar_PORT) log_disk_fifo_size(10000000) template(t_tmgfw)); };
destination d_remote_tmgweb { tcp("QRadar_IP" port(QRadar_PORT) log_disk_fifo_size(10000000) template(t_tmgweb)); };
```

Where:

*QRadar\_IP* is the IP address of your QRadar Console or Event Collector.

*QRadar\_Port* is the port number that is required for QRadar to receive syslog events. By default, QRadar receives syslog events on port 514.

4. Save the syslog configuration changes.
5. Restart Syslog-ng PE to force the configuration file to be read.

The BalaBit Syslog-ng PE configuration is complete. Syslog events that are forwarded from the BalaBit Syslog-ng relay are automatically discovered by QRadar as Microsoft Windows Security Event Logs on the Log Activity tab. For more information, see the *IBM QRadar Users Guide*.

**Note:** When you are using multiple syslog destinations, messages are considered to be delivered when they successfully arrive at the primary syslog destination.

## Syslog log source parameters for BalaBit IT Security for Microsoft ISA or TMG Events

If QRadar does not automatically detect the log source, add a BalaBit IT Security for Microsoft ISA or TMG Events log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from BalaBit IT Security for Microsoft ISA or TMG Events:

Table 278. Syslog log source parameters for the BalaBit IT Security for Microsoft ISA or TMG Events DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for the log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source type</b>	Microsoft <b>ISA</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for Microsoft ISA or Microsoft Threat Management Gateway events from the BalaBit Syslog-ng Agent.

### Related tasks

# Chapter 28. Barracuda

IBM QRadar supports a range of Barracuda devices.

## Barracuda Spam & Virus Firewall

You can integrate Barracuda Spam & Virus Firewall with IBM QRadar.

The Barracuda Spam & Virus Firewall DSM for QRadar accepts both mail syslog events and web syslog events from Barracuda Spam & Virus Firewall appliances.

Mail syslog events contain the event and action that is taken when the firewall processes email. Web syslog events record information on user activity, and configuration changes that occur on your Barracuda Spam & Virus Firewall appliance.

### Before you begin

Syslog messages are sent to QRadar from Barracuda Spam & Virus Firewall by using UDP port 514. You must verify that any firewalls between QRadar and your Barracuda Spam & Virus Firewall appliance allow UDP traffic on port 514.

## Configuring syslog event forwarding

You can configure syslog forwarding for Barracuda Spam & Virus Firewall.

### Procedure

1. Log in to the Barracuda Spam & Virus Firewall web interface.
2. Click the **Advanced** tab.
3. From the **Advanced** menu, select **Advanced Networking**.
4. In the **Mail Syslog** field, type the IP address of your QRadar Console or Event Collector.
5. Click **Add**.
6. In the **Web Interface Syslog** field, type the IP address of your QRadar Console or Event Collector.
7. Click **Add**.

## Syslog log source parameters for Barracuda Spam Firewall

If QRadar does not automatically detect the log source, add a Barracuda Spam & Virus Firewall log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Barracuda Spam & Virus Firewall:

Table 279. Syslog log source parameters for the Barracuda Spam & Virus Firewall DSM	
<b>Parameter</b>	<b>Value</b>
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source type</b>	<b>Barracuda Spam &amp; Virus Firewall</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.

## Barracuda Web Application Firewall

The IBM QRadar DSM for Barracuda Web Application Firewall collects syslog LEEF and custom events from Barracuda Web Application Firewall devices.

The following table identifies the specifications for the Barracuda Web Application Firewall DSM:

Table 282. Barracuda Web Application Firewall DSM specifications	
Specification	Value
Manufacturer	Barracuda
DSM name	Web Application Firewall
RPM file name	DSM-BarracudaWebApplicationFirewall-QRadar_version-build_number.noarch.rpm
Supported versions	V7.0.x and later
Protocol type	Syslog
QRadar recorded event types	System Web Access Audit
Automatically discovered?	If LEEF-formatted payloads, the log source is automatically discovered. If custom-formatted payloads, the log source is not automatically discovered.
Included identity?	Yes
More information	<a href="https://www.barracuda.com">Barracuda Networks website</a> ( <a href="https://www.barracuda.com">https://www.barracuda.com</a> )

To collect syslog events from Barracuda Web Application Firewall, use the following steps:

1. If automatic updates are not enabled, download the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Barracuda Web Application Firewall DSM RPM
  - DSMCommon RPM
2. Configure your Barracuda Web Application Firewall device to send syslog events to QRadar.
3. Add a Barracuda Web Application Firewall log source on the QRadar Console. The following table describes the parameters that require specific values that are required for Barracuda Web Application Firewall event collection:

Table 283. Barracuda Web Application Firewall log source parameters

Parameter	Value
Log Source type	Barracuda Web Application Firewall
Protocol Configuration	Syslog

# Configuring Barracuda Web Application Firewall to send syslog events to QRadar

Configure your Barracuda Web Application Firewall appliance to send syslog events to IBM QRadar.

## Before you begin

Verify that firewalls between the Barracuda appliance and QRadar allow UDP traffic on port 514.

## Procedure

1. Log in to the Barracuda Web Application Firewall web interface.
2. Click the **Advanced** tab.
3. From the **Advanced** menu, select **Export Logs**.
4. Click **Add Syslog Server**.
5. Configure the parameters:

Option	Description
<b>Name</b>	The name of the QRadar Console or Event Collector
<b>Syslog Server</b>	The IP address of your QRadar Console or Event Collector.
<b>Port</b>	The port that is associated with the IP address of your QRadar Console or Event Collector. If syslog messages are sent by UDP, use the default port, 514.
<b>Connection Type</b>	The connection type that transmits the logs from the Barracuda Web Application Firewall to the QRadar Console or Event Collector. UDP is the default protocol for syslog communication.
<b>Validate Server Certificate</b>	<b>No</b>

6. In the **Log Formats** pane, select a format from the list box for each log type.
  - If you are using newer versions of Barracuda Web Application Firewall, select **LEEF 1.0 (QRadar)**.
  - If you are using older versions of Barracuda Web Application Firewall, select **Custom Format**.
7. Click **Save Changes**.

# Configuring Barracuda Web Application Firewall to send syslog events to QRadar for devices that do not support LEEF

If your device does not support LEEF, you can configure syslog forwarding for Barracuda Web Application Firewall.

## Procedure

1. Log in to the Barracuda Web Application Firewall web interface.
2. Click the **Advanced** tab.
3. From the **Advanced** menu, select **Export logs**.
4. Click **Syslog Settings**.
5. Configure a syslog facility value for the following options:

Option	Description
<b>Web Firewall Logs Facility</b>	Select a syslog facility between <b>Local0</b> and <b>Local7</b> .

Option	Description
<b>Access Logs Facility</b>	Select a syslog facility between <b>Local0</b> and <b>Local7</b> .
<b>Audit Logs Facility</b>	Select a syslog facility between <b>Local0</b> and <b>Local7</b> .
<b>System Logs Facility</b>	Select a syslog facility between <b>Local0</b> and <b>Local7</b> .

Setting a syslog unique facility for each log type allows the Barracuda Web Application Firewall to divide the logs in to different files.

6. Click **Save Changes**.
7. In the **Name** field, type the name of the syslog server.
8. In the **Syslog** field, type the IP address of your QRadar Console or Event Collector.
9. From the **Log Time Stamp** option, select **Yes**.
10. From the **Log Unit Name** option, select **Yes**.
11. Click **Add**.
12. From the **Web Firewall Logs Format** list box, select **Custom Format**.
13. In the **Web Firewall Logs Format** field, type the following custom event format:  
`t=%t|ad=%ad|ci=%ci|cp=%cp|au=%au`
14. From the **Access Logs Format** list box, select **Custom Format**.
15. In the **Access Logs Format** field, type the following custom event format:  
`t=%t|p=%p|s=%s|id=%id|ai=%ai|ap=%ap|ci=%ci|cp=%cp|si=%si|sp=%sp|cu=%cu`
16. From the **Audit Logs Format** list box, select **Custom Format**.
17. In the **Audit Logs Format** field, type the following custom event format:  
`t=%t|trt=%trt|an=%an|li=%li|lp=%lp`
18. Click **Save Changes**.
19. From the navigation menu, select **Basic > Administration**
20. From the System/Reload/Shutdown pane, click **Restart**.

## Results

The syslog configuration is complete after your Barracuda Web Application Firewall restarts. Events that are forwarded to QRadar by Barracuda Web Application Firewall are displayed on the **Log Activity** tab.

## Barracuda Web Filter

---

You can integrate Barracuda Web Filter appliance events with IBM QRadar.

The Barracuda Web Filter DSM for IBM QRadar accepts web traffic and web interface events in syslog format that are forwarded by Barracuda Web Filter appliances.

Web traffic events contain the events, and any actions that are taken when the appliance processes web traffic. Web interface events contain user login activity and configuration changes to the Web Filter appliance.

### Before you begin

Syslog messages are forward to QRadar by using UDP port 514. You must verify that any firewalls between QRadar and your Barracuda Web Filter appliance allow UDP traffic on port 514.

## Configuring syslog event forwarding

Configure syslog forwarding for Barracuda Web Filter.

### Procedure

1. Log in to the Barracuda Web Filter web interface.
2. Click the **Advanced** tab.
3. From the **Advanced** menu, select **Syslog**.
4. From the **Web Traffic Syslog** field, type the IP address of your QRadar Console or Event Collector.
5. Click **Add**.
6. From the **Web Interface Syslog** field, type the IP address of your QRadar Console or Event Collector.
7. Click **Add**.

The syslog configuration is complete.

## Syslog log source parameters for Barracuda Web Filter

If QRadar does not automatically detect the log source, add a Barracuda Web Filter log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Barracuda Web Filter:

Table 284. Syslog log source parameters for the Barracuda Web Filter DSM	
Parameter	Value
<b>Log Source Name</b>	The name of your log source.
<b>Log Source Description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Barracuda Web Filter</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Barracuda Web Filter appliance.

# Chapter 29. BeyondTrust Privilege Management for Unix, Linux and Networked Devices

The IBM QRadar DSM for BeyondTrust Privilege Management for Unix, Linux and Networked Devices logs all events to a multi-line format in a single event log that is viewed by using Beyond Trust's *pblog* utility.

**Note:** BeyondTrust Privilege Management for Unix, Linux and Networked Devices was previously called BeyondTrust PowerBroker.

You must be on a Linux, Unix or AIX® operating system to integrate BeyondTrust Privilege Management for Unix, Linux and Networked Devices with QRadar.

To integrate BeyondTrust Privilege Management for Unix, Linux and Networked Devices with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM RPM on your QRadar Console.
2. Configure BeyondTrust Privilege Management for Unix, Linux and Networked Devices to communicate with QRadar. See [Configuring BeyondTrust Privilege Management for Unix, Linux and Networked Devices to communicate with QRadar](#).

For more information about TLS syslog log source parameters, see [TLS syslog protocol configuration options](#).

## Related concepts

[“TLS Syslog protocol configuration options” on page 231](#)

Configure a TLS Syslog protocol log source to receive encrypted syslog events from network devices that support TLS Syslog event forwarding for each listener port.

[“BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM specifications” on page 540](#)

The following table describes the specifications for the BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM.

[“BeyondTrust Privilege Management for Unix, Linux and Networked Devices sample event message” on page 541](#)

Use this sample event messages as a way of verifying a successful integration with QRadar.

## Syslog log source parameters for BeyondTrust Privilege Management for Unix, Linux and Networked Devices

If QRadar does not automatically detect the log source, add a BeyondTrust Privilege Management for Unix, Linux and Networked Devices log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from BeyondTrust Privilege Management for Unix, Linux and Networked Devices:

*Table 286. Syslog log source parameters for the BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM*

Parameter	Value
<b>Log Source type</b>	<b>BeyondTrust Privilege Management for Unix, Linux and Networked Devices</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type a unique IP address or host name.
<b>Store Event Payload</b>	Select this check box to enable or disable QRadar from storing the event payload.  Automatically discovered log sources use the default value from the <b>Store Event Payload</b> list in the <b>System Settings</b> window, which is accessible on the <b>Admin</b> tab. However, when you create a new log source or update the configuration for an automatically discovered log source, you can override the default value by configuring this check box for each log source.

#### Related tasks

[“Adding a log source” on page 5](#)

## TLS Syslog log source parameters for BeyondTrust Privilege Management for Unix, Linux and Networked Devices

If QRadar does not automatically detect the log source, add a BeyondTrust Privilege Management for Unix, Linux and Networked Devices log source on the QRadar Console by using the TLS Syslog protocol.

When using the TLS Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect TLS Syslog events from BeyondTrust Privilege Management for Unix, Linux and Networked Devices:

*Table 287. TLS Syslog log source parameters for the BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM*

Parameter	Value
<b>Log Source type</b>	<b>BeyondTrust Privilege Management for Unix, Linux and Networked Devices</b>
<b>Protocol Configuration</b>	<b>TLS Syslog</b>
<b>Log Source Identifier</b>	Type a unique IP address or host name.

#### Related tasks

[“Adding a log source” on page 5](#)

## Configuring BeyondTrust Privilege Management for Unix, Linux and Networked Devices to communicate with QRadar

If you use a Linux, Unix or AIX operating system, complete the following procedure.

BeyondTrust *pblogs* must be reformatted by using a script and then forwarded to IBM QRadar. You need to download and configure a script for your BeyondTrust Privilege Management for Unix, Linux and Networked Devices appliance before you can forward events to QRadar.

## Procedure

1. Download the following file from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>):

`pbforwarder.pl.gz`

2. Copy the file to the device that hosts BeyondTrust Privilege Management for Unix, Linux and Networked Devices.

**Note:** Perl 5.8 must be installed on the device that hosts BeyondTrust Privilege Management for Unix, Linux and Networked Devices.

3. Type the following command to extract the file:

`gzip -d pbforwarder.pl.gz`

4. Type the following command to set the script file permissions:

`chmod +x pbforwarder.pl`

5. Use SSH to log in to the device that hosts BeyondTrust Privilege Management for Unix, Linux and Networked Devices.

The credentials that are used need to have read, write, and execute permissions for the log file.

6. Type the appropriate command parameters:

*Table 288. Command parameters*

Parameters	Description
<b>-h</b>	The <b>-h</b> parameter defines the syslog host that receives the events from BeyondTrust Privilege Management for Unix, Linux and Networked Devices. This is the IP address of your QRadar Console or QRadar Event Collector.
<b>-t</b>	The <b>-t</b> parameter defines that the command-line is used to tail the log file and monitor for new output from the listener.  For Privilege Management for Unix, Linux and Networked Devices, this command must be specified as "pblog -l -t".
<b>-p</b>	The <b>-p</b> parameter defines the TCP port to be used when forwarding events. If nothing is specified, the default is port 514.
<b>-H</b>	The <b>-H</b> parameter defines the host name or IP address for the syslog header of all sent events. This should be the IP address of the BeyondTrust Privilege Management for Unix, Linux and Networked Devices.
<b>-r</b>	The <b>-r</b> parameter defines the directory name where you want to create the process ID (.pid) file. The default is /var/run.  This parameter is ignored if <b>-D</b> is specified.
<b>-l</b>	The <b>-l</b> parameter defines the directory name where you want to create the lock file. The default is /var/lock.  This parameter is ignored if <b>-D</b> is specified.
<b>-D</b>	The <b>-D</b> parameter defines that the script runs in the foreground. The default setting is to run as a daemon and log all internal messages to the local syslog server.

Table 288. Command parameters (continued)

Parameters	Description
<b>-f</b>	The <b>-f</b> parameter defines the syslog facility and optionally, the severity for messages that are sent to the Event Collector. If no value is specified, user.info is used.
<b>-a</b>	The <b>-a</b> parameter enables an AIX compatible <i>ps</i> method. This command is only needed when you run BeyondTrust Privilege Management for Unix, Linux and Networked Devices on AIX systems.
<b>-d</b>	The <b>-d</b> parameter enables debug logging.
<b>-v</b>	The <b>-v</b> parameter displays the script version information.

7. Type the following command to start the *pbforwarder.pl* script. Use the following example as a guide.

```
pbforwarder.pl -h <IP address> -t "pblog -l -t"
```

Where *<IP address>* is the IP address of your QRadar or Event Collector.

8. Optional: If you want to stop the script from forwarding events to QRadar, type the following command to stop the *pbforwarder.pl* script:

```
kill -QUIT `cat /var/run/pbforwarder.pid`
```

9. Optional: If the script loses connection or stops working, type the following command to reconnect the *pbforwarder.pl* script:

```
kill -HUP `cat /var/run/pbforwarder.pid`
```

QRadar automatically detects and creates a log source from the syslog events that are forwarded from a BeyondTrust Privilege Management for Unix, Linux and Networked Devices.

## BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM specifications

The following table describes the specifications for the BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM.

Table 289. BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM specifications

Specification	Value
Manufacturer	BeyondTrust
DSM name	BeyondTrust Privilege Management for Unix, Linux and Networked Devices
RPM file name	DSM-BeyondTrustPowerBroker-QRadar_version-build_number.noarch.rpm
Supported versions	4.0
Protocol	Syslog, TLS syslog
Event format	System, Application
Recorded event types	All events

*Table 289. BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM specifications (continued)*

Specification	Value
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.beyondtrust.com/products/Privilege Management for Unix, Linux and Networked Devices/">BeyondTrust web page</a> ( <a href="https://www.beyondtrust.com/products/Privilege Management for Unix, Linux and Networked Devices/">https://www.beyondtrust.com/products/Privilege Management for Unix, Linux and Networked Devices/</a> )

## BeyondTrust Privilege Management for Unix, Linux and Networked Devices sample event message

Use this sample event messages as a way of verifying a successful integration with QRadar.

The following table provides a sample event message for the BeyondTrust Privilege Management for Unix, Linux and Networked Devices DSM:

*Table 290. BeyondTrust Privilege Management for Unix, Linux and Networked Devices sample syslog message*

Event name	Low level category	Sample log message

---

# Chapter 30. BlueCat Networks Adonis

The BlueCat Networks Adonis DSM for IBM QRadar accepts events that are forwarded in Log Event Extended Format (LEEF) by using syslog from BlueCat Adonis appliances that are managed with BlueCat Proteus.

QRadar supports BlueCat Networks Adonis appliances by using version 6.7.1-P2 and later.

You might be required to include a patch on your BlueCat Networks Adonis to integrate DNS and DHCP events with QRadar. For more information, see [KB-4670](#) and your *BlueCat Networks documentation*.

## Supported event types

---

IBM QRadar is capable of collecting all relevant events related to DNS and DHCP queries.

This includes the following events:

- DNS IPv4 and IPv6 query events
- DNS name server query events
- DNS mail exchange query events
- DNS text record query events
- DNS record update events
- DHCP discover events
- DHCP request events
- DHCP release events

## Event type format

---

The LEEF format consists of a pipe ( | ) delimited syslog header and a space delimited event payload.

For example:

```
Aug 10 14:55:30 <Server> LEEF:1.0|BCN|Adonis|6.7.1|DNS_Query|cat=A_record  
src=<Source_IP_address> url=test.example.com
```

If the syslog events forwarded from your BlueCat Adonis appliances are not formatted similarly to the sample above, you must examine your device configuration. Properly formatted LEEF event messages are automatically discovered by the BlueCat Networks Adonis DSM and added as a log source to IBM QRadar.

### Before you begin

BlueCat Adonis must be configured to generate events in Log Event Extended Format (LEEF) and to redirect the event output to QRadar using syslog.

BlueCat Networks provides a script on their appliances to assist you with configuring syslog. To complete the syslog redirection, you must have administrative or root access to the command line interface of the BlueCat Adonis or your BlueCat Proteus appliance. If the syslog configuration script is not present on your appliance, contact your BlueCat Networks representative.

## Configuring BlueCat Adonis

---

You can configure your BlueCat Adonis appliance to forward DNS and DHCP events to IBM QRadar SIEM.

### Procedure

1. Using SSH, log in to your BlueCat Adonis appliance.

2. On the command-line interface type the following command to start the syslog configuration script:

```
/usr/local/bluecat/QRadar/setup-QRadar.sh
```

3. Type the IP address of your QRadar Console or Event Collector.

4. Type yes or no to confirm the IP address.

The configuration is complete when a success message is displayed.

The log source is added to QRadar as BlueCat Networks Adonis syslog events are automatically discovered. Events that are forwarded to QRadar are displayed on the **Log Activity** tab. If the events are not automatically discovered, you can manually configure a log source.

## Syslog log source parameters for BlueCat Networks Adonis

If QRadar does not automatically detect the log source, add a Blue Cat Networks Adonis log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Blue Cat Networks Adonis:

Table 291. Syslog log source parameters for the Blue Cat Networks Adonis DSM	
Parameter	Value
<b>Log Source name</b>	The name of your log source.
<b>Log Source description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>BlueCat Networks Adonis</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your BlueCat Networks Adonis appliance.

### Related tasks

# Chapter 31. Blue Coat

IBM QRadar supports a range of Blue Coat products.

## Blue Coat SG

The IBM QRadar DSM for Blue Coat SG collects events from Blue Coat SG appliances.

The following table lists the specifications for the Blue Coat SG DSM:

Table 292. Blue Coat SG DSM specifications	
Specification	Value
Manufacturer	Blue Coat
DSM name	Blue Coat SG Appliance
RPM file name	DSM-BlueCoatProxySG-Qradar_version-build_number.noarch.rpm
Supported versions	SG v4.x and later
Protocol	Syslog Log File Protocol
Recorded event types	All events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	Yes
More information	<a href="http://www.bluecoat.com">Blue Coat website</a> ( <a href="http://www.bluecoat.com">http://www.bluecoat.com</a> )

To send events from Blue Coat SG to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Blue Coat SG DSM RPM from the [IBM Support Website](https://www.ibm.com/support/fixcentral) (<https://www.ibm.com/support/fixcentral>) onto your QRadar Console.
2. Configure your Blue Coat SG device to communicate with QRadar. Complete the following steps:
  - a. Create a custom event format.
  - b. Create a log facility.
  - c. Enable access logging.
  - d. Configure Blue Coat SG for either Log File protocol or syslog uploads.

The instructions provided describe how to configure Blue Coat SG by using a custom name-value pair format. However, QRadar supports the following formats:

- Custom Format
- SQUID
- NCSA
- main
- IM
- Streaming
- smartreporter

- bcreportermain\_v1
- bcreporterssl\_v1
- p2p
- SSL
- bcreportercifs\_v1
- CIFS
- MAPI

These standard formats can change between Blue Coat SG versions, which might keep them from being parsed correctly. When you configure Blue Coat SG by using a custom name-value pair format, parsing is more reliable.

### Related concepts

### Related tasks

[Creating a log facility](#)

To use the custom log format that you created for IBM QRadar, you must associate the custom log format to a facility.

[Enabling access logging](#)

You must enable access logging on your Blue Coat SG device.

[Configuring Blue Coat SG for syslog](#)

To allow syslog event collection, you must configure your Blue Coat SG appliance to forward syslog events to IBM QRadar.

## Creating a custom event format for Blue Coat SG

To collect events from Blue Coat SG, create a custom event format.

### Procedure

1. Log in to the **Blue Coat Management Console**.
2. Select **Configuration > Access Logging > Formats**.
3. Select **New**.
4. Type a format name for the custom format.
5. Select **Custom format string**.
6. Type the following custom format:

**Attention:** The line breaks in these examples will cause this configuration to fail. Copy the code blocks into a text editor, remove the line breaks, and paste as a single line in the **Custom Format** column.

```
Bluecoat|src=$(c-ip)|srcport=$(c-port)|dst=$(cs-uri-address)
|dstport=$(cs-uri-port)|username=$(cs-username)|devicetime=$(gmttime)|s-action=$(s-action)
|sc-status=$(sc-status)|cs-method=$(cs-method)|time-taken=$(time-taken)|sc-bytes=$(sc-bytes)
|cs-bytes=$(cs-bytes)|cs-uri-scheme=$(cs-uri-scheme)|cs-host=$(cs-host)|cs-uri-path=$(cs-
uri-path)|cs-uri-query=$(cs-uri-query)|cs-uri-extension=$(cs-uri-extension)|cs-auth-group=$
(cs-auth-group)|rs(Content-Type)=$(rs(Content-Type))|cs(User-Agent)=$(cs(User-Agent))|
cs(Rererer)=$(cs(Rererer))|sc-filter-result=$(sc-filter-result)|filter-category=$(sc-filter-
category)|cs-uri=$(cs-uri)
```

7. Select **Log Last Header** from the list.
8. Click **OK**.
9. Click **Apply**.

**Note:** The custom format for QRadar supports more key-value pairs by using the Blue Coat ELFF format. For more information, see [“Creating extra custom format key-value pairs” on page 552](#).

## What to do next

Create a log facility on your Blue Coat device.

### Related tasks

#### [Creating a log facility](#)

To use the custom log format that you created for IBM QRadar, you must associate the custom log format to a facility.

## Creating a log facility

To use the custom log format that you created for IBM QRadar, you must associate the custom log format to a facility.

### Procedure

1. Select **Configuration > Access Logging > Logs**.
2. Click **New**.
3. Configure the following parameters:

Parameter	Description
<b>Log Name</b>	A name for the log facility.
<b>Log Format</b>	The custom format you that created.
<b>Description</b>	A description for the log facility.

4. Click **OK**.
5. Click **Apply**.

### Related tasks

#### [Enabling access logging](#)

You must enable access logging on your Blue Coat SG device.

## Enabling access logging

You must enable access logging on your Blue Coat SG device.

### Procedure

1. Select **Configuration > Access Logging > General**.
2. Select the **Enable Access Logging** check box.
3. Optional: If you use Blue Coat SGOS 6.2.11.2 Proxy Edition, complete the following steps:
  - a) Select **Config > Policy > Visual Policy Manager**.
  - b) In the **Policy** section, add **Web Access Layer for Logging**.
  - c) Select **Action > Edit** and enable logging to the log facility.
4. Click **Apply**.

## Configuring Blue Coat SG for FTP uploads

To collect Blue Coat SG events using FTP, configure the Blue Coat SC to upload events to a FTP server using the Blue Coat upload client.

### Procedure

1. Select **Configuration > Access Logging > Logs > Upload Client**.

2. From the **Log** list, select the log that contains your custom format.
3. From the **Client type** list, select **FTP Client**.
4. Select the **text file** option.
5. Click **Settings**.
6. From the **Settings For** list, select **Primary FTP Server**.
7. Configure the following values:

Parameter	Description
<b>Host</b>	The IP address of the FTP server that you want to forward the Blue Coat events.
<b>Port</b>	The FTP port number.
<b>Path</b>	The directory path for the log files.
<b>Username</b>	The user name to access the FTP server.

8. Click **OK**.
9. Select the **Upload Schedule** tab.
10. From the **Upload the access log** option, select **Periodically**.
11. Configure the **Wait time between connect attempts** option.
12. Select to upload the log file to the FTP daily or on an interval.
13. Click **Apply**.

## Syslog log source parameters for Blue Coat SG

If QRadar does not automatically detect the log source, add a Blue Coat SG log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Blue Coat SG:

Table 293. Syslog log source parameters for the Blue Coat SG DSM	
<b>Parameter</b>	<b>Value</b>
<b>Log Source name</b>	Type a name of your log source.
<b>Log Source description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Blue Coat SG Appliance</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type an IP address, host name, or name to identify the event source. IP addresses or host names are recommended as they allow QRadar to identify a log file to a unique event source.

For a complete list of Log File protocol parameters and their values, see [Log File protocol configuration options](#).

### Related tasks

[“Adding a log source” on page 5](#)

## Log File log source parameters for Blue Coat SG

If QRadar does not automatically detect the log source, add a Blue Coat SG log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from Blue Coat SG:

Table 294. Log File log source parameters for the Blue Coat SG DSM	
Parameter	Value
<b>Log Source name</b>	Type a name of your log source.
<b>Log Source description</b>	Type a description for your log source.
<b>Log Source type</b>	<b>Blue Coat SG Appliance</b>
<b>Protocol Configuration</b>	<b>Log File</b>
<b>Log Source Identifier</b>	Type an IP address, host name, or name to identify the event source. IP addresses or host names are recommended as they allow QRadar to identify a log file to a unique event source.
<b>Service Type</b>	From the list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.  The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.
<b>Remote IP or Hostname</b>	Type the IP address or host name of the device that stores your event log files.
<b>Remote Port</b>	Type the TCP port on the remote host that is running the selected Service Type. The valid range is 1 - 65535.  The options include: <ul style="list-style-type: none"><li>• FTP - TCP Port 21</li><li>• SFTP - TCP Port 22</li><li>• SCP - TCP Port 22</li></ul> If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.
<b>Remote User</b>	Type the user name necessary to log in to the host that contains your event files.  The user name can be up to 255 characters in length.
<b>Remote Password</b>	Type the password necessary to log in to the host.
<b>Confirm Password</b>	Confirm the password necessary to log in to the host.
<b>SSH Key File</b>	If you select <b>SCP</b> or <b>SFTP</b> as the Service Type, this parameter gives you the option to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> field is ignored.

Table 294. Log File log source parameters for the Blue Coat SG DSM (continued)

Parameter	Value
<b>Remote Directory</b>	Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.  For FTP only. If your log files are in the remote user's home directory, you can leave the remote directory blank. This is to support operating systems where a change in the working directory (CWD) command is restricted.
<b>Recursive</b>	Select this check box if you want the file pattern to search sub folders in the remote directory. By default, the check box is clear.  The Recursive option is ignored if you configure SCP as the Service Type.
<b>FTP File Pattern</b>	If you select <b>SFTP</b> or <b>FTP</b> as the Service Type, this option gives you the option to configure the regular expression (regex) required to filter the list of files that are specified in the Remote Directory. All matching files are included in the processing.  The FTP file pattern that you specify must match the name you assigned to your event files. For example, to collect files that end with .log, type the following:  .*/.log  Use of this parameter requires knowledge of regular expressions (regex). For more information, see the following website: <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">https://docs.oracle.com/javase/tutorial/essential/regex/</a>
<b>FTP Transfer Mode</b>	This option appears only if you select <b>FTP</b> as the Service Type. The <b>FTP Transfer Mode</b> parameter gives you the option to define the file transfer mode when you retrieve log files over FTP.  From the list, select the transfer mode that you want to apply to this log source:  You must select <b>NONE</b> for the Processor parameter and <b>LINEBYLINE</b> the Event Generator parameter when you use ASCII as the FTP Transfer Mode.
<b>SCP Remote File</b>	If you select <b>SCP</b> as the Service Type you must type the file name of the remote file.
<b>Start Time</b>	Type the time of day you want the processing to begin. For example, type 00:00 to schedule the Log File protocol to collect event files at midnight.  This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24 hour clock, in the following format: HH:MM.

Table 294. Log File log source parameters for the Blue Coat SG DSM (continued)

Parameter	Value
<b>Recurrence</b>	Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D).  For example, type 2H if you want the remote directory to be scanned every 2 hours from the start time. The default is 1H.
<b>Run On Save</b>	Select this check box if you want the log file protocol to run immediately after you click <b>Save</b> .  After the <b>Run On Save</b> completes, the log file protocol follows your configured start time and recurrence schedule.  Selecting <b>Run On Save</b> clears the list of previously processed files for the <b>Ignore Previously Processed File</b> parameter.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The valid range is 100 to 5000.
<b>Processor</b>	If the files located on the remote host are stored in a zip, gzip, tar, or tar+gzip archive format, select the processor that allows the archives to be expanded and contents processed.
<b>Ignore Previously Processed File(s)</b>	Select this check box to track and ignore files that have already been processed by the log file protocol.  QRadar examines the log files in the remote directory to determine if a file has been previously processed by the log file protocol. If a previously processed file is detected, the log file protocol does not download the file for processing. All files that have not been previously processed are downloaded.  This option only applies to FTP and SFTP Service Types.
<b>Change Local Directory?</b>	Select this check box to define a local directory on your QRadar system for storing downloaded files during processing.  We recommend that you leave this check box clear. When this check box is selected, the Local Directory field is displayed, which allows you to configure the local directory to use for storing files.
<b>Event Generator</b>	From the <b>Event Generator</b> list, select LineByLine.  The Event Generator applies additional processing to the retrieved event files. Each line of the file is a single event. For example, if a file has 10 lines of text, 10 separate events are created.

For a complete list of Log File protocol parameters and their values, see [Log File protocol configuration options](#).

#### Related concepts

[Blue Coat SG](#)

The IBM QRadar DSM for Blue Coat SG collects events from Blue Coat SG appliances.

#### Related tasks

[“Adding a log source” on page 5](#)

## Configuring Blue Coat SG for syslog

To allow syslog event collection, you must configure your Blue Coat SG appliance to forward syslog events to IBM QRadar.

### Before you begin

**Note:** When you send syslog events to multiple syslog destinations, a disruption in availability in one syslog destination might interrupt the stream of events to other syslog destinations from your Blue Coat SG appliance.

### Procedure

1. Select **Configuration > Access Logging > Logs > Upload Client**.
2. From the **Log** list, select the log that contains your custom format.
3. From the **Client type** list, select **Custom Client**.
4. Click **Settings**.
5. From the **Settings For** list, select **Primary Custom Server**.
6. In the **Host** field, type the IP address for your QRadar system.
7. In the **Port** field, type 514.
8. Click **OK**.
9. Select the **Upload Schedule** tab.
10. From the **Upload the access log** list, select **Continuously**.
11. Click **Apply**.

## Creating extra custom format key-value pairs

Use the Extended Log File Format (ELFF) custom format to forward specific Blue Coat data or events to IBM QRadar.

The custom format is a series of pipe-delimited fields that start with the **Bluecoat|** field and contains the **\$(Blue Coat ELFF)** parameter.

For example:

Bluecoat|src=\$(c-ip)|srcport=\$(c-port)|dst=\$(cs-uri-address)|dstport=\$(cs-uri-port)|username=\$(cs-username)|devicetime=\$(gmttime)|s-action=\$(s-action)|sc-status=\$(sc-status)|cs-method=\$(cs-method)

Table 295. Custom Format examples	
Blue Coat ELFF Parameter	QRadar Custom Format Example
sc-bytes	\$(sc-bytes)
rs(Content-type)	\$(rs(Content-Type))

For more information about available Blue Coat ELFF parameters, see your Blue Coat appliance documentation.

## Blue Coat SG sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Blue Coat SG sample message when you use the Syslog protocol

The following sample event message shows that access was denied by a filter.

```
2016-11-07 13:13:54 44 172.28.51.1 407 TCP_DENIED 2251 492 GET http clients5.example.com 80 /complete/search ?hl=de-DE&q=t&client=ie8&inputencoding=UTF-8&outputencoding=UTF-8 - - - - - "Mozilla/5.0 (Windows NT 6.1; Trident/7.0; rv:11.0) like Gecko" DENIED "Search Engines/Portals" - 192.168.165.34
```

```
2016-11-07 13:13:54 44 172.28.51.1 407 TCP_DENIED 2251 492 GET http clients5.example.com 80 /complete/search ?hl=de-DE&q=t&client=ie8&inputencoding=UTF-8&outputencoding=UTF-8 - - - - - "Mozilla/5.0 (Windows NT 6.1; Trident/7.0; rv:11.0) like Gecko" DENIED "Search Engines/Portals" - 192.168.165.34
```

*Table 296. Highlighted values in the Blue Coat SG event*

QRadar field name	Highlighted values in the event payload
Event ID	<b>TCP_DENIED</b>
Event Category	For this DSM, the value in QRadar is always <b>WebProxy</b>
Source IP	<b>172.28.51.1</b>
Destination IP	<b>192.168.165.34</b>
Destination port	<b>80</b>

## Blue Coat Web Security Service

The IBM QRadar DSM for Blue Coat Web Security Service collects events from the Blue Coat Web Security Service.

The following table describes the specifications for the Blue Coat Web Security Service DSM:

*Table 297. Blue Coat Web Security Service DSM specifications*

Specification	Value
Manufacturer	Blue Coat
DSM name	Blue Coat Web Security Service
RPM file name	DSM-BlueCoatWebSecurityService-Qradar_version-build_number.noarch.rpm
Event format	Blue Coat ELFF
Recorded event types	Access
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.bluecoat.com">Blue Coat website (https://www.bluecoat.com)</a>

To integrate Blue Coat Web Security Service with QRadar, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol Common RPM
  - Blue Coat Web Security Service REST API Protocol RPM
  - Blue Coat Web Security Service DSM RPM
- Configure Blue Coat Web Security Service to allow QRadar access to the Sync API.
- Add a Blue Coat Web Security Service log source on the QRadar Console. The following table describes the parameters that require specific values for Blue Coat Web Security Service event collection:

*Table 298. Blue Coat Web Security Service log source parameters*

Parameter	Value
Protocol Configuration	The protocol that is used to receive events from the Blue Coat Web Security Service. You can specify the following protocol configuration options: Blue Coat Web Security Service REST API (recommended) Forwarded
API Username	The API user name that is used for authenticating with the Blue Coat Web Security Service. The API user name is configured through the Blue Coat Threat Pulse Portal.
Password	The password that is used for authenticating with the Blue Coat Web Security Service.
Confirm Password	The password that is used for authenticating with the Blue Coat Web Security Service.
Use Proxy	When you configure a proxy, all traffic for the log source travels through the proxy for QRadar to access the Blue Coat Web Security Service.  Configure the <b>Proxy IP or Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
Automatically Acquire Server Certificate(s)	Select <b>Yes</b> for QRadar to automatically download the server certificate and begin trusting the target server.
Recurrence	You can specify the frequency of data collection. The format is M/H/D for Minutes/Hours/Days. The default is 5 M.
EPS Throttle	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.

## Related tasks

[“Adding a DSM” on page 4](#)

## Configuring Blue Coat Web Security Service to communicate with QRadar

To collect events from Blue Coat Web Security Service, you must create an API key for IBM QRadar. If an API key exists, Blue Coat Web Security Service is already configured.

### Procedure

1. Log in to the Blue Coat Threat Pulse portal.
2. Switch to **Service** mode.
3. Click **Account Maintenance > MDM, API Keys**.
4. Click **Add API key**, type a user name and password for the API key, and then click **Add**.

You need the user name and password when you configure the log source for the API.

## Blue Coat Web Security Service sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

### Blue Coat Web Security Service sample message when you use the Blue Coat Web Security REST API protocol

**Important:** Due to formatting, paste the message format into a text editor and then remove any carriage return or line feed characters.

```

Username	<b>cs-userdn</b>

## Chapter 32. Box

The IBM QRadar DSM for Box collects enterprise events from a Box enterprise account.

The following table describes the specifications for the Box DSM:

Table 300. Box DSM specifications	
Specification	Value
Manufacturer	Box
DSM name	Box
RPM file name	DSM-BoxBox-QRadar_version-build_number.noarch.rpm
Supported versions	N/A
Protocol	Box REST API
Event format	JSON
Recorded event types	Administrator and enterprise events Box Shield Alerts
Automatically discovered?	No
Includes identity?	Yes
Includes custom properties?	No
More information	For more information, see the Box link to the public site website ( <a href="https://www.box.com/home">https://www.box.com/home</a> ).

To integrate Box with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](https://www.ibm.com/support/fixcentral) (<https://www.ibm.com/support/fixcentral>) onto your QRadar Console:
  - Protocol Common RPM
  - Box REST API Protocol RPM
  - Box DSM RPM
2. Configure your Box Enterprise account for API access. For more information, see your Box documentation (<https://docs.box.com/docs/configuring-box-platform>).
3. The following table describes the parameters that require specific values for Box event collection:

Table 301. Box log source parameters

Parameter	Value
Log Source type	Box
Protocol Configuration	Box REST API
Client ID	Generated in the <b>OAuth2 parameters</b> pane of the Box administrator configuration.
Client Secret	Generated in the <b>OAuth2 parameters</b> pane of the Box administrator configuration.

Table 301. Box log source parameters (continued)

Parameter	Value
Key ID	Generated in the <b>Public Key Management</b> pane after you submit the public key.
Enterprise ID	Used for access token request.
Private Key File Name	The private key file name in the /opt/qradar/conf/trusted_certificates/box/ directory in QRadar.
Use Proxy	If QRadar accesses the Box API by using a proxy, select the <b>Use Proxy</b> checkbox. If the proxy requires authentication, configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, configure the <b>Proxy Server</b> and <b>Proxy Port</b> fields.
EPS Throttle	The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle. The default is 5000.
Recurrence	The time interval between log source queries to the Box API for new events. The time interval can be in hours (H), minutes (M), or days (D). The default is 10 minutes.

#### Related tasks

## Configuring Box to communicate with QRadar

To retrieve administrator logs from your Box enterprise account, configure Box and your IBM QRadar Console. You must have a Box developer account.

### Before you begin

Generate a private and public RSAkey pair for the JSON Web Token (JWT) assertion.

**Tip:** If you are a QRadar on Cloud user and the Target Collector is either Console or Events Processor, you must open a case and upload the Private Key (in DER format). DevOps then adds that Private Key to /opt/qradar/conf/trusted\_certificates/box.

1. Log in to the Console or Linux server that has an openssl command.

- For a private key, type the following command:

```
openssl genrsa -out box_private_key.pem 2048
```

- For a public key, type the following command:

```
openssl rsa -pubout -in box_private_key.pem -out box_public_key.pem
```

2. Save a copy of the public key. You paste the contents of the public key into the **Add Public Key** text box when you configure Box for API access.
3. Convert the private key to DER by typing the following command on one line:

```
openssl pkcs8 -topk8 -inform PEM -outform DER -in box_private_key.pem -out  
box_private_key.der -nocrypt
```

4. Store the private key on your managed host in QRadar.
  - a. Create a directory called "box" in the /opt/qradar/conf/trusted\_certificates/ directory in QRadar.
  - b. Copy the private key .DER file to the /opt/qradar/conf/trusted\_certificates/box directory that you created. Do not store the private key in any other location.
  - c. Configure the log source by using only the file name of the private key file in the /opt/qradar/conf/trusted\_certificates/box directory. Ensure that you type the file name correctly in the **Private Key File Name** field when you configure the log source.
5. Copy the private key to the /opt/qradar/conf/trusted\_certificates/box directory.

**Tip:** If you configure the log source before you store the private key, an error message is displayed.

## Procedure

1. Create and configure an application for your QRadar appliance.
  - a) Log in to the Box **Developers** portal (<http://developers.box.com/>). You now have access to the Admin and Box Consoles.
  - b) Click **Create New App > Custom App**.
  - c) In the **Custom App** window, select **Server Authentication (with JWT)**.
  - d) In the **App Name** field, type a name for the app, and then click **Create App**.
  - e) On the **Configuration** tab, from the **OAuth2 Credentials** row, record the **Client ID** and the **Client Secret**. You need the **Client ID** and the **Client Secret** when you add a log source in QRadar.
  - f) In the **App Access Level** row, select **App + Enterprise Access**.
  - g) In the **Application Scopes** row, configure the following parameters.

Table 302. Application Scopes parameters

Parameter	Value
<b>Content Actions</b>	Ensure that the <b>Read all files and folders stored in Box</b> and <b>Write all files and folders stored in Box</b> checkboxes are selected.
<b>Administrative Actions</b>	Ensure that the <b>Manage enterprise properties</b> checkbox is selected. Ensure that the <b>Manage users</b> , <b>Manage groups</b> , and <b>Manage retention policies</b> checkboxes are cleared.
<b>Developer Actions</b>	Ensure that all the checkboxes are cleared.

- h) In the **Add and Manage Public Keys** row, click **Add a Public Key**.
- i) Open the public key file that you copied from QRadar. In the **Add a new Public Key** window, paste the contents of the public key file in the **Public Key** field.
- j) Click **Verify and Save**, and then record the **Key ID**. You need the **Key ID** when you add the log source in QRadar.

- k) To ensure that the properties are stored on the server, click **Save Changes**.  
A Successfully updated the app. message is displayed.
2. To submit the app, on the **Authorization** tab, click **Review and Submit**.
3. In the **Review App Authorization Submission** window, click **Submit**.
4. Locate your Box Enterprise ID.
- Log in to the Admin Console, and then click **Account & Billing > Enterprise ID**.
  - Click the **Account Info** tab and record your Box **Enterprise ID**.
5. Authorize your application.
- Log in to the Box Console.
  - From the navigation menu, click **Apps**.
  - On the **Custom Apps Manager** tab, find your app and click **More (...)**.
  - In the **Authorize App** window, verify that the **Application Access** level is **All Users** and that the API key is the **Client ID** that you recorded, and then click **Authorize**.  
If your app is configured correctly, the **Authorization Status** displays as **Authorized** and the **Enablement Status** displays as **Enabled**.

For more information about configuring Box, see [Applications](https://developer.box.com/guides/applications/) (<https://developer.box.com/guides/applications/>).

## What to do next

Verify that QRadar is configured to receive events from your Box DSM. If QRadar is configured correctly, no error messages appear in the **Edit a log source** window.

## Box sample event messages

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Box sample messages when you use the Box REST protocol

**Sample 1:** The following sample event message shows that the user *User Name*, from IP address *10.0.0.1*, added an application key to Box.

```
{"source": {"type": "application", "name": "QRadarBox", "api_key": "aaaaaaaaaaaaaaaaaaaaaaaaaaaa"}, "created_by": {"type": "user", "id": "262196057", "name": "User Name", "login": "user.name@domain.test"}, "created_at": "2016-02-10T07:49:07-08:00", "event_id": "403702014", "event_type": "APPLICATION_PUBLIC_KEY_ADDED", "ip_address": "10.0.0.1", "type": "event", "session_id": null, "additional_details": null}
```

Table 303. Highlighted fields

QRadar field name	Highlighted payload field name
Username	name
Device Time	created_at
Event ID	event_type
Source IP Address	ip_address

**Sample 2:** The following sample event message shows that a Suspicious Location alert was generated based on Download activity by the user *Some name*.

```
{"source": null, "created_by": {"type": "user", "id": "2", "name": "Unknown User", "login": ""}, "action_by": null, "created_at": "2019-12-20T11:38:56-08:00", "event_id": "97f1b31f"}
```

```

-f143-4777-81f8-1b557b39ca33", "event_type": "SHIELD_ALERT", "ip_address": "10.1.2.3", "type": "event"
,"session_id":null,"additional_details": {"shield_alert": {"rule_category": "Suspicious Locations", "rule_id": "123", "rule_name": "Suspicious Location", "risk_score": 60, "alert_summary": {"alert_activities": [{"occurred_at": "2019-12-20T11:37:05-08:00", "event_type": "Download", "item_name": "xyz.txt", "item_type": "file", "item_id": "127", "item_path": "ABC/DEF", "ip_info": {"ip": "10.2.3.4", "latitude": "44.9727", "longitude": "-65.8609", "registrant": "Registrant Company Name", "country_code": "CA", "city_name": "Saint John", "region_name": "New Brunswick"}, "service_name": "Box Excel Online Previewer"}]}, "alert_id": 2398, "priority": "medium", "user": {"id": 2320, "name": "Some name", "email": "some@domain.test"}, "link": "https://app.box.com/master/shield/alerts/123412341234", "created_at": "2019-12-20T11:37:15-08:00"}}

```

*Table 304. Highlighted fields*

QRadar field name	Highlighted payload field name
Device Time	<b>created_at</b>
Source IP Address	<b>ip_address</b>
Event ID	<b>rule_category</b> When the <b>event_type</b> value is <b>SHIELD_ALERT</b> , a Box Shield alert is indicated and the <b>rule_category</b> field is used for the <b>Event ID</b> .
Severity	<b>risk_score</b> The <b>risk_score</b> field severity value range is 1 - 100. In QRadar, the severity value range is 1 - 10. QRadar divides the <b>risk_score</b> field severity value by 10, and then rounds it to the nearest integer.
Username	<b>name</b>

# Chapter 33. Bridgewater

The Bridgewater Systems DSM for IBM QRadar accepts events by using syslog.

QRadar records all relevant events that are forwarded from Bridgewater AAA Service Controller devices by using syslog.

## Configuring Syslog for your Bridgewater Systems Device

You must configure your Bridgewater Systems appliance to send syslog events to IBM QRadar.

### Procedure

1. Log in to your Bridgewater Systems device command-line interface (CLI).

2. To log operational messages to the RADIUS and Diameter servers, open the following file:

`/etc/syslog.conf`

3. To log all operational messages, uncomment the following line:

`local1.info /WideSpan/logs/oplog`

4. To log error messages only, change the `local1.info /WideSpan/logs/oplog` line to the following line:

`local1.err /WideSpan/logs/oplog`

**Note:** RADIUS and Diameter system messages are stored in the `/var/adm/messages` file.

5. Add the following line:

`local1.*@<IP address>`

Where `<IP address>` is the IP address your QRadar Console.

6. The RADIUS and Diameter server system messages are stored in the `/var/adm/messages` file. Add the following line for the system messages:

`<facility>*@<IP address>`

Where:

`<facility>` is the facility that is used for logging to the `/var/adm/messages` file.

`<IP address>` is the IP address of your QRadar Console.

7. **Save** and exit the file.

8. Send a hang-up signal to the syslog daemon to make sure that all changes are enforced:

`kill -HUP `cat /var/run/syslog.pid``

The configuration is complete. The log source is added to QRadar as Bridgewater Systems appliance events are automatically discovered. Events that are forwarded to QRadar by your Bridgewater Systems appliance are displayed on the **Log Activity** tab.

## Syslog log source parameters for Bridgewater Systems

If QRadar does not automatically detect the log source, add a Bridgewater Systems log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Bridgewater:

*Table 305. Syslog log source parameters for the Bridgewater Systems DSM*

<b>Parameter</b>	<b>Value</b>
<b>Log Source name</b>	Type a name for your log source.
<b>Log Source description</b>	Type a description for the log source.
<b>Log Source type</b>	<b>Bridgewater Systems AAA Service Controller</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Bridgewater Systems appliance.

# Chapter 34. Broadcom

---

Broadcom is formerly known as CA Technologies. The name remains as CA Technologies in QRadar. IBM QRadar supports a number of Broadcom DSMs.

## Broadcom CA ACF2

---

Broadcom CA ACF2 is formerly known as CA Technologies ACF2. The name remains CA ACF2 in QRadar.

The Broadcom CA Access Control Facility (ACF2) DSM collects events from a Broadcom CA ACF2 image on an IBM z/OS mainframe by using IBM Security zSecure.

When you use a zSecure process, events from the System Management Facilities (SMF) can be transformed into Log Event Extended Format (LEEF) events. These events can be sent near real-time by using UNIX Syslog protocol or IBM QRadar can retrieve the LEEF event log files by using the Log File protocol and then process the events. When you use the Log File protocol, you can schedule QRadar to retrieve events on a polling interval, which enables QRadar to retrieve the events on the schedule that you define.

To collect CA ACF2 events, complete the following steps:

1. Verify that your installation meets any prerequisite installation requirements.  
For more information about prerequisite requirements, see the [IBM Security zSecure Suite 2.2.1 Prerequisites](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/prereqs\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html)).
2. Configure your IBM z/OS image to write events in LEEF format. For more information, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/setup\\_data\\_prep\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html)).
3. Create a log source in QRadar for CA ACF2.
4. If you want to create a custom event property for CA ACF2 in QRadar, for more information, see the [IBM Security Custom Event Properties for IBM z/OS technical note](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf) ([http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM\\_zOS\\_CustomEventProperties.pdf](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf)).

### Before you begin

Before you can configure the data collection process, you must complete the basic zSecure installation process and complete the post-installation activities to create and modify the configuration.

The following prerequisites are required:

- You must ensure parmlib member IFAPRDxx is enabled for IBM Security zSecure Audit on your z/OS® image.
- The SCKRLOAD library must be APF-authorized.
- If you are using the direct SMF INMEM real-time interface, you must have the necessary software installed (APAR OA49263) and set up the SMFPRMxx member to include the INMEM keyword and parameters. If you decide to use the CDP interface, you must also have CDP installed and running. For more information, see the [IBM Security zSecure Suite 2.2.1: Procedure for near real-time](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smfp_real_time_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/smfp\\_real\\_time\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smfp_real_time_qradar.html)).
- You must configure a process to periodically refresh your CKFREEZE and UNLOAD data sets.
- If you are using the Log File protocol method, you must configure a SFTP, FTP, or SCP server on your z/OS image for QRadar to download your LEEF event files.

- If you are using the Log File protocol method, you must allow SFTP, FTP, or SCP traffic on firewalls that are located between QRadar and your z/OS image.

For instructions on installing and configuring zSecure, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](https://www-01.ibm.com/servers/resourcelink/svc00100.nsf/zSecureV240sc275638?OpenDocument) (<https://www-01.ibm.com/servers/resourcelink/svc00100.nsf/zSecureV240sc275638?OpenDocument>).

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Create a log source for near real-time event feed

The Syslog protocol enables IBM QRadar to receive System Management Facilities (SMF) events in near real-time from a remote host.

The following DSMs are supported:

- IBM z/OS
- IBM CICS®
- IBM RACF®
- IBM DB2
- CA Top Secret
- CA ACF2

If QRadar does not automatically detect the log source, add a log source for your DSM on the QRadar console.

The following table describes the parameters that require specific values for event collection for your DSM:

<i>Table 306. Log source parameters</i>	
<b>Parameter</b>	<b>Value</b>
Log Source type	Select your DSM name from the list.
Protocol Configuration	Syslog
Log Source Identifier	Type a unique identifier for the log source.

## Log File log source parameter

If QRadar does not automatically detect the log source, add a IBM z/OS, IBM CICS, IBM RACF, IBM DB2, Broadcom CA Top Secret, or Broadcom CA ACF2 log source on the QRadar Console by using the Log File Protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from IBM z/OS, IBM CICS, IBM RACF, IBM DB2, CA Top Secret, or CA ACF2:

<i>Table 307. Log File log source parameters</i>	
<b>Parameter</b>	<b>Value</b>
<b>Log Source name</b>	Type a name for your log source.
<b>Log Source description</b>	Type a description for the log source.
<b>Log Source type</b>	Select your DSM name.
<b>Protocol Configuration</b>	<b>Log File</b>

Table 307. Log File log source parameters (continued)

Parameter	Value
<b>Log Source Identifier</b>	<p>Type an IP address, host name, or name to identify the event source. IP addresses or host names are suggested as they allow QRadar to identify a log file to a unique event source.</p> <p>For example, if your network contains multiple devices, such as multiple z/OS images or a file repository that contains all of your event logs, you must specify a name, IP address, or host name for the image or location that uniquely identifies events for the DSM log source. This specification enables events to be identified at the image or location level in your network that your users can identify.</p>
<b>Service Type</b>	<p>From the <b>Service Type</b> list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.</p> <ul style="list-style-type: none"> <li>• SFTP - SSH File Transfer Protocol</li> <li>• FTP - File Transfer Protocol</li> <li>• SCP - Secure Copy</li> </ul> <p>The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server that is specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p>
<b>Remote IP or Hostname</b>	<p>Type the IP address or host name of the device that stores your event log files.</p>
<b>Remote Port</b>	<p>Type the TCP port on the remote host that is running the selected <b>Service Type</b>. The valid range is 1 - 65535.</p> <p>The options include ports:</p> <ul style="list-style-type: none"> <li>• FTP - TCP Port 21</li> <li>• SFTP - TCP Port 22</li> <li>• SCP - TCP Port 22</li> </ul> <p>If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.</p>

Table 307. Log File log source parameters (continued)

Parameter	Value
<b>Remote User</b>	Type the user name or user ID necessary to log in to the system that contains your event files. <ul style="list-style-type: none"> <li>If your log files are on your IBM z/OS image, type the user ID necessary to log in to your IBM z/OS. The user ID can be up to 8 characters in length.</li> <li>If your log files are on a file repository, type the user name necessary to log in to the file repository. The user name can be up to 255 characters in length.</li> </ul>
<b>Remote Password</b>	Type the password necessary to log in to the host.
<b>Confirm Password</b>	Confirm the password necessary to log in to the host.
<b>SSH Key File</b>	If you select <b>SCP</b> or <b>SFTP</b> as the <b>Service Type</b> , this parameter gives you the option to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> field is ignored.
<b>Remote Directory</b>	Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.
<b>Recursive</b>	If you want the file pattern to search sub folders in the remote directory, select this check box. By default, the check box is clear.  If you configure SCP as the Service Type, the Recursive option is ignored.
<b>FTP File Pattern</b>	If you select <b>SFTP</b> or <b>FTP</b> as the <b>Service Type</b> , you can configure the regular expression (regex) needed to filter the list of files that are specified in the <b>Remote Directory</b> . All matching files are included in the processing.  The IBM z/OS mainframe that uses IBM Security zSecure Audit writes event files by using the pattern: <product_name>.<timestamp>.gz  The FTP file pattern that you specify must match the name that you assigned to your event files. For example, to collect files that start with zOS and end with .gz, type the following code:  zOS.*\.gz  Use of this parameter requires knowledge of regular expressions (regex). For more information about regex, see <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">Lesson: Regular Expressions</a> ( <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">https://docs.oracle.com/javase/tutorial/essential/regex/</a> ).

Table 307. Log File log source parameters (continued)

Parameter	Value
<b>FTP Transfer Mode</b>	<p>This option displays only if you select <b>FTP</b> as the <b>Service Type</b>. From the list, select <b>Binary</b>.</p> <p>The binary transfer mode is needed for event files that are stored in a binary or compressed format, such as zip, gzip, tar, or tar+gzip archive files.</p>
<b>SCP Remote File</b>	If you select <b>SCP</b> as the <b>Service Type</b> you must type the file name of the remote file.
<b>Start Time</b>	<p>Type the time of day you want the processing to begin. For example, type 00 : 00 to schedule the Log File protocol to collect event files at midnight.</p> <p>This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.</p>
<b>Recurrence</b>	<p>Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D).</p> <p>For example, type 2H if you want the remote directory to be scanned every 2 hours from the start time. The default is 1H.</p>
<b>Run On Save</b>	<p>If you want the Log File protocol to run immediately after you click <b>Save</b>, select this check box.</p> <p>After the <b>Run On Save</b> completes, the Log File protocol follows your configured start time and recurrence schedule.</p> <p>Selecting <b>Run On Save</b> clears the list of previously processed files for the Ignore Previously Processed File parameter.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 5000.</p>

Table 307. Log File log source parameters (continued)

Parameter	Value
<b>Processor</b>	From the list, select <b>gzip</b> . Processors enable event file archives to be expanded and contents are processed for events. Files are processed after they are downloaded to QRadar. QRadar can process files in zip, gzip, tar, or tar+gzip archive format.
<b>Ignore Previously Processed File(s)</b>	Select this check box to track and ignore files that are already processed by the Log File protocol.  QRadar examines the log files in the remote directory to determine whether a file is previously processed by the Log File protocol. If a previously processed file is detected, the Log File protocol does not download the file for processing. All files that are not previously processed are downloaded.  This option applies only to FTP and SFTP service types.
<b>Change Local Directory?</b>	Select this check box to define a local directory on your QRadar for storing downloaded files during processing.  It is suggested that you leave this check box clear. When this check box is selected, the <b>Local Directory</b> field is displayed, which gives you the option to configure the local directory to use for storing files.
<b>Event Generator</b>	From the <b>Event Generator</b> list, select <b>LineByLine</b> .  The Event Generator applies more processing to the retrieved event files. Each line is a single event. For example, if a file has 10 lines of text, 10 separate events are created.

#### Related tasks

[“Adding a log source” on page 5](#)

## Integrate Broadcom CA ACF2 with IBM QRadar by using audit scripts

The Broadcom CA Access Control Facility (ACF2) DSM collects events and audit transactions on the IBM mainframe with the Log File protocol.

`QexACF2.load.trs` is a TERSED file that contains a PDS loadlib with the QEXACF2 program. A TERSED file is similar to a zip file and requires you to use the TRSMAIN program to decompress the contents. The TRSMAIN program is available from [IBM Support](#) ([www.ibm.com/support](http://www.ibm.com/support)).

To upload a TRS file from a workstation, you must preallocate a file with the following DCB attributes: DSORG=PS, RECFM=FB, LRECL= 1024, BLKSIZE=6144. The file transfer type must be BINARY APPEND. If the transfer type is TEXT or TEXT APPEND, then the file cannot decompress properly.

After you upload the file to the mainframe into the allocated dataset, the TERSED file can be UNPACKED with the TRSMAIN utility by using the sample JCL also included in the tar package. A return code of 0008 from the TRSMAIN utility indicates that the dataset is not recognized as a valid TERSED file. This code

(0008) error might be the result of the file not being uploaded to the mainframe with the correct DCB attributes, or because the transfer was not performed with the BINARY APPEND transfer mechanism.

After you have successfully UNPACKED the loadlib file, you can run the QEXACF2 program with the sample JCL file. The sample JCL file is contained in the tar collection. To run the QEXACF2 program, you must modify the JCL to your local naming conventions and JOB card requirements. You might also need to use the STEPLIB DD if the program is not placed in a LINKLISTED library.

To integrate CA ACF2 events into IBM QRadar:

1. The IBM mainframe records all security events as Service Management Framework (SMF) records in a live repository.
2. The CA ACF2 data is extracted from the live repository with the SMF dump utility. The SMF file contains all of the events and fields from the previous day in raw SMF format.
3. The QexACF2.load.trs program pulls data from the SMF formatted file. The QexACF2.load.trs program pulls only the relevant events and fields for QRadar and writes that information in a compressed format for compatibility. The information is saved in a location accessible by QRadar.
4. QRadar uses the Log File protocol source to retrieve the output file information on a scheduled basis. QRadar then imports and processes this file.

## Configuring Broadcom CA ACF2 that uses audit scripts to integrate with IBM QRadar

IBM QRadar uses scripts to audit events from Broadcom CA ACF2 installations, which are collected by using the log file protocol.

### Procedure

1. From the IBM support website (<http://www.ibm.com/support>), download the following compressed file:

```
qexacf2_bundled.tar.gz
```

2. On a Linux operating system, extract the file:

```
tar -zxvf qexacf2_bundled.tar.gz
```

The following files are contained in the archive:

- QexACF2.JCL.txt - Job Control Language file
- QexACF2.load.trs - Compressed program library (requires IBM TRSMAIN)
- trsmain sample JCL.txt - Job Control Language for TRSMAIN to decompress the .trs file

3. Load the files onto the IBM mainframe by using the following methods:

Upload the sample QexACF2\_trsmain\_JCL.txt and QexACF2.JCL.txt files by using the TEXT protocol.

4. Upload the QexACF2.load.trs file by using a BINARY mode transfer and append to a preallocated data set. The QexACF2.load.trs file is a terced file that contains the executable file (the mainframe program QexACF2). When you upload the .trs file from a workstation, preallocate a file on the mainframe with the following DCB attributes: DSORG=PS, RECFM=FB, LRECL=1024, BLKSIZE=6144. The file transfer type must be binary mode and not text.

**Note:** QexACF2 is a small C mainframe program that reads the output of the TSSUTIL (EARLOUT data) line by line. QexACF2 adds a header to each record that contains event information, for example, record descriptor, the date, and time. The program places each field into the output record, suppresses trailing blank characters, and delimits each field with the pipe character. This output file is formatted for QRadar and the blank suppression reduces network traffic to QRadar. This program does not consume CPU or I/O disk resources.

5. Customize the trsmain sample\_JCL.txt file according to your installation-specific parameters.

**Example:** Jobcard, data set naming conventions, output destinations, retention periods, and space requirements.

The `trsmain sample_JCL.txt` file uses the IBM utility TRSMAIN to extract the program that is stored in the `QexACF2.load.trs` file.

An example of the `QexACF2_trsmain_JCL.txt` file includes the following information:

```
//TRSMAIN JOB (yourvalidjobcard),Q1labs,  
// MSGCLASS=V  
//DEL EXEC PGM=IEFBR14  
//D1 DD DISP=(MOD,DELETE),DSN=<yourhlq>.QEXACF2.LOAD.TRS  
// UNIT=SYSDA,  
// SPACE=(CYL,(10,10))  
//TRSMAIN EXEC PGM=TRSMAIN,PARM='UNPACK'  
//SYSPRINT DD SYSOUT=*,DCB=(LRECL=133,BLKSIZE=12901,RECFM=FBA)  
//INFILE DD DISP=SHR,DSN=<yourhlq>.QEXACF2.LOAD.TRS  
//OUTFILE DD DISP=(NEW,CATLG,DELETE),  
// DSN=<yourhlq>.LOAD,  
// SPACE=(CYL,(10,10,5),RLSE),UNIT=SYSDA  
//
```

The `.trs` input file is an IBM TERSE formatted library and is extracted by running the JCL, which calls the TRSMAIN. This terSED file, when extracted, creates a PDS linklib with the QexACF2 program as a member.

6. You can STEPLIB to this library or choose to move the program to one of the LINKLIBs that are in LINKLST. The program does not require authorization.
7. After you upload, copy the program to an existing link listed library or add a STEPLIB DD statement with the correct data set name of the library that will contain the program.
8. The `QexACF2_jcl.txt` file is a text file that contains a sample JCL. You must configure the job card to meet your configuration.

The `QexACF2_jcl.txt` sample file includes:

```
//QEXACF2 JOB (T,JXPO,JKSD0093),DEV,NOTIFY=Q1JACK,  
// MSGCLASS=P,  
// REGION=0M  
/*  
//**QEXACF2 JCL VERSION 1.0 OCTOBER, 2010  
//**  
//*****  
//** Change below dataset names to sites specific datasets names*  
  
//QEXACF2 JOB (T,JXPO,JKSD0093),DEV,NOTIFY=Q1JACK,  
// MSGCLASS=P,  
// REGION=0M  
/*  
//**QEXACF2 JCL VERSION 1.0 OCTOBER, 2010  
//**  
//*****  
//** Change below dataset names to sites specific datasets names*  
//*****  
//SET1 SET SMFIN='MVS1.SMF.RECORDS(0)',  
// QEXOUT='Q1JACK.QEXACF2.OUTPUT',  
// SMFOUT='Q1JACK.ACF2.DATA'  
//*****  
//* Delete old datasets *  
//*****  
//DEL EXEC PGM=IEFBR14

//EXTRACT EXEC PGM=QEXACF2,DYNAMNBR=10,
// TIME=1440
//STEPLIB DD DISP=SHR,DSN=Q1JACK.C.LOAD
//SYSTSIN DD DUMMY

//SYSTSPRT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
//CFG DD DUMMY
//ACFIN DD DISP=SHR,DSN=&SMFOUT
//ACFOUT DD DISP=SHR,DSN=&QEXOUT
//*****
//FTP EXEC PGM=FTP,REGION=3800K
//INPUT DD *
<IPADDR>
<USER>
<PASSWORD>
PUT '<ACFOUT>' EARL_<THEIPOFTHEMAINFRAMEDEVICE>/<ACFOUT>
QUIT
//OUTPUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
//*

```

- After the output file is created, schedule a job to transfer the output file to an interim FTP server. The output file is forwarded to an interim FTP server.

You must configure the following parameters in the sample JCL to successfully forward the output to an interim FTP server:

**Example:**

```

//FTP EXEC PGM=FTP,REGION=3800K
//INPUT DD *
<IPADDR>
<USER>
<PASSWORD>
PUT '<ACFOUT>' EARL_<THEIPOFTHEMAINFRAMEDEVICE>/<ACFOUT>
QUIT
//OUTPUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*

```

Where:

<IPADDR> is the IP address or host name of the interim FTP server to receive the output file.

<USER> is the user name that is needed to access the interim FTP server.

<PASSWORD> is the password that is needed to access the interim FTP server.

<THEIPOFTHEMAINFRAMEDEVICE> is the destination of the mainframe or interim FTP server that receives the output.

**Example:**

```
PUT 'xxxxxx.xxxxxxx.OUTPUT.C320' /<IP_address>/ACF2/QEXACF2.OUTPUT.C320
```

<QEXOUTDSN> is the name of the output file that is saved to the interim FTP server.

You are now ready to configure the Log File protocol.

- Schedule QRadar to retrieve the output file from CA ACF2.

If the zOS platform is configured to serve files through FTP, SFTP, or allow SCP, then no interim FTP server is needed and QRadar can pull the output file directly from the mainframe. The following text must be commented out using ///\* or deleted from the QexACF2\_jcl.txt file:

```
//FTP EXEC PGM=FTP,REGION=3800K
//INPUT DD *
<IPADDR>
<USER>
<PASSWORD>
PUT '<ACFOUT>' EARL_<THEIPOFTHEMAINFRAMEDEVICE>/<ACFOUT>
QUIT
//OUTPUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
```

## What to do next

You are now ready to configure the log source in QRadar.

## Broadcom CA Top Secret

Broadcom CA Top Secret is formerly known as CA Technologies Top Secret. The name remains CA Top Secret in QRadar.

The Broadcom CA Top Secret DSM collects events from a Broadcom CA Top Secret image on an IBM z/OS mainframe by using IBM Security zSecure.

When you use a zSecure process, events from the System Management Facilities (SMF) can be transformed into Log Event Extended Format (LEEF) events. These events can be sent near real-time by using UNIX Syslog protocol or IBM QRadar can retrieve the LEEF event log files by using the Log File protocol and then process the events. When you use the Log File protocol, you can schedule QRadar to retrieve events on a polling interval, which enables QRadar to retrieve the events on the schedule that you define.

To collect CA Top Secret events, complete the following steps:

1. Verify that your installation meets any prerequisite installation requirements.

For more information about prerequisite requirements, see the [IBM Security zSecure Suite 2.2.1 Prerequisites](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/prereqs\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html)).

2. Configure your IBM z/OS image to write events in LEEF format. For more information, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/setup\\_data\\_prep\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html)).
3. Create a log source in QRadar for CA Top Secret.
4. If you want to create a custom event property for CA Top Secret in QRadar, for more information, see the [IBM Security Custom Event Properties for IBM z/OS technical note](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf) ([http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM\\_zOS\\_CustomEventProperties.pdf](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf)).

## Before you begin

Before you can configure the data collection process, you must complete the basic zSecure installation process and complete the post-installation activities to create and modify the configuration.

The following prerequisites are required:

- You must ensure parmlib member IFAPRDxx is enabled for IBM Security zSecure Audit on your z/OS image.
- The SCKRLOAD library must be APF-authorized.
- If you are using the direct SMF INMEM real-time interface, you must have the necessary software installed (APAR OA49263) and set up the SMFPRMxx member to include the

INMEM keyword and parameters. If you decide to use the CDP interface, you must also have CDP installed and running. For more information, see the [IBM Security zSecure Suite 2.2.1: Procedure for near real-time](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smf_proc_real_time_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/smf\\_proc\\_real\\_time\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smf_proc_real_time_qradar.html))

- You must configure a process to periodically refresh your CKFREEZE and UNLOAD data sets.
- If you are using the Log File protocol method, you must configure a SFTP, FTP, or SCP server on your z/OS image for QRadar to download your LEEF event files.
- If you are using the Log File protocol method, you must allow SFTP, FTP, or SCP traffic on firewalls that are located between QRadar and your z/OS image.

For instructions on installing and configuring zSecure, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](https://www-01.ibm.com/servers/resourcelink/svc00100.nsf/pages/zSecureV240sc275638?OpenDocument) (<https://www-01.ibm.com/servers/resourcelink/svc00100.nsf/pages/zSecureV240sc275638?OpenDocument>).

## Log File log source parameter

If QRadar does not automatically detect the log source, add a IBM z/OS, IBM CICS, IBM RACF, IBM DB2, Broadcom CA Top Secret, or Broadcom CA ACF2 log source on the QRadar Console by using the Log File Protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from IBM z/OS, IBM CICS, IBM RACF, IBM DB2, CA Top Secret, or CA ACF2:

Table 308. Log File log source parameters	
Parameter	Value
<b>Log Source name</b>	Type a name for your log source.
<b>Log Source description</b>	Type a description for the log source.
<b>Log Source type</b>	Select your DSM name.
<b>Protocol Configuration</b>	<b>Log File</b>
<b>Log Source Identifier</b>	Type an IP address, host name, or name to identify the event source. IP addresses or host names are suggested as they allow QRadar to identify a log file to a unique event source.  For example, if your network contains multiple devices, such as multiple z/OS images or a file repository that contains all of your event logs, you must specify a name, IP address, or host name for the image or location that uniquely identifies events for the DSM log source. This specification enables events to be identified at the image or location level in your network that your users can identify.

Table 308. Log File log source parameters (continued)

Parameter	Value
<b>Service Type</b>	<p>From the <b>Service Type</b> list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.</p> <ul style="list-style-type: none"> <li>• SFTP - SSH File Transfer Protocol</li> <li>• FTP - File Transfer Protocol</li> <li>• SCP - Secure Copy</li> </ul> <p>The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server that is specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p>
<b>Remote IP or Hostname</b>	Type the IP address or host name of the device that stores your event log files.
<b>Remote Port</b>	<p>Type the TCP port on the remote host that is running the selected <b>Service Type</b>. The valid range is 1 - 65535.</p> <p>The options include ports:</p> <ul style="list-style-type: none"> <li>• FTP - TCP Port 21</li> <li>• SFTP - TCP Port 22</li> <li>• SCP - TCP Port 22</li> </ul> <p>If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.</p>
<b>Remote User</b>	<p>Type the user name or user ID necessary to log in to the system that contains your event files.</p> <ul style="list-style-type: none"> <li>• If your log files are on your IBM z/OS image, type the user ID necessary to log in to your IBM z/OS. The user ID can be up to 8 characters in length.</li> <li>• If your log files are on a file repository, type the user name necessary to log in to the file repository. The user name can be up to 255 characters in length.</li> </ul>
<b>Remote Password</b>	Type the password necessary to log in to the host.
<b>Confirm Password</b>	Confirm the password necessary to log in to the host.
<b>SSH Key File</b>	If you select <b>SCP</b> or <b>SFTP</b> as the <b>Service Type</b> , this parameter gives you the option to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> field is ignored.

Table 308. Log File log source parameters (continued)

Parameter	Value
<b>Remote Directory</b>	Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.
<b>Recursive</b>	If you want the file pattern to search sub folders in the remote directory, select this check box. By default, the check box is clear.  If you configure SCP as the Service Type, the Recursive option is ignored.
<b>FTP File Pattern</b>	If you select <b>SFTP</b> or <b>FTP</b> as the <b>Service Type</b> , you can configure the regular expression (regex) needed to filter the list of files that are specified in the <b>Remote Directory</b> . All matching files are included in the processing.  The IBM z/OS mainframe that uses IBM Security zSecure Audit writes event files by using the pattern: <product_name>.<timestamp>.gz  The FTP file pattern that you specify must match the name that you assigned to your event files. For example, to collect files that start with zOS and end with .gz, type the following code:  zOS.*\.gz  Use of this parameter requires knowledge of regular expressions (regex). For more information about regex, see <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">Lesson: Regular Expressions</a> ( <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">https://docs.oracle.com/javase/tutorial/essential/regex/</a> ).
<b>FTP Transfer Mode</b>	This option displays only if you select <b>FTP</b> as the <b>Service Type</b> . From the list, select <b>Binary</b> .  The binary transfer mode is needed for event files that are stored in a binary or compressed format, such as zip, gzip, tar, or tar+gzip archive files.
<b>SCP Remote File</b>	If you select <b>SCP</b> as the <b>Service Type</b> you must type the file name of the remote file.
<b>Start Time</b>	Type the time of day you want the processing to begin. For example, type 00 : 00 to schedule the Log File protocol to collect event files at midnight.  This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.

Table 308. Log File log source parameters (continued)

Parameter	Value
<b>Recurrence</b>	Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D).  For example, type 2H if you want the remote directory to be scanned every 2 hours from the start time. The default is 1H.
<b>Run On Save</b>	If you want the Log File protocol to run immediately after you click <b>Save</b> , select this check box.  After the <b>Run On Save</b> completes, the Log File protocol follows your configured start time and recurrence schedule.  Selecting <b>Run On Save</b> clears the list of previously processed files for the <b>Ignore Previously Processed File</b> parameter.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The valid range is 100 to 5000.
<b>Processor</b>	From the list, select <b>gzip</b> .  Processors enable event file archives to be expanded and contents are processed for events. Files are processed after they are downloaded to QRadar. QRadar can process files in zip, gzip, tar, or tar+gzip archive format.
<b>Ignore Previously Processed File(s)</b>	Select this check box to track and ignore files that are already processed by the Log File protocol.  QRadar examines the log files in the remote directory to determine whether a file is previously processed by the Log File protocol. If a previously processed file is detected, the Log File protocol does not download the file for processing. All files that are not previously processed are downloaded.  This option applies only to FTP and SFTP service types.

Table 308. Log File log source parameters (continued)

Parameter	Value
<b>Change Local Directory?</b>	Select this check box to define a local directory on your QRadar for storing downloaded files during processing.  It is suggested that you leave this check box clear. When this check box is selected, the <b>Local Directory</b> field is displayed, which gives you the option to configure the local directory to use for storing files.
<b>Event Generator</b>	From the <b>Event Generator</b> list, select <b>LineByLine</b> .  The Event Generator applies more processing to the retrieved event files. Each line is a single event. For example, if a file has 10 lines of text, 10 separate events are created.

#### Related tasks

[“Adding a log source” on page 5](#)

## Create a log source for near real-time event feed

The Syslog protocol enables IBM QRadar to receive System Management Facilities (SMF) events in near real-time from a remote host.

The following DSMs are supported:

- IBM z/OS
- IBM CICS
- IBM RACF
- IBM DB2
- CA Top Secret
- CA ACF2

If QRadar does not automatically detect the log source, add a log source for your DSM on the QRadar console.

The following table describes the parameters that require specific values for event collection for your DSM:

Table 309. Log source parameters

Parameter	Value
Log Source type	Select your DSM name from the list.
Protocol Configuration	Syslog
Log Source Identifier	Type a unique identifier for the log source.

## Integrate Broadcom CA Top Secret with IBM QRadar by using audit scripts

The Broadcom CA Top Secret DSM collects events and audit transactions on the IBM mainframe with the Log File protocol.

IBM QRadar records all relevant and available information from the event.

To integrate CA Top Secret events into QRadar:

1. The IBM mainframe records all security events as Service Management Framework (SMF) records in a live repository.
2. At midnight, the CA Top Secret data is extracted from the live repository by using the SMF dump utility. The SMF file contains all of the events and fields from the previous day in raw SMF format.
3. The qextopsloadlib program pulls data from the SMF formatted file. The qextopsloadlib program only pulls the relevant events and fields for QRadar and writes that information in a condensed format for compatibility. The information is saved in a location accessible by QRadar.
4. QRadar uses the Log File protocol source to retrieve the output file information on a scheduled basis. QRadar then imports and processes this file.

## Configuring Broadcom CA Top Secret that uses audit scripts to integrate with IBM QRadar

The Broadcom CA Top Secret DSM collects events and audit transactions on the IBM mainframe by using the Log File protocol.

### Procedure

1. From the IBM support website (<http://www.ibm.com/support>), download the following compressed file:

```
qextops_bundled.tar.gz
```

2. On a Linux operating system, extract the file:

```
tar -zxvf qextops_bundled.tar.gz
```

The following files are contained in the archive:

- qextops\_jcl.txt
- qextopsloadlibtrs
- qextops\_trsmain\_JCL.txt

3. Load the files onto the IBM mainframe by using any terminal emulator file transfer method.

Upload the sample qextops\_trsmain\_JCL.txt and qextops\_jcl.txt files by using the TEXT protocol.

4. Upload the qextopsloadlibtrs file by using a BINARY mode transfer. The qextopsloadlibtrs file is a terced file that contains the executable (the mainframe program qextops). When you upload the .trs file from a workstation, preallocate a file on the mainframe with the following DCB attributes: DSORG=PS, RECFM=FB, LRECL=1024, BLKSIZE=6144. The file transfer type must be binary mode and not text.

**Note:** Qextops is a small C mainframe program that reads the output of the TSSUTIL (EARLOUT data) line by line. Qextops adds a header to each record that contains event information, for example, record descriptor, the date, and time. The program places each field into the output record, suppresses trailing blank characters, and delimits each field with the pipe character. This output file is formatted for QRadar and the blank suppression reduces network traffic to QRadar. This program does not consume CPU or I/O disk resources.

5. Customize the qextops\_trsmain\_JCL.txt file according to your installation-specific requirements.

The qextops\_trsmain\_JCL.txt file uses the IBM utility TRSMAIN to extract the program that is stored in the qextopsloadlibtrs file.

An example of the qextops\_trsmain\_JCL.txt file includes:

```
//TRSMAIN JOB (yourvalidjobcard),Q1labs,  
// MSGCLASS=V  
//DEL EXEC PGM=IEFBR14
```

```

//D1 DD DISP=(MOD,DELETE) ,DSN=<yourhlq>.QEXTOPS.TRS
// UNIT=SYSDA,
// SPACE=(CYL,(10,10))
//TRSMAIN EXEC PGM=TRSMAIN,PARM='UNPACK'
//SYSPRINT DD SYSOUT=*,DCB=(LRECL=133,BLKSIZE=12901,RECFM=FBA)
//INFILE DD DISP=SHR,DSN=<yourhlq>.QEXTOPS.TRS
//OUTFILE DD DISP=(NEW,CATLG,DELETE),
// DSN=<yourhlq>.LOAD,
// SPACE=(CYL,(10,10,5),RLSE),UNIT=SYSDA
//

```

You must update the file with your installation specific information for parameters, such as, jobcard, data set naming conventions, output destinations, retention periods, and space requirements.

The .trs input file is an IBM TERSE formatted library and is extracted by running the JCL, which calls the TRSMAIN. This terSED file, when extracted, creates a PDS linklib with the qextops program as a member.

6. You can STEPLIB to this library or choose to move the program to one of the LINKLIBs that are in the LINKLST. The program does not require authorization.
7. Following the upload, copy the program to an existing link listed library or add a STEPLIB DD statement with the correct data set name of the library that contains the program.
8. The qextops\_jcl.txt file is a text file that contains a sample JCL. You must configure the job card to meet your configuration.

The qextops\_jcl.txt sample file includes:

```

//QEXTOPS JOB (T,JXP0,JKSD0093),DEV,NOTIFY=Q1JACK,
// MSGCLASS=P,
// REGION=OM
//*
//**QEXTOPS JCL version 1.0 September, 2010
//**
//***** Change below dataset names to sites specific datasets names*
//*****
//SET1 SET TSSOUT='Q1JACK.EARLOUT.ALL',
// EARLOUT='Q1JACK.QEXTOPS.PROGRAM.OUTPUT'
//*****
//** Delete old datasets *
//*****

```

```

DEL EXEC PGM=IEFBR14
//DD1 DD DISP=(MOD,DELETE) ,DSN=&TSSOUT,
// UNIT=SYSDA,
// SPACE=(CYL,(10,10)),
// DCB=(RECFM=FB,LRECL=80)
//DD2 DD DISP=(MOD,DELETE) ,DSN=&EARLOUT,
// UNIT=SYSDA,
// SPACE=(CYL,(10,10)),
// DCB=(RECFM=FB,LRECL=80)
//*****
//** Allocate new dataset *
//*****
//ALLOC EXEC PGM=IEFBR14

// DISP=(,CATLG),UNIT=SYSDA,SPACE=(CYL,(50,10),RLSE),
// DCB=(RECFM=FB,LRECL=133,BLKSIZE=0)
//EARLOUT DD DSN=&TSSOUT,
// DISP=(NEW,CATLG),UNIT=SYSDA,
// SPACE=(CYL,(200,100),RLSE),
// DCB=(RECFM=VB,LRECL=456,BLKSIZE=27816)
//UTILIN DD *
NOLEGEND
REPORT EVENT(ALL) END
/*

```

```

//*****
//EXTRACT EXEC PGM=QEXTOPS,DYNAMNBR=10,
// TIME=1440
//STEPLIB DD DISP=SHR,DSN=Q1JACK.C.LOAD
//SYSTSIN DD DUMMY
//SYSTSPRT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
//CFG DD DUMMY
//EARLIN DD DISP=SHR,DSN=&TSSOUT
//EARLOUT DD DISP=SHR,DSN=&EARLOUT
//*****
//FTP EXEC PGM=FTP,REGION=3800K
//INPUT DD *
<IPADDR>
<USER>
<PASSWORD>
PUT '<EARLOUT>' EARL_<THEIPOFTHEMAINFRAMEDEVICE>/<QUIT
//OUTPUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*

```

- After the output file is created, schedule a job to a transfer the output file to an interim FTP server. The output file is forwarded to an interim FTP server.

You must configure the following parameters in the sample JCL to successfully forward the output to an interim FTP server:

**Example:**

```

//FTP EXEC PGM=FTP,REGION=3800K
//INPUT DD *
<IPADDR>
<USER>
<PASSWORD>
PUT '<EARLOUT>' EARL_<THEIPOFTHEMAINFRAMEDEVICE>/<EARLOUT>
QUIT
//OUTPUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*

```

Where:

<IPADDR> is the IP address or host name of the interim FTP server to receive the output file.

<USER> is the user name that is needed to access the interim FTP server.

<PASSWORD> is the password that is needed to access the interim FTP server.

<THEIPOFTHEMAINFRAMEDEVICE> is the destination of the mainframe or interim FTP server that receives the output.

**Example:**

```
PUT 'xxxxxx.xxxxxxx.OUTPUT.C320' /<IP_address>/CA/QEXTOPS.OUTPUT.C320
```

<QEXTOUTDSN> is the name of the output file that is saved to the interim FTP server.

You are now ready to configure the Log File protocol.

- Schedule QRadar to collect the output file from CA Top Secret.

If the zOS platform is configured to serve files through FTP, SFTP, or allow SCP, then no interim FTP server is needed and QRadar can pull the output file directly from the mainframe. The following text must be commented out using ///\* or deleted from the qextops\_jcl.txt file:

```

//FTP EXEC PGM=FTP,REGION=3800K
//INPUT DD *
<IPADDR>
<USER>
<PASSWORD>
PUT '<EARLOUT>' EARL_<THEIPOFTHEMAINFRAMEDEVICE>/<EARLOUT>
QUIT
//OUTPUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*

```

## What to do next

You are now ready to configure the log source in QRadar.

## Broadcom Symantec SiteMinder

Broadcom Symantec SiteMinder is formerly known as CA SiteMinder. The name remains as CA SiteMinder in QRadar.

The IBM QRadar Symantec SiteMinder DSM collects syslog-*ng* events from Symantec SiteMinder appliances.

The Symantec SiteMinder DSM collects access and authorization events that are logged in the smaccess.log file, then forwards the events to IBM QRadar by using syslog-*ng*.

To integrate Symantec SiteMinder with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent version of the CA SiteMinder DSM RPM from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
2. Configure your Symantec SiteMinder appliance to send events to QRadar. For more information, see [Configuring syslog-\*ng\* for Symantec SiteMinder](#).
3. Add a Symantec SiteMinder log source on the QRadar Console.

## Broadcom Symantec SiteMinder DSM specifications

When you configure the Broadcom Symantec SiteMinder DSM, understanding the specifications for the Broadcom Symantec SiteMinder DSM can help ensure a successful integration. For example, knowing what the supported version of Broadcom Symantec SiteMinder is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Symantec SiteMinder DSM.

<i>Table 310. Symantec SiteMinder DSM specifications</i>	
<b>Specification</b>	<b>Value</b>
Manufacturer	Broadcom
DSM name	CA SiteMinder
RPM file name	DSM-CASiteMinder-QRadar_version-build_number.noarch.rpm
Supported version	SiteMinder 12.8
Protocol	Syslog, Log File
Event format	Syslog
Recorded event types	All events
Automatically discovered?	No
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.broadcom.com/products/cyber-security/identity/siteminder">Symantec SiteMinder documentation</a> ( <a href="https://www.broadcom.com/products/cyber-security/identity/siteminder">https://www.broadcom.com/products/cyber-security/identity/siteminder</a> )

## Syslog log source parameters for Broadcom Symantec SiteMinder

If QRadar does not automatically detect the log source, add a Broadcom Symantec SiteMinder log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Symantec SiteMinder:

Table 311. Syslog log source parameters for the Symantec SiteMinder DSM	
Parameter	Value
<b>Log Source name</b>	Type a name for your log source.
<b>Log Source description</b>	Type a description for the log source.
<b>Log Source type</b>	<b>CA SiteMinder</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for your Symantec SiteMinder appliance.
<b>Enabled</b>	Select this check box to enable the log source. By default, this check box is selected.
<b>Credibility</b>	From the list, type the credibility value of the log source. The range is 0 - 10.  The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source device. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	From the list, select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	Select this check box to enable the log source to coalesce (bundle) events.  Automatically discovered log sources use the default value that is configured in the <b>Coalescing Events</b> list in the <b>System Settings</b> window, which is accessible on the <b>Admin</b> tab. However, when you create a new log source or update the configuration for an automatically discovered log source that you can override the default value by configuring this check box for each log source. For more information, see the IBM QRadar <i>Administration Guide</i> .

Table 311. Syslog log source parameters for the Symantec SiteMinder DSM (continued)

Parameter	Value
<b>Store Event Payload</b>	Select this check box to enable or disable QRadar from storing the event payload.  Automatically discovered log sources use the default value from the <b>Store Event Payload</b> list in the <b>System Settings</b> window, which is accessible on the <b>Admin</b> tab. When you create a new log source or update the configuration for an automatically discovered log source that you can override the default value by configuring this check box for each log source. For more information, see the IBM QRadar Administration Guide.

## Configuring syslog-ng for Broadcom Symantec SiteMinder

You must configure your Broadcom Symantec SiteMinder appliance to forward syslog-ng events to your QRadar Console or Event Collector.

#### About this task

IBM QRadar can collect syslog-ng events from TCP or UDP syslog sources on port 514.

To configure syslog-ng for Symantec SiteMinder:

#### Procedure

1. Using SSH, log in to your Symantec SiteMinder appliance as a root user.
2. Edit the syslog-ng configuration file.

/etc/syslog-ng.conf

3. Add the following information to specify the access log as the event file for syslog-ng:

```
source s_siteminder_access { file("/opt/apps/siteminder/sm66/siteminder/log/
smaccess.log"); };
```

4. Add the following information to specify the destination and message template:

```
destination d_remote_q1_siteminder {udp("<QRadar IP>" port(514) template ("$PROGRAM
$MSG\n"));};
```

Where <QRadar IP> is the IP address of the QRadar Console or Event Collector.

5. Add the following log entry information:

```
log {source(s_siteminder_access);destination(d_remote_q1_siteminder);};
```

6. Save the syslog-ng.conf file.
7. Type the following command to restart syslog-ng:

```
service syslog-ng restart
```

After the syslog-ng service restarts, the Symantec SiteMinder configuration is complete. Events that are forwarded to QRadar by Symantec SiteMinder are displayed on the **Log Activity** tab.

## Broadcom Symantec SiteMinder sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Symantec SiteMinder sample message when you use the Syslog protocol

**Sample 1:** The following sample event message shows that authorization is accepted.

Log Source Time	24/May/2012:14:14:50 -0500 (extracted from date and time fields)

# Chapter 35. Brocade Fabric OS

IBM QRadar can collect and categorize syslog system and audit events from Brocade switches and appliances that use Fabric OS V7.x.

To collect syslog events, you must configure your switch to forward syslog events. Each switch or appliance must be configured to forward events.

Events that you forward from Brocade switches are automatically discovered. A log source is configured for each switch or appliance that forwards events to QRadar.

## Configuring syslog for Brocade Fabric OS appliances

To collect events, you must configure syslog on your Brocade appliance to forward events to IBM QRadar.

### Procedure

1. Log in to your appliance as an admin user.
2. To configure an address to forward syslog events, type the following command:

```
syslogdipadd <IP address>
```

Where *<IP address>* is the IP address of the QRadar Console, Event Processor, Event Collector, or all-in-one system.

3. To verify the address, type the following command:

```
syslogdipshow
```

### Results

As the Brocade switch generates events the switch forwards events to the syslog destination you specified. The log source is automatically discovered after enough events are forwarded by the Brocade appliance. It typically takes a minimum of 25 events to automatically discover a log source.

### What to do next

Administrators can log in to the QRadar Console and verify that the log source is created on the QRadar Console and that the **Log Activity** tab displays events from the Brocade appliance.

## Brocade Fabric OS sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Brocade Fabric OS sample message when you use the Syslog protocol

The following sample event shows that a simple network management protocol (SNMP) login occurred. An IP address is displayed when the login occurs over a remote connection.

```
<190>Nov 3 15:08:04 brocade.fabricos.test raslogd: AUDIT, 2020/11/03-15:08:04

# Chapter 36. Carbon Black

Several Carbon Black DSMs can be integrated with IBM QRadar

## Carbon Black

The IBM QRadar DSM for Carbon Black collects endpoint protection events from a Carbon Black server.

The following table describes the specifications for the Carbon Black DSM:

Table 315. Carbon Black DSM specifications	
Specification	Value
Manufacturer	Carbon Black
DSM name	Carbon Black
RPM file name	DSM-CarbonBlackCarbonBlack-QRadar_version-build_number.noarch.rpm
Supported versions	5.1 and later
Protocol	Syslog
Recorded event types	Watchlist hits
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.carbonblack.com/products/cb-response/">Carbon Black website (https://www.carbonblack.com/products/cb-response/)</a>

To integrate Carbon Black with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Carbon Black DSM RPM
  - DSMCommon RPM
2. Configure your Carbon Black device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Carbon Black log source on the QRadar Console. The following table describes the parameters that require specific values for Carbon Black event collection:

Table 316. Carbon Black log source parameters

Parameter	Value
Log Source type	Carbon Black
Protocol Configuration	Syslog

[“Adding a log source” on page 5](#)

# Configuring Carbon Black to communicate with QRadar

To collect events from Carbon Black, you must install and configure cb-event-forwarder to send Carbon Black events to IBM QRadar.

## Before you begin

Install the Carbon Black Enterprise RPM and ensure that it is running. You can install the cb-event-forwarder on any 64-bit Linux computer that is running CentOS 6.x. It can be installed on the same computer as the Carbon Black server, or on another computer. If you are forwarding many events, for example, all file modifications, registry modifications, or both, to QRadar, install cb-event-forwarder on a separate server. If you are not forwarding many events to QRadar, you can install the cb-event-forwarder on the Carbon Black server.

If you are installing the cb-event-forwarder on a computer other than the Carbon Black server, you must configure the Carbon Black server:

1. Ensure that TCP port 5004 is open through the iptables firewall on the Carbon Black server. The event-forwarder connects to TCP port 5004 on the Carbon Black server to connect to the Cb message bus.
2. Get the RabbitMQ user name and password from the /etc/cb/cb.conf file on the Carbon Black server. Search for the RabbitMQUser and RabbitMQPassword variables and note their values.

## About this task

You can find the following instructions, source code, and quick start guide on the [GitHub website](https://github.com/carbonblack/cb-event-forwarder) (<https://github.com/carbonblack/cb-event-forwarder/>).

## Procedure

1. If it is not already installed, install the CbOpenSource repository:

```
cd /etc/yum.repos.d
curl -O https://opensource.carbonblack.com/release/x86_64/CbOpenSource.repo
```

2. Install the RPM for cb-event-forwarder:

```
yum install cb-event-forwarder
```

3. Modify the /etc/cb/integrations/event-forwarder/cb-event-forwarder.conf file to include `udpout=<QRadar_IP_address>:514`, and then specify LEEF as the output format: `output_format=leef`.
4. If you are installing on a computer other than the Carbon Black server, copy the RabbitMQ user name and password into the `rabbit_mq_username` and `rabbit_mq_password` variables in the /etc/cb/integrations/event-forwarder/cb-event-forwarder.conf file. In the `cb_server_hostname` variable, enter the host name or IP address of the Carbon Black server.
5. Ensure that the configuration is valid by running the cb-event-forwarder in check mode:

```
/usr/share/cb/integrations/event-forwarder/cb-event-forwarder -check.
```

If valid, the message `Initialized` output displays. If there are errors, the errors are printed to your screen.

6. Choose the type of event that you want to capture.

By default, Carbon Black publishes the all feed and watchlist events over the bus. If you want to capture raw sensor events or all binaryinfo notifications, you must enable those features in the /etc/cb/cb.conf file.

- To capture raw sensor events, edit the `DatastoreBroadcastEventTypes` option in the /etc/cb/cb.conf file to enable broadcast of the raw sensor events that you want to export.

- To capture binary observed events, edit the EnableSolrBinaryInfoNotifications option in the /etc/cb/cb.conf file and set it to True.
7. If any variables were changed in /etc/cb/cb.conf, restart the Carbon Black server: "service cb-enterprise restart".
  8. Start the cb-event-forwarder service by using the initctl command: `initctl start cb-event-forwarder`.

**Note:** You can stop the cb-event-forwarder service by using the initctl command: `initctl stop cb-event-forwarder`.

## Carbon Black sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Carbon Black sample message when you use the Syslog protocol

**Sample 1:** The following sample event message shows a watchlist query that is matching a process.

```
LEEF:1.0|CB|CB|5.1|alert.watchlist.hit.query.process|alert_severity=50.625

Username	<b>username</b>
Device time	<b>created_time</b>

## Carbon Black Bit9 Parity

To collect events, you must configure your Carbon Black Bit9 Parity device to forward syslog events in Log Event Extended Format (LEEF).

### Procedure

1. Log in to the Carbon Black Bit9 Parity console with Administrator or PowerUser privileges.
2. From the navigation menu on the left side of the console, select **Administration > System Configuration**.

The **System Configuration** window is displayed.

3. Click **Server Status**.

The **Server Status** window is displayed.

4. Click **Edit**.
5. In the **Syslog address** field, type the IP address of your QRadar Console or Event Collector.
6. From the **Syslog format** list, select **LEEF (Q1Labs)**.
7. Select the **Syslog enabled** check box.
8. Click **Update**.

The configuration is complete. The log source is added to IBM QRadar as Carbon Black Bit9 Parity events are automatically discovered. Events that are forwarded to QRadar by Carbon Black Bit9 Parity are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Carbon Black Bit9 Parity

If QRadar does not automatically detect the log source, add a Carbon Black Bit9 Parity log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Carbon Black Bit9 Parity:

<i>Table 318. Syslog log source parameters for the Carbon Black Bit9 Parity DSM</i>	
Parameter	Value
<b>Log Source type</b>	Carbon Black Bit9 Parity
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	The IP address or host name for the Carbon Black Bit9 Parity device.

### Related tasks

[“Adding a log source” on page 5](#)

## Bit9 Security Platform

Use the IBM QRadar SIEM DSM for Carbon Black Bit9 Security Platform to collect events from Carbon Black Bit9 Parity devices.

The following table identifies the specifications for the Bit9 Security Platform DSM:

<i>Table 319. DSM specifications for Bit9 Security Platform</i>	
Specification	Value
Manufacturer	Carbon Black
DSM name	Bit9 Security Platform
RPM file name	DSM-Bit9Parity-build_number.noarch.rpm
Supported versions	V6.0.2 and up
Event format	Syslog
Supported event types	All events
Automatically discovered?	Yes
Included identity?	Yes
More information	<a href="http://www.bit9.com">Bit9 website (http://www.bit9.com)</a>

To integrate Bit9 Security Platform with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent version of the Bit9 Security Platform DSM RPM.
2. Configure your Bit9 Security Platform device to enable communication with QRadar. You must create a syslog destination and forwarding policy on the Bit9 Security Platform device.
3. If QRadar does not automatically detect Bit9 Security Platform as a log source, create a Bit9 Security Platform log source on the QRadar Console. Use the following Bit9 Security Platform values to configure the log source parameters:

Parameter	Value
Log Source Identifier	The IP address or host name of the Bit9 Security Platform device
Log Source Type	Bit9 Security Platform
Protocol Configuration	Syslog

#### Related tasks

[“Adding a log source” on page 5](#)

## Configuring Carbon Black Bit9 Security Platform to communicate with QRadar

Configure your Carbon Black Bit9 Security Platform device to forward events to IBM QRadar in LEEF format.

### Procedure

1. Log in to the Carbon Black Bit9 Security Platform console with Administrator or PowerUser privileges.
2. From the navigation menu, select **Administration > System Configuration**.
3. Click **Server Status** and click **Edit**.
4. In the **Syslog address** field, type the IP address of your QRadar Console or Event Collector.
5. From the **Syslog format** list, select **LEEF (Q1Labs)**.
6. Select the **Syslog enabled** check box and click **Update**.

# Chapter 37. Centrify Infrastructure Services

The IBM QRadar DSM for Centrify Infrastructure Services collects events from Centrify Infrastructure Services standard logs.

The following table describes the specifications for the Centrify Infrastructure Services DSM:

Table 320. Centrify Infrastructure Services DSM specifications	
Specification	Value
Manufacturer	Centrify
DSM name	Centrify Infrastructure Services
RPM file name	DSM-CentrifyInfrastructureServices-QRadar_version-build_number.noarch.rpm
Supported versions	Centrify Infrastructure Services 2017
Protocol	Syslog, TLS Syslog and WinCollect
Event format	name-value pair (NVP)
Recorded event types	Audit Events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.centrify.com/support/documentation/server-suite/">Centrify website (https://www.centrify.com/support/documentation/server-suite/)</a>

To integrate Centrify Infrastructure Services with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of Centrify Infrastructure Services DSM RPM on your QRadar Console.  
**Note:** If you use the WinCollect protocol configuration option, install the latest WinCollect agent bundle (.sfs file) on your QRadar Console.
2. To send syslog or Windows events to QRadar, configure your UNIX, Linux, or Windows device where the Centrify Infrastructure Services standard logs are available.
3. If QRadar does not automatically detect the log source, add a Centrify Infrastructure Services log source on the QRadar Console.

The following table describes the parameters that require specific values to collect events from Centrify Infrastructure Services:

Table 321. Centrify Infrastructure Services log source parameters	
Parameter	Value
<b>Log Source type</b>	Centrify Infrastructure Services
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	The IP address or host name of the UNIX, Linux, or Windows device that sends Centrify Infrastructure Services events to QRadar.

4. Optional: To add a Centrify Infrastructure Services log source to receive Syslog events from network devices that support TLS Syslog event forwarding, configure the log source on the QRadar Console to use the TLS Syslog protocol.

*Table 322. Centrify Infrastructure Services TLS Syslog log source parameters*

Parameter	Value
Log Source type	Centrify Infrastructure Services
Protocol Configuration	TLS Syslog
Log Source Identifier	Type a unique identifier for the log source.
TLS Protocols	Select the version of TLS that is installed on the client.

**Note:** To receive encrypted Syslog events from up to 50 network devices that support TLS Syslog event forwarding, configure a log source to use the TLS Syslog protocol.

#### Related concepts

## Configuring WinCollect agent to collect event logs from Centrify Infrastructure Services

You can forward Windows events to IBM QRadar by using WinCollect.

To forward Windows events by using WinCollect, install WinCollect agent on a Windows host. Download the WinCollect agent setup file from the [IBM Support website](#) (<https://www.ibm.com/support>). Add a Centrify Infrastructure Services log source and assign it to the WinCollect agent.

The following table describes the values that are required for the WinCollect log source parameters.

<i>Table 323. WinCollect log source parameters</i>	
Parameter	Value
<b>Log Source type</b>	Centrify Infrastructure Services
<b>Protocol Configuration</b>	WinCollect
<b>Log Source Identifier</b>	The IP address or host name of the Windows machine from which you want to collect Windows events. The log source identifier must be unique for the log source type.
<b>Local System</b>	Select the <b>Local System</b> check box to disable the remote collection of events for the log source. The log source uses local system credentials to collect and forward logs to QRadar.  You need to configure the <b>Domain</b> , <b>Username</b> , and <b>Password</b> parameters if remote collection is required.

*Table 323. WinCollect log source parameters (continued)*

Parameter	Value
<b>Event Rate Tuning Profile</b>	<p>For the default polling interval of 3000 ms, the approximate Events per second (EPS) rates attainable are as follows:</p> <ul style="list-style-type: none"> <li>• Default (Endpoint): 33-50 EPS</li> <li>• Typical Server: 166-250 EPS</li> <li>• High Event Rate Server: 416-625 EPS</li> </ul> <p>For a polling interval of 1000 ms, the approximate EPS rates are as follows:</p> <ul style="list-style-type: none"> <li>• Default (Endpoint): 100-150 EPS</li> <li>• Typical Server: 500-750 EPS</li> <li>• High Event Rate Server: 1250-1875 EPS</li> </ul> <p>For more information about tuning WinCollect, go to the <a href="http://www.ibm.com/support/docview.wss?uid=swg21672193">IBM Support website</a> (<a href="http://www.ibm.com/support/docview.wss?uid=swg21672193">http://www.ibm.com/support/docview.wss?uid=swg21672193</a>).</p>
<b>Polling Interval (ms)</b>	The interval, in milliseconds, between times when WinCollect polls for new events.
<b>Application or Service Log Type</b>	Select <b>None</b> for the <b>Application or Service Log Type</b> .
<b>Standard Log Types</b>	<p>Do not enable the check box for any of the log types.</p> <p>Select <b>No Filtering</b> as the log filter type for the following log types: <b>Security</b>, <b>System</b>, <b>Application</b>, <b>DNS Server</b>, <b>File Replication Service</b>, and <b>Directory Service</b>.</p>
<b>Event Types</b>	You must select at least one event type.

Table 323. WinCollect log source parameters (continued)

Parameter	Value
<b>XPath Query</b>	<p>To forward only Centrify Audit events, you must specify the XPath filter. The query is in XML format and can be created by using Custom View Properties of Microsoft Event Viewer.</p> <p>For more information about creating an XPath query, go to the <a href="#">Creating a custom view documentation</a> on the IBM Support website (<a href="https://www.ibm.com/support/knowledgecenter/SS42VS_7.3.0/com.ibm.wincollect.doc/t_ug_wincollect_creating_customview.html">https://www.ibm.com/support/knowledgecenter/SS42VS_7.3.0/com.ibm.wincollect.doc/t_ug_wincollect_creating_customview.html</a>).</p> <p><b>Important:</b> When you create the custom view, ensure that the <b>By Source</b> option is selected. From the <b>Event sources</b> list, select the application name of the Centrify Audit Events.</p> <p>Example XPath query:</p> <pre>&lt;QueryList&gt; &lt;Query Id="0" Path="Application"&gt; &lt;SelectPath="Application"&gt;*[System [Provider[@Name='Centrify AuditTrail V2']]］&lt;/Select&gt; &lt;/Query&gt; &lt;/QueryList&gt;</pre>
<b>Enable Active Directory Lookups</b>	Do not select the check box.
<b>WinCollectAgent</b>	Select your WinCollect agent from the list.
<b>Target Internal Destination</b>	Use any managed host with an event processor component as an internal destination.

For more information about WinCollect log source parameters, go to the [Common WinCollect log source parameters documentation](#) on the IBM Support website ([https://www.ibm.com/support/knowledgecenter/en/SS42VS\\_SHR/com.ibm.wincollect.doc/r\\_ug\\_wincollect\\_comon\\_parameters.html](https://www.ibm.com/support/knowledgecenter/en/SS42VS_SHR/com.ibm.wincollect.doc/r_ug_wincollect_comon_parameters.html)).

## Configuring Centrify Infrastructure Services on a UNIX or Linux device to communicate with QRadar

You can configure your UNIX or Linux device to send audit events to IBM QRadar. The audit events are available locally in the syslog event logs where the Centrify Infrastructure Services is installed and configured.

### Procedure

1. Log in to your Centrify Infrastructure Services device.
2. Ensure that syslog or rsyslog is installed:
  - To verify that syslog is installed, type `service syslog status`.
  - To verify that rsyslog is installed, type `service rsyslog status`.
3. If syslog or rsyslog is not installed, install them by using your preferred method based on your UNIX or Linux device. For example, you can type the following command to install rsyslog on a Linux device:
 

```
yum install rsyslog
```

- To forward events to your QRadar Event Collector, open the `rsyslog.conf` file or the `syslog.conf` file that is located in `/etc/` directory, and then add the following line:

```
:msg, contains, "AUDIT_TRAIL" @@<QRadar Event Collector IP>:514
```

**Example:** `:msg, contains, "AUDIT_TRAIL" @@127.0.0.1:514`

- Restart the syslog or rsyslog service:

- If you are using syslog, type `service syslog restart`.
- If you are using rsyslog, type `service rsyslog restart`.

**Note:** The Centrify Linux agent might forward some Linux system messages with the Audit Trail logs. If no specific category is found, the Linux OS log source type in QRadar discovers the Linux messages and normalizes them as stored.

## Centrify Infrastructure Services sample event messages

---

Use these sample event messages as a way of verifying a successful integration with QRadar.

The following table shows sample event messages from Centrify Infrastructure Services:

Table 324. Centrify Infrastructure Services sample message

---

# Chapter 38. Check Point

Several Check Point products can be integrated with IBM QRadar.

The following products are supported:

- Firewall
- SmartDefense
- IPS
- Anti Malware
- Anti-Bot
- Antivirus
- Mobile Access
- DDoS Protector
- Security Gateway/Management
- Threat Emulation
- URL Filtering
- DLP
- Application Control
- Identity Logging
- VPN
- Endpoint Security
- VPN-1 and FireWall-1

Depending on your Operating System, the procedures for the Check Point device might vary. The documented procedures are based on the Check Point SecurePlatform Operating system.

## Integrate Check Point by using syslog

---

This section describes how to ensure that the IBM QRadar Check Point DSMs accept Check Point events by using syslog.

To configure Check Point to forward syslog events to IBM QRadar complete the following steps:

**Important:** If Check Point SmartCenter is installed on Microsoft Windows, you must integrate Check Point with QRadar by using OPSEC.

1. Type the following command to access the Check Point console as an expert user:

```
expert
```

A password prompt appears.

2. Type your expert console password. Press the Enter key.

3. Open the following file:

```
/etc/rc.d/rc3.d/S99local
```

4. Add the following lines:

```
$FWDIR/bin/fw log -ftn | /usr/bin/logger -p <facility>. <priority> /dev/null  
2>&1 &
```

Where:

- <facility> is a syslog facility, for example, local3.

- <priority> is a syslog priority, for example, info.

For example:

```
$FWDIR/bin/fw log -ftn | /usr/bin/logger -p local3.info > /dev/null 2>&1 &
```

5. Save and close the file.

6. Open the `syslog.conf` file.

7. Add the following line:

```
<facility>.<priority> <TAB><TAB>@<host>
```

Where:

- <facility> is the syslog facility, for example, local3. This value must match the value that you typed in Step 4.

- <priority> is the syslog priority, for example, info or notice. This value must match the value that you typed in Step 4.

<TAB> indicates you must press the Tab key.

<host> indicates the QRadar Console or managed host.

8. Save and close the file.

9. Enter the following command to restart syslog:

- In Linux: `service syslog restart`
- In Solaris: `/etc/init.d/syslog start`

10. Enter the following command:

```
nohup $FWDIR/bin/fw log -ftn | /usr/bin/logger -p <facility>.<priority>
> /dev/null 2>&1 &
```

Where:

- <facility> is a Syslog facility, for example, local3. This value must match the value that you typed in Step 4.
- <priority> is a Syslog priority, for example, info. This value must match the value that you typed in Step 4.

The configuration is complete. The log source is added to QRadar as Check Point syslog events are automatically discovered. Events that are forwarded to QRadar are displayed on the **Log Activity** tab.

## Syslog log source parameters for Check Point

If QRadar does not automatically detect the log source, add a Check Point log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Check Point:

Table 325. Syslog log source parameters for the Check Point DSM	
Parameter	Value
<b>Log Source type</b>	<b>Check Point</b>
<b>Protocol Configuration</b>	<b>Syslog</b>

Table 325. Syslog log source parameters for the Check Point DSM (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Check Point devices.

#### Related tasks

[Adding a log source](#)

## Syslog sample event messages for Check Point

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Check Point sample message when you use the Syslog protocol

**Sample 1:** The following sample event message shows that a trusted connection is identified and marked as an elephant flow.

```
<13>Sep 30 07:13:59 checkpoint.checkpoint.test 30Sep2020 07:13:59

## Integrate Check Point by using OPSEC

This section describes how to ensure that IBM QRadar accepts Check Point events using Open Platform for Security (OPSEC/LEA).

To integrate Check Point OPSEC/LEA with QRadar, you must create two Secure Internal Communication (SIC) files and enter the information in to QRadar as a Check Point log source.

### Check Point configuration overview

To integrate Check Point with QRadar, you must complete the following procedures in sequence:

1. Add QRadar as a host for Check Point.
2. Add an OPSEC application to Check Point.
3. Locate the Log Source Secure Internal Communications DN.
4. In QRadar, configure the OPSEC LEA protocol.
5. Verify the OPSEC/LEA communications configuration.

## Adding a Check Point Host

You can add IBM QRadar as a host in Check Point SmartCenter:

### Procedure

1. Log in to the Check Point SmartCenter user interface.
2. Select **Objects > New Host**.
3. Enter the information for your Check Point host:
  - **Object Name** - Specify a name for the host. For example, QRadar.
  - **IP address** - The IP address of QRadar
4. Click **OK**.

### What to do next

[Creating an OPSEC Application Object](#)

## Creating an OPSEC Application Object

After you add IBM QRadar as a host in Check Point SmartCenter, you can create the OPSEC Application Object.

### Procedure

1. Open the Check Point SmartConsole user interface.

2. Select **Objects > More Object Types > Server > OPSEC Application > New Application.**
3. Configure your OPSEC Application:
  - a) Configure the following **OPSEC Application Properties** parameters.

Parameter	Value
Name	Specify a name for the OPSEC application. For example, QRadar-OPSEC
Host	QRadar
Client Entities	LEA

  - b) Click **Communication**.
  - c) In the **One-time password** field, type the password that you want to use.
  - d) In the **Confirm one-time password** field, type the password that you used for **One-time password**.
  - e) Click **Initialize**.
  - f) Click **Close**.

4. Select **Menu > Install Policy**

5. Click **Publish & Install**.

6. Click **Install**.

7. Select **Menu > Install Database**.

8. Click **Install**.

**Note:** The SIC value is required for the OPSEC Application Object SIC attribute parameter when you configure the Check Point log source in QRadar. The value can be found by viewing the OPSEC Application Object after it is created.

The OPSEC Application Object resembles the following example:

```
CN=QRadar=OPSEC,0=cpmodule..tdfaaz
```

## Results

If you have issues after you install the database policy, contact your system administrator to restart Check Point services on the central SmartCenter server that hosts the policy files. After services restart, the updated policies are pushed to all Check Point appliances.

## Locating the log source SIC

After you create the OPSEC Application Object, you can locate the Log Source SIC from the Check Point SmartConsole.

### Procedure

1. Select **Objects > Object Explorer**.
2. In the Categories tree, select **Gateways and Servers** under **Networks Objects**.
3. Select your Check Point Log Host object.
4. Copy the Secure Internal Communication (SIC).

**Important:** Depending on your Check Point version, the **Communication** button displays the SIC attribute. You can locate the SIC attribute from the Check Point Management Server command-line interface. You must use the **cPCA\_client lsCert** command from the command-line interface of the Management Server to display all certificates.

**Important:** The Log Source SIC Attribute resembles the following example:  
cn=cp\_mgmt,o=cpmodule...tdfaaz. For more information, see your *Check Point Command Line Interface Guide*.

You must now install the Security Policy from the Check Point SmartConsole user interface.

## What to do next

You are now ready to configure the OPSEC LEA protocol. For more information, see [OPSEC/LEA log source parameters for Check Point](#).

## OPSEC/LEA log source parameters for Check Point

If QRadar does not automatically detect the log source, add a Check Point log source on the QRadar Console by using the OPSEC/LEA protocol.

When using the OPSEC/LEA protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect OPSEC/LEA events from Check Point:

Table 329. OPSEC/LEA log source parameters for the Check Point DSM	
Parameter	Value
<b>Log Source type</b>	<b>Check Point</b>
<b>Protocol Configuration</b>	<b>OPSEC/LEA</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Check Point devices.

For a complete list of OPSEC/LEA protocol parameters and their values, see [“OPSEC/LEA protocol configuration options” on page 203](#).

### Related tasks

[Adding a log source](#)

## Edit your OPSEC communications configuration

This section describes how to modify your Check Point configuration to allow OPSEC communications on non-standard ports.

It also explains how to configure communications in a clear text, unauthenticated stream, and verify the configuration in IBM QRadar.

## Change your Check Point Custom Log Manager (CLM) IP address

If your Check Point configuration includes a Check Point Custom Log Manager (CLM), you might eventually need to change the IP address for the CLM, which impacts any of the automatically discovered Check Point log sources from that CLM in QRadar. When you manually add the log source for the CLM by using the OPSEC/LEA protocol, all Check Point firewalls that forward logs to the CLM are automatically discovered by QRadar. These automatically discovered log sources cannot be edited. If the CLM IP address changes, you must edit the original Check Point CLM log source that contains the OPSEC/LEA protocol configuration and update the server IP address and log source identifier.

After you update the log source for the new Check Point CLM IP address, then any new events reported from the automatically discovered Check Point log sources are updated.

**Important:** Do not delete and re-create your Check Point CLM or automatically discovered log sources in QRadar. Deleting a log source does not delete event data, but can make finding previously recorded events more difficult.

## Changing the default port for OPSEC LEA communication

Change the default port (18184) on which OPSEC LEA communicates.

### Procedure

- At the command-line prompt of your Check Point SmartCenter Server, type the following command to stop the firewall services:

```
cpstop
```

- Depending on your Check Point SmartCenter Server operating system, open the following file:

- Linux - \$FWDIR\conf\fwopsec.conf
- Windows - %FWDIR%\conf\fwopsec.conf

The default contents of this file are as follows:

```
# The VPN-1 default settings are:  
# # sam_server auth_port 0 # sam_server port 18183  
# # lea_server auth_port 18184 # lea_server port 0  
# # ela_server auth_port 18187 # ela_server port 0  
# # cpmi_server auth_port 18190  
# # uaa_server auth_port 19191 # uaa_server port 0 #
```

- Change the default **lea\_server auth\_port** from 18184 to another port number.

- Remove the hash (#) mark from that line.

#### Example:

```
lea_server auth_port 18888 # lea_server port 0
```

- Save and close the file.

- Type the following command to start the firewall services:

```
cpstart
```

## Configuring OPSEC LEA for unencrypted communications

You can configure the OPSEC LEA protocol for unencrypted communications:

### Procedure

- At the command-line prompt of your Check Point SmartCenter Server, stop the firewall services by typing the following command:

```
cpstop
```

- Depending on your Check Point SmartCenter Server operating system, open the following file:

- Linux - \$FWDIR\conf\fwopsec.conf
- Windows - %FWDIR%\conf\fwopsec.conf

- Change the default **lea\_server auth\_port** from 18184 to 0.

- Change the **default lea\_server port** from 0 to 18184.

- Remove the hash (#) marks from both lines.

#### Example:

```
lea_server auth_port 0 lea_server port 18184
```

- Save and close the file.

- Type the following command to start the firewall services:

```
cpstart
```

# Integrating Check Point by using TLS Syslog

Before you can add a log source in IBM QRadar, you need to generate certificates on the QRadar Console and then copy the certificates on your Check Point device.

## Procedure

1. Using SSH, log in to your QRadar Console.
2. Generate the root CA key by typing the following command:

```
openssl genrsa -out RootCA.key 2048
```

3. Generate the root CA pem by typing the following command:

```
openssl req -x509 -new -nodes -key RootCA.key -days 2048 -out RootCA.pem
```

**Important:** When prompted to provide Distinguished Name (DN) information about the certificate, you might want to use CheckpointRootCA as the **Common Name** value. The **Common Name** value can't be the same **Common Name** value that you use for any other certificates. All other fields are optional and can be left blank. However, if you purchase an SSL certificate from a certificate authority, you might need to configure more fields, such as **Organization** to accurately reflect your organization's information.

4. To generate the client key, type the following command:

```
openssl genrsa -out log_exporter.key 2048
```

**Important:** Do not share the client key with anyone.

5. To generate the client certificate sign request, type the following command:

```
openssl req -new -key log_exporter.key -out log_exporter.csr
```

**Important:** When prompted to provide Distinguished Name (DN) information about the certificate, you might want to use the Check Point IP address as the **Common Name** value. The **Common Name** value can't be the same **Common Name** value that you use for any other certificates. All other fields are optional and can be left blank. When you type a value for the **A challenge password** field, do not use special characters for the password. If you purchase an SSL certificate from a certificate authority, you might need to configure more fields, such as **Organization** to accurately reflect your organization's information.

6. To sign the certificate by using the CA files, type the following command:

```
openssl x509 -req -in log_exporter.csr -CA RootCA.pem -CAkey RootCA.key -CAcreateserial -out log_exporter.crt -days 2048 -sha256
```

7. To convert the certificate to p12 format, type the following command:

```
openssl pkcs12 -inkey log_exporter.key -in log_exporter.crt -export -out log_exporter.p12
```

**Important:** When you type a value for the **Export password field**, do not use special characters for the password.

8. Generate the server key by typing the following command:

```
openssl genrsa -out syslogServer.key 2048
```

**Important:** Do not share the server key with anyone.

9. Generate the server certificate sign request by typing the following command:

```
openssl req -new -key syslogServer.key -out syslogServer.csr
```

**Important:** When prompted to provide Distinguished Name (DN) information about the certificate, you might want to use the QRadar IP address as the **Common Name** value. The **Common Name**

value can't be the same **Common Name** value that you use for any other certificates. All other fields are optional and can be left blank. When you type a value for the **A challenge password** field, do not use special characters for the password. If you purchase an SSL certificate from a certificate authority, you might need to configure more fields, such as **Organization** to accurately reflect your organization's information.

10. To sign the certificate by using the CA files, type the following command:

```
openssl x509 -req -in syslogServer.csr -CA RootCA.pem -CAkey RootCA.key -CAcreateserial  
-out syslogServer.crt -days 2048 -sha256
```

11. To convert the server certificate and key to a p12 file, type the following command:

```
openssl pkcs12 -inkey syslogServer.key -in syslogServer.crt -export -out syslogServer.p12
```

**Important:** When you type a value for the **Enter Export Password** field, do not use special characters for the password.

12. Using SSH, log in to your Check Point device.

13. To access expert mode, type the following command:

```
Expert
```

14. Create a certs directory inside your deployment directory:

```
mkdir -p $EXPORTERDIR/targets/<deployment_name>/certs
```

Where <deployment\_name> is the hostname of your QRadar Console.

15. Copy the RootCA.pem and log\_exporter.p12 that you created in Steps 3 and 7 to the directory that you created on your Check Point device in Step 13 by typing the following command:

```
scp root@qradar_ip:RootCA.pem log_exporter.p12 $EXPORTERDIR/targets/<deployment_name>/certs/
```

16. Type the following commands:

```
chmod +r RootCA.pem
```

```
chmod +r log_exporter.p12
```

```
cp_log_export add name <deployment_name> target-server <QRadar_host_IP> protocol  
tcp target-port <port_from_log_source_config> format leef encrypted true ca-cert  
$EXPORTERDIR/targets/<deployment_name>/certs/RootCA.pem client-cert $EXPORTERDIR/targets/  
<deployment_name>/certs/log_exporter.p12 client-secret <password_for_p12>
```

For more information about TLS configuration, see your [Check Point documentation](#) ([https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit\\_doGoviewsolutiondetails=&solutionid=sk122323#TLS Configuration](https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit_doGoviewsolutiondetails=&solutionid=sk122323#TLS Configuration)).

## What to do next

Add a log source in QRadar by using the TLS Syslog protocol. For more information, see [TLS Syslog log source parameters for Check Point](#) and [Adding a log source](#).

## TLS syslog log source parameters for Check Point

If QRadar does not automatically detect the log source, add a Check Point log source on the QRadar Console by using the TLS syslog protocol.

When using the TLS Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect TLS Syslog events from Check Point:

*Table 330. TLS Syslog log source parameters for the Check Point DSM*

<b>Parameter</b>	<b>Value</b>
<b>Log Source type</b>	<b>Check Point</b>
<b>Protocol Configuration</b>	<b>TLS Syslog</b>
<b>Log Source Identifier</b>	Type the IP address of your Check Point server as an identifier for events from your Check Point devices.
<b>TLS Listen Port</b>	6514
<b>Authentication Mode</b>	<b>TLS and Client Authentication</b>
<b>Client Certificate Path</b>	<full_path_to_file>/log_exporter.crt
<b>Certificate Type</b>	<b>PKCS12 Certificate Chain and Password</b>
<b>PKCS12 Certificate Path</b>	<full_path_to_the_file>/syslogServer.p12
<b>PKCS12 Password</b>	The password for the PKCS12 Certificate.
<b>Certificate Alias</b>	This field must be empty.
<b>Max Payload Length</b>	4096
<b>Maximum Connections</b>	50

For a complete list of TLS Syslog protocol parameters and their values, see [TLS syslog protocol configuration options](#).

#### Related tasks

# Configuring Check Point to forward LEEF events to QRadar

To forward LEEF events to IBM QRadar, use the Check Point Log Exporter and configure a new target for the logs.

## Before you begin

Log Exporter can be installed on several versions of Check Point. Before you send events in LEEF format to QRadar, ensure that you have the correct version of Check Point and Log Exporter installed in your environment.

The following table describes where LEEF events are supported.

Table 332. Check Point versions that support LEEF	
Check Point version	Comments
R81.10	Log Exporter is included in this version.
R80.20	Log Exporter is included in this version.
R80.10	Install Log Exporter and then install the hotfix after.
R77.30	Install Log Exporter and then install the hotfix after.

### Check Point R80.20

If you want to preserve the Log Exporter configuration before you upgrade to Check Point R80.20, follow the backup and restore Log Exporter instructions on the [Check Point website](https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit_doGoviewsolutiondetails=&solutionid=sk127653). ([https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit\\_doGoviewsolutiondetails=&solutionid=sk127653](https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit_doGoviewsolutiondetails=&solutionid=sk127653)).

### Check Point R80.10

Ensure that Check Point version R80.10 is installed on the following servers:

- R80.10 Multi-Domain Log Server
- Security Management Server
- Log Server
- SmartEvent Server

You can install Log Exporter on version R80.10 Jumbo Hotfix Take 56 or later. The hotfix must be installed after Jumbo is installed. If you want to upgrade Jumbo, uninstall the hotfix, upgrade Jumbo, and then reinstall the hotfix. For more information, see the [installation topic on the Check Point website](https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit_doGoviewsolutiondetails=&solutionid=sk122323#Installation) ([https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit\\_doGoviewsolutiondetails=&solutionid=sk122323#Installation](https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit_doGoviewsolutiondetails=&solutionid=sk122323#Installation)).

### Check Point R77.30

Ensure that Check Point version R77.30 is installed on the following servers:

- Multi-Domain server
- Multi-Domain Log Server
- Log Server
- SmartEvent Server

You can install Log Exporter on version R77.30 Jumbo Hotfix Take 292 or later. The hotfix must be installed after Jumbo is installed. If you want to upgrade Jumbo, uninstall the hotfix, upgrade Jumbo, and then reinstall the hotfix. For more information, see the [installation topic on the Check Point website](https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit_doGoviewsolutiondetails=&solutionid=sk122323#Installation) ([https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit\\_doGoviewsolutiondetails=&solutionid=sk122323#Installation](https://supportcenter.checkpoint.com/supportcenter/portal?eventSubmit_doGoviewsolutiondetails=&solutionid=sk122323#Installation)).

## Procedure

1. To access the expert mode on the Check Point Log Exporter console by using the command-line interface, type `expert`, then press Return.
2. Type your expert password, then press Return.
3. Type the following command:

```
cp_log_export add name <name> [domain-server <domain-server> target-server <target-server IP address> target-port <target-port> protocol <(udp/tcp)> format <(syslog)/(cef)/(leef)> [optional arguments]
```

**Tip:** If your server is not part of a domain, do not include the **domain-server** field in the setup command.

A new target directory and default files are created in the `$EXPORTERDIR/targets/<deployment_name>` directory.

The following table shows sample parameters and their values.

Table 333. Sample target configuration	
Parameter	Value
<b>Name</b>	<service_name>
<b>Enabled</b>	True
<b>Target-server</b>	<QRadar_IP_address>
<b>Target-port</b>	514
<b>Protocol</b>	TCP
<b>Format</b>	LEEF
<b>Read-mode</b>	Semi-unified  The default value for the Read-mode parameter is Semi-unified to ensure that complete data is collected.

For more information about other commands, go to the Check Point website (

4. To change a configuration, type `cp_log_export set`.
5. To verify a configuration in an existing deployment, type `cp_log_export show`.
6. To start Log Exporter automatically, type the following command: `cp_log_export restart`.

By default, Log Exporter doesn't start automatically.

## Results

If QRadar isn't receiving events from Check Point, try these troubleshooting tips:

- Check the `$EXPORTERDIR/targets/<deployment_name>/conf/LeefFieldsMapping.xml` file for attributes-mapping issues.
- Check the `$EXPORTERDIR/targets/<deployment_name>/conf/LeefFormatDefinition.xml` file for LEEF header-mapping issues.
- Check the file paths. File paths might change with Check Point updates. If a configuration file can't be found, contact your Check Point administrator.

For more troubleshooting information, see the [Troubleshooting Check Point Syslog LEEF Events from the Log Exporter \(cp\\_log\\_export\) Utility technote](https://www.ibm.com/support/docview.wss?uid=ibm10876650) (<https://www.ibm.com/support/docview.wss?uid=ibm10876650>).

## Configuring QRadar to receive LEEF events from Check Point

---

By default, Check Point LEEF events are mapped to the legacy OPSEC LEA event-mapping schema. If you want to change the way that IBM QRadar maps events, you can use the DSM Editor to disable legacy event mapping.

### Procedure

1. Click the **Admin** tab.
2. In the **Data Sources** section, click **DSM Editor**.
3. From the **Select Log Source Type** window, select **Check Point** from the list, and click **Select**.
4. On the **Configuration** tab, set **Display DSM Parameters Configuration** to **on**.
5. From the **Event Collector** list, select the event collector for the log source.
6. Set **Disable legacy event mapping** to **on**.
7. Set **Enable SmartDefense Signature Event IDs** to **on**.

The value in the **signature** field is used as the event ID for SmartDefense. By default, events for Check Point SmartDefense use the value in the **attack** field for parsing.

8. Click **Save** and close out the DSM Editor.

## Integration of Check Point Firewall events from external syslog forwarders

---

Check Point Firewall events can be forwarded from external sources, such as Splunk Forwarders, or other third-party syslog forwarders that send events to IBM QRadar.

When Check Point Firewall events are provided from external sources in syslog format, the events identify with the IP address in the syslog header. This identification causes events to identify incorrectly when they are processed with the standard syslog protocol. The syslog redirect protocol provides administrators a method to substitute an IP address from the event payload into the syslog header to correctly identify the event source.

To substitute an IP address, administrators must identify a common field from their Check Point Firewall event payload that contains the proper IP address. For example, events from Splunk Forwarders use **orig=** in the event payload to identify the original IP address for the Check Point firewall. The protocol substitutes in the proper IP address to ensure that the device is properly identified in the log source. As Check Point Firewall events are forwarded, QRadar automatically discovers and creates new log sources for each unique IP address.

Substitutions are performed with regular expressions and can support either TCP or UDP syslog events. The protocol automatically configures iptables for the initial log source and port configuration. If an administrator decides to change the port assignment a Deploy Full Configuration is required to update the iptables configuration and use the new port assignment.

## Check Point Multi-Domain Management (Provider-1)

---

You can configure IBM QRadar to integrate with a Check Point Multi-Domain Management (Provider-1) device.

All events from Check Point Multi-Domain Management (Provider-1) are parsed by using the Check Point DSM. You can integrate Check Point Multi-Domain Management (Provider-1) using one of the following methods:

- [“Integrating syslog for Check Point Multi-Domain Management \(Provider-1\)” on page 616](#)

- “Configuring OPSEC for Check Point Multi-Domain Management (Provider-1) ” on page 617

**Note:** Depending on your Operating System, the procedures for using the Check Point Multi-Domain Management (Provider-1) device can vary. The following procedures are based on the Check Point SecurePlatform operating system.

## Integrating syslog for Check Point Multi-Domain Management (Provider-1)

This method ensures that the Check Point Multi-Domain Management (Provider-1) DSM for IBM QRadar accepts Check Point Multi-Domain Management (Provider-1) events by using syslog.

### About this task

QRadar records all relevant Check Point Multi-Domain Management (Provider-1) events.

Configure syslog on your Check Point Multi-Domain Management (Provider-1) device:

### Procedure

1. Type the following command to access the console as an expert user:

```
expert
```

A password prompt is displayed.

2. Type your expert console password. Press the Enter key.

3. Type the following command:

```
csh
```

4. Select the wanted customer logs:

```
mdsenv <customer name>
```

5. Input the following command:

```
# nohup $FWDIR/bin/fw log -ftn | /usr/bin/logger -p <facility>. <priorty>
2>&1 &
```

Where:

- <facility> is a syslog facility, for example, local3.
- <priorty> is a syslog priority, for example, info.

You are now ready to configure the log source in QRadar.

The configuration is complete. The log source is added to QRadar as the Check Point Multi-Domain Management Provider-1 syslog events are automatically discovered. Events that are forwarded to QRadar are displayed on the **Log Activity** tab.

## Syslog log source parameters for Check Point Multi-Domain Management (Provider-1)

If QRadar does not automatically detect the log source, add a Check Point Multi-Domain Management (Provider-1) log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Check Point Multi-Domain Management (Provider-1):

Table 334. Syslog log source parameters for the Check Point Multi-Domain Management (Provider-1) DSM	
Parameter	Value
<b>Log Source type</b>	<b>Check Point</b>

Table 334. Syslog log source parameters for the Check Point Multi-Domain Management (Provider-1) DSM (continued)

Parameter	Value
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for your Check Point Multi-Domain Management (Provider-1) appliance.

#### Related tasks

[“Adding a log source” on page 5](#)

## Configuring OPSEC for Check Point Multi-Domain Management (Provider-1)

This method ensures that the IBM QRadar Check Point FireWall-1 DSM accepts Check Point Multi-Domain Management (Provider-1) events by using OPSEC.

#### About this task

In the Check Point Multi-Domain Management (Provider-1) Management Domain GUI (MDG), create a host object that represents the QRadar. The *lepipe* is the connection between the Check Point Multi-Domain Management (Provider-1) and QRadar.

To reconfigure the Check Point Multi-Domain Management (Provider-1) SmartCenter (MDG):

#### Procedure

1. To create a host object, open the Check Point SmartDashboard user interface and select **Manage > Network Objects > New > Node > Host**.
2. Type the Name, IP address, and write comments if needed.
3. Click **OK**.
4. Select **Close**.
5. To create the OPSEC connection, select **Manage > Servers and OPSEC Applications > New > OPSEC Application Properties**.
6. Type a Name, and write comments if needed.  
The Name that you enter must be different than the name used in Step 2.
7. From the **Host** drop-down menu, select the QRadar **host object** that you created.
8. From **Application Properties**, select **User Defined** as the Vendor type.
9. From **Client Entries**, select **LEA**.
10. To configure the Secure Internal Communication (SIC) certificate, click **Communication** and enter an activation key.
11. Select **OK** and then **Close**.
12. To install the Policy on your firewall, select **Policy > Install > OK**.

## OPSEC/LEA log source parameters for Check Point Multi-Domain Management (Provider-1)

If QRadar does not automatically detect the log source, add a Check Point Multi-Domain Management (Provider-1) log source on the QRadar Console by using the OPSEC/LEA protocol.

When using the OPSEC/LEA protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect OPSEC/LEA events from Check Point Multi-Domain Management (Provider-1):

Table 335. OPSEC/LEA log source parameters for the Check Point Multi-Domain Management (Provider-1) DSM

Parameter	Value
<b>Log Source type</b>	<b>Check Point</b>
<b>Protocol Configuration</b>	<b>OPSEC/LEA</b>
<b>Log Source Identifier</b>	Type the IP address for the log source. This value must match the value that you typed in the <b>Server IP</b> parameter.

For a complete list of OPSEC/LEA protocol parameters and their values, see “[OPSEC/LEA protocol configuration options](#)” on page 203.

## Check Point Multi-Domain Management (Provider-1) sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Check Point Multi-Domain Management (Provider-1) sample messages when you use the LEEF protocol

**Sample 1:** The following sample event message shows an informational event that was generated by the clock daemon.

```
LEEF:2.0|Check Point|Syslog|1.0|Check Point Log|cat=Syslog devTime=1537528801
ifdir=inbound loguid={0x0,0x0,0x0,0x0} origin=172.16.150.106 sequencenum=1
version=5 default_device_message=<78>crond[30156]: (root) CMD (/usr/lib/sa/sa1 1 1)
facility=clock daemon syslog_severity=Informational
```

**Sample 2:** The following sample event message shows an application control event that contains specific details about the application; such as the category, name, description, ID, and properties of the application. This sample also contains rules that determine who can access the application and the matched category that is matched by the rule base.

```

# Chapter 39. Cilasoft QJRN/400

IBM QRadar collects detailed audit events from Cilasoft QJRN/400 software for IBM i.

To collect events, administrators can configure Cilasoft QJRN/400 to forward events with syslog, or optionally configure the integrated file system (IFS) to write events to a file. Syslog provides real-time events to QRadar and provides automatic log source discovery for administrators, which is the easiest configuration method for event collection. The IFS option provides an optional configuration to write events to a log file, which can be read remotely by using the log file protocol. QRadar supports syslog events from Cilasoft QJRN/400 V5.14.K and later.

To configure Cilasoft QJRN/400, complete the following tasks:

1. On your Cilasoft QJRN/400 installation, configure the Cilasoft Security Suite to forward syslog events to QRadar or write events to a file.
2. For syslog configurations, administrators can verify that the events forwarded by Cilasoft QJRN/400 are automatically discovered on the Log Activity tab.

Cilasoft QJRN/400 configurations that use IFS to write event files to disk are considered an alternative configuration for administrators that cannot use syslog. IFS configurations require the administrator to locate the IFS file and configure the host system to allow FTP, SFTP, or SCP communications. A log source can then be configured to use the log file protocol with the location of the event log file.

## Configuring Cilasoft QJRN/400

To collect events, you must configure queries on your Cilasoft QJRN/400 to forward syslog events to IBM QRadar.

### Procedure

1. To start the Cilasoft Security Suite, type the following command:

IJRN/QJRN

The account that is used to make configuration changes must have ADM privileges or USR privileges with access to specific queries through an **Extended Access** parameter.

2. To configure the output type, select one of the following options:

To edit several selected queries, type 2EV to access the Execution Environment and change the **Output Type** field and type SEM.

3. To edit large numbers of queries, type the command CHGQJQRYA and change the **Output Type** field and type SEM.

4. On the Additional Parameters screen, configure the following parameters:

Table 336. Cilasoft QJRN/400 output parameters

Parameter	Description
<b>Format</b>	Type *LEEF to configure the syslog output to write events in Log Event Extended Format (LEEF).  LEEF is a special event format that is designed to for IBM QRadar.

Table 336. Cilasoft QJRN/400 output parameters (continued)

Parameter	Description
<b>Output</b>	To configure an output type, use one of the following parameters to select an output type: *SYSLOG - Type this parameter to forward events with the syslog protocol. This option provides real-time events. *IFS - Type this parameter to write events to a file with the integrated file system. This option requires the administrator to configure a log source with the log file protocol. This option writes events to a file, which can be read in only 15-minute intervals.
<b>IP Address</b>	Enter the IP address of your IBM QRadar system. If an IP address for IBM QRadar is defined as a special value in the WRKQJVAL command, you can type *CFG. Events can be forwarded to either the QRadar Console, an Event Collector, an Event Processor, or your IBM QRadar all-in-one appliance.
<b>Port</b>	Type 514 or *CFG as the port for syslog events. By default, *CFG automatically selects port 514.
<b>Tag</b>	This field is not used by IBM QRadar.
<b>Facility</b>	This field is not used by IBM QRadar.
<b>Severity</b>	Select a value for the event severity. For more information about severity that is assigned to *QRY destinations, look up the command <b>WRKQJFVAL</b> in your <i>Cilasoft documentation</i> .

For more information on Cilasoft configuration parameters, see the *Cilasoft QJRN/400 User's Guide*.

Syslog events that are forwarded to IBM QRadar are viewable on the **Log Activity** tab.

## Syslog log source parameters for Cilasoft QJRN/400

If QRadar does not automatically detect the log source, add a Cilasoft QJRN/400 log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cilasoft QJRN/400:

Table 337. Syslog log source parameters for the Cilasoft QJRN/400 DSM

Parameter	Value
<b>Log Source type</b>	Cilasoft QJRN/400

Table 337. Syslog log source parameters for the Cilasoft QJRN/400 DSM (continued)

Parameter	Value
<b>Protocol Configuration</b>	Syslog  If Cilasoft QJRN/400 is configured to write events to the integrated file system with the *IFS option, the administrator must select <b>Log File</b> , and then configure the log file protocol.
<b>Log Source Identifier</b>	Type the IP address of your Cilasoft QJRN/400 installation.
<b>Enabled</b>	Select the <b>Enabled</b> check box to enable the log source.  By default, the check box is selected.
<b>Credibility</b>	Select the <b>Credibility</b> of the log source. The range is 0 - 10.  The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	Select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	Select this check box to enable the log source to coalesce (bundle) events.  By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in IBM QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Incoming Event Payload</b>	From the list, select the <b>Incoming Event Payload</b> encoder for parsing and storing the logs.
<b>Store Event Payload</b>	Select the <b>Store Event Payload</b> check box to enable the log source to store event payload information.  By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in IBM QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

# Chapter 40. Cisco

Several Cisco DSMs can be integrated with IBM QRadar.

## Cisco ACE Firewall

The IBM QRadar DSM for Cisco ACE Firewall collects syslog events from a Cisco ACE Firewall device.

QRadar accepts events that are forwarded from Cisco ACE Firewall by using the Syslog protocol. QRadar records all relevant events. Before you configure QRadar to integrate with an ACE firewall, you must configure your Cisco ACE Firewall to forward all device logs to QRadar.

### Configuring Cisco ACE Firewall

Before you can collect Cisco ACE Firewall logs in IBM QRadar, you must forward Cisco ACE device logs to QRadar.

#### Procedure

1. Log in to your Cisco ACE device.
2. From the **Shell Interface**, select **Main Menu > Advanced Options > Syslog Configuration**.
3. The **Syslog Configuration** menu varies depending on whether there are any syslog destination hosts configured yet. If no syslog destinations are configured, create one by selecting the **Add First Server** option. Click **OK**.
4. Type the host name or IP address of the destination host and port in the **First Syslog Server** field. Click **OK**.

The system restarts with new settings. When finished, the Syslog server window displays the host that is configured.

5. Click **OK**.

The **Syslog Configuration** menu is displayed. Notice that options for editing the server configuration, removing the server, or adding a second server are now available.

6. If you want to add another server, click **Add Second Server**.

At any time, click the **View Syslog options** to view existing server configurations.

7. To return to the **Advanced** menu, click **Return**.

The configuration is complete. The log source is added to QRadar as Cisco ACE Firewall events are automatically discovered. Events that are forwarded to QRadar by Cisco ACE Firewall appliances are displayed on the **Log Activity** tab of QRadar.

### Syslog log source parameters for Cisco ACE Firewall

If QRadar does not automatically detect the log source, add a Cisco ACE Firewall log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco ACE Firewall:

Table 338. Syslog log source parameters for the Cisco ACE Firewall DSM	
Parameter	Value
<b>Log Source type</b>	Cisco ACE Firewall
<b>Protocol Configuration</b>	Syslog

Table 338. Syslog log source parameters for the Cisco ACE Firewall DSM (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The identifier helps you determine which events came from your Cisco ACE Firewall.

#### Related tasks

[“Adding a log source” on page 5](#)

## Cisco ACS

The Cisco ACS DSM for IBM QRadar accepts syslog ACS events by using syslog and UDP multiline.

QRadar records all relevant and available information from the event. You can integrate Cisco ACS with QRadar by using one of the following methods:

- Configure your Cisco ACS device to directly send syslog to QRadar for Cisco ACS v5.x. See [“Configuring Syslog for Cisco ACS v5.x” on page 624](#).
- Configure your Cisco ACS device to directly send syslog to QRadar for Cisco ACS v4.x. See [“Configuring Syslog for Cisco ACS v4.x” on page 626](#).
- Configure your Cisco ACS device to directly send UDP multiline syslog to QRadar. See [“UDP Multiline Syslog log source parameters for Cisco ACS” on page 627](#)

## Configuring Syslog for Cisco ACS v5.x

The configuration of syslog forwarding from a Cisco ACS appliance with software version 5.x involves several steps.

### About this task

You must complete the following tasks:

### Procedure

- Create a Remote Log Target
- Configure global logging categories
- Configure a log source

## Creating a Remote Log Target

Creating a remote log target for your Cisco ACS appliance.

Log in to your Cisco ACS appliance.

On the navigation menu, click **System Administration > Configuration > Log Configuration > Remote Log Targets**.

The **Remote Log Targets** page is displayed.

Click **Create**.

Configure the following parameters:

*Table 339. Remote target parameters*

Parameter	Description
<b>Name</b>	Type a name for the remote syslog target.
<b>Description</b>	Type a description for the remote syslog target.
<b>Type</b>	Select <b>Syslog</b> .
<b>IP address</b>	Type the IP address of QRadar or your Event Collector.

Click **Submit**.

You are now ready to configure global policies for event logging on your Cisco ACS appliance.

## Configuring global logging categories

To configure Cisco ACS to forward log failed attempts to IBM QRadar:

### Procedure

1. On the navigation menu, click **System Administration > Configuration > Log Configuration > Global**.  
The **Logging Categories** window is displayed.
2. Select the **Failed Attempts** logging category and click **Edit**.
3. Click **Remote Syslog Target**.
4. From the **Available targets** window, use the arrow key to move the syslog target for QRadar to the **Selected targets** window.
5. Click **Submit**.

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Cisco ACS v5.x

If QRadar does not automatically detect the log source, add a Cisco ACS v5.x log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco ACS v5.x:

*Table 340. Syslog log source parameters for the Cisco ACS DSM*

Parameter	Value
<b>Log Source type</b>	Cisco ACS
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or hostname for the log source.  The identifier helps you determine which events came from your Cisco ACS appliance.

### Related tasks

[“Adding a log source” on page 5](#)

## Configuring Syslog for Cisco ACS v4.x

The configuration of syslog forwarding from a Cisco ACS appliance with software version 4.x involves a few steps.

### About this task

Complete the following steps:

### Procedure

1. Configure syslog forwarding
2. Configure a log source

## Configuring syslog forwarding for Cisco ACS v4.x

Configuration of an ACS device to forward syslog events to IBM QRadar.

### About this task

Take the following steps to configure the ACS device to forward syslog events to QRadar

### Procedure

1. Log in to your Cisco ACS device.
2. On the navigation menu, click **System Configuration**.

The **System Configuration** page opens.

3. Click **Logging**.

The logging configuration is displayed.

4. In the Syslog column for **Failed Attempts**, click **Configure**.

The **Enable Logging** window is displayed.

5. Select the **Log to Syslog Failed Attempts report** check box.

6. Add the following Logged Attributes:

- **Message-Type**
- **User-Name**
- **Nas-IP-Address**
- **Authen-Failure-Code**
- **Caller-ID**
- **NAS-Port**
- **Author-Data**
- **Group-Name**
- **Filter Information**
- **Logged Remotely**

7. Configure the following syslog parameters:

Table 341. Syslog parameters

Parameter	Description
<b>IP</b>	Type the IP address of QRadar.
<b>Port</b>	Type the syslog port number of IBM QRadar. The default is port 514.

*Table 341. Syslog parameters (continued)*

Parameter	Description
<b>Max message length (Bytes) - Type</b>	Type 1024 as the maximum syslog message length.

**Note:** Cisco ACS provides syslog report information for a maximum of two syslog servers.

8. Click **Submit**.

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Cisco ACS v4.x

If QRadar does not automatically detect the log source, add a Cisco ACS v4.x log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco ACS v4.x:

*Table 342. Syslog log source parameters for the Cisco ACS DSM*

Parameter	Value
<b>Log Source type</b>	Cisco ACS
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or hostname for the log source. The identifier helps you determine which events came from your Cisco ACS appliance.

### Related tasks

[“Adding a log source” on page 5](#)

## UDP Multiline Syslog log source parameters for Cisco ACS

The Cisco ACS DSM for IBM QRadar accepts syslog events from Cisco ACS appliances with log sources that are configured to use the UDP Multiline Syslog protocol.

If QRadar does not automatically detect the log source, add a Cisco ACS log source on the QRadar Console by using the UDP Multiline Syslog protocol.

The following table describes the parameters that require specific values to collect UDP Multiline Syslog events from Cisco ACS:

*Table 343. UDP Multiline Syslog log source parameters for the Cisco ACS DSM*

Parameter	Value
<b>Log Source type</b>	Cisco ACS
<b>Protocol Configuration</b>	UDP Multiline Syslog

Table 343. UDP Multiline Syslog log source parameters for the Cisco ACS DSM (continued)

Parameter	Value
<b>Log Source Identifier</b>	The Packet IP address of the source data.  If you select <b>Show Advanced options</b> and you select the <b>Use As A Gateway Log Source</b> option, the <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one Cisco ACS log source that is configured, you might want to identify the first log source as <i>ciscoacs1</i> , the second log source as <i>ciscoacs2</i> , and the third log source as <i>ciscoacs3</i> .  For more information about using a gateway, see “ <a href="#">UDP multiline syslog protocol configuration options</a> ” on page 237.
<b>Listen Port</b>	The default port number that is used by QRadar to accept incoming UDP Multiline Syslog events is 517.  You can use a different port. The valid port range is 1 - 65535.
<b>Message ID Pattern</b>	\s(\d{10})\s
<b>Event Formatter</b>	Select <b>Cisco ACS Multiline</b> from the list.

For a complete list of UDP Multiline Syslog protocol parameters and their values, see “[UDP multiline syslog protocol configuration options](#)” on page 237.

## Cisco ACS sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Cisco ACS sample message when you use the Syslog protocol

The following sample event is a passed authentication event.

```
<181>Jul 22 06:43:25 cisco.acs.test CSC0acs_Passed_Authentications 0082331393 3

## Configuring Cisco Aironet to forward events

The IBM QRadar DSM for Cisco Aironet accepts Cisco EMBLEM Format events by using Syslog.

### Procedure

1. Establish a connection to the Cisco Aironet device by using one of the following methods:

- Telnet to the wireless access point
- Access the console

2. Type the following command to access privileged EXEC mode:

```
enable
```

3. Type the following command to access global configuration mode:

```
config terminal
```

4. Type the following command to enable message logging:

```
logging on
```

5. Configure the syslog facility. The default is local7.

```
logging <facility>
```

where <facility> is, for example, local7.

6. Type the following command to log messages to your QRadar:

```
logging <IP address>
```

where <IP address> is the IP address of your QRadar.

7. Enable **timestamp** on log messages:

```
service timestamp log datatime
```

8. Return to privileged EXEC mode:

```
end
```

9. View your entries:

```
show running-config
```

10. Save your entries in the configuration file:

```
copy running-config startup-config
```

The configuration is complete. The log source is added to QRadar as Cisco Aironet events are automatically discovered. Events that are forwarded to QRadar by Cisco Aironet appliances are displayed on the **Log Activity** tab of QRadar.

## Results

The log source is added to QRadar as Cisco Aironet events are automatically discovered. Events that are forwarded to QRadar by Cisco Aironet appliances are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Cisco Aironet

If QRadar does not automatically detect the log source, add a Cisco Aironet log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco Aironet:

Table 345. Syslog log source parameters for the Cisco Aironet DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Aironet
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.  The identifier helps you determine which events came from your Cisco Aironet appliance.

### Related tasks

["Adding a log source" on page 5](#)

## Cisco ASA

You can integrate a Cisco Adaptive Security Appliance (ASA) with IBM QRadar.

A Cisco ASA DSM accepts events through syslog or NetFlow by using NetFlow Security Event Logging (NSEL). QRadar records all relevant events. Before you configure QRadar, you must configure your Cisco ASA device to forward syslog or NetFlow NSEL events.

Choose one of the following options:

- Forward events to QRadar by using syslog. See ["Integrate Cisco ASA Using Syslog" on page 630](#)
- Forward events to QRadar by using NetFlow (NSEL). See ["Integrate Cisco ASA for NetFlow by using NSEL" on page 632](#)

## Integrate Cisco ASA Using Syslog

Integrating Cisco ASA by using syslog involves the configuration of a log source, and syslog forwarding.

Use the following information to help you integrate Cisco ASA by using the syslog protocol:

- ["Configuring syslog forwarding" on page 631](#)
- ["Syslog log source parameters for Cisco ASA" on page 631](#)

## Configuring syslog forwarding

To configure Cisco ASA to forward syslog events, some manual configuration is required.

### Procedure

1. Log in to the Cisco ASA device.
2. Type the following command to access privileged EXEC mode:  
`enable`
3. Type the following command to access global configuration mode:  
`conf t`
4. Enable logging:

```
logging enable
```

5. Configure the logging details:

```
logging console warning
```

```
logging trap warning
```

```
logging asdm warning
```

**Note:** The Cisco ASA device can also be configured with `logging trap informational` to send additional events. However, this may increase the event rate (Events Per Second) of your device.

6. Type the following command to configure logging to IBM QRadar:

```
logging host <interface> <IP address>
```

Where:

- `<interface>` is the name of the Cisco Adaptive Security Appliance interface.
- `<IP address>` is the IP address of QRadar.

**Note:** Using the command `show interfaces` displays all available interfaces for your Cisco device.

7. Disable the output object name option:

```
no names
```

Disable the output object name option to ensure that the logs use IP addresses and not the object names.

8. Exit the configuration:

```
exit
```

9. Save the changes:

```
write mem
```

### Results

The configuration is complete. The log source is added to QRadar as Cisco ASA syslog events are automatically discovered. Events that are forwarded to QRadar by Cisco ASA are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Cisco ASA

If QRadar does not automatically detect the log source, add a Cisco ASA log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco ASA:

Table 346. Syslog log source parameters for the Cisco ASA DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Adaptive Security Appliance (ASA)
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	<p>Type the IP address or host name for the log source.</p> <p>The identifier helps you determine which events came from your Cisco ASA appliance.</p>

#### Related tasks

[“Adding a log source” on page 5](#)

## Integrate Cisco ASA for NetFlow by using NSEL

Integrating Cisco ASA for Netflow by using NSEL involves two steps.

Use the following information to help you integrate Cisco ASA for Netflow by using the NSEL protocol:

- [“Configuring NetFlow Using NSEL” on page 632](#)
- [“Cisco NSEL log source parameters for Cisco ASA” on page 633](#)

## Configuring NetFlow Using NSEL

You can configure Cisco ASA to forward NetFlow events by using NSEL.

### Procedure

1. Log in to the Cisco ASA device command-line interface (CLI).
2. Type the following command to access privileged EXEC mode:

```
enable
```

3. Type the following command to access global configuration mode:

```
conf t
```

4. Disable the output object name option:

```
no names
```

5. Type the following command to enable NetFlow export:

```
flow-export destination <interface-name> <ipv4-address or hostname> <udp-port>
```

Where:

- <interface-name> is the name of the Cisco Adaptive Security Appliance interface for the NetFlow collector.
- <ipv4-address or hostname> is the IP address or host name of the Cisco ASA device with the NetFlow collector application.
- <udp-port> is the UDP port number to which NetFlow packets are sent.

**Note:** IBM QRadar typically uses port 2055 for NetFlow event data on QRadar QFlow Collectors. You must configure a different UDP port on your Cisco Adaptive Security Appliance for NetFlow by using NSEL.

6. Type the following command to configure the NSEL class-map:

```
class-map flow_export_class
```

7. Choose one of the following traffic options:

To configure a NetFlow access list to match specific traffic, type the command:

```
match access-list flow_export_acl
```

8. To configure NetFlow to match any traffic, type the command:

```
match any
```

**Note:** The Access Control List (ACL) must exist on the Cisco ASA device before you define the traffic match option in “Configuring NetFlow Using NSEL” on page 632.

9. Type the following command to configure the NSEL policy-map:

```
policy-map flow_export_policy
```

10. Type the following command to define a class for the flow-export action:

```
class flow_export_class
```

11. Type the following command to configure the flow-export action:

```
flow-export event-type all destination <IP address>
```

Where <IP address> is the IP address of QRadar.

**Note:** If you are using a Cisco ASA version before v8.3 you can skip “Configuring NetFlow Using NSEL” on page 632 as the device defaults to the flow-export destination. For more information, see your *Cisco ASA documentation*.

12. Type the following command to add the service policy globally:

```
service-policy flow_export_policy global
```

13. Exit the configuration:

```
exit
```

14. Save the changes:

```
write mem
```

You must verify that your collector applications use the **Event Time** field to correlate events.

## Cisco NSEL log source parameters for Cisco ASA

If QRadar does not automatically detect the log source, add a Cisco ASA log source on the QRadar Console by using the Cisco NSEL protocol.

**Note:** Your system must be running the current version of the NSEL protocol to integrate with a Cisco ASA device that uses NetFlow and NSEL. The NSEL protocol is available on IBM Support, <http://www.ibm.com/support>, or through auto updates in QRadar.

The following table describes the parameters that require specific values to collect Cisco NSEL events from Cisco ASA:

Table 347. Cisco NSEL log source parameters for the Cisco ASA DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Adaptive Security Appliance (ASA)
<b>Protocol Configuration</b>	Cisco NSEL
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.  The identifier helps you determine which events came from your Cisco ASA appliance.

Table 347. Cisco NSEL log source parameters for the Cisco ASA DSM (continued)

Parameter	Value
<b>Collector Port</b>	Type the UDP port number that is used by Cisco ASA to forward NSEL events. The valid range of the <b>Collector Port</b> parameter is 1-65535.  QRadar typically uses port 2055 for NetFlow event data on the QRadar QFlow Collector. You must define a different UDP port on your Cisco Adaptive Security Appliance for NetFlow that uses NSEL.

For a complete list of Cisco NSEL protocol parameters and their values, see [“Cisco NSEL protocol configuration options” on page 116](#).

## Removing leading domain names from usernames when Cisco ASA events are processed

If you want to change the way that IBM QRadar processes Cisco Adaptive Security Appliance (ASA) events, use the DSM Editor to remove leading domain names from usernames.

By default, Cisco ASA events include leading domain names in usernames.

#### Procedure

1. On the **Admin** tab, in the **Data Sources** section, click **DSM Editor**.
2. From the **Select Log Source Type** window, select **Cisco Adaptive Security Appliance (ASA)** from the list, and then click **Select**.
3. Click the **Configuration** tab, and then set **Display DSM Parameters Configuration** to **on**.
4. From the **Event Collector** list, select the event collector for the log source.
5. Set **Remove leading domain name from username** to **on**.
6. Click **Save** and then close the DSM Editor.

## Collecting IP addresses for Cisco ASA Teardown TCP connection events

If you want IBM QRadar to collect IP addresses for Teardown TCP collection events from Cisco Adaptive Security Appliance (ASA), use the DSM Editor.

#### Procedure

1. On the **Admin** tab, in the **Data Sources** section, click **DSM Editor**.
2. From the **Select Log Source Type** window, select **Cisco Adaptive Security Appliance (ASA)** from the list, and then click **Select**.
3. Click the **Configuration** tab, and then set **Display DSM Parameters Configuration** to **on**.
4. Set **Teardown IP Connection** to **on**.
5. Click **Save** and then close the DSM Editor.

## Cisco ASA sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## Cisco ASA sample message when you use the Syslog protocol

The following sample event message shows that the Internet Key Exchange (IKE) protocol obtained an address for the client private IP address from DHCP, or from the address pool. The sample event message also shows that the IP address is assigned to the client.

```
Aug 11 08:10:34 cisco.asa.test %ASA-6-713228: Group = groupx, Username = userx, IP = 192.0.2.10,  
Assigned private IP address 192.0.2.11 to remote user
```

```
Aug 11 08:10:34 cisco.asa.test %ASA-6-713228: Group = groupx, Username = userx, IP =  
192.0.2.10, Assigned private IP address 192.0.2.11 to remote user
```

*Table 348. QRadar field names and highlighted values in the event payload*

QRadar field name	Highlighted values in the event payload
Event ID	<b>713228</b>
Source IP	<b>192.0.2.10</b>
Username	<b>userx</b>
Post NAT Source IP	<b>192.0.2.11</b>
Identity IP	<b>192.0.2.11</b>
Identity Group Name	<b>groupx</b>
Identity Username	<b>userx</b>
Device Time	<b>Aug 11 08:10:34</b>

## Cisco AMP

The IBM QRadar DSM for Cisco Advanced Malware Protection (Cisco AMP) collects event logs from your Cisco AMP for Endpoints platform. The DSM for Cisco AMP uses the RabbitMQ protocol.

**Important:** The Cisco AMP integration does not support private cloud if the Server Name Indication (SNI) is required. Contact Cisco for more details.

To integrate Cisco AMP with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the following RPMs on your QRadar Console.

**Important:** You need QRadar V7.2.8 Patch 9 (V7.2.8.20170726184122) or later to install the RabbitMQ Protocol RPM.

- Protocol Common RPM
- DSMCommon RPM
- RabbitMQ Protocol RPM
- Cisco AMP DSM RPM

2. Create a Cisco AMP Client ID and API key. Alternatively, you can request access to an already created event stream from your administrator. For more information about creating these values, go to the [Creating a Cisco AMP Client ID and API key procedure](#).
3. Create a Cisco AMP event stream. For more information about creating the event stream, go to the [“Creating a Cisco AMP event stream” on page 637](#) procedure.
4. Add a Cisco AMP log source on the QRadar Console for a user to manage the Cisco AMP event stream.

### Related concepts

[“Cisco AMP event stream configuration” on page 639](#)

Configure a log source in QRadar to manage a specific event stream that you want QRadar to collect events from.

## Cisco AMP DSM specifications

The following table describes the specifications for the Cisco AMP DSM.

Table 349. Cisco AMP DSM specifications	
Specification	Value
Manufacturer	Cisco
DSM	Cisco AMP
RPM name	DSM-CiscoAMP-QRadar_version-Build_number.noarch.rpm
Supported versions	N/A
Protocol	RabbitMQ
Event format	Cisco AMP
Recorded event types	All security events  For a detailed list of supported events, go to the <a href="#">Cisco AMP for Endpoints API documentation</a> . ( <a href="https://api-docs.amp.cisco.com/api_actions/details?api_action=GET+%2Fv1%2Fevent_types&amp;api_host=api.amp.cisco.com&amp;api_resource=Event+Type&amp;api_version=v1">https://api-docs.amp.cisco.com/api_actions/details?api_action=GET+%2Fv1%2Fevent_types&amp;api_host=api.amp.cisco.com&amp;api_resource=Event+Type&amp;api_version=v1</a> )  <b>Note:</b> Network traffic is supported only for Data Flow Control (DCF) events.
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://api-docs.amp.cisco.com/">Cisco website</a> ( <a href="https://api-docs.amp.cisco.com/">https://api-docs.amp.cisco.com/</a> )

## Creating a Cisco AMP Client ID and API key for event queues

A Cisco AMP administrator must create a Client ID and an API key in the Cisco AMP for Endpoints portal. These keys are used to manage queues.

### Before you begin

If you do not have administrator privileges, request the Client ID and API key values from your administrator. If you want QRadar to automatically manage the event stream, you need these values when you configure a log source in QRadar.

### Procedure

1. Log in to the Cisco AMP for Endpoints portal as an administrator.
2. Click **Accounts > API Credentials**.
3. In the **API Credentials** pane, click **New API Credential**.

4. In the **Application name** field, type a name, and then select **Read & Write**.

You must have read & write access to manage event streams on your Cisco AMP for Endpoints platform.

5. Click **Create**.

6. From the **API Key Details** section, copy the values for the **3rd Party API Client ID** and the **API Key**.  
You need these values to manage queues.

## What to do next

Create a Cisco AMP event stream.

### Related concepts

[“Cisco AMP event stream configuration” on page 639](#)

Configure a log source in QRadar to manage a specific event stream that you want QRadar to collect events from.

### Related tasks

[“Creating a Cisco AMP event stream” on page 637](#)

The Cisco AMP for Endpoints API returns the Advanced Message Queuing Protocol (AMQP) credentials in several Cisco AMP for Endpoints API query responses.

[“Adding a log source” on page 5](#)

## Creating a Cisco AMP event stream

The Cisco AMP for Endpoints API returns the Advanced Message Queuing Protocol (AMQP) credentials in several Cisco AMP for Endpoints API query responses.

### Procedure

1. Download the curl command line tool from the [curl download website](#) (<https://curl.haxx.se/download.html>).

You can run the curl command on your Cisco server or QRadar Console.

2. To create a Cisco AMP event stream, type one of the following command examples. You need the parameter values when you configure a log source in IBM QRadar.

This command can run on any device. It does not need to run on the Event Collector.

**Important:** Due to formatting issues, paste the queries into a text editor and then remove any carriage return or line feed characters.

### Example 1: Default API call to get all Event IDs and all Group GUIDs in a single event stream.

```
curl -X POST -H 'accept: application/json' \-H 'content-type: application/json' \-H 'accept: application/json' \-H 'accept-encoding: identity' --compressed \-H 'Accept-Encoding: gzip, deflate' \-d '{"name": "<STREAMNAME>"}' \-u <CLIENTID:APIKEY> '\https://api.amp.cisco.com/v1/event_streams'
```

### Example 2: API call with multiple defined Event IDs and Group GUIDs.

```
curl -X POST -H 'accept: application/json' \-H 'content-type: application/json' \-H 'accept: application/json' \-H 'accept-encoding: identity' --compressed \-H 'Accept-Encoding: gzip, deflate' \-d '{"name": "<STREAMNAME>", "event_type": [1090519105, 1090519102, 553648199, 1090519112], "group_guid": ["0a00a0aa-0000-000a-0a00-0a0aa0aaa0", "aa00a0aa-0000-000a-a000-0a0aa0a0aaa0"]}' \-u <CLIENTID:APIKEY> '\https://api.amp.cisco.com/v1/event_streams'
```

### Example 3: API call with a single defined Event ID and Group GUID.

```
curl -X POST -H 'accept: application/json' \-H 'content-type: application/json' \-H 'accept: application/json' \-H 'accept-encoding: identity' --compressed \-H 'Accept-Encoding: gzip, deflate' \-d '{"name": "<STREAMNAME>", "event_type": [1090519112], "group_guid": ["aa00a0aa-0000-000a-a000-0a0aa0a0aaa0"]}' \-u <CLIENTID:APIKEY> '\https://api.amp.cisco.com/v1/event_streams'
```

When you input the query, the following values must be configured:

- <STREAMNAME> is a name of your choosing for the event stream.
- <group\_guid> is the group GUID that you want to use to link to the <0a00a0aa-0000-000a-a000-0a0aa0a0aaa0> event stream. You can consult your Cisco AMP API to find a group GUID value, or you can leave this value blank.
- <CLIENTID:APIKEY> is the **Client ID** and the **API key** that you created.

If you are in the Asia Pacific Japan and China (APJC) region, change 'https://api.amp.cisco.com/v1/event\_streams' to 'https://api.apjc.amp.cisco.com/v1/event\_streams'.

If you are in the European region, change 'https://api.amp.cisco.com/v1/event\_streams' to 'https://api.eu.amp.cisco.com/v1/event\_streams'.

### Sample Query Response:

```
{  
    "version": "v1.2.0",  
    "metadata": {  
        "links": {  
            "self": "https://api.amp.cisco.com/v1/event_streams"  
        }  
    },  
    "data": {  
        "id": 2216,  
        "name": "STREAMNAME",  
        "group_guids": [  
            "0a00a0aa-0000-000a-a000-0a0aa0a0aaa0"  
        ],  
        "event_types": [  
            553648130,  
            554696714  
        ],  
        "amqp_credentials": {  
            "user_name": "1116-aa00a000000000000000a0",  
            "queue_name": "event_stream_1116",  
            "password": "0a0aa0a0aa000000a0000aa0000aa0a00000a",  
            "host": "export-streaming.amp.cisco.com",  
            "port": "443",  
            "proto": "https"  
        }  
    }  
}
```

Each log source can accept a single stream regardless of the number of event types or group\_guids requested in the stream. If the Cisco AMP API accepts the request and returns the stream connection information, you can connect to that information.

For more information, see [Cisco documentation](https://api-docs.amp.cisco.com/api_actions/details?api_action=POST+%2Fv1%2Fevent_streams&api_host=api.amp.cisco.com&api_resource=EventStream&api_version=v1) ([https://api-docs.amp.cisco.com/api\\_actions/details?api\\_action=POST+  
%2Fv1%2Fevent\\_streams&api\\_host=api.amp.cisco.com&api\\_resource=EventStream&api\\_version=v1](https://api-docs.amp.cisco.com/api_actions/details?api_action=POST+%2Fv1%2Fevent_streams&api_host=api.amp.cisco.com&api_resource=EventStream&api_version=v1)).

## What to do next

## Cisco AMP event stream configuration

Configure a log source in QRadar to manage a specific event stream that you want QRadar to collect events from.

To connect to a specific Cisco AMP event stream, you also need to have access to the Advanced Message Queuing Protocol (AMQP) credentials that are provided by the Cisco AMP for Endpoints API.

The Cisco AMP for Endpoints API is used to manage event streams. For more information about supported queries to manage the Cisco AMP for Endpoint API, see [Cisco AMP for Endpoints API](#).

**Important:** If an issue occurs while you use the Cisco AMP for Endpoints API, contact your Cisco administrator for assistance. For Cisco contact information, see [Cisco Support](#).

The following table describes the parameters that require specific values to collect events from the Cisco AMP for Endpoints API by using the RabbitMQ protocol:

Table 350. RabbitMQ protocol log source parameters	
Parameter	Description
<b>Log Source Type</b>	<b>Cisco AMP</b>
<b>Protocol Configuration</b>	<b>RabbitMQ</b>
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If more than one Cisco AMP log source is configured, you might identify the first log source as <i>CiscoAMP1</i> , the second log source as <i>CiscoAMP2</i> , and so on.
<b>Event Format</b>	You must select <b>Cisco AMP</b> .
<b>IP or Hostname</b>	The IP address or host name that is used for the Cisco AMP for Endpoints API event stream. You can find the IP or host name in the <b>AMQP credentials</b> field. For more information about AMQP credentials, see <a href="#">Creating a Cisco AMP event stream</a> .
<b>Port</b>	The port that is used for the Cisco AMP for Endpoints API event stream. You can find the port number in the <b>AMQP credentials</b> field. For more information about AMQP credentials, see <a href="#">Creating a Cisco AMP event stream</a> .
<b>Queue</b>	The queue name that is used for the Cisco AMP for Endpoints API event stream. You can find the queue name value in the <b>AMQP credentials</b> field. For more information about the AMQP credentials, see <a href="#">“Creating a Cisco AMP event stream” on page 637</a> .
<b>Username</b>	The user name that is used for the Cisco AMP for Endpoints API event stream. You can find the user name value in the <b>AMQP credentials</b> field. For more information about AMQP credentials, see <a href="#">“Creating a Cisco AMP event stream” on page 637</a> .

Table 350. RabbitMQ protocol log source parameters (continued)

Parameter	Description
<b>Password</b>	The password that is used for the Cisco AMP for Endpoints API event stream. You can find the password value in the <b>AMQP credentials</b> field. For more information about AMQP credentials, see “Creating a Cisco AMP event stream” on page 637.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 5000.
<b>Allow Untrusted Certificates</b>	Enable this option when the endpoint is using a certificate that cannot be verified via the Certificate Chain. This would include a self-signed certificate, or one from a private CA that you do not want to import into your CA trust.  This option should not be used for endpoints with a certificate issued by a Public CA (SaaS Products, Public Cloud Infrastructure, and so on.)  The certificate must be downloaded in PEM or DER encoded binary format and then placed in the /opt/qradar/conf/trusted_certificates/ directory with a .cert or .crt file extension.

### Related concepts

[“Copy the server certificate” on page 210](#)

You need a server certificate to support HTTPS connections. QRadar supports certificates with the .crt, .cert, or .der file extensions.

### Related tasks

[“Adding a log source” on page 5](#)

## Copy the server certificate

You need a server certificate to support HTTPS connections. QRadar supports certificates with the .crt, .cert, or .der file extensions.

To copy a certificate to the /opt/qradar/conf/trusted\_certificates directory, choose one of the following options:

- Manually copy the certificate to the /opt/qradar/conf/trusted\_certificates directory by using SCP or SFTP.
- Use SSH to log in to the QRadar Console or managed host and retrieve the certificate by typing the following command:

```
/opt/qradar/bin/getcert.sh <IP or Hostname for RabbitMQ> <Port for RabbitMQ>
```

A certificate is downloaded from the specified host name or IP address and placed into the /opt/qradar/conf/trusted\_certificates directory in the appropriate format.

## Cisco AMP sample event message

Use this sample event to verifying a successful integration with QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

### Cisco AMP sample message when you use the RabbitMQ protocol

The following sample event message shows that a DFC threat is detected.

```
{"id":6629038896162275332,"timestamp":1543443393,"timestamp_nanoseconds":258000000,"date":"2018-11-28T22:16:33+00:00","event_type":"DFC Threat Detected","event_type_id":1090519084,"detection_id":"6629038896162275330","connector_guid":"connector_guid","group_guids":["group_guids"],"severity":"High","computer":{"connector_guid":"connector_guid","hostname":"example.com","external_ip":"172.16.0.0","user":"root","active":true,"network_addresses":[{"ip":"172.16.0.0","mac":"00-00-5E-00-53-00"}],"links":{"computer": "computer","trajectory": "trajectory","group": "group"}}, "network_info": {"remote_ip": "172.16.0.1", "remote_port": 443, "local_ip": "10.51.100.0", "local_port": 55807, "nfm": {"direction": "Outgoing connection from", "protocol": "UDP"}, "parent": {"process_id": 2608, "disposition": "Clean", "file_name": "chrome.exe", "identity": {"sha256": "sha256", "sha1": "sha1", "md5": "md5"}}}
```

Table 351. Highlighted values in the Cisco AMP sample event message

QRadar field name	Highlighted payload field name
Event ID	event_type_id

## Cisco CallManager

The Cisco CallManager DSM for IBM QRadar collects application events that are forwarded from Cisco CallManager devices that are using Syslog.

Before events can be received in QRadar, you must configure your Cisco Call Manager device to forward events. After you forward Syslog events from Cisco CallManager, QRadar automatically detects and adds Cisco CallManager as a log source.

### Configuring syslog forwarding

Before events can be received in QRadar, you must configure your Cisco CallManager device to forward events.

#### Procedure

1. Log in to your Cisco CallManager.
2. Select **System Enterprise > Parameters**.

The **Enterprise Parameters Configuration** is displayed.

3. In the **Remote Syslog Server Name** field, type the IP address of the QRadar Console.
4. From the **Syslog Severity For Remote Syslog messages** list, select **Informational**.

This option configures the severity level of the messages that are collected.

5. Click **Save**.
6. Click **Apply Config**.

## What to do next

You are now ready to configure a syslog log source for Cisco CallManager.

## Syslog log source parameters for Cisco CallManager

If QRadar does not automatically detect the log source, add a Cisco CallManager log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco CallManager:

Table 352. Syslog log source parameters for the Cisco CallManager DSM	
Parameter	Value
<b>Log Source type</b>	Cisco CallManager
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	<p>Type the IP address or host name for the log source.</p> <p>The identifier helps you determine which events came from your Cisco CallManager device.</p>

### Related tasks

[“Adding a log source” on page 5](#)

## Cisco CallManager sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Cisco CallManager sample message when you use the syslog protocol

The following sample event message shows that a user is successfully added to a group.

```
<179>10499: : : 7454: cisco.callmanager.test Aug 21 2020
17:02:45 UTC : %UC_CALLMANAGER-3-DeviceUnregistered: %[DeviceName=DEVICENAME]

## Cisco CatOS for Catalyst Switches

The IBM QRadar DSM for Cisco Catalyst Switches running Cisco CatOS accepts events by using syslog.

QRadar records all relevant device events. Before you configure a Cisco CatOS device in QRadar, you must configure your device to forward syslog events.

### Configuring syslog forwarding for Cisco CatOS devices

Before you configure a Cisco CatOS device in IBM QRadar, you must configure your device to forward syslog events.

#### Procedure

1. Log in to your Cisco CatOS user interface.
2. Type the following command to access privileged EXEC mode:

```
enable
```

3. Configure the system to **timestamp** messages:

```
set logging timestamp enable
```

4. Type the following command with the IP address of IBM QRadar:

```
set logging server <IP address>
```

5. Limit messages that are logged by selecting a severity level:

```
set logging server severity <server severity level>
```

6. Configure the facility level to be used in the message. The default is local7.

```
set logging server facility <server facility parameter>
```

7. Enable the switch to send syslog messages to the QRadar.

```
set logging server enable
```

#### What to do next

You are now ready to configure the log source in QRadar.

### Syslog log source parameters for Cisco CatOS for Catalyst Switches

If QRadar does not automatically detect the log source, add a Cisco CatOS for Catalyst Switches log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco CatOS for Catalyst Switches:

Table 354. Syslog log source parameters for the Cisco CatOS for Catalyst Switches DSM

Parameter	Value
Log Source type	Cisco CatOS for Catalyst Switches
Protocol Configuration	Syslog

*Table 354. Syslog log source parameters for the Cisco CatOS for Catalyst Switches DSM (continued)*

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The identifier helps you determine which events came from your Cisco CatOS for Catalyst Switch device.

#### Related tasks

## Cisco Cloud Web Security

The IBM QRadar DSM for Cisco Cloud Web Security (CWS) collects web usage logs from a Cisco Cloud Web Security (CWS) storage by using an Amazon S3 - compatible API.

The following table describes the specifications for the Cisco Cloud Web Security DSM:

Table 357. Cisco Cloud Web Security DSM specifications	
Specification	Value
Manufacturer	Cisco
DSM name	Cisco Cloud Web Security
RPM file name	DSM-CiscoCloudWebSecurity-QRadar_version-build_number.noarch.rpm
Supported versions	N/A
Protocol	Amazon AWS S3 REST API
Event format	W3C
Recorded event types	All web usage logs
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.cisco.com/go/cws">Cisco CWS product information (https://www.cisco.com/go/cws)</a>

To integrate Cisco Cloud Web Security with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#), in the order that they are listed, on your QRadar Console:
  - Protocol Common RPM
  - Amazon AWS REST API Protocol RPM
  - DSMCommon RPM
  - Cisco Cloud Web Security DSM RPM
2. Enable Log Extraction in your Cisco ScanCenter (administration portal).
3. Add a Cisco Cloud Web Security log source on the QRadar Console. The following table describes the parameters that require specific values for Cisco Cloud Web Security event collection:

Table 358. Cisco Cloud Web Security log source parameters

Parameter	Value
Log Source type	Cisco Cloud Web Security
Protocol Configuration	Amazon AWS S3 REST API
Log Source Identifier	The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you configured more than one Cisco CWS log source, you might want to identify the first log source as ciscocws1, the second log source as ciscocws2, and the third log source as ciscocws13.

Table 358. Cisco Cloud Web Security log source parameters (continued)

Parameter	Value
<b>Signature Version</b>	Select <b>Signature Version 2</b> . If your Cisco CWS API is using <b>Signature Version 4</b> , contact your system administrator.
<b>Region Name</b> (Signature V4 only)	The region that is associated with the Amazon S3 bucket.
<b>Service Name</b> (Signature V4 only)	Type s3. The name of the Amazon Web Service.
<b>Bucket Name</b>	The name of the Cisco CWS bucket where the log files are stored.
<b>Endpoint URL</b>	<a href="https://vault.scansafe.com/">https://vault.scansafe.com/</a>
<b>Public Key</b>	The access key to enable log extraction from the Cisco CWS bucket.
<b>Access Key</b>	The secret key to enable log extraction from the Cisco CWS bucket.
<b>Directory Prefix</b>	The location of the root directory on the Cisco CWS storage bucket from where the Cisco CWS logs are retrieved. For example, the root directory location might be cws-logs/.
<b>File Pattern</b>	.*?\.\txt\.\gz
<b>Event Format</b>	<b>W3C</b> . The log source retrieves W3C text formatted events.
<b>Use Proxy</b>	When a proxy is configured, all traffic for the log source travels through the proxy so that QRadar can access the Amazon AWS S3 buckets. Configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Automatically Acquire Server Certificate(s)</b>	If you select <b>Yes</b> , QRadar downloads the certificate and begins trusting the target server.
<b>Recurrence</b>	Specifies how often the Amazon AWS S3 REST API Protocol connects to the Cisco CWS API to check for new files, and retrieves them if they exist. The format is M/H/D for Minutes/Hours/ Days. The default is 5 M.  Every access to an AWS S3 bucket incurs a monetary cost to the account that owns the bucket. Therefore, a smaller recurrence value increases the cost.

The following table shows a sample event message from Cisco Cloud Web Security:

Table 359. Cisco Cloud Web Security sample message

Event name	Low level category	Sample log message
c:comp - block	Access Denied	<pre>2016-08-22 18:22:34 GMT &lt;IP_address1&gt; &lt;IP_address1&gt; GET http www.example.com 80 / Mozilla/5.0 (Windows NT 6.1; WOW64; rv:45.0) Gecko/20100101 Firefox/45.0 - 0 0 0 &lt;IP_address2&gt; c:comp Block all block category Computers and Internet &lt;IP_address1&gt; 0 Unknown</pre> <pre>2016-08-22 18:22:34 GMT &lt;IP_address1&gt; &lt;IP_address1&gt; GET http www.example.com 80 / Mozilla/5.0 (Windows NT 6.1; WOW64; rv:45.0) Gecko/20100101 Firefox/45.0 - 0 0 0 &lt;IP_address2&gt; c:comp Block all block category Computers and Internet &lt;IP_address1&gt; 0 Unknown</pre>

[“Adding a log source” on page 5](#)

## Configuring Cloud Web Security to communicate with QRadar

To send events from Cloud Web Security to IBM QRadar, you must enable log extraction in Cisco CWS ScanCenter.

### Before you begin

The log extraction service must be enabled and provisioned for your company. You must have super user administrator privileges to access the **Log Extraction** page.

### Procedure

1. Log in to your Cisco ScanCenter account.
2. Click the **Admin** tab to view the administration menus.
3. From the **Your Account** menu, click **Log Extraction**.
4. In the **Actions** column in the **Credentials** area, click **Issue Key**.
5. In the **Warning** dialog box, click **Issue & Download**.

A key pair is issued and the keypair.csv file is downloaded.

The **Access Key** and **Last issued** column values are updated. The secret key does not display in the user interface (UI).

6. Open the keypair.csv file and make a copy of the **accessKey** and **secretKey**.

The keypair.csv file contains a 20 character string access key and a 40 character string secret key. The key pair values that you copied are used when you configure the log source in QRadar.

7. From the **Connection Details** pane, copy and record the values in the **Endpoint** and **Bucket** columns.

The connection details values that you copied are used when you configure the log source in QRadar.

## What to do next

Configure the log source in QRadar.

For more information about Cisco CWS log extraction, see the *Cisco ScanCenter Administrator Guide, Release 5.2* on the [Cisco website](https://search.cisco.com/search?query=cisco%20scancenter%20administrator%20guide&locale=enUS&tab=Cisco) (<https://search.cisco.com/search?query=cisco%20scancenter%20administrator%20guide&locale=enUS&tab=Cisco>).

### Related tasks

## Cisco CSA

---

You can integrate a Cisco Security Agent (CSA) server with IBM QRadar.

The Cisco CSA DSM accepts all events by using the syslog, SNMPv1 and SNMPv2 protocols. QRadar records all configured Cisco CSA alerts.

## Configuring Cisco CSA to send events to IBM QRadar

Configuration of your Cisco CSA server to forward events.

### About this task

Take the following steps to configure your Cisco CSA server to forward events:

### Procedure

1. Open the **Cisco CSA** user interface.

2. Select **Events > Alerts**.

3. Click **New**.

The **Configuration View** window is displayed.

4. Type in values for the following parameters:

- **Name** - Type a name that you want to assign to your configuration.

- **Description** - Type a description for the configuration. This step is not a requirement.

5. From the **Send Alerts**, select the event set from the list to generate alerts.

6. Select the **SNMP** check box.

7. Type a Community name.

The Community name that is entered in the CSA user interface must match the Community name that is configured on IBM QRadar. This option is only available for the SNMPv2 protocol.

8. For the **Manager IP address** parameter, type the IP address of QRadar.

9. Click **Save**.

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Cisco CSA

If QRadar does not automatically detect the log source, add a Cisco CSA log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco CSA devices:

*Table 360. Syslog log source parameters for the Cisco CSA DSM*

Parameter	Value
<b>Log Source type</b>	Cisco CSA
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.  The identifier helps you determine which events came from your Cisco CSA device.

**Related tasks**

[“Adding a log source” on page 5](#)

## SNMPv1 log source parameters for Cisco CSA

If QRadar does not automatically detect the log source, add a Cisco CSA log source on the QRadar Console by using the SNMPv1 protocol.

When using the SNMPv1 protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SNMPv1 events from Cisco CSA devices:

*Table 361. SNMPv1 log source parameters for the Cisco CSA DSM*

Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source type</b>	Cisco CSA
<b>Protocol Configuration</b>	SNMPv1
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.  The identifier helps you determine which events came from your Cisco CSA device.
<b>Community</b>	Type the SNMP community name required to access the system containing SNMP events. The default is Public.
<b>Include OIDs in Event Payload</b>	Clear the Include OIDs in Event Payload checkbox, if selected.  This options allows the SNMP event payload to be constructed using name-value pairs instead of the standard event payload format. Including OIDs in the event payload is required for processing SNMPv2 or SNMPv3 events from certain DSMs.

**Related tasks**

[“Adding a log source” on page 5](#)

## SNMPv2 log source parameters for Cisco CSA

If QRadar does not automatically detect the log source, add a Cisco CSA log source on the QRadar Console by using the SNMPv2 protocol.

When using the SNMPv2 protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SNMPv2 events from Cisco CSA devices:

Table 362. SNMPv2 log source parameters for the Cisco CSA DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source type</b>	Cisco CSA
<b>Protocol Configuration</b>	SNMPv2
<b>Log Source Identifier</b>	<p>Type the IP address or host name for the log source.</p> <p>The identifier helps you determine which events came from your Cisco CSA device.</p>
<b>Community</b>	Type the SNMP community name required to access the system containing SNMP events. The default is Public.
<b>Include OIDs in Event Payload</b>	<p>Clear the Include OIDs in Event Payload checkbox, if selected.</p> <p>This option allows the SNMP event payload to be constructed using name-value pairs instead of the standard event payload format. Including OIDs in the event payload is required for processing SNMPv2 or SNMPv3 events from certain DSMs.</p>

For more information about the SNMPv2 protocol, see [SNMPv2 protocol configuration options](#).

## Cisco Duo

The IBM QRadarDSM for Cisco Duo collects Cisco Duo logs by using the Cisco Duo protocol.

To integrate Cisco Duo with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](#) (<https://www.ibm.com/support>).
  - Universal Cloud REST API protocol
  - Cisco Duo protocol RPM
  - Cisco Duo DSM RPM
2. Configure Cisco Duo to communicate with QRadar by configuring the Admin API on your Cisco Duo dashboard. For more information, see [Configuring Cisco Duo to communicate with QRadar](#).
3. Add a Cisco Duo log source on the QRadar Console by using the Cisco Duo protocol. For more information, see [Cisco Duo protocol log source parameters for Cisco Duo](#).

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Cisco Duo DSM specifications

When you configure the Cisco Duo DSM, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported version of Cisco Duo is before you begin can help reduce frustration during the configuration process.

The QRadar DSM for Cisco Duo collects authentication events from the Cisco Duo Admin API.

The following table describes the specifications for the Cisco Duo DSM.

Table 363. Cisco Duo DSM specifications	
Specification	Value
Manufacturer	Cisco
DSM name	Cisco Duo
RPM file name	DSM-CiscoDuoSecurity-QRadar_version-build_number.noarch.rpm
Supported version	Admin API v2
Protocol	Cisco Duo
Event format	JSON
Recorded event types	Authentication logs
Automatically discovered?	yes
Includes identity?	yes
Includes custom properties?	no
More information	<a href="https://duo.com/docs/adminapi#about-the-admin-api">Cisco Duo documentation about the Admin API</a> ( <a href="https://duo.com/docs/adminapi#about-the-admin-api">https://duo.com/docs/adminapi#about-the-admin-api</a> )

## Configuring Cisco Duo to communicate with QRadar

Before you can add a log source in IBM QRadar, you need to configure the Admin API from your Cisco Dashboard.

### Procedure

1. Log in to the Duo Admin Panel as an administrator.
2. Go to **Applications**, then click **Protect an Application**.
3. Find **Admin API** in the list, then click **Protect**.
4. From the permissions menu, select **Grant read log** permission.

This permission is required for the Cisco Duo protocol to read authentication logs from the Admin API.

5. Record the values for the **Integration Key**, **Secret Key**, and **API hostname**. You need these values when you configure the Cisco Duo log source in QRadar.

6. Click **Save changes**.

**Important:** Because Cisco Duo has rate limits on API calls, you can create only one log source for each customer account.

### Related tasks

[“Adding a log source” on page 5](#)

## Cisco Duo protocol log source parameters for Cisco Duo

If QRadar does not automatically detect the log source, add a Cisco Duo log source on the QRadar Console by using the Cisco Duo protocol.

When you use the Cisco Duo protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect authentication events from the Cisco Duo Admin API:

Table 364. Cisco Duo log source parameters for the Cisco Duo DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Duo
<b>Protocol Configuration</b>	Cisco Duo
<b>Log Source Identifier</b>	Type a unique name for the log source as an identifier for events from Cisco Duo.  The value of the <b>Log Source Identifier</b> parameter must match the <b>Host</b> parameter when you are using the Cisco Duo default workflow. If the Cisco Duo default workflow is modified, then the <b>Log Source Identifier</b> must match the <b>Source</b> value - <code>-source="\$\{/host\}"</code> that is used under the PostEvents section. For more information, see <a href="#">Cisco Duo protocol workflow</a> .

For a complete list of Cisco Duo protocol parameters and their values, see [Cisco Duo protocol configuration options](#).

## Cisco Firepower Management Center

The IBM QRadar DSM for Cisco Firepower Management Center collects Cisco Firepower Management Center events by using the eStreamer API service.

Cisco Firepower Management Center is formerly known as Cisco FireSIGHT Management Center.

QRadar supports Cisco Firepower Management Center V 5.2 to V 7.1.

### Configuration overview

To integrate QRadar with Cisco Firepower Management Center, you must create certificates in the Firepower Management Center interface, and then add the certificates to the QRadar appliances that receive eStreamer event data.

If your deployment includes multiple Cisco Firepower Management Center appliances, you must copy the certificate for each appliance that sends eStreamer events to any temporary location on the QRadar Event Collector. The certificate allows the Cisco Firepower Management Center appliance and the QRadar Console or QRadar Event Collectors to communicate by using the eStreamer API to collect events.

To integrate QRadar with Cisco Firepower Management Center, complete the following steps:

1. Create the eStreamer certificate on your Firepower Management Center appliance. For more information about creating eStreamer certificates, see [“Creating Cisco Firepower Management Center 5.x, 6.x, and 7.x certificates” on page 656](#).
2. Import a Cisco Firepower Management Center certificate in QRadar. For more information about importing a certificate, see [“Importing a Cisco Firepower Management Center certificate in QRadar” on page 657](#).

3. Add a Cisco Firepower Management Center log source on the QRadar Console. For more information about Cisco Firepower Management Center log source parameters, see “[Cisco Firepower Management Center log source parameters](#)” on page 658.

## Supported event types

QRadar supports the following event types from Cisco Firepower Management Center:

- Discovery Events
- Correlation and White List Events
- Impact Flag Alerts
- User Activity
- Malware Events
- File Events
- Connection Events
- Intrusion Events
- Intrusion Event Packet Data
- Intrusion Event Extra Data

Intrusion events that are categorized by the Cisco Firepower Management Center DSM in QRadar use the same QRadar Identifiers (QIDs) as the Snort DSM to ensure that all intrusion events are categorized properly.

Intrusion events in the 1,000,000 - 2,000,000 range are user-defined rules in Cisco Firepower Management Center. User-defined rules that generate events are added as an **Unknown** event in QRadar, and include additional information that describes the event type. For example, a user-defined event can identify as **Unknown:Buffer Overflow** for Cisco Firepower Management Center.

The following table provides sample event messages for the Cisco Firepower Management Center DSM:

Table 367. Cisco Firepower Management Center sample messages supported by the Cisco Firepower Management Center device.		
Event name	Low level category	Sample log message

# Creating Cisco Firepower Management Center 5.x, 6.x, and 7.x certificates

IBM QRadar requires a certificate for every Cisco Firepower Management Center appliance in your deployment. Certificates are generated in pkcs12 format and must be converted to a keystore and a truststore file, which are usable by QRadar appliances.

## Procedure

1. Log in to your Cisco Firepower Management Center interface.
  - If you are using version 5.x, select **System > Local > Registration**.
  - If you are using version 6.x, select **System > Integration**.
  - If you are using version 7.x, click the **System** gear icon, then select **Integration**.
2. Click the **eStreamer** tab.
3. Select the types of events that you want Cisco Firepower Management Center to send to QRadar, and then click **Save**.

The following image lists the types of events that Cisco Firepower Management Center sends to QRadar.

Figure 34. Cisco Firepower Management Center eStreamer Event Configuration

4. Click **Create Client** in the upper right side of the window.
5. In the **Hostname** field, type the IP address or host name, depending on which of the following conditions applies to your environments.
  - If you use a QRadar Console or you use a QRadar All-in-One appliance to collect eStreamer events, type the IP address or host name of your QRadar Console.
  - If you use a QRadar Event Collector to collect eStreamer events, type the IP address or host name for the Event Collector.
  - If you use QRadar High Availability (HA), type the virtual IP address.
6. In the **Password** field, type a password for your certificate. If you choose to provide a password, the password is required to import the certificate.
7. Click **Save**.

The new client is added to the eStreamer Client list and the host can communicate with the eStreamer API on port 8302.

8. Click **Download Certificate** for your host to save the pkcs12 certificate to a file location.
9. Click **OK** to download the file.

## What to do next

You are now ready to import your Cisco Firepower Management Center certificate to your QRadar appliance.

### Related tasks

[“Importing a Cisco Firepower Management Center certificate in QRadar” on page 657](#)

The `estreamer-cert-import.pl` script for QRadar converts your pkcs12 certificate file to a keystore and truststore file and copies the certificates to your QRadar appliance. Repeat this procedure for each Firepower Management Center pkcs12 certificate that you need to import to your QRadar Console or Event Collector.

## Importing a Cisco Firepower Management Center certificate in QRadar

The `estreamer-cert-import.pl` script for QRadar converts your pkcs12 certificate file to a keystore and truststore file and copies the certificates to your QRadar appliance. Repeat this procedure for each Firepower Management Center pkcs12 certificate that you need to import to your QRadar Console or Event Collector.

### Before you begin

You must have `root` or `su - root` privileges to run the `estreamer-cert-import.pl` import script.

### About this task

The `estreamer-cert-import.pl` import script is stored on your QRadar Event Collector when you install the Cisco Firepower eStreamer protocol.

The script converts and imports only 1 pkcs12 file at a time. You are required to import a certificate only for the QRadar appliance that receives the Firepower Management Center events. For example, after the Firepower Management Center event is categorized and normalized by an Event Collector in a QRadar deployment, it is forwarded to the QRadar Console. In this scenario, you would import a certificate to the Event Collector.

When you import a new certificate, existing Firepower Management Center certificates on the QRadar appliance are renamed to `estreamer.keystore.old` and `estreamer.truststore.old`.

### Procedure

1. Log in as the root user by using SSH on the QRadar appliance that will receive the events.
2. Copy the downloaded certificate from your Firepower Management Center appliance to a temporary directory on the QRadar Event Collector.
3. Type the following command to import your pkcs12 file.

```
/opt/qradar/bin/estreamer-cert-import.pl -f <pkcs12_absolute_filepath> options
```

The `-f` parameter is required. All other parameters that are described in the following table are optional.

Table 368. Import script command parameters

Parameter	Description
<code>-f</code>	Identifies the file name of the pkcs12 files to import.

Table 368. Import script command parameters (continued)

Parameter	Description
-o	Overrides the default eStreamer name for the keystore and truststore files. Use the <b>-o</b> parameter when you integrate multiple Firepower Management Center devices. For example, /opt/qradar/bin/estreamer-cert-import.pl -f <file name> -o <IP_address>  The import script creates the following files: <ul style="list-style-type: none"><li>• /opt/qradar/conf/&lt;IP_address&gt;.keystore</li><li>• /opt/qradar/conf/&lt;IP_address&gt;.truststore</li></ul>
-d	Enables verbose mode for the import script. Verbose mode is intended to display error messages for troubleshooting purposes when pkcs12 files fail to import properly.
-p	Specifies a password if a password was provided when you generated the pkcs12 file.
-v	Displays the version information for the import script.
-h	Displays a help message about using the import script.

## Results

The import script displays the location where the import files were copied.

### Example:

```
[root@VM199-22 ~]# /opt/qradar/bin/estreamer-cert-import.pl -f yourCertificate.pkcs12 -o 61estreamer
Successfully generated truststore file [/opt/qradar/conf/61estreamer.truststore].
Successfully generated keystore file [/opt/qradar/conf/61estreamer.keystore].
```

Figure 35. Sample import script output

## Cisco Firepower Management Center log source parameters

When you add a Cisco Firepower Management Center log source on the QRadar Console by using the Cisco Firepower eStreamer protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Cisco Firepower Management Center events from the eStreamer API service.

Table 369. Cisco Firepower eStreamer protocol log source parameters for the Cisco Firepower Management Center DSM

Parameter	Value
<b>Log Source type</b>	Cisco Firepower Management Center
<b>Protocol Configuration</b>	Cisco Firepower eStreamer

For a complete list of Cisco Firepower eStreamer protocol parameters and their values, see [Cisco Firepower eStreamer protocol configuration options](#).

## Related tasks

[“Adding a log source” on page 5](#)

## Cisco Firepower Threat Defense

The IBM QRadar DSM for Cisco Firepower Threat Defense (FTD) collects syslog events from a Cisco Firepower Threat Defense appliance. The syslog events that are collected by the Cisco Firepower Threat Defense DSM were previously collected by the Cisco Firepower Management Center DSM.

QRadar collects the following event types from Cisco Firepower Threat Defense appliances:

- Device health and network-related logs from FTD devices
- Connection, security intelligence, and intrusion logs from FTD devices
- Logs for file and malware events.

For more information about syslog message types for Cisco Firepower Threat Defense, see [Firepower Syslog Message Types](#) on the Cisco website. ([https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/analyze\\_events\\_using\\_external\\_tools.html#id\\_85461](https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/analyze_events_using_external_tools.html#id_85461))

To integrate Cisco Firepower Threat Defense with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - Cisco Firepower Threat Defense DSM RPM
  - Cisco Firewall Devices DSM RPM
2. Configure your Cisco Firepower Threat Defense device to send events to QRadar. For more information, see [Configuring Cisco Firepower Threat Defense to communicate with QRadar](#).
3. If QRadar does not automatically detect the log source, add a Cisco Firepower Threat Defense log source on the QRadar Console.

[“Adding a log source” on page 5](#)

## Cisco Firepower Threat Defense DSM specifications

When you configure the Cisco Firepower Threat Defense, understanding the specifications for the Cisco Firepower Threat Detection DSM can help ensure a successful integration. For example, knowing what the supported version of Cisco Firepower Threat Defense is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Cisco Firepower Threat Defense DSM.

Table 370. Cisco Firepower Threat Defense DSM specifications	
Specification	Value
Manufacturer	Cisco
DSM name	Cisco Firepower Threat Defense
RPM file name	DSM-CiscoFirepowerThreatDefense-QRadar_version-build_number.noarch.rpm
Supported version	6.3
Protocol	Syslog

Table 370. Cisco Firepower Threat Defense DSM specifications (continued)

Specification	Value
Event format	Syslog Comma-separated values (CSV) Name-value pair (NVP)
Recorded event types	Intrusion Connection
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/analyze_events_using_external_tools.html">Firepower Management Center Configuration Guide, Version 6.6</a> ( <a href="https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/analyze_events_using_external_tools.html">https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/analyze_events_using_external_tools.html</a> )

## Configuring Cisco Firepower Threat Defense to communicate with QRadar

To send intrusion or connection events to QRadar by using the syslog protocol, you need to enable external logging and configure basic settings on your Cisco Firepower appliance.

### Procedure

1. Log in to your Cisco Firewall appliance.
2. Enable external logging. For more information, see [FTD Platform Settings That Apply to Security Event Syslog Messages](https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/platform_settings_for_firepower_threat_defense.html#id_84926) ([https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/platform\\_settings\\_for\\_firepower\\_threat\\_defense.html#id\\_84926](https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/platform_settings_for_firepower_threat_defense.html#id_84926)).
3. Enable Logging Destinations. For more information, see [FTD Platform Settings That Apply to Security Event Syslog Messages](https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/platform_settings_for_firepower_threat_defense.html#id_84926) ([https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/platform\\_settings\\_for\\_firepower\\_threat\\_defense.html#id\\_84926](https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/platform_settings_for_firepower_threat_defense.html#id_84926)).
4. Deploy changes. For more information, see [Deploy Configuration Changes](https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/policy_management.html#task_75E181687ECF4EFC8EB6AF4509C20C0B) ([https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/policy\\_management.html#task\\_75E181687ECF4EFC8EB6AF4509C20C0B](https://www.cisco.com/c/en/us/td/docs/security/firepower/660/configuration/guide/fpmc-config-guide-v66/policy_management.html#task_75E181687ECF4EFC8EB6AF4509C20C0B)).

### What to do next

If QRadar does not automatically detect the log source, add a log source in QRadar. For more information, see [Adding a log source](#).

## Configuring QRadar to use previous connection event processing for Cisco Firepower Threat Defense

If you want to change the way that IBM QRadar parses connection events and enable earlier behavior without adding action results, use the DSM Editor to enable previous connection event processing.

By default, Cisco Firepower Threat Defense connection events are extended with firewall action results **ALLOW** or **BLOCK**.

## Procedure

1. On the **Admin** tab, in the **Data Sources** section, click **DSM Editor**.
2. From the **Select Log Source Type** window, select **Cisco Firepower Threat Defense** from the list, and then click **Select**.
3. Click the **Configuration** tab, and then set **Display DSM Parameters Configuration** to on.
4. Set **Use Previous Connection Event Processing** to on.
5. Click **Save**.

## Cisco Firepower Threat Defense sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

## Cisco Firepower Threat Defense sample message when you use the Syslog protocol

The following sample shows an intrusion event that has a Generator ID (GID) and Snort IDs (SID).

```
Aug 14 08:59:30 192.168.0.7 SFIMS : %FTD-5-430001: Protocol: tcp, SrcIP: 10.1.1.57, DstIP: 10.5.12.209, SrcPort: 2049, DstPort: 746, Priority: 1, GID: 1, SID: 648, Revision: 18, Message: \"INDICATOR-SHELLCODE x86 NOOP\", Classification: Executable Code was Detected, User: No Authentication Required, ACPPolicy: test, NAPPolicy: Balanced Security and Connectivity, InlineResult: Blocked
```

*Table 371. Highlighted values in the Cisco Firepower Threat Defense sample event message*

QRadar field name	Highlighted payload values
<b>Event ID</b>	As an intrusion event, a concatenation of the <b>GID</b> and <b>SID</b> is used.
<b>Category</b>	As an intrusion event, the category is set to Snort.
<b>Device Time</b>	If not provided in the DSM, <b>Aug 14 08:59:30</b> is taken from the syslog header.
<b>Source IP</b>	<b>SrcIP</b>
<b>Destination IP</b>	<b>DstIP</b>
<b>Source Port</b>	<b>SrcPort</b>
<b>Destination Port</b>	<b>DstPort</b>
<b>Protocol</b>	<b>Protocol</b>
<b>Severity</b>	<b>5</b> The value in this field is converted and mapped to an appropriate QRadar severity value.

## Cisco FWSM

You can integrate Cisco Firewall Service Module (FWSM) with IBM QRadar.

The Cisco FWSM DSM for QRadar accepts FWSM events by using syslog. QRadar records all relevant Cisco FWSM events.

## Configuring Cisco FWSM to forward syslog events

To integrate Cisco FWSM with IBM QRadar, you must configure your Cisco FWSM appliances to forward syslog events to QRadar.

### Procedure

1. Use a console connection, telnet, or SSH, to log in to the Cisco FWSM.
2. Enable logging:

```
logging on
```

3. Change the logging level:

```
logging trap <level>
```

Where `<level>` is set from levels 1-7. By default, the logging trap level is set to 3 (error).

4. Designate QRadar as a host to receive the messages:

```
logging host [interface] ip_address [tcp[/port] | udp[/port]] [format emblem]
```

For example:

```
logging host dmz1 192.0.2.1
```

Where 192.0.2.1 is the IP address of your QRadar system.

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Cisco FWSM

If QRadar does not automatically detect the log source, add a Cisco FWSM log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco FWSM :

Table 372. Syslog log source parameters for the Cisco FWSM DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Firewall Services Module (FWSM)
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.  The identifier helps you determine which events came from your Cisco FWSM device.

### Related tasks

[“Adding a log source” on page 5](#)

## Cisco Identity Services Engine

The IBM QRadar DSM for Cisco Identity Services Engine (ISE) collects device events from Cisco ISE appliances by using the UDP multiline syslog protocol.

The following table describes the specifications for the Cisco Identity Services Engine DSM:

*Table 373. Cisco Identity Services Engine DSM specifications*

<b>Specification</b>	<b>Value</b>
Manufacturer	Cisco
DSM name	Cisco Identity Services Engine
RPM file name	DSM-CiscoISE-QRadar_version-build_number.noarch.rpm
Supported versions	1.1 to 2.2
Protocol	UDP Multiline Syslog
Event format	Syslog
Recorded event types	Device events
Automatically discovered?	No
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.cisco.com/c/en/us/products/security/identity-services-engine/index.html">Cisco website</a> ( <a href="https://www.cisco.com/c/en/us/products/security/identity-services-engine/index.html">https://www.cisco.com/c/en/us/products/security/identity-services-engine/index.html</a> )

To integrate Cisco ISE with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs on your QRadar Console. RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>):
  - DSMCommon RPM
  - Cisco Identity Services Engine DSM RPM
2. Configure your Cisco ISE appliance to send UDP multiline syslog events to QRadar.
3. Add a Cisco Identity Services Engine log source on the QRadar Console. The following table describes the parameters that require specific values to collect events from Cisco ISE:

*Table 374. Cisco Identity Services Engine log source parameters*

<b>Parameter</b>	<b>Value</b>
<b>Log Source type</b>	Cisco Identity Service Engine
<b>Protocol Configuration</b>	UDP Multiline Syslog
<b>Log Source Identifier</b>	The IP address or host name of the Cisco Identity Service Engine device that sends UDP Multiline Syslog events to QRadar.

Table 374. Cisco Identity Services Engine log source parameters (continued)

Parameter	Value
<b>Listen Port</b>	<p>Type 517 as the port number used by QRadar to accept incoming UDP Multiline Syslog events. The valid port range is 1 - 65535.</p> <p><b>Note:</b> UDP Multiline Syslog events can be assigned to any port that is not in use, except for port 514. The default port that is assigned to the UDP Multiline protocol is UDP port 517. For a list of ports that are used by QRadar, see <i>Common ports and servers used by QRadar</i> in the <i>IBM QRadar Administration Guide</i> or in the <a href="https://www.ibm.com/support/knowledgecenter/SS42VS_7.3.0/com.ibm.qradar.doc/c_qradar_adm_ports_and_servers.html">IBM Knowledge Center</a> (<a href="https://www.ibm.com/support/knowledgecenter/SS42VS_7.3.0/com.ibm.qradar.doc/c_qradar_adm_ports_and_servers.html">https://www.ibm.com/support/knowledgecenter/SS42VS_7.3.0/com.ibm.qradar.doc/c_qradar_adm_ports_and_servers.html</a>).</p> <p>To edit a saved configuration to use a new port number, complete the following steps:</p> <ol style="list-style-type: none"> <li>In the <b>Listen Port</b> field, type the new port number for receiving UDP Multiline Syslog events.</li> <li>Click <b>Save</b>.</li> </ol> <p>The port update is complete and event collection starts on the new port number.</p>
<b>Message ID Pattern</b>	<p>Type the following regular expression (regex) to filter the event payload messages:</p> <p>CISE_\S+ (\d{10})</p>

For a complete list of UDP multiline syslog protocol parameters and their values, see [UDP multiline syslog protocol configuration options](#).

- Configure a remote logging target on your Cisco ISE appliance.
- Configure the event logging categories on your Cisco ISE appliance.

### Related concepts

[“UDP multiline syslog protocol configuration options” on page 237](#)

To create a single-line syslog event from a multiline event, configure a log source to use the UDP multiline protocol. The UDP multiline syslog protocol uses a regular expression to identify and reassemble the multiline syslog messages into single event payload.

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

[“Configuring a remote logging target in Cisco ISE” on page 665](#)

To forward syslog events to IBM QRadar, you must configure your Cisco ISE appliance with a remote logging target.

[“Configuring logging categories in Cisco ISE” on page 665](#)

The Cisco Identity Services Engine DSM for IBM QRadar collects syslog events from multiple event logging categories. To define which events are forwarded to QRadar, you must configure each event logging category on your Cisco ISE appliance.

## Configuring a remote logging target in Cisco ISE

To forward syslog events to IBM QRadar, you must configure your Cisco ISE appliance with a remote logging target.

### Procedure

1. Log in to your Cisco ISE Administration Interface.
2. From the navigation menu, select **Administration > System > Logging > Remote Logging Targets**.
3. Click **Add**, and then configure the following parameters:

Option	Description
<b>Name</b>	Type a unique name for the remote target system.
<b>Description</b>	You can uniquely identify the target system for users.
<b>IP Address</b>	Type the IP address of the QRadar Console or Event Collector.
<b>Port</b>	Type 517 or use the port value that you specified in your Cisco ISE log source for QRadar
<b>Facility Code</b>	From the <b>Facility Code</b> list, select the syslog facility to use for logging events.
<b>Maximum Length</b>	Type 1024 as the maximum packet length allowed for the UDP syslog message.

4. Click **Submit**.

### What to do next

Configure the logging categories that are forwarded by Cisco ISE to QRadar.

## Configuring logging categories in Cisco ISE

The Cisco Identity Services Engine DSM for IBM QRadar collects syslog events from multiple event logging categories. To define which events are forwarded to QRadar, you must configure each event logging category on your Cisco ISE appliance.

### Procedure

1. Log in to your Cisco ISE Administration Interface.
2. From the navigation menu, select **Administration > System > Logging > Logging Categories**.

The following list shows the supported event logging categories for the IBM QRadar DSM for Cisco Identity Services Engine:

- AAA audit
- Failed attempts
- Passed authentication
- AAA diagnostics
- Administrator authentication and authorization
- Authentication flow diagnostics
- Identity store diagnostics
- Policy diagnostics
- Radius diagnostics

- Guest
- Accounting
- Radius accounting
- Administrative and operational audit
- Posture and client provisioning audit
- Posture and client provisioning diagnostics
- Profiler
- System diagnostics
- Distributed management
- Internal operations diagnostics
- System statistics

3. Select an event logging category, and then click **Edit**.
4. From the **Log Severity** list, select a severity for the logging category.
5. In the **Target** field, add your remote logging target for QRadar to the **Select** box.
6. Click **Save**.
7. Repeat this process for each logging category that you want to forward to QRadar.

Events that are forwarded by Cisco ISE are displayed on the **Log Activity** tab in QRadar.

## Cisco Identity Services Engine sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

### Cisco Identity Services Engine sample message when you use the UDP multiline syslog protocol

The following sample event shows that the endpoint failed authentication several times for the same scenario and was rejected.

```

## Cisco IDS/IPS

You can integrate a Cisco IDS/IPS security device with IBM QRadar.

The Cisco IDS/IPS DSM for IBM QRadar collects Cisco IDS/IPS for events by using the Security Device Event Exchange (SDEE) protocol.

The SDEE specification defines the message format and the protocol that is used to communicate the events that are generated by your Cisco IDS/IPS security device. QRadar supports SDEE connections by polling directly to the IDS/IPS device and not the management software, which controls the device.

**Note:** You must have security access or web authentication on the device before you connect to QRadar.

After you configure your Cisco IDS/IPS device, you must configure the SDEE protocol in QRadar. When you configure the SDEE protocol, you must define the URL that is used to access the device. An example of a URL that defines the device is <https://www.example.com/cgi-bin/sdee-server>.

You must use http or https in the URL, which is specific to your Cisco IDS version.

- When you use RDEP (for Cisco IDS 4.0), ensure that the URL has /cgi-bin/event-server at the end of the URL. An example URL is <https://www.example.com/cgi-bin/event-server>.
- When you use SDEE/CIDEE (for Cisco IDS 5.x and later), ensure that the URL has /cgi-bin/sdee-server at the end of the URL. An example URL is <https://www.example.com/cgi-bin/sdee-server>.

### SDEE log source parameters for Cisco IDS/IPS

If QRadar does not automatically detect the log source, add a Cisco Intrusion Prevention System (IPS) log source on the QRadar Console by using the Security Device Event Exchange (SDEE) protocol.

The following table describes the parameters that require specific values to collect SDEE events from Cisco IDS/IPS devices:

Table 375. SDEE log source parameters for the Cisco IDS/IPS DSM	
<b>Parameter</b>	<b>Value</b>
<b>Log Source type</b>	Cisco Intrusion Prevention System (IPS)
<b>Protocol Configuration</b>	SDEE
<b>Log Source Identifier</b>	Type an IP address, host name, or name to identify the SDEE event source.  The identifier helps you determine which events came from your Cisco IDS/IPS device.
<b>URL</b>	Type the URL address to access the log source.  You must use an http or https in the URL. Here are some examples: <ul style="list-style-type: none"><li>• If you are using SDEE/CIDEE (for Cisco IDS v5.x and later), check that /cgi-bin/sdee-server is at the end of the URL. For example, <a href="https://www.example.com/cgi-bin/sdee-server">https://www.example.com/cgi-bin/sdee-server</a>.</li><li>• If you are using RDEP (for Cisco IDS v4.0), check that /cgi-bin/event-server is at the end of the URL. For example, <a href="https://www.example.com/cgi-bin/event-server">https://www.example.com/cgi-bin/event-server</a>.</li></ul>

Table 375. SDEE log source parameters for the Cisco IDS/IPS DSM (continued)

Parameter	Value
<b>Username</b>	Type the user name. This user name must match the SDEE URL user name that is used to access the SDEE URL. The user name can be up to 255 characters in length.
<b>Password</b>	Type the user password. This password must match the SDEE URL password that is used to access the SDEE URL. The password can be up to 255 characters in length.
<b>Events / Query</b>	Type the maximum number of events to retrieve per query. The valid range is 0 - 501 and the default is 100.
<b>Force Subscription</b>	Select this check box if you want to force a new SDEE subscription. The check box forces the server to drop the least active connection and accept a new SDEE subscription connection for this log source. By default, the check box is selected. Clearing the check box continues with any existing SDEE subscription.
<b>Severity Filter Low</b>	Select this check box if you want to configure the severity level as low. Log sources that support SDEE return only the events that match this severity level. By default, the check box is selected.
<b>Severity Filter Medium</b>	Select this check box if you want to configure the severity level as medium. Log sources that support SDEE return only the events that match this severity level. By default, the check box is selected.
<b>Severity Filter High</b>	Select this check box if you want to configure the severity level as high. Log sources that support SDEE return only the events that match this severity level. By default, the check box is selected.

For a complete list of SDEE protocol parameters and their values, see “[SDEE protocol configuration options](#)” on page 210.

## Cisco IOS

---

The IBM QRadar DSM for Cisco IOS accepts Cisco IOS events by using syslog. QRadar records all relevant events.

The following Cisco switches and routers are automatically discovered as Cisco IOS series devices, and their events are parsed by the DSM for Cisco IOS:

- Cisco 12000 Series Routers
- Cisco 6500 Series Switches
- Cisco 7600 Series Routers
- Cisco Carrier Routing System
- Cisco Integrated Services Router.

Make sure that all access control lists (ACLs) are set to LOG.

## Configuring Cisco IOS to forward events

You can configure a Cisco IOS-based device to forward events.

### About this task

Take the following steps to configure your Cisco device:

### Procedure

1. Log in to your Cisco IOS Server, switch, or router.
2. Type the following command to log in to the router in privileged-exec:

```
enable
```

3. Type the following command to switch to configuration mode:

```
conf t
```

4. Type the following commands:

```
logging <IP address>
```

```
logging source-interface <interface>
```

Where:

- <IP address> is the IP address of the IBM QRadar host and the SIM components.

- <interface> is the name of the interface, for example, dmz, lan, ethernet0, or ethernet1.

5. Type the following to configure the priority level:

```
logging trap warning
```

```
logging console warning
```

Where *warning* is the priority setting for the logs.

6. Configure the syslog facility:

```
logging facility syslog
```

7. Save and exit the file.

8. Copy the running-config to startup-config by typing the following command:

```
copy running-config startup-config
```

You are now ready to configure the log source in QRadar.

The configuration is complete. The log source is added to QRadar as Cisco IOS events are automatically discovered. Events that are forwarded to QRadar by Cisco IOS-based devices are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Cisco IOS

If QRadar does not automatically detect the log source, add a Cisco IOS log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from a Cisco IOS device:

Table 376. Syslog log source parameters for the Cisco IOS DSM	
Parameter	Value
<b>Log Source type</b>	Select one of the following devices: <ul style="list-style-type: none"><li>• Cisco IOS</li><li>• Cisco 12000 Series Routers</li><li>• Cisco 6500 Series Switches</li><li>• Cisco 7600 Series Routers</li><li>• Cisco Carrier Routing System</li><li>• Cisco Integrated Services Router</li></ul>
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The identifier helps you determine which events came from your Cisco IOS device.

## Cisco IronPort

IBM QRadar DSM for Cisco IronPort retrieves logs from the following Cisco products: Cisco IronPort, Cisco Email Security Appliance (ESA), and Cisco Web Security Appliance (WSA). The Cisco IronPort DSM retrieves web content filtering events (W3C format), Text Mail Logs, and System Logs.

To integrate Cisco IronPort with QRadar, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](https://www.ibm.com/support/fixcentral/) (<https://www.ibm.com/support/fixcentral/>) onto your QRadar Console:
  - Log File Protocol RPM
  - Cisco IronPort DSM RPM
- Configure Cisco IronPort to communicate with QRadar.
- Optional: Add a Cisco IronPort log source by using the Log File protocol.
- Optional: Add a Cisco IronPort log source by using the Syslog protocol.

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Cisco IronPort DSM specifications

The following table describes the specifications for the Cisco IronPort DSM.

Table 379. Cisco IronPort DSM specifications	
Specification	Value
Manufacturer	Cisco
DSM name	Cisco IronPort
RPM file name	DSM-CiscoIronPort-QRadar_version-build_number.noarch.rpm
Supported versions	<ul style="list-style-type: none"><li>Cisco IronPort: V5.5, V6.5, V7.1, V7.5</li><li>Cisco ESA: V10.0</li><li>Cisco WSA: V10.0</li></ul>
Protocol	Syslog: Cisco IronPort, Cisco WSA Log File Protocol: Cisco IronPort, Cisco ESA
Event format	W3C
Recorded event types	Text Mail Logs, System Logs, Web Content, Filtering Events <b>Important:</b> Critical, Warning and Information logs are supported.
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.cisco.com/c/en/us/products/security/email-security/index.html">Cisco Email Security Appliance</a> <a href="http://www.cisco.com/c/en/us/products/security/web-security-appliance/index.html">Cisco Web Security Appliance</a>

## Configuring Cisco IronPort appliances to communicate with QRadar

Complete the configuration on Cisco IronPort appliances so that they can send events to QRadar.

### Procedure

1. To configure your Cisco IronPort Appliance to push Web Content Filter events, you must configure a log subscription for the Web Content Filter that uses the W3C format. For more information, see your Cisco IronPort documentation.
2. To configure your Cisco Email Security Appliance (ESA) to push message data, anti-virus events, you must configure a log subscription. For more information, see the Cisco ESA documentation: [Configuring Log Subscriptions](https://www.cisco.com/c/dam/en/us/td/docs/security/esa/esa10-0/ESA_10-0_User_Guide.pdf) ([https://www.cisco.com/c/dam/en/us/td/docs/security/esa/esa10-0/ESA\\_10-0\\_User\\_Guide.pdf](https://www.cisco.com/c/dam/en/us/td/docs/security/esa/esa10-0/ESA_10-0_User_Guide.pdf)).
3. To configure your Cisco Web Security Appliance (WSA) to push Web Proxy filtering and traffic monitoring activity events, you must configure a log subscription. For more information, see the Cisco WSA documentation: [Adding and Editing Log Subscriptions](https://www.cisco.com/c/dam/en/us/td/docs/security/wsa/wsa_10-0/WSA_10-1-0_UserGuide.pdf) ([https://www.cisco.com/c/dam/en/us/td/docs/security/wsa/wsa\\_10-0/WSA\\_10-1-0\\_UserGuide.pdf](https://www.cisco.com/c/dam/en/us/td/docs/security/wsa/wsa_10-0/WSA_10-1-0_UserGuide.pdf)).

**Note:** When you add a log subscription on your Cisco Web Security Appliance (WSA), the **Log Style** parameter value must be **Squid**.

## Configuring a Cisco IronPort and Cisco ESA log source by using the log file protocol

You can configure a log source on the QRadar Console so that Cisco IronPort and Cisco Email Security Appliance (ESA) can communicate with QRadar by using the log file protocol.

### Procedure

Configure a Cisco IronPort log source on the QRadar Console by using the log file protocol. The following tables describe the Log File log source parameters that require specific values for retrieving logs from Cisco IronPort and Cisco ESA.

Table 380. Cisco IronPort log source parameters for Log File	
Parameter	Value
Log Source type	Cisco IronPort
Protocol Configuration	Log File Protocol
Log Source Identifier	The <b>Log Source Identifier</b> can be any valid value, including the same value as the <b>Log Source Name</b> parameter, and doesn't need to reference a specific server.
Service Type	From the list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.  The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server that is specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.
Remote IP or Hostname	Type the IP address or host name of the device that contains the event log files.
Remote Port	Type the port that is used to communicate with the remote host. The valid range is 1 - 65535. The options include: <ul style="list-style-type: none"><li>• FTP - TCP Port 21</li><li>• SFTP - TCP Port 22</li><li>• SCP - TCP Port 22</li></ul> If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.
Remote User	Type the user name necessary to log in to the host that contains the event files.
Remote Password	Type the password necessary to log in to the host.
Confirm Password	Confirm the password necessary to log in to the host.

Table 380. Cisco IronPort log source parameters for Log File (continued)

Parameter	Value
SSH Key File	If the system is configured to use key authentication, type the path to the SSH key. When an SSH key file is used, the <b>Remote Password</b> field is ignored.
Remote Directory	Type the directory location on the remote host from which the files are retrieved. The directory path is relative to the user account that is used to log in. <b>Note:</b> For FTP only. If the log files are in the remote user's home directory, you can leave the remote directory blank. A blank remote directory field supports systems where a change in the working directory (CWD) command is restricted.
Recursive	Select this check box to enable the file pattern to search sub folders. By default, the check box is clear. This option is ignored for SCP file transfers.
FTP File Pattern	Must use a regular expression that matches the log files that are generated. The FTP file pattern that you specify must match the name that you assigned to your event files. For example, to collect files that end with .log, type the following command: <code>.*\.\log</code> . For more information, see the <a href="http://docs.oracle.com/javase/tutorial/essential/regex/">Oracle Java documentation</a> ( <a href="http://docs.oracle.com/javase/tutorial/essential/regex/">http://docs.oracle.com/javase/tutorial/essential/regex/</a> ).
Start Time	Type the time of day for the log source to start the file import. This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files.
Recurrence	Type a time interval to determine how frequently the remote directory is scanned for new event log files. The minimum value is 15 minutes. The time interval can include values in hours (H), minutes (M), or days (D). For example, a recurrence of 2H scans the remote directory every 2 hours.

Table 380. Cisco IronPort log source parameters for Log File (continued)

Parameter	Value
Run On Save	Select this check box to start the log file import immediately after the administrator saves the log source.  After the first file import, the log file protocol follows the start time and recurrence schedule that is defined by the administrator.  When selected, this check box clears the list of previously downloaded and processed files.
EPS Throttle	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The valid range is 100 to 5000.
Processor	From the list, select <b>gzip</b> .
Ignore Previously Processed File(s)	Select this check box to track files that were processed by the log file protocol. QRadar examines the log files in the remote directory to determine if a file was previously processed by the log file protocol. If a previously processed file is detected, the log file protocol does not download the file for processing. All files that weren't previously processed are downloaded.  This option only applies to FTP and SFTP Service Types.
Change Local Directory?	Select this check box to define the local directory on the QRadar Console for storing downloaded files during processing.  Administrators can leave this check box clear for more configurations. When this check box is selected, the <b>Local Directory</b> field is displayed so that you can configure the local directory to use for storing files.
Event Generator	W3C. The Event Generator uses W3C to process the web content filter log files.
File Encoding	From the list box, select the character encoding that is used by the events in your log file.

*Table 380. Cisco IronPort log source parameters for Log File (continued)*

Parameter	Value
Folder Separator	Type the character that is used to separate folders for your operating system. The default value is /. Most configurations can use the default value in <b>Folder Separator</b> field. This field is intended for operating systems that use a different character to define separate folders. For example, periods that separate folders on mainframe systems.

## Configuring a Cisco IronPort and Cisco WSA log source by using the Syslog protocol

You can configure a log source on the QRadar Console so that the Cisco IronPort Appliance and Cisco Web Security Appliance (WSA) can communicate with QRadar by using the Syslog protocol.

#### Procedure

Configure a Cisco IronPort log source on the QRadar Console by using Syslog. The following tables describe the Syslog log source parameters that require specific values for retrieving logs from Cisco IronPort and Cisco WSA.

*Table 381. Cisco IronPort log source parameters for Syslog*

Parameter	Value
Log Source type	Cisco IronPort
Protocol Configuration	Syslog
Log Source Identifier	The IPv4 address or host name that identifies the log source. If your network contains multiple devices that are attached to a single management console, specify the IP address of the individual device that created the event. A unique identifier, such as an IP address, prevents event searches from identifying the management console as the source for all of the events.

## Cisco IronPort sample event message

Use this sample event message as a way of verifying a successful integration with QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## Cisco IronPort sample message when you use the Syslog protocol

The following sample event message shows that authentication is failed with Cisco IronPort for an IP.

```
<38>Oct 27 10:45:17 cisco.ironport.test proxylogs: Info: PROX_AUTH : 36407 : [22607] Basic Authentication failed for IP: (172.16.0.1)
```

*Table 382. Highlighted fields in the Cisco IronPort event*

QRadar field name	Highlighted payload field name
<b>Event ID</b>	Login Failed (The value in QRadar is always Login Failed for a payload that contains <b>Basic Authentication failed for IP</b> ).
<b>Event Category</b>	The value in QRadar is <b>IronPort</b> .
<b>Source IP</b>	<b>172.16.0.1</b>
<b>Log Source Time</b>	<b>Oct 27 10:45:17</b>

## Cisco Meraki

The IBM QRadar DSM for Cisco Meraki collects Syslog events from a Cisco Meraki device.

To integrate Cisco Meraki with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the Cisco Meraki DSM RPM on your QRadar Console.
2. Configure your Cisco Meraki device to send Syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Cisco Meraki log source on the QRadar Console. The following table describes the parameters that require specific values to collect Syslog events from Cisco Meraki:

*Table 383. Cisco Meraki Syslog log source parameters*

Parameter	Value
<b>Log Source type</b>	Cisco Meraki
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	<p>The IPv4 address or host name that identifies the log source.</p> <p>If your network contains multiple devices that are attached to a single management console, specify the IP address of the individual device that created the event. A unique identifier, such as an IP address, prevents event searches from identifying the management console as the source for all of the events.</p>

**Tip:** Cisco Meraki does not send events with RFC3164 or RFC5424 headers. As a result, log sources are auto discovered with the log source identifier of the packet IP of the event instead of the hostname or IP address that is in the header. Use the Syslog redirect protocol to use the value in the header instead of the value in the packet IP. For more information, see the [QRadar: Syslog Redirect Protocol FAQ documentation](#) on the support website (<https://www.ibm.com/support/pages/qradar-syslog-redirect-protocol-faq>).

[QRadar: Syslog Redirect Protocol FAQ](#)

## Cisco NAC

The Cisco NAC DSM for IBM QRadar accepts events by using syslog.

QRadar records all relevant audit, error, failure events, quarantine, and infected system events. Before you configure a Cisco NAC device in QRadar, you must configure your device to forward syslog events.

## Configuring Cisco NAC to forward events

You can configure Cisco NAC to forward syslog events:

### Procedure

1. Log in to the Cisco NAC user interface.
2. In the Monitoring section, select **Event Logs**.
3. Click the **Syslog Settings** tab.
4. In the **Syslog Server Address** field, type the IP address of your IBM QRadar.
5. In the **Syslog Server Port** field, type the syslog port number. The default is 514.
6. In the **System Health Log Interval** field, type the frequency, in minutes, for system statistic log events.
7. Click **Update**.

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Cisco NAC

If QRadar does not automatically detect the log source, add a Cisco NAC log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco NAC devices :

Table 387. Syslog log source parameters for the Cisco NAC DSM

Parameter	Value
<b>Log Source type</b>	Cisco NAC appliance
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The identifier helps you determine which events came from your Cisco NAC device.

## Cisco Nexus

The Cisco Nexus DSM for IBM QRadar supports alerts from Cisco NX-OS devices.

Syslog is used to forward events from Cisco Nexus to QRadar. Before you can integrate events with QRadar, you must configure your Cisco Nexus device to forward syslog events.

## Configuring Cisco Nexus to forward events

You can configure syslog on your Cisco Nexus server to forward events:

### Procedure

1. Type the following command to switch to configuration mode:

```
config t
```

2. Type the following commands:

```
logging server <IP address> <severity>
```

Where:

- <IP address> is the IP address of your QRadar Console.
- <severity> is the severity level of the event messages, that range 0 - 7 in value.

For example, `logging server 192.0.2.1 6` forwards information level (6) syslog messages to 192.0.2.1.

3. Type the following command to configure the interface for sending syslog events:

```
logging source-interface loopback
```

4. Type the following command to save your current configuration as the startup configuration:

```
copy running-config startup-config
```

The configuration is complete. The log source is added to IBM QRadar as Cisco Nexus events are automatically discovered. Events that are forwarded to QRadar by Cisco Nexus are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Cisco Nexus

If QRadar does not automatically detect the log source, add a Cisco Nexus log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco Nexus devices :

*Table 388. Syslog log source parameters for the Cisco Nexus DSM*

Parameter	Value
<b>Log Source type</b>	Cisco Nexus
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The identifier helps you determine which events came from your Cisco Nexus device.

For information about configuring a Virtual Device Context (VDC) on your Cisco Nexus device, see your vendor documentation.

## Cisco Nexus sample event message

Use these sample event messages to verify a successful integration with IBM QRadar.

### Cisco Nexus sample message when you use the Syslog protocol

The following sample event message shows a pluggable authentication module (PAM) authentication failed event.

```
<187>Jul 1 15:21:27 <domain> : 2014 Jul 1 15:21:27.206 CEST: %AUTHPRIV-3-SYSTEM_MSG:  
pam_aaa:Authentication failed for user <user> from <IP> - sshd[XXXX]
```

The following sample shows a Radius error message.

```
<187>XXXX: 2016 Jun 30 22:05:09 GMTuno: %RADIUS-3-RADIUS_ERROR_MESSAGE: RADIUS server <IP> failed  
to respond
```

## Cisco Pix

You can integrate Cisco Pix security appliances with IBM QRadar.

The Cisco Pix DSM for QRadar accepts Cisco Pix events by using syslog. QRadar records all relevant Cisco Pix events.

## Configuring Cisco Pix to forward events

You can configure Cisco Pix to forward events.

### Procedure

1. Log in to your Cisco PIX appliance by using a console connection, telnet, or SSH.
2. Type the following command to access Privileged mode:

```
enable
```

3. Type the following command to access Configuration mode:

```
conf t
```

4. Enable logging and time stamp the logs:

```
logging on
```

```
logging timestamp
```

5. Set the log level:

```
logging trap warning
```

6. Configure logging to IBM QRadar:

```
logging host <interface> <IP address>
```

Where:

- <interface> is the name of the interface, for example, DMZ, LAN, ethernet0, or ethernet1.
- <IP address> is the IP address of the QRadar host.

The configuration is complete. The log source is added to QRadar as Cisco Pix Firewall events are automatically discovered. Events that are forwarded to QRadar by Cisco Pix Firewalls are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Cisco Pix

If QRadar does not automatically detect the log source, add a Cisco Pix Firewall log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco Pix Firewall devices :

Table 389. Syslog log source parameters for the Cisco Pix DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Pix Firewall
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.  The identifier helps you determine which events came from your Cisco Pix Firewall.

## Configuring Cisco Stealthwatch to communicate with QRadar

Cisco Stealthwatch can forward events of different message types, including customized syslog messages, to third parties.

### Procedure

1. Log in to the Stealthwatch Management Console (SMC) as an administrator.
2. In the menu bar, click **Configuration > Response Management**.
3. From the **Actions** section in the **Response Management** menu, click **Add > Syslog Message**.
4. In the Add Syslog Message Action window, configure the following parameters:

Parameter	Value
Name	The name for the syslog message action.
Enabled	This check box is enabled by default.

Parameter	Value
<b>IP Address</b>	The IP address of the QRadar Event Collector.
<b>Port</b>	The default port is port 514.
<b>Format</b>	Select <b>Syslog Formats</b> .

5. Enter the following custom format:

```
LEEF:2.0|Lancope|Stealthwatch|6.8|{alarm_type_id}|0x7C|src={source_ip}|
dst={target_ip}|dstPort={port}|proto={protocol}|msg={alarm_type_description}|
fullmessage={details}|start={start_active_time}|end={end_active_time}|
cat={alarm_category_name}|alarmID={alarm_id}|sourceHG={source_host_group_names}|
targetHG={target_host_group_names}|sourceHostSnapshot={source_url}|
targetHostSnapshot={target_url}|flowCollectorName={device_name}|flowCollectorIP={device_ip}|
domain={domain_name}|exporterName={exporter_hostname}|exporterIPAddress ={exporter_ip}|
exporterInfo={exporter_label}|targetUser={target_username}|targetHostname={target_hostname}|
sourceUser={source_username}|alarmStatus={alarm_status}|alarmSev={alarm_severity_name}
```

6. Select the custom format from the list and click **OK**.

**Note:** Use the **Test** button to send test message to QRadar

7. Click **Response Management > Rules**.

8. Click **Add** and select **Host Alarm**.

9. Provide a rule name in the **Name** field.

10. Create rules by selecting values from the **Type** and **Options** menus. To add more rules, click the ellipsis icon. For a Host Alarm, combine as many possible types in a statement as possible.

11. In the **Action** dialog, select **IBM QRadar syslog action** for both **Active** and **Inactive** conditions. The event is forwarded to QRadar when any predefined condition is satisfied.

## Cisco Stealthwatch sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Cisco Stealthwatch sample messages when you use the Syslog protocol

## Cisco Umbrella

The IBM QRadar DSM for Cisco Umbrella collects DNS logs from Cisco Umbrella storage by using an Amazon S3 compatible API.

To integrate Cisco Umbrella with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console in the order that they are listed.
  - Protocol Common RPM
  - Amazon AWS REST API Protocol RPM
  - Cisco Cloud Web Security DSM RPM
  - Cisco Umbrella DSM RPM
2. [Configure your Cisco Umbrella to communicate with QRadar](#).
3. Add a Cisco Umbrella log source on the QRadar Console. The following table describes the parameters that require specific values for Cisco Umbrella event collection.

*Table 397. Amazon AWS S3 REST API log source parameters*

Parameter	Value
<b>Log Source type</b>	Cisco Umbrella
<b>Protocol Configuration</b>	Amazon AWS S3 REST API

Table 397. Amazon AWS S3 REST API log source parameters (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you configured more than one Cisco Umbrella log source, you might want to identify the first log source as <code>ciscoumbrella1</code> , the second log source as <code>ciscoumbrella2</code> , and the third log source as <code>ciscoumbrella3</code> .
<b>Region Name</b> (Signature V4 only)	The region that is associated with the Amazon S3 bucket.
<b>Bucket Name</b>	The name of the AWS S3 bucket where the log files are stored. For example, the bucket name might be <code>cisco-managed-us-west-1</code> .
<b>S3 Endpoint URL</b>	<code>https://s3.amazonaws.com/&lt;bucketname&gt;</code> The endpoint URL that is used to query the AWS S3 REST API. The endpoint URL can be different depending on the device configurations. <b>Important:</b> You must have an Endpoint URL to configure a Cisco managed AWS S3 bucket and a customer-managed AWS S3 bucket.
<b>Directory Prefix</b>	<code>&lt;path&gt;/</code> The location of the root directory on the Cisco Umbrella storage bucket from where the Cisco Umbrella logs are retrieved. For example, the root directory location might be <code>dnslogs/</code> .
<b>File Pattern</b>	<code>.*?\.\csv\.\gz</code>
<b>Event Format</b>	Select <b>Cisco Umbrella CSV</b> from the list. The log source retrieves CSV formatted events.

For a complete list of Amazon AWS S3 REST API protocol parameters and their values, see [Amazon AWS S3 REST API protocol configuration options](#).

### Related concepts

## Configure Cisco Umbrella to communicate with QRadar

IBM QRadar collects Cisco Umbrella events from an Amazon S3 bucket. You must configure your Cisco Umbrella to forward events to QRadar.

To configure Cisco Umbrella, see [Cisco documentation](https://support.umbrella.com/hc/en-us/articles/231248488-Configuring-QRadar-for-use-with-Cisco-Umbrella-Log-Management-in-AWS-S3) (<https://support.umbrella.com/hc/en-us/articles/231248488-Configuring-QRadar-for-use-with-Cisco-Umbrella-Log-Management-in-AWS-S3>).

**Important:** You must have an Endpoint URL to configure a Cisco managed AWS S3 bucket and a customer managed AWS S3 bucket.

## Cisco Umbrella DSM specifications

The following table describes the specifications for the Cisco Umbrella DSM.

<i>Table 398. Cisco Umbrella DSM specifications</i>	
Specification	Value
Manufacturer	Cisco
DSM name	Cisco Umbrella
RPM file name	DSM-CiscoUmbrella-QRadar_version-build_number.noarch.rpm
Supported versions	N/A
Protocol	Amazon AWS S3 REST API
Event format	Cisco Umbrella CSV
Recorded event types	DNS Proxy IP
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://umbrella.cisco.com">Cisco Umbrella product information page</a> ( <a href="https://umbrella.cisco.com">https://umbrella.cisco.com</a> )

## Cisco Umbrella sample event messages

Use these sample event messages as a way of verifying a successful integration with QRadar.

The following tables provide sample event messages for the Cisco Umbrella DSM:

Table 399. Cisco Umbrella sample syslog message

Event name	Low level category	Sample log message
NOERROR	18081 (DNS In Progress)	<pre>{"sourceFile": "test_2017-11-17-15-30-dcd8.csv.gz", "EventType": "DNSLog", "Timestamp": "2017-11-17 15:30:27", "MostGranularIdentity": "Test", "Identities": "Test", "InternalIp": "&lt;IP_address&gt;", "ExternalIp": "&lt;External_IP_address&gt;", "Action": "Allowed", "QueryType": "28(AAAA)", "ResponseCode": "NOERROR", "Domain": "abc.aws.amazon.com.", "Categories": "Ecommerce/Shopping"}   {"sourceFile": "test_2017-11-17-15-30-dcd8.csv.gz", "EventType": "DNSLog", "Timestamp": "2017-11-17 15:30:27", "MostGranularIdentity": "Test", "Identities": "Test", "InternalIp": "&lt;IP_address&gt;", "ExternalIp": "&lt;External_IP_address&gt;", "Action": "Allowed", "QueryType": "28(AAAA)", "ResponseCode": "NOERROR", "Domain": "abc.aws.amazon.com.", "Categories": "Ecommerce/Shopping"}</pre>

Table 400. Cisco Umbrella sample event message

Event name	Low level category	Sample log message
NOERROR	18081 (DNS In Progress)	<pre>"2015-01-16 17:48:41", "ActiveDirectoryUserName", "ActiveDirectoryUserName", ADSite, Network", "&lt;IP_address1&gt;", "&lt;IP_address2&gt;", "Allowed", "1 (A)", "NOERROR", "domain-visited.com.", "Chat, Photo Sharing, Social Networking, Allow List"   "2015-01-16 17:48:41", "ActiveDirectoryUserName", "ActiveDirectoryUserName", ADSite, Network", "&lt;IP_address1&gt;", "&lt;IP_address2&gt;", "Allowed", "1 (A)", "NOERROR", "domain-visited.com.", "Chat, Photo Sharing, Social Networking, Allow List"</pre>

## Cisco VPN 3000 Concentrator

The IBM QRadar DSM for Cisco VPN 3000 Concentrator accepts Cisco VPN Concentrator events by using syslog.

### About this task

QRadar records all relevant events. Before you can integrate with a Cisco VPN concentrator, you must configure your device to forward syslog events to QRadar.

### Procedure

1. Log in to the Cisco VPN 3000 Concentrator command-line interface (CLI).
2. Type the following command to add a syslog server to your configuration:

```
set logging server <IP address>
```

Where *<IP address>* is the IP address of QRadar or your Event Collector.

3. Type the following command to enable system messages to be logged to the configured syslog servers:

```
set logging server enable
```

- Set the facility and severity level for syslog server messages:
  - `set logging server facility <server_facility_parameter>`
  - `set logging server severity <server_severity_level>`

## Results

The log source is added to QRadar as Cisco VPN Concentrator events are automatically discovered. Events that are forwarded to QRadar are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Cisco VPN 3000 Concentrator

If QRadar does not automatically detect the log source, add a Cisco VPN 3000 Series Concentrator log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco VPN 3000 Series Concentrator devices:

Table 401. Syslog log source parameters for the Cisco VPN 3000 Concentrator DSM	
Parameter	Value
<b>Log Source type</b>	Cisco VPN 3000 Series Concentrator
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	<p>Type the IP address or host name for the log source.</p> <p>The identifier helps you determine which events came from your Cisco VPN 3000 Series Concentrator devices.</p>

### Related tasks

## Cisco Wireless LAN Controllers

The IBM QRadar DSM for Cisco Wireless LAN Controllers collects events that are forwarded from Cisco Wireless LAN Controller devices by using Syslog or SNMPv2.

If you collect events from Cisco Wireless LAN Controllers, select the best collection method for your configuration. The Cisco Wireless LAN Controller DSM for QRadar supports both syslog and SNMPv2 events. However, syslog provides all available Cisco Wireless LAN Controller events, whereas SNMPv2 sends only a limited set of security events to QRadar.

## Configuring syslog for Cisco Wireless LAN Controller

You can configure the Cisco Wireless LAN Controller to forward syslog events to IBM QRadar.

### Procedure

- Log in to your Cisco Wireless LAN Controller interface.
- Click the **Management** tab.
- From the menu, select **Logs > Config**.
- In the **Syslog Server IP Address** field, type the IP address of your QRadar Console.
- Click **Add**.
- From the **Syslog Level** list, select a logging level.

The **Information** logging level allows the collection of all Cisco Wireless LAN Controller events above the **Debug** logging level.

7. From the **Syslog Facility** list, select a facility level.
8. Click **Apply**.
9. Click **Save Configuration**.

## What to do next

You are now ready to configure a syslog log source for Cisco Wireless LAN Controller.

## Syslog log source parameters for Cisco Wireless LAN Controllers

If QRadar does not automatically detect the log source, add a Cisco Wireless LAN Controller log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco Wireless LAN Controllers:

Table 402. Syslog log source parameters for the Cisco Wireless LAN Controller DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Wireless LAN Controllers
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.  The identifier helps you determine which events came from your Cisco Wireless LAN Controller.
<b>Enabled</b>	Select the <b>Enabled</b> check box to enable the log source. By default, the check box is selected.
<b>Credibility</b>	From the list, select the credibility of the log source. The range is 0 - 10.  The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	From the list, select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	Select this check box to enable the log source to coalesce (bundle) events.  Automatically discovered log sources use the default value that is configured in the <b>Coalescing Events</b> drop-down list in the QRadar <b>Settings</b> window on the <b>Admin</b> tab.  However, when you create a new log source or update the configuration for an automatically-discovered log source, you can override the default value by configuring this check box for each log source. For more information on settings, see the <i>IBM QRadar Administration Guide</i> .

Table 402. Syslog log source parameters for the Cisco Wireless LAN Controller DSM (continued)

Parameter	Value
<b>Incoming Event Payload</b>	From the list, select the incoming payload encoder for parsing and storing the logs.
<b>Store Event Payload</b>	Select this check box to enable or disable QRadar from storing the event payload.  Automatically discovered log sources use the default value from the <b>Store Event Payload</b> drop-down list in the QRadar <b>Settings</b> window on the <b>Admin</b> tab.  However, when you create a new log source or update the configuration for an automatically discovered log source that you can override the default value by configuring this check box for each log source.

#### Related tasks

[“Adding a log source” on page 5](#)

## Configuring SNMPv2 for Cisco Wireless LAN Controller

SNMP event collection for Cisco Wireless LAN Controllers allows the capture of events for IBM QRadar

#### About this task

The following events are collected:

- SNMP Config Event
- bsn Authentication Errors
- LWAPP Key Decryption Errors

#### Procedure

1. Log in to your Cisco Wireless LAN Controller interface.

2. Click the **Management** tab.

3. From the menu, select **SNMP > Communities**.

You can use the one of the default communities that are created or create a new community.

4. Click **New**.

5. In the **Community Name** field, type the name of the community for your device.

6. In the **IP Address** field, type the IP address of QRadar.

The IP address and IP mask that you specify is the address from which your Cisco Wireless LAN Controller accepts SNMP requests. You can treat these values as an access list for SNMP requests.

7. In the **IP Mask** field, type a subnet mask.

8. From the **Access Mode** list, select **Read Only** or **Read/Write**.

9. From the **Status** list, select **Enable**.

10. Click **Save Configuration** to save your changes.

#### What to do next

You are now ready to create a SNMPv2 trap receiver.

## Configuring a trap receiver for Cisco Wireless LAN Controller

Trap receivers that are configured on Cisco Wireless LAN Controllers define where the device can send SNMP trap messages.

### About this task

To configure a trap receiver on your Cisco Wireless LAN Controller, take the following steps:

### Procedure

1. Click the **Management** tab.
2. From the menu, select **SNMP > Trap Receivers**.
3. In the **Trap Receiver Name** field, type a name for your trap receiver.
4. In the **IP Address** field, type the IP address of IBM QRadar.

The IP address you specify is the address to which your Cisco Wireless LAN Controller sends SNMP messages. If you plan to configure this log source on an Event Collector, you want to specify the Event Collector appliance IP address.

5. From the **Status** list, select **Enable**.
6. Click **Apply** to commit your changes.
7. Click **Save Configuration** to save your settings.

### What to do next

You are now ready to create a SNMPv2 log source in QRadar.

## SNMPv2 log source parameters for Cisco Wireless LAN Controllers

If QRadar does not automatically detect the log source, add a Cisco Wireless LAN Controller log source on the QRadar Console by using the SNMPv2 protocol.

The following table describes the parameters that require specific values to collect SNMPv2 events from Cisco Wireless LAN Controllers:

Table 403. SNMPv2 log source parameters for the Cisco Wireless LAN Controller DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Wireless LAN Controllers
<b>Protocol Configuration</b>	SNMPv2
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The identifier helps you determine which events came from your Cisco Wireless LAN Controller.
<b>Community</b>	Type the SNMP community name that is needed to access the system that contains the SNMP events. The default is Public.
<b>Include OIDs in Event Payload</b>	Select the <b>Include OIDs in Event Payload</b> check box. This option allows the SNMP event payload to be constructed by using name-value pairs instead of the standard event payload format. OIDs in the event payload are needed to process SNMPv2 or SNMPv3 events from certain DSMs.

Table 403. SNMPv2 log source parameters for the Cisco Wireless LAN Controller DSM (continued)

Parameter	Value
<b>Enabled</b>	Select the <b>Enabled</b> check box to enable the log source. By default, the check box is selected.
<b>Credibility</b>	<p>From the list, select the credibility of the log source. The range is 0 - 10.</p> <p>The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.</p>
<b>Target Event Collector</b>	From the list, select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	<p>Select this check box to enable the log source to coalesce (bundle) events.</p> <p>Automatically discovered log sources use the default value that is configured in the <b>Coalescing Events</b> drop-down in the QRadar <b>Settings</b> window on the <b>Admin</b> tab.</p> <p>However, when you create a new log source or update the configuration for an automatically discovered log source, you can override the default value by configuring this check box for each log source.</p>
<b>Store Event Payload</b>	<p>Select this check box to enable or disable QRadar from storing the event payload.</p> <p>Automatically discovered log sources use the default value from the <b>Store Event Payload</b> drop-down in the QRadar <b>Settings</b> window on the <b>Admin</b> tab.</p> <p>However, when you create a new log source or update the configuration for an automatically discovered log source, you can override the default value by configuring this check box for each log source.</p>

For a complete list of SNMPv2 protocol parameters and their values, see “[SNMPv2 protocol configuration options](#)” on page 219.

#### Related tasks

[“Adding a log source” on page 5](#)

## Cisco Wireless Services Module

You can integrate a Cisco Wireless Services Module (WiSM) device with IBM QRadar.

A Cisco WiSM DSM for QRadar accepts events by using syslog. Before you can integrate QRadar with a Cisco WiSM device, you must configure Cisco WiSM to forward syslog events.

# Configuring Cisco WiSM to forward events

You can configure Cisco WiSM to forward syslog events to IBM QRadar.

## Procedure

1. Log in to the Cisco Wireless LAN Controller user interface.
2. Click **Management > Logs > Config**.  
The **Syslog Configuration** window is displayed.
3. In the **Syslog Server IP Address** field, type the IP address of the QRadar host that receives the syslog messages.
4. Click **Add**.
5. Using the **Syslog Level** list, set the severity level for filtering syslog messages to the syslog servers by using one of the following severity levels:
  - **Emergencies** - Severity level 0
  - **Alerts** - Severity level 1 (Default)
  - **Critical** - Severity level 2
  - **Errors** - Severity level 3
  - **Warnings** - Severity level 4
  - **Notifications** - Severity level 5
  - **Informational** - Severity level 6
  - **Debugging** - Severity level 7If you set a syslog level, only those messages whose severity level is equal to or less than the selected syslog level are sent to the syslog server. For example, if you set the syslog level to **Warnings** (severity level 4), only those messages whose severity is 0 - 4 are sent to the syslog servers.
6. From the **Syslog Facility** list, set the facility for outgoing syslog messages to the syslog server by using one of the following facility levels:
  - **Kernel** - Facility level 0
  - **User Process** - Facility level 1
  - **Mail** - Facility level 2
  - **System Daemons** - Facility level 3
  - **Authorization** - Facility level 4
  - **Syslog** - Facility level 5 (default value)
  - **Line Printer** - Facility level 6
  - **USENET** - Facility level 7
  - **Unix-to-Unix Copy** - Facility level 8
  - **Cron** - Facility level 9
  - **FTP Daemon** - Facility level 11
  - **System Use 1** - Facility level 12
  - **System Use 2** - Facility level 13
  - **System Use 3** - Facility level 14
  - **System Use 4** - Facility level 15
  - **Local Use 0** - Facility level 16
  - **Local Use 1** - Facility level 17
  - **Local Use 2** - Facility level 18

- **Local Use 3** - Facility level 19
- **Local Use 4** - Facility level 20
- **Local Use 5** - Facility level 21
- **Local Use 6** - Facility level 22
- **Local Use 7** - Facility level 23

7. Click **Apply**.

8. From the **Buffered Log Level** and the **Console Log Level** lists, select the severity level for log messages sent to the controller buffer and console by using one of the following severity levels:

- **Emergencies** - Severity level 0
- **Alerts** - Severity level 1
- **Critical** - Severity level 2
- **Errors** - Severity level 3 (default value)
- **Warnings** - Severity level 4
- **Notifications** - Severity level 5
- **Informational** - Severity level 6
- **Debugging** - Severity level 7

If you set a logging level, only those messages whose severity is equal to or less than that level are logged by the controller. For example, if you set the logging level to **Warnings** (severity level 4), only those messages whose severity is 0 - 4 are logged.

9. Select the **File Info** check box if you want the message logs to include information about the source file. The default value is enabled.

10. Select the **Proc Info** check box if you want the message logs to include process information. The default value is disabled.

11. Select the **Trace Info** check box if you want the message logs to include trace back information. The default value is disabled.

12. Click **Apply** to commit your changes.

13. Click **Save Configuration** to save your changes.

The configuration is complete. The log source is added to QRadar as Cisco WiSM events are automatically discovered. Events that are forwarded by Cisco WiSM are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Cisco WiSM

If QRadar does not automatically detect the log source, add a Cisco Wireless Services Module (WiSM) log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Cisco WiSM devices:

Table 404. Syslog log source parameters for the Cisco Wireless Services Module DSM	
Parameter	Value
<b>Log Source type</b>	Cisco Wireless Services Module (WiSM)
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source.  The identifier helps you determine which events came from your Cisco WiSM device.

# Chapter 41. Citrix

The Citrix NetScaler DSM for IBM QRadar accepts all relevant audit log events by using syslog.

The Citrix Access Gateway DSM accepts access, audit, and diagnostic events that are forwarded from your Citrix Access Gateway appliance by using syslog.

## Citrix Access Gateway

Configure Syslog on your Citrix Access Gateway to forward events to the QRadar Console or Event Collector.

### Procedure

1. Log in to your Citrix Access Gateway web interface.
2. Click the **Access Gateway Cluster** tab.
3. Select **Logging/Settings**.
4. In the **Server** field, type the IP address of your QRadar Console or Event Collector.
5. From the **Facility** list, select a syslog facility level.
6. In the **Broadcast interval (mins)**, type 0 to continuously forward syslog events to QRadar.
7. Click **Submit** to save your changes.

### Results

The configuration is complete. The log source is added to QRadar as Citrix Access Gateway events are automatically discovered. Events that are forwarded to QRadar by Citrix Access Gateway are displayed on the **Log Activity** tab in QRadar.

## Syslog log source parameters for Citrix Access Gateway

If QRadar does not automatically detect the log source, add a Citrix Access Gateway log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Citrix Access Gateway:

Table 405. Syslog log source parameters for the Citrix Access Gateway DSM	
Parameter	Value
<b>Log Source type</b>	<b>Citrix Access Gateway</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Citrix Access Gateway appliance.

### Related tasks

[“Adding a log source” on page 5](#)

# Citrix NetScaler

---

To integrate Citrix NetScaler events with IBM QRadar, you must configure Citrix NetScaler to forward syslog events.

## Procedure

1. Using SSH, log in to your Citrix NetScaler device as a root user.
2. Type the following command to add a remote syslog server:

```
add audit syslogAction <ActionName> <IP Address> -serverPort 514 -logLevel Info -dateFormat DDMMYYYY
```

Where:

<ActionName> is a descriptive name for the syslog server action.

<IP Address> is the IP address or host name of your QRadar Console.

### Example:

```
add audit syslogAction action-QRadar 192.0.2.1 -serverPort 514 -logLevel Info -dateFormat DDMMYYYY
```

3. Type the following command to add an audit policy:

```
add audit syslogPolicy <PolicyName> <Rule> <ActionName>
```

Where:

<PolicyName> is a descriptive name for the syslog policy.

<Rule> is the rule or expression the policy uses. The only supported value is ns\_true.

<ActionName> is a descriptive name for the syslog server action.

### Example:

```
add audit syslogPolicy policy-QRadar ns_true action-QRadar
```

4. Type the following command to bind the policy globally:

```
bind system global <PolicyName> -priority <Integer>
```

Where:

<PolicyName> is a descriptive name for the syslog policy.

<Integer> is a number value that is used to rank message priority for multiple policies that are communicating by using syslog.

### Example:

```
bind system global policy-QRadar -priority 30
```

When multiple policies have priority (represented by a number value that is assigned to them) the lower number value is evaluated before the higher number value.

5. Type the following command to save the Citrix NetScaler configuration.

```
save config
```

6. Type the following command to verify that the policy is saved in your configuration:

```
sh system global
```

**Note:** For information on configuring syslog by using the Citrix NetScaler user interface, see <http://support.citrix.com/article/CTX121728> or your vendor documentation.

The configuration is complete. The log source is added to QRadar as Citrix NetScaler events are automatically discovered. Events that are forwarded by Citrix NetScaler are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Citrix NetScaler

If QRadar does not automatically detect the log source, add a Citrix NetScaler log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Citrix NetScaler:

Table 406. Syslog log source parameters for the Citrix NetScaler DSM	
Parameter	Value
<b>Log Source type</b>	<b>Citrix NetScaler</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Citrix NetScaler devices.

### Related tasks

## Citrix NetScaler sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Citrix NetScaler sample message when you use the Syslog protocol

The following sample event message shows a successful SSL handshake.

**Tip:** Citrix NetScaler does not send events with RFC3164 or RFC5424 headers, so the log source is not discovered by using a hostname or IP address in the header. Instead, log sources are automatically discovered by using the log source identifier of the event's packet IP. Use the Syslog Redirect protocol to use the value in the header instead of the value in the packet IP. For more information, see [QRadar: Syslog Redirect Protocol FAQ](#) (<https://www.ibm.com/support/pages/qradar-syslog-redirect-protocol-faq>).

# Chapter 42. Cloudera Navigator

The IBM QRadar DSM for Cloudera Navigator collects events from Cloudera Navigator.

The following table identifies the specifications for the Cloudera Navigator DSM:

Table 408. Cloudera Navigator DSM specifications	
Specification	Value
Manufacturer	Cloudera
DSM name	Cloudera Navigator
RPM file name	DSM-ClouderaNavigator-Qradar_version-build_number.noarch.rpm
Supported versions	v2.0
Protocol	Syslog
Recorded event types	Audit events for HDFS, HBase, Hive, Hue, Cloudera Impala, Sentry
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.cloudera.com">Cloudera Navigator website (www.cloudera.com)</a>

To integrate Cloudera Navigator with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Cloudera Navigator DSM RPM
2. Configure your Cloudera Navigator device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Cloudera Navigator log source on the QRadar Console. The following table describes the parameters that require specific values for Cloudera Navigator event collection:

Table 409. Cloudera Navigator log source parameters

Parameter	Value
Log Source type	Cloudera Navigator
Protocol Configuration	Syslog
Log Source Identifier	The IP address or host name in the Syslog header. Use the packet IP address, if the Syslog header does not contain an IP address or host name.

# Configuring Cloudera Navigator to communicate with QRadar

---

You can configure Cloudera Navigator device to send JSON format syslog events to IBM QRadar.

## Before you begin

Ensure that Cloudera Navigator can access port 514 on the QRadar system.

## About this task

When you install Cloudera Navigator, all audit logs are collected automatically. However, you must configure Cloudera Navigator to send audits logs to QRadar by using syslog.

## Procedure

1. Do one of the following tasks:
  - Click **Clusters > Cloudera Management Service > Cloudera Management Service**.
  - On the **Status** tab of the **Home** page, click the **Cloudera Management Service** link in **Cloudera Management Service** table.
2. Click the **Configuration** tab.
3. Search for **Navigator Audit Server Logging Advanced Configuration Snippet**.
4. Depending on the format type, enter one of the following values in the **Value** field:
  - `log4j.logger.auditStream = TRACE,SYSLOG`
  - `log4j.appenders.SYSLOG = org.apache.log4j.net.SyslogAppender`
  - `log4j.appenders.SYSLOG.SyslogHost = <QRadar Hostname>`
  - `log4j.appenders.SYSLOG.Facility = Local2`
  - `log4j.appenders.SYSLOG.FacilityPrinting = true`
  - `log4j.additivity.auditStream = false`
5. Click **Save Changes**.

# Chapter 43. Cloudflare Logs

The IBM QRadar DSM for Cloudflare Logs collects Cloudflare instance events by using the HTTP Receiver protocol or the Amazon AWS S3 REST API protocol.

## Integrate Cloudflare Logs with QRadar by using the HTTP Receiver protocol

To integrate Cloudflare Logs with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol Common RPM
  - HTTP Receiver Protocol RPM
  - DSM Common RPM
  - Cloudflare Logs DSM RPM
2. Configure your Cloudflare instance to send events to QRadar. For more information, see [Configure Cloudflare to send events to QRadar when you use the HTTP Receiver protocol](#).
3. If QRadar does not automatically detect the log source, add a Cloudflare Logs log source on the QRadar Console. For more information, see [HTTP Receiver log source parameters for Cloudflare Logs](#).

## Integrate Cloudflare Logs with QRadar by using the Amazon AWS S3 REST API protocol

To integrate Cloudflare Logs with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol Common RPM
  - Amazon AWS S3 REST API Protocol RPM
  - DSM Common RPM
  - Cloudflare Logs DSM RPM
2. Configure your Cloudflare instance to send events to QRadar. For more information, see [Configuring Cloudflare Logs to forward logs to send events to QRadar when you use the Amazon S3 REST API protocol](#).
3. If QRadar does not automatically detect the log source, add a Cloudflare Logs log source on the QRadar Console. For more information, see [Amazon REST S3 REST API log source parameters for Cloudflare Logs](#).

## Cloudflare Logs DSM specifications

When you configure Cloudflare Logs, understanding the specifications for the Cloudflare Logs DSM can help ensure a successful integration. For example, knowing what protocols are supported for Cloudflare Logs before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Cloudflare Logs DSM.

Table 410. Cloudflare Logs DSM specifications

Specification	Value
Manufacturer	Cloudflare
DSM name	Cloudflare Logs
RPM file name	DSM-CloudflareLogs-QRadar_version-build_number.noarch.rpm
Protocols	HTTP Receiver Amazon AWS S3 REST API
Event format	JSON
Recorded event types	HTTP events, Firewall events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.cloudflare.com">Cloudflare website</a> ( <a href="https://www.cloudflare.com">https://www.cloudflare.com</a> )

## Configure Cloudflare to send events to IBM QRadar when you use the HTTP Receiver protocol

To send Cloudflare Firewall or Cloudflare HTTP events to QRadar when you use the HTTP Receiver protocol, you need to start the Logpush job that you created.

1. To send Cloudflare Firewall events to QRadar, start the Logpush job that you created by typing the following command:

```
curl -s https://api.cloudflare.com/client/v4/zones/<zone_id>/logpush/jobs -X POST -d
'{"name": "<name>", "logpull_options":
"fields=Action,ClientIP,ClientASN,ClientASNDescription,ClientCountry,ClientIPClass,ClientRefererHost,ClientRefererPath,ClientRefererQuery,ClientRefererScheme,ClientRequestHost,ClientRequestMethod,ClientRequestPath,ClientRequestProtocol,ClientRequestQuery,ClientRequestScheme,ClientRequestUserAgent,EdgeColoCode,EdgeResponseStatus,Kind,MatchIndex,Metadata,OriginResponseStatus,OriginatorRayID,RayID,RuleID,Source,Datetime&timestamps=rfc3339", "destination_conf": "<QRadar_URL:LogSource_Port>", "max_upload_bytes": 5000000, "max_upload_records": 1000,
"dataset": "firewall_events", "enabled": true}" -H "X-Auth-Email: <X-Auth-Email>" -H "X-Auth-Key: <X-Auth-Key>"
```

2. To send Cloudflare HTTP events to QRadar, start the Logpush job that you created by typing the following command:

```
curl -s https://api.cloudflare.com/client/v4/zones/<zone_id>/logpush/jobs -X POST -d
'{"name": "<name>", "logpull_options":
"fields=ClientRequestMethod,EdgeResponseStatus,ClientIP,ClientSrcPort,CacheCacheStatus,ClientCountry,ClientDeviceType,ClientIPClass,ClientMTLSAuthCertFingerprint,ClientMTLSAuthStatus,ClientRegionCode,ClientRequestBytes,ClientRequestHost,ClientRequestPath,ClientRequestProtocol,ClientRequestReferer,ClientRequestScheme,ClientRequestSource,ClientRequestURI,ClientRequestUserAgent,ClientSSLCipher,ClientSSLProtocol,ClientXRequestedWith,EdgeEndTimestamp,EdgeRequestHost,EdgeResponseBodyBytes,EdgeResponseBytes,EdgeServerIP,EdgeStartTimestamp,SecurityActions,SecurityRuleIDs,SecuritySources,OriginIP,OriginResponseStatus,OriginSSLProtocol,ParentRayID,RayID,SecurityAction,WAFAttackScore,SecurityRuleID,SecurityRuleDescription,WAFSQLiAttackScore,WAFXSSAttackScore,EdgeStartTimestamp&timestamps=rfc3339", "destination_conf": "<QRadar_URL:LogSource_Port>", "max_upload_bytes": 5000000, "max_upload_records": 1000,
"dataset": "http_requests", "enabled": true}" -H "X-Auth-Email: <X-Auth-Email>" -H "X-Auth-Key: <X-Auth-Key>"
```

### Important:

- For the LogSource Port, you must choose one of the following open ports from Cloudflare:
  - 443 Do not use on QRadar console

- 8088 QRadar on Cloud or On-premises
- 2433 QRadar on On-premises only

When the command is executed, the events are forwarded to QRadar.

## Configuring Cloudflare Logs to send events to IBM QRadar when you use the Amazon S3 REST API protocol

---

When you use the Amazon S3 REST API protocol, IBM QRadar collects Cloudflare Log events from an Amazon S3 bucket.

### Before you begin

Complete the following steps:

1. Configure your Cloudflare instance to push events by creating a Logpush job. For more information, see [Manage via the Cloudflare UI](#) (<https://developers.cloudflare.com/logs/logpush/logpush-dashboard>).
2. To create a Logpush job to send Firewall events, you need to configure and manage jobs by using the Logpush API. For more information, see [Manage via the Logpush API](#) (<https://developers.cloudflare.com/logs/logpush/logpush-configuration-api>).

### About this task

If the Logpush job is created in the Cloudflare UI or by using the Logpush REST API, you must complete the following procedure.

### Procedure

1. Log in to the [Cloudflare UI](#) (<https://dash.cloudflare.com/login>).
2. Select the site where you are configuring logs.
3. Click **Analysis > Logs**.
4. If the **Pushing** switch is in the off position, toggle the switch to **On**.
5. Click **Edit** and then ensure that the appropriate fields are selected, based on which data set is selected.
  - HTTP requests - **ClientRequestMethod**, **Client IP**, **ClientSrcPort**, **EdgeResponseStatus**, **EdgeStartTimestamp**
  - Firewall events - **Action**, **Datetime**, **ClientIP**

### What to do next

Create an SQS Queue and configure S3 ObjectCreated Notifications.

## Create an SQS queue and configure S3 ObjectCreated notifications

---

Before you can add a log source in IBM QRadar, you must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

Complete the following procedures:

1. [Finding the S3 Bucket that contains the data that you want to collect](#).

2. [Creating the SQS queue that is used to receive the ObjectCreated notifications from the S3 Bucket that you used in Step 1.](#)
3. [Setting up SQS queue permissions.](#)
4. [Creating ObjectCreated notifications.](#)
5. [Configuring security credentials for your AWS user account.](#)
6. [Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge.](#)
7. [Adding an Amazon AWS CloudTrail log source on the QRadar Console using an SQS queue.](#)

## Finding the S3 bucket that contains the data that you want to collect

You must find and note the region for S3 bucket that contains the data that you want to collect.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to **S3**.
3. From the **AWS Region** column in the **Buckets** list, note the region where the bucket that you want to collect data from is located. You need the region for the **Region Name** parameter value when you add a log source in IBM QRadar.
4. Enable the checkbox beside the bucket name, and then from the panel that opens to the right, click **Copy Bucket ARN** to copy the value to the clipboard. Save this value or leave it on the clipboard. You need this value when you set up **SQS queue permissions**.

## Creating the SQS queue that is used to receive ObjectCreated notifications

You must create an SQS queue and configure S3 ObjectCreated notifications in the AWS Management Console when you use the Amazon AWS S3 REST API protocol.

### Before you begin

You must complete **Finding the S3 Bucket that contains the data that you want to collect**. The SQS Queue must be in the same region as the AWS S3 bucket that the queue is collecting from.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, and then go to the Simple Queue Service Management Console.
3. In the upper right of the window, change the region to where the bucket is located. You noted this value when you completed the **Finding the S3 Bucket that contains the data that you want to collect** procedure.
4. Select **Create New Queue**, and then type a value for the **Queue Name**.
5. Click **Standard Queue**, select **Configure Queue**, and then change the default values for the following **Queue Attributes**.
  - **Default Visibility Timeout** - 60 seconds (You can use a lower value. In the case of load balanced collection, duplicate events might occur with values of less than 30 seconds. This value can't be 0.)
  - **Message Retention Period** - 14 days (You can use a lower value. In the event of an extended collection, data might be lost.)

Use the default value for the remaining **Queue Attributes**.

More options such as **Redrive Policy** or **SSE** can be used depending on the requirements for your AWS environment. These values should not affect the data collection.

Queue Attributes

<b>Default Visibility Timeout</b>	<input type="text" value="60"/>	<b>seconds</b>	Value must be between 0 seconds and 12 hours.
<b>Message Retention Period</b>	<input type="text" value="14"/>	<b>days</b>	Value must be between 1 minute and 14 days.
<b>Maximum Message Size</b>	<input type="text" value="256"/>	<b>KB</b>	Value must be between 1 and 256 KB.
<b>Delivery Delay</b>	<input type="text" value="0"/>	<b>seconds</b>	Value must be between 0 seconds and 15 minutes.
<b>Receive Message Wait Time</b>	<input type="text" value="0"/>	<b>seconds</b>	Value must be between 0 and 20 seconds.

---

Picture © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

#### 6. Select **Create Queue**.

## Setting up SQS queue permissions

You must set up SQS queue permissions for users to access the queue.

### Before you begin

You must complete **Creating the SQS queue that is used to receive ObjectCreated notifications**.

You can set the SQS queue permissions by using either the Permissions Editor or a JSON policy document.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Go to the SQS Management Console, and then select the queue that you created from the list.
3. From the **Details** panel, record the **ARN** field value.

For example: **arn:aws:sqs:us-east-1:123456789012:MySQSQueueName**

4. To set the SQS queue **Access policy (Permissions)** by using the **AWS Policy generator**, complete the following steps:
  - a) Select **Policy Type > SQS Queue Policy**.
  - b) Add an Access Policy statement.
  - c) From the **Access policy** tab, click **Policy generator**, and then configure the following parameters:

Table 411. Permission parameters

Parameter	Value
<b>Effect</b>	Click <b>Allow</b> .
<b>Principal</b>	Type <b>*</b> (Everybody).
<b>Actions</b>	From the list, select <b>SendMessage</b>
<b>Amazon Resource Name (ARN)</b>	Type your queue ARN: <b>arn:aws:sqs:us-east-1:123456789012:MySQSQueueName</b>

- d) Click **Add Conditionals (Optional)**, and then configure the following parameters:

Table 412. Add Conditionals (Optional) parameters

Parameter	Value
<b>Qualifier</b>	None
<b>Condition</b>	<b>ARNLike</b>
<b>Key</b>	Type aws:SourceArn.
<b>Value</b>	<p>The ARN of the S3 bucket from when you completed the “<a href="#">Finding the S3 bucket that contains the data that you want to collect</a>” on page 308 procedure.</p> <p>For example: aws:s3:::my-example-s3bucket</p>

5. To set the SQS queue permissions by using a JSON policy document, complete the following steps:

a) Click **Add Condition** > **Add Statement**. > **Generate Policy**.

b) Copy and paste the following JSON policy into the **Access policy** window:

Copy and paste might not preserve the white space in the JSON policy. The white space is required. If the white space is not preserved when you paste the JSON policy, paste it into a text editor and restore the white space. Then, copy and paste the JSON policy from your text editor into the **Edit Policy Document** window.

```
{
  "Version": "2008-10-17",
  "Id": "example-ID",
  "Statement": [
    {
      "Sid": "example-statement-ID",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "SQS:SendMessage",
      "Resource": "arn:aws:sqs:us-east-1:123456789012:MySQSQueueName",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::my-example-s3bucket"
        }
      }
    }
  ]
}
```

6. Click **Review Policy**. Ensure that the data is correct, and then click **Save Changes**.

## Creating ObjectCreated notifications

Configure ObjectCreated notifications for the folders that you want to monitor in the bucket.

### Procedure

1. Log in to the AWS Management Console as an administrator.
2. Click **Services**, go to **S3**, and then select a bucket.
3. Click the **Properties** tab, and in the **Events** pane, click **Add notification**. Configure the parameters for the new event.

The following table shows an example of an ObjectCreated notification parameter configuration:

Table 413. Example: New ObjectCreated notification parameter configuration

Parameter	Value
Name	Type a name of your choosing.
Events	Select <b>All object create events</b> .
Prefix	AWSLogs/  <b>Tip:</b> You can choose a prefix that contains the data that you want to find, depending on where the data is located and what data that you want to go to the queue. For example, AWSLogs/, CustomPrefix/AWSLogs/, AWSLogs/123456789012/.
Suffix	json.gz
Send to	SQS queue  <b>Tip:</b> You can send the data from different folders to the same or different queues to suit your collection or QRadar tenant needs. Choose one or more of the following methods: <ul style="list-style-type: none"> <li>• Different folders that go to different queues</li> <li>• Different folders from different buckets that go to the same queue</li> <li>• Everything from a single bucket that goes to a single queue</li> <li>• Everything from multiple buckets that go to a single queue</li> </ul>
SQS	The <b>Queue Name</b> from step 4 of <b>Creating the SQS queue that is used to receive the ObjectCreated notifications</b> .

## Create event notification

The notification configuration identifies the events you want Amazon S3 to publish and the destinations where you want Amazon S3 to send the notifications. [Learn more](#)

### General configuration

Event name  
NewS3ObjectToSQS

Event name can contain up to 255 characters.

Prefix - optional  
Limit the notifications to objects with key starting with specified characters.  
 Example. This value must match the location of the data that you want to collect.

Suffix - optional  
Limit the notifications to objects with key ending with specified characters.  
 Example. Enter a value so that you can filter out unwanted files that match the prefix.

### Event types

Specify at least one type of event for which you want to receive notifications. [Learn more](#)

All object create events  
s3:ObjectCreated:  

- Put  
s3:ObjectCreated:Put
- Post  
s3:ObjectCreated:Post
- Copy  
s3:ObjectCreated:Copy
- Multipart upload completed  
s3:ObjectCreated:CompleteMultipartUpload

Figure 36. Example: Events

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

In the example in figure 1 of a parameter configuration, notifications are created for AWSLogs / from the root of the bucket. When you use this configuration, All ObjectCreated events trigger a notification. If there are multiple accounts and regions in the bucket, everything gets processed. In this example, json.gz is used. This file type can change depending on the data that you are collecting. Depending on the content in your bucket, you can omit the extension or choose an extension that matches the data you are looking for in the folders where you have events set up.

After approximately 5 minutes, the queue that contains data displays. In the **Messages Available** column, you can view the number of messages.

*Figure 37. Number of available messages*

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

4. Click **Services**, then go to **Simple Queue Services**.
  5. Right-click the **Queue Name** from step 4 of **Creating the SQS queue that is used to receive the ObjectCreated notifications**, then select **View/Delete Messages** to view the messages.

*Figure 38. SecureQueue TEST list*

Picture: © 2019 Amazon.com Inc. or its subsidiaries. All Rights Reserved.

## Example: Sample message

```
{ "Records": [ { "eventVersion": "2.1", "eventSource": "aws:s3", "awsRegion": "us-east-2", "eventTime": "2018-12-19T01:51:03.251Z", "eventName": "ObjectCreated:Put", "userIdentity": { "principalId": "AWS:AIDAIZLCFC5TZD36YHNZY" }, "requestParameters": { "sourceIPAddress": "52.46.82.38" }, "responseElements": { "x-amz-request-id": "6C05F1340AA50D21", "x-amz-id-2": "9e8KovdAUJwmYu1qnEv+urr08T0vQ+U0pkPnFYLE6agmJSn745 /T3/tVs0Low/vXonTdATvW23M=" }, "s3": { "s3SchemaVersion": "1.0", "configurationId": "test_SQS_Notification_1", "bucket": { "name": "myBucketName", "ownerIdentity": { "principalId": "A2SGQBYRFBZET" }, "arn": "arn:aws:s3:::myBucketName" }, "object": { "key": "AWSLogs/123456789012/CloudTrail/eu-west-1" } } } ] }
```

```

3/2018/12/19/123456789012_CloudTrail_eu-west-3_TestAccountTrail
_us-east-2_20181219T014838Z.json.gz",
    "size":713,
    "eTag":"1ff1209e4140b4ff7a9d2b922f57f486",
    "sequencer":"005C19A40717D99642"
}
]
}
}

```

**Tip:** In the **key** value, your DSM name displays.

6. Click **Services**, then navigate to **IAM**.
7. Set a **User or Role** permission to access the SQS queue and for permission to download from the target bucket. The user or user role must have permission to read and delete from the SQS queue. For information about adding, managing and changing permissions for IAM users, see the [IAM Users documentation](#). After QRadar reads the notification, and then downloads and processes the target file, the message must be deleted from the queue.

Sample Policy:

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sqs:DeleteMessage",
                "sqs:ReceiveMessage",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket_name>/AWSLogs/*",
                "arn:aws:sqs:us-east-2:<AWS_account_number>:<queue_name>"
            ]
        }
    ]
}

```

You can add multiple buckets to the S3 queue. To ensure that all objects are accessed, you must have a trailing `/*` at the end of the folder path that you added.

You can add this policy directly to a user, a user role, or you can create a minimal access user with **sts:AssumeRole** permissions only. When you configure a log source in QRadar, configure the **assume Role ARN** parameter for QRadar to assume the role. To ensure that all files waiting to be processed in a single run (emptying the queue) can finish without retries, use the default value of 1 hour for the **API Session Duration** parameter.

When you use assumed roles, ensure that the ARN of the user that is assuming the role is in the **Trusted Entities** for that role. You can view the trusted entities that can assume the rule from the **Trust Relationship** tab in **IAM Role**. In addition, the user must have permission to assume roles in that (or any) account. The following examples show a sample trust policy:

#### Allow all IAM users within a specific AWS account to assume a role

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:root"
            },
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"
        }
    ]
}

```

## Allow a specific user to assume a role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::YOUR_ACCOUNT_ID:user/USERNAME"  
            },  
            "Action": "sts:AssumeRole",  
            "Resource": "arn:aws:iam::YOUR_ACCOUNT_ID:role/ROLE_NAME"  
        }  
    ]  
}
```

The following image example shows a sample Amazon AWS CloudTrail log source configuration in QRadar.

**Tip:** Use the Amazon AWS S3 REST API log source parameter values for your DSM when you configure your log source.

# Forwarding ObjectCreated notifications to the SQS queue by using Amazon EventBridge

Create an Amazon EventBridge rule to forward ObjectCreated notifications to a target SQS queue.

## Before you begin

Before you can create a rule in Amazon EventBridge, you must enable Amazon EventBridge on your AWS Management console. For more information, see [Enabling Amazon EventBridge](#).

## Procedure

1. Open the [Amazon EventBridge console](#).
2. From the **Navigation** menu, click **Rules > Create rule**.
3. On the **Create rule** window, complete the following steps:
  - a) Enter a name and description for the rule.  
**Important:** A rule can't have the same name as another rule that is both in the same region and on the same event bus.
  - b) For **Event bus**, select the event bus that you want to associate with this rule. If you select **AWS default event bus**, the rule matches the events that come from your account.
  - c) For **Rule type**, select **Rule with an event pattern**.
4. Click **Next**.
5. For **Event source**, select **AWS events or EventBridge partner events**.
6. For **Creation method**, select **Use pattern form**.
7. In the **Event pattern** window, configure the event pattern by completing the following steps:
  - a) Select the values listed in the table for the following parameters:

Parameter	Value
<b>Event source</b>	<b>AWS services</b>
<b>AWS service</b>	<b>Simple Storage Service (S3)</b>
<b>Event type</b>	<b>Amazon S3 Event Notification</b>

- b) Click the **Specific event(s)** option and select **Object Created**.
- c) Click **Specific bucket(s) by name** and enter the name of the specific bucket that you want to collect events from.
- d) Optional: To enable notifications for a specific folder prefix or file extension, choose **Custom pattern (JSON editor)** instead of **Use pattern form** for the creation method, and create your custom event pattern.

For example, this event pattern filters for Object Created events in your bucket. In this example, example/directory is the directory prefix and .png is the suffix.

```
{  
  "source": ["aws.s3"],  
  "detail-type": ["Object Created"],  
  "detail": {  
    "bucket": {  
      "name": ["<example-bucket>"]  
    },  
    "object": {  
      "key": [{  
        "prefix": "example/directory/"  
      }],  
      "key": [{  
        "suffix": ".png"  
      }]  
    }  
  }  
}
```

- e) Click **Add**, then click **Next**.
8. Choose the SQS queue that you want to use as the target. Enter the name of the queue, then click **Next**.
9. On the **Review and create** page, click **Create rule**.

## Configuring security credentials for your AWS user account

---

You must have your AWS user account access key and the secret access key values before you can configure a log source in QRadar.

### Procedure

1. Log in to your [IAM console](#).
2. Select **Users** from left navigation pane and then select your user name from the list.
3. To create the access keys, click the **Security Credentials** tab, and in the **Access Keys** section, click **Create access key**.
4. Download the CSV file that contains the keys or copy and save the keys.

**Tip:** Save the Access key ID and Secret access key. You need them when you configure a log source in QRadar.

You can view the Secret access key only when it is created.

## HTTP Receiver log source parameters for Cloudflare Logs

---

If IBM QRadar does not automatically detect the log source, add a Cloudflare Logs log source on the QRadar Console by using the HTTP Receiver protocol.

When you use the HTTP Receiver protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect HTTP Receive events from Cloudflare Logs:

Table 414. HTTP Receiver log source parameters for the Cloudflare Logs DSM	
<b>Parameter</b>	<b>Value</b>
<b>Log Source type</b>	Cloudflare Logs
<b>Protocol Configuration</b>	HTTP Receiver
<b>Log Source Identifier</b>	<p>Type a unique name for the log source.</p> <p>The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b>. If you have more than one Cloudflare Logs log source that is configured, you might want to identify the first log source as Cloudflare1, the second log source as Cloudflare2, and the third log source as Cloudflare3.</p>
<b>Communication Type</b>	HTTP or HTTPS, depending on the QRadar url that is used to integrate with QRadar.
<b>TLS version</b>	TLSv1.2

*Table 414. HTTP Receiver log source parameters for the Cloudflare Logs DSM (continued)*

Parameter	Value
<b>Listen Port</b>	The QRadar port that is used to integrate with Cloudflare and is used in the command to start the Logpush job.
<b>Message Pattern</b>	.*

For a complete list of HTTP Receiver protocol parameters and their values, see [HTTP Receiver protocol configuration options](#).

## Amazon AWS S3 REST API log source parameters for Cloudflare Logs

If IBM QRadar does not automatically detect the log source, add a Cloudflare Logs log source on the QRadar Console by using the Amazon AWS S3 REST API protocol.

When you use the Amazon AWS S3 REST API protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Amazon AWS S3 REST API events from Cloudflare Logs:

*Table 415. Amazon AWS S3 REST API log source parameters for the Cloudflare Logs DSM*

Parameter	Value
<b>Log Source type</b>	Cloudflare Logs
<b>Protocol Configuration</b>	Amazon AWS S3 REST API
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you have more than one Cloudflare Logs log source that is configured, you might want to identify the first log source as Cloudflare1, the second log source as Cloudflare2, and the third log source as Cloudflare3.
<b>Event Format</b>	Select <b>LINEBYLINE</b> from the list.
<b>Use as a Gateway Log Source</b>	Select this option for the collected events to flow through the QRadar Traffic Analysis engine and for QRadar to automatically detect one or more log sources.

Table 415. Amazon AWS S3 REST API log source parameters for the Cloudflare Logs DSM (continued)

Parameter	Value
<b>Log Source Identifier Pattern</b>	<p>This option is available when <b>Use as a Gateway Log Source</b> is set to yes.</p> <p>Use this option if you want to define a custom Log Source Identifier for events being processed. This field accepts key value pairs to define the custom Log Source Identifier, where the key is the Identifier Format String, and the value is the associated regex pattern. You can define multiple key value pairs by entering a pattern on a new line. When multiple patterns are used, they are evaluated in order until a match is found and a custom Log Source Identifier can be returned.</p>
<b>Show Advanced Options</b>	Select this option.
<b>File Pattern</b>	<p>This option is available when Show Advanced Options is set to yes.</p> <p>Type a regex for the file pattern that matches the files that you want to pull; for example, <code>.*?\.\log\.\gz</code></p>

For a complete list of Amazon AWS S3 REST API protocol parameters and their values, see [Amazon AWS S3 REST API protocol configuration options](#).

# Chapter 44. CloudPassage Halo

The CloudPassage Halo DSM for IBM QRadar can collect event logs from the CloudPassage Halo account.

The following table identifies the specifications for the CloudPassage Halo DSM:

Table 422. CloudPassage Halo DSM Specifications	
Specification	Value
Manufacturer	CloudPassage
DSM name	CloudPassage Halo
RPM file name	DSM-CloudPassageHalo-build_number.noarch.rpm
Supported versions	All
Event format	Syslog, Log file
QRadar recorded event types	All events
Automatically discovered?	Yes
Included identity?	No
More information	<a href="http://www.cloudpassage.com">CloudPassage website (www.cloudpassage.com)</a>

To integrate CloudPassage Halo with QRadar, use the following steps:

1. If automatic updates are not enabled, download the latest versions of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - CloudPassage Halo RPM
2. Configure your CloudPassage Halo to enable communication with QRadar.
3. If QRadar does not automatically detect CloudPassage Halo as a log source, create a CloudPassage Halo log source on the QRadar Console.

## Configuring CloudPassage Halo for communication with QRadar

To collect CloudPassage Halo events, download and configure the CloudPassage Halo Event Connector script to send syslog events to QRadar.

### Before you begin

Before you can configure the Event Connector, you must create a read-only CloudPassage API key. To create a read-only key, log in to your CloudPassage Portal and click **Add New Key** on the **Site Administration** window.

### About this task

The Event Connector script requires Python 2.6 or later to be installed on the host on which the Event Connector script runs. The Event Connector makes calls to the CloudPassage Events API, which is available to all Halo subscribers.

**Note:** You can configure the CloudPassage Halo Event Collect to write the events to file for QRadar to retrieve by using the Log File Protocol, however, this method is not recommended.

### Procedure

1. Log in to the CloudPassage Portal.

2. Go to **Settings > Site Administration**.
3. Click the **API Keys** tab.
4. Click **Show** for the key you want to use.
5. Copy the key ID and secret key into a text file.

Ensure that the file contains only one line, with the key ID and the secret key separated by a vertical bar/pipe (|), for example, `your_key_id|your_secret_key`. If you want to retrieve events from multiple Halo accounts, add an extra line for each account.

6. Save the file as `haloEvents.auth`.
7. Download the Event Connector script and associated files from <https://github.com/cloudpassage/halo-event-connector-python>.
8. Copy the following files to a Linux or Windows system that has Python 2.6 (or later) installed:

- `haloEvents.py`
- `cpapi.py`
- `cputils.py`
- `remote_syslog.py` (use this script only if you deploy the Event Connector on Windows and you want to send events through syslog)
- `haloEvents.auth`

9. Set the environment variables on the Linux or Windows system:

- On Linux, include the full path to the Python interpreter in the PATH environment variable.
- On Windows, set the following variables:
  - Set the PATH variable to include the location of `haloEvents.py` and the Python interpreter.
  - Set the PYTHONPATH variable to include the location of the Python libraries and the Python interpreter.

10. To send events through syslog with the Event Connector is deployed on a Windows system, run the `haloEvents.py` script with the **--leefsyslog=<QRadar IP>** switch:

```
haloEvents.py --leefsyslog=192.0.2.1
```

By default, the Event Connector retrieves existing events on initial connection and then retrieves only new events thereafter. To start event retrieval from a specific date, rather than retrieving all historical events on startup, use the **--starting=<date>** switch, where date is in the YYYY-MM-DD format:

```
haloEvents.py --leefsyslog=192.0.2.1 --starting=2014-04-02
```

11. To send events through syslog and deploy the Event Connector on a Linux system, configure the local logger daemon.

- a) To check which logger the system uses, type the following command:

```
ls -d /etc/*syslog*
```

Depending on what Linus distribution you have, the following files might be listed:

- `rsyslog.conf`
- `syslog-nginx.conf`
- `syslog.conf`

- b) Edit the appropriate `.conf` file with relevant information for your environment.

Example configuration for `syslog-nginx`:

```
source s_src {
    file("/var/log/leefEvents.txt");
};

destination d_qradar {
    udp("qradar_hostname" port(514));
};

log {
```

```
    source(s_src); destination(d_qradar);
};
```

- c) To run the `haloEvents.py` script with the `--leeffile=<filepath>` switch, type the following command:

```
haloEvents.py --leeffile=/var/log/leefEvents.txt
```

You can include `--starting=YYYY-MM-DD` switch to specify the date from which you want events to be collected for on initial startup.

**Notice:** As an alternative to using syslog, you can write events to a file for QRadar to retrieve by using the Log File protocol. For Windows or Linux to write the events to a file instead, use the `--leeffile=<filename>` switch to specify the file to write to.

## Syslog log source parameters for CloudPassage Halo

If QRadar does not automatically detect the log source, add a CloudPassage Halo log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from CloudPassage Halo:

Table 423. Syslog log source parameters for the CloudPassage Halo DSM	
Parameter	Value
<b>Log Source type</b>	<b>CloudPassage Halo</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your CloudPassage Halo devices.

### Related tasks

## Log File log source parameters for CloudPassage Halo

If QRadar does not automatically detect the log source, add a CloudPassage Halo log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from CloudPassage Halo:

Table 424. Log File log source parameters for the CloudPassage Halo DSM	
Parameter	Value
<b>Log Source type</b>	<b>CloudPassage Halo</b>
<b>Protocol Configuration</b>	<b>Log File</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your CloudPassage Halo devices.

For a complete list of Log File protocol parameters and their values, see [Log File protocol configuration options](#).

# Chapter 45. CloudLock Cloud Security Fabric

The IBM QRadar DSM for CloudLock Cloud Security Fabric collects events from the CloudLock Cloud Security Fabric service.

The following table describes the specifications for the CloudLock Cloud Security Fabric DSM:

Table 425. CloudLock Cloud Security Fabric DSM specifications	
Specification	Value
Manufacturer	CloudLock
DSM name	CloudLock Cloud Security Fabric
RPM file name	DSM-CloudLockCloudSecurityFabric-Qradar_version-build_number.noarch.rpm
Supported versions	NA
Protocol	Syslog
Event format	Log Event Extended Format (LEEF)
Recorded event types	Incidents
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.cloudlock.com/products/">Cloud Cybersecurity</a> ( <a href="https://www.cloudlock.com/products/">https://www.cloudlock.com/products/</a> )

To integrate CloudLock Cloud Security Fabric with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console in the order that they are listed:
  - DSMCommon RPM
  - CloudLock Cloud Security Fabric DSM RPM
2. Configure your CloudLock Cloud Security Fabric service to send Syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a CloudLock Cloud Security Fabric log source on the QRadar Console. The following table describes the parameters that require specific values for CloudLock Cloud Security Fabric event collection:

Table 426. CloudLock Cloud Security Fabric log source parameters

Parameter	Value
<b>Log Source type</b>	CloudLock Cloud Security Fabric
<b>Protocol Configuration</b>	Syslog

The following table provides a sample event message for the CloudLock Cloud Security Fabric DSM:

Table 427. CloudLock Cloud Security Fabric sample message supported by the CloudLock Cloud Security Fabric service

Event name	Low level category	Sample log message

## Configuring CloudLock Cloud Security Fabric to communicate with QRadar

You can configure CloudLock Cloud Security Fabric to communicate with QRadar by using a Python script.

#### Before you begin

- To collect incidents from CloudLock, a script that makes CloudLock API calls is required. This script collects incidents and converts them to Log Event Extended Format (LEEF).
- Python is required.

#### Procedure

- Generate a CloudLock API token. To generate an API token in CloudLock, open the Settings. Go to the **Integrations** panel. Copy the Access token that appears on the page.
- Go to the [CloudLock Support website](https://www.cloudlock.com/support/) (<https://www.cloudlock.com/support/>). Open a support case to obtain the `cl_sample_incidents.py` file and then schedule the script for event collection.

# Chapter 46. Correlog Agent for IBM z/OS

The CorreLog Agent for IBM z/OS DSM for IBM QRadar can collect event logs from your IBM z/OS servers. The following table identifies the specifications for the CorreLog Agent for IBM z/OS DSM:

Specification	Value
Manufacturer	CorreLog
DSM name	CorreLog Agent for IBM z/OS
RPM file name	DSM-CorreLogzOSAgent_qradar-version_build-number.noarch.rpm
Supported versions	7.1 7.2
Protocol	Syslog LEEF
QRadar recorded events	All events
Automatically discovered	Yes
Includes identity	No
Includes custom event properties	No
More information	<a href="https://correlog.com/solutions-and-services/sas-correlog-mainframe.html">Correlog website</a> ( <a href="https://correlog.com/solutions-and-services/sas-correlog-mainframe.html">https://correlog.com/solutions-and-services/sas-correlog-mainframe.html</a> )

To integrate CorreLog Agent for IBM z/OS DSM with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent CorreLog Agent for IBM z/OS RPM from the [IBM Support Website](#) onto your QRadar Console.
2. For each CorreLog Agent instance, configure your CorreLog Agent system to enable communication with QRadar.
3. If QRadar does not automatically discover the DSM, create a log source on the QRadar Console for each CorreLog Agent system you want to integrate. Configure all the required parameters, but use the following table for specific Correlog values:

Parameter	Description
Log Source Type	CorreLog Agent for IBM zOS
Protocol Configuration	Syslog

# Configuring your CorreLog Agent system for communication with QRadar

---

For the procedure to configure your Correlog Agent system for communication with QRadar, see the CZA - CorreLog Agent for z/OS manual that you received from CorreLog with your Agent for z/OS software distribution.

## About this task

Use the following sections of the CZA - CorreLog Agent for z/OS manual:

- General considerations in **Section 1: Introduction**.
- Procedure in **Section 2: Installation**.
- Procedure in the **Section 3: Configuration**.

Ensure that you complete the **Tailoring the Installation for a Proprietary Syslog Extension/IBM QRadar instructions**.

When you start the CorreLog agent, if QRadar does not collect z/OS events, see the **Troubleshooting topic in Section 3**.

- If you want to customize the optional CorreLog Agent parameter file, review QRadar normalized event attributes in **Appendix G: Fields**.

# Chapter 47. CrowdStrike Falcon

The IBM QRadar DSM for CrowdStrike Falcon collects Syslog events that are forwarded by a Falcon SIEM Connector.

To integrate CrowdStrike Falcon with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - CrowdStrike Falcon Host DSM RPM
2. Configure your Falcon SIEM connector to send events to QRadar. For more information, see [Configuring CrowdStrike Falcon to communicate with QRadar](#).
3. If QRadar does not automatically detect the log source, add a CrowdStrike Falcon log source on the QRadar Console. For more information, see [Syslog log source parameters for CrowdStrike Falcon](#).

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## CrowdStrike Falcon DSM specifications

When you configure CrowdStrike Falcon understanding the specifications for the CrowdStrike Falcon DSM can help ensure a successful integration. For example, knowing what the supported version of CrowdStrike Falcon is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the CrowdStrike Falcon DSM.

Table 428. CrowdStrike Falcon DSM specifications	
Specification	Value
Manufacturer	CrowdStrike
DSM name	CrowdStrike Falcon
RPM file name	DSM-CrowdStrikeFalconHost-QRadar_version-build_number.noarch.rpm
Protocol	Syslog
Event format	LEEF, JSON

Table 428. CrowdStrike Falcon DSM specifications (continued)

Specification	Value
Recorded event types	Incident Incident summary Detection summary Authentication Detection status update Uploaded IoCs Network containment IP whitelisting Policy management CrowdStrike store Falcon firewall management Real time response Event streams
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.crowdstrike.com/endpoint-security-products/falcon-platform/">CrowdStrike Falcon Platform website</a> ( <a href="https://www.crowdstrike.com/endpoint-security-products/falcon-platform/">https://www.crowdstrike.com/endpoint-security-products/falcon-platform/</a> )

## Configuring CrowdStrike Falcon to communicate with QRadar

To send LEEF events from CrowdStrike Falcon to IBM QRadar, you must install and configure Falcon SIEM connector.

**Tip:** To obtain CrowdStrike event data, you can also use the CrowdStrike app extension from the IBM Security App Exchange. For more information, see [How to Use CrowdStrike with IBM's QRadar](https://www.crowdstrike.com/blog/tech-center/crowdstrike-qradar/) (<https://www.crowdstrike.com/blog/tech-center/crowdstrike-qradar/>).

### Before you begin

You must have Falcon Administrator privileges to generate API credentials.

### Procedure

1. Obtain a Client ID, Client Secret key and Base URL to configure Falcon SIEM Connector.
  - a) Log in to your CrowdStrike Falcon.
  - b) From the Falcon menu, in the **Support** pane, click **API Clients and KeysSelect**.
  - c) Click **Add new API client**.
  - d) In the **API SCOPES** pane, select **Event streams** and then enable the **Read** option.
  - e) To save your changes, click **Add**.
  - f) Record the **Client ID**, **Client Secret** and **Base URL** values.
2. Install the Falcon SIEM Connector. You must have **Admin (root)** privileges.

**Note:** The SIEM Connector must be deployed on premise, on a system that has one of the following operating systems:

- CentOS/RHEL 6.x - 7.x (64 bit)
- Ubuntu 14.x (64 bit)
- Ubuntu 16.04 (64-bit)
- Ubuntu 18.04 (64-bit)

a) Download the RPM installer package for your operating system to your Linux server.

b) To install the package, type one of the following commands:

- If you have a CentOS operating system, type the `sudo rpm -Uvh <installer package>` command.
- If you have a Ubuntu operating system, type the `sudo dpkg -i <installer package>` command.

The Falcon SIEM Connector installs in the `/opt/crowdstrike/` directory by default.

A service is created in the `/etc/init.d/cs.falconhoseclientd/` directory.

### 3. Configure the SIEM Connector to forward LEEF events to QRadar.

The configuration files are located in the `/opt/crowdstrike/etc/` directory.

- Rename `cs.falconhoseclient.leep.cfg` to `cs.falconhoseclient.cfg` for LEEF configuration settings. The SIEM Connector uses `cs.falconhoseclient.cfg` configuration by default.

The following table describes some of the key parameter values for forwarding LEEF events to QRadar.

*Table 429. Key parameter values*

Key	Description	Value
version	The version of authentication to be used. In this case, it is the API Key Authentication version.	2
api_url	The SIEM connector connects to this endpoint URL.	Specify one of the following values based on your Cloud. <ul style="list-style-type: none"><li>• <code>https://api.crowdstrike.com/sensors/entities/datafeed/v2(US-1)</code></li><li>• <code>https://api.us-2.crowdstrike.com/sensors/entities/datafeed/v2 (US-2)</code></li><li>• <code>https://api.eu-1.crowdstrike.com/sensors/entities/datafeed/v2 (EU-1)</code></li><li>• <code>https://api.laggar.gcw.crowdstrike.com/sensors/entities/datafeed/v2 (US-GOV-1)</code></li></ul>
app_id	An arbitrary string identifier for connecting to Falcon Streaming API.	Any string. For example, FHAPI-LEEF
client_id	The client_id value is used as the credential for client verification.	Obtained at Step 1

Table 429. Key parameter values (continued)

Key	Description	Value
client_secret	The client_secret value is used as the credential for client verification.	Obtained at Step 1
send_to_syslog_server	To enable or disable Syslog push to Syslog server, set the flag to true or false.	True
host	The IP or host name of the SIEM.	The QRadar SIEM IP or host name where the Connector is forwarding the LEEF events.
header_delim	Header prefix and fields are delimited by this value.	The value must be a pipe ( ).
field_delim	The delimiter value that is used to separate key-value pairs.	The value must be a tab (\t).
time_fields	This datetime field value is converted to a specified time format.	The default field is devTime (device time). If a custom LEEF key is used for setting the device time, use a different field name .

4. To start the SIEM Connector service, type one of the following one of the following commands:

- If you have a CentOS operating system, type the `sudo service cs.falconhoseclientd start` command.
- If you have a Ubuntu 14.x operating system, type the `sudo start cs.falconhoseclientd` command.
- If you have a Ubuntu 16.04 or later operating system, type the `sudo systemctl start cs.falconhoseclientd.service` command.

5. Optional: If you want to stop the SIEM Connector service, type one of the following commands:

- If you have a CentOS operating system, type the `sudo service cs.falconhoseclientd stop` command.
- If you have a Ubuntu 14.x operating system, type the `sudo stop cs.falconhoseclientd` command.
- If you have a Ubuntu 16.04 or later operating system, type the `sudo systemctl stop cs.falconhoseclientd.service` command.

6. Optional: If you want to restart the SIEM Connector service, type one of the following commands:

- If you have a CentOS operating system, type the `sudo service cs.falconhoseclientd restart` command.
- If you have a Ubuntu 14.x operating system, type the `sudo restart cs.falconhoseclientd` command.
- If you have an Ubuntu 16.04 or later operating system, type the `sudo systemctl restart cs.falconhoseclientd.service` command.

## What to do next

Add a Syslog log source in QRadar. For more information, see [Syslog log source parameters for CrowdStrike Falcon](#).

## Syslog log source parameters for CrowdStrike Falcon

If QRadar does not automatically detect the log source, add a CrowdStrike Falcon log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Syslog events from CrowdStrike Falcon Connector:

Table 430. Syslog log source parameters for the CrowdStrike Falcon DSM	
Parameter	Value
<b>Log Source type</b>	CrowdStrike Falcon
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	The IP address or host name where the Falcon SIEM Connector is installed.

For more information about the protocol parameters and their values, see [Adding a log source](#).

## CrowdStrike Falcon Host sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

### CrowdStrike Falcon Host sample message when you use the Syslog protocol

The following sample shows a detection summary event that was generated when a known malware accessed a document on the host. This event contains the details of the document and the time that the document was accessed.

```
LEEF:1.0|CrowdStrike|FalconHost|1.0|Suspicious Activity| devTime=2016-06-09 02:57:28  
src=10.1.1.1 srcPort=49220 dst=10.1.1.2 domain=I cat=NetworkAccesses usrName=test

# Chapter 48. CrowdStrike Falcon Data Replicator

The IBM QRadar DSM for CrowdStrike Falcon Data Replicator collects JSON events from a CrowdStrike Falcon Data Replicator.

To integrate the CrowdStrike Falcon Data Replicator with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the IBM support website (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console.
  - Protocol Common RPM
  - Amazon AWS S3 REST API Protocol RPM
  - DSM Common RPM
  - CrowdStrike Falcon Host DSM RPM
2. Configure your CrowdStrike Falcon Data Replicator device to send events to QRadar. For more information, see [“Configuring CrowdStrike Falcon Data Replicator to communicate with IBM QRadar” on page 740](#).
3. If QRadar does not automatically detect the log source, add a CrowdStrike Falcon Data Replicator log source on the QRadar Console. For more information, see [“Amazon AWS S3 REST API parameters for CrowdStrike Falcon Data Replicator log source” on page 740](#).

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## CrowdStrike Falcon Data Replicator DSM specifications

The IBM QRadar DSM for CrowdStrike Falcon Data Replicator supports events that are collected from CrowdStrike FDR by using the Amazon AWS S3 REST API protocol.

The following table lists the specifications for the CrowdStrike Falcon Data Replicator DSM.

Table 432. CrowdStrike Falcon Data Replicator DSM specifications	
Specification	Value
Manufacturer	CrowdStrike
DSM name	Falcon Data Replicator
RPM file name	DSM-CrowdStrikeFalconDataReplicator-QRadar_version-Build_number.noarch.rpm
Supported protocols	Amazon AWS S3 REST API
Event format	JSON
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://falcon.us-2.crowdstrike.com/documentation/page/fa572b1c/falcon-data-replicator">Falcon Data Replicator</a> ( <a href="https://falcon.us-2.crowdstrike.com/documentation/page/fa572b1c/falcon-data-replicator">https://falcon.us-2.crowdstrike.com/documentation/page/fa572b1c/falcon-data-replicator</a> )

# Configuring CrowdStrike Falcon Data Replicator to communicate with IBM QRadar

---

To collect CrowdStrike Falcon Data Replicator events, configure your Falcon Data Replicator to send JSON events to QRadar.

The IBM QRadar DSM for CrowdStrike Falcon Data Replicator supports events that are collected from the Falcon Data Replicator, with the help of Amazon AWS S3 REST API protocol.

## Procedure

Configure CrowdStrike Falcon Data Replicator to communicate with QRadar by following the *Configuration* steps under **Falcon Data Replicator setup** at [Crowdstrike FDR](https://falcon.us-2.crowdstrike.com/documentation/page/fa572b1c/falcon-data-replicator)(<https://falcon.us-2.crowdstrike.com/documentation/page/fa572b1c/falcon-data-replicator>).

## What to do next

Add a CrowdStrike Falcon Data Replicator - Amazon AWS S3 REST log source in QRadar. For more information, see “Amazon AWS S3 REST API parameters for CrowdStrike Falcon Data Replicator log source” on page [740](#).

## Amazon AWS S3 REST API parameters for CrowdStrike Falcon Data Replicator log source

---

The IBM QRadar DSM for CrowdStrike Falcon Data Replicator collects JSON events from a CrowdStrike Falcon Data Replicator.

If QRadar does not automatically detect the log source, add a CrowdStrike Falcon Data Replicator log source on the QRadar Console by using the Amazon AWS REST API protocol.

Configure specific parameters when you are using the Amazon AWS REST API protocol.

The following table describes the parameters that require specific values to collect the Amazon AWS REST API events from CrowdStrike Falcon Data Replicator:

Table 433. CrowdStrike Falcon Data Replicator log source parameters	
Parameter	Value
<b>Log Source type</b>	CrowdStrike Falcon Data Replicator
<b>Protocol Configuration</b>	Amazon AWS REST API
<b>Log Source Identifier</b>	Type a unique name for the log source.
<b>Event Format</b>	Select <b>LINEBYLINE</b>

For a complete list of Amazon AWS S3 REST API protocol parameters and their values, see [Amazon AWS S3 REST API protocol configuration options](#).

For more information about the protocol parameters and their values, see [Adding a log source](#).

## CrowdStrike Falcon Data Replicator sample event message

---

The Falcon Data Replicator feed consists of regular transfers of data (data memory dumps) rather than ongoing streams of data.

The following sample event message shows primary and secondary events that are collected from falcon data replicator.

## Primary Events

```
{
  "event_simpleName": "SensorHeartbeat", "ConfigStateHash": "401382615", "NetworkContainmentState": "0",
  "aip": "10.0.0.0", "ConfigIDBase": "65994763", "SensorStateBitMap": "0", "ConfigBuild": "1007.3.0017706.11",
  "event_platform": "Win", "ConfigurationVersion": "10", "Entitlements": "15", "name": "SensorHeartbeatV4",
  "ConfigIDPlatform": "3", "id": "*****-****-490e-*****-****8", "ConfigIDBuild": "17706", "EffectiveTransmissionClass": "0",
  "aid": "****11****", "ProvisionState": "1", "timestamp": "1705904285259", "cid": "56177c****11****0a0d64485abf698b5018d95f6c"
}
```

Table 434. Highlighted values in the CrowdStrike Falcon Data Replicator sample primary event

QRadar field name	Highlighted payload field name
Event ID	event_simpleName
Source IP	aip
Device Time	timestamp

```
{
  "eid": 118, "UserIp": "10.0.0.3", "CustomerIdString": "56177c****11****0a0d64485abf698b5018d95f6c",
  "EventType": "Event_ExternalApiEvent", "OperationName": "logged", "UTCTimestamp": 1705980053283,
  "AuditKeyValues": [{"ValueString": "123*****", "Key": "APIClientID"}, {"ValueString": "56177c****11****0a0d64485abf698b5018d95f6c", "Key": "cid"}], "Success": true,
  "ExternalApiType": "Event_AuthActivityAuditEvent", "Nonce": 1, "ServiceName": "api_request", "UserId": "", "AgentIdString": "",
  "cid": "56177c****11****0a0d64485abf698b5018d95f6c", "timestamp": "2024-01-23T03:20:53Z"
}
```

Table 435. Highlighted values in the CrowdStrike Falcon Data Replicator sample primary event

QRadar field name	Highlighted payload field name
Event ID	EventType
Source IP	UserIp
Device Time	timestamp

## Secondary Events

```
{
  "GatewayIP": "172.31.80.1", "GatewayMAC": "00-00-5E-00-53-00", "InterfaceAlias": "Ethernet2",
  "InterfaceDescription": "AWS PV Network Device #0", "LocalAddressIP4": "10.0.0.12", "MAC": "00-00-5E-00-53-01",
  "MACPrefix": "00-00-5E", "_time": "1704503615.475", "aid": "123*****", "cid": "123*****"
}
```

Table 436. Highlighted values in the CrowdStrike Falcon Data Replicator sample secondary event

QRadar field name	Highlighted payload field name
Event ID	falcondatareplicator_secondary_event(Fixed for secondary events)
Source IP	aip
Source Mac	MAC
Device Time	time

**Note:** Secondary events are considered as metadata for primary events. If the feed is configured for secondary events, then the Event ID is parsed as described in table 3.

## Types of Secondary Events

The different types of Secondary Events that are supported by IBM QRadar for CrowdStrike Falcon Data Replicator are given in the table.

*Table 437. Types of secondary events in CrowdStrike Falcon Data Replicator*

<b>Event name</b>	<b>Description</b>
<b>aid_master</b>	Contains information for each host, such as hostname, domain, country, and sensor version. <b>Note:</b> This event is updated approx. every 5 minutes.
<b>managedassets</b>	Contains a list of assets that are running the Falcon sensor.
<b>notmanaged</b>	Contains a list of assets that are discovered by Falcon, which do not have the sensor installed.
<b>appinfo</b>	Contains information for every visible application in the environment such as company, file name, and version.
<b>userinfo</b>	Contains user information such as username, login time, and also when the password was last set.

# Chapter 49. CRYPTOCard CRYPTO-Shield

The IBM QRadar DSM for CRYPTOCard CRYPTO-Shield for QRadar accepts events by using syslog.

To integrate CRYPTOCard CRYPTO-Shield events with QRadar, you must manually create a log source to receive syslog events.

Before you can receive events in QRadar, you must configure a log source, then configure your CRYPTOCard CRYPTO-Shield to forward syslog events. Syslog events that are forwarded from CRYPTOCard CRYPTO-Shield devices are not automatically discovered. QRadar can receive syslog events on port 514 for both TCP and UDP.

## Configuring syslog for CRYPTOCard CRYPTO-Shield

To configure your CRYPTOCard CRYPTO-Shield device to forward syslog events:

### Procedure

1. Log in to your CRYPTOCard CRYPTO-Shield device.
2. Configure the following System Configuration parameters:

**Important:** You must have CRYPTOCard Operator access with the assigned default Super-Operator system role to access the System Configuration parameters.

- `log4j.appenders.<protocol>` - Directs the logs to a syslog host where:
  - `<protocol>` is the type of log appender, that determines where you want to send logs for storage. The options are as follows: ACC, DBG, or LOG. For this parameter, type the following entry:  
`org.apache.log4j.net.SyslogAppender`
- `log4j.appenders.<protocol>.SyslogHost <IP address>` - Type the IP address or host name of the syslog server where:
  - `<Protocol>` is the type of log appender, that determines where you want to send logs for storage. The options are as follows: ACC, DBG, or LOG.
  - `<IP address>` is the IP address of the IBM QRadar host to which you want to send logs.

Specify the `IP address` parameter after the `log4j.appenders.<protocol>` parameter is configured.

The configuration is complete. Events that are forwarded to QRadar by CRYPTOCard CRYPTO-Shield are displayed on the **Log Activity** tab.

## Syslog log source parameters for CRYPTOCard CRYPTO-Shield

If QRadar does not automatically detect the log source, add a CRYPTOCard CRYPTO-Shield log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from CRYPTOCard CRYPTO-Shield:

Table 438. Syslog log source parameters for the CRYPTOCard CRYPTO-Shield DSM	
Parameter	Value
Log Source type	CRYPTOCard CRYPTOShield
Protocol Configuration	Syslog

*Table 438. Syslog log source parameters for the CRYPTOCard CRYPTO-Shield DSM (continued)*

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your CRYPTOCard CRYPTO-Shield devices.

# Chapter 50. CyberArk

IBM QRadar provides DSMs to support several different CyberArk devices.

## CyberArk Identity

The IBM QRadar DSM for CyberArk Identity collects logs from a CyberArk Identity log source.

**Important:** The Centrify Identity Platform DSM name is now the CyberArk Identity DSM. The DSM RPM name remains as Centrify Identity Platform in QRadar.

To integrate CyberArk Identity with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol Common RPM
  - Centrify Redrock REST API Protocol RPM
  - DSMCommon RPM
  - Centrify Identity Platform DSM RPM
2. Configure your CyberArk Identity DSM to communicate with QRadar.
3. Add a CyberArk Identity log source on the QRadar Console. The following table describes the Centrify Redrock REST API protocol parameters that require specific values to collect events from CyberArk Identity:

*Table 439. Centrify Redrock REST API protocol log source parameters*

Parameter	Value
<b>Log Source type</b>	CyberArk Identity
<b>Protocol Configuration</b>	Centrify Redrock REST API

For a complete list of Centrify Redrock REST API protocol parameters and their values, see [Centrify Redrock REST API protocol configuration options](#).

### Related concepts

[“CyberArk Identity DSM specifications” on page 745](#)

The following table describes the specifications for the CyberArk Identity DSM.

[“CyberArk Identity sample event message” on page 747](#)

Use this sample event message as a way of verifying a successful integration with QRadar.

### Related tasks

[“Adding a log source” on page 5](#)

[“Configuring CyberArk Identity to communicate with QRadar” on page 746](#)

## CyberArk Identity DSM specifications

The following table describes the specifications for the CyberArk Identity DSM.

**Note:** The CyberArk Identity DSM was formerly called Centrify Identity Platform.

*Table 440. CyberArk Identity DSM specifications*

Specification	Value
Manufacturer	Centrify

Table 440. CyberArk Identity DSM specifications (continued)

Specification	Value
DSM name	CyberArk Identity
RPM file name	DSM-CentrifyIdentityPlatform-QRadar_version-build_number.noarch.rpm
Supported versions	N/A
Protocol	Centrify Redrock REST API
Event format	JSON
Recorded event types	SaaS Core Internal Mobile
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.cyberark.com">CyberArk website</a> ( <a href="https://www.cyberark.com">https://www.cyberark.com</a> )

## Configuring CyberArk Identity to communicate with QRadar

To send events to QRadar from CyberArk Identity, create a user role and configure a user policy on CyberArk Identity. The QRadar user can then create a log source in QRadar.

**Important:** Centrify Identity Platform is now CyberArk Identity. The DSM RPM name remains as Centrify Identity Platform in QRadar.

### Before you begin

Ensure that you have the Tenant ID and admin login details that are supplied by CyberArk. Ensure that you have the correct user permissions for the CyberArk admin portal to complete the following steps:

### Procedure

1. Log in to your CyberArk Identity admin portal.
2. Create a CyberArk Identity user role:
  - a) From the navigation pane, click **Roles > Add Role**.
  - b) In the **Name** field, type the name for the role.
  - c) Select **Members**, and then click **Add**.
  - d) In the **Add Members** window, search for the user name to assign to the role, and then select the member.
  - e) Click **Add**.
  - f) Select **Administrative Rights**, and then click **Add**.
  - g) From the **Description** list, select **Read Only System Administrator**.
  - h) Click **Save**.
3. Create an authentication profile:
  - a) From the navigation pane, click **Settings > Authentication**.
  - b) From the **Platform** menu, click **Authentication Profiles**.

- c) Click **Add Profile**, and then type a name for the profile in the **Profile Name** field.
- d) From the **Challenge 1** pane in the **Authentication Mechanisms** window, select **Password**.
- e) From the **Challenge Pass-Through Duration** list, select **30 minutes**, and then click **OK**. The default is 30 minutes.

**Important:** Do not select any options from the **Challenge 2** pane in the **Authentication Mechanisms** window. Select options only from the **Challenge 1** pane.

#### 4. Configure a user policy:

- a) From the navigation pane, click **Policies > Add Policy Set**.
- b) From the **Policy Setting** pane, type a name for the policy in the **Name** field.
- c) From the **Policy Assignment** pane, click **Specified Roles**.
- d) Click **Add**.
- e) From the **Select Role** window, select the role that you created in Step 2 from the **Role** list, and then click **Add**.
- f) From the **Policy Settings** menu, select **Login Policies > Centrify Portal**.
- g) From the **Enable authentication policy controls** window, select **Yes**.
- h) From the **Default Profile** pane, select the authentication profile that you created in Step 3 from the **Default Profile** list.
- i) Click **Save**.

**Note:** If you have difficulty when configuring CyberArk Identity to communicate with QRadar, contact your CyberArk administrator or your CyberArk contact.

## CyberArk Identity sample event message

Use this sample event message as a way of verifying a successful integration with QRadar.

The following sample event message shows a user login attempt when you use the Centrify Redrock REST API protocol for the CyberArk Identity DSM:

```
{"RequestIsMobileDevice": false, "AuthMethod": "MultiAuth", "Level": "Error", "UserGuid": "c2c7bcc6-9560-44e0-8dff-5be221cd37ee", "Mechanism": "EMail", "Tenant": "AAM0428", "FromIPAddress": "<IP_address>", "ID": "772c2e1908a4f11b.W03.c5ab.a936852233b2232d", "RequestDeviceOS": "Windows", "EventType": "Cloud.Core.Login.MultiFactorChallenge", "RequestHostName": "192.0.2.1", "ThreadType": "RestCall", "UserName": "username@example.com", "NormalizedUser": "username@example.com", "WhenLogged": "/Date(1472679431199)/", "WhenOccurred": " / Date(1472679431199)/", "Target": "username@example.com"}
```

## CyberArk Privileged Threat Analytics

The IBM QRadar DSM for CyberArk Privileged Threat Analytics collects events from a CyberArk Privileged Threat Analytics device.

The following table describes the specifications for the CyberArk Privileged Threat Analytics DSM:

Table 441. CyberArk Privileged Threat Analytics DSM specifications	
Specification	Value
Manufacturer	CyberArk
DSM name	CyberArk Privileged Threat Analytics
RPM file name	DSM-CyberArkPrivilegedThreatAnalytics-Qradar_version-build_number.noarch.rpm
Supported versions	V3.1
Protocol	Syslog

*Table 441. CyberArk Privileged Threat Analytics DSM specifications (continued)*

Specification	Value
Recorded event types	Detected security events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.cyberark.com">CyberArk website</a> ( <a href="http://www.cyberark.com">http://www.cyberark.com</a> )

To integrate CyberArk Privileged Threat Analytics with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - CyberArk Privileged Threat Analytics DSM RPM
  - DSMCommon RPM
2. Configure your CyberArk Privileged Threat Analytics device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a CyberArk Privileged Threat Analytics log source on the QRadar Console. The following table describes the parameters that require specific values for CyberArk Privileged Threat Analytics event collection:

*Table 442. CyberArk Privileged Threat Analytics log source parameters*

Parameter	Value
Log Source type	CyberArk Privileged Threat Analytics
Protocol Configuration	Syslog

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring CyberArk Privileged Threat Analytics to communicate with QRadar

To collect all events from CyberArk Privileged Threat Analytics, you must specify IBM QRadar as the syslog server and configure the syslog format. The CyberArk Privileged Threat Analytics device sends syslog events that are formatted as Log Event Extended Format (LEEF).

#### Procedure

1. On the CyberArk Privileged Threat Analytics machine, go to the `/opt/tomcat/diamond-resources/local/` directory, and open the `systemparm.properties` file in a text editor such as vi.
2. Uncomment the `syslog_outbound` property and then edit the following parameters:

Parameter	Value
<b>Host</b>	The host name or IP address of the QRadar system.
<b>Port</b>	514
<b>Protocol</b>	UDP
<b>Format</b>	LEEF

The following is an example of the syslog\_outbound property:

```
syslog_outbound=[{"host": "SIEM_MACHINE_ADDRESS", "port": "514", "format": "LEEF", "protocol": "UDP"}]
```

The following is an example of the syslog\_outbound property specifying multiple syslog recipients, separated by commas:

```
syslog_outbound=[{"host": "SIEM_MACHINE_ADDRESS", "port": "514", "format": "LEEF", "protocol": "UDP"}, {"host": "SIEM_MACHINE_ADDRESS1", "port": "514", "format": "LEEF", "protocol": "UDP"}, ...]
```

3. Save the `systemparm.properties` configuration file, and then close it.
4. Restart CyberArk Privileged Threat Analytics.

## CyberArk Vault

---

The CyberArk Vault DSM for IBM QRadar accepts events by using syslog that is formatted for Log Event Extended Format (LEEF).

QRadar records both user activities and safe activities from the CyberArk Vault in the audit event logs. CyberArk Vault integrates with QRadar to forward audit logs by using syslog to create a detailed log of privileged account activities.

### Event type format

CyberArk Vault must be configured to generate events in Log Event Extended Format (LEEF) and to forward these events by using syslog. The LEEF format consists of a pipe ( | ) delimited syslog header, and tab separated fields in the log payload section.

If the syslog events from CyberArk Vault are not formatted properly, examine your device configuration or software version to ensure that your appliance supports LEEF. Properly formatted LEEF event messages are automatically discovered and added as a log source to QRadar.

## Configuring syslog for CyberArk Vault

To configure CyberArk Vault to forward syslog events to IBM QRadar, you must edit a file to specify parameters.

### Procedure

1. Log in to your CyberArk device.
2. Edit the `DBParm.ini` file.
3. Configure the following parameters:

*Table 443. Syslog parameters*

Parameter	Description
<b>SyslogServerIP</b>	Type the IP address of QRadar.
<b>SyslogServerPort</b>	Type the UDP port that is used to connect to QRadar. The default value is 514.

Table 443. Syslog parameters (continued)

Parameter	Description
<b>SyslogMessageCodeFilter</b>	Configure which message codes are sent from the CyberArk Vault to QRadar. You can define specific message numbers or a range of numbers. By default, all message codes are sent for user activities and safe activities. <b>Example:</b> To define a message code of 1,2,3,30 and 5-10, you must type: 1,2,3,5-10,30.
<b>SyslogTranslatorFile</b>	Type the file path to the LEEF .xsl translator file. The translator file is used to parse CyberArk audit records data in the syslog protocol.

4. Copy LEEF.xsl to the location specified by the **SyslogTranslatorFile** parameter in the DBParm.ini file.

## Results

The configuration is complete. The log source is added to QRadar as CyberArk Vault events are automatically discovered. Events that are forwarded by CyberArk Vault are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for CyberArk Vault

If QRadar does not automatically detect the log source, add a CyberArk Vault log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from CyberArk Vault:

Table 444. Syslog log source parameters for the CyberArk Vault DSM

Parameter	Value
<b>Log Source type</b>	<b>CyberArk Vault</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your CyberArk Vault devices.

### Related tasks

# Chapter 51. CyberGuard Firewall/VPN Appliance

The CyberGuard Firewall VPN Appliance DSM for IBM QRadar accepts CyberGuard events by using syslog. QRadar records all relevant CyberGuard events for CyberGuard KS series appliances that are forwarded by using syslog.

## Configuring syslog events

To configure a CyberGuard device to forward syslog events:

### Procedure

1. Log in to the CyberGuard user interface.
2. Select the **Advanced** page.
3. Under **System Log**, select **Enable Remote Logging**.
4. Type the IP address of IBM QRadar.
5. Click **Apply**.

The configuration is complete. The log source is added to QRadar as CyberGuard events are automatically discovered. Events that are forwarded by CyberGuard appliances are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for CyberGuard

If QRadar does not automatically detect the log source, add a CyberGuard log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from CyberGuard:

Table 445. Syslog log source parameters for the CyberGuard DSM	
Parameter	Value
<b>Log Source type</b>	<b>CyberGuard TSP Firewall/VPN</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your CyberGuard devices.

### Related tasks

[Adding a log source](#)

# Chapter 52. Damballa Failsafe

The Failsafe DSM for IBM QRadar accepts syslog events by using the Log Event Extended Format (LEEF), enabling QRadar to record all relevant Damballa Failsafe events.

Damballa Failsafe must be configured to generate events in Log Event Extended Format(LEEF) and forward these events by using syslog. The LEEF format consists of a pipe ( | ) delimited syslog header, and tab separated fields in the log event payload.

If the syslog events that are forwarded from your Damballa Failsafe are not correctly formatted in LEEF format, you must check your device configuration or software version to ensure that your appliance supports LEEF. Properly formatted LEEF event messages are automatically discovered and added as a log source to QRadar.

## Configuring syslog for Damballa Failsafe

To collect events, you must configure your Damballa Failsafe device to forward syslog events to IBM QRadar.

### Procedure

1. Log in to your Damballa Failsafe Management Console.
2. From the navigation menu, select **Setup > Integration Settings**.
3. Click the QRadar tab.
4. Select **Enable Publishing to IBM QRadar**.
5. Configure the following options:
  - **Hostname** - Type the IP address or Fully Qualified Name (FQN) of your QRadar Console.
  - **Destination Port** - Type 514. By default, QRadar uses port 514 as the port for receiving syslog events.
  - **Source Port** - This input is not a requirement. Type the Source Port your Damballa Failsafe device uses for sending syslog events.
6. Click **Save**.

The configuration is complete. The log source is added to QRadar as Damballa Failsafe events are automatically discovered. Events that are forwarded by Damballa Failsafe are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Damballa Failsafe

If QRadar does not automatically detect the log source, add a Damballa Failsafe log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Damballa Failsafe:

Table 446. Syslog log source parameters for the Damballa Failsafe DSM	
Parameter	Value
<b>Log Source type</b>	<b>Damballa Failsafe</b>
<b>Protocol Configuration</b>	<b>Syslog</b>

*Table 446. Syslog log source parameters for the Damballa Failsafe DSM (continued)*

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Damballa Failsafe devices.

# Chapter 53. DG Technology MEAS

The IBM QRadar DSM for DG Technology MEAS can collect event logs from your DG Technology MEAS servers.

The following table identifies the specifications for the DG Technology MEAS DSM:

Table 447. DSM Specifications for DG Technology MEAS	
Specification	Value
Manufacturer	DG Technology
Log source type	DG Technology MEAS
RPM file name	DSM-DGTechnologyMEAS-build_number.noarch.rpm
Supported versions	8.x
Protocol configuration	LIEEEF Syslog
Supported event types	Mainframe events
Automatically discovered?	Yes
Includes identity?	No
Includes custom event properties	No
More information	<a href="http://www.dgtechllc.com">DG Technology website</a> ( <a href="http://www.dgtechllc.com">http://www.dgtechllc.com</a> )

To integrate DG Technology MEAS DSM with QRadar, use the following procedures:

1. If automatic updates are not enabled, download and install the most recent DG Technology MEAS RPM from the [IBM Support Website](#) onto your QRadar Console.
2. For each instance of DG Technology MEAS, configure your DG Technology MEAS system to enable communication with QRadar.

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring your DG Technology MEAS system for communication with QRadar

To collect all audit logs and system events from DG Technology MEAS, you must specify QRadar as the syslog server.

### Procedure

1. Log in to your DG Technology MEAS server.
2. Type the following command:

```
java meas/MeasServer 41000 m=qwl lo=IP_address_of_QRadar_host
```

### Results

When QRadar receives events from your DG Technology MEAS, a log source is automatically created and listed on the **Log Sources** window.

---

# Chapter 54. Digital China Networks (DCN)

The Digital China Networks (DCN) DCS/DCRS Series DSM for IBM QRadar can accept events from Digital China Networks (DCN) switches by using syslog.

IBM QRadar records all relevant IPv4 events that are forwarded from DCN switches. To integrate your device with QRadar, you must configure a log source, then configure your DCS or DCRS switch to forward syslog events.

## Supported Appliances

The DSM supports the following DCN DCS/DCRS Series switches:

- DCS - 3650
- DCS - 3950
- DCS - 4500
- DCRS - 5750
- DCRS - 5960
- DCRS - 5980
- DCRS - 7500
- DCRS - 9800

## Configuring a DCN DCS/DCRS Series Switch

---

To collect events, you must configure your DCN DCS/DCRS Series switch in IBM QRadar.

### Procedure

1. Log in to your DCN DCS/DCRS Series Switch command-line interface (CLI).
2. Type the following command to access the administrative mode:

```
enable
```

3. Type the following command to access the global configuration mode:

```
config
```

The command-line interface displays the configuration mode prompt:

```
Switch(Config)#
```

4. Type the following command to configure a log host for your switch:

```
logging <IP address> facility <local> severity <level>
```

Where:

- <IP address> is the IP address of the QRadar Console.
- <local> is the syslog facility, for example, local0.
- <level> is the severity of the syslog events, for example, informational. If you specify a value of informational, you forward all information level events and later (more severe), such as, notifications, warnings, errors, critical, alerts, and emergencies.

For example,

```
logging <IP_address> facility local0 severity informational
```

5. Type the following command to save your configuration changes:

```
write
```

The configuration is complete. You can verify the events that are forwarded to QRadar by viewing events in the **Log Activity** tab.

## Syslog log source parameters for DCN DCS/DCRS Series switches

If QRadar does not automatically detect the log source, add a DCN DCS/DCRS Series switches log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from DCN DCS/DCRS Series switches:

Table 448. Syslog log source parameters for the DCN DCS/DCRS Series switches DSM	
Parameter	Value
<b>Log Source type</b>	<b>DCN DCS/DCRS Series</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your DCN DCS/DCRS Series switches devices.

# Chapter 55. Enterprise-IT-Security.com SF-Sherlock

The IBM QRadar DSM for Enterprise-IT-Security.com SF-Sherlock collects logs from your Enterprise-IT-Security.com SF-Sherlock servers.

The following table describes the specifications for the Enterprise-IT-Security.com SF-Sherlock DSM:

Table 449. Enterprise-IT-Security.com SF-Sherlock DSM specifications	
Specification	Value
Manufacturer	Enterprise-IT-Security.com
DSM name	Enterprise-IT-Security.com SF-Sherlock
RPM file name	DSM-EnterpriseITSecuritySFSherlock-Qradar_version-build_number.noarch.rpm
Supported versions	v8.1 and later
Event format	Log Event Extended Format (LEEF)
Recorded event types	All_Checks, DB2_Security_Configuration, JES_Configuration, Job_Entry_System_Attack, Network_Parameter, Network_Security, No_Policy, Resource_Access_Viol, Resource_Allocation, Resource_Protection, Running_System_Change, Running_System_Security, Running_System_Status, Security_Dbbase_Scan, Security_Dbbase_Specialty, Security_Dbbase_Status, Security_Parm_Change, Security_System_Attack, Security_System_Software, Security_System_Status, SF-Sherlock, Sherlock_Diverse, Sherlock_Diverse, Sherlock_Information, Sherlock_Specialties, Storage_Management, Subsystem_Scan, Sysplex_Security, Sysplex_Status, System_Catalog, System_File_Change, System_File_Security, System_File_Specialty, System_Log_Monitoring, System_Module_Security, System_Process_Security, System_Residence, System_Tampering, System_Volumes, TSO_Status, UNIX_OMVS_Security, UNIX_OMVS_System, User Defined_Monitoring, xx_Resource_Prot_Templ
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.enterprise-it-security.com">Enterprise-IT-Security website</a> ( <a href="http://www.enterprise-it-security.com">http://www.enterprise-it-security.com</a> )

To integrate Enterprise-IT-Security.com SF-Sherlock with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Enterprise-IT-Security.com SF-Sherlock DSM RPM
  - DSM Common RPM
2. Configure your Enterprise-IT-Security.com SF-Sherlock device to send syslog events to QRadar.

3. If QRadar does not automatically detect the log source, add a Enterprise-IT-Security.com SF-Sherlock log source on the QRadar Console. The following table describes the parameters that require specific values for Enterprise-IT-Security.com SF-Sherlock event collection:

*Table 450. Enterprise-IT-Security.com SF-Sherlock log source parameters*

Parameter	Value
Log Source type	Enterprise-IT-Security.com SF-Sherlock

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring Enterprise-IT-Security.com SF-Sherlock to communicate with QRadar

Before you can send SF-Sherlock events and assessment details to QRadar, implement the SF-Sherlock 2 QRadar connection kit.

### About this task

The information that is sent to QRadar can be defined and selected in detail. Regardless of the selected transfer method, all information reaches QRadar as LEEF-formatted records.

### Procedure

1. Install the UMODQR01 and UMODQR02 SF-Sherlock SMP/E user modifications by using the corresponding SHERLOCK.SSHKSAMP data set members.
2. If you send SF-Sherlock’s LEEF records to a QRadar syslog daemon, which is generally the preferred transfer method, you must install the SF-Sherlock universal syslog message router in the USS environment of z/OS. You will find all installation details within the UNIXCMDL member of the SHERLOCK.SSHKSAMP data set.
3. Optional: If you transfer the logs by FTP or another technique, you must adapt the UMODQR01 user modification.
4. Enter the IP address for the QRadar LEEF syslog server, transfer method (UDP or TCP), and port number (514) in the QRADARSE member of SF-Sherlock’s `init-deck` parameter configuration file.
5. Allocate the QRadar related log data set by using the ALLOCQRG job of the SHERLOCK.SSHKSAMP data set. It is used by the SHERLOCK started procedure (STC) to keep all QRadar LEEF records transferring to QRadar.
6. The QRDARTST member of the SHERLOCK.SSHKSAMP data set can be used to test the SF-Sherlock 2 QRadar message routing connection. If QRadar receives the test events, the implementation was successful.
7. Enable the SF-Sherlock 2 QRadar connection in your SF-Sherlock installation by activating QRADAR00 (event monitoring) and optionally, the QRADAR01 (assessment details) `init-deck` members, through the already prepared ADD QRADARxx statements within the \$BUILD00 master control member.
8. Refresh or recycle the SHERLOCK started procedure to activate the new master control member that enables the connection of SF-Sherlock to QRadar.

# Chapter 56. Epic SIEM

The IBM QRadar DSM for Epic SIEM can collect event logs from your Epic SIEM.

The following table identifies the specifications for the Epic SIEM DSM:

Table 451. Epic SIEM DSM specifications	
Specification	Value
Manufacturer	Epic
DSM name	Epic SIEM
RPM file name	DSM-EpicSIEM-QRadar_version-build_number.noarch.rpm
Supported versions	Epic 2014, Epic 2015, Epic 2017, Epic 2022
Event format	LEEF
Recorded event types	Audit Authentication
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="#">Epic website</a>

To integrate Epic SIEM DSM with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Epic SIEM DSM RPM
  - DSMCommon RPM
2. Configure your Epic SIEM device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an Epic SIEM log source on the QRadar Console. The following table describes the parameters that require specific values for Epic SIEM event collection:

Table 452. Epic SIEM log source parameters

Parameter	Value
Log Source type	Epic SIEM
Protocol Configuration	Syslog

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring Epic SIEM 2014 to communicate with QRadar

To collect syslog events from Epic SIEM 2014, you must add an external syslog server for the IBM QRadar host.

### Procedure

1. If all web services are not enabled for your instance of Interconnect, complete the following steps to run the required **SendSIEMSyslogAudit** service:
  - a) To access the **Interconnect Configuration Editor**, click **Start > Epic 2014 > Interconnect > your\_instance > Configuration Editor**.
  - b) In the **Configuration Editor**, select the **Business Services** form.
  - c) On the **Service Category** tab, click **SendSIEMSyslogAudit**.
  - d) Click **Save**
2. Log in to your Epic server.
3. Click **Epic System Definitions (%ZeUSTBL) > Security > Auditing Options > SIEM Syslog Settings > SIEM Syslog Configuration**.
4. Use the following table to configure the parameters:

Parameter	Description
<b>SIEM Host</b>	The host name or IP address of the QRadar appliance.
<b>SIEM Port</b>	514
<b>SIEM Format</b>	LEEF (Log Event Extended Format).

5. From the **SIEM Syslog Settings** menu, click **SIEM Syslog** and set it to enabled.

The SIEM Syslog Sending daemon is automatically started when the environment is set to **runlevel Up** or when you enable **SIEM Syslog**.

6. If you want to stop the daemon, from the **SIEM Syslog Settings** menu, click **SIEM Syslog** and set it to disabled.

**Important:** If you stop the daemon when the syslog setting is enabled, the system continues to log data without purging. If you want to stop the daemon when the syslog setting is enabled, contact your Epic representative or your system administrator.

## Configuring Epic SIEM 2015 to communicate with QRadar

To collect events in IBM QRadar, you must configure the messaging queue values on your Epic SIEM 2015 system.

### Procedure

1. From the command line, select **Interconnect Administrator's Menu > Messaging Queues Setup**.
2. Type an asterisk (\*) to create the EMPSYNC queue.
3. Enter the queue values identified in the following table for each of the prompts.

Table 453. Queue values for EMPSYNC prompts

Prompt	Value
Queue ID	Type an ID for the queue.
Queue Name	EMPSYNC
Descriptor	EMPSYNC

*Table 453. Queue values for EMPSYNC prompts (continued)*

Prompt	Value
Run on Node	Press the <b>Enter</b> key. The value is automatically populated.
IC Servers	Press the <b>Enter</b> key, without typing a value.
Edit advanced settings for this queue?	<b>Yes</b>
Does this queue handle synchronous outgoing messages?	<b>Yes</b>
Associate this descriptor with a queue type for outgoing communication?	<b>Yes</b>
Queue Type	<b>EMP</b>

4. Type an asterisk (\*) to create the EMPASYNC queue.
5. Enter the queue values identified in the following table for each of the prompts.

*Table 454. Queue values for EMPASYNC prompts*

Prompt	Value
Queue ID	Type an ID for the queue.
Queue Name	EMPASYNC
Descriptor	EMPASYNC
Run on Node	Press the <b>Enter</b> key. The value is automatically populated.
IC Servers	Press the <b>Enter</b> key, without typing a value.
Edit advanced settings for this queue?	<b>Yes</b>
Does this queue handle synchronous outgoing messages?	<b>No</b>
Associate this descriptor with a queue type for outgoing communication?	<b>Yes</b>
Queue Type	<b>EMP</b>

6. Deploy a new interconnect instance by using Kuiper.
7. Access the **Interconnect Configuration Editor** in Windows, by clicking **Start > Epic 2015 > Interconnect > your\_instance > Configuration Editor**.
8. Select the **General Web Service Host** role.
9. In **Cache Connections**, manually add the queue by the queue type, **EMP**.
10. Set the number of threads to **2**.  
For more information about thread count recommendations, refer to your Epic documentation.  
**Important:** Do not enable any services on the **Business Services** tab.
11. Log in to your Epic server.
12. Click **Epic System Definitions (%ZeUSTBL) > Security > Auditing Options > SIEM Syslog Settings**.
13. Select **SIEM Syslog Configuration**, and then configure the following parameters:

Parameter	Value
<b>SIEM Host</b>	Your QRadar Event Collector host name or IP address.

Parameter	Value
<b>SIEM Port</b>	514
<b>SIEM Format</b>	LEEF (Log Event Extended Format)
<b>Check Application Layer Response</b>	Disable

14. Return to the **SIEM Syslog Settings Menu**.

15. Select **SIEM Syslog** and set it to **Enabled**.

**Note:** The SIEM Syslog Sending daemon is automatically started when the environment is set to **runlevel Up** or when you enable **SIEM Syslog**. If you want to stop the daemon, from the **SIEM Syslog Settings** menu, click **SIEM Syslog** and set it to **Disabled**.

## Configuring Epic SIEM 2017 to communicate with QRadar

To collect events in IBM QRadar, you must configure the messaging queue values on your Epic SIEM 2017 system.

### Procedure

1. From the command line, select **Interconnect Administrator's Menu > Messaging Queues Setup**.
2. Type an asterisk (\*) to create the EMPSYNC queue.
3. Enter the queue values identified in the following table for each of the prompts.

*Table 455. Queue values for EMPSYNC prompts*

Prompt	Value
Queue ID	Type an ID for the queue.
Queue Name	EMPSYNC
Descriptor	EMPSYNC
Run on Node	Press the <b>Enter</b> key. The value is automatically populated.
IC Servers	Press the <b>Enter</b> key, without typing a value.
Edit advanced settings for this queue?	<b>Yes</b>
Does this queue handle synchronous outgoing messages?	<b>Yes</b>
Associate this descriptor with a queue type for outgoing communication?	<b>Yes</b>
Queue Type	<b>EMP</b>

4. Type an asterisk (\*) to create the EMPASYNC queue.

5. Enter the queue values identified in the following table for each of the prompts.

*Table 456. Queue values for EMPASYNC prompts*

Prompt	Value
Queue ID	Type an ID for the queue.
Queue Name	EMPASYNC
Descriptor	EMPASYNC

Table 456. Queue values for EMPASYNC prompts (continued)

Prompt	Value
Run on Node	Press the <b>Enter</b> key. The value is automatically populated.
IC Servers	Press the <b>Enter</b> key, without typing a value.
Edit advanced settings for this queue?	<b>Yes</b>
Does this queue handle synchronous outgoing messages?	<b>No</b>
Associate this descriptor with a queue type for outgoing communication?	<b>Yes</b>
Queue Type	<b>EMP</b>

6. Deploy a new interconnect instance by using Kuiper.
7. Access the **Interconnect Configuration Editor** in Windows, by clicking **Start > Epic 2017 > Interconnect > your\_instance > Configuration Editor**.
8. Select the **General Web Service Host** role.
9. In **Cache Connections**, manually add the queue by the queue type, **EMP**.
10. Set the number of threads to **2**.

For more information about thread count recommendations, see your Epic documentation.

**Important:** Do not enable any services on the **Business Services** tab.

11. Log in to your Epic server.
12. Click **Epic System Definitions (%ZeUSTBL) > Security > Auditing Options > SIEM Syslog Settings**.
13. Select **SIEM Syslog Configuration**, and then configure the following parameters:

Parameter	Value
<b>SIEM Host</b>	Your QRadar Event Collector host name or IP address.
<b>SIEM Port</b>	514
<b>SIEM Format</b>	LEEF (Log Event Extended Format)
<b>Check Application Layer Response</b>	Disable

14. Return to the **SIEM Syslog Settings Menu**.
15. If you want to reduce traffic that comes in to your SIEM system, disable the auditing events that your system does not require:
  - a) Click **SIEM Syslog Configuration Options > Edit Events List**.
  - b) From the **Edit Events List**, select **T** for each event that you want to disable.
  - c) Click **Q** to quit.
16. Select **SIEM Syslog** and set it to **Enabled**.

**Note:** The SIEM Syslog Sending daemon is automatically started when the environment is set to **runlevel Up** or when you enable **SIEM Syslog**. If you want to stop the daemon, from the **SIEM Syslog Settings** menu, click **SIEM Syslog** and set it to **Disabled**.

# Configuring Epic SIEM 2022 to communicate with QRadar

To collect events in IBM QRadar, you must configure the messaging queue values on your Epic SIEM 2022 system.

## Procedure

1. Create two custom queues by following the steps in the [Create an Interconnect Queue](#).  
**Important:** Verify that the **EMPSYNC** queue is synchronous and the **EMPASYNC** queue is asynchronous.  
Enter **EMP** as the **Queue Type** for both queues.
2. Configure a new interconnect instance based on the SIEM use case.
3. Configure the **Syslog** protocol.
4. Click **Epic System Definitions (%ZeUSTBL or Epic Application Access) > Client Systems > Epic System Definitions**.  
**Important:** **Epic System Definitions** are accessible only to system administrators.
5. Click **Security > Auditing Options > SIEM Syslog Settings**.
6. Select **SIEM Syslog Configuration**, and configure the following parameters:

Parameter	Value
<b>SIEM Host</b>	Your QRadar Event Collector host name or IP address.
<b>SIEM Port</b>	514
<b>SIEM Format</b>	LEEF (Log Event Extended Format)
<b>TCP Response</b>	No
<b>End Chars</b>	ENDTAGNULL. The tag <SyslogEnd> is sent and then 10.
<b>Starting in August 2023:</b>	Use TLS

7. Return to the **SIEM Syslog Settings Menu**.
8. If you want to reduce traffic that comes in to your SIEM system, disable the auditing events that your system does not require:
  - a) Click **SIEM Syslog Configuration Options > Edit Events List**.
  - b) From the **Edit Events List**, select **T** for each event that you want to disable.
  - c) Click **Q** to quit.
9. Select **SIEM Syslog** and set it to **Enabled**.

**Important:** The SIEM Syslog Sending daemon is automatically started when the environment is set to **runlevel Up** or when you enable **SIEM Syslog**. If you want to stop the daemon, from the **SIEM Syslog Settings** menu, click **SIEM Syslog** and set it to **Disabled**.

# Chapter 57. ESET Remote Administrator

The IBM QRadar DSM for ESET Remote Administrator collects logs from ESET Remote Administrator.

The following table describes the specifications for the ESET Remote Administrator DSM:

Table 457. ESET Remote Administrator DSM specifications	
Specification	Value
Manufacturer	ESET
DSM name	ESET Remote Administrator
RPM file name	DSM-ESETRemoteAdministrator-QRadar_version-build_number.noarch.rpm
Supported versions	6.4.270
Protocol	Syslog
Event format	Log Event Extended Format (LEEF)
Recorded event types	Threat Firewall aggregated Host Intrusion Protection System (HIPS) aggregated Audit
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.eset.com/us/support/download/business/remote-administrator-6">ESET website</a> ( <a href="https://www.eset.com/us/support/download/business/remote-administrator-6">https://www.eset.com/us/support/download/business/remote-administrator-6</a> )

To integrate ESET Remote Administrator with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) in the order that they are listed, on your QRadar Console:
  - DSMCommon RPM
  - ESET Remote Administrator DSM RPM
2. Configure your ESET Remote Administrator server to send LEEF formatted syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an ESET Remote Administrator log source on the QRadar Console. The following table describes the parameters that require specific values for ESET Remote Administrator event collection:

Table 458. ESET Remote Administrator log source parameters

Parameter	Value
Log Source type	ESET Remote Administrator
Protocol Configuration	Syslog
Log Source Identifier	The IP address or host name of the ESET Remote Administration server.

4. To check that QRadar parses the events correctly, review the following sample event message.

The following table shows a sample event message from ESET Remote Administrator:

*Table 459. ESET Remote Administrator sample message*

Event name	Low level category	Sample log message
Native user login	User Login Success	<pre>&lt;14&gt;1 2016-08-15T14:52:31.888Z hostname ERAserver 28021 - - LEEF:1.0 ESET RemoteAdministrator  &lt;Version&gt; Native user login cat= ESET RA Audit Event sev=2 devTime =Aug 15 2016 14:52:31 devTime Format=MMM dd yyyy HH:mm:ss src= &lt;Source_IP_address&gt; domain=Native user action=Login attempt target= username detail=Native user 'username' attempted to authenticate. result=Success  &lt;14&gt;1 2016-08-15T14:52:31.888Z hostname ERAserver 28021 - - LEEF:1.0 ESET RemoteAdministrator  &lt;Version&gt; Native user login cat=ESET RA Audit Event sev=2 devTime=Aug 15 2016 14:52:31 devTimeFormat=MMM dd yyyy HH:mm:ss src=&lt;Source_IP_address&gt; domain=Native user action=Login attempt target=username detail=Native user 'username' attempted to authenticate. result=Success</pre>

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring ESET Remote Administrator to communicate with QRadar

Configure your ESET Remote Administrator (ERA) server to send LEEF formatted syslog events to IBM QRadar.

### About this task

To complete the configuration, you must enable the Syslog server, and then configure the logging settings.

#### Note:

The required parameters listed in the following steps are configured in the **Server Settings** pane. To see a graphic, go to the [ESET website](#). ([http://help.eset.com/era\\_admin/64/en-US/index.html?admin\\_server\\_settings\\_export\\_to\\_syslog.htm](http://help.eset.com/era_admin/64/en-US/index.html?admin_server_settings_export_to_syslog.htm))

### Procedure

1. Log in to your ERA web console.
2. In the **Admin** navigation pane, click **Server Settings**.
3. In the **SYSLOG SERVER** area, select the **Use Syslog server** check box.
4. In the **Host** field, type the host name for your QRadar Event Collector.
5. In the **Port** field, type 514.
6. In the **LOGGING** area, select the **Export logs to Syslog** check box.
7. From the **Exported logs format** list, select **LEEF**.
8. Click **Save**.

# Chapter 58. Exabeam

The IBM QRadar DSM for Exabeam collects events from an Exabeam device.

The following table describes the specifications for the Exabeam DSM:

Table 460. Exabeam DSM specifications	
Specification	Value
Manufacturer	Exabeam
DSM name	Exabeam
RPM file name	DSM-ExabeamExabeam-QRadar_version-build_number.noarch.rpm
Supported versions	1.7 and v2.0
Recorded event types	Critical Anomalous
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.exabeam.com">Exabeam website</a> ( <a href="http://www.exabeam.com">http://www.exabeam.com</a> )

To integrate Exabeam with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Exabeam DSM RPM from the [IBM Support Website](#) onto your QRadar Console:
2. Configure your Exabeam device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an Exabeam log source on the QRadar Console. The following table describes the parameters that require specific values for Exabeam event collection:

Table 461. Exabeam log source parameters

Parameter	Value
Log Source type	Exabeam
Protocol Configuration	Syslog

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring Exabeam to communicate with QRadar

To collect syslog events from Exabeam, you must add a destination that specifies QRadar as the syslog server.

### Procedure

1. Log in to your Exabeam user interface ([https://<Exabeam\\_IP>:8484](https://<Exabeam_IP>:8484)).
2. Select [#setup](https://<Exabeam_IP>:8484) at the end of the url address.

[https://<Exabeam\\_IP>:8484/#setup](https://<Exabeam_IP>:8484/#setup)

3. In the **Navigation** pane, click **Incident Notification**.
4. Select **Send via Syslog** and configure the following syslog parameters.

Parameter	Description
<b>IP Address or Hostname</b>	The IP address of the QRadar Event Collector .
<b>Protocol</b>	TCP
<b>Port</b>	514
<b>Syslog Severity Level</b>	Emergency

## Exabeam sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Exabeam sample message when you use the Syslog protocol

The following sample event message shows a critical Exabeam event. A high risk user session is detected.

```
<85>Apr 06 22:03:02 exabeam.exabeam.test Exabeam: timestamp="2015-04-21T15:55:21.503+08:00"

# Chapter 59. Extreme

IBM QRadar accepts events from a range of Extreme DSMs.

## Extreme 800-Series Switch

The Extreme 800-Series Switch DSM for IBM QRadar accepts events by using syslog.

QRadar records all relevant audit, authentication, system, and switch events. Before you configure your Extreme 800-Series Switch in QRadar, you must configure your switch to forward syslog events.

### Configuring your Extreme 800-Series Switch

Configuring the Extreme 800-Series Switch to forward syslog events.

#### About this task

To manually configure the Extreme 800-Series Switch:

#### Procedure

1. Log in to your Extreme 800-Series Switch command-line interface.

You must be a system administrator or operator-level user to complete these configuration steps.

2. Type the following command to enable syslog:

```
enable syslog
```

3. Type the following command to create a syslog address for forwarding events to QRadar:

```
create syslog host 1 <IP address> severity informational facility local7  
udp_port 514 state enable
```

Where: <IP address> is the IP address of your QRadar Console or Event Collector.

4. Type the following command to forward syslog events by using an IP interface address:

```
create syslog source_ipif <name> <IP address>
```

Where:

- <name> is the name of your IP interface.
- <IP address> is the IP address of your QRadar Console or Event Collector.

The configuration is complete. The log source is added to QRadar as Extreme 800-Series Switch events are automatically discovered. Events that are forwarded to QRadar by Extreme 800-Series Switches are displayed on the **Log Activity** tab of QRadar.

### Syslog log source parameters for Extreme 800-Series Switches

If QRadar does not automatically detect the log source, add a Extreme 800-Series Switches log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Extreme 800-Series Switches:

Table 463. Syslog log source parameters for the Extreme 800-Series Switches DSM	
Parameter	Value
Log Source type	Extreme 800-Series Switch

Table 463. Syslog log source parameters for the Extreme 800-Series Switches DSM (continued)

Parameter	Value
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Extreme 800-Series Switches devices.

#### Related tasks

[Adding a log source](#)

## Extreme Dragon

The Extreme Dragon DSM for IBM QRadar accepts Extreme events by using syslog to record all relevant Extreme Dragon events.

#### About this task

To configure your QRadar Extreme Dragon DSM, use the following procedure:

#### Procedure

1. Create an Alarm Tool policy by using a Syslog notification rule. See “[Creating a Policy for Syslog](#)” on page 772.
2. Configure the log source within QRadar. See “[Syslog log source parameters for Extreme Dragon](#)” on page 774.
3. Configure Dragon Enterprise Management Server (EMS) to forward syslog messages. See “[Configure the EMS to forward syslog messages](#)” on page 774.

## Creating a Policy for Syslog

This procedure describes how to configure an Alarm Tool policy by using a syslog notification rule in the Log Event Extended Format (LEEF) message format.

#### About this task

LEEF is the preferred message format for sending notifications to Dragon Network Defense when the notification rate is high or when IPv6 addresses are displayed. If you do not want to use syslog notifications in LEEF format, refer to your *Extreme Dragon documentation* for more information.

To configure Extreme Dragon with an Alarm Tool policy by using a syslog notification rule, complete the following steps:

#### Procedure

1. Log in to the Extreme Dragon EMS.
2. Click the **Alarm Tool** icon.
3. Configure the Alarm Tool Policy:

In the **Alarm Tool Policy View > Custom Policies** menu tree, right-click and select **Add Alarm Tool Policy**.

4. In the **Add Alarm Tool Policy** field, type a policy name.

For example:

QRadar

5. Click **OK**.
6. In the menu tree, select **QRadar**.
7. To configure the event group:
  - Click the **Events Group** tab.
8. Click **New**.
 

The **Event Group Editor** is displayed.

  9. Select the event group or individual events to monitor.
  10. Click **Add**.
 

A prompt is displayed.
  11. Click **Yes**.
  12. In the right column of the **Event Group Editor**, type Dragon-Events.
  13. Click **OK**.
  14. Configure the Syslog notification rule:
    - Click the **Notification Rules** tab.
  15. Click **New**.
  16. In the name field, type QRadar-RuleSys.
  17. Click **OK**.
  18. In the **Notification Rules** pane, select the newly created QRadar-**RuleSys** item.
  19. Click the **Syslog** tab.
  20. Click **New**.
 

The **Syslog Editor** is displayed.
  21. Update the following values:
    - **Facility** - Using the **Facility** list, select a facility.
    - **Level** - Using the **Level** list, select **notice**.
    - **Message** - Using the **Type** list, select **LEEF**.

```
LEEF:Version=1.0|Vendor|Product|ProductVersion|eventID|devTime|
proto|src|sensor|dst|srcPort|dstPort|direction|eventData|
```

The LEEF message format delineates between fields by using a pipe delimiter between each keyword.
  22. Click **OK**.
  23. Verify that the notification events are logged as separate events:
    - Click the **Global Options** tab.
  24. Click the **Main** tab.
  25. Make sure that **Concatenate Events** is not selected.
  26. Configure the alarm information:
    - Click the **Alarms** tab.
  27. Click **New**.
  28. Type values for the parameters:
    - **Name** - Type QRadar-**Alarm**.
    - **Type** - Select **Real Time**.
    - **Event Group** - Select Dragon-Events.
    - **Notification Rule** - Select the QRadar-**RuleSys** check box.
  29. Click **OK**.

30. Click **Commit**.
31. Navigate to the **Enterprise View**.
32. Right-click on the **Alarm Tool** and select **Associate Alarm Tool Policy**.
33. Select the newly created QRadar **policy**. Click **OK**.
34. In the **Enterprise** menu, right-click the policy and select **Deploy**.

You are now ready to configure a syslog log source in QRadar.

## Syslog log source parameters for Extreme Dragon

If QRadar does not automatically detect the log source, add a Extreme Dragon log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Extreme Dragon:

Table 464. Syslog log source parameters for the Extreme Dragon DSM	
Parameter	Value
<b>Log Source type</b>	<b>Extreme Dragon Network IPS</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Extreme Dragon devices.

### Related tasks

[Adding a log source](#)

## Configure the EMS to forward syslog messages

Starting with Dragon Enterprise Management Server (EMS) v7.4.0 appliances, you must use syslog-*ng* for forwarding events to a Security and Information Manager such as IBM QRadar.

Syslogd has been replaced by syslog-*ng* in Dragon EMS v7.4.0 and later.

To configure EMS to forward syslog messages, you must choose one of the following:

- If you are using syslog-*ng* and Extreme Dragon EMS v7.4.0 and later, see “[Configuring syslog-\*ng\* Using Extreme Dragon EMS V7.4.0 and later](#)” on page 774.
- If you are using syslogd and Extreme Dragon EMS v7.4.0 and below, see “[Configuring syslogd Using Extreme Dragon EMS V7.4.0 and earlier](#)” on page 775.

## Configuring syslog-*ng* Using Extreme Dragon EMS V7.4.0 and later

This section describes the steps to configure syslog-*ng* in non-encrypted mode and syslogd to forward syslog messages to IBM QRadar.

### About this task

If you are using encrypted syslog-*ng*, refer to your *Extreme documentation*.

Do not run both syslog-*ng* and syslogd at the same time.

To configure syslog-*ng* in non-encrypted mode:

## Procedure

1. On your EMS system, open the following file:

```
/opt/syslog-ng/etc/syslog-ng.conf
```

2. Configure a **Facility** filter for the Syslog notification rule.

For example, if you selected **facility** local1:

```
filter filt_facility_local1 {facility(local1);};
```

3. Configure a **Level** filter for the Syslog notification rule.

For example, if you selected **level** notice:

```
filter filt_level_notice {level(notice);};
```

4. Configure a destination statement for the QRadar.

For example, if the IP address of the QRadar is 192.0.2.1 and you want to use syslog port of 514, type:

```
destination siem { tcp("192.0.2.1" port(514));};
```

5. Add a log statement for the notification rule:

```
log { source(s_local); filter (filt_facility_local1); filter (filt_level_notice); destination(siem);};
```

6. Save the file and restart syslog-*ng*.

```
cd /etc/rc.d ./rc.syslog-ng stop ./rc.syslog-ng start
```

7. The Extreme Dragon EMS configuration is complete.

## Configuring syslogd Using Extreme Dragon EMS V7.4.0 and earlier

If your Dragon Enterprise Management Server (EMS) is using a version earlier than V7.4.0 on the appliance, you must use syslogd for forwarding events to a Security and Information Manager such as IBM QRadar.

## Procedure

1. On the Dragon EMS system, open the following file:

```
/etc/syslog.conf
```

2. Add a line to forward the **facility** and **level** you configured in the syslog notification rule to QRadar.

For example, to define the **facility** local1 and **level** notice:

```
local1.notice @<IP address>
```

Where:

<IP address> is the IP address of the QRadar system.

3. Save the file and restart syslogd.

```
cd /etc/rc.d ./rc.syslog stop ./rc.syslog start
```

The Extreme Dragon EMS configuration is complete.

## Extreme HiGuard Wireless IPS

The Extreme HiGuard Wireless IPS DSM for IBM QRadar records all relevant events by using syslog

Before you configure the Extreme HiGuard Wireless IPS device in QRadar, you must configure your device to forward syslog events.

## Configuring Enterasys HiGuard

To configure the device to forward syslog events:

### Procedure

1. Log in to the HiGuard Wireless IPS user interface.
2. In the left navigation pane, click **Syslog**, which allows the management server to send events to designated syslog receivers.

The **Syslog Configuration** pane is displayed.

3. In the **System Integration Status** section, enable syslog integration.

Enabling syslog integration allows the management server to send messages to the configured syslog servers. By default, the management server enables syslog.

The **Current Status** field displays the status of the syslog server. The choices are: **Running** or **Stopped**. An error status is displayed if one of the following occurs:

- One of the configured and enabled syslog servers includes a host name that cannot be resolved.
- The management server is stopped.
- An internal error occurred. If this error occurs, contact Enterasys Technical Support.

4. From **Manage Syslog Servers**, click **Add**.

The **Syslog Configuration** window is displayed.

5. Type values for the following parameters:

- **Syslog Server (IP Address/Hostname)** - Type the IP address or host name of the syslog server where events are sent.

**Note:** Configured syslog servers use the DNS names and DNS suffixes configured in the **Server initialization and Setup Wizard** on the HWMH Config Shell.

- **Port Number** - Type the port number of the syslog server to which HWMH sends events. The default is 514.
- **Message Format** - Select **Plain Text** as the format for sending events.
- **Enabled?** - Select **Enabled?** if you want events to be sent to this syslog server.

6. Save your configuration.

The configuration is complete. The log source is added to IBM QRadar as HiGuard events are automatically discovered. Events that are forwarded to QRadar by Enterasys HiGuard are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Extreme HiGuard

If QRadar does not automatically detect the log source, add a Extreme HiGuard log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Extreme HiGuard:

Table 465. Syslog log source parameters for the Extreme HiGuard DSM	
Parameter	Value
<b>Log Source type</b>	<b>Extreme HiGuard</b>
<b>Protocol Configuration</b>	<b>Syslog</b>

Table 465. Syslog log source parameters for the Extreme HiGuard DSM (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Extreme HiGuard devices.

#### Related tasks

[Adding a log source](#)

## Extreme HiPath Wireless Controller

The Extreme HiPath Wireless Controller DSM for IBM QRadar records all relevant events by using syslog.

QRadar supports the following Extreme HiPath Wireless Controller events:

- Wireless access point events
- Application log events
- Service log events
- Audit log events

## Configuring your HiPath Wireless Controller

To integrate your Extreme HiPath Wireless Controller events with IBM QRadar, you must configure your device to forward syslog events.

#### About this task

To forward syslog events to QRadar:

#### Procedure

1. Log in to the HiPath Wireless Assistant.
2. Click **Wireless Controller Configuration**.  
The **HiPath Wireless Controller Configuration** window is displayed.
3. From the menu, click **System Maintenance**.
4. From the **Syslog section**, select the **Syslog Server IP** check box and type the IP address of the device that receives the syslog messages.
5. Using the **Wireless Controller Log Level** list, select **Information**.
6. Using the **Wireless AP Log Level** list, select **Major**.
7. Using the **Application Logs** list, select **local.0**.
8. Using the **Service Logs** list, select **local.3**.
9. Using the **Audit Logs** list, select **local.6**.
10. Click **Apply**.

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Extreme HiPath

If QRadar does not automatically detect the log source, add a Extreme HiPath log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Extreme HiPath:

Table 466. Syslog log source parameters for the Extreme HiPath DSM	
Parameter	Value
<b>Log Source type</b>	<b>Extreme HiPath</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Extreme HiPath devices.

#### Related tasks

## Extreme Matrix Router

The Extreme Matrix Router DSM for IBM QRadar accepts Extreme Matrix events by using SNMPv1, SNMPv2, SNMPv3, and syslog.

#### About this task

You can integrate Extreme Matrix Router version 3.5 with QRadar. QRadar records all SNMP events, syslog login, logout, and login failed events. Before you configure QRadar to integrate with Extreme Matrix, you must take the following steps:

#### Procedure

1. Log in to the switch/router as a privileged user.
2. Type the following command:

```
set logging server <server number> description <description> facility <facility> ip_addr <IP address> port <port> severity <severity>
```

Where:

- <server number> is the server number with values 1 - 8.
- <description> is a description of the server.
- <facility> is a syslog facility, for example, local0.
- <IP address> is the IP address of the server that receives the syslog messages.
- <port> is the default UDP port that the client uses to send messages to the server. Use port 514 unless otherwise stated.
- <severity> is the server severity level with values 1 - 9, where 1 indicates an emergency, and 8 is debug level.

For example:

```
set logging server 5 description ourlogserver facility local0 ip_addr 192.0.2.1 port 514 severity 8
```

3. You are now ready to configure the log source in QRadar.

Select **Extreme Matrix E1 Switch** from the **Log Source Type** list.

m. set logging application Router level 8  
n. set logging application AddrNtfy level 8  
o. set logging application OSPF level 8  
p. set logging application VRRP level 8  
q. set logging application RtrArpProc level 8  
r. set logging application LACP level 8  
s. set logging application RtrNat level 8  
t. set logging application RtrTwcb level 8  
u. set logging application HostDoS level 8  
v. set policy syslog extended-format enable
```

For more information on configuring the Matrix Series routers or switches, consult your vendor documentation.

3. You are now ready to configure the log sources in QRadar.

To configure QRadar to receive events from an Extreme Matrix Series device, select **Extreme Matrix K/N/S Series Switch** from the **Log Source Type** list.

# Extreme NetSight Automatic Security Manager

---

The Extreme NetSight Automatic Security Manager DSM for IBM QRadar accepts events by using syslog.

## About this task

QRadar records all relevant events. Before you configure an Extreme NetSight Automatic Security Manager device in QRadar, you must configure your device to forward syslog events.

To configure the device to send syslog events to QRadar:

## Procedure

1. Log in to the Automatic Security Manager user interface.
2. Click the **Automated Security Manager** icon to access the **Automated Security Manager Configuration** window.  
**Note:** You can also access the **Automated Security Manager Configuration** window from the **Tool** menu.
3. From the left navigation menu, select **Rule Definitions**.
4. Choose one of the following options:
  - If a rule is configured, highlight the rule. Click **Edit**.
  - 5. To create a new rule, click **Create**.
  - 6. Select the **Notifications** check box.
  - 7. Click **Edit**.  
The **Edit Notifications** window is displayed.
  - 8. Click **Create**.  
The **Create Notification** window is displayed.
  - 9. Using the **Type** list, select **Syslog**.
  - 10. In the **Syslog Server IP/Name** field, type the IP address of the device that receives syslog traffic.
  - 11. Click **Apply**.
  - 12. Click **Close**.
  - 13. In the **Notification** list, select the notification that is configured.
  - 14. Click **OK**.
  - 15. You are now ready to configure the log source in QRadar.

To configure QRadar to receive events from an Extreme NetSight Automatic Security Manager device, select **Extreme NetsightASM** from the **Log Source Type** list.

For more information about your Extreme NetSight Automatic Security Manager device, see your vendor documentation.

# Extreme NAC

---

The Extreme NAC DSM for IBM QRadar accepts events by using syslog. QRadar records all relevant events.

For details on configuring your Extreme NAC appliances for syslog, consult your vendor documentation. After the Extreme NAC appliance is forwarding syslog events to QRadar, the configuration is complete. The log source is added to QRadar as Extreme NAC events are automatically discovered. Events that are forwarded by Extreme NAC appliances are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Extreme NAC

If QRadar does not automatically detect the log source, add a Extreme NAC log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Extreme NAC:

Table 467. Syslog log source parameters for the Extreme NAC DSM	
Parameter	Value
<b>Log Source type</b>	<b>Extreme NAC</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Extreme NAC devices.

### Related tasks

## Configuring Extreme stackable and stand-alone switches

The Extreme stackable and stand-alone switches DSM for IBM QRadar accepts events by using syslog.

### About this task

QRadar records all relevant events. Before you configure an Extreme stackable and stand-alone switches device in QRadar, you must configure your device to forward syslog events.

To configure the device to forward syslog events to QRadar:

### Procedure

1. Log in to the Extreme stackable and stand-alone switch device.
2. Type the following command:

```
set logging server <index> [ip-addr <IP address>] [facility <facility>]  
[severity <severity>] [descr <description>] [port <port>] [state <enable |  
disable>]
```

Where:

- <index> is the server table index number (1 - 8) for this server.
- <IP address> is the IP address of the server you want to send syslog messages. You do not have to enter an IP address. If you do not define an IP address, an entry in the Syslog server table is created with the specified index number, and a message is displayed indicating that there is no assigned IP address.
- <facility> is a syslog facility. Valid values are local0 to local7. You do not have to enter a facility value. If the value is not specified, the default value that is configured with the **set logging** default command is applied.
- <description> is a description of the facility/server. You do not have to enter a description.
- <port> is the default UDP port that the client uses to send messages to the server. If not specified, the default value that is configured with the **set logging** default command is applied. You do not have to enter a port value.

- <enable | disable> enables or disables this facility/server configuration. You do not have to choose an option. If the state is not specified, it does not default to either enable or disable.
- <severity> is the server severity level that the server will log messages. The valid range is 1 - 8. If not specified, the default value that is configured with the **set logging** default command is applied. You do not have to input a severity value. The following are valid values:
  - 1: Emergencies (system is unusable)
  - 2: Alerts (immediate action needed)
  - 3: Critical conditions
  - 4: Error conditions
  - 5: Warning conditions
  - 6: Notifications (significant conditions)
  - 7: Informational messages
  - 8: Debugging message

3. You can now ready to configure the log source in QRadar.

To configure QRadar to receive events from an Extreme stackable and stand-alone switch device:

From the **Log Source Type** list, select one of the following options:

- **Extreme stackable and stand-alone switches**
- **Extreme A-Series**
- **Extreme B2-Series**
- **Extreme B3-Series**
- **Extreme C2-Series**
- **Extreme C3-Series**
- **Extreme D-Series**
- **Extreme G-Series**
- **Extreme I-Series**

For more information about your Extreme stackable and stand-alone switches, see your vendor documentation.

## Extreme XSR Security Router

The Extreme XSR Security Router DSM for IBM QRadar accepts events by using syslog.

### About this task

QRadar records all relevant events. Before you configure an Extreme XSR Security Router in QRadar, you must configure your device to forward syslog events.

For more information about your Extreme XSR Security Router, see your vendor documentation.

To configure the device to send syslog events to QRadar:

### Procedure

1. Using Telnet or SSH, log in to the XSR Security Router command-line interface.

2. Type the following commands to access config mode:

a. enable

b. config

3. Type the following command:

```
logging <IP address> low
```

Where: <IP address> is the IP address of your QRadar.

4. Exit from config mode.

```
exit
```

5. Save the configuration:

```
copy running-config startup-config
```

You are now ready to configure the log sources in QRadar.

# Chapter 60. F5 Networks

IBM QRadar accepts events from a range of F5 Networks DSMs.

## F5 Networks BIG-IP AFM

The F5 Networks BIG-IP Advanced Firewall Manager (AFM) DSM for IBM QRadar accepts syslog events that are forwarded from F5 Networks BIG-IP AFM systems in name-value pair format.

### About this task

QRadar can collect the following events from F5 BIG-IP appliances with Advanced Firewall Managers:

- Network events
- Network Denial of Service (DoS) events
- Protocol security events
- DNS events
- DNS Denial of Service (DoS) events

Before you can configure the Advanced Firewall Manager, you must verify that your BIG-IP appliance is licensed and provisioned to include Advanced Firewall Manager.

### Procedure

1. Log in to your BIG-IP appliance Management Interface.
2. From the navigation menu, select **System > License**.
3. In the **License Status** column, verify that the Advanced Firewall Manager is licensed and enabled.
4. To enable the Advanced Firewall Manager, select **System > Resource > Provisioning**.
5. From the **Provisioning** column, select the check box and select **Nominal** from the list.
6. Click **Submit** to save your changes.

## Configuring a logging pool

A logging pool is used to define a pool of servers that receive syslog events. The pool contains the IP address, port, and a node name that you provide.

### Procedure

1. From the navigation menu, select **Local Traffic > Pools**.
2. Click **Create**.
3. In the **Name** field, type a name for the logging pool.  
For example, Logging\_Pool.
4. From the **Health Monitor** field, in the **Available** list, select **TCP** and click **<<**.  
This clicking action moves the TCP option from the Available list to the Selected list.
5. In the **Resource** pane, from the **Node Name** list, select **Logging\_Node** or the name you defined in “Configuring a logging pool” on page 785.
6. In the **Address** field, type the IP address for the QRadar Console or Event Collector.
7. In the **Service Port** field, type 514.
8. Click **Add**.
9. Click **Finish**.

## Creating a high-speed log destination

The process to configure logging for BIG-IP AFM requires that you create a high-speed logging destination.

### Procedure

1. From the navigation menu, select **System > Logs > Configuration > Log Destinations**.
2. Click **Create**.
3. In the **Name** field, type a name for the destination.  
For example, Logging\_HSL\_dest.
4. In the **Description** field, type a description.
5. From the **Type** list, select **Remote High-Speed Log**.
6. From the **Pool Name** list, select a logging pool from the list of remote log servers.  
For example, Logging\_Pool.
7. From the **Protocol** list, select **TCP**.
8. Click **Finish**.

## Creating a formatted log destination

The formatted log destination is used to specify any special formatting that is required on the events that are forwarded to the high-speed logging destination.

### Procedure

1. From the navigation menu, select **System > Logs > Configuration > Log Destinations**.
2. Click **Create**.
3. In the **Name** field, type a name for the logging format destination.  
For example, Logging\_Format\_dest.
4. In the **Description** field, type a description.
5. From the **Type** list, select **Remote Syslog**.
6. From the **Syslog Format** list, select **Syslog**.
7. From the **High-Speed Log Destination** list, select your high-speed logging destination.  
For example, Logging\_HSL\_dest.
8. Click **Finished**.

## Creating a log publisher

Creating a publisher allows the BIG-IP appliance to publish the formatted log message to the local syslog database.

### Procedure

1. From the navigation menu, select **System > Logs > Configuration > Log Publishers**.
2. Click **Create**.
3. In the **Name** field, type a name for the publisher.  
For example, Logging\_Pub.
4. In the **Description** field, type a description.
5. From the **Destinations** field, in the Available list, select the log destination name that you created in [“Configuring a logging pool” on page 785](#) and click **<<** to add items to the Selected list.

This clicking action moves your logging format destination from the Available list to the Selected list. To include local logging in your publisher configuration, you can add **local-db** and **local-syslog** to the Selected list.

## Creating a logging profile

Use the Logging profile to configure the types of events that your Advanced Firewall Manager is producing and to associate these events with the logging destination.

### Procedure

1. From the navigation menu, select **Security > Event Logs > Logging Profile**.
2. Click **Create**.
3. In the **Name** field, type a name for the log profile.  
For example, Logging\_Profile.
4. In the **Network Firewall** field, select the **Enabled** check box.
5. From the **Publisher** list, select the log publisher that you configured.  
For example, Logging\_Pub.
6. In the **Log Rule Matches** field, select the **Accept**, **Drop**, and **Reject** check boxes.
7. In the **Log IP Errors** field, select the **Enabled** check box.
8. In the **Log TCP Errors** field, select the **Enabled** check box.
9. In the **Log TCP Events** field, select the **Enabled** check box.
10. In the **Storage Format** field, from the list, select **Field-List**.
11. In the **Delimiter** field, type , (comma) as the delimiter for events.
12. In the **Storage Format** field, select all of the options in the **Available Items** list and click <<. This clicking action moves all of the Field-List options from the **Available** list to the **Selected** list.
13. In the **IP Intelligence** pane, from the **Publisher** list, select the log publisher that you configured.  
For example, Logging\_Pub.
14. Click **Finished**.

## Associating the profile to a virtual server

The log profile you created must be associated with a virtual server in the **Security Policy** tab. This association allows the virtual server to process your network firewall events, along with local traffic.

### About this task

Take the following steps to associate the profile to a virtual server.

### Procedure

1. From the navigation menu, select **Local Traffic > Virtual Servers**.
2. Click the name of a virtual server to modify.
3. From the **Security** tab, select **Policies**.
4. From the **Log Profile** list, select **Enabled**.
5. From the **Profile** field, in the **Available** list, select **Logging\_Profile** or the name you specified in “[Creating a logging profile](#)” on page 787 and click <<. This clicking action moves the Logging\_Profile option from the **Available** list to the **Selected** list.
6. Click **Update** to save your changes.

The configuration is complete. The log source is added to IBM QRadar as F5 Networks BIG-IP AFM syslog events are automatically discovered. Events that are forwarded to QRadar by F5 Networks BIG-IP AFM are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for F5 Networks BIG-IP AFM

If QRadar does not automatically detect the log source, add a F5 Networks BIG-IP AFM log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from F5 Networks BIG-IP AFM:

Table 470. Syslog log source parameters for the F5 Networks BIG-IP AFM DSM	
Parameter	Value
<b>Log Source type</b>	<b>F5 Networks BIG-IP AFM</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your F5 Networks BIG-IP AFM devices.

### Related tasks

## F5 Networks BIG-IP APm

The F5 Networks BIG-IP Access Policy Manager (APM) DSM for IBM QRadar collects access and authentication security events from a BIG-IP APM device by using syslog.

To configure your BIG-IP LTM device to forward syslog events to a remote syslog source, choose your BIG-IP APM software version:

- [“Configuring Remote Syslog for F5 BIG-IP APM V11.x to V14.x” on page 789](#)
- [“Configuring a Remote Syslog for F5 BIG-IP APM 10.x” on page 789](#)

### Configuring Remote Syslog for F5 BIG-IP APM V11.x to V14.x

You can configure syslog for F5 BIG-IP APM V11.x to V14.x.

#### About this task

To configure a remote syslog for F5 BIG-IP APM V11.x to V14.x take the following steps:

#### Procedure

1. Log in to the command-line of your F5 BIG-IP device.
2. Type the following command to add a single remote syslog server:

```
tmsh syslog remote server {<Name> {host <IP address>}}
```

Where:

- <Name> is the name of the F5 BIG-IP APM syslog source.
- <IP address> is the IP address of the QRadar Console.

For example,

```
bigpipe syslog remote server {BIGIP_APM {host 192.0.2.1}}
```

3. Type the following to save the configuration changes:

```
tmsh save sys config partitions all
```

The configuration is complete. The log source is added to QRadar as F5 Networks BIG-IP APM events are automatically discovered. Events that are forwarded to QRadar by F5 Networks BIG-IP APM are displayed on the **Log Activity** tab in QRadar.

### Configuring a Remote Syslog for F5 BIG-IP APM 10.x

You can configure syslog for F5 BIG-IP APM 10.x

#### About this task

To configure a remote syslog for F5 BIG-IP APM 10.x take the following steps:

#### Procedure

1. Log in to the command-line of your F5 BIG-IP device.
2. Type the following command to add a single remote syslog server:

```
bigpipe syslog remote server {<Name> {host <IP address>}}
```

Where:

- <Name> is the name of the F5 BIG-IP APM syslog source.
- <IP address> is the IP address of QRadar Console.

For example,

```
bigpipe syslog remote server {BIGIP_APM {host 192.0.2.1}}
```

3. Type the following to save the configuration changes:

```
bigpipe save
```

The configuration is complete. The log source is added to IBM QRadar as F5 Networks BIG-IP APM events are automatically discovered. Events that are forwarded to QRadar by F5 Networks BIG-IP APM are displayed on the **Log Activity** tab.

## Syslog log source parameters for F5 Networks BIG-IP APM

If QRadar does not automatically detect the log source, add a F5 Networks BIG-IP APM log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from F5 Networks BIG-IP APM:

Table 471. Syslog log source parameters for the F5 Networks BIG-IP APM DSM	
Parameter	Value
<b>Log Source type</b>	<b>F5 Networks BIG-IP APM</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your F5 Networks BIG-IP APM devices.

### Related tasks

## F5 Networks BIG-IP APM sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

## F5 Networks BIG-IP APM sample message when you use the syslog protocol

The following sample event message shows that an ACL is matched. It also shows that the TCP traffic from 192.168.194.160:54636 to 172.16.0.12:4446 is allowed.

```
<173>Oct 25 11:52:34 f5networks.bigipapm.test notice tmm[20338]: 01580002:5: /path/to_file_123:Common:b77e0b8e: allow ACL: /path/to_other_file_123:2 packet: tcp 192.168.194.160:54636 -> 172.16.0.12:4446
```

```
<173>Oct 25 11:52:34 f5networks.bigipapm.test notice tmm[20338]: 01580002:5: /path/to_file_123:Common:b77e0b8e: allow ACL: /path/to_other_file_123:2 packet: tcp 192.168.194.160:54636 -> 172.16.0.12:4446
```

**Note:** For more information about F5 APM DSM, see the "Log message format" section in the *Reviewing BIG-IP log files* article. <https://my.f5.com/manage/s/article/K16197>

## F5 Networks BIG-IP ASM

---

The IBM QRadar F5 Networks BIG-IP Application Security Manager (ASM) DSM collects web application security events from BIG-IP ASM appliances by using syslog.

### About this task

To forward syslog events from an F5 Networks BIG-IP ASM appliance to QRadar, you must configure a logging profile.

A logging profile can be used to configure remote storage for syslog events, which can be forwarded directly to QRadar.

### Procedure

1. Log in to the F5 Networks BIG-IP ASM appliance user interface.
2. In the **navigation** pane, select **Application Security > Options**.
3. Click **Logging Profiles**.
4. Click **Create**.
5. From the **Configuration** list, select **Advanced**.
6. Type a descriptive name for the **Profile Name** property.
7. Optional: Type a **Profile Description**.

If you do not want data logged both locally and remotely, clear the **Local Storage** check box.

8. Select the **Remote Storage** check box.
9. From the **Type** list, select 1 of the following options:
  - a) In BIG-IP ASM V12.1.2 or earlier, select **Reporting Server**.
  - b) In BIG-IP ASM V13.0.0 or later, select **key-value pairs**.
  - c) Or, select **Common Event Format**. Log messages are in Common Event Format (CEF).
10. From the **Protocol** list, select **TCP**.
11. In the **IP Address** field, type the IP address of the QRadar Console and in the **Port** field, type a port value of 514.
12. Select the **Guarantee Logging** check box.

**Note:** Enabling the **Guarantee Logging** option ensures the system log requests continue for the web application when the logging utility is competing for system resources. Enabling the **Guarantee Logging** option can slow access to the associated web application.

13. Select the **Report Detected Anomalies** check box to allow the system to log details.
14. Click **Create**.

The display refreshes with the new logging profile. The log source is added to QRadar as F5 Networks BIG-IP ASM events are automatically discovered. Events that are forwarded by F5 Networks BIG-IP ASM are displayed on the Log Activity tab of QRadar.

### Syslog log source parameters for F5 Networks BIG-IP ASM

If QRadar does not automatically detect the log source, add a F5 Networks BIG-IP ASM log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from F5 Networks BIG-IP ASM:

Table 472. Syslog log source parameters for the F5 Networks BIG-IP ASM DSM

Parameter	Value
<b>Log Source type</b>	<b>F5 Networks BIG-IP ASM</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your F5 Networks BIG-IP ASM devices.

## F5 Networks BIG-IP ASM sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

### F5 Networks BIG-IP ASM sample messages when you use the syslog protocol

**Sample 1:** The following sample event message shows a distributed attack event.

```
<134>Jul 25 11:47:52 f5networks.asm.test
ASM:software_version="14.1.0",current_mitigation="alarm",unit_hostname="f5networks.asm.test",management_ip_address="10.192.138.11",management_ip_address_2="",operation_mode="Transparent",date_time="2019-07-25 11:41:38",policy_apply_date="2019-07-23 15:24:21",policy_name="/Common/extranet_onstige",vs_name="/Common/extranet-t.qradar.example.test_443",anomaly_attack_type="Distributed Attack",uri="/qradar.example.test",attack_status="ongoing",detection_mode="Number of Failed Logins Increased",severity="Emergency",mitigated_entity_name="username",mitigated_entity_value="exnyjtgk",mitigated_ipaddr_geo="N/A",attack_id="2508639270",mitigated_entity_failed_logins="0",mitigated_entity_failed_logins_threshold="3",mitigated_entity_total_mitigations="0",mitigated_entity_passed_challenges="0",mitigated_entity_passed_captchas="0",mitigated_entity_rejected_logins="0",leaked_username_login_attempts="0",leaked_username_failed_logins="0",leaked_username_time_of_last_login_attempt="2497667872",normal_failed_logins="78",detected_failed_logins="70",failed_logins_threshold="100",normal_login_attempts="91",detected_login_attempts="78",login_attempts_matching_leaked_credentials="0",total_mitigated_login_attempts="60",total_client_side_integrity_challenges="0",total_captcha_challenges="0",total_blocking_page_challenges="0",total_passed_client_side_integrity_challenges="0",total_passed_captcha_challenges="0",total_drops="0",total_successful_mitigations="0",protocol="HTTPS",login_attempts_matching_leaked_credentials_threshold="100",login_stress="73"
```

**Sample 2:** The following sample event shows multiple violations. The event contains the following violations:

1. Illegal URL length
2. Illegal request length
3. Illegal query string length
4. Illegal meta character in parameter value
5. Illegal file type
6. Illegal URL
7. Attack signature detected

When the sample event is parsed in QRadar, a separate event is created for each of the seven violations.

```
"Aug 18 11:16:29 f5networks.asm.test.com

## F5 Networks BIG-IP LTM

The F5 Networks BIG-IP Local Traffic Manager (LTM) DSM for IBM QRadar collects networks security events from a BIG-IP device by using syslog.

Before events can be received in QRadar, you must configure a log source for QRadar, and then configure your BIG-IP LTM device to forward syslog events. Create the log source before events are forwarded

as QRadar does not automatically discover or create log sources for syslog events from F5 BIG-IP LTM appliances.

## F5 Networks BIG-IP LTM DSM specifications

When you configure F5 Networks BIG-IP LTM, understanding the specifications for the F5 Networks BIG-IP LTM DSM can help ensure a successful integration. For example, knowing what the supported version of F5 Networks BIG-IP LTM is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the F5 Networks BIG-IP LTM DSM.

Table 476. F5 Networks BIG-IP LTM DSM specifications	
Specification	Value
Manufacturer	F5 Networks
DSM name	F5 Networks BIG-IP LTM
RPM file name	DSM-F5NetworksBigIP-QRadar_version-build_number.noarch.rpm
Supported version	9.4.2 to 14.x
Protocol	Syslog
Event format	Syslog, CSV
Recorded event types	All events
Automatically discovered?	No
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.f5.com/services/resources">F5 Networks product resources</a> ( <a href="https://www.f5.com/services/resources">https://www.f5.com/services/resources</a> )

## Syslog log source parameters for F5 Networks BIG-IP LTM

Add a F5 Networks BIG-IP LTM log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from F5 Networks BIG-IP LTM:

Table 477. Syslog log source parameters for the F5 Networks BIG-IP LTM DSM	
Parameter	Value
Log Source type	<b>F5 Networks BIG-IP LTM</b>
Protocol Configuration	<b>Syslog</b>
Log Source Identifier	Type the IP address or host name for the log source as an identifier for events from your F5 Networks BIG-IP LTM devices.

### Related tasks

[Adding a log source](#)

## Configuring syslog forwarding in BIG-IP LTM

You can configure your BIG-IP LTM device to forward syslog events.

You can configure syslog for the following BIG-IP LTM software version:

- [“Configuring Remote Syslog for F5 BIG-IP LTM V11.x to V14.x” on page 796](#)
- [“Configuring Remote Syslog for F5 BIG-IP LTM V10.x” on page 796](#)
- [“Configuring Remote Syslog for F5 BIG-IP LTM V9.4.2 to V9.4.8” on page 797](#)

## Configuring Remote Syslog for F5 BIG-IP LTM V11.x to V14.x

You can configure syslog for F5 BIG-IP LTM 11.x to V14.x.

### About this task

To configure syslog for F5 BIG-IP LTM V11.x to V14.x take the following steps:

### Procedure

1. Log in to the command-line of your F5 BIG-IP device.

2. To log in to the Traffic Management Shell (tmsh), type the following command:

```
tmsh
```

3. To add a syslog server, type the following command:

```
modify /sys syslog remote-servers add {<Name> {host <IP address> remote-port 514}}
```

Where:

- <Name> is a name that you assign to identify the syslog server on your BIG-IP LTM appliance.

- <IP address> is the IP address of IBM QRadar.

For example,

```
modify /sys syslog remote-servers add {BIGIPsyslog {host 192.0.2.1 remote-port 514}}
```

4. Save the configuration changes:

```
save /sys config
```

Events that are forwarded from your F5 Networks BIG-IP LTM appliance are displayed on the **Log Activity** tab in QRadar.

## Configuring Remote Syslog for F5 BIG-IP LTM V10.x

You can configure syslog for F5 BIG-IP LTM V10.x.

### About this task

To configure syslog for F5 BIG-IP LTM V10.x take the following steps:

### Procedure

1. Log in to the command line of your F5 BIG-IP device.

2. Type the following command to add a single remote syslog server:

```
bigpipe syslog remote server {<Name> {host <IP_address>}}
```

Where:

- <Name> is the name of the F5 BIG-IP LTM syslog source.

- <IP\_address> is the IP address of IBM QRadar.

For example:

```
bigpipe syslog remote server {BIGIPsyslog {host 192.0.2.1}}
```

### 3. Save the configuration changes:

```
bigpipe save
```

**Note:** F5 Networks modified the syslog output format in BIG-IP V10.x to include the use of local/ before the host name in the syslog header. The syslog header format that contains local/ is not supported in QRadar, but a workaround is available to correct the syslog header. For more information, see <http://www.ibm.com/support>.

Events that are forwarded from your F5 Networks BIG-IP LTM appliance are displayed on the **Log Activity** tab in QRadar.

## Configuring Remote Syslog for F5 BIG-IP LTM V9.4.2 to V9.4.8

You can configure syslog for F5 BIG-IP LTM V9.4.2 to V9.4.8.

### About this task

To configure syslog for F5 BIG-IP LTM V9.4.2 to V9.4.8 take the following steps:

### Procedure

1. Log in to the command-line of your F5 BIG-IP device.
2. Type the following command to add a single remote syslog server:

```
bigpipe syslog remote server <IP address>
```

Where: <IP address> is the IP address of IBM QRadar.

For example:

```
bigpipe syslog remote server 192.0.2.1
```

3. Type the following to save the configuration changes:

```
bigpipe save
```

The configuration is complete. Events that are forwarded from your F5 Networks BIG-IP LTM appliance are displayed on the **Log Activity** tab in QRadar.

## F5 Networks BIG-IP LTM sample event messages

Use these sample event messages as a way of verifying a successful integration with QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### F5 Networks BIG-IP LTM sample event messages when you use the Syslog protocol

**Sample 1:** The following sample event message shows a Pool member's monitor status.

## F5 Networks FirePass

The F5 Networks FirePass DSM for IBM QRadar collects system events from an F5 FirePass SSL VPN device using syslog.

By default, remote logging is disabled and must be enabled in the F5 Networks FirePass device. Before receiving events in QRadar, you must configure your F5 Networks FirePass device to forward system events to QRadar as a remote syslog server.

### Configuring syslog forwarding for F5 FirePass

To forward syslog events from an F5 Networks BIG-IP FirePass SSL VPN appliance to IBM QRadar, you must enable and configure a remote log server.

#### About this task

The remote log server can forward events directly to your QRadar Console or any Event Collector in your deployment.

#### Procedure

1. Log in to the F5 Networks FirePass Admin Console.

2. On the navigation pane, select **Device Management > Maintenance > Logs**.
3. From the **System Logs** menu, select the **Enable Remote Log Server** check box.
4. From the **System Logs** menu, clear the **Enable Extended System Logs** check box.
5. In the **Remote host** parameter, type the IP address or host name of your QRadar.
6. From the **Log Level** list, select **Information**.

The **Log Level** parameter monitors application level system messages.

7. From the **Kernel Log Level** list, select **Information**.

The **Kernel Log Level** parameter monitors Linux kernel system messages.

8. Click **Apply System Log Changes**.

The changes are applied and the configuration is complete. The log source is added to QRadar as F5 Networks FirePass events are automatically discovered. Events that are forwarded to QRadar by F5 Networks BIG-IP ASM are displayed on the **Log Activity** tab in QRadar.

## Syslog log source parameters for F5 Networks FirePass

If QRadar does not automatically detect the log source, add a F5 Networks FirePass log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from F5 Networks FirePass:

Table 480. Syslog log source parameters for the F5 Networks FirePass DSM	
Parameter	Value
<b>Log Source type</b>	<b>F5 Networks FirePass</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your F5 Networks FirePass devices.

### Related tasks

# Chapter 61. Fair Warning

The Fair Warning DSM for IBM QRadar retrieves event files from a remote source by using the log file protocol.

QRadar records event categories from the Fair Warning log files about user activity that is related to patient privacy and security threats to medical records. Before you can retrieve log files from Fair Warning, you must verify that your device is configured to generate an event log. Instructions for generating the event log can be found in your *Fair Warning documentation*.

When you configure the log file protocol, make sure that the host name or IP address that is configured in the Fair Warning system is the same as configured in the **Remote Host** parameter in the log file protocol configuration.

## Log File log source parameters for Fair Warning

If QRadar does not automatically detect the log source, add a Fair Warning log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from Fair Warning:

Table 481. Log File log source parameters for the Fair Warning DSM	
Parameter	Value
<b>Log Source type</b>	<b>Fair Warning</b>
<b>Protocol Configuration</b>	<b>Log File</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Fair Warning devices.
<b>FTP File Pattern</b>	Type a regular expression that matches the log files that are generated by the Fair Warning system.
<b>Remote Directory</b>	Type the path to the directory that contains logs from your Fair Warning device.
<b>Event Generator</b>	<b>Fair Warning</b>

For a complete list of Log File protocol parameters and their values, see [Log File protocol configuration options](#).

## Chapter 62. Fasoo Enterprise DRM

The IBM QRadar DSM for Fasoo Enterprise DRM (Digital Rights Management) collects logs from a Fasoo Enterprise DRM device.

The following table describes the specifications for the Fasoo Enterprise DRM DSM:

Table 484. Fasoo Enterprise DRM DSM specifications	
Specification	Value
Manufacturer	Fasoo
DSM name	Fasoo Enterprise DRM
RPM file name	DSM-FasooFED-QRadar_version-build_number.noarch.rpm
Supported versions	5.0
Protocol	JDBC
Event format	name-value pair (NVP)
Recorded event types	Usage events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://en.fasoo.com/Fasoo-Enterprise-DRM">Fasoo website (http://en.fasoo.com/Fasoo-Enterprise-DRM)</a>

To integrate Fasoo Enterprise DRM with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - JDBC Protocol RPM
  - DSMCommon RPM
  - FasooFED DSM RPM
2. Configure a log source to connect to the Fasoo Enterprise DRM database and retrieve event.
3. Add a Fasoo Enterprise DRM log source on the QRadar Console. The following table describes the parameters that require specific values to collect event from Fasoo Enterprise DRM:

Table 485. Fasoo Enterprise DRM JDBC log source parameters

Parameter	Value
<b>Log Source type</b>	Fasoo Enterprise DRM
<b>Protocol Configuration</b>	JDBC

Table 485. Fasoo Enterprise DRM JDBC log source parameters (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
<b>Database Type</b>	From the list, select the type of the Fasoo Enterprise DRM database.
<b>Database Name</b>	The name of the Fasoo Enterprise DRM database.
<b>IP or Hostname</b>	The IP address or host name of the Fasoo Enterprise DRM database server.
<b>Port</b>	The port number that is used by the database server.
<b>Username</b>	The user name that is required to connect to the database.
<b>Password</b>	The password that is required to connect to the database. The password can be up to 255 characters in length.
<b>Confirm Password</b>	The confirmation password must be identical to the password that you typed for the <b>Password</b> parameter.
<b>Authentication Domain</b>	If you did not select <b>Use Microsoft JDBC</b> , <b>Authentication Domain</b> is displayed.  The domain for MSDE that is a Windows domain. If your network does not use a domain, leave this field blank.
<b>Database Instance</b>	The database instance, if required. MSDE databases can include multiple SQL server instances on one server.  When a non-standard port is used for the database or access is blocked to port 1434 for SQL database resolution, the <b>Database Instance</b> parameter must be blank in the log source configuration.
<b>Predefined Query (Optional)</b>	Select a predefined database query for the log source. If a predefined query is not available for the log source type, administrators can select the <b>none</b> option.
<b>Table Name</b>	view_fut_log  The name of the view that includes the event records.

Table 485. Fasoo Enterprise DRM JDBC log source parameters (continued)

Parameter	Value
<b>Select List</b>	Type an asterisk (*) to select all fields from the table or view.  The list of fields to include when the table is polled for events.
<b>Compare Field</b>	log_date  The <b>Compare Field</b> is used to identify new events that are added between queries to the table.
<b>Start Date and Time</b> (Optional)	Type the start date and time for database polling in the following format: yyyy-MM-dd HH:mm, with HH specified by using a 24-hour clock. If the start date or time is clear, polling begins immediately and repeats at the specified polling interval.
<b>Use Prepared Statements</b>	Select the check box if you want to use prepared statements.  Prepared statements enable the JDBC protocol source to set up the SQL statement, and then run the SQL statement numerous times with different parameters. For security and performance reasons, most JDBC protocol configurations can use prepared statements.
<b>Polling Interval</b>	The amount of time between queries to the event table. The default polling interval is 10 seconds. You can define a longer polling interval by appending H for hours or M for minutes to the numeric value. The maximum polling interval is 1 week in any time format. Numeric values that are entered without an H or M poll in seconds.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 20,000 EPS.
<b>Use Named Pipe Communication</b>	If you did not select <b>Use Microsoft JDBC</b> , <b>Use Named Pipe Communication</b> is displayed.  MSDE databases require the user name and password field to use a Windows authentication user name and password and not the database user name and password. The log source configuration must use the default that is named pipe on the MSDE database.
<b>Database Cluster Name</b>	If you selected <b>Use Named Pipe Communication</b> , the <b>Database</b> parameter displays. If you are running your SQL server in a cluster environment, define the cluster name to ensure named pipe communication functions properly.

Table 485. Fasoo Enterprise DRM JDBC log source parameters (continued)

Parameter	Value
<b>Use NTLMv2</b>	If you did not select <b>Use Microsoft JDBC</b> , <b>Use NTLMv2</b> is displayed.  Select this option if you want MSDE connections to use the NTLMv2 protocol when they are communicating with SQL servers that require NTLMv2 authentication. This option does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.  Does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.
<b>Use Microsoft JDBC</b>	If you want to use the Microsoft JDBC driver, you must enable <b>Use Microsoft JDBC</b> .
<b>Use SSL</b>	Select this option if your connection supports SSL.
<b>Microsoft SQL Server Hostname</b>	If you selected <b>Use Microsoft JDBC</b> and <b>Use SSL</b> , the <b>Microsoft SQL Server Hostname</b> parameter is displayed.  You must type the host name for the Microsoft SQL server.

For more information about configuring JDBC parameters, see [c\\_logsource\\_JDBCprotocol.dita](#)

- Verify that QRadar is configured correctly.

The following table shows a sample normalized event message from Fasoo Enterprise DRM:

Table 486. Fasoo Enterprise DRM sample message

Event name	Low level category	Sample log message
Edit - successful	Update Activity Succeeded	<pre> log_id: "xxxxxxxxxxxxxxxxxxxxxxxxxx" log_date: "2016-03-21 14:17:36.000" log_type: "1" product: "1" purpose: "16" usage_result: "1" license_status: "0" ip: "&lt;Numeric&gt;" user_code: "usercode" user_name: "username" user_dept_code: "xxxxxxxxxxxxxxxxxxxxxx" user_dept_name: "userdeptname" position_code: "P001" position_name: "Employee" content_code: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx" current_content_name: "New Microsoft PowerPoint Presentation.pptx" content_name: "New Microsoft PowerPoint Presentation.pptx" sec_level_code: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx" sec_level_name: "Basic" system_code: "NULL" system_name: "NULL" owner_code: "ownercode" owner_name: "ownername" owner_dept_code: "xxxxxxxxxxxxxxxxxxxxxx" owner_dept_name: "ownerdeptname" content_create-date: "2016-03-21 03:41:28.000" entry_date: "2016-03-21 13:18:26.670"  log_id: "xxxxxxxxxxxxxxxxxxxxxxxxxx" log_date: "2016-03-21 14:17:36.000" log_type: "1" product: "1" purpose: "16" usage_result: "1" license_status: "0" ip: "&lt;Numeric&gt;" user_code: "usercode" user_name: "username" user_dept_code: "xxxxxxxxxxxxxxxxxxxxxx" user_dept_name: "userdeptname" position_code: "P001" position_name: "Employee" content_code: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx" current_content_name: "New Microsoft PowerPoint Presentation.pptx" content_name: "New Microsoft PowerPoint Presentation.pptx" sec_level_code: "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx" sec_level_name: "Basic" system_code: "NULL" system_name: "NULL" owner_code: "ownercode" owner_name: "ownername" owner_dept_code: "xxxxxxxxxxxxxxxxxxxxxx" owner_dept_name: "ownerdeptname" content_create-date: "2016-03-21 03:41:28.000" entry_date: "2016-03-21 13:18:26.670" </pre>

# Configuring Fasoo Enterprise DRM to communicate with QRadar

For IBM QRadar to collect log event data, you must create a database view.

## Before you begin

The script in this procedure is only intended for MS SQL Servers. For other database types, modifications to the script will be required for the target database type.

## Procedure

1. Log in to SQL Server Management Studio.
2. Create a custom view in your Fasoo database.

```
USE fed5;
GO
CREATE VIEW view_fut_log
AS
SELECT
dbo.fut_log.log_id,
dbo.fut_log.log_date,
dbo.fut_log.log_type,
dbo.fut_log.product,
dbo.fut_log.purpose,
dbo.fut_log.usage_result,
dbo.fut_log.license_status,
dbo.fut_log.ip,
dbo.fut_user.user_code,
dbo.fut_user.user_name,
dbo.fut_user.user_dept_code,
dbo.fut_user.user_dept_name,
dbo.fut_log.position_code,
dbo.fut_log.position_name,
dbo.fut_content.content_code,
dbo.fut_content.current_content_name,
dbo.fut_content.content_name,
dbo.fut_content.sec_level_code,
dbo.fut_content.sec_level_name,
dbo.fut_content.system_code,
dbo.fut_content.system_name,
dbo.fut_log.owner_code,
dbo.fut_log.owner_name,
dbo.fut_log.owner_dept_code,
dbo.fut_log.owner_dept_name,
dbo.fut_content.content_create_date,
dbo.fut_log.entry_date
FROM dbo.fut_log
INNER JOIN dbo.fut_user
ON dbo.fut_log.user_id =
dbo.fut_user.user_id
INNER JOIN dbo.fut_content
ON dbo.fut_log.content_id =
dbo.fut_content.content_id
GO
```

# Chapter 63. Fidelis XPS

The Fidelis XPS DSM for IBM QRadar accepts events that are forwarded in Log Event Extended Format (LEEF) from Fidelis XPS appliances by using syslog.

QRadar can collect all relevant alerts that are triggered by policy and rule violations that are configured on your Fidelis XPS appliance.

## Event type format

Fidelis XPS must be configured to generate events in Log Event Extended Format (LEEF) and forward these events by using syslog. The LEEF format consists of a pipe ( | ) delimited syslog header, and tab separated fields that are positioned in the event payload.

If the syslog events forwarded from your Fidelis XPS are not formatted in LEEF format, you must examine your device configuration or software version to ensure that your appliance supports LEEF. Properly formatted LEEF event messages are automatically discovered and added as a log source to QRadar.

## Configuring Fidelis XPS

You can configure syslog forwarding of alerts from your Fidelis XPS appliance.

### Procedure

1. Log in to CommandPost to manage your Fidelis XPS appliance.
2. From the navigation menu, select **System > Export**.

A list of available exports is displayed. The list is empty the first time you use the export function.

3. Select one of the following options:

- Click **New** to create a new export for your Fidelis XPS appliance.
- Click **Edit** next to an export name to edit an existing export on your Fidelis XPS appliance.

The **Export Editor** is displayed.

4. From the **Export Method** list, select **Syslog LEEF**.
5. In the **Destination** field, type the IP address or host name for IBM QRadar.

For example, 192.0.2.1:::514

The **Destination** field does not support non-ASCII characters.

6. From **Export Alerts**, select one of the following options:
  - **All alerts** - Select this option to export all alerts to QRadar. This option is resource-intensive and it can take time to export all alerts.
  - **Alerts by Criteria** - Select this option to export specific alerts to QRadar. This option displays a new field where you can define your alert criteria.
7. From **Export Malware Events**, select **None**.
8. From **Export Frequency**, select **Every Alert / Malware**.
9. In the **Save As** field, type a name for your export.
10. Click **Save**.
11. Optional: To verify that events are forwarded to QRadar, you can click **Run Now**.

**Run Now** is intended as a test tool to verify that alerts selected by criteria are exported from your Fidelis appliance. This option is not available if you selected to export all events in [“Configuring Fidelis XPS” on page 809](#).

The configuration is complete. The log source is added to QRadar as Fidelis XPS syslog events are automatically discovered. Events that are forwarded to QRadar by Fidelis XPS are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Fidelis XPS

If QRadar does not automatically detect the log source, add a Fidelis XPS log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Fidelis XPS:

Table 487. Syslog log source parameters for the Fidelis XPS DSM	
Parameter	Value
<b>Log Source type</b>	<b>Fidelis XPS</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Fidelis XPS devices.

### Related tasks

[Adding a log source](#)

## Fidelis XPS sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Fidelis XPS sample message when you use the Syslog protocol

The following sample event message is generated when a packet contains excess data.

```

# Chapter 44. FireEye

The IBM QRadar DSM for FireEye accepts syslog events in Log Event Extended Format (LEEF) and Common Event Format (CEF).

This DSM applies to FireEye CMS, MPS, EX, AX, NX, FX, and HX appliances. QRadar records all relevant notification alerts that are sent by FireEye appliances.

The following table identifies the specifications for the FireEye DSM.

Table 489. FireEye DSM specifications	
Specification	Value
Manufacturer	FireEye
DSM name	FireEye MPS
Supported versions	CMS, MPS, EX, AX, NX, FX, and HX
RPM file name	DSM-FireEyeMPS-QRadar_version-Build_number.noarch.rpm
Protocol	<b>Syslog and TLS Syslog</b>
Event Format	Common Event Format (CEF). CEF:0 is supported.
QRadar recorded event types	All relevant events
Auto discovered?	Yes
Includes identity?	No
More information	<a href="http://www.fireeye.com">FireEye website (www.fireeye.com)</a>

To integrate FireEye with QRadar, use the following procedures:

1. If automatic updates are not enabled, download and install the DSM Common and FireEye MPS RPM from the [IBM Support Website](#) onto your QRadar Console.
2. Download and install the latest TLS Syslog Protocol RPM on QRadar.
3. For each instance of FireEye in your deployment, configure the FireEye system to forward events to QRadar.
4. For each instance of FireEye, create an FireEye log source on the QRadar Console. The following tables explain how to configure a log source in Syslog and TLS Syslog for FireEye.

Table 490. Configuring the Syslog log source protocols for FireEye

Parameter	Description
<b>Log Source Type</b>	<b>FireEye</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your device.

Table 491. Configuring the TLS Syslog log source protocols for FireEye

Parameter	Description
Log Source Type	<b>FireEye</b>

Table 491. Configuring the TLS Syslog log source protocols for FireEye (continued)

Parameter	Description
Protocol Configuration	<b>TLS Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your device.
<b>TLS Listen Port</b>	The default TLS listen port is 6514.
<b>Authentication Mode</b>	The mode by which your TLS connection is authenticated. If you select the TLS and Client Authentication option, you must configure the certificate parameters.
<b>Certificate Type</b>	The type of certificate to use for authentication. If you select the <b>Provide Certificate</b> option, you must configure the file paths for the server certificate and the private key.
<b>Provided Server Certificate Path</b>	The absolute path to the server certificate.
<b>Provided Private Key Path</b>	The absolute path to the private key. <b>Note:</b> The corresponding private key must be a DER-encoded PKCS8 key. The configuration fails with any other key format.
<b>Maximum Connections</b>	The Maximum Connections parameter controls how many simultaneous connections the TLS Syslog protocol can accept for each Event Collector.  The connection limit across all TLS syslog log source configurations is 1000 connections for each Event Collector. The default for each device connection is 50.  <b>Note:</b> Automatically discovered log sources that share a listener with another log source, such as if you use the same port on the same event collector, count only one time towards the limit.

Look at “[Adding a log source](#)” on page 5 for more common parameters that occur in Syslog and “[TLS Syslog protocol configuration options](#)” on page 231 for more TLS Syslog protocol-specific parameters and their configurations.

## Related tasks

## Configuring your FireEye system for communication with QRadar

---

To enable FireEye to communicate with IBM QRadar, configure your FireEye appliance to forward syslog events.

### Procedure

1. Log in to the FireEye appliance by using the CLI.
2. To activate configuration mode, type the following commands:

```
enable
configure terminal
```
3. To enable rsyslog notifications, type the following command:

```
fenotify rsyslog enable
```
4. To add QRadar as an rsyslog notification consumer, type the following command:

```
fenotify rsyslog trap-sink QRadar
```
5. To specify the IP address for the QRadar system that you want to receive rsyslog trap-sink notifications, type the following command:

```
fenotify rsyslog trap-sink QRadar address <QRadar_IP_address>
```
6. To define the rsyslog event format, type the following command:

```
fenotify rsyslog trap-sink QRadar prefer message format leef
```
7. To save the configuration changes to the FireEye appliance, type the following command:

```
write memory
```

### Related tasks

[“Configuring your FireEye HX system for communication with QRadar” on page 815](#)

To enable FireEye HX to communicate with IBM QRadar, configure your FireEye HX appliance to forward syslog events.

## Configuring your FireEye HX system for communication with QRadar

---

To enable FireEye HX to communicate with IBM QRadar, configure your FireEye HX appliance to forward syslog events.

### Procedure

1. Log in to the FireEye HX appliance by using the CLI.
2. To activate configuration mode, type the following commands:

```
enable
configure terminal
```
3. To add a remote syslog server destination, type the following commands:

```
logging <remote_IP_address> trap none
logging <remote_IP_address> trap override class cef priority info
```
4. To save the configuration changes to the FireEye HX appliance, type the following command:

```
write mem
```

# Configuring a FireEye log source in QRadar

IBM QRadar automatically creates a log source after your QRadar Console receives FireEye events. If QRadar does not automatically discover FireEye events, you can manually add a log source for each instance from which you want to collect event logs.

## About this task

If you are using QRadar 7.3.1 and later, you can add a log source by using the [QRadar Log Source Management app](#).

In QRadar 7.5.0 Update Package 4 and later, when you click the **Log Sources** icon, the QRadar Log Source Management app opens.

## Procedure

1. Log in to QRadar
2. Click the **Admin** tab.
3. On the navigation menu, click **Data Sources**.
4. Click the **Log Sources** icon.
5. Click **Add**.
6. From the **Log Source Type** list, select **FireEye**.
7. Using the **Protocol Configuration** list, select **Syslog**.
8. In the **Log Source Identifier** field, type the IP address or host name of the FireEye appliance.
9. Configure the remaining parameters.
10. Click **Save**.
11. On the **Admin** tab, click **Deploy Changes**.

## FireEye sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## FireEye sample message when you use the Syslog or TLS syslog protocol

The following sample event message shows that an Indicator of Compromise (IOC) was detected.

```
<149>Jul 23 18:54:24 fireeye.mps.test cef[5159]: CEF:0|fireeye|HX|4.8.0|IOC Hit Found|IOC Hit Found|10|rt=Jul 23 2019 16:54:24 UTC dvchost=fireeye.mps.test categoryDeviceGroup=/IDS categoryDeviceType=Forensic Investigation categoryObject=/Host cs1Label=Host Agent Cert Hash cs1=fwvqcmXUHVcbm4AFK01cim dst=192.168.1.172 dmac=00-00-5e-00-53-00 dhost=test-host1 dntdom=test deviceCustomDate1Label=Agent Last Audit deviceCustomDate1=Jul 23 2019 16:54:22 UTC cs2Label=FireEye Agent Version cs2=29.7.0 cs5Label=Target GMT Offset cs5=+PT2H cs6Label=Target OS cs6=Windows 10 Pro 17134 externalId=17688554 start=Jul 23 2019 16:53:18 UTC categoryOutcome=/Success categorySignificance=/Compromise categoryBehavior=/Found cs7Label=Resolution cs7=ALERT cs8Label=Alert Types cs8=exc act=Detection IOC Hit msg=Host test-host1 IOC compromise alert categoryTupleDescription=A Detection IOC found a compromise indication. cs4Label=IOC Name cs4=SVCHOST SUSPICIOUS PARENT PROCESS

# Chapter 65. Forcepoint

IBM QRadar supports a range of Forcepoint DSMs.

FORCEPOINT is formerly known as Websense.

## Related concepts

WebsenseQRadar supports a range of Websense DSMs.

## Forcepoint Stonesoft Management Center

The IBM QRadar DSM for Forcepoint Stonesoft Management Center collects events from a StoneGate device by using syslog.

The following table describes the specifications for the Stonesoft Management Center DSM:

Table 493. Stonesoft Management Center DSM specifications	
Specification	Value
Manufacturer	FORCEPOINT
DSM name	Stonesoft Management Center
RPM file name	DSM-StonesoftManagementCenter-QRadar_version-build_number.noarch.rpm
Supported versions	5.4 to 6.1
Protocol	Syslog
Event format	LEEF
Recorded event types	Management Center, IPS, Firewall, and VPN events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.forcepoint.com">FORCEPOINT website (https://www.forcepoint.com)</a>

To integrate FORCEPOINT Stonesoft Management Center with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - Stonesoft Management Center DSM RPM
2. Configure your StoneGate device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Stonesoft Management Center log source on the QRadar Console. The following table describes the parameters that require specific values to collect events from Stonesoft Management Center:

Table 494. Stonesoft Management Center log source parameters

Parameter	Value
Log Source type	Stonesoft Management Center
Protocol Configuration	Syslog

*Table 494. Stonesoft Management Center log source parameters (continued)*

Parameter	Value
Log Source Identifier	Type a unique name for the log source.

- Verify that QRadar is configured correctly.

The following table shows a sample normalized event message from Stonesoft Management Center:

*Table 495. Stonesoft Management Center sample message*

Event name	Low level category	Sample log message
Generic_UDP-Rugged-Director-Denial-Of-Service	Misc DoS	<pre>LEEF:1.0 FORCEPOINT IPS 5.8.5  Generic_UDP-Rugged-Director-Denial-Of- Service devTimeFormat=MMM dd yyyy HH:mm:ss srcMAC=00:00:00:00:00:00 sev=2 dstMAC=00:00:00:00:00:00 devTime=Feb 23 201710:13:58 proto=17 dstPort=00000 srcPort=00000 dst=127.0.0.1 src=127.0.0.1 action=Permit logicalInterface=NY2-1302- DMZ_IPSASA_Primary sender="username" Sensor</pre>

[“Adding a log source” on page 5](#)

## Configuring FORCEPOINT Stonesoft Management Center to communicate with QRadar

Configure Stonesoft Management Center to communicate with QRadar by editing the LogServerConfiguration.txt file. Configuring the text file allows Stonesoft Management Center to forward events in LEEF format by using syslog to QRadar.

### Procedure

- Log in to the appliance that hosts your Stonesoft Management Center.
- Stop the Stonesoft Management Center Log Server.
- In Windows, select one of the following methods to stop the Log Server.
  - Stop the Log Server in the Windows **Services** list.
  - Run the batch file <installation path>/bin/sgStopLogSrv.bat.
- Edit the LogServerConfiguration.txt file. The configuration file is located in the following directory:  
`<installation path>/data/LogServerConfiguration.txt`
- Configure the following parameters in the LogServerConfiguration.txt file:

*Table 496. Log server configuration options*

Parameter	Value	Description
SYSLOG_EXPORT_FORMAT	LEEF	Type LEEF as the export format to use for syslog.

Table 496. Log server configuration options (continued)

Parameter	Value	Description
SYSLOG_EXPORT_ALERT	YES   NO	Type one of the following values: <ul style="list-style-type: none"><li>• Yes - Exports alert entries to QRadar by using the syslog protocol.</li><li>• No - Alert entries are not exported.</li></ul>
SYSLOG_EXPORT_FW	YES   NO	Type one of the following values: <ul style="list-style-type: none"><li>• Yes - Exports firewall and VPN entries to QRadar by using the syslog protocol.</li><li>• No - Firewall and VPN entries are not exported.</li></ul>
SYSLOG_EXPORT_IPS	YES   NO	Type one of the following values: <ul style="list-style-type: none"><li>• Yes - Exports IPS logs to QRadar by using the syslog protocol.</li><li>• No - IPS logs are not exported.</li></ul>
SYSLOG_PORT	514	Type 514 as the UDP port for forwarding syslog events to QRadar.
SYSLOG_SERVER_ADDRESS	QRadar IPv4 Address	Type the IPv4 address of your QRadar Console or Event Collector.

6. Save the LogServerConfiguration.txt file.

7. Start the Log Server.

- Windows - Type <installation path>/bin/sgStartLogSrv.bat.
- Linux - Type <installation path>/bin/sgStartLogSrv.sh.

For detailed configuration instructions, see the StoneGate Management Center Administrator's Guide.

## What to do next

You are now ready to configure a traffic rule for syslog.

**Note:** A firewall rule is only required if your QRadar Console or Event Collector is separated by a firewall from the Stonesoft Management Server. If no firewall exists between the Stonesoft Management Server and QRadar, you need to configure the log source in QRadar.

## Configuring a syslog traffic rule for FORCEPOINT Stonesoft Management Center

If your Stonesoft Management Center and QRadar are separated by a firewall in your network, you must modify your firewall or IPS policy to allow traffic between the Stonesoft Management Center and QRadar.

### Procedure

1. From the Stonesoft Management Center, select one of the following methods for modifying a traffic rule.
  - **Firewall policies** - Select **Configuration > Configuration > Firewall**.
  - **IPS policies** - Select **Configuration > Configuration > IPS**.

- Select the type of policy to modify.
  - Firewall** - Select **Firewall Policies > Edit Firewall Policy**.
  - IPS** - Select **IPS Policies > Edit Firewall Policy**.
- Add an IPv4 Access rule by configuring the following parameters for the firewall policy:

Parameter	Value
<b>Source</b>	Type the IPv4 address of your Stonesoft Management Center Log server.
<b>Destination</b>	Type the IPv4 address of your QRadar Console or Event Collector.
<b>Service</b>	Select <b>Syslog (UDP)</b> .
<b>Action</b>	Select <b>Allow</b> .
<b>Logging</b>	Select <b>None</b> .

**Note:** In most cases, you might want to set the logging value to **None**. Logging syslog connections without configuring a syslog filter can create a loop. For more information, see the *StoneGate Management Center Administrator's Guide*.

- Save your changes and then refresh the policy on the firewall or IPS.

## What to do next

You are now ready to configure the log source in QRadar.

## Forcepoint Sidewinder

Forcepoint Sidewinder is formerly known as McAfee Firewall Enterprise. The IBM QRadar DSM for Forcepoint Sidewinder collects logs from a Forcepoint Sidewinder Firewall Enterprise device by using the Syslog protocol.

To integrate Forcepoint Sidewinder with QRadar, complete the following steps:

- If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the Forcepoint Sidewinder DSM RPM on your QRadar Console.
- Configure Forcepoint Sidewinder to communicate with QRadar.
- If QRadar does not automatically detect the log source, add a Forcepoint Sidewinder log source on the QRadar Console. The following table describes the parameters that require specific values for Forcepoint Sidewinder event collection:

Table 497. Forcepoint Sidewinder log source parameters

Parameter	Value
Log Source type	Forcepoint Sidewinder
Protocol Configuration	Syslog

### Related concepts

["Configure Forcepoint Sidewinder to communicate with QRadar" on page 823](#)

Before you can configure QRadar to integrate with Forcepoint Sidewinder, you must configure syslog on your Forcepoint Sidewinder Firewall Enterprise device.

### Related tasks

["Adding a DSM" on page 4](#)

## Forcepoint Sidewinder DSM specifications

The following table describes the specifications for the Forcepoint Sidewinder DSM.

Table 498. Forcepoint Sidewinder DSM specifications	
Specification	Value
Manufacturer	Forcepoint
DSM name	Forcepoint Sidewinder
RPM file name	DSM-ForcepointSidewinder-QRadar_version-build_number.noarch.rpm
Supported versions	V6.1
Event format	Syslog
Recorded event types	Forcepoint Sidewinder audit events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.forcepoint.com">Forcepoint website</a> ( <a href="https://www.forcepoint.com">https://www.forcepoint.com</a> )

## Configure Forcepoint Sidewinder to communicate with QRadar

Before you can configure QRadar to integrate with Forcepoint Sidewinder, you must configure syslog on your Forcepoint Sidewinder Firewall Enterprise device.

When you configure your Forcepoint Sidewinder device to forward syslog events to QRadar, export the logs in Sidewinder Export Format (SEF).

For more information about configuring your Forcepoint Sidewinder device, see the [Forcepoint Sidewinder Administration Guide](https://www.websense.com/content/support/library/si/v70/mgmt_si_70103_ag_a_en-us.pdf) ([https://www.websense.com/content/support/library/si/v70/mgmt\\_si\\_70103\\_ag\\_a\\_en-us.pdf](https://www.websense.com/content/support/library/si/v70/mgmt_si_70103_ag_a_en-us.pdf)).

### Related tasks

[“Adding a log source” on page 5](#)

## Forcepoint Sidewinder sample event message

Use this sample event message as a way of verifying a successful integration with QRadar.

The following table provides a sample event message when you use the Syslog protocol for the Forcepoint Sidewinder DSM:

Table 499. Forcepoint Sidewinder sample message supported by Forcepoint Sidewinder.

Event name	Low-level category	Sample log message
nettraffic@status_conn_close	Firewall Session Closed	<pre>&lt;131&gt;May 16 11:41:11 auditd: date="May 16 15:41:11 2006 GMT",fac=f_ftpproxy,area=a_server,type=t_nettra ffic,pri=p_major,pid=2718,ruid=0,euid=0,pgid=27 18,logid=0,cmd=pftp,domain=PFTx,edomain=PFTx,sr cip=192.168.0.1,srcport=4597,srcburb=internal,d stip=192.168.0.2,dstport=21,dstburb=external,pr otocol=6,bytes_written_to_client=0,bytes_writte n_to_server=0,service_name=pftp,reason="closing connection",status=conn_close,acl_id=default- outgoingrule,cache_hit=0,remote_logname=anonymo us,request_command=QUIT,request_status=1,start_ time="Tue May 16 11:41:06 2006",netsessid=4469f2920002870e</pre>

## Forcepoint TRITON

The Forcepoint V-Series Content Gateway DSM for IBM QRadar supports events for web content from several Forcepoint TRITON solutions, including Web Security, Web Security Gateway, Web Security Gateway Anywhere, and V-Series appliances.

### About this task

Forcepoint TRITON collects and streams event information to QRadar by using the Forcepoint Multiplexer component. Before you configure QRadar, you must configure the Forcepoint TRITON solution to provide LEEF formatted syslog events.

Before you can configure Forcepoint TRITON Web Security solutions to forward events to QRadar, you must ensure that your deployment contains a Forcepoint Multiplexer.

The Forcepoint Multiplexer is supported on Windows, Linux, and on Forcepoint V-Series appliances.

To configure a Forcepoint Multiplexer on a Forcepoint Triton or V-Series appliance:

### Procedure

1. Install an instance of Forcepoint Multiplexer for each Forcepoint Policy Server component in your network.
  - For Microsoft Windows - To install the Forcepoint Multiplexer on Windows, use the TRITON Unified Installer. The Triton Unified Installer is available for download at <http://www.myforcepoint.com>.
  - For Linux - To install the Forcepoint Multiplexer on Linux, use the Web Security Linux Installer. The Web Security Linux Installer is available for download at <http://www.myforcepoint.com>.
 For information on adding a Forcepoint Multiplexer to software installations, see your *Forcepoint Security Information Event Management (SIEM) Solutions* documentation.
2. Enable the Forcepoint Multiplexer on a V-Series appliance that is configured as a full policy source or user directory and filtering appliance:
  - a) Log in to your Forcepoint TRITON Web Security Console or V-Series appliance.
3. From the Appliance Manager, select **Administration > Toolbox > Command Line Utility**.
4. Click the **Forcepoint Web Security** tab.
5. From the **Command** list, select **multiplexer**, then use the **enable** command.
6. Repeat “Forcepoint TRITON” on page 824 and “Forcepoint TRITON” on page 824 to enable one Multiplexer instance for each Policy Server instance in your network.

If more than one Multiplexer is installed for a Policy Server, only the last installed instance of the Forcepoint Multiplexer is used. The configuration for each Forcepoint Multiplexer instance is stored by its Policy Server.

## What to do next

You can now configure your Forcepoint TRITON appliance to forward syslog events in LEEF format to QRadar.

## Configuring syslog for Forcepoint TRITON

To collect events, you must configure syslog forwarding for Forcepoint TRITON.

### Procedure

1. Log in to your Forcepoint TRITON Web Security Console.
2. On the **Settings** tab, select **General > SIEM Integration**.
3. Select the **Enable SIEM integration for this Policy Server** check box.
4. In the **IP address or hostname** field, type the IP address of your QRadar.
5. In the **Port** field, type 514.
6. From the **Transport protocol** list, select either the **TCP** or **UDP** protocol option.

QRadar supports syslog events for TCP and UDP protocols on port 514.

7. From the **SIEM format** list, select **syslog/LEEF (QRadar)**
8. Click **OK** to cache any changes.
9. Click **Deploy** to update your Forcepoint TRITON security components or V-Series appliances.

The Forcepoint Multiplexer connects to Forcepoint Filtering Service and ensures that event log information is provided to QRadar.

## Syslog log source parameters for Forcepoint TRITON

When you add a Forcepoint TRITON log source on the QRadar Console by using the syslog protocol, there are specific parameters you must use.

The following table describes the parameters that require specific values to collect syslog events from Forcepoint TRITON:

Table 500. Syslog log source parameters for the Forcepoint TRITON DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for your log source.
<b>Log Source Type</b>	Forcepoint V Series
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier or events from Forcepoint TRITON or V-series appliance.

### Related tasks

# Forcepoint V-Series Data Security Suite

The Forcepoint V-Series Data Security Suite DSM for IBM QRadar supports Forcepoint V-Series appliances and the Data Security Suite (DSS) software.

## Configuring syslog for Forcepoint V-Series Data Security Suite

The Forcepoint V-Series Data Security Suite DSM accepts events using syslog. Before you can integrate IBM QRadar you, must enable the Forcepoint V-Series appliance to forward syslog events in the Data Security Suite (DSS) Management Console.

### Procedure

1. Select **Policies > Policy Components > Notification Templates**.
2. Select an existing Notification Template or create a new template.
3. Click the **General** tab.
4. Click **Send Syslog Message**.
5. Select **Options > Settings > Syslog** to access the Syslog window.

The syslog window enables administrators to define the IP address/host name and port number of the syslog in their organization. The defined syslog receives incident messages from the Forcepoint Data Security Suite DSS Manager.

6. The syslog is composed of the following fields:

```
DSS Incident|ID={value}|action={display value - max}|urgency= {coded}|policy  
categories={values,,,}|source={value-display name}|destinations={values...}|channel={display  
name}|matches= {value}|details={value}
```

- Max length for policy categories is 200 characters.
- Max length for destinations is 200 characters.
- Details and source are reduced to 30 characters.

7. Click **Test Connection** to verify that your syslog is accessible.

### What to do next

You can now configure the log source in QRadar. The configuration is complete. The log source is added to QRadar as OSSEC events are automatically discovered. Events that are forwarded to QRadar by OSSEC are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Forcepoint V-Series Data Security Suite

If QRadar does not automatically detect the log source, add a Forcepoint V-Series Data Security Suite log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Forcepoint V-Series Data Security Suite:

Table 501. Syslog log source parameters for the Forcepoint V-Series Data Security Suite DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Forcepoint V Series
<b>Protocol Configuration</b>	Syslog

Table 501. Syslog log source parameters for the Forcepoint V-Series Data Security Suite DSM (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Forcepoint V-Series Data Security Suite DSM.

#### Related tasks

[“Adding a log source” on page 5](#)

## Forcepoint V-Series Data Security Suite sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Forcepoint V-Series Data Security Suite sample message when you use the Syslog protocol

The following sample event message shows that a protected cloud app request was forwarded.

```

## Forcepoint V-Series Content Gateway

The Forcepoint V-Series Content Gateway DSM for IBM QRadar supports events for web content on Forcepoint V-Series appliances with the Content Gateway software.

The Forcepoint V-Series Content Gateway DSM accepts events using syslog to stream events or by using the log file protocol to provide events to QRadar. Before you can integrate your appliance with QRadar, you must select one of the following configuration methods:

- To configure syslog for your Forcepoint V-Series, see [Configure Syslog for Forcepoint V-Series Data Security Suite](#).

- To configure the log file protocol for your Forcepoint V-Series, see [Log file protocol for Forcepoint V-Series Content Gateway](#).

## Configure syslog for Forcepoint V-Series Content Gateway

The Forcepoint V-Series DSM supports Forcepoint V-Series appliances that run the Forcepoint Content Gateway on Linux software installations.

Before you configure IBM QRadar, you must configure the Forcepoint Content Gateway to provide LEEF formatted syslog events.

## Configuring the Management Console for Forcepoint V-Series Content Gateway

You can configure event logging in the Content Gateway Manager.

### Procedure

1. Log into your Forcepoint Content Gateway Manager.
2. Click the **Configure** tab.
3. Select **Subsystems > Logging**.

The **General Logging Configuration** window is displayed.

4. Select **Log Transactions and Errors**.
5. Select **Log Directory** to specify the directory path of the stored event log files.

The directory that you define must exist and the Forcepoint user must have read and write permissions for the specified directory.

The default directory is /opt/WGC/logs.

6. Click **Apply**.
7. Click the **Custom** tab.
8. In the **Custom Log File Definitions** window, type the following text for the LEEF format.

```

<LogFormat>           <Name = "leef"/>           <Format = "LEEF:1.0|Forcepoint|WCG|
7.6|           %<wsds>|cat=%<wc>           src=%<chi> devTime=%<cqtn>
devTimeFormat=dd/MMM/yyyy:HH:mm:ss Z           http-username=%<caun> url=%<cquc>
method=%<cqhm> httpversion=%<cqh>           srcBytes=%<pscl> proxy-status-
cacheCode=%<ccrc>dstBytes=%<sscl> dst=%<pqsi>           server-status-code=%<sssc> usrName=%<wui>
code=%<pssc>           duration=%<ttms>"/>           duration=%<ttms>"/>

<LogObject>           <Format = "leef"/>           <Filename = "leef"/>
</LogObject>

```

**Note:** The fields in the LEEF format string are *tab separated*. You might be required to type the LEEF format in a text editor and then cut and paste it into your web browser to retain the tab separations. The definitions file ignores extra white space, blank lines, and all comments.

9. Select **Enabled** to enable the *custom logging* definition.
10. Click **Apply**.

### What to do next

You can now enable event logging for your Forcepoint Content Gateway.

## Enabling Event Logging for Forcepoint V-Series Content Gateway

If you are using a Forcepoint V-Series appliance, contact Forcepoint Technical Support to enable this feature.

### Procedure

1. Log in to the command-line Interface (CLI) of the server running Forcepoint Content Gateway.
2. Add the following lines to the end of the /etc/rc.local file:

```
( while [ 1 ] ; do tail -n1000 -F /opt/WCG/logs/leef.log | nc <IP Address> 514 sleep 1  
done ) &
```

Where <IP Address> is the IP address for IBM QRadar.

3. To start logging immediately, type the following command:

```
nohup /bin/bash -c "while [ 1 ] ; do tail -F /opt/WCG/logs/leef.log | nc <IP Address> 514;  
sleep 1; done" &
```

**Note:** You might need to type the logging command in “[Enabling Event Logging for Forcepoint V-Series Content Gateway](#)” on page 829 or copy the command to a text editor to interpret the quotation marks.

The configuration is complete. The log source is added to QRadar as syslog events from Forcepoint V-Series Content Gateway are automatically discovered. Events forwarded by Forcepoint V-Series Content Gateway are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Forcepoint V-Series Content Gateway

If QRadar does not automatically detect the log source, add a Forcepoint V-Series Content Gateway log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Forcepoint V-Series Content Gateway:

Table 503. Syslog log source parameters for the Forcepoint V-Series Content Gateway DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Forcepoint V Series
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Forcepoint V-Series Content Gateway appliance.

### Related tasks

[“Adding a log source” on page 5](#)

## Log file protocol for Forcepoint V-Series Content Gateway

The log file protocol allows IBM QRadar to retrieve archived log files from a remote host.

The Forcepoint V-Series DSM supports the bulk loading of log files from your Forcepoint V-Series Content Gateway using the log file protocol to provide events on a scheduled interval. The log files contain transaction and error events for your Forcepoint V-Series Content Gateway:

## Configuring the Content Management Console for Forcepoint V-Series Content Gateway

Configure event logging in the Content Management Console.

### Procedure

1. Log into your Forcepoint Content Gateway interface.
2. Click the **Configure** tab.
3. Select **Subsystems > Logging**.
4. Select **Log Transactions and Errors**.
5. Select **Log Directory** to specify the directory path of the stored event log files.

The directory you define must already exist and the Forcepoint user must have read and write permissions for the specified directory.

The default directory is /opt/WGC/logs .

6. Click **Apply**.
7. Click the **Formats** tab.
8. Select **Netscape Extended Format** as your format type.
9. Click **Apply**.

### What to do next

You can now enable event logging for your Forcepoint V-Series Content Gateway.

## Log File log source parameters for Forcepoint V-Series Content Gateway

If QRadar does not automatically detect the log source, add a Forcepoint V-Series Content Gateway log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from Forcepoint V-Series Content Gateway:

Table 504. Log File log source parameters for the Forcepoint V-Series Content Gateway DSM	
Parameter	Value
<b>Log Source type</b>	<b>Forcepoint V Series</b>
<b>Protocol Configuration</b>	<b>Log File</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Forcepoint V-Series Content Gateway devices.
<b>Service Type</b>	<b>Secure File Transfer Protocol (SFTP)</b>
<b>FTP File Pattern</b>	extended.log_.*.old
<b>Remote Directory</b>	/opt/WCG/logs
<b>Event Generator</b>	<b>LINEBYLINE</b>

For a complete list of Log File protocol parameters and their values, see [Log File protocol configuration options](#).

# Chapter 66. ForeScout CounterACT

The ForeScout CounterACT DSM for IBM QRadar accepts Log Event Extended Format (LEEF) events from CounterACT using syslog.

QRadar records the following ForeScout CounterACT events:

- Denial of Service (DoS)
- Authentication
- Exploit
- Suspicious
- System

## Syslog log source parameters for ForeScout CounterACT

If QRadar does not automatically detect the log source, add a ForeScout CounterACT log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from ForeScout CounterACT:

Table 507. Syslog log source parameters for the ForeScout CounterACT DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	ForeScout CounterACT
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your ForeScout CounterACT appliance.

### Related tasks

## Configuring the ForeScout CounterACT Plug-in

Before you configure IBM QRadar, you must install a plug-in for your ForeScout CounterACT appliance and configure ForeScout CounterACT to forward syslog events to QRadar.

### About this task

To integrate QRadar with ForeScout CounterACT, you must download, install, and configure a plug-in for CounterACT. The plug-in extends ForeScout CounterACT and provides the framework for forwarding LEEF events to QRadar.

### Procedure

1. From the [ForeScout website](https://www.forescout.com) (<https://www.forescout.com>), download the plug-in for ForeScout CounterACT.
2. Log in to your ForeScout CounterACT appliance.

3. From the CounterACT Console toolbar, select **Options > Plugins > Install**. Select the location of the plug-in file.

The plug-in is installed and displayed in the **Plug-ins** pane.
  4. From the **Plug-ins** pane, select the QRadar plug-in and click **Configure**.

The **Add** QRadar wizard is displayed.
  5. In the **Server Address** field, type the IP address of QRadar.
  6. From the **Port** list, select **514**.
  7. Click **Next**.
  8. From the **Assigned CounterACT devices** pane, choose one of the following options:
    - **Default Server** - Select this option to make all devices on this ForeScout CounterACT, forward events to QRadar.
    - **Assign CounterACT devices** - Select this option to assign which individual devices that are running on ForeScout CounterACT forward events to QRadar. The Assign CounterACT devices option is only available if you have one or more ForeScout CounterACT servers.
  9. Click **Finish**.
- The plug-in configuration is complete. You are now ready to define the events that are forwarded to QRadar by ForeScout CounterACT policies.

## Configuring ForeScout CounterACT Policies

---

ForeScout CounterACT policies test conditions to trigger management and remediation actions on the appliance.

### About this task

The plug-in provides an extra action for policies to forward the event to the IBM QRadar by using syslog. To forward events to QRadar, you must define a CounterACT policy that includes the QRadar update action.

The policy condition must be met at least one time to initiate an event send to QRadar. You must configure each policy to send updates to QRadar for events you want to record.

### Procedure

1. Select a policy for ForeScout CounterACT.
2. From the **Actions tree**, select **Audit > Send Updates** to QRadar Server.
3. From the **Contents** tab, configure the following value:

Select the **Send host property results** check box.
4. Choose one of the type of events to forward for the policy:
  - **Send All** - Select this option to include all properties that are discovered for the policy to QRadar.
  - **Send Specific** - Select this option to select and send only specific properties for the policy to QRadar.
5. Select the **Send policy status** check box.
6. From the **Trigger** tab, select the interval ForeScout CounterACT uses for forwarding the event to QRadar:
  - **Send when the action starts** - Select this check box to send a single event to QRadar when the conditions of your policy are met.
  - **Send when information is updated** - Select this check box to send a report when there is a change in the host properties that are specified in the **Contents** tab.

- **Send periodically every** - Select this check box to send a reoccurring event to QRadar on an interval if the policy conditions are met.

7. Click **OK** to save the policy changes.

8. Repeat this process to configure any additional policies with an action to send updates to QRadar.

The configuration is complete. Events that are forwarded by ForeScout CounterACT are displayed on the **Log Activity** tab of QRadar.

## ForeScout CounterACT sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### ForeScout CounterACT sample messages when you use the Syslog protocol

**Sample 1:** The following sample event message shows that an authentication certificate issuer is detected.

```
LEEF:1.0|ForeScout|CounterACT|8.0.1-99|agent_auth_issuer|cat=Property    sev=1

# Chapter 67. Fortinet FortiGate Security Gateway

The IBM QRadar SIEM DSM for Fortinet FortiGate Security Gateway collects events from Fortinet FortiGate Security Gateway and Fortinet FortiAnalyzer products.

The following table identifies the specifications for the Fortinet FortiGate Security Gateway DSM:

Table 510. Fortinet FortiGate Security Gateway DSM specifications	
Specification	Value
Manufacturer	Fortinet
DSM name	Fortinet FortiGate Security Gateway
RPM file name	DSM-FortinetFortiGate-QRadar_version-build_number.noarch.rpm
Supported versions	FortiOS 6.4 and earlier
Protocol	Syslog Syslog Redirect
Recorded event types	All events
Auto discovered?	Yes
Includes identity?	Yes
Includes custom properties?	Yes
More information	<a href="http://www.fortinet.com">Fortinet website</a> ( <a href="http://www.fortinet.com">http://www.fortinet.com</a> )

To integrate Fortinet FortiGate Security Gateway DSM with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent version of the Fortinet FortiGate Security Gateway RPM from the [IBM Support Website](#) onto your QRadar Console:
2. Download and install the Syslog Redirect protocol RPM to collect events through Fortinet FortiAnalyzer. When you use the Syslog Redirect protocol, QRadar can identify the specific Fortinet FortiGate Security Gateway firewall that sent the event.
3. For each instance of Fortinet FortiGate Security Gateway, configure your Fortinet FortiGate Security Gateway system to send syslog events to QRadar.
4. If QRadar does not automatically detect the log source for Fortinet FortiGate Security Gateway, you can manually add the log source. For the protocol configuration type, select **Syslog**, and then configure the parameters.
5. If you want QRadar to receive events from Fortinet FortiAnalyzer, manually add the log source. For the protocol configuration type, select **Syslog Redirect**, and then configure the parameters.

The following table lists the specific parameter values that are required for Fortinet FortiAnalyzer event collection:

Parameter	Value
Log Source Identifier Regex	<code>devname="?([\w-]+)</code>
Listen Port	<b>517</b>
Protocol	<b>UDP</b>

For more information about configuring Syslog Redirect protocol parameters, see [Syslog Redirect protocol overview](#).

Use these sample event messages to verify a successful integration with IBM QRadar.

### Related tasks

[Configuring a syslog destination on your Fortinet FortiGate Security Gateway device](#)

To forward Fortinet FortiGate Security Gateway events to IBM QRadar, you must configure a syslog destination.

[Configuring a syslog destination on your Fortinet FortiAnalyzer device](#)

To forward Fortinet FortiAnalyzer events to IBM QRadar, you must configure a syslog destination.

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring a syslog destination on your Fortinet FortiGate Security Gateway device

To forward Fortinet FortiGate Security Gateway events to IBM QRadar, you must configure a syslog destination.

### Procedure

1. Log in to the command line on your Fortinet FortiGate Security Gateway appliance.
2. Type the following commands, in order, replacing the variables with values that suit your environment.

```
config log syslogd setting
set status enable
set facility <facility_name>
set csv {disable | enable}
set port <port_integer>
set reliable enable
set server <IP_address>
end
example: set facility syslog
```

**Note:** If you set the value of `reliable` as `enable`, it sends as TCP; if you set the value of `reliable` as `disable`, it sends as UDP.

### What to do next

Your deployment might have multiple Fortinet FortiGate Security Gateway instances that are configured to send event logs to FortiAnalyzer. If you want to send FortiAnalyzer events to QRadar, see [Configuring a syslog destination on your Fortinet FortiAnalyzer device](#).

# Configuring a syslog destination on your Fortinet FortiAnalyzer device

To forward Fortinet FortiAnalyzer events to IBM QRadar, you must configure a syslog destination.

## Procedure

1. Log in to your FortiAnalyzer device.
2. On the **Advanced** tree menu, select **Syslog Forwarder**.
3. On the toolbar, click **Create New**.
4. Configure the **Syslog Server** parameters:

Parameter	Description
<b>Port</b>	The default port is 514.

5. Click **OK**.

## Fortinet FortiGate Security Gateway sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

### Fortinet FortiGate Security Gateway sample messages when you use the Syslog or the Syslog Redirect protocol

**Important:** Due to formatting, paste the message format into a text editor and then remove any carriage return or line feed characters.

**Sample 1:** The following sample shows an attempt to use a remote-access vulnerability that affects Microsoft Exchange Server. A remote attacker uses the vulnerability by sending an email with a meeting request that contains specially crafted vCal and iCal calendar data. As a result, the attacker might be able to take control of a vulnerable system.

The IBM QRadar SIEM DSM for Fortinet FortiGate Security Gateway collects events from Fortinet FortiGate Security Gateway and Fortinet FortiAnalyzer products.

## Configuring QRadar to categorize App Ctrl events for Fortinet Fortigate Security Gateway

---

If you want to categorize App Ctrl events based on the **Action** field in IBM QRadar, use the DSM Editor to enable the **App Ctrl** events.

By default, Fortinet Fortigate Security Gateway **App Ctrl** events are categorized as **notice/informational**.

### Procedure

1. On the **Admin** tab, in the **Data Sources** section, click **DSM Editor**.
2. From the **Select Log Source Type** window, select **Fortinet FortiGate Security Gateway** from the list, and click **Select**.
3. On the **Configuration** tab, set **Display DSM Parameters Configuration** to **On**.
4. From the **Event Collector** list, select the event collector for the log source, and click **Select**.
5. Set **Categorize App Ctrl Logs Based on Action Field** to **On**.
6. Click **Save** and close the DSM Editor.

# Chapter 68. Foundry FastIron

You can integrate a Foundry FastIron device with IBM QRadar to collect all relevant events using syslog. To do this you must configure syslog and your log source.

## Configuring syslog for Foundry FastIron

To integrate IBM QRadar with a Foundry FastIron RX device, you must configure the appliance to forward syslog events.

### Procedure

1. Log in to the Foundry FastIron device command-line interface (CLI).
2. Type the following command to enable logging:

```
logging on
```

Local syslog is now enabled with the following defaults:

- Messages of all syslog levels (Emergencies - Debugging) are logged.
- Up to 50 messages are retained in the local syslog buffer.
- No syslog server is specified.

3. Type the following command to define an IP address for the syslog server:

```
logging host <IP Address>
```

Where <IP Address> is the IP address of your QRadar.

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Foundry FastIron

If QRadar does not automatically detect the log source, add a Foundry FastIron log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Foundry FastIron:

Table 514. Syslog log source parameters for the Foundry FastIron DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Foundry FastIron
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Foundry FastIron appliance.

### Related tasks

# Chapter 69. FreeRADIUS

The IBM QRadar DSM for FreeRADIUS collects events from your FreeRADIUS device.

The following table lists the specifications for the FreeRADIUS DSM:

Table 515. FreeRADIUS DSM specifications	
Specification	Value
Manufacturer	FreeRADIUS
DSM name	FreeRADIUS
RPM file name	DSM-FreeRADIUS-Qradar_version-build_number.noarch.rpm
Supported versions	V2.x
Event format	Syslog
Recorded event types	All events
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	FreeRADIUS website ( <a href="http://freeradius.org">http://freeradius.org</a> )

To send logs from FreeRADIUS to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the FreeRADIUS DSM RPM from the IBM Support Website onto your QRadar Console.
2. Configure your FreeRADIUS device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a FreeRADIUS log source on the QRadar Console. The following table describes the parameters that require specific values for FreeRADIUS event collection:

Table 516. FreeRADIUS log source parameters	
Parameter	Value
Log Source type	FreeRADIUS
Protocol Configuration	Syslog

## Configuring your FreeRADIUS device to communicate with QRadar

Configure FreeRADIUS to send logs to the syslog daemon of the host and configure the daemon to send events to QRadar.

### Before you begin

You must have a working knowledge of syslog configuration and the Linux distribution.

### About this task

FreeRADIUS has multiple distributions. Some files might not be in the same locations that are described in this procedure. For example, the location of the FreeRADIUS startup script is based on distribution. Conceptually, the configuration steps are the same for all distributions.

## Procedure

1. Log in to the system that hosts FreeRADIUS.
2. Edit the /etc/freeradius/radius.conf file.
3. Change the text in the file to match the following lines:

```
logdir = syslog
Log_destination = syslog
log{
    destination = syslog
    syslog_facility = daemon
    stripped_names = no
    auth = yes
    auth_badpass = no
    auth_goodpass = no
}
```

4. Edit the /etc/syslog.conf file.
5. To configure log options, add the following text.

```
# .=notice logs authentication messages (L_AUTH).
# <facility_name>.=notice
@<IP_address_of_QRadar_Event_Collector_or_QRadar_Console>

# .=err logs module errors for FreeRADIUS.
#<facility_name>.=err
@<IP_address_of_QRadar_Event_Collector_or_QRadar_Console>

# .* logs messages to the same target.
# <facility_name>./*
@<IP_address_of_QRadar_Event_Collector_or_QRadar_Console>
```

An example syslog facility name is *local1*. You can rename it.

To configure a log option, remove the comment tag (#) from one of the active lines that contains an @ symbol.

6. If the configuration change does not load automatically, restart the syslog daemon. The method to restart the syslog daemon depends on the distribution that is used. The following table lists possible methods.

Operating system distribution	Command to restart daemon
Red Hat Enterprise Linux	service syslog restart
Debian Linux or Ubuntu Linux	/etc/init.d/syslog restart
FreeBSD operating system	/etc/rc.d/syslogd restart

7. Add the following options to the FreeRADIUS startup script:

- -l syslog
- -g <facility\_name>

The -g value must match the facility name in Step 5.

8. Restart FreeRADIUS.

# Chapter 70. Generic

---

The generic DSMs for IBM QRadar record all relevant authorization and firewall events by using Syslog. Generic refers to a non-vendor specific group of supported application types.

You must configure QRadar to interpret the incoming generic events, and manually create a log source.

QRadar supports the following generic DSMs:

- [Generic authorization server](#)
- [Generic firewall](#)

## Generic authorization Server

---

The generic authorization server DSM for IBM QRadar records all relevant generic authorization events by using Syslog. Generic refers to a non-vendor specific group of supported application types.

You must configure QRadar to interpret the incoming generic authorization events, and manually create a log source.

## Configuring event properties for authorization events

You must manually configure IBM QRadar to interpret the incoming generic authorization events:

### Procedure

1. Forward all authentication server logs to your QRadar system.

For information about forwarding authentication server logs to QRadar, see the vendor documentation for your authorized server.

2. Open the following file:

`/opt/QRadar/conf/genericAuthServer.conf`

Make sure you copy this file to systems that host the Event Collector and the QRadar Console.

3. Restart the Tomcat server:

`service tomcat restart`

A message is displayed indicating that the Tomcat server is restarted.

4. Enable or disable regular expressions in your patterns by setting the **regex\_enabled** property. By default, regular expressions are disabled.

For example:

`regex_enabled=false`

When you set the **regex\_enabled** property to `false`, the system generates regular expressions (regex) based on the tags you entered when you try to retrieve the corresponding data values from the logs.

When you set the **regex\_enabled** property to `true`, you can define custom regex to control patterns. These regex configurations are applied directly to the logs and the first captured group is returned. When you define custom regex patterns, you must adhere to regex rules, as defined by the Java programming language. For more information, see <http://download.oracle.com/javase/tutorial/essential/regex/>.

To integrate the generic authorization server with QRadar, make sure that you specify the classes directly instead of using the predefined classes. For example, the digit class `(/\d/)` becomes `/[0-9]/`. Rewrite the expression to use the primitive qualifiers `(/?/, /*/` and `/+/-`) rather than using numeric qualifiers.

5. Add the following lines to the genericAuthServer.conf file:

```
login_success_pattern=<login success pattern>
login_failed_pattern=<login failure pattern>
logout_pattern=<logout pattern>
source_ip_pattern=<source IP pattern>
source_port_pattern=<source port pattern>
user_name_pattern=<for pattern>
```

The following table provides examples of values that you can use for each pattern.

<b>Pattern</b>	<b>Value</b>	<b>Example</b>
login_success=<login success pattern>	Accepted password	The following log message shows login_success_pattern=Accepted password: Jun 27 12:11:21 expo sshd[19926]: Accepted password for root from <IP_address> port 1727 ssh2
login_failed_pattern=<login failure pattern>	Failed password	The following log message shows login_failed_pattern=Failed password: Jun 27 12:58:33 expo sshd[20627]: Failed password for root from <IP_address> port 1849 ssh2
logout_pattern=<logout pattern>	session closed	The following log message shows logout_pattern=session closed: Jun 27 13:00:01 expo su(<Username>)[22723]: session closed for user genuser
source_ip_pattern=<source IP pattern>	from	The following log message shows source_ip_pattern=from: Jun 27 12:11:21 expo sshd[19926]: Accepted password for root from <IP_address> port 1727 ssh2

Pattern	Value	Example
source_port_pattern=<source port pattern>	port	The following log message shows source_port_pattern=port:  Jun 27 12:11:21 expo sshd[19926]: Accepted password for root from <IP_address> port 1727 ssh2
user_name_pattern=<for pattern>	for	The following log message shows user_name_pattern=for:  Jun 27 12:11:21 expo sshd[19926]: Accepted password for root from <IP_address> port 1727 ssh2

**Tip:** All entries are case-insensitive.

## What to do next

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for generic authorization server

If QRadar does not automatically detect the log source, add a non-vendor specific generic authorization server log source on the QRadar Console by using the Syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from generic authorization server:

Table 517. Syslog log source parameters for the generic authorization server DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Configurable Authentication
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your generic authorization appliance.

### Related tasks

[“Adding a log source” on page 5](#)

## Generic firewall

---

The generic firewall DSM for IBM QRadar records all relevant events by using Syslog.

You must configure QRadar to interpret the incoming generic firewall events, and manually create a log source.

## Configuring event properties for generic firewall events

You must manually configure IBM QRadar to interpret the incoming generic firewall events.

### Procedure

1. Forward all firewall logs to QRadar.

For information about forwarding firewall logs from your generic firewall to QRadar, see the vendor documentation for your firewall events.

2. Open the following file:

```
/opt/QRadar/conf/genericFirewall.conf
```

Make sure you copy this file to systems that host the Event Collector and the QRadar Console.

3. Restart the Tomcat server:

```
service tomcat restart
```

A message is displayed indicating that the Tomcat server is restarted.

4. Enable or disable regular expressions in your patterns by setting the **regex\_enabled** property. By default, regular expressions are disabled.

For example:

```
regex_enabled=false
```

When you set the **regex\_enabled** property to **false**, the system generates regular expressions based on the tags you entered while you try to retrieve the corresponding data values from the logs.

When you set the **regex\_enabled** property to **true**, you can define custom regex to control patterns. These regex configurations are directly applied to the logs and the first captured group is returned. When you define custom regex patterns, you must adhere to regex rules, as defined by the Java programming language. For more information, see <http://download.oracle.com/javase/tutorial/essential/regex/>.

To integrate a generic firewall with QRadar, make sure that you specify the classes directly instead of using the predefined classes. For example, the digit class `(/\d/)` becomes `/[0-9]/`. Rewrite the expression to use the primitive qualifiers `(?//, /*/ and /*+)` rather than using numeric qualifiers.

5. Add the following lines to the `genericFirewall.conf` file:

```
accept_pattern=<accept pattern>
deny_pattern=<deny pattern>
source_ip_pattern=<source ip pattern>
source_port_pattern=<source port pattern>
destination_ip_pattern=<destination ip pattern>
```

The following table provides examples of values that you can use for each pattern.

<b>Pattern</b>	<b>Value</b>	<b>Example</b>
accept pattern=<accept pattern>	Packet accepted	The following log message shows accept pattern=Packet accepted: Aug. 5, 2005 08:30:00 Packet accepted. Source IP: <Source_IP_address> Source Port: 80 Destination IP: <Destination_IP_address> Destination Port: 80 Protocol: tcp
deny_pattern=<deny pattern>	Packet denied	The following log message shows deny_pattern=Packet denied: Aug. 5, 2005 08:30:00 Packet denied. Source IP: <Source_IP_address> Source Port: 21 Destination IP: <Destination_IP_address> Destination Port: 21 Protocol: tcp
source_ip_pattern=<source IP pattern>	from	The following log message shows source_ip_pattern=Source IP: Aug. 5, 2005 08:30:00 Packet accepted. Source IP: <Source_IP_address> Source Port: 80 Destination IP: <Destination_IP_address> Destination Port: 80 Protocol: tcp
source_port_pattern=<source port pattern>	port	The following log message shows source_port_pattern=Source Port: Aug. 5, 2005 08:30:00 Packet accepted. Source IP: <Source_IP_address> Source Port: 80 Destination IP: <Destination_IP_address> Destination Port: 80 Protocol: tcp

Pattern	Value	Example
destination_ip_pattern=<destination IP pattern>	from	The following log message shows destination_ip_pattern=Destination IP. Aug. 5, 2005 08:30:00 Packet accepted. Source IP: <Source_IP_address> Source Port: 80 Destination IP: <Destination_IP_address> Destination Port: 80 Protocol: tcp
destination_port_pattern=<destination port pattern>	port	The following log message shows destination_port_pattern=Destination Port: Aug. 5, 2005 08:30:00 Packet accepted. Source IP: <Source_IP_address> Source Port: 80 Destination IP: <Destination_IP_address> Destination Port: 80 Protocol: tcp
protocol_pattern=<protocol pattern>	protocol	The following log message shows protocol_pattern=Protocol: Aug. 5, 2005 08:30:00 Packet accepted. Source IP: <Source_IP_address> Source Port: 80 Destination IP: <Destination_IP_address> Destination Port: 80 Protocol: tcp

**Tip:** Patterns are case-insensitive and you can add multiple patterns. For multiple patterns, separate by using a # symbol.

- Save and exit the file.

## What to do next

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for generic firewall

If QRadar does not automatically detect the log source, add a generic firewall log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from generic firewall:

*Table 518. Syslog log source parameters for the generic firewall DSM*

Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Configurable Firewall Filter
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your generic firewall appliance.

**Related tasks**

[“Adding a log source” on page 5](#)

# Chapter 71. genua genugate

The IBM QRadar DSM for genua genugate collects events from a genua genugate device.

genua genugate produces logs from third-party software such as openBSD and sendMail. The genua genugate DSM provides basic parsing for the logs from these third-party devices. To achieve more specific parsing for these logs, install the specific DSM for that device.

The following table lists the specifications for the genua genugate DSM:

Table 519. genua genugate DSM specifications	
Specification	Value
Manufacturer	genua
DSM name	genua genugate
RPM file name	DSM-GenuaGenugate-Qradar_version-build_number.noarch.rpm
Supported versions	8.2 and later
Protocol	Syslog
Recorded event types	General error messages High availability General relay messages Relay-specific messages genua programs/daemons EPSI Accounting Daemon - gg/src/acctd Configfw FWConfig ROFWConfig User-Interface Webserver
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.genua.de/en/solutions/high-resistance-firewall-genugate.html">genua website</a> ( <a href="https://www.genua.de/en/solutions/high-resistance-firewall-genugate.html">https://www.genua.de/en/solutions/high-resistance-firewall-genugate.html</a> )

To send genua genugate events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - genua genugate DSM RPM
2. Configure your genua genugate device to send syslog events to QRadar.

3. If QRadar does not automatically detect the log source, add a genua genugate log source on the QRadar Console. Configure all required parameters and use the following table to identify specific values for genua genugate:

*Table 520. genua genugate log source parameters*

Parameter	Value
Log Source type	genua genugate
Protocol Configuration	Syslog

# Chapter 72. Google

IBM QRadar supports a range of Google products.

## Google Cloud Audit Logs

The IBM QRadar DSM for Google Cloud Audit Logs collects JSON events from a Google Cloud service.

To integrate Google Cloud Audit Logs with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - GoogleCloudAudit DSM RPM
  - DSM Common RPM
  - GoogleCloudPubSub protocol RPM
  - GoogleCommon protocol RPM
  - Protocol Common RPM
2. Configure your Google Cloud Audit Logs service to send events to QRadar.
3. If QRadar does not automatically detect the log source, add a log source for Google Cloud Audit Logs on the QRadar Console.

### Related tasks

[“Adding a DSM” on page 4](#)

## Google Cloud Audit Logs DSM specifications

When you configure the Google Cloud Audit Logs, understanding the specifications for the Google Cloud Audit Logs DSM can help ensure a successful integration. For example, knowing what the supported services of Google Cloud Audit Logs is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Google Cloud Audit Logs DSM.

<i>Table 522. Google Cloud Audit Logs DSM specifications</i>	
<b>Specification</b>	<b>Value</b>
Manufacturer	Google
DSM name	Google Cloud Audit Logs
RPM file name	DSM-GoogleCloudAudit-7.4-QRadar_version-build_number.noarch.rpm
Supported services	Google Compute Engine Identity Access Management Identity Platform Cloud Storage
Protocol	Google Cloud Pub/Sub
Event format	JSON

Table 522. Google Cloud Audit Logs DSM specifications (continued)

Specification	Value
Recorded event types	Storage, list, update
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://cloud.google.com/logging/docs/audit">Google Cloud Audit Logs documentation (https://cloud.google.com/logging/docs/audit)</a>

## Configuring Google Cloud Audit Logs to communicate with QRadar

Before you can add a log source in IBM QRadar, you must set up a functioning Pub/Sub system on your Google Cloud console.

### Procedure

1. Create a Google account. For more information, see [Create a Google Account \(https://support.google.com/accounts/answer/27441?hl=en\)](https://support.google.com/accounts/answer/27441?hl=en).
2. Set up a Pub/Sub system on your Google Cloud console. For more information, see [Quickstart: building a functioning Pub/Sub system \( https://cloud.google.com/pubsub/docs/quickstart-py-mac\)](https://cloud.google.com/pubsub/docs/quickstart-py-mac).

**Important:** When you create service account credentials on the Google Cloud platform, use the following service account credentials:

```
{
  "type": "service_account",
  "project_id": "<project_id>",
  "private_key_id": "<private_key_id>",
  "private_key": "<private_key>",
  "client_email": "<client_email>",
  "client_id": "1111111111111111",
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",
  "token_uri": "https://oauth2.googleapis.com/token",
  "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
  "client_x509_cert_url": "< client_x509_cert_url >"
}
```

### What to do next

Add a log source in QRadar. For more information, see [Google Cloud Pub/Sub protocol log source parameters for Google Cloud Audit Logs](#).

## Google Cloud Pub/Sub protocol log source parameters for Google Cloud Audit Logs

If QRadar does not automatically detect the log source, add a Google Cloud Audit Logs log source on the QRadar Console by using the Google Cloud Pub/Sub protocol.

When using the Google Cloud Pub/Sub protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Google Cloud Pub/Sub events from Google Cloud Audit Log Service:

Table 523. Google Cloud Pub/Sub protocol log source parameters for the Google Cloud Audit Log DSM

Parameter	Value
<b>Log Source type</b>	Google Cloud Audit Logs

*Table 523. Google Cloud Pub/Sub protocol log source parameters for the Google Cloud Audit Log DSM (continued)*

Parameter	Value
<b>Protocol Configuration</b>	Google Pub/Sub Protocol
<b>Log Source Identifier</b>	Use the IP address as a identifier for events from your Google Cloud Audit Log Service. The log source identifier must be a unique value.

For a complete list of Google Cloud Pub/Sub protocol parameters and their values, see [Google Cloud Pub/Sub protocol configuration options..](#)

## Google Cloud Platform - Cloud DNS

The IBM QRadar DSM for Google Cloud Platform - Cloud DNS collects JSON events from a Google Cloud DNS service.

To integrate Google Cloud Platform - Cloud DNS with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - GoogleCloudDNS DSM RPM
  - DSM Common RPM
  - GoogleCloudPubSub protocol RPM
  - GoogleCommon protocol RPM
  - Protocol Common RPM
2. Configure your Google Cloud Platform - Cloud DNS service to send events to QRadar.
3. If QRadar does not automatically detect the log source, add a log source for Google Cloud Platform - Cloud DNS on the QRadar Console.

## Google Cloud Platform - Cloud DNS DSM specifications

When you configure Google Cloud Platform - Cloud DNS, understanding the specifications for the Google Cloud Platform - Cloud DNS DSM can help ensure a successful integration. For example, knowing what the supported services of Google Cloud Platform - Cloud DNS are before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Google Cloud Platform - Cloud DNS DSM.

<i>Table 526. Google Cloud Platform - Cloud DNS DSM specifications</i>	
<b>Specification</b>	<b>Value</b>
Manufacturer	Google
DSM name	Google Cloud Platform - Cloud DNS
RPM file name	DSM-GoogleCloudDNS-7.4-QRadar_version-build_number.noarch.rpm
Supported services	Google Cloud DNS
Protocol	Google Cloud Pub/Sub Syslog
Event format	JSON
Recorded event types	Cloud DNS
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://cloud.google.com/dns/docs/overview">Google Cloud Platform - Cloud DNS documentation</a> ( <a href="https://cloud.google.com/dns/docs/overview">https://cloud.google.com/dns/docs/overview</a> )

# Configuring Google Cloud Platform - Cloud DNS to communicate with QRadar

Before you can add a log source in IBM QRadar, you must set up a functioning Pub/Sub system on your Google Cloud console.

## Procedure

1. Create a Google account. For more information, see [Create a Google Account](https://support.google.com/accounts/answer/27441?hl=en) (<https://support.google.com/accounts/answer/27441?hl=en>).
2. Set up a Pub/Sub system on your Google Cloud console. For more information, see [Quickstart: building a functioning Pub/Sub system](https://cloud.google.com/pubsub/docs/quickstart-py-mac) (<https://cloud.google.com/pubsub/docs/quickstart-py-mac>).

**Important:** When you create service account credentials on the Google Cloud platform, use the following service account credentials:

```
{  
  "type": "service_account",  
  "project_id": "<project_id>",  
  "private_key_id": "<private_key_id>",  
  "private_key": "<private_key>",  
  "client_email": "<client_email>",  
  "client_id": "11111111111111111111",  
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",  
  "token_uri": "https://oauth2.googleapis.com/token",  
  "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",  
  "client_x509_cert_url": "< client_x509_cert_url >"  
}
```

## What to do next

Add a log source in QRadar. For more information, see [Google Cloud Pub/Sub protocol log source parameters for Google Cloud Platform - Cloud DNS](#).

## Google Cloud Pub/Sub protocol log source parameters for Google Cloud Platform - Cloud DNS

If QRadar does not automatically detect the log source, add a Google Cloud Platform - Cloud DNS log source on the QRadar Console by using the Google Cloud Pub/Sub protocol.

When you use the Google Cloud Pub/Sub protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Google Cloud Pub/Sub events from Google Cloud DNS Service:

<i>Table 527. Google Cloud Pub/Sub protocol log source parameters for the Google Cloud Platform - Cloud DNS DSM</i>	
Parameter	Value
<b>Log Source type</b>	Google Cloud Platform - Cloud DNS
<b>Protocol Configuration</b>	Google Pub/Sub Protocol
<b>Log Source Identifier</b>	Use the IP address as a identifier for events from your Google Cloud DNS Service.  The log source identifier must be a unique value.

For a complete list of Google Cloud Pub/Sub protocol parameters and their values, see [Google Cloud Pub/Sub protocol configuration options](#).

## Google Cloud Platform Firewall

The IBM QRadar DSM for Google Cloud Platform Firewall collects Google Cloud Pub/Sub events from a Google Cloud Platform Firewall service.

To integrate Google Cloud Platform Firewall with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - Google Cloud Firewall Platform DSM RPM
  - Protocol GoogleCloudPubSub RPM
  - Protocol GoogleCommon RPM
2. Configure your Google Cloud Platform Firewall service to send events to QRadar. For more information, see [Configuring Google Cloud Platform Firewall to communicate with QRadar](#).
3. Add a Google Cloud Platform Firewall log source on the QRadar Console. For more information, see [Google Cloud Pub/Sub log source parameters for Google Cloud Platform Firewall](#).

## Google G Suite Activity Reports

The IBM QRadar DSM for Google G Suite Activity Reports receives JSON events from the Google G Suite Activity Reports API.

**Important:** Google G Suite Activity Reports is supported in QRadar 7.3.2.6, build number 20191022133252 or later.

To integrate Google G Suite Activity Reports with QRadar, complete the following steps:

- If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol Common RPM
  - Google Common RPM
  - Google G Suite Activity Reports REST API protocol RPM
  - Google G Suite Activity Reports DSM RPM
- Configure your Google G Suite Activity Reports device to send events to QRadar. For more information, see [“Configuring Google G Suite Activity Reports to communicate with QRadar” on page 869](#).
- Add a Google G Suites Activity Reports log source on the QRadar Console. For more information about configuring the log source, see [“Google G Suite Activity Reports log source parameters” on page 872](#).

#### Related concepts

[“Google G Suite Activity Reports” on page 868](#)

The IBM QRadar DSM for Google G Suite Activity Reports receives JSON events from the Google G Suite Activity Reports API.

## Configuring Google G Suite Activity Reports to communicate with QRadar

Before you can add a log source in QRadar, you must assign a role to a user, create a custom role with reports access, create a service account and grant API access to a service account in Google G Suite.

You must be a Google administrator with the ability to manage users. If you do not have access, contact your Google administrator.

## Assigning a role to a user

### Procedure

1. Log in to the [Google Admin console](https://admin.google.com) (<https://admin.google.com>), and then click **Users** to access the **Users** page.

The screenshot shows the Google Admin console interface. At the top, there's a navigation bar with 'Google Admin' and a search bar. Below it, a 'Users' section header. Underneath, there's a table with columns: Name, Email, Status, Last sign in, and Email usage. The table contains three rows for users 'Test 1', 'Test 2', and 'Test 3', each with a small profile picture icon.

Name	Email	Status	Last sign in	Email usage
Test 1	test1@example.page	Active	3 months ago	0 GB
Test 2	test2@example.page	Active	2 months ago	0 GB
Test 3	test3@example.page	Active	3 days ago	0 GB

Figure 40. Google Admin users

Picture: ©2018 Google LLC, used with permission. Google and the Google logo are registered trademarks of Google LLC.

2. Click the name of the user that you want to grant access to.
3. Click in the **Admin roles and privileges** section to open the **Admin roles and privileges** page, and then click **Edit** to assign a role that includes reports access for the selected user.

Figure 41. Admin roles and privileges

Picture: ©2018 Google LLC, used with permission. Google and the Google logo are registered trademarks of Google LLC.

4. Optional: If the **Super Admin** role was not used in Step 3, create a new role that has reports access. By default, the **Super Admin** role has this privilege.

a) Click **CREATE CUSTOM ROLE**.

b) On the **Admin roles** page, click **CREATE A NEW ROLE**.

Figure 42. Create a new role

Picture: ©2018 Google LLC, used with permission. Google and the Google logo are registered trademarks of Google LLC.

- c) On the **Privileges** tab, select the **Reports** check box, and then click **Save**.

Figure 43. New role privileges

Picture: ©2018 Google LLC, used with permission. Google and the Google logo are registered trademarks of Google LLC.

This role appears in the roles section as an option when you assign a role to a user.

# Creating a service account with viewer access

## Procedure

1. On the [Google Cloud Platform \(GCP\) APIs & Services page](https://console.cloud.google.com/apis/dashboard) (<https://console.cloud.google.com/apis/dashboard>), click **Credentials**.
2. From the navigation menu, select **Credentials**.
3. Click **+CREATE CREDENTIALS** > **Service account**.
4. In the **Service account name** field, type a name for the service account, then click **CREATE AND CONTINUE**.
5. From the **Select a role** list, select **Actions Viewer**, then click **CONTINUE**.
6. In the **Service account user role** field, type the name for your user.
7. In the **Service account admins role** field, type the name for your user.
8. Click **DONE**.
9. In the **Service Accounts** section, select the service account that you created.
10. In the **API Keys** section, click **Add Key**.

You need the contents of the key for the **Service Account Credentials** parameter value when you add a log source in QRadar.

# Granting API client access to a service account

## Procedure

1. On the [Google Admin page](https://admin.google.com/ac/home?hl=en) (<https://admin.google.com/ac/home?hl=en>), from the navigation menu, select **Security > API Controls**.
2. In the Domain wide delegation section, click **MANAGE DOMAIN WIDE DELEGATION**

Figure 44. Manage Domain-wide Delegation

Picture: ©2021 Google LLC, used with permission. Google and the Google logo are registered trademarks of Google LLC.

3. To add a new client ID, click **Add new**.
4. In the **Client ID** field, enter the value for the API key that you added when you created a service account.
5. In the **OAuth Scopes (comma-delimited)** field, type <https://www.googleapis.com/auth/admin.reports.audit.readonly>.
6. Click **AUTHORIZE**.

## What to do next

Add a Google G Suite Activity Reports log source on the QRadar Console by using the Google G Suite Activity Reports REST API. For more information, see [“Google G Suite Activity Reports log source parameters” on page 872](#).

## Google G Suite Activity Reports log source parameters

When you add a Google G Suite Activity Reports log source on the QRadar Console by using the Google G Suite Activity Reports REST API, you must use specific parameters.

The following table describes the parameters that require specific values to collect Google G Suite Activity Reports events from Google G Suite.

Table 533. Google G Suite Activity Reports REST API protocol log source parameters for the Google G Suite Activity Reports DSM	
Parameter	Value
<b>Log Source type</b>	Google G Suite Activity Reports
<b>Protocol Type</b>	Google G Suite Activity Reports REST API
<b>Service Account Credentials</b>	Authorizes access to Google's APIs for retrieving the events.  Copy and paste the contents of the JSON formatted file that you downloaded when you completed <a href="#">“Configuring Google G Suite Activity Reports to communicate with QRadar” on page 869</a> .
<b>Delegated User Account Email</b>	The Google user account that has report privileges.

For a complete list of Google G Suite Activity Reports REST API protocol parameters and their values, see [Google G Suite Activity Reports REST API protocol options](#).

Use these sample event messages as a way of verifying a successful integration with QRadar.

The following table provides sample event messages when you use the Google G Suite Activity Reports REST API protocol for the Google G Suite Activity Reports DSM.

Table 534. Google G Suite Activity Reports sample message supported by Google G Suite Activity Reports.

Event name	Low-level category	Sample log message
Login_success	User login success	<pre>{   "actor": {     "email": "xxx@xxxxxx.xxx",     "profileId": "xxxxxxxxxxxxxxxxx"   },   "etag": "\\"3InmzELrmhMYx7Wvxlz3Nl10opE/m2bw4uWdXlHjVQ4P1Az5ED46P4w\\\"",   "events": [     {       "name": "login_success",       "parameters": [         {           "name": "login_type",           "value": "google_password"         },         {           "name": "login_challenge_method"         }       ],       "boolValue": false,       "name": "is_suspicious"     }   ],   "id": {     "applicationName": "login",     "customerId": "xxxxxx",     "time": "2019-05-22T20:03:42.047Z",     "uniqueQualifier": "239837479183"   },   "ipAddress": "&lt;IP_address&gt;",   "kind": "admin#reports#activity" }  {   "actor": {     "email": "xxx@xxxxxx.xxx",     "profileId": "xxxxxxxxxxxxxxxxx"   },   "etag": "\\"3InmzELrmhMYx7Wvxlz3Nl10opE/m2bw4uWdXlHjVQ4P1Az5ED46P4w\\\"",   "events": [     {       "name": "login_success",       "parameters": [         {           "name": "login_type",           "value": "google_password"         },         {           "multiValue": [             "password"           ],           "name": "login_challenge_method"         }       ],       "boolValue": false,       "name": "is_suspicious"     }   ],   "id": {     "applicationName": "login",     "customerId": "xxxxxx",     "time": "2019-05-22T20:03:42.047Z",     "uniqueQualifier": "239837479183"   },   "ipAddress": "&lt;IP_address&gt;",   "kind": "admin#reports#activity" } </pre>
edit	Update Activity Succeeded	<pre>{   "actor": {     "email": "xxx@xxxxxx.xxx",     "profileId": "xxxxxxxxxxxxxxxxx"   },   "etag": "\\"3InmzELrmhMYx7Wvxlz3Nl10opE/9tDfe88oL_ydXHALurRrMoRrLH4\\\"",   "events": [     {       "name": "edit",       "parameters": [         {           "boolValue": true,           "name": "primary_event"         },         {           "boolValue": true,           "name": "billable"         }       ],       "name": "doc_id",       "value": "1rLEPjwJTitDL08LKhU0Q1GxWE7yzNWRicVrRQ0KfN9Y"     }   ],   "id": {     "applicationName": "drive",     "customerId": "xxxxxx",     "time": "2019-0603T16:38:11.461Z",     "uniqueQualifier": "6949699212699371308"   },   "ipAddress": "&lt;IP_address&gt;",   "kind": "admin#reports#activity" } </pre>

## Troubleshooting Google G Suite Activity Reports

To resolve issues with the Google G Suite Activity Reports DSM, use the troubleshooting and support information. Errors can be found by using the protocol testing tools in the QRadar Log Source Management app.

### General troubleshooting

The following steps apply to all user input. The general troubleshooting procedure contains the first steps to follow for any errors with the Google G Suite Activity Reports REST API protocol. Many of the errors related to the Google G Suite Activity Reports REST API protocol can be solved with these basic steps.

1. Check for any spelling mistakes or unnecessary characters in the **User Account** field.
2. Reenter all fields.

3. Create a service account credential file and enter it into the **Service Account Credentials** field.

For more information, see:

- “[Invalid private keys](#)” on page 874
- “[Authorization errors](#)” on page 874
- “[Invalid email or username errors](#)” on page 875
- “[Invalid JSON formatting](#)” on page 875
- “[Network errors](#)” on page 875
- “[Google G Suite Activity Reports FAQ](#)” on page 876

## Invalid private keys

### Symptoms

Error: “An I/O operation failed or was interrupted. For further details, see the “Raw Error Message” and the additional messages”

Error: “List of potentially invalid parameters: Service Account Credentials”

Error: “Unexpected exception reading PKCS data”

### Causes

These errors indicate that the Service Account Credentials contain an invalid private key value. This error is commonly caused by issues with the value that is entered into the **Service Account** field.

### Resolving the problem

Follow these steps to resolve your invalid private key error.

1. Check for any spelling mistakes or unnecessary characters in the **User Account** field.
2. Reenter all fields.
3. Create a service account credential file and enter it into the **Service Account Credentials** field.

## Authorization errors

### Symptoms

Error: “An I/O operation failed or was interrupted. For further details see the “Raw Error Message” and the additional messages”

Error: “List of potentially invalid parameters : Service Account Credentials”

Error: “Client is unauthorized to retrieve access tokens using this method, or client not authorized for any of the scopes requested.”

### Causes

These errors relate to service account authorization. Authorization issues commonly occur when required permissions are not provided to the service account or user account. The service account needs domain-wide read access. The user account requires reports access.

### Resolving the problem

Follow these steps to resolve your authorization error.

1. Verify that the service account is correctly configured with domain-wide services.
2. Ensure that the user account has a role with reports access.

## Invalid email or username errors

### Symptoms

Error: "An I/O operation failed or was interrupted."

Error: "error\_description" : "Not a valid email or user ID."

Error: "List of potentially invalid parameters : User Account and Service Account Credentials"

### Causes

These errors usually occur if the provided user account doesn't exist, or the **client\_email** field within the service account credentials is invalid. A common reason for this error is typographical errors in the user account field.

### Resolving the problem

Ensure that the user account exists.

Ensure that the **Delegated User Account Email** account is the Google user account that has reports privileges and not the **client\_email** property value in the Service Account Credentials JSON file.

## Invalid JSON formatting

### Symptoms

Error: "Service Account Credentials don't appear to be in a valid json format."

Error: "An error occurred indicating a json parsing problem. Usually used when non-well-formed content (content that does not conform to JSON syntax as per specification) is encountered. For further details see the "Raw Error Message" and the additional messages"

Error: "Invalid UTF-8 start byte"

Error: "An error occurred indicating a json parsing problem. Usually used when non-well-formed content (content that does not conform to JSON syntax as per specification) is encountered. For further details see the "Raw Error Message" and the additional messages"

### Causes

These errors occur when the service account credentials are not in a valid JSON format.

### Resolving the problem

Follow these steps to resolve your invalid JSON formatting error.

1. Verify that the service account credentials are in a valid JSON format.

**Tip:** An online JSON formatter can identify problems with the JSON format.

2. If the error persists, generate a new service account credentials key.

## Network errors

### Symptoms

Error: "Error obtaining sample events :: Network is unreachable (connect failed)"

## **Causes**

IBM QRadar cannot connect to Google servers to receive Google G Suite Activity Reports events. This error can be related to many network issues, including proxy issues.

## **Resolving the problem**

Follow these steps to resolve your network error.

1. Ensure that the target event collector has access to the internet.
2. Ensure that there are no network configurations that are blocking access to Google Admin. Contact your network administrator if you are unable to connect to Google Admin.
3. Check that the network can access the following hosts:
  - googleapis.com:443
  - oauth2.googleapis.com:443

## **Google G Suite Activity Reports FAQ**

Use these frequently asked questions and answers to help you understand Google G Suite Activity Reports.

- “[Why does the service account need domain-wide read access?](#)” on page 876
- “[Why does the user account need reports access?](#)” on page 876
- “[Why does Google G Suite Activity Reports use service accounts to authorize access instead of other authentication methods?](#)” on page 876
- “[What types of events are collected by the Google G Suite Activity Reports API?](#)” on page 876
- “[Why do you need a user account if you have service account credentials?](#)” on page 877
- “[What does a standard Service Account Credentials file look like?](#)” on page 877
- “[What host and ports are used by this protocol?](#)” on page 877
- “[Are there any alternatives to the officially documented authorization method?](#)” on page 877

### **Why does the service account need domain-wide read access?**

The domain-wide read access allows the service account to impersonate a user. Without domain-wide read access, the service account is unable to obtain reports access.

### **Why does the user account need reports access?**

The events that the Google Activity Reports protocol retrieves all come from the reports function of Google Admin. This access is required to retrieve any events from the Google Activity Reports API.

### **Why does Google G Suite Activity Reports use service accounts to authorize access instead of other authentication methods?**

The following document contains a section that is named “Service accounts,” which explains in detail the difference between service accounts and other methods of authorization. Service accounts are different from other methods of authorization because they can act without requiring user consent. Service accounts are intended for server to server communications. For more information, see [Using OAuth 2.0 to Access Google APIs](#) (<https://developers.google.com/identity/protocols/OAuth2>).

### **What types of events are collected by the Google G Suite Activity Reports API?**

This protocol collects only admin, user accounts, login, and drive events. These events are detailed in the reports section of the [G Suite Admin SDK Activities list](#) (<https://developers.google.com/admin-sdk/reports/v1/reference/activities/list>).

## **Why do you need a user account if you have service account credentials?**

For a service account to have access to the reports API it needs to impersonate an existing user. For more information, see [domain-wide delegation](https://developers.google.com/admin-sdk/directory/v1/guides/delegation) (<https://developers.google.com/admin-sdk/directory/v1/guides/delegation>).

## **What does a standard Service Account Credentials file look like?**

In a real Service Account Credentials file, the empty fields are populated with values that are related to the service account.

```
{  
  "type": "service_account",  
  "project_id": "",  
  "private_key_id": "",  
  "private_key": "-----BEGIN PRIVATE KEY-----\n=\n-----END PRIVATE KEY-----\n",  
  "client_email": "",  
  "client_id": "",  
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",  
  "token_uri": "https://oauth2.googleapis.com/token",  
  "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",  
  "client_x509_cert_url": ""  
}
```

## **What host and ports are used by this protocol?**

The following hosts and ports are used by this protocol:

Host	Description
oauth2.googleapis.com:443	Authentication server used by Google to authenticate API access.
googleapis.com:443	Googles API server. Used to access the Google G Suite Activity Reports API.

## **Are there any alternatives to the officially documented authorization method?**

The Google G Suite Activity Reports API requires both a user account and a service account. Due to these restrictions, it is not possible to delegate the required permissions to just the service account or just the user account. If the offered authorization method is not satisfactory, contact IBM Support.

[\(Back to top\)](#)

# Chapter 73. Great Bay Beacon

The Great Bay Beacon DSM for IBM QRadar supports syslog alerts from the Great Bay Beacon Endpoint Profiler.

QRadar records all relevant Endpoint security events. Before you can integrate Great Bay Beacon with QRadar, you must configure your Great Bay Beacon Endpoint Profiler to forward syslog event messages to QRadar.

## Configuring syslog for Great Bay Beacon

You can configure your Great Bay Beacon Endpoint Profiler to forward syslog events.

### Procedure

1. Log in to your Great Bay Beacon Endpoint Profiler.
2. To create an event, select **Configuration > Events > Create Events**.

A list of currently configured events is displayed.

3. From the **Event Delivery Method** pane, select the **Syslog** check box.
4. To apply your changes, select **Configuration Apply Changes > Update Modules**.
5. Repeat “[Configuring syslog for Great Bay Beacon](#)” on page 879 to configure all of the events that you want to monitor in IBM QRadar.

6. Configure QRadar as an external log source for your Great Bay Beacon Endpoint Profiler.

For information on configuring QRadar as an external log source, see the *Great Bay Beacon Endpoint Profiler Configuration Guide*.

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Great Bay Beacon

If QRadar does not automatically detect the log source, add a Great Bay Beacon log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Great Bay Beacon:

Table 535. Syslog log source parameters for the Great Bay Beacon DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Great Bay Beacon
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Great Bay Beacon appliance.

### Related tasks

[“Adding a log source” on page 5](#)

# Chapter 74. H3C Technologies

IBM QRadar accepts events from a range of H3C Technologies DSMs.

## H3C Comware Platform

The IBM QRadar DSM for the H3C Comware Platform collects events from a number of network devices from H3C Technologies. QRadar supports H3C Switches, H3C Routers, H3C Wireless LAN Devices, and H3C IP Security Devices.

The following table describes the specifications for the H3C Comware Platform DSM:

Table 536. H3C Comware Platform DSM specifications	
Specification	Value
Manufacturer	H3C Technologies Co., Limited
DSM name	H3C Comware Platform, H3C Switches, H3C Routers, H3C Wireless LAN Devices, and H3C IP Security Devices.
RPM file name	DSM-H3CComware-QRadar_version-build_number.noarch.rpm
Supported versions	V7
Protocol	Syslog
Event format	NVP
Recorded event types	System
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.h3c.com">H3C Technologies</a> ( <a href="http://www.h3c.com">http://www.h3c.com</a> )

To integrate H3C Comware Platform, H3C Switches, H3C Routers, H3C Wireless LAN Devices, or H3C IP Security Devices with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the H3C Comware Platform DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
2. Configure your H3C Comware Platform router or device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a H3C Comware Platform log source on the QRadar Console. The following table describes the parameters that require specific values for H3C Comware Platform event collection:

Table 537. H3C Comware Platform log source parameters

Parameter	Value
Log Source type	H3C Comware Platform
Protocol Configuration	Syslog

The following table provides a sample syslog event message for the H3C Comware Platform DSM:

Table 538. H3C Comware Platform sample syslog message

Event name	Low level category	Sample log message
A user's AAA request is rejected	AAA Session Denied	<pre>&lt;188&gt;Jun 14 17:11:11 2013 HP %%10AAA/5/AAA_FAILURE: -AAAType=AUTHOR-AAADomain =domain1-Service=login- UserName=cwf@system; AAA is failed.  &lt;188&gt;Jun 14 17:11:11 2013 HP %%10AAA/5/AAA_FAILURE: -AAAType=AUTHOR- AAADomain=domain1- Service=login- UserName=cwf@system; AAA is failed.</pre>

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring H3C Comware Platform to communicate with QRadar

To collect H3C Comware Platform events, enable syslog settings and configure a log host. H3C Switches, H3C Routers, H3C Wireless LAN Devices, and H3C IP Security Devices are supported by QRadar.

### Procedure

1. Log in to the **command line** interface by using the console port, or by using Telnet or SSH. For more information about login methods, see the *Logging into the CLI* section in the configuration guide for your H3C devices.
2. To access the system view, type the `<system_name> system-view` command.
3. To enable the syslog settings, type the following commands in the order that they are listed.
  - a. `info-center source default loghost deny`
  - b. `info-center source AAA loghost level informational`
  - c. `info-center source ACL loghost level informational`
  - d. `info-center source FIPS loghost level informational`
  - e. `info-center source HTTPD loghost level informational`
  - f. `info-center source IKE loghost level informational`
  - g. `info-center source IPSEC loghost level informational`
  - h. `info-center source LOGIN loghost level informational`
  - i. `info-center source LS loghost level informational`
  - j. `info-center source PKI loghost level informational`
  - k. `info-center source PORTSEC loghost level informational`
  - l. `info-center source PWDCTL loghost level informational`
  - m. `info-center source RADIUS loghost level informational`
  - n. `info-center source SHELL loghost level informational`
  - o. `info-center source SNMP loghost level informational`
  - p. `info-center source SSHS loghost level informational`
  - q. `info-center source TACACS loghost level informational`
  - r. `info-center loghost <QRadar Event Collector IP> 514`
4. To exit the system view, type the `quit <system_name>` command.

# Chapter 75. HBGary Active Defense

The HBGary Active Defense DSM for IBM QRadar accepts several event types that are forwarded from HBGary Active Defense devices, such as access, system, system configuration, and policy events.

Events from Active Defense are forwarded in the Log Event Extended Format (LEEF) to QRadar using syslog. Before you can configure QRadar, you must configure a route for your HBGary Active Defense device to forward events to a syslog destination.

## Configuring HBGary Active Defense

You can configure a route for syslog events in Active Defense for QRadar.

### Procedure

1. Log in to the Active Defense Management Console.
2. From the navigation menu, select **Settings > Alerts**.
3. Click **Add Route**.
4. In the **Route Name** field, type a name for the syslog route you are adding to Active Defense.
5. From the **Route Type** list, select **LEEF (Q1 Labs)**.
6. In the **Settings** pane, configure the following values:
  - **Host** - Type the IP address or hostname for your QRadar Console or Event Collector.
  - **Port** - Type 514 as the port number.
7. In the **Events** pane, select any events that you want to forward to QRadar.
8. Click **OK** to save your configuration changes.

The Active Defense device configuration is complete. You are now ready to configure a log source in QRadar. For more information on configuring a route in Active Defense, see your *HBGary Active Defense User Guide*.

## Syslog log source parameters for HBGary Active Defense

If QRadar does not automatically detect the log source, add a HBGary Active Defense log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from HBGary Active Defense:

Table 539. Syslog log source parameters for the HBGary Active Defense DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	HBGary Active Defense
<b>Protocol Configuration</b>	Syslog

*Table 539. Syslog log source parameters for the HBGary Active Defense DSM (continued)*

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for your HBGary Active Defense device. The IP address or host name identifies your HBGary Active Defense device as a unique event source in QRadar.

**Related tasks**

[“Adding a log source” on page 5](#)

# Chapter 76. HCL BigFix (formerly known as IBM BigFix)

If IBM QRadar does not automatically detect the log source, add an HCL BigFix log source on the QRadar Console by using the IBM BigFix SOAP protocol.

**Important:** HCL BigFix is formerly known as IBM BigFix. The name remains as IBM BigFix in QRadar.

When you use the IBM BigFix SOAP protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect IBM BigFix SOAP events from HCL BigFix:

Table 540. IBM BigFix SOAP log source parameters for the HCL BigFix DSM	
Parameter	Value
<b>Log Source type</b>	IBM BigFix
<b>Protocol Configuration</b>	HCL BigFix SOAP
<b>Log Source Identifier</b>	Type the IP address or host name for your HCL BigFix appliance. The IP address or host name identifies your HCL BigFix as a unique event source in QRadar.
<b>Port</b>	Type the port number that is used to connect to HCL BigFix by using the SOAP API.  By default, port 80 is the port number for communicating with HCL BigFix. If you are use HTTPS, you must update this field to the HTTPS port number for your network. Most configurations use port 443 for HTTPS communications.
<b>Use HTTPS</b>	Enable this option to connect by using HTTPS.  If you enable this option, the host name or IP address you specify uses HTTPS to connect to your HCL BigFix. If a certificate is required to connect by using HTTPS, you must copy any certificates that are required by the QRadar Console or managed host to the following directory:  <code>/opt/qradar/conf/trusted_certificates</code>  QRadar support certificates with the following file extensions: <code>.crt</code> , <code>cert</code> , or <code>.der</code> . Copy any required certificates to the trusted certificates directory before you save and deploy your changes.
<b>Username</b>	Type the username that you use to access your HCL BigFix.
<b>Password</b>	Type the password that you use to access your HCL BigFix.
<b>Confirm Password</b>	Confirm the password that is required to access your HCL BigFix.

For a complete list of IBM BigFix SOAP protocol parameters and their values, see [IBM BigFix SOAP protocol configuration options](#).

For more information about configuring QRadar to import HCL BigFix vulnerabilities assessment information, see the *IBM QRadar Vulnerability Assessment Configuration Guide*.

[“Adding a log source” on page 5](#)

---

# Chapter 77. Honeycomb Lexicon File Integrity Monitor (FIM)

You can use the Honeycomb Lexicon File Integrity Monitor (FIM) DSM with IBM QRadar to collect detailed file integrity events from your network.

QRadar supports syslog events that are forwarded from Lexicon File Integrity Monitor installations that use Lexicon mesh v3.1 and later. The syslog events that are forwarded by Lexicon FIM are formatted as Log Event Extended Format (LEEF) events by the Lexicon mesh service.

To integrate Lexicon FIM events with QRadar, you must complete the following tasks:

1. On your Honeycomb installation, configure the Lexicon mesh service to generate syslog events in LEEF.
2. On your Honeycomb installation, configure any Lexicon FIM policies for your Honeycomb data collectors to forward FIM events to your QRadar Console or Event Collector.
3. On your QRadar Console, verify that a Lexicon FIM log source is created and that events are displayed on the **Log Activity** tab.
4. Optional. Ensure that no firewall rules block communication between your Honeycomb data collectors and the QRadar Console or Event Collector that is responsible for receiving events.

## Supported Honeycomb FIM event types logged by QRadar

---

The Honeycomb FIM DSM for IBM QRadar can collect events from several event categories.

Each event category contains low-level events that describe the action that is taken within the event category. For example, file rename events might have a low-level category of either file rename successful or file rename failed.

The following list defines the event categories that are collected by QRadar for Honeycomb file integrity events:

- Baseline events
- Open file events
- Create file events
- Rename file events
- Modify file events
- Delete file events
- Move file events
- File attribute change events
- File ownership change events

QRadar can also collect Windows and other log files that are forwarded from Honeycomb Lexicon. However, any event that is not a file integrity event might require special processing by a custom log source type or a log source extension in QRadar.

## Configuring the Lexicon mesh service

---

To collect events in a format that is compatible with IBM QRadar, you must configure your Lexicon mesh service to generate syslog events in LEEF.

### Procedure

1. Log in to the Honeycomb LexCollect system that is configured as the dbContact system in your network deployment.

2. Locate the Honeycomb installation directory for the `installImage` directory.

For example, `c:\Program Files\Honeycomb\installImage\data`.

3. Open the `mesh.properties` file.

If your deployment does not contain Honeycomb LexCollect, you can edit `mesh.properties` manually.

For example, `c:\Program Files\mesh`

4. To export syslog events in LEEF, edit the **formatter** field.

For example, `formatter=leef`.

5. Save your changes.

The mesh service is configured to output LEEF events. For information about the Lexicon mesh service, see your *Honeycomb documentation*.

## Syslog log source parameters for Honeycomb Lexicon File Integrity Monitor

If QRadar does not automatically detect the log source, add a Honeycomb Lexicon File Integrity Monitor log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Honeycomb Lexicon File Integrity Monitor:

Table 541. Syslog log source parameters for the Honeycomb Lexicon File Integrity Monitor DSM

Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Honeycomb Lexicon File Integrity Monitor
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Honeycomb Lexicon FIM installation. The <b>Log Source Identifier</b> must be unique value.
<b>Enabled</b>	Select this check box to enable the log source. By default, the check box is selected.
<b>Credibility</b>	From the list, select the <b>Credibility</b> of the log source. The range is 0 - 10.  The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	From the list, select the <b>Target Event Collector</b> to use as the target for the log source.

*Table 541. Syslog log source parameters for the Honeycomb Lexicon File Integrity Monitor DSM (continued)*

Parameter	Value
<b>Coalescing Events</b>	Select this check box to enable the log source to coalesce (bundle) events.  By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Incoming Event Payload</b>	From the list, select the incoming payload encoder for parsing and storing the logs.
<b>Store Event Payload</b>	Select this check box to enable the log source to store event payload information.  By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

#### Related tasks

[“Adding a log source” on page 5](#)

# Chapter 78. Hewlett Packard Enterprise

IBM QRadar can be integrated with several Hewlett Packard Enterprise (HPE) DSMs.

## HPE Network Automation

The IBM QRadar DSM for HPE Network Automation collects events from HPE Network Automation software.

The following table describes the specifications for the HPE Network Automation DSM:

Table 542. HPE Network Automation DSM specifications	
Specification	Value
Manufacturer	Hewlett Packard Enterprise
DSM name	HP Network Automation
RPM file name	DSM-HPNetworkAutomation-QRadar_version-build_number.noarch.rpm
Supported versions	V10.11
Protocol	Syslog
Event format	LEEF
Recorded event types	All operational and configuration network events.
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.hpe.com/us/en/solutions/telecom-network-automation.html">Hewlett Packard Enterprise Network Automation</a> ( <a href="https://www.hpe.com/us/en/solutions/telecom-network-automation.html">https://www.hpe.com/us/en/solutions/telecom-network-automation.html</a> )

To integrate HPE Network Automation software with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the following RPMs from the [IBM Support Website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
  - DSMCommon DSM RPM
  - HP Network Automation DSM RPM
2. Configure your HPE Network Automation software to send LEEF events to QRadar.
3. If QRadar does not automatically detect the log source, add an HPE Network Automation log source on the QRadar Console. The following table describes the parameters that require specific values for HPE Network Automation event collection:

Table 543. HPE Network Automation log source parameters

Parameter	Value
Log Source type	HP Network Automation
Protocol Configuration	Syslog

*Table 543. HPE Network Automation log source parameters (continued)*

Parameter	Value
Log Source Identifier	The IP address or host name of the device from where QRadar collects HP Network Automation events.

The following table shows a sample LEEF message from the HPE Network Automation DSM:

*Table 544. HPE Network Automation sample message supported by the HPE Network Automation software*

Event name	Low level category	Sample log message
Device Snapshot	Information	<pre>LEEF:1.0 HP Network Automation v10 Device Snapshot  devTime=Wed Jul 06 08:26:45 UTC 2016 devTimeFormat=EEE MMM dd HH:mm:ss Z yyyy src=&lt;Source_IP_address&gt; eventId=11111111 userName=UserName eventText=Snapshot of configuration taken</pre> <pre>LEEF:1.0 HP Network Automation v10  Device Snapshot devTime=Wed Jul 06 08:26:45 UTC 2016 devTimeFormat=EEE MMM dd HH:mm:ss Z yyyy src=&lt;Source_IP_address&gt; eventId=11111111 userName=UserName eventText=Snapshot of configuration taken</pre>

## Configuring HPE Network Automation Software to communicate with QRadar

Configure HPE Network Automation Software to send LEEF events to IBM QRadar.

### Before you begin

You must have administrator access to the HPE Network Automation Software user interface.

### Procedure

1. Log in to the HPE Network Automation Software user interface.
2. In the **Admin** menu, select **Event Notification & Response Rules**.
3. Click **New Event Notification & Response Rule**.
4. Configure the parameters for HPE Network Automation.

The following table describes the parameter values to send LEEF events to QRadar:

Parameter	Value
Add Email and Event Rule named	You can use any string. For example, QRadar_logs.
To take this action	Select <b>Send Syslog Message</b> from the list.

Parameter	Value
<b>When the following events occur</b>	a. Select all of the events. b. Enable the <b>of any importance</b> button. c. To take action for For Policy No-Compliance events, enable the <b>for all policies</b> button.
<b>Rule Status</b>	Enable the <b>Active</b> button.
<b>Syslog Hostname</b>	QRadar host name or IP address.
<b>Syslog Port</b>	514
<b>Syslog Message</b>	<pre>LEEF:1.0 HP Network Automation v10 \$EventType\$ devTime=\$EventDate\$ devTimeFormat=EEE MMM dd HH:mm:ss Z yyyy src=\$IPAddress\$ eventId=\$EventID\$ usrName=\$EventUserName\$ eventText=\$EventText\$</pre> <p><b>Tip:</b> All event attributes are tab delimited. For example, devTime, devTimeFormat, and more. Copy the <b>Syslog Message</b> value into a text editor, and then verify that the attributes are tab delimited and remove any new line characters.</p> <p>The version number v10 in the LEEF header can be replaced with the exact version of your HPE Network Automation software. If you change any other components of the format string, events might not normalize or unknown events might occur.</p>

- Click **Save**.

## HPE ProCurve

You can integrate an HPE ProCurve device with IBM QRadar to record all relevant HPE Procurve events using syslog.

### About this task

Take the following steps to configure your HPE ProCurve device to forward syslog events to QRadar.

### Procedure

- Log into the HPE ProCurve device.
- Type the following command to make global configuration level changes.

`config`

If successful, the CLI will change to the following prompt:

`ProCurve(config)#`

- Type the following command:

`logging <syslog-ip-addr>`

Where: `<syslog-ip-addr>` is the IP address of QRadar.

- To exit config mode, press **CTRL+Z**.
- Type the following command: `write mem` to save the current configuration to the startup configuration for your HPE ProCurve device.

You are now ready to configure the log source in QRadar.

## What to do next

[Adding a log source](#)

## Syslog log source parameters for HPE ProCurve

If QRadar does not automatically detect the log source, add an HPE ProCurve log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from HPE ProCurve:

Table 545. Syslog log source parameters for the HPE ProCurve DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	HP ProCurve
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for your HPE ProCurve appliance.

## HPE Tandem

You can integrate an HPE Tandem device with IBM QRadar. An HPE Tandem device accepts SafeGuard Audit file events by using a log file protocol source.

### About this task

A log file protocol source allows QRadar to retrieve archived log files from a remote host. The HPE Tandem DSM supports the bulk loading of log files by using the log file protocol source.

When you configure your HPE Tandem device to use the log file protocol, ensure that the hostname or IP address that is configured in the HPE Tandem device and in the Remote Host parameter are the same.

The SafeGuard Audit file names use the following format:

Annnnnnn

The single alphabet character A is followed by a seven-digit decimal integer nnnnnnn, which increments by 1 each time a name is generated in the same audit pool.

You are now ready to configure the log source and protocol in QRadar.

### Procedure

1. From the **Log Source Type** list, select **HP Tandem**.
2. To configure the log file protocol, from the **Protocol Configuration** list, select **Log File**.
3. From the **Event Generator** list, select **HPTANDEM**

**Note:** Your system must be running the current version of the log file protocol to integrate with an HPE Tandem device:

For more information about HPE Tandem, see your vendor documentation.

For more information about configuring the Log File protocol in QRadar, see [Log File protocol configuration options](#).

## HPE Tandem sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## HPE Tandem sample message when you use the Syslog protocol

The following sample event message shows that permission to attempt the requested operation is denied.
